

Appendix H

Modeling the Costs and Emissions Reductions

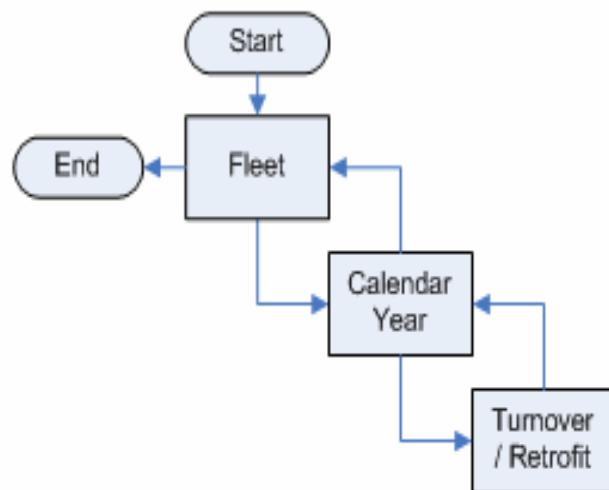

A. Introduction

This document describes a modeling tool used to estimate the costs of compliance and the NOx and PM reductions expected from the proposed in-use off-road diesel vehicle regulation. ARB staff have developed the ARB Off-road Compliance Model (model), using Access and Visual Basic, which will model a compliance strategy and the resulting costs and emissions reductions for a fleet that is subject to the proposed regulation. Staff used fleet data collected from actual construction and mining companies operating in California for use in the model. This section provides a brief description of the model, followed by a more detailed description of the model, and then the model calculations of the regulation costs and emissions benefits.

The model accepts an input parameter that determines whether it will follow the constraints of the proposed regulation or not. If the model is run following the regulation constraints, the model will generate database tables that will contain data for a "scenario" run; alternately, if the model is run with no regulation constraints, the model will generate database tables that contain data for a "baseline" run. Both the scenario and baseline runs are needed for each fleet to calculate costs of compliance and the associated emission reductions.

Under either the scenario or baseline run, the model starts with the fleet information from actual fleets for a given calendar year and then copies the fleet information for an individual fleet into the next calendar year. Then, the model starts modifying this fleet with turnover and retrofits. As mentioned, depending on an input parameter the model may follow the constraints given in the regulation while turning over and retrofitting vehicles or not, but in either case, the model will modify the fleet over time. The model then projects the fleet into the next calendar year and repeats the process for the fleet through calendar year 2030. That process is then repeated for each fleet until all fleets have been modified. The process is illustrated in Figure 1.

Figure 1: Summary Model Flowchart

At the conclusion of a model run, database tables will contain data that reflects the changes to the fleet and the cost of those changes. After both the scenario and baseline runs are complete, various database queries are run to complete the process and extract various datasets.

For example, a query is run to assign NOx and PM emissions to each vehicle in both the scenario and baseline runs using data from the ARB's Off-road Emissions Inventory (ARB, 2006). (Note: The indices used for the fleet averages and fleet targets are only surrogates of actual vehicle emissions.) The emissions reduction for each vehicle is the difference between the vehicle's emission under the scenario run and the baseline run. The cost is the difference between a fleet's cost under the scenario run and baseline run.

The following sections describe the model in more detail including the input data used in the model, the output data, and the model procedures, logic, and the assumptions built into the model. This is followed by a more detailed description of the calculations of the regulation costs and emissions benefits

B. Input Data

The data upon which the model is run resides in the Fleet table. The Fleet table includes information on 200¹ fleets that are currently operating in California with 10,152 construction vehicles with a total of 2,163,669 horsepower. Each row in the table contains information on a distinct vehicle within a fleet including the fleet name, equipment name, vehicle model year, and vehicle horsepower. This table is supplemented with additional information as described under section D.

Some of the input data consist of lookup tables; i.e., tables that have information that doesn't change, but supplements the information in the Fleet table. Lookup tables include Class, Equipment, EquipmentHPandLife, EquipmentReplacementCost, EquipmentTierPMNOx, FleetTarget, Inventory, and Offroad. Each of these lookup tables contain information which may be used either before, during, or after the model runs.

The Offroad table, which incorporates the ARB's Inventory data, includes 209,164 rows of data for calendar years 2000 through 2025 for the construction and mining, industrial, oil, and airport ground support equipment categories. Each row represents the statewide cumulative PM, NOx, and other pollutants emissions and activity (hours of operation) of a particular model year of a particular vehicle or piece of equipment in a particular calendar year. For example, there is a row that contains the tons per day of NOX, PM, and other pollutants emitted in California for all 1982 model year crawler tractors with a maximum horsepower of 175 horsepower in calendar year 2017. The row would also contain the activity, or total hours per day that all vehicles of this particular type of equipment would operate in California. More information on the ARB's California Off-road Emission Inventory can be found at <http://www.arb.ca.gov/ei/ei.htm>.

