The comment states that the "signals" that ARB's new California GREET 2.0 and indirect land-use change models provide for corn-starch, corn-stover and sugarcane ethanol do not reflect the best available scientific and economic information, and therefore do not provide the accurate "signals" to the downstream industry that are needed to maximize GHG reductions while minimizing costs.

Agency Response: ARB staff has relied on the latest scientific information and models to create the LCFS policy framework and the "signals" sent are accurate and reflect the latest science available. The results of the independent peer review confirm, once again, that Staff continues to make every effort to use the best science to assign CI values.

376. Comment: **LCFS 46-11**

The comment states that ARB has not addressed the efforts by stakeholders to improve the quality of ARB's Indirect Land Use Change (ILUC) and indirect-emissions models. The comment also states that ARB has not taken into account recommendations provided by the Expert Working Group that ARB established when it first adopted the LCFS regulation.

Agency Response: See response to **LCFS 8-1** for ARB staff's reasons for including the iLUC analysis.

Since 2009, there have been numerous peer-reviewed literature and scientific reviews of iLUC for biofuels. Empirical data, real-world observations, updated modeling methodology, and improved assessment methods have all been considered in these scientific publications. In preparing the current (2014) proposal, ARB staff has reviewed such articles, recommendations by the Expert Working Group, and comments presented after public workshops, and implemented appropriate modifications to the methodology for the current analysis. Some recommendations that were not considered for the current analysis were either due to lack of detailed data or because modeling structure did not allow for the inclusion of such effects. In the latter situations, ARB concluded that making adjustments outside of the model for a particular feedstock (versus using the same model for all similar feedstocks) created a real danger of unequal treatment.

377. Comment: **LCFS 46-12**

The comment claims that ARB staff has not supplied critical missing information from the Davis review that was requested, that ARB relied on that "non peer-reviewed" report, and that the staff's work on price-yield responses has not been transparent or based on the "best available" information.

Agency Response: The analysis conducted by staff has been provided to stakeholders in the ISOR, and Appendix I thereto. As is clear from the ISOR, although ARB considered the report by U.C. Davis Professor David Rocke, ARB did not adopt his conclusion that the YPE factor should be zero or close to zero. Similarly, although ARB considered a study by Dr. J.F.R. Perez, ARB did not adopt his conclusion that YPE should be 0.29. ARB did not rely on the data that Drs. Rocke and Perez report that they analyzed. In connection with sharing the Perez/Rocke data with one stakeholder interested in iLUC, ARB decided to place that data into the rulemaking record for comment, so that other stakeholders might have an equal chance to consider it. See also response to **LCFS 8-9**.

378. Comment: **LCFS 46-13**

The commenter sets out several abstract legal points in a footnote without tying them to any particular part of the LCFS proposal or the process by which it has been adopted. The comment is phrased as instructions telling ARB what it must do in the future, and telling some future court how to analyze legal challenges in some unstated future litigation.

Agency Response: The comment is not pertinent to the proposal and does not constitute an objection or recommendation regarding how the proposal could be changed. No response is required, but ARB notes that it remains committed to following the law.

379. Comment: **LCFS 46-14**

The comment states that GTAP is unable to account for multiple cropping and that an Iowa State University (ISU) study confirms that increases in crop prices will result in multiple cropping.

Agency Response: A preliminary review of U.S. agricultural data has concluded that double cropping is small and is not expected to contribute significantly to 'intensification effects' as mentioned in the November 2014 submission. As for other regions of the world, significant work has to be completed to collect and disaggregate data to provide accurate information on double cropping. When detailed data become available, ARB staff will consider updates to modeling structure to explicitly account for double cropping in the analysis. It should also be noted that any benefits from double cropping are likely to be offset by increased use of fertilizers and pesticides and these impacts also need to be accounted for in any future analysis (and are not included in the current analysis).

ARB staff has implemented several updates and modifications to the 2009 version of the GTAP model. All of these changes are reflected in the current analysis. New sectors, biofuels, co-products, disaggregation of irrigated/rain-fed cropland, new land transformation structure and elasticities are among some of the updates since 2009. A complete list of all changes is provided in Appendix I of the ISOR. Refinements and modifications to the GTAP model require collection of large data sets, changes to modeling structure, and comprehensive testing to ensure robustness of model outputs. For issues that were not considered for this round of rulemaking, lack of detailed data was a major issue that limited ARB staff's ability to include these in the current analysis.

As described earlier, ARB staff's preliminary review of the November 2014 submission concluded that additional detailed data would be required to evaluate the inclusion of the conclusions of the submission. Lacking detailed data at this time, ARB staff could not complete a comprehensive evaluation of the results presented in the November 2014 submission.

See also response to **LCFS 8-5**.

380. Comment: **LCFS 46-15**

The comment asserts that ARB staff has refused to include the effects of the Conservation Reserve Program (CRP) land in mitigating the land-use-related emissions impacts that ARB staff attributes to corn-starch ethanol.

Agency Response: See response to **LCFS 46-110**.

381. Comment: **LCFS 46-16**

The comment requests to know why the ARB staff has chosen to use the "Agro-ecological Zone Emission Factor" (AEZ-EF) model rather than the "Carbon Calculator for Land Use Change from Biofuels Production" (CCLUB) model to estimate GHG release caused by various theoretical land transitions

Agency Response: The Agro-ecological Zone Emission Factor (AEZ-EF) model is a peer-reviewed carbon emissions model that uses the best available science, data, and methodology to estimate carbon release (or sequester) when land is converted from one use to another. When ARB was made aware of the Carbon Calculator for Land Use Change from Biofuels Production (CCLUB) model developed by Steffen Mueller, a comprehensive review of this model was initiated. The review determined that although the CCLUB uses county-level data and sophisticated biogeochemical modeling, it also involves numerous problematic assumptions in the application of these data. Some of these issues include:

- CCLUB assumes that all cropland-pasture conversion transition only to the biofuel feedstock being examined, when in fact, GTAP more realistically results suggests changes in the harvested area of all crops. Therefore, despite the more complex biogeochemical modeling used in CCLUB, there's no basis for the specific assumption of land transitioning from cropland-pasture to a single biofuel feedstock.

- The Century model, which is used in CCLUB to calculate GHG flows to and from land, requires initialization ("spin-up") to estimate conditions prior to the modeled land conversions. To do this, CCLUB authors assumed that all cropland-pasture land was in crops from 1880-1950, in pasture/hay/grasslands from 1950-2010, and then in corn-corn or miscanthus/switchgrass from 2011-2040, according to which feedstock is being examined. Even if Century models this land-use history perfectly, if the land-use history of the land converted deviates from these assumptions, the Century projection will misrepresent the actual state of the land. The actual land-use history of the converted cropland-pasture strongly determines conversion emissions: land recently in crops will have very low emissions, while lands taken out of crop production long ago will have high emissions when converted. Simply assuming a single land-use history across all land does not address this key information gap. Cropland-pasture is defined as land that transitions between cropland and pasture; assuming it was in pasture/hay/grasslands continuously from 1950-2010 contradicts this definition.

- The CCLUB model cannot be used with GTAP because CCLUB arbitrarily introduces a lower-carbon-density "young forest-shrub" category that is a landcover category that is not part of the GTAP framework; in short CCLUB cannot properly be used with GTAP.

See also response to **LCFS 46-94**.

382. Comment: **LCFS 46-17**

The comment suggests that the Board has not been given the "best available" information regarding iLUC.

Agency Response: ARB staff disagrees that the information presented in the commenter's Appendix A is an improvement over the staff's analysis. ARB staff's analysis has used the latest data and best available science. All information used by ARB staff in the rulemaking process is referenced and appropriately included in the rulemaking file. For the current proposal, ARB staff used a small range of input values for critical parameters to complete 30 scenario runs and the average of the scenario runs is being proposed as an iLUC value for each biofuel. To further validate the scenario estimates, ARB staff completed an uncertainty analysis for which ARB staff reviewed published literature and consulted with experts to develop ranges and corresponding distributions for parameters used in the GTAP and AEZ-EF models. Utilizing the entire range of likely values for the different parameters in the two models, the analysis estimated a mean iLUC value for each of the six biofuels analyzed for the current proposal. The iLUC estimate from the uncertainty analysis is similar to the average iLUC value for each biofuel supporting ARB staff's approach. Therefore, staff does not support the commenter's views that the potential for errors in the iLUC values is large. Also, the LCFS program is designed to evaluate all fuels based on their complete life cycle analysis and not reward fuels that are likely to increase greenhouse gas emissions. The inclusion of iLUC for food-crop-derived biofuels and indirect land use emissions for crude production serve to support ARB staff's approach to accounting for greenhouse gas emissions from all steps starting from feedstock production to final use in a transportation vehicle.

The iLUC analysis is developed using sound scientific principles and the latest data and does not warrant that the Board consider suspending the LCFS program or continue with the regulatory status quo. ARB staff does recognize that the understanding of land use change is constantly evolving, as is the supporting data. ARB staff remains committed to periodically reviewing data and updates in land use science, updating iLUC analysis and presenting new proposals to the Board as warranted.

383. Comment: **LCFS 46-18**

The comment suggests that the Board is relying on conjecture and unsupported assumptions, rather than the "best available" information.

Agency Response: See response to **LCFS 42-16** and **LCFS 46-17**.

384. Comment: **LCFS 46-19**

The commenter states in a footnote that "it is impossible to know" whether other parties submitted comments on the proposal.

Agency Response: The commenter's ignorance on that point does not appear to be an objection or recommendation regarding the proposal. ARB does note, however, that while the Administrative Procedure Act (APA) requires much, it does not require an agency to catalogue tens of thousands of documents for a commenter's convenience. ARB staff notes that over a period of several years there were 21 LCFS public workshops, and 26 ADF public workgroup or workshop meetings as part of developing these two related regulations. Along the way, ARB staff posted, as is its practice, all public comments regarding the proposal received by ARB, including those submitted as part of ARB's many workshops, as well as a wide range of materials on the program web pages ARB maintains. Such materials have long been public.

385. Comment: **LCFS 46-20**

The comment contends that instead of recreating Argonne's work, ARB staff included arbitrary assumptions when creating their CA GREET 2.0 model as it relates to distillers grain solubles (DGS).

Agency Response: See response to **LCFS 8-13**.

386. Comment: **LCFS 46-21**

The comment claims that the omission of "backhaul emissions" for sugarcane ethanol has a significant impact on its assigned CI value and producers of sugarcane ethanol should be required to account for those emissions in their applications.

Agency Response: ARB staff acknowledges that there may be small differences in ethanol transport distance assumptions to the blending terminal between corn ethanol and sugarcane ethanol. These differences arise since corn ethanol arrives primarily from the Midwest by rail car where it is transported from the rail yard to the bulk terminal over an estimated distance of 100 miles. Sugarcane ethanol arrives at a port terminal via ocean tanker. However, the input for this parameter in both pathways is provided for the user to provide, based on actual ethanol transport operations. Therefore, the commenter's suggestion that both transport distances to the blending terminals should be equal is not a concern.

With regard to the comment on estimating a backhaul energy charge for ocean tankers delivering ethanol to California ports, ARB staffs understanding of ethanol transport by ocean has increased significantly since the original assumptions were made in CA-GREETv1.8b. Staff now believes the ocean tanker cargo (ethanol) payloads are much smaller (lowered from 150,000 tons for supertanker to 22,000 tons for medium range tanker), and the tanker energy use (Btu per ton-mile) is substantially higher (from 32 to 145 Btu per ton-mile).

With respect to the back-haul assumption, ARB staff believes that it would be a highly inefficient operation for transport companies to export ethanol from Brazil to California and return the tanker back to Brazil empty. In 2009, UNICA; a consortium of Brazilian sugarcane ethanol producers had contested the validity of the Back-Haul energy charge with the assertion that "UNICA believes that it is highly speculative and arbitrary to assume that the energy consumption and associated emissions of the ocean tanker's round trip be attributed to sugarcane ethanol." UNICA has further responded by saying that "there are no specific data to support the claim that the commenter makes regarding the return trip of the ocean tanker to Brazil after unloading the ethanol. There may be instances where this may happen but verification of such claims across all the shipments is difficult." ARB staff will continue to investigate the onward journey of tanker operations after ethanol is unloaded onto a California port, and propose revisions for considerations as necessary.