¹ The 200 fleet data was gathered from the 2003 TIAx survey (TIAx, 2003) and the ARB Off-road Equipment survey (ARB, 2005).

The Inventory table contains limited summary data from the Offroad table. This table was created to avoid the CPU overhead associated with accessing the much larger Offroad table. The Inventory table contains just 31 rows, each row containing the calendar years 2000 to 2025 totals for horsepower, population, NOx, PM, ROG, and CO for all off-road vehicles subject to the regulation.

The FleetTarget table contains the NOx and PM targets for the various horsepower engines for each calendar year for small, medium and large fleets. This is the same information that is contained in Appendix A.

The EquipmentTierPMNOx table contains the NOx and PM Index for each engine for the various model years and horsepower as shown in Appendix A. The EquipmentReplacementCost table contains the estimated cost of replacing a given equipment type of a given age in dollars per horsepower. For example, a 10 year old crawler tractor would cost \$457 per horsepower to replace. As mentioned in Chapter 11, the estimated replacement costs were derived from actual auction prices. The Class, Equipment, EquipmentHPandLife contain the equipment useful life as reflected in the ARB's Off-road Emissions Inventory. (The tables are separated to better normalize the database.)

C. Output Data

Data is output in the form of tables and queries. Output tables include FleetBase, FleetScenario, Results, and Emissions Results tables.

The FleetBase and FleetScenario both contain the same type of information; however, as described in the introduction, the actual information contained in Fleetbase reflects the model output with no regulation constraints and the FleetScenario reflects the model output with regulation constraints. Each row in these tables contains information on a specific vehicle for a given calendar year. The information includes the calendar year that the vehicle is turned over or retrofit, the relative life (i.e., useful life/(calendar year - model year)), the NOx and PM index, turnover cost for vehicles that are turned over, and the activity, NOx, PM, ROG, and CO per piece. (This is more fully described in the next section.)

Each row of the Results table contains information on an individual fleet for a given calendar year. The fleet information is an aggregate of the individual vehicle information. The fleet information includes for each calendar year the fleet NOx target, the fleet NOx average, the percent turnover, the turnover carryover, the fleet PM target, the fleet PM average, the percent retrofit, the retrofit carryover, and the aggregated turnover, repower, and retrofit costs.

The Emissions Results table contains the estimated base and scenario NOx, PM, ROG, and CO for each fleet in each calendar year from 2010 to 2025.

Output data from queries include the total annual cost to each fleet in dollars per horsepower, the statewide cost in dollars per horsepower, the statewide percent NOx

and PM reductions, the statewide tons per day reductions on NOx and PM, and the statewide relative cost of turnover, repower, and retrofits.

D. Model Procedures, Logic, and Assumptions

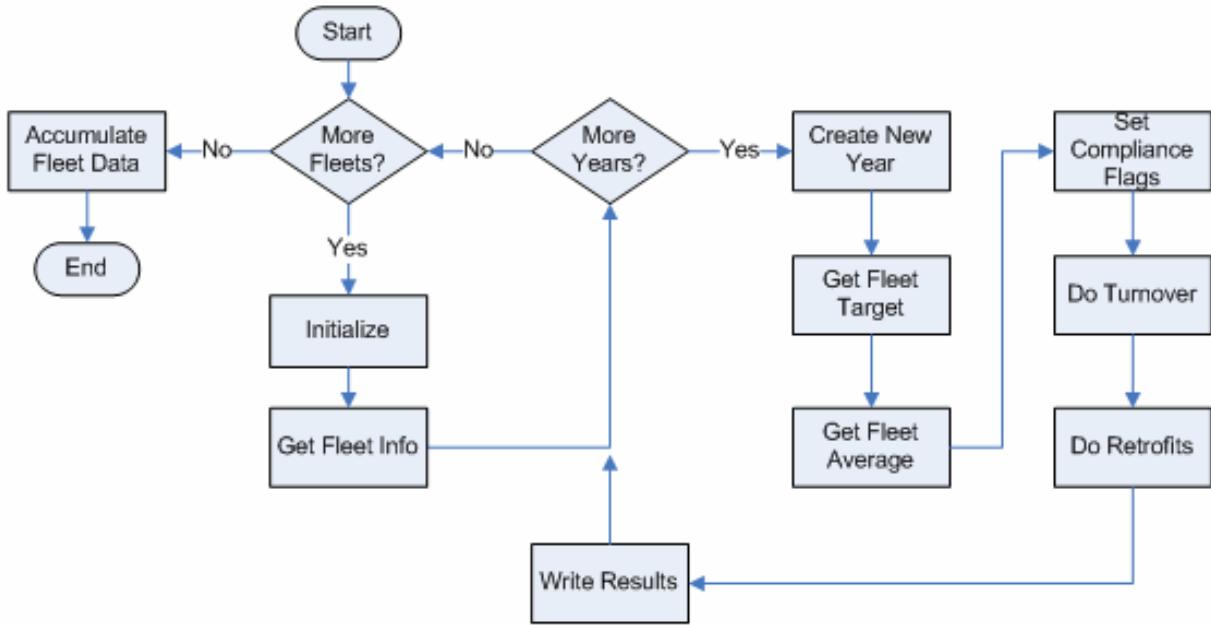

As described earlier, the Fleet table includes fleet name, equipment type, model year, horsepower, and other information. As the data reported for the fleets represented the fleet composition in 2005 and other reporting years, the model year for each piece of equipment was increased by three or more years to maintain the same aggregate fleet age in 2008 as the reporting year. The calendar year, 2008, is the starting year from which the model projects changes to the fleet in future years.

Prior to running the model, the data collected from the fleet owners is further massaged and supplemented using queries working on the Fleet table as follows. The name of each vehicle type is made consistent with the type names contained in the ARB Inventory. A query will add an “average horsepower” to the Fleet table for each vehicle (i.e., each row) to enable linking with the ARB Inventory. For example, the ARB Inventory has an average horsepower of 31, 82, 151, 207, 323, 579, and 820 horsepower for crawler tractors. If the Fleet table contains rows for crawler tractors of 137 and 455 horsepower, then the row with the 137 horsepower crawler tractor would include an entry for 151 average horsepower and the row with the 455 horsepower crawler tractor would include an entry for 323 average horsepower . The actual horsepower reported is used to calculate fleet averages, fleet targets, and costs. The average horsepower, which links to the inventory, is used to estimate emission reductions. Queries would add to each vehicle in the Fleet table a useful life for each vehicle as defined in the Inventory, a relative life, the engine tier, and the NOx and PM index.

A number of input parameters can be set within the model to control the model runs, these include a parameter to specify whether the run is to conform to the regulation or not, the retrofit rate, the life of the retrofit device, the turnover rate and other parameters specified in the regulation.

The model includes procedures that initialize variables, gets fleet information, creates new calendar years, gets the fleet targets, gets the fleet averages, sets compliance flags, modifies the fleet table with turnover and retrofits, writes the results to the database, and accumulates the fleet data. Figure 2 is a flowchart listing the model procedures and the transfer of control between the procedures as the model is run.

Figure 2 Model Procedures

The model starts with the 2008 fleets as contained in the Fleet table; if the table is not empty and it finds a fleet, it then initializes all variables (sets them to zero or other constants) for processing the new fleet.

1. **Get Fleet Information and Create New Year Procedures**

After all the variables are initialized, the fleet information is retrieved (i.e., it retrieves, calculates, and stores in variables the fleet total horsepower, fleet size, the age, the replacement vehicle age, natural turnover, and useful life factor).

The fleet total horsepower is simply the sum of the horsepower of all vehicles in the fleet. The model does not consider any vehicles as low use or specialty vehicles since there was no basis for designating any vehicle as such, therefore all vehicles are included in the calculation of the total horsepower (Equation 1).

$$\text{Equation 1: } \text{TotalHorsepower} = \sum_{i=1}^n \text{Horsepower}_i$$

Where n = Number of vehicles in the fleet.

From the total horsepower, the model designates the fleet as small, medium, or large.

The fleet age is a measure of the average age of the fleet as a whole. The fleet age is calculated in Equation 2.

$$\text{Equation 2: } \text{FleetAge} = \frac{\sum_{i=1}^n (\text{CalendarYear} - \text{ModelYear}_i)}{n}$$

The fleet age is used to determine the typical age of a replacement vehicle. That is, the model assumes that an older fleet would typically purchase older vehicles and a younger fleet would purchase newer vehicles. Also, the model assumes that fleet owner business practices would change under the regulation, with fleet owners buying slightly newer vehicles as shown in Table 1.