387. Comment: **LCFS 46-22**

The comment states that CA GREET 2.0 wrongly assumes that all sugarcane ethanol from Brazil is delivered in 22,000-ton shipments, understates GHG emissions from inbound ocean transport by 100 percent, and uses unrealistic assumptions about the relationship between oceangoing vessel power requirements and vessel speed.

Agency Response: The default cargo payload for ethanol transport from Brazil to California ports via ocean-tanker is 22,000 tons in the draft CA-GREETv2.0 life cycle analysis model being proposed for adoption. The commenter has alleged that this assumption in CA-GREETv2.0 understates GHG emissions from inbound ocean transport by 100 percent. Staff believes the CA-GREET 2.0 estimate to be accurate and may likely be conservative. Staff has determined[16] that the Medium Range tankers are typically employed for ethanol transport from the Port of Santos in Sao Paulo State to a California port. These Medium Range tankers have the capacity to load 10-13 million gallons of ethanol, which implies a cargo payload of at least 33,000 tons. Since larger vessels have more cargo carrying capacity, they can more effectively transport ethanol with fewer GHG emissions per unit-mile. The energy expended to transport ethanol (in Btus/ton-mile) was however conservatively estimated, since increasing the cargo payload only decreases the energy intensity for transport. Therefore, the cargo payload recommended in draft CA-GREETv2.0 may represent, on average, the vessels employed to transport ethanol from Brazil to California. Staff will recommend that the cargo payload parameter be maintained at the proposed value (22,000 tons) until further data and studies become available.

388. Comment: **LCFS 46-23**

The commenter alleges that the draft CA-GREETv2.0 model being proposed for adoption does not reflect accurate parameters for corn ethanol, corn stover ethanol, and sugarcane farming. According to the commenter, these “failures to use the best available information” are described in their report-letter in Appendices B and C.

Agency Response: Staff addresses the comments from these appendices as separate comments, which are listed below for ease of reference.

[16] Pursuant to staff email correspondence received from Chris Hessler on April 1, 2015.

Commenter's Appendix B	Commenter's Appendix C
LCFS 46-115 through **LCFS 46-129**	**LCFS 46-130** through **LCFS 46-162**

389. Comment: **LCFS 46-24**

The commenter asserts that the CI values assigned to corn and sugarcane ethanol are not based on reliable data and methodologies, and need to be corrected before ARB moves forward with the LCFS re-adoption process.

Agency Response: ARB disagrees that the CI values are not based on reliable information. As described in the ISOR, the CA-GREETv2.0 being proposed for adoption incorporates the collective learning of two agencies - namely the ARB and Argonne National Laboratory (ANL), and the best available information on life cycle assessment of fuel pathways, scientific research, and evolution of factors from empirical evidence.

390. Comment: **LCFS 46-25**

The comment asserts that the incorrect regulatory "signals" created by the CI values assigned to corn and sugarcane ethanol will skew the California renewable fuels market away from corn-starch ethanol, and toward sugarcane ethanol.

Agency Response: While ARB agrees that the LCFS is intended to provide a signal away from high-carbon fuels and toward low-carbon fuels, ARB rejects the commenter's suggestion that the signal is "incorrect." The proposed LCFS regulation uses thoroughly reviewed, scientifically credible lifecycle CI values determined from a peer reviewed process and subjected to extensive review and feedback from stakeholders and the public. See responses to **LCFS 46-21** through **LCFS 46-24**.

The LCFS regulation is a market-based program that allows industry to decide the most effective strategy for compliance. However, the credible lifecycle CI calculations ensure that California residents are achieving real CI reductions in the most cost-effective manner.

ARBs illustrative scenario shows a reduction of corn ethanol use by 2020 and an increase in other types of ethanol, primarily sugarcane, to reflect a market response to more favorable CI values.

Note that ARB's illustrative scenario is intended to be just that – illustrative. It demonstrates one plausible path. Different companies will pursue different options based on their business strategies and the availability and price of low carbon fuels (as well as other market factors). Contrary to the comment provided, a scenario that provides a shift to cleaner (lower CI) ethanol (whatever the source) is consistent with ARB's statutory requirements and policies.

With regard to the footnote, the analysis assumes the price of each credit is $100 for every year of the program. From 2012 through 2013, while the LCFS standards for gasoline and diesel were declining, the average credit price reported in the LRT was $57[17]. However, this average price only accounts for the credits purchased on the market. In 2013, California's seven major refineries self-generated a vast majority of their compliance credits through the purchase of low-CI fuels[18]. Thus, if all credits (including those that are self-generated) were purchased in the market, as our analysis assumes, the average price would have been lower than reported. Therefore, ARB assumes an average of $100 per LCFS credit across all years of compliance to be a plausible upper bound.

391. Comment: **LCFS 46-26**

The commenter believes that the LCFS, which rewards and incrementally requires the provision of alternative fuels such as biofuels with lower carbon intensity than petroleum-based fuels, somehow interferes with the federal Renewable Fuels Standard (RFS), which rewards and incrementally requires the provision of biofuels with lower carbon intensity than petroleum-based fuels.

Agency Response: The comment is wrong as a legal and factual matter. Both the RFS and the LCFS can operate in harmony; there is simply no interference. The commenter's theory is also the basis for two lawsuits (one brought by the commenter) that have proceeded for almost six years without success in the United States District Court, and the United States Court of Appeals, before being rejected for further review by the United States Supreme Court. Parts of those lawsuits have yet to be addressed by the courts, but ARB's response to the argument that the Federal RFS somehow preempts or precludes adoption of the LCFS can be found in

[17] Weighted average of quarterly LCFS credit prices reported through the LRT available at: http://www.arb.ca.gov/fuels/lcfs/lrtmonthlycreditreports.htm.

[18] Information obtained through business confidential transactions reported through the LRT.

pleadings and briefs available in the court's public file in *Rocky Mountain Farmers Union v. Corey,* (U.S.D.C., Eastern District) Case 1:09-cv-02234-LJO-BAM. The commenter's attorneys have been directly served with all such pleadings and briefs through an electronic docket maintained by the court.

392. Comment: **LCFS 46-27**

The comment states that the increased imports of Brazilian cane ethanol, combined with the proposed LCFS regulation's generous allowance of credit to the California electric utilities, will result in a combination of lost production or even shutdowns at Midwest biorefineries, and increased logistics costs as those American biorefineries seek foreign markets.

Agency Response: This comment makes assumptions about what may happen in the future under the LCFS and demands that the Board respond to them. These are not objections to or recommendations for the proposal, particularly since the proposed regulation allows the market to decide which fuels will be used to comply with California's carbon intensity standards. As the comment appears to reflect, the LCFS encourages the use of low-carbon fuels in California, regardless of origin and type, which means that the LCFS does not require Midwest biorefineries to shut down or to seek alternative markets (although ARB notes that the ethanol industry has itself been promoting the prospect of increased exports.[19]) The program, in fact, welcomes Midwest biofuel refiners to produce lower carbon intensity fuels for sale in California. A number of Midwest corn ethanol plants have begun to do so, and ARB staff see no reason why such developments would cease. The commenter also notes that Midwest biofuel refiners are investing in the development of cellulosic ethanol, a fuel anticipated to be very low in carbon intensity and therefore highly desirable in the California market under the LCFS.

393. Comment: **LCFS 46-28**

The comment states that possible responses to the LCFS from Midwest corn ethanol facilities are: (1) reduced output and potential plant closures due to loss of any commercially practicable way to continue to serve the California market or (2) export outside the

[19] *Going Global 2015 Ethanol Industry Outlook*, at p. 4, available at http://www.ethanolrfa.org.

United States to make up reduced demand from California that will not produce reductions in global GHG emissions.

Agency Response: The LCFS program is designed to encourage reductions in the average CI of transportation fuels sold for use in California. Corn ethanol plants in particular have been successful in changing their practices to reduce the CI at their facilities. While this comment presents two static alternatives, the world post-regulation is dynamic and will likely yield very different results.

Midwestern corn ethanol plants may continue to lower their CI by using innovative strategies, as illustrated by the Method 2a and 2b applications received under the 2009 LCFS. Such changes would further GHG emissions reductions and assist regulated parties in complying with the LCFS.

394. Comment: **LCFS 46-36**

The comment states that the ISOR does not cite facts in support of ARB staff's claims that there has been a steady decline in the average CI of the mix of biofuels sold in California or the staff's expectation that these trends will continue and actually accelerate as the stringency of the LCFS increases and credits become more valuable. The comment states that Staff's observation of a historic decline in the average CI of the mix of biofuels sold in California is contradicted by the relevant evidence from the corn-starch ethanol industry.

Agency Response: ARB staff disagrees with the commenter's statement "no biorefinery selling ethanol for blending into gasoline has made any significant changes in its production methods, feedstocks, methods of transport or any other factor relevant to GHG emissions, in order to specifically obtain a lower CI value for purposes of the California LCFS regulation."

Staff is aware of these specific actions to reduce CI in part from reviewing applications for CI values under the current regulation, and, in fact, the decline in CI value of the mix of biofuels used in California is readily apparent from the data reported in the LRT. For example, as indicated in the quarterly reports available on ARB's website, the volume of lower-CI ethanol has increased and the volume of higher-CI ethanol decreased since the LCFS went into effect.[20] The expectation that this trend will continue is reasonable,

[20] http://www.arb.ca.gov/fuels/lcfs/lrtqsummaries.htm.

and is consistent with the ethanol industry's own claims and predictions.[21]

The comment refers to testimony claiming any innovation in the corn ethanol industry is motivated only by competition within the industry to maximize profitability by minimizing operational costs. ARB staff recognizes that fuel producers have multiple incentives to reduce operational costs (including energy costs) and that it is challenging to assign causality for an individual CI improving investment to just one factor. The LCFS, the federal RFS, other state and federal incentives, and the normal competitive pressures that would exist without these programs all contribute to the business case for individual CI reducing projects. To the extent other pre-existing incentives align with the LCFS's incentives to reduce CI, the two sets of incentives reinforce each other to the benefit of the producer and those needing to comply with California's carbon intensity standards. The incentives from the LCFS, of course, will increase as the regulatory standard gets more stringent.

395. Comment: **LCFS 46-37**

The comment states that no biorefinery selling ethanol for blending into gasoline has made any significant changes in its production methods, feedstocks, methods of transport, or any other factor relevant to GHG emissions, in order to specifically obtain a lower CI value for purposes of the California LCFS regulation.

Agency Response: See response **LCFS 46-36**.

396. Comment: **LCFS 46-38**

The comment states that not all corn-starch ethanol plants that were able to participate in the California market before 2011 have been able to remain in that market because not all such plants have been able to document production processes, methods, and energy usage that would qualify them for competitive CI values.

Agency Response: ARB staff encourages any producer who cannot document input values that would qualify for a competitive CI value to work with staff to identify specific pieces of evidence that would be necessary to accurately calculate CI as well as any areas of potential process improvements that could help to reduce the

[21] *E.g.,* http://www.ethanolrfa.org/page/-/rfa-association-site/studies/LCA_Summary.pdf?nocdn=1 (Figure S.1).

carbon intensity of their fuel. Staff also notes that in America's capitalist economy, no existing federal, state or local law, including the prior LCFS, guaranteed any fuel producer a set market share, revenue, or income. The readopted LCFS did not change that reality.

397. Comment: **LCFS 46-39**

The commenter claims that ARB staff may believe that it cannot put any information into the public record that contradicts Growth Energy's understanding of how corn starch ethanol biorefineries have gained lower-CI pathways to date, owing to concerns about business confidentiality.

Agency Response: Although staff does receive confidential business information as part of pathway applications, staff does not need to employ this information to observe that CI improvement opportunities exist at corn starch ethanol facilities. Also, see response to **LCFS 46-27** and **LCFS 46-36**.