Table 1: Replacement Vehicle Age By Fleet Age

Fleet age	Replacement Vehicle Age Baseline	Replacement Vehicle Age Scenario
< 8	0	0
8 to < 12	2	1
12 to < 16	4	2
16 to < 20	6	3
20 plus	8	4

The natural turnover is a measure of how frequently a fleet replaces its vehicles in the course of its normal business practice. The natural turnover is calculated in Equation 3.

$$\text{Equation 3: } \text{NaturalTurnover} = \frac{\text{TotalHorsepower}}{\sum_{i=1}^n \text{Horsepower}_i * \text{UsefulLife}_i}$$

Where: UsefulLife is looked up from the EquipmentHPandLife table. (The useful life is the age at which 50% of a particular vehicle type is scrapped.)

The useful life factor is used to adjust the natural turnover to account for fleets that keep their vehicles either shorter or longer than the useful life specified in the ARB's Inventory; the useful life factor is calculated in Equation 4.

$$\text{Equation 4: } \text{UsefulLifeFactor} = \frac{\sum_{i=1}^n \text{Horsepower}_i * (\text{CalendarYear} - \text{ModelYear}_i) / \text{UsefulLife}_i}{2 * \text{TotalHorsepower}}$$

And the adjusted natural turnover is calculated in Equation 5.

$$\text{Equation 5: } \text{NaturalTurnoverAdjusted} = \frac{\text{NaturalTurnover}}{\text{UsefulLifeFactor}}$$

After the model gets the fleet information, it then copies the fleet information into the fleet table but as the next calendar year.

2. Get Fleet Target, Get Fleet Average, Set Compliance Flags Procedures

Using the fleet equipment model year and horsepower, the model will look up the emissions targets as outlined in the rule and the associated emissions factors for the respective engines. The model will calculate the Fleet Targets and Fleet Average using Equation 6 and Equation 7.

$$\text{Equation 6: } \text{FleetTarget} = \frac{\sum \text{Horsepower} * \text{EmissionTarget}}{\text{TotalHorsepower}}$$

$$\text{Equation 7: } \text{FleetAverage} = \frac{\sum \text{Horsepower} * \text{EmissionFactor}}{\text{TotalHorsepower}}$$

After the model has calculated the fleet NOx and PM averages and targets, the model will compare them and set compliance flags, i.e., it will set certain variables that will determine whether the turnover and retrofit procedures are executed. If the NOx compliance flag is set to false, then the model will attempt to turnover vehicles until the fleet does meet the NOx fleet target. If the PM compliance flag is set to false, then the model will attempt to retrofit vehicles until the fleet does meet the PM fleet target.

The model will do all turnover before it begins retrofitting, this is because turnover will reduce both NOx and PM, whereas retrofits (assuming retrofits do not control NOx) will only reduce PM.

3. Do Turnover Procedure

The model assumes that a fleet will turn over vehicles under both the baseline and scenario runs but likely at different rates. The model defines an average natural turnover that describes turnover of fleets not subject to the regulation but as a matter of usual business practices. The average natural turnover is calculated using Equation 8.

Equation 8:

$$AverageNaturalTurnover = NaturalTurnoverAdjusted * (CalendarYear - 2008) - \sum PreviousTurnover$$

Where: PreviousTurnover = The turnover rate in previous years from 2008 to the year prior to the current calendar year.

Whereas, the natural turnover rate is a function of the fleet age and will vary considerably for different fleets but is unique for a given fleet, the forced turnover rate, i.e., the 8 or 10 percent specified by the regulation is fixed. In cases where a fleet is forced to turnover at a rate faster than its usual business practices due to the regulation, the model assumes that after the fleet meets the NOx fleet average that it would not immediately return to its natural turnover rate but would wait before beginning turnover until its average turnover for the cumulative years was less than its natural turnover rate.

For the scenario run, the model recognizes four possible permutations of natural vs forced turnover rates for fleets that meet or do not meet fleet targets and the resulting turnover rate used by the model.

1.) Fleets for which Natural Turnover > Forced Turnover Rate

- a.) While a fleet does not meet the NOx fleet target

$$Turnover\ Rate = Natural\ Turnover$$

- b.) When a fleet does meet the NOx fleet target

$$Turnover\ Rate = Natural\ Turnover$$

2.) Fleets for which Natural Turnover = < Forced Turnover Rate

- a.) While a fleet does not meet the NOx fleet target

$$Turnover\ Rate = Forced\ Turnover$$

- b.) When a fleet does meet the NOx fleet target

$$Turnover\ Rate = max[Average\ Natural\ Turnover, 0]$$

However, since the natural turnover = average natural turnover for fleets that have a natural turnover > forced turnover, the four permutations are equivalent to:

1.) While a fleet meets the NOx fleet target

$$Turnover\ Rate = Maximum[Average\ Natural\ Turnover, 0]$$

2.) While a fleet does not meet the NOx fleet target

$$Turnover\ Rate = Maximum[Average\ Natural\ Turnover, Forced\ Turnover]$$

For example:

Say Fleet C has a natural turnover of 6% and is a medium fleet not subject to a NOx fleet average until 2013 and it takes two years, 2013 and 2014 at 10% turnover to meet the fleet average, then the model would calculate the turnover as follows (Table 2):

Table 2: Model Calculated Turnover

Year	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018
Percent Turnover	6	6	6	6	10	10	0	4	6	6

For example the turnover rate would be calculated as:

$$\begin{aligned}\text{Turnover Rate (2015)} &= \text{Max}[6 * 7 \text{ years} - 44(\text{sum of previous turnover}), 0] \\ &= \text{Max}[-2,0]=0\end{aligned}$$

$$\text{Turnover Rate (2016)} = \text{Max}[6 * 8 \text{ years} - 44(\text{sum of previous turnover}), 0] = 4$$

$$\text{Turnover Rate (2017)} = \text{Max}[6 * 9 \text{ years} - 48(\text{sum of previous turnover}), 0] = 6$$

The model excludes vehicles that are exempt under the regulation from the pool of vehicles subject to turnover; i.e., vehicles less than 10 years old, Tier 4 vehicles and before 2013, Tier 1 or newer vehicles. From the pool of eligible vehicles, the model will rank them by Tier and then by relative age, where relative age is calculated using Equation 9.

$$\text{Equation 9: } \text{RelativeAge} = \frac{\text{CalendarYear} - \text{ModelYear}}{\text{UsefulLife}}$$

From the vehicle ranking, the model will select the lowest tier and relative oldest vehicle for turnover or repower.

The model will treat the emissions reductions associated with a repower and a replacement as equivalent, i.e, replacing an older vehicle with a 2010 vehicle will reduce the same amount of emissions as replacing the engine in an older vehicle with a 2010 engine. Upon replacement or repower, the model updates the PM and NOx index, the model year, tier, and the relative age associated with the vehicle. The model assumes that any retrofit device is removed upon repower or replacement.

For the purposes of calculating the costs associated with repowers and replacements, the model assumes that any vehicle that is relatively new, over 250 horsepower, and not a tier 4 will be repowered rather than replaced. The variable *vearly* is used as a measure of vehicles that are considered relatively new; *vearly* is calculated using Equation 10.

$$\text{Equation 10: } \text{vearly} = \text{ModelYear} + (\text{UsefulLife} * \text{UsefulLifeFactor}) - \text{CalendarYear}$$

The model has an input parameter set to 10 years and assumes that if *vearly* ≥ 10 years then the vehicle would be repowered (if over 250 hp and not a tier 4). For example, a 300 horsepower 1996 crawler tractor in calendar year 2017 with a useful life factor of 1.5 would have:

$$vearly = 1996 + (29 * 1.5) - 2017 = 22.5$$

Since, in this case, $vearly > 10$, the vehicle would preferentially be repowered rather than replaced.

Using an input parameter set to \$270 per horsepower, the calculation for the cost to repower a vehicle is shown in Equation 11.

Equation 11: *Cost of Re power = \$270 * Horsepower*

The equations used for calculating accelerated turnover are shown in Chapter 11.

Since tier 4s are likely to have an engine manufacturer installed retrofit to meet the new engine PM standards, turnover to a tier 4 is assumed to have a cost premium equal to the cost of a retrofit for a similar sized engine which is added to the turnover cost. These costs are shown in the next section, the discussion of retrofits.

The Turnover Procedure inserts into the Fleet table the turnover cost for each vehicle turned over and records the calendar year the vehicle is turned over. Also, the Turnover Procedure inserts new tier, PM and NOx indexes into the Fleet table looked up from EquipmentTierPMNOx table, then recalculates the fleet NOx average and resets the compliance flags after each engine is turned over or repowered. If the fleet still does not meet the fleet NOx targets and there are still vehicles eligible for turnover or repower, then the procedure repeats the turnover process until the fleet either meet the fleet NOx target, the fleet hits the maximum required turnover, or there are no more vehicles eligible for turnover or repower.

In instances where a fleet turns over more horsepower than is required, the model will accumulate and track turnover carryover for the fleet. Carryover will accrue when the last vehicle required to be turned over does not match exactly the maximum horsepower required to be turned over, i.e., the 8 or 10 percent or when a fleet for other business purposes turns over more than required. The turnover carryover can be used in subsequent years to meet the maximum horsepower required to be turned over.

Typically, the turnover carryover is negligible for medium and large fleets. Small fleets are not subject to the turnover requirements.

4. Do Retrofit Procedure

The model assumes that fleets will not retrofit any vehicles under the baseline run nor when a fleet meets the PM target. Retrofits are assumed to be driven solely by the regulation; i.e., the model assumes the fleet owner has no motivation to retrofit in the absence of the regulation. Hence, unlike the turnover rate, the retrofit rate is fixed at 20 percent. The model will retrofit eligible vehicles as long as a fleet does not meet the PM target or if it has not yet retrofit at least 20 percent of its fleet horsepower.

The model excludes vehicles that are exempt under the regulation from the pool of vehicles subject to retrofit; i.e., vehicles less than five years old, tier 4s, and vehicles already equipped with a retrofit.

The model assumes that retrofits are all Level 3 devices that achieve at least 85% PM control. The model assumes a retrofit cost as shown in Table 3; retrofit operating and maintenance cost are calculated off-model as described in Appendix J.

Table 3: Cost of Retrofits

Vehicle Horsepower	Cost of Retrofit
< 50	\$8,000
50 to < 175	\$12,000
175 to < 400	\$18,000
400 plus	\$30,000

The Retrofit Procedure inserts into the Fleet table the retrofit cost for each vehicle turned over, inserts a PM factor in a field in the Fleet table which reduces the PM attributed to the vehicle, and records the calendar year the vehicle is retrofit. The Retrofit Procedure then recalculates the fleet PM average and resets the compliance flags after each engine retrofit. If the fleet still does not meet the fleet PM targets and there are still vehicles eligible for retrofit, then the procedure repeats the retrofit process until the fleet either meet the fleet PM target, hits the maximum required retrofit, or there are no more vehicles eligible for retrofit.

Retrofit carryover, similar to turnover carryover, accumulates as the last vehicle to be retrofit exceeds the maximum required or due to business practices that retrofit more horsepower than is required. The retrofit carryover for medium and large fleets is typically negligible. On the other hand, retrofit carryover may be significant for small fleets, and indeed, the carryover provisions were developed to accommodate the needs of the small fleets.

For example, if a small fleet with just three older vehicles, all at 333 horsepower, did not meet the PM target, then in 2015 the fleet would be required to retrofit one vehicle representing approximately 33% of the fleet horsepower accruing 13% retrofit carryover in excess of the 20% required. If the fleet does not meet the PM fleet target in 2016 it will have to once again retrofit since the retrofit carryover not meet the required 20% maximum retrofit. After retrofitting a second engine in 2016, the fleet would have accrued 26% retrofit carryover credit which could be used in 2017 in lieu of meeting the PM fleet target. Although this example is not likely, it is provided to illustrate how the model would utilize retrofit carryover.

5. Write Results and Accumulate Fleet Data Procedures

All of the preceding turnover and retrofit would be modeled for a given calendar year on multiple vehicles for a specific fleet. All of the vehicle data would be recorded in the Fleet table.

After the model repeats the procedure for turnover until the fleet meets the NOx fleet average, or the fleet hits its maximum required 8 or 10% turnover, or there are no eligible engines the model transfer control to the retrofit procedure. After the model repeats the procedure for retrofit until the fleet meets the PM fleet average, or the fleet hits its maximum required 20% turnover, or there are no eligible engines the model transfer control to the Write Results procedure.

The Write Results Procedure records a snapshot of the entire Fleet for a given calendar year in the Results table. The model records for the calendar year the final NOx and PM fleet averages, the percent turn over and retrofit, any carryover, as well as annual turn over, repower, and retrofit costs. The model calculates the present value annual costs (Equation 15) using Equation 12 through Equation 14.

$$\text{Equation 12: } PV_{AnnualTurnoverCost} = \sum TurnoverCost * (1.05)^{-(\text{CalendarYear} - 2006)}$$

$$\text{Equation 13: } PV_{AnnualRepowerCost} = \sum RepowerCost * (1.05)^{-(\text{CalendarYear} - 2006)}$$

$$\text{Equation 14: } PV_{AnnualRetrofitCost} = \sum RetrofitCost * (1.05)^{-(\text{CalendarYear} - 2006)}$$

Equation 15:

$$PV_{AnnualCost} = PV_{AnnualTurnoverCost} + PV_{AnnualRepowerCost} + PV_{AnnualRetrofitCost}$$

After the Write Results Procedure passes control, the model will iterate through all of the calendar years for a selected fleet through 2025. Then, the model will look for another fleet in the Fleet table and repeat the process. After all fleets in the Fleet table have been processed, the model passes control to the final procedure which simply copies all of the data in the Fleet table to either the FleetBase table or the FleetScenario table depending on the setting of the input parameter designating whether the run was a baseline run or scenario run.