398. Comment: **LCFS 46-40**

The comment states that the current LCFS regulation has led to "fuel shuffling" and that the LCFS has not resulted in any reductions in GHG emissions from corn starch ethanol.

Agency Response: The comment addresses a prior regulation, not the proposal, thus needs no response. To the extent the comment is meant to imply that the readopted LCFS will not reduce GHGs, ARB disagrees. The same commenter has made the contradictory complaint that the LCFS will result in high CI corn ethanol being replaced in California by low-CI cellulosic and cane ethanol. Resulting GHG reductions from the program are detailed in the ISOR. Fuel shuffling is not an expected long-term market response to an increased and growing demand for a product. Suppliers will look for more efficient processes to provide lower CI fuels and to the extent any fuel shuffling occurs, it is expected to be limited in amount and duration. See also response to **LCFS 46-36**.

399. Comment: **LCFS 46-42**

The comment states that the ISOR offers no technical analysis or informed expert opinion to support the speculation that remaining ethanol production processes will achieve on average the first lower-CI level, and then year-over-year reductions.

Agency Response: Staff projected the volumes and types of fuels demanded for compliance with the proposed regulations in the illustrative compliance scenario. This scenario represents one of many potential paths to compliance with the LCFS, and reflects staff's analysis of alternative fuel availability and feasible assumptions regarding increased production of low-CI fuels.

Over the first three years of the LCFS, there has been a steady decline in the average CI of the mix of biofuels used in California. Concurrently, there has been a great expansion of the applications for fuel-pathway CIs. These lower CI pathways will provide additional opportunities to produce more credits per unit of fuel used. ARB staff expects these trends to continue and actually accelerate as the stringency of the LCFS increases and credits become more valuable.

However, Midwestern corn ethanol plants could take the example of Poet[22] who put in an application for a facility-specific CI based upon their diversion of methane from a city landfill to power their ethanol plant. The corn ethanol plants that wish to invest in cleaner energy will be able to compete in a changing market and ensure they meet or even exceed the illustrative compliance scenario outlined in the ISOR.

Staff also note that the commenter's own website currently contains a graph projecting that ethanol plants will continue to reduce their lifecycle emissions dramatically through "innovation[s]" such as "alternative energy sources."[23] Also see response to **LCFS 46-36**.

400. Comment: **LCFS 46-43**

The comment makes a number of assertions regarding the method which ARB staff used to calculate CI values for corn ethanol. The comment suggests that cornstarch ethanol producers may struggle to compete in the market.

Agency Response: The comment makes six points about how ARB staff has calculated CI values for corn ethanol.

1. *The commenter states that the Midwest corn ethanol plants are operating optimally, and that they cannot achieve significant future optimization*.

[22] http://www.arb.ca.gov/fuels/lcfs/2a2b/apps/poet-cha-sum-022014.pdf
[23] http://www.growthenergy.org/ethanol-issues-policy/environment/, visited on August 24, 2015.

What may have been optimal prior to the incentives created by the LCFS may no longer be optimal after the value of the LCFS credits is considered (i.e., given the additional credit value certain investments that previously were uneconomic become economic). The higher the LCFS credit price, the higher the value on the low-CI fuels, and the larger the incentive for investment in reducing the CI values for all fuels.

2. *The commenter states that corn-starch ethanol plants are assigned a large ILUC emissions factor, which they are powerless to change.*

   A full life cycle analysis is important to reflect the GHG emissions associated with each fuel's production, transport, storage, and use. The indirect GHGs can often be significant, and therefore ARB considers land use change effects in the determination of CI. Based on the work with land use change academics and researchers, ARB staff concluded that the land use impacts of crop-based biofuels, including corn-starch ethanol, were significant, and must be included in LCFS fuel CIs. Although it is interesting to note that the iLUC value for corn ethanol is lower in the proposed LCFS regulation.

3. *The commenter states that corn-starch ethanol plants can work with only a fraction of their production processes ─ chiefly, energy, for which they are already likely optimized ─ to achieve lower CI scores*.

   According to page ES-6 of the ISOR, the indirect land use value for corn ethanol is 19.8, leaving the direct emissions driving much of the value of the CI (for a corn ethanol plant with a CI of 70, the direct emissions would be 50.2, over 70% of the total CI). The LCFS credit value is designed to incent GHG reductions across the full lifecycle of the fuel—plant changes, agricultural practices and fuel transport choices.

4. *The commenter states that the ISOR does not address what the commenter sees as a key fact that any costs incurred to reduce the CI score of the ethanol that corn ethanol plants would produce would have to be recovered in the California market against competition from sugarcane ethanol and electricity. The deeper the reductions in CI, assuming any such reductions were possible, the greater the costs, and the longer the period needed to remain competitive in California*.

The comment does not relate that asserted "fact" to the proposal, making it difficult to respond. If those facts are true, they do not constitute an objection or recommendation regarding the proposal. Because ARB has chosen to employ a market-based approach, competition is both expected and desired.

5. *The commenter adds a largely unintelligible series of statements that corn ethanol is used in the compliance scenarios, that absent that ethanol, the LCFS credits will trigger the cap, there won't be GHG reductions and asking whether ARB has a basis to "disagree with the prediction of market exist".*

   To the extent that the commenter seems to be predicting an ethanol shortage, no evidence is provided. As discussed elsewhere, ARB believes that fuel providers can supply sufficient transportation fuel to California in a way that allows parties to comply with the LCFS. Please see ISOR and ISOR Appendix B. Carbon intensities are calculated under the LCFS on a full life cycle basis. This means that the CI value assigned to each fuel reflects the GHG emissions associated with that fuel's production, transport, storage, and use. Staff uses the best available science to update the CI value of each fuel in order to be as accurate as possible and account for the entirety of GHG emissions reductions from each low-CI fuel; the LCFS is fuel neutral and cannot give special treatment to one fuel over another. Staff analysis of the price cap suggests that $200/ton is high enough to provide a sufficient value added to stimulate the investments in and production of low-CI fuels and is sufficiently high to overcome any transportation costs incurred.

   To the extent that the commenter fears credit prices will increase to the cap in any year, ARB notes that the higher credit prices, particularly if they are sustained, will increase the incentive to innovate and invest because revenues generated by LCFS credit can be used to increase profit margins or to offset up-front capital costs; these additional revenues will attract investments in low-CI fuels. The commenter suggests that the recovery of the costs to lower direct emissions to compete with other CI fuels will be have to be passed onto California consumers, however, if there is a constraint on the number of credits (or a shortage such that the credit clearance market is necessary), the higher credit prices can help offset the additional investment required to lower CI values, and put Midwest ethanol at an advantage above other higher-CI fuels.

401. Comment: **LCFS 46-70**

The comment highlights the fact that the LCFS regulation will impose present costs on California consumers and businesses, and questions why ARB did not offer an explanation to justify the need for the present costs along with the direct costs of the LCFS program in the near term.

Agency Response: The present costs to the LCFS program are necessary to meet the goals of the LCFS program, which was designed as a discrete early action measure to achieve the long term goals of AB 32, as outlined in S-01-07 (2007). Additionally, in order to meet "a statewide goal… to reduce the carbon intensity of California's transportation fuels by at least 10 percent by 2020" as outlined in the aforementioned Executive Order, the LCFS program is necessary. Staff also notes that the commenter's own description of the purported present costs, which includes words like "if" and "likely," marks those costs as speculative.

402. Comment: **LCFS 46-71**

The comment questions the basis of imposing the present costs on consumers and businesses if liquid biofuels are destined for a diminishing and no long-term role in ARB's GHG reduction strategy.

Agency Response: The basic arguments and conclusions of this comment were based on the findings of ARB's Vision Scenario Planning Projects, not on the LCFS proposal. To the extent the commenter believes that intermediate regulatory steps and associated burdens are not appropriate unless the steps can immediately and completely accomplish all future goals (such as electrification). ARB disagrees. In the agency's experience, progress toward reducing air pollution has been made incrementally. In decades of regulating vehicles and fuels, ARB has never seen evidence suggesting that California's transportation sector, vehicle manufacturers, fuel suppliers and consumers will all be able to abruptly change from the current fuel mix and vehicle population to 100% electric with no intermediate steps. ARB disagrees with the premise that incremental progress and some attendant costs is a poor or unworkable strategy. Commenter has not submitted – and cannot – any examples where more than 38 million people suddenly abandoned all vehicles using one fuel and purchased new ones using another fuel virtually overnight.

403. Comment: **LCFS 46-72**

The comment questions why ARB did not provide supporting information to justify that the proposed regulation is a superior alternative among all the options considered.

Agency Response: The commenter believes that the Notice of Proposed Rulemaking, the ISOR, and the SRIA all fail to provide "supporting information" for the determination that there was no alternative that would be "as effective and less burdensome". ARB clearly outlined the reasons for rejection of alternatives proposed by the commenter in the SRIA analysis that can be found in Appendix E of the ISOR with updated results in Appendix F, and further explained in Chapter VII of the ISOR. These explain in detail why the various alternatives proposed by the commenter and others are not, in fact, "as effective and less burdensome."

404. Comment: **LCFS 46-73**

The comment requests ARB to delay the final rule making until commenter's issues are addressed.

Agency Response: The commenter repeats comments **LCFS 46-34** and **LCFS 46-68**. See responses to those comments.

405. Comment: **LCFS 46-74**

The comment asserts that ARB staff has not included all necessary materials in the rulemaking file, as required by Government Code section 11347.3(a), (b)(6).

Agency Response: ARB staff disagrees, having included all necessary materials in a rulemaking file comprised of over 1,200 pages (ISOR and appendices) and 710 references of varying length.

The commenter assumes that some additional documents in possession of ARB's 11 board members and approximately 1300 employees *also* belonged in the record. The comment is not sufficiently specific to allow a response; what documents are missing? The commenter's repeated quotation in italics of the word "all" suggests that the commenter pictures a collection of documents potentially so broad as to make the rulemaking file too voluminous for the purpose of meaningful public participation. ARB does not favor deluging interested parties in an overload of information or documents.

ARB followed the long-standing practice of administrative agencies in California by (1) assembling the material on which it relied to form a proposal, (2) making a proposal, (3) making items (1) and (2) available to the public, then (4) receiving public comments and making those available, (5) considering those comments, and (6) responding publicly to those comments. That system, which the Legislature set forth in the APA, works reasonably well.

406. Comment: **LCFS 46-75/ADF 17-11**

The commenter expresses its concern about the completeness of the rulemaking files in the ADF and LCFS rulemakings.

Agency Response: The commenter expresses its concern about the completeness of the rulemaking files in the ADF and LCFS rulemakings. Only ARB can determine what ARB did rely upon in creating a proposal, and conversely what information, data or theories ARB did not rely on for any number of reasons. Such is the very essence of the discretion invested in an expert agency charged by the Legislature to address important, complex problems such as air pollution. While the commenter and any other member of the public are entitled to participate in the rulemaking process, it is manifestly ARB's province to determine what constitutes the relevant, credible, necessary foundation for any proposal.

The commenter goes on to propound a series of *questions* that "CARB legal staff" should respond to. Absent knowing what answers the commenter believes to be correct, the questions do not constitute "an objection or recommendation regarding the specific adoption . . . proposed" within the meaning of Government Code section 11346.9(a)(3).

Some of the commenter's questions are not legal in nature, but requests that CARB perform detailed clerical and paralegal tasks to assist the commenter's attorneys in pursuing litigation against CARB. For example, the commenter requests that "CARB legal staff" explain various matters and identify:

> [1] "each document or other file made available to the public under section 39601.5 prior to January 2, 2015, in connection with these two rulemakings;"
>
> [2] provide "the date it was made available;" and
>
> [3] provide "the method by which it was made available."

While the Administrative Procedure Act (APA) requires much, it does not require an agency to catalogue tens of thousands of documents for a commenter's convenience. ARB staff notes that over a period of several years there were 21 LCFS public workshops, and 26 ADF public workgroup or workshop meetings as part of developing these two related regulations. Along the way, ARB staff posted, as is its practice, a wide range of materials on the program web pages ARB maintains. Such materials have long been public.

This comment response is duplicated in the Alternative Diesel Regulation Final Statement of Reasons under Comment Letter **17_OP_ADF_GE**.

407. Comment: **LCFS 46-76**

The comment seeks clarifications on the inclusion of external communications in the rulemaking file.

Agency Response: See response to **LCFS 46-75**.

408. Comment: **LCFS 46-77**

The comment requests ARB staff to identify all information covered by section 39601.5 in connection with the current LCFS and ADF rulemakings.

Agency Response: See response to **LCFS 46-75**.

Appendix A

Comments on ARB's Corn Ethanol Land Use Emissions
February 10, 2015
Air Improvement Resource, Inc.

Introduction

ARB presented a new land use emission estimate for corn ethanol in the Initial Statement of Reasons (ISOR). The derivation of this estimate was discussed in Appendix I to the ISOR. ARB developed the corn ethanol estimate from the average of 30 scenarios, where each scenario represented a unique run of the Global Trade and Analysis Project (GTAP) model. The 30-scenario average is 19.8 g CO2 e/MJ. This value is 10.2 gCO2/MJ lower than ARB's current estimate of 30 g CO2e/MJ.

ARB held 3 workshops in developing the new LUC values; one in March 2014, one in September 2014, and a final one in November 2014. AIR participated in all 3 workshops, and submitted comments to the Staff on all 3 workshops. Our previous comments are included as Attachments 1-3 to this document.

Very little changed in ARB's emissions for corn between the November 22 workshop and the ISOR. The value at the November 22 workshop was 20.0 g CO2e/MJ.

Through the workshop process, we have made a number of comments on the Staff's approach and analysis. One comment was adopted, but the remainder were either ignored or shifted to ARB's "Long Term" project list. Table 1 below summarizes the status of comments made. We have divided the recommendations into two categories – GTAP, and AEZ-EF. [1] We have included 3 categories for the status – adopted, ignored, or shifted to long-term.

[1] GTAP determines how much and what type land is needed and where, and the AEZ-EF model determines the emissions of the various land transitions. Both models are needed to estimate LUC for a biofuel.

Table 1. Status of Recommended Items					
Category	AIR Recommendation	Adopted	Ignored	Long-Term	
GTAP	Revise the model land supply structure	X			
	Drop the lower price-yield values		X	X	LCFS 46-79
	Include multiple cropping effects			X	LCFS 46-80
	Evaluate land intensification effects		X	X	
	Include effects of conservation reserve program (CRP)			X	LCFS 46-81
	Include additional effects of fertilizer, livestock, paddy rice emissions			X	LCFS 46-82
	Develop and include cropland-pasture from other regions			X	LCFS 46-84
AEZ-EF	Do a comparison of CCLUB to AEZ-EF		X	X	LCFS 46-85

Table 1 shows that many of the items recommended have simply been shifted for future study. Most of these items were raised by both AIR and the Expert Working Group (EWG) at least 4 years ago (two examples are (1) including CRP in the analysis, and (2) including the effects of livestock and rice paddy emissions). We have listed several items as either being ignored and shifted to the future or just being ignored, because either Staff's response to our input was inadequate, or it was not addressed at all in the ISOR, or both.

For many of the items that have been shifted to further study, we have presented in comments submitted previously, information showing they could be included now (examples are land intensification effects). Some items shifted to further study legitimately require further study, for example, including cropland-pasture from other regions.

Overall, we believe the LUC value of 19.8 gCO2e/MJ for corn ethanol is still too high. The implications of overestimating the LUC value for corn ethanol are that it could lead to shuffling of fuels without any reduction in greenhouse gases and increased costs of compliance with the LCFS. LCFS 46-78

The following section discusses each of the comments above. We skip a discussion of the model structure, since that comment was adopted by the staff.

Price-Yield Values

The ARB analysis uses five price-yield values: 0.05, 0.10, 0.175, 0.25, and 0.35. The average of these 5 values is 0.19. The Purdue recommended value is 0.25, and the EWG recommended 0.25. ARB sponsored research indicating that there was little or no price-yield response (i.e., 0.0). Our comments on price yield were that ARB should drop the lower price yield values (0.05 and 0.10) because the research supporting these lower values was developed over the very short term (1-3 years of price and yield data), and the GTAP model is a longer-term model (5-10 years). [2] ARB utilizes an 11.59 billion gallon per year shock of corn ethanol in its corn ethanol modeling, clearly illustrating that ARB is exercising the model with a medium-term shock, and not a short term shock. Thus, ARB's use of short term price yield responses with the medium or longer term GTAP model is clearly inconsistent.

In the ISOR, ARB references a recent analysis by David Rocke at UC Davis in support of using lower price-yield responses. [3] The Rocke analysis utilized one set of data from a 2012 dissertation by Juan Francisco Rosas Perez. [4] The dissertation indicated that the price-yield response was in the region of 0.29, very close to the Purdue default value. Rocke obtained the data from the dissertation, conducted his own statistical analysis, and concluded that the data did not support the 0.29 price yield value.

LCFS 46-79 cont.

Because of the differences between these two analyses (Perez and Rocke), which are clearly important to understand fully, AIR requested the data Rocke used for his analysis from ARB staff. While staff said they were trying to get the data for AIR, the data was never supplied by staff. Therefore, we were unable to replicate Rocke's analysis of the Perez data. There is not enough information in Rocke's write-up to reject the Perez analysis (the rebuttal is only 3 pages). In addition, this is only one of two sources (according to Rocke) that were used to support the 0.25 price-yield value, Rocke did not attempt to critique the other source. Thus, because we were not able to replicate Rocke's sketchy analysis, and Rocke only critiqued one source, ARB cannot rely on the Rocke analysis for its use of low price-yield values, and should therefore eliminate the lowest value (0.05), or the lowest two values (0.05 and 0.10).

The impacts of eliminating one or both of these values on corn ethanol LUC emissions is shown in Table 1. Without the lowest price yield value of 0.05, the LUC value for corn is 17.62. Without both 0.05 and 0.10, the LUC value is 15.53

[4] "Essays on the Environmental Effects of Agricultural Production", Dissertation, Perez, Juan Francisco Rosas, Iowa State University.

gCO2e/MJ. As before, we recommend that ARB eliminate the lowest two price-yield values. LCFS 46-79 cont.

Table 1. Impact of the Low Price-Yield Values		
Average of ARB Scenarios	Average price-yield	LUC (gCO2e/MJ)
All (ARB value)	0.19	19.84
w/o 0.05 price-yield	0.21	17.62
w/o 0.05, 0.1 price-yield	0.26	15.53

Multiple-Cropping and Land Intensification

GTAP currently does not include any double or multiple cropping. When crop prices increase, producers get more out of the same piece of land by planting second and even third crops. This is particularly true in Brazil, where corn is planted on soybeans, and even in the US, where wheat is planted and corn/soybeans are planted in the same year. This is one process of land "intensification", whereby existing cropland is used to a greater degree before conversion of non-cropland.

In our September 2014 workshop comments (Attachment 2) we pointed out that multiple cropping can be conservatively modeled by increasing the price yield value. We recommended a +0.05 increase in price yield from about the 0.25 Purdue default level to 0.30, other commenters have recommended similar and higher amounts. Ignoring multiple cropping, as ARB is currently doing (or, just deferring including it to some unknown future date) is not technically acceptable or defensible.

LCFS 46-80 cont.

The empirical evidence for intensification globally was developed from data by the Babcock/Iqbal analysis, which we covered in detail in our comments on the November 22 workshop. [5] This analysis showed that over the last 10-15 years of biofuel expansion, there has been no net land conversion from forest and pasture to crops in many regions such as the US, Western Europe, and China. In our November comments (Attachment 3), we developed a filter that could be applied to the ARB results based on GTAP to estimate LUC of biofuels. We showed that application of this filter would reduce LUC from corn ethanol from 20 gCO2/MJ to a range of 6-13 g CO2e/MJ (see Table 2 in Attachment 3).

ARB has known about the inability of GTAP to account for multiple cropping since the last time land use values were adopted in 2009. It is inexcusable that ARB would still be relying on LUC values that do not include multiple cropping or more generally, some accounting for land intensification. We have provided two methods to ARB for accounting for these effects in this version of LUC estimates – either use a somewhat high price-yield factor, or use the filter we developed from the

[5] Using Recent Land Use Changes to Validate Land use Change Models", Babcock and Iqbal, Staff Report 14-SR- 109, Center for Agriculture and Rural Development, Iowa State University, www.card.iastate.edu.

Babcock/Iqbal study. These methods can be applied conservatively to avoid over-accounting for their effects. Of course, this, as well as many other issues, could also be studied further in the future. But some accounting for multiple cropping and land intensification should be included with this LCFS re-adoption. LCFS 46-80 cont.

Conservation Reserve Program

Our comments have also consistently pointed out that ARB should also include the effects of Conservation Reserve Program land (CRP) in mitigating land use emissions. The GTAP model already includes the computer code to access CRP land.[6] We have also presented direct evidence from USDA statistics that conversion of CRP back to crop has already occurred over the last five years (see Table 2 of our comments on the March 11 workshop, Attachment 1). Therefore, we are not discussing a theoretical possibility of this conversion occurring in the future with biofuel expansion. It has already happened, and ARB has ignored it.

Inclusion of US CRP land in estimating LUC of biofuels would clearly lower LUC values. The carbon stored on CRP (above and below ground) reactivated to crops would be similar to ARB's current estimate for pasture. It could even be a little higher than pasture, if shrubs and other plants had started to grow on this land. In some cases, CRP land could even include some young forest. However, it is not likely that forest CRP land would be reactivated back to crops, rather the CRP converted back to crops would be land relatively easy to convert. But the inclusion of CRP land in GTAP modeling would reduce overall the forest estimated to be converted in the US, thereby showing a reduction in GHG emissions from the case of not including CRP land in the analysis. LCFS 46-81 cont.

Include Livestock and Paddy Rice Emission Credits

These are other indirect effects that were identified at the time the last land use values were finalized by the ARB. The biofuel shocks increase crop prices, thereby reducing livestock herds and also reducing the paddy rice crop. Livestock and rice produce prodigious amounts of methane, so the reduction in these two items reduces GHG emissions from biofuels. EPA included these effects in its implementation of the Renewable Fuel Standard in 2010. Given that EPA included these effects several years ago, it is surprising that ARB postponed the inclusion of these effects in their modeling. LCFS 46-82 cont.

Include Fallow Land

---

[6] The AEZ-EF appendix indicates that "GTAP-BIO does not consider conversion of CRP land." This is not exactly true. The computer code for including this land is in the model, and it is easy to activate. AIR has activated this code, and GTAP, along with AEZ-EF (assuming CRP land is similar to pasture) predicts a 1-2 gCO2/MJ reduction for including CRP land in the analysis.

We showed in Table 6 of our comments on the November workshop (Attachment 3) that worldwide there are 193 million hectares of fallow land. The model currently has no capability of accessing this land for increased crop production even though it is probably the most likely land to respond to higher crop demand and is land that could be brought into production without any land use change. LCFS 46-83

Include Cropland-Pasture from other Regions

The GTAP model includes cropland-pasture for the US and Brazil. Cropland-pasture is land that is used alternatively for either cropland or pasture, depending on economics to the producer and other factors. The inclusion of the land type for these two countries reduced LUC emission predictions from GTAP significantly. The US and Brazil are not the only regions with cropland-pasture. Canada, Western Europe, and some other regions also utilize cropland-pasture. LCFS 46-84 cont.

Compare CCLUB to AEZ-EF

ARB uses its AEZ-EF model to estimate the emissions of various land transitions, for example, forest to crop, pasture to crop, crop to pasture and so on. The model was not finalized and released until late November 2014.