E. Calculation of the Regulation Costs and Emissions Benefits

The preceding sections described the procedures executed by the model; the following section describes queries that are stored in the database that are executed manually. These queries extract more information from the data generated by the model, such as costs and emissions benefits and scale the model results to the statewide level.

During the last procedure of the baseline run, data is copied from the Fleet table to the Fleetbase table. Each of the rows contains information on a specific vehicle for a given calendar year under the baseline. Similarly, the FleetScenario table contains vehicle information representing the scenario.

After both the scenario run and the baseline run are completed, the Fleetbase and Fleetscenario tables are supplement with information contained in the Offroad table by executing several queries manually. As described earlier, the Offroad table contains

statewide cumulative NOx and PM emissions for each model year and type of off-road vehicle. The query, “Insert Activity Nox and PM Base”, will attempt to link each row of the fleetBase table with a row in the Offroad table. The query inserts activity per piece and NOx and PM emission per piece. The activity per piece is calculated using Equation 16.

$$\text{Equation 16: } \text{ActivityPerPiece} = \text{StatewideActivity} / \text{Population}$$

Where: Population - The number of vehicles of a given type, horsepower, and model year in California for a given calendar year.

The NOx and PM per piece is similarly calculated simply dividing by the population. Another query, “Insert Activity Nox and PM Scenario” will also insert information on the activity per piece, and NOx and PM emission per piece in the Fleetscenario table.

The query “Adjust Emissions with Activity” then calculates the baseline and scenario NOx and PM emissions for each fleet for each calendar year. It calculates the baseline NOx emissions for a fleet using Equation 17:

$$\text{Equation 17: } \text{BaselineFleetNOxEmissions} = \sum_{i=1}^n \text{BaselineNOxPerPiece}_i$$

On the other hand, the scenario NOx emissions for a fleet are calculated in Equation 18:

Equation 18:

$$\text{ScenarioFleetNOxEmissions} = \sum_{i=1}^n \text{ScenarioNOxPerPiece}_i * \frac{\text{ActivityPerPiece}_{\text{Baseline}}}{\text{ActivityPerPiece}_{\text{Scenario}}}$$

The ratio of the baseline to scenario activity is needed to adjust for the different activities associated with a newer and older vehicle. The emissions inventory, and the Offroad table, include tons per day of NOx emissions for a class of vehicles for a given model year. Associated with the emissions of an older vehicle is a lower number of hours of operation per day than the hours of operation of a newer vehicle with its associated emissions. To keep the total fleet hours of operation constant and to avoid inadvertently increasing the assumed number of hours of operation when a vehicle is turned over to a newer vehicle, the activity is proportioned.

Using this ratio is a conservative approach since it does not reflect what would likely happen in actual practice, i.e., a newer vehicle would be used more hours than the older vehicle being replaced and the remaining vehicles that were older than the new vehicle would be used less. By using the remaining older and dirtier vehicles less, emissions reductions would be even greater than assuming the new vehicle would be used so little as calculated using this method.

The query “Make Results Emissions table” works off of the “Adjust Emissions with Activity” query and makes the Results Emissions table, inserting into the table the baseline, scenario, reductions, and the percent reductions for NOx, PM, ROG, and CO. The reductions are calculated using Equation 19.

$$\text{Equation 19: Reductions} = \text{BaselineEmissions} - \text{ScenarioEmissions}$$

And the percent reductions are calculated with Equation 20.

$$\text{Equation 20: Percent Reductions} = \frac{(\text{BaselineEmissions} - \text{ScenarioEmissions})}{\text{BaselineEmissions}}$$

The query “Total Annual Cost” works off of the “Total Annual Cost Baseline” query and the “Total Annual Cost Scenario” query. The baseline and scenario query add all of the PVAnnualCosts that were stored in the Results table for each fleet for the calendar years 2010 through 2025. The total annual cost provides a dollar per horsepower cost for each fleet and is calculated using Equation 21.

$$\text{Equation 21: } PVTotAlAnnulCost = \frac{\sum_{i=1}^n PVTotAlAnnulCost_{scenario} - \sum_{i=1}^n PVTotAlAnnulCost_{baseline}}{TotalHorsepower}$$

For the purposes of calculating the regulation costs and emissions benefits a sample of 22 fleets from the 200 fleets was selected (the 22 fleets are described in more detail in Section F). The parameters upon which the fleets were selected were the fleet age and the fleet size. Prior analysis had shown a direct relationship between fleet age and the cost of compliance on a dollar per horsepower basis with older fleets having a higher cost of compliance than newer fleets. Also, the different requirements imposed on fleets of different size by the proposed regulation would impose different costs and achieve different benefits on different size fleets. Accordingly, fleets from the 200 fleets were divided into age bins of 0 to 4, 4 to 8, 8 to 12, 12 to 16, 16 to 20, and 20 plus average fleet age and at least one small, medium, and large fleet was selected for each age bin.