AIR has previously commented that ARB should also evaluate LUC emissions with the CCLUB model. [7]CCLUB is used by Argonne to estimate LUC emissions for various biofuels in the GREET model (GREET2013, GREET2014). CCLUB was available in late 2013. CCLUB basically uses the same international emissions that EPA used in the RFS, but has much more detailed emissions for the US. CCLUB is not even referenced by the AEZ-EF documentation. ARB claims to have evaluated CCLUB, but there is no indication of that in either the AEZ-EF documentation, in Appendix I, or in the ISOR. [8] Therefore, due to the fact that ARB released the final AEZ-EF model so late in the process, and that there are no references to CCLUB in any of the ARB documentation, we are not clear on what the advantages there are to AEZ-EF over CCLUB. There was little time for us to perform an in-depth analysis of the differences in these two models that estimate the emissions of various land transitions. LCFS 46-85 cont.

AIR evaluated the impact of using CCLUB instead of AEZ-EF for predicting emissions. The impacts are shown in Table 2. LUC emissions with CCLUB are less than ½ of ARB's AEZ-EF model. AEZ-EF is not superior to CCLUB, certainly the most technically defensible parts of both models should be combined.

---

[7] Dunn, J., Mueller, S, Kwon, H.Y., Wander, M., Wang, M., "Carbon Calculator for Land Use Change from Biofuels Production (CCLUB)", Argonne National Laboratory, ANL/ESD/13-8, September 2013.

[8] In their list of long-term updates to LUC in the ISOR, ARB's number 2 item is to "use improved emission factors, as they become available." However, it appears ARB has not fully evaluated emission factors in CCLUB, which were available long before ARB finalized its AEZ-EF model.

Table 2. Comparison of Corn Ethanol LUC Emissions	
Scenario	LUC (g CO2e/MJ)

Attachment 1

Comments on ARB's March 11 Workshop on
The Low Carbon Fuel Standard
Air Improvement Resource, Inc.
April 6, 2013

These comments are primarily on the workshop presentations provided by CARB, and some of the documentation provided by CARB on the AEZ-EF model shortly after the workshop. The following comments focus on Land Use Change and Facility Registration components of the LCFS.

Land use Change Emissions

There are two models used to estimate the land use change emissions – the Agri-Economic Zone Emission Factor (AEZ-EF) model, and the Global Trade Analysis Project (GTAP). GTAP is a general equilibrium model used to determine land transitions (like pasture to cropland and forest to cropland) in similar agro-economic zones in various regions of the world. The AEZ-EF model is used in conjunction with the GTAP to determine emissions released by the land-use transitions.

We discuss the GTAP model first, followed by the AEZ-EF Model. We then use the ARB-GTAP model and a much more appropriate Purdue GTAP model to estimate the impacts of our recommendations of changes on land use change (LUC) emissions for corn ethanol.

Global Trade Analysis Project (GTAP)

GTAP contains global land pools of cropland, forest, pasture, Conservation Resource Program (CRP) land (in the US), and cropland pasture (in the US and Brazil). The base year for the current model is calendar year 2004. In modeling biofuel increases, the model is "shocked" with the biofuel increase (corn ethanol, for example), and since this requires a significant increase in corn production, the model converts some other cropland to corn production, converts some pasture to crop production, and converts some forest to crop production. The model also contains a price-yield elasticity, such that when the model is shocked for increased corn ethanol, crop prices increase, and yields also increase somewhat on all cropland. Thus, increased production is met through (1) cropland expansion into non-cropland (which creates land use change emissions), and (2) yield increases on existing cropland.

LCFS 46-86

There are other ways in which crop production increases in addition to land expansion and yield increases. A 2013 study by Roy and Foley shows there are three other ways crop production increases: (1) using the existing standing cropland area more frequently by multiple cropping, (2) leaving less land fallow, and (3) having fewer crop failures.[9] None of these 3 ways involves a land use change, or land use change emissions. Furthermore, GTAP does not include these 3 factors: GTAP does not account for double cropping, has no fallow land inventory, and cannot model reduced crop failures. Roy and Foley point out that the influence in these 3 factors on crop production can be estimated by comparing trends in total harvested area to total cropland.

> The growth in annually harvested cropland and standing cropland has been changing in recent decades. Analyzing the 177 crops traced by FAO since 1961 shows that the amount of annually harvested land has increased much faster than the reported total standing cropland on the globe. While standing cropland has increased at the rate of 3.5 mha/year, the annually harvested land increased at a much faster rate of 5.5 mha/yr.

The difference in the above growth rates – 2.0 mha/year – is due to the 3 factors mentioned earlier, which have no land use emissions impact. The authors also examine the potential for the increase in harvested area to continue to increase faster than standing cropland in the future, and find that these trends should continue.

It is difficult to incorporate these factors into the current GTAP model, because these factors require a dynamic GTAP model, and the current model is a static model.[10] However, the analysis of these trends can be used to inform the ranges of input elasticities for the current static GTAP model used by ARB, particularly the price-yield elasticity. Increasing the price yield elasticity in GTAP increases crop production without a land use impact. Thus, the Ray/Foley study argues for a relatively high price-yield elasticity range. ARB, however, has selected a very low price yield elasticity range. This is discussed in more detail in the next section.

LCFS 46-86 cont.

Review of CARB's GTAP Modeling

Price-Yield Elasticity Range

GTAP includes a price-yield elasticity of 0.25 as a default. This level is in part based on extensive research by the GTAP modeling community. [11] The Expert Working Group also recommended this value. The EWG also recommended higher values for regions with significant double cropping, since GTAP does not explicitly include double cropping. GTAP researchers have also pointed out GTAP is a medium-term model, with projections being applicable in the 5-10 year timeframe. CARB appears to concur with this timeframe for GTAP, because CARB describes the model as a

[9] Ray, D.K., and Foley, J.A., *Increasing global harvest frequency: recent trends and future directions,* Environmental Research Letters, (2013), 044041, IOP Publishing.

[10] Purdue is continuing to develop a dynamic GTAP model for these and other reasons.

[11] Keeney and Hertel, "Yield Response to Prices: Implications for Policy Modeling", Working Paper #08-13, August 2008, Department of Agricultural Economics, Purdue University.

"Current" model, meaning, that its estimates are applicable to the 2013/2014 timeframe, even though its primary data is for 2004.[12]

CARB, however, performed sensitivity analyses using price-yield elasticity values from 0.05-0.30 (20%-120% of the default value). CARB's selection of the lower end of the range came from a variety of price-yield studies that were very short term (1-2 years) in nature, and were clearly not appropriate for the GTAP timeframe. All studies on data less than about 4 years should not even be considered in establishing the range of this parameter to use in modeling. Furthermore, CARB did not consider the analysis by Ray and Foley in determining the range of price-yield values to use.

LCFS 46-86 cont.

CARB performed sensitivity analyses on several other parameters. Most of these values were in the range of 80%-120% of the GTAP default level, for example, CARB performed sensitivity modeling of the ETA parameter at the baseline (default), 80% of the baseline, and 120% of the baseline. We support performing sensitivity modeling at different price-yield levels, however, the range should be at least 80%-120% of the Purdue baseline value of 0.25, or 0.20 to 0.30. However even this range is not nearly high enough to properly reflect the increase in crop production that has occurred without land use changes reflected by Ray and Foley analysis referenced earlier.

ETL1 and ETL2 Values

CARB updated the land transformation elasticities (ETL1 and ETL2) in GTAP prior to estimating land use changes. ETL1 governs the transformations between forest, crops, and pasture, and ETL2 governs the transformations between various crops. CARB appears to have used some, but not all, ETL1 and ETL2 values from a 2013 Applied Science paper by Taheripour and Tyner. [13] In the Applied Sciences paper, Taheripour and Tyner indicate

LCFS 46-87

> We tune the regional land transformation elasticities based on actual historical observations on changes in land cover and distribution of cropland among alternative crops during the past two decades. To accomplish this task we use published data on cropland use around the world by the Food and Agriculture Organization (FAO) of the United Nations over the period 1990-2010.

The differences in ETL1 and ETL2 values between the Applied Sciences paper and CARB are shown in Table 1 below.

LCFS 46-87 cont.

It is not clear why CARB chose different ETL1 and ETL2 values than Purdue, and what analysis or data CARB based these values on. An explanation of this should be provided for review, or CARB should use the ETL1 and ETL2 values that were developed by Taheripour and Tyner.

Model Nesting Structure

The Applied Science paper referenced above also included another major improvement in GTAP. According to the paper

> The GTAP-BIO model puts three types of land cover items (forest, pasture, and cropland) into one nest an implicitly assumes that the economic costs of converting one hectare of forest to cropland is similar to the economic cost of converting one hectare of pasture land to cropland and vice versa. This set up another key deficiency of the GTAP-BIO model. Including cropland, forest, and pastureland in the same nest could cause systematic bias in land conversion processes among land cover types due to biofuel production. In general this is not the case and often the opportunity costs of converting forest to cropland is higher than the economic cost of converting pastureland to cropland.

LCFS 46-88

The Expert Working group studying elasticity parameters in GTAP identified this nesting structure as a key deficiency in the model and recommended using a revised nesting structure.

Taheripour and Tyner altered the land cover component of the land supply tree to have forest and pasture land in two different nests. Then they re-evaluated global land use impacts due to the USA ethanol program using the improved model tuned with actual observations. They showed that, compared to the old model

> The new model projects: (1) less expansion in global cropland, (2) lower share for the USA economy in global cropland expansion, (3) and lower forest share in global cropland expansion.

CARB did not include the model nesting structure changes implemented by Taheripour and Tyner, and recommended by the Expert Working Group, even though this revised model was available to CARB in early 2013. CARB should include this critical change in the GTAP model. LCFS 46-88 cont.

Additional Cropland/Pasture Areas in Canada and EU27

GTAP has been updated to include cropland/pasture in the US and Brazil (CARB used the model with these additions). Other regions of the world, such as Canada and the EU27 (and probably many other regions of the world) also have a significant amount of cropland/pasture and idle land. These land areas should be added to GTAP. LCFS 46-89

Conservation Resource Program Impacts

The GTAP model includes the ability to include CRP land in the land inventory for the US. There has been a significant amount of land converted to production from CRP land in the last seven years. Table 2 shows data from the Conservation Resource Program. [14] These data show over 10 million acres of CRP land have gone back into production. These are not forest acres that have gone into production. Over the period from 2007-2011, CRP acreage in wetlands and buffers increased. Clearly, GTAP should be run to access CRP land in the US prior to converting forests or even cropland/pasture. LCFS 46-90

AEZ-EF Model

Use of Carbon Data on Accessible and Inaccessible Forests to Determine Emissions from Forest Conversion

The AEZ-EF report indicates

> The carbon data used in AEZ-EF have been aggregated to GTAP-BIO boundaries, but they include both accessible and inaccessible forests, as well as grasslands other than those used for livestock grazing, and thus represent broader resources than those represented in GTAP-BIO.

LCFS 46-91

It is not clear why CARB is including inaccessible forests in developing forest carbon stocks. If forests are inaccessible, then it is highly unlikely they would be converted to pasture or cropland. CARB should instead develop forest carbon from accessible or commercial forests. Detailed carbon data on public, private, and other forests is utilized by EPA in estimating its annual GHG inventories.[15] The carbon in private forests (most likely of forests to be converted to pasture/cropland) is much lower than public or other forests.

Wood Used to Produce Energy

In the new AEZ-EF model, for forest converted to cropland or pasture, CARB is now accounting for carbon stored in hardwood products (HWP). The storage rates are different for different regions, and are based on a 2012 study by Earles, Yeh, and Skog. The HWP fraction ranges between 2-36%.

LCFS 46-92

In addition to accounting for carbon stored in HWP, CARB should also account for wood mass that is used for fuel during forest clearing. Wood that is burned to

[15] USDA Forest Service (2010a), Forest Inventory and Analysis National Program:User Information. U.S. Department of Agriculture Forest Service. Washington, DC. Available online at http://fia.fs.fed.us/tools-data/docs/default.asp.

produce energy (for a sawmill, for example) is replacing fossil-fueled energy, and is renewable. CARB does not count CO_2 emissions from facilities that use waste wood to produce energy for fuel production (CARB does, however, count non-CO_2 GHG emissions, which is appropriate). Heath et al estimate that 35% of carbon from forest clearing is used for energy.[16] In the US, Canada, and the EU27, CARB should not count the CO_2 from wood used to produce energy.

LCFS 46-92 cont.

CCLUB Model

CARB should consider using the Carbon Calculator for Land Use Change from Biofuels Production (CCLUB) model for estimating emissions.[17] Like AEZ-EF, the model was designed to be integrated with GTAP. It has several advantages over AEZ-EF. First, instead of using the Harmonized World Database (HWD) for soil, it uses the CENTURY model, which contains much more specific information on soil carbon for the US than the HWD, on a county-by-county basis. Second, it uses county-by-county carbon data from forest ecosystems for the US from the Carbon Online Estimator (COLE) database, developed by Van Deusen and Heath in 2010 and 2013. [18,19] Third, it allows the user to input HWP fractions, and fourth, it does not count CO_2 from the forest wood used to produce energy. For areas outside of the US, it utilizes Winrock emissions.

CARB has conducted uncertainty analysis of its land use estimates using only AEZ-EF and GTAP. Using the CCLUB model with GTAP to estimate land use change emissions would also provide more information on the uncertainty of CARB's estimates.

Updated LUC Modeling

AIR downloaded ARB's GTAP model and the AEZ-EF model to determine the impacts of some of our suggestions. ARB did not supply example run results for any particular biofuel shock. ARB ran the models under 1440 different input conditions, for 5 different biofuel shocks, and determined the average emissions for each of the 1440 runs (a total of 7200 runs). The results are shown in Table 3.

Table 3. ARB Land Use Results, March 11 Workshop

Biofuel	LUC Emissions (gCO2e/MJ)
Corn Ethanol	23.2
Sugarcane Ethanol	26.5
Soy Biodiesel	30.2
Canola Biodiesel	41.6
Sorghum Ethanol	17.5

In this analysis we test the impact of three factors that should be changed in the ARB modeling:

- ARB's ETL1 and ETL2 values
- Model Nesting Structure
- Price-Yield Range

LCFS 46-94

It is clearly impractical for us to run the model 1440 times to test the impact of these 3 items. However, it is possible to test the impact with a representative model run. To create the representative model run, we first estimated the average of the ARB inputs. Next, we ran the model with a corn ethanol shock to determine the LUC emissions. Finally, we changed the price yield elasticity, until the model run gave the same answer as corn ethanol in Table 3. The average model inputs are shown in Table 4.

Table 4. Average ARB GTAP Inputs

Input Parameter	Average Value
Price Yield (Ydel)	0.175
PAEL, US	0.3250
PAEL, Brazil	0.1875
ETA	ARB Baseline
ETL1, ETL2	ARB Baseline

When we ran the case in Table 4, we obtained corn ethanol emissions of 21.66 gCO2e/MJ. We then reduced the price yield elasticity from 0.175 to 0.1507, and obtained emissions of 23.22 gCO2e/MJ, which is the same as ARB's corn ethanol estimate. This is our single run that generally represents CARB's 1440 cases.

The impact of the 3 changes on LUC emissions for the corn ethanol shock are shown in Table 5.

Table 5. Impacts of Changes in GTAP Modeling	
Scenario	LUC Emissions (gCO2e/MJ)
AIR "Representative" Case	23.22
Change ETL1 and ETL2 parameters to Purdue "tuned" values	21.20
Implement Purdue GTAP Nesting Structure	19.00
Use Purdue Default Price-Yield Range	14.63
Include CRP Land Conversions	13.75

Table 5 shows likely emissions of 13.75 g CO2e/MJ instead of 23.22 gCO2e/MJ if these changes are implemented and the various runs are repeated. The emissions would be even lower if the model were modified to more properly reflect (1) the Ray and Foley analysis that a major part of crop production has increased without a land use change, and (2) the ARB analysis properly accounted for wood from forest that is used for fuel and replaces fossil fuel during forest clearing.

LCFS 46-94 cont.

2.0 Fuel Pathways and Producer Facility Registration

Growth Energy supports the streamlining of the application process for biofuel production facilities, however, Growth Energy does not support limiting the pathways a facility can apply for, nor does Growth Energy support implementation of CI "bins" that facilities must use when registering the facilities. These changes would both severely limit continued innovation in biofuel facilities.

LCFS 46-95

At the workshop, CARB envisioned bins of either 5, 7, or 9 CI values, with all facilities falling in a bin range getting the same, midpoint value of the bin. For a 7 CI bin case, for example, facilities falling in a bin from 61-67 would all be assigned a value of 64, whether their CI is 61.1 or 66.9. Furthermore, a facility with an actual CI of 65 (assigned value of 64) would not be able to obtain a lower CI value unless it reduced its actual CI to the upper part of the next bin range, or 60.9 (a difference of 4.1 CI). A facility at 61.1, however, with an assigned value of 64 would be able to get into the next lowest bin by reducing its CI to the same value of 60.9, a difference of only 0.2 CI. Clearly, if we are understanding CARB's bin approach correctly, it appears to have significant problems, no matter how the bins are designed.

LCFS 46-96

A second major concern we have with the bin approach is that it is not at all consistent with what ARB is proposing for refineries producing gasoline and diesel. CARB's GHG Emission Reductions for Refineries proposal indicates that CARB is willing to provide credit under the LCFS regulations to refineries, with no minimum CI reduction required. In other words, a refinery that has a project to reduce its CI by 0.1 CI would receive consideration. But under the binning approach for

LCFS 46-97

biorefineries above, there is a much higher minimum threshold for consideration of a lower bin. Thus, gasoline/diesel refineries receive special treatment that biofuel facilities do not.

LCFS 46-97 cont.

Attachment 2

Comments on ARB's September 29th Workshop
On Land Use Change Emissions
Air Improvement Resource, Inc.
October 17, 2014

Introduction

On September 29, 2014 ARB held a workshop on land use change emissions. ARB presented new information on their analysis of LUC emissions for corn ethanol, soybean biodiesel, canola biodiesel, cane ethanol and sorghum ethanol.

We have reviewed the information CARB presented at the workshop and thereafter, and also have obtained the new GTAP model and performed some additional modeling runs. We appreciate the additional time that the staff has provided for us to provide these comments. We will have additional comments later. The comments are presented here are organized into the following sections:

- Irrigated/Rain-Fed Cropland Category
- Land Supply Structure
- ETL11, ETL12, ETL4 and ETL5
- ARB's 30-Scenario Average
- Yield-Price Elasticity
- Cropland Pasture Elasticity
- Corn Ethanol LUC Impacts of our Recommendations

Please add these comments to the page on ARB's website that has been previously established for workshop comments.

Irrigated/Rain-fed Cropland Category

LCFS 46-98

Earlier versions of the GTAP model used an average of irrigated and rain-fed cropland. The expansion of cropland in the model did not differentiate between irrigated or rain-fed areas. Irrigated cropland typically has a higher yield compared to rained cropland in a given Region and AEZ. If cropland expansion occurs on irrigated land, higher yields translate into smaller land requirements. But availability of water for irrigation may limit expansion into irrigated land.

The new version of GTAP developed by Purdue for ARB includes an option to differentiate between irrigated and rainfed cropland. The availability of irrigated land for cropland expansion then can be constrained in certain regions and AEZs, if there is sufficient evidence to constrain expansion of irrigated lands.

ARB used analyses and data from the World Resources Institute (WRI) to determine which regions and AEZs within these regions to constrain expansion into irrigated land.

Figure 1 shows the Regions and AEZs where irrigated land is constrained for the ARB LUC analyses. These regions and AEZs were determined from the WRI reports. [20][21]

LCFS 46-98 cont.

Figure 1

1 indicates water constrained

We reviewed the WRI reports, but were unable to determine how ARB used the information in these reports to identify the regions and AEZs that should have irrigated land constrained. Because we have been unable to locate the technical documentation that would explain how ARB used the WRI reports to draw the conclusions shown in Figure 1, we request that the staff provide the public with that documentation, and then allow at least five business days for comment.

ARB presented little information at the workshop to evaluate the size of this impact on land use emissions. To evaluate the impact of constraining expansion on irrigated land, AIR ran GTAP with and without the irrigation constraint for corn ethanol, using Purdue and ARB's average elasticity inputs. The results are shown in Table 1.

[20] *Aqueduct Global Maps 2.1: Constructing Decision-Relevant Global Water Risk Indictors*, WRI, April 2014.

[21] *A Weighted Aggregation of Spatially Distinct Hyrdrological Indicators*, WRI, December 2013.

Table 1. LUC Impact of Constraining Crop Expansion on Irrigated Land in Some Areas: Corn Ethanol					
Scenario	Ydel	PAEL	ETA	Irrigation Constrained?	LUC (gCO2e/MJ)
Purdue Best Estimates	0.25	0.4/0.2	Baseline	No	14.23
				Yes	13.32
ARB Average	0.19	0.3/0.15	Baseline	No	17.22
				Yes	16.09

For corn ethanol, constraining expansion on irrigated land adds 0.89 g/MJ for the Purdue default case, and by 1.13 g/MJ for the ARB average. ARB must document how the WRI data was used to develop areas on which cropland cannot be expanded, before including this effect for the various biofuel feedstocks.

LCFS 46-98 cont.

Land Supply Structure

The land supply structure in GTAP was revised in 2013 to include four nesting structures instead of two.[22] Prior to 2013, one nest included the substitution of different types of land – forestland, cropland, and pastureland – and a second nest under cropland that included different types of crops. One elasticity – ETL1 – governed the substitution between forestland, cropland, and pastureland, and a second elasticity – ETL2 – governed the substitution between crop types. A significant concern of ARB's Expert Working Group (EWG) was that forestland, cropland, and pastureland were all in the same nest with one elasticity, which meant that forestland is as readily converted to cropland (and vice versa) as pastureland. Clearly this is not the case – the economics of converting forest to crops must be much different than converting pasture to crops.

In 2013, the land supply structure was modified by Purdue such that the first nest includes only forestland and a second category called cropland+pasture. The second nest under cropland+pasture was divided into cropland and pastureland. The third nest under cropland was divided into irrigated and rain-fed. Finally, both irrigated and rain-fed cropland was divided into different crops. The following new elasticities were defined:

LCFS 46-99 cont.

- ETL11: substitution at the first level between forest and cropland+pasture
- ETL12: substitution at the second level between cropland and pasture
- ETL2: substitution between irrigated and rain-fed
- ETL4: substitution between crops under irrigated land
- ETL5: substitution between crops under rain-fed land

The new land supply structure allows the use of more disaggregated elasticities of transformation between land types.

ARB modeled two approaches in estimating land use emissions – Approach A, which assumes ETL11=ETL12, and Approach B, which provides separate estimates for ETL11

[22] See reference 13.

and ETL12. Approach A is essentially the GTAP model prior to the land supply improvements (i.e., only 1 elasticity which governs conversion of forest, crop, and pasture), while Approach B is the GTAP model with the improvements (expanded nesting supply structure). Elasticity values for Approaches A and B are shown in Attachment 1. In both approaches, the ETL2 values are identical; it is only the ETL11 and ETL12 values that are different between the approaches.

ARB did not implement Approach B in its materials presented at the March 11, 2014 workshop, in spite of the fact that GTAP was updated for land supply structure more than a year ago in January 2013. One of Growth Energy's primary comments on the materials ARB supplied at the March 11 workshop was that ARB should utilize a GTAP model with the updated land supply structure with different elasticities of conversion for forest and pasture. (i.e., Approach B). Approach A must be recognized as unrealistic, and not appropriate for use in the new regulation to set the indirect emissions factor for land use change attributed to biofuel expansion. Approach A is *not* an equally technically appropriate alternative to Approach B. Purdue no longer utilizes Approach A – it is simply now an approach that tries to mimic the old GTAP model prior to the significant improvements made in early 2013. LCFS 46-99 cont.