Table 4 represents the percent horsepower distribution (by average age and fleet size) of fleets compiled from data from over 200 fleets. The weighting for each age and size bin was calculated using Equation 22.

$$\text{Equation 22: } PercentAgeSizeBin = \frac{\sum TotalHorsePower(AllFleetsInAgeSizeBin)}{\sum TotalHorsePower(All200Fleets)}$$

Table 4: Horsepower Distribution by Fleet Age

Percent Horsepower Distribution in the Two Hundred Fleets						
Fleet Size	Average Fleet Age					
	0-3.999	4-7.999	8-11.999	12-15.999	16-19.999	20+
Small	0.04%	0.36%	0.65%	0.65%	0.57%	0.37%
Medium	0.07%	0.53%	1.02%	0.22%	1.49%	1.29%
Large	0.58%	15.43%	32.41%	26.66%	15.69%	1.96%

The 200 fleets were assumed to represent the statewide fleet, thus the statewide costs and benefits were estimated by taking a weighted average of the costs and benefits of the 22 fleets. Each selected fleet within an age size bin was assumed to be representative of the age size bin as a whole and therefore the percent age size bin was taken as the weighting factor for the fleet. The statewide percent reductions in NOx and PM emissions for each calendar year were calculated using Equation 23.

$$\text{Equation 23: } \text{PercentStatewideReductions} = \sum_{i=1}^{22} \text{Percent Reductions}_i * \text{PercentAgeSizeBin}_i$$

The statewide reductions in NOx and PM emissions for each calendar year were calculated using Equation 24.

$$\text{Equation 24: } \text{Statewide Reductions} = \text{PercentStatewideReductions} * \text{StatewideInventory}$$

The statewide dollar per horsepower cost was calculated using Equation 25.

$$\text{Equation 25: } \text{StatewideCostPerHorsepower} = \sum_{i=1}^{22} \text{PVTotalAnnualCost}_i * \text{PercentAgeSizeBin}_i$$

The cost of the regulation was calculated using Equation 26.

$$\text{Equation 26: } \text{StatewideCost} = \text{StatewideCostPerHorsepower} * \text{TotalStatewideHorsePower}$$

Where: TotalStatewideHorsePower = From the ARB Off-Road Inventory (ARB, 2006).

Additional cost methodology, such as calculating the costs for operation and maintenance of retrofit devices, are presented in Appendix J.

F. Sample Fleets Selected From the Two Hundred Fleets

The 22 fleets selected from the 200 fleets were selected based on the fleet age and size. At least one fleet was selected from each age and size bin as described earlier. In some cases two fleets were selected either to reduce the total weighting for a single

fleet or because further analysis was needed on specific fleets for other purposes. Table 5 lists the Fleet ID for each fleet selected within each age and size bin.

Table 5: Fleet Age and Fleet Size for Fleets

Fleet Size	Fleet ID					
	Average Fleet Age					
	0-3.999	4-7.999	8-11.999	12-15.999	16-19.999	20+
Small	1	4	8, 9	13	17	20
Medium	2	5	10	14	18	21
Large	3	6,7	11, 12	15,16	19	22

Table 6 provides a summary of the total horsepower and total population for each of the selected fleets.

Table 6: Summary Information on the 22 Selected Fleets

Fleet ID	Fleet Average Age	Total Horsepower	Total Population
1	3.3	206	3
2	1.0	1,592	13
3	2.6	12,520	175
4	5.7	255	3
5	6.7	2,928	23
6	6.7	181,927	758
7	5.4	7,607	43
8	11.3	324	4
9	11.0	391	5

20	23.2	882	6
21	23.6	2,990	14
22	20.8	36,633	88

From the 200 fleets, Table 7 and Table 8 provide fleet information for the medium and large fleets and the small fleets respectively including average age, total horsepower and total vehicle population. The combined total population of the 200 fleets is 10,152

vehicles representing 2,163,669 horsepower. (Note: The fleet ID from the 22 fleets does not correspond to the fleet ID for the 200 fleets.)

Table 7: Fleet Information for Medium and Large Fleets

Fleet	Average Age	Total HP	Total Population
1	1.0	1,592	13