ETL11, ETL12, ET4, ETL5

ARB's ETL11, ETL12, ETL4, and ETL5 values for Approach B were presented in Slide 24 of the September 29 presentation. Based on the information that is currently available, we believe those values are more appropriate than some alternatives. LCFS 46-100

ARB's 30-Scenario Average LUC Emissions

In the March 11 workshop, ARB modeled 1440 separate scenarios for each biofuel, and averaged the results of these scenarios to estimate LUC for each biofuels. In the September 29 workshop, Staff had reduced this to 30 separate GTAP runs, varying 3 separate input elasticities: the yield price elasticity (YPE, or Ydel), the cropland pasture elasticity (PAEL) for the US and Brazil, and the elasticity of crop yields with respect to area expansion (ETA). There are five values for Ydel, 2 for PAEL, and 3 for ETA (5*3*2 = 30). LCFS 46-101

Growth Energy has commented previously that the number of runs should be reduced (and they have), and further support doing GTAP runs at varying elasticities, since these can affect the results. (See Attachment 2.) However, we believe that ARB has selected the wrong range of values to use for two of the input elasticities.

It is worth noting that Purdue has "best estimates" for each of these inputs. The ARB input values and Purdue best estimates are shown in Table 2.

Table 2. ARB Input Elasticities Compared to Purdue Best Estimates				
Parameter	Description	ARB Values	ARB Average Value	Purdue Best Estimate
YPE	Yield Price Elasticity	0.05, 0.125, 0.175, 0.25, 0.35	0.19	0.25
PAEL	Cropland pasture elasticity*	0.2/0.1, 0.4/0.2	0.3/0.15	0.4/0.2
ETA**	Elasticity of crop yields with respect to area expansion	Baseline, 80% of baseline, 120% of baseline	Baseline	Baseline

*The first value is for the US, the second for Brazil
** ETA varies by region. The baseline values used by ARB are the same as used by Purdue

For YPE, the ARB range is from 0.05 to 0.35, with an average value of 0.19. The range in the March 11 workshop was from 0.05 to 0.30, so ARB has increased the upper end of this range by 0.05. The average value is lower than the Purdue best estimate of 0.25, and lower values yield to higher land use emissions. For PAEL, ARB selected the ARB best estimate and an estimate one-half of that. The average of the two ETA values for Brazil and the US is lower than the Purdue best estimate. Again, lower values lead to higher land use emissions. Finally for ETA, ARB selected the Purdue best estimate as the central value, and values higher and low than the best estimate. The average of the three is at the Purdue best estimate. LCFS 46-101 cont.

For PAEL, ARB seems to have followed the methodology of selecting values higher than and lower than the Purdue best estimate. This approach makes sense to us. However, for YPE and ETA, ARB selected values rather arbitrarily that yield an average value that is significantly different than the Purdue best estimate. ARB has not presented reasons or a rationale why it did this, so it appears they did this for the sole purpose of increasing the land use emissions of crop-based biofuels. We therefore ask that ARB explain those reasons to the public and allow at least five business days for comment. Because ARB must use the best available scientific information when writing its greenhouse gas regulations, we believe that ARB needs to explain why, if it maintains the current approach, it believes that its approach is scientifically superior and uses the best available scientific data.

We present the impacts of this arbitrary decision making process later in these comments.

<u>Yield Price Elasticity (YPE, also Ydel)</u>

In our comments on the previous workshop, we indicated that GTAP is a medium term model, and that YPE values developed over the very short term were not appropriate -- as previously noted, ARB is required to use the best available scientific information under the 2006 law that applies here. The values below 0.15 referenced by ARB were short- LCFS 46-102 term values, therefore, ARB should not be using values below 0.15 (i.e., 0.05 and 0.125), as they are not consistent with GTAP's general timeframe.

In addition, in our previous comments we presented information showing that Purdue's best estimate value of 0.25 does not include double-cropping, conversion of fallow land to cropland in the US, Canada and the EU27 regions, and conversion of Conservation Reserve Program (CRP) land in the United States.[23] We presented significant, substantial and compelling evidence on the conversion of fallow land and CRP land in those comments. CRP land is in the GTAP land supplies and could be utilized directly. We pointed out that both double cropping and fallow land conversion could be simulated with higher Ydel values (i.e., values above 0.25).

LCFS 46-102 cont.

As indicated in the previous section, ARB used two values below 0.15 – 0.05 and 0.15. We believe these should be dropped from the Ydel analysis since they are not consistent with GTAP. Second, we believe ARB should expand the upper limit of Ydel to 0.50. The values we are recommending are 0.15, 0.2, 0.25 (Purdue best estimate), 0.3, and 0.5. The average of these values is 0.28, which is only 0.03 above the Purdue best estimate, and a reasonable conservative average to reflect a small amount of double cropping and/or fallow land conversion. If the staff does not agree, we ask that it explain why in a manner that we and other interested parties can address in a timely manner, and that the staff can consider before it proposes the new regulation.

Cropland Pasture Elasticity (PAEL)

ARB used the Purdue best estimate (0.4/0.2) and one-half of the best estimate (0.2/0.1). There is no information given on why ARB used one-half of the Purdue best estimate without also using something above the Purdue best estimate, for example, 0.6/0.3. The purpose of sensitivity analysis is determine how the model inputs affect the results. Using a sensitivity analysis on only the "low" side of the Purdue best estimate skews the land use values higher, and is not consistent with scientific norms or the requirement to use the best available scientific information. We recommend running three PAEL values, where one is the Purdue best estimate and the other two are higher and lower than the Purdue best estimate. If the staff does not agree with that recommendation, we ask that it fully explain why it is not doing so, in time for the public to comment

LCFS 46-103

Corn Ethanol LUC Impacts of our Recommendations for Elasticity Inputs

The time allowed by the staff to prepare these comments did not permit us to run all of CARB's 30 cases to establish a baseline, but instead, we ran the average of the elasticity inputs, and the high and low. Results are shown in Table 3 compared to ARB's results of

LCFS 46-104

[23] Double cropping refers to the practice of growing two crops on the same land in the same season. For example, often corn or soybeans are grown after winter wheat on the same land in the US. In Brazil, because the growing season is longer, often corn is grown after soybeans. The Conservation Reserve Program is a cost-share and rental payment program under the United States Department of Agriculture (USDA), and is administered by the USDA Farm Service Agency (FSA). The CRP encourages farmers to convert erodible cropland or other environmentally sensitive acreage to vegetative cover.

the 30 runs. As shown in Table 3, values generated by us are lower than ARB's values. The reasons for this are not clear. Our program files have been provided to the staff for these cases for review. For now, we have also constrained expansion on irrigated land, even though we have not had a chance to review the method ARB used to incorporate data and information from the two WRI reports.

Table 3. ARB Average, Low and High LUC Emissions for Corn Ethanol (Approach B with Irrigation Constrained)

Case	Ydel	PAEL	ETA	AIR LUC gCO2e/MJ	ARB LUC gCO2e/MJ
Average of ARB Inputs	0.19	0.3/0.15	Baseline	17.22	21.6
ARB "High"	0.05	0.2/0.1	80% of Baseline	34.49	37.0
ARB "Low"	0.35	0.4/0.2	120% of Baseline	9.68	11.5

Basically, we are recommending that ARB use the Purdue best estimates for elasticity inputs, except for Ydel, which we believe should average about 0.28 or so to reflect some double-cropping which typically takes place in Brazil and also in the US and other areas, and also conversion of some fallow land in the US, Canada, and the EU27, at a minimum. We have estimated emissions by utilizing average input parameters, instead of making 45 runs; but acknowledge that it would be more precise to perform the 45 runs and determine average emissions, since some of the effects are likely not to be linear.[24] Results are shown in Table 4.

LCFS 46-104 cont.

Table 4. ARB Average and Recommended Values for Corn Ethanol (Approach B with Irrigation Constrained)

Case	Ydel	PAEL	ETA	LUC (gCO2e/MJ)
Average of ARB Inputs	0.19	0.3/0.15	Baseline	17.22
Purdue Best Estimate	0.25	0.4/0.2	Baseline	14.23
AIR Recommended*	0.28	0.4/0.2	Baseline	13.23

* We recommend performing the 45 runs and determining the average emissions, which may differ from 13.23 g/MJ.

The LUC with the Purdue best estimate inputs is 14.23 gCO2e/MJ. Our recommendation results in LUC emissions of 13.23 gCO2e/MJ, based on these inputs. Here again, we would like to know if the staff agrees with this recommendation, and, if not, we request an explanation why it does not agree in time for us to provide further input, that the staff can consider as it develops the new regulatory proposal.

[24] 45 = 5 Ydel values (0.15, 0.2, 0.25, 0.3, 0.5), 3 PAEL values (0.2/0.1, 0.4/0.2, 0.6/0.3), and 3 ETA values (baseline, 80%, 120%).

Attachment 3

Comments on November 20 ARB iLUC Workshop
Air Improvement Resource, Inc.
December 4, 2014

Introduction

On November 20 ARB held a third workshop on indirect land use (iLUC) emissions of various biofuels. New land use emission values were presented by the Staff. A summary of the emissions for corn ethanol from the different workshops is shown in Table 1. The emissions of corn ethanol dropped slightly from 21.6 g/MJ to 20 g/MJ.

Table 1. Corn Ethanol iLUC Values (gCO2e/MJ)

Biofuel	Current Regulation	March 2014	September 2014, Approach B	November 2014, Approach B
Corn Ethanol	30.0	23.2	21.6	20.0

Very little new information was presented at this workshop. One decision that ARB made was to use GTAP "Approach B" in estimating land use emissions. Putting to the side numerous other issues related to the iLUC analysis being undertaken by the Staff and stakeholders, the use of "Approach B" is an improvement worthy of support, because it makes the GTAP model ARB is using consistent with the GTAP model developed by Purdue that is described in detail in the January 2013 Applied Science report by Purdue.[25] This approach uses separate elasticities of transformation of Forest-to-Crops and Pasture-to-Crops. LCFS 46-105

ARB made some changes in the AEZ-EF model, but as of November 30 has not released the AEZ-EF model for review and comment. As a consequence, we cannot comment on this model until it is provided for review. In order to permit effective participation in the rulemaking, ARB should make the model fully available without further delay. Waiting until the 45-day process is not appropriate given the complexity and importance of the issues that the AEZ-EF model is supposed to address.

ARB's price-yield elasticity range stayed the same as the previous workshop. According to ARB, this decision was based on a study by UC Davis. However, the UC Davis study was also not made available, so it is impossible to comment on that decision. ARB should provide public access to the relevant study and supporting materials without further delay. Consequently, our comments on price-yield remain the same as they before, i.e., that ARB should disregard th`e two lowest price-yield LCFS 46-106

[25] See reference 13.

elasticities it is currently using, and use somewhat higher price-yield elasticities, so that the average price-yield elasticity is around 0.28 or 0.30, in order to reflect multiple cropping in some countries. Our previous comments on the September 29 workshop that discuss price-yield in more detail are included as Attachment 1 to this document. LCFS 46-106 cont.

This document summarizes our further comments on the workshop and ARB's current land use estimates. It is important to note at the outset that shortly before the workshop, a significant report on using recent land use change data to validate land use change models was released by Iowa State University.[26] The study has important implications for ARB's current land use emission estimates, and thus, important implications for the overall lifecycle emissions of various biofuels as compared to petroleum-derived fuels. In response to a question from a workshop participant, ARB indicated that they had a copy of this study and were reviewing it. We believe that the Staff should address the new study in the ISOR and provide it to the peer reviewers who will be engaged to examine iLUC issues. The ISU report's findings must be used by ARB in conjunction with ARB's GTAP modeling to derive new and updated land use emission estimates for the various biofuels prior to proposing re-adoption of the Low Carbon Fuel Standard (LCFS). Failure to do this would mean that ARB would not be using the latest and best available scientific and economic information to develop its lifecycle emissions for biofuels, which we understand to be required by the governing statute, A.B 32. LCFS 46-107

Our comments are organized in the following sections:

- Summary of the Babcock/Iqbal study
- Impacts on ARB's iLUC estimates for corn ethanol
- Other Comments

<u>Summary of Babcock/Iqbal Study</u>

The study developed new methods of using existing land cover data to evaluate the extent of land transitions in the time period between 2004-2006 and 2012-2014, the time period of fairly rapid expansion of biofuel in the US. These were compared to both the FAPRI and GTAP model estimates. In short, the paper concludes that the models used by EPA and ARB significantly overestimate pasture and forest conversions to crops in many parts of the world (including the US), because they do not include land "intensification", which includes increased double-cropping, reduced fallow land, and reduced land that is planted but not harvested (in other words, increasing the harvested to planted ratio). The authors purposely did not consider crop yield improvements, which is another form of intensification and, which if also included, would further reduce iLUC GHG estimates. [27] LCFS 46-108

[26] See reference 5.

[27] Land "extensification" means conversion of forest and pasture to cropland, whereas "intensification means making existing land (cropland and idle or fallow land) more productive.

The paper first summarizes annual inflation-adjusted price changes in a number of crops from 1965 to 2012, and shows that prices of a number of key crops increased for a number of years from 2004-2012. The paper cites another study by Babcock and others that opines that about one-third of the corn price increase during this time period was due to the biofuel mandate (RFS), other factors such as crop shortfalls and other sources of increased demand account for the rest of the price increase. The reason for showing these price trends was that "the magnitude of these real price increases after such a prolonged and sustained period of flat or falling prices presents a unique opportunity to quantify how world agriculture responds to incentives to produce more." The paper goes on to state that "because indirect land use is a response to higher market prices, model predictions of land use change should be similar whether the higher prices came from increased biofuel production, increased world demand for beef, or from drought that decreased supply. This implies that the pattern of actual land use changes that we have seen since the mid-2000s should be useful to determine the reliability and accuracy of model that have been used to measure indirect land use."

The study then examines changes in "harvested land" between the two periods. The source of this information is the Statistics Division of the Food and Agriculture Organization of the United Nations (FAOSTAT).[28] These data have been widely used to measure the impact of biofuel production on expansion of land used in agriculture and to calibrate the land cover change parameter in the GTAP model used by ARB. [29,30] But the study points out that harvested land is not equal to planted land, and that harvested land will deviate from planted land "when a portion of planted land is not harvested, and when a portion of land is double or triple- cropped." The study examines data from specific countries, and shows that existing land intensification has accounted for 76% of the increase in production in Brazil, and nearly all of the increase in production in India and China.

LCFS 46-108 cont.

An alternative measure of land use is developed, which is the change in FAO's arable land plus permanent crops. Figure 8, which plots the changes in this metric from 2004-2006 to 2012-2014 from the report, is shown below. The report states: "The countries in Figure 8 that either had negligible or negative extensive land use changes should be presumed to not have converted pasture or forest to crops in response to biofuel-induced higher prices. Rather, the presumption should be that any predicted change in land used in agriculture came from cropland that did not go out of production." The regions in Figure 8 with negligible or negative extensive land use changes are: Rest of Asia, the European Union, Canada, Russia, Oceania, China, South Africa, India, Central and Caribbean America, Bangladesh, Japan, Rest

of East Asia, Other Europe and Remainder of Former Soviet Union, Ukraine, and the US.

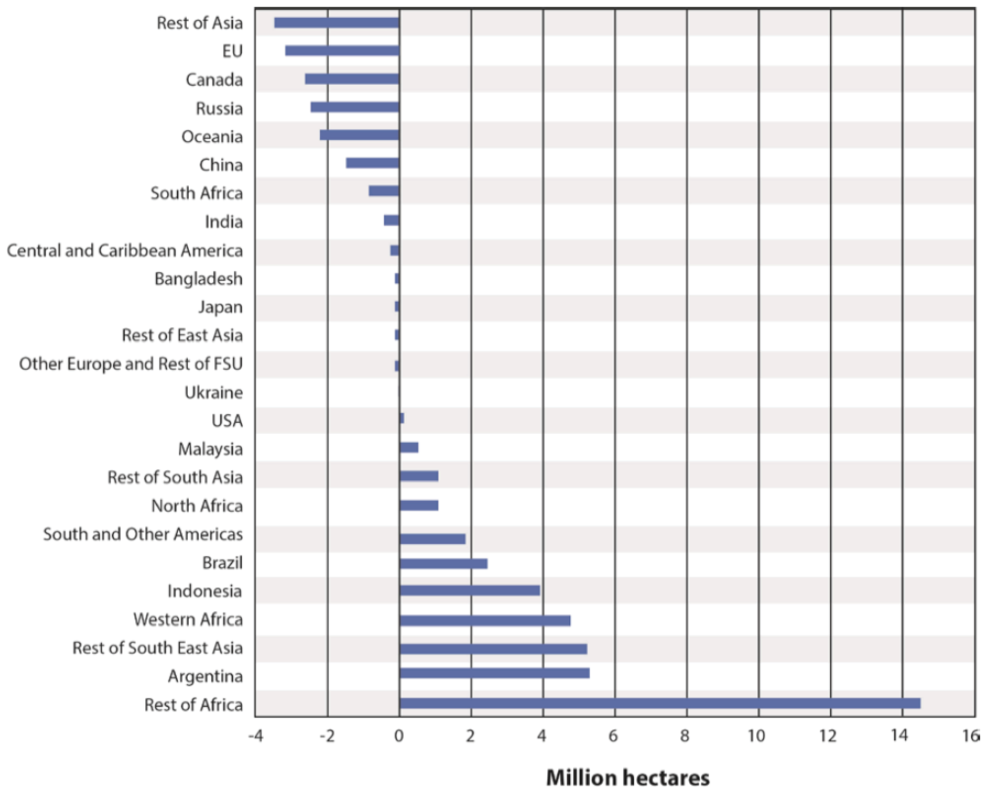

Figure 8. Change in Arable Land Plus Permanent Crops: 2004–2006 to 2010–2012

Figure 8 does show that Western Africa, and the "Rest of Africa", have significant extensive changes in arable land plus permanent crops (see Attachment 2 for countries included in the Africa regions of Figure 8). However, the study indicates that "the extent to which extensive expansion in African countries was caused by high world prices is small for the simple reason that higher world prices were not transmitted to growers in many African countries. Babcock and Iqbal cite a number of studies to support this conclusion.

LCFS 46-108 cont.

Impacts of Babcock/Iqbal Study on ARB's ILUC Estimates for Corn Ethanol

As indicated earlier, we do not have ARB's most recent AEZ-EF model so we cannot replicate ARB's 20 g/MJ value for corn ethanol (the 20 g/MJ value is an average based on 30 individual runs of the GTAP model, coupled with the AEZ-EF model). We can, however, use GTAP runs with the ARB GTAP model and AEZ-EF model ARB released as a part of the September 29th workshop to develop an estimate of the impact of Babcock/Iqbal's recommendations.

The primary conclusion from the Babcock/Iqbal study is that there are regions/countries of the world that had negative or negligible extensive land use changes between 2004-2006 and 2012-2014, and these countries and regions should be presumed not to have any forest or pasture conversion to cropland in response to biofuel expansion. The countries and regions in this category were listed earlier. Other countries not on this list can still be presumed to have some extensive land use conversions (i.e., conversion of forest and pasture to crops). Thus, the Babcock/Iqbal study can be used as a filter on the existing GTAP results.

Table 2 shows our GTAP modeling from our comments on the September 29 workshop (found in Table 4 of that report). We show the iLUC for 3 cases:

LCFS 46-108 cont.

- Average of ARB inputs
- Purdue best estimate
- AIR recommended inputs

Table 2. ARB Average and Recommended Values (Approach B with Irrigation Constrained) for Corn Ethanol

Case	Ydel	PAEL	ETA	AIR Estimated LUC gCO2e/MJ
Average of ARB Inputs	0.19	0.3/0.15	Baseline	17.22
Purdue Best Estimate	0.25	0.4/0.2	Baseline	14.23
AIR Recommended*	0.28	0.4/0.2	Baseline	13.23

The case with the "Average of ARB Inputs" is 17.22 gCO2e/MJ. This is less than ARB obtained with its average of the 30 scenario runs (21.6 gCO2e/MJ), but nonetheless, we can use this case to estimate the impacts of applying the country/region filter from the Babcock/Iqbal analysis.

Table 3 shows emissions from land transitions for the ARB average case. As shown in the table, Forest-to Crop transitions comprise 60% of emissions, and Pasture-to-Crop transitions comprise 21% of emissions.

Table 3. Land Transition Emissions for the ARB Average Case	
Land Transition	ARB Average, Megagrams CO2e
Forest-to-Crop	305,579,609
Pasture-to-Crop	109,196,645
Cropland-pasture to Crop	114,309,541
Crop-to-Forest	0
Crop-to-Pasture	0
Crop-to-Cropland pasture	0
Pasture-to-Forest	-20,801,279
Forest-to-Pasture	124,717
Total	508,409,234

The breakdown of Forest-to-Crop and Pasture-to-Crop emissions by GTAP region for the ARB average case are shown in Table 4. We have not shown areas with less than 1% contribution. We also have bolded the regions that Babcock/Iqbal indicate would not have Forest-to-Cropland or Pasture-to-Cropland transitions. (Our mapping of the Babcock/Iqbal regions which come from FAOSTAT, to the GTAP regions is shown in Attachment 3.)

LCFS 46-108 cont.

We have shaded the sub-Sahara region[31] for several reasons – (1) GTAP predicts it is the largest contributor to emissions for the corn-ethanol expansion, (2) the Babcock/Iqbal analysis shows that the country of South Africa, part of sub-Sahara Africa, should not have forest to crop and pasture to crop transitions, and (3) we are not sure how to separate South Africa from the sub-Sahara region in GTAP, and (4) the Babcock/Iqbal report also indicates that the expansion of cropland from forest and pasture in many African countries is not price-induced.

Thus, on one hand, Babcock/Iqbal are making the case that the extensive land changes in Africa are not price driven, and therefore, not related to biofuel expansion, and so in one case the sub-Saharan region can be omitted from the corn ethanol emissions analysis. On the other hand, if these countries are included in the emissions analysis because they do have extensive land use changes, the emissions will be over-predicted because of our current inability to remove South Africa from the sub-Saharan region. Nonetheless, we will estimate iLUC emissions for these two cases – one without sub-Sahara Africa, and one with.

[31] The sub-Sahara region in GTAP includes Botswana, South Africa, Rest of South African Customs Union, Malawi, Mozambique, Tanzania, Zambia, Zimbabwe, Rest of South African Development Community, Madagascar, Uganda, and rest of sub-Saharan Africa.

Table 4. Regional Forest-Crop Plus Pasture-Crop Transition Emissions for ARB Average		
Region	Megagrams	Percent of Total Forest-to-Crop and Pasture-to-Crop Emissions
USA	**43,316,687**	**10%**
EU27	**15,681,094**	**4%**
Brazil	56,258,521	14%
Canada	**14,911,705**	**4%**
Japan	**3,745,849**	**1%**
China + Hong Kong	**16,121,420**	**4%**
India	**7,732,753**	**2%**
South America (w/o Brazil)	14,930,904	4%
Rest of Southeast Asia	13,248,332	3%
Rest of South Asia	5,810,952	1%
Other CEE_CIS	**7,867,793**	**2%**
Mideast North Africa	**2,629,014**	**1%**
Sub-Sahara Africa	**204,901,423**	**49%**
Oceania	2,628,749	1%

LCFS 46-108 cont.

The results of our analysis of iLUC emissions for the ARB average case, with and without sub-Sahara Africa being included with the other areas without Forest-to-Crop and Pasture-to-Crop transitions, is shown in Table 5. Application of the Babcock/Iqbal analysis reduces iLUC emissions between 21% and 65%, depending on the treatment of emissions in sub-Sahara Africa. The range for corn ethanol for the Purdue Best Estimate (input elasticities) is between 5 and 11 g CO2e/MJ, far lower than ARB's current 20 g CO2e/MJ estimate.

Table 5. Impacts of the Babcock/Iqbal Filter on GTAP Results (g/CO2e/MJ)		
Scenario	ARB Average	Purdue Best Estimate
No Filter (from Table 2)	17.2	14.2
Filter without sub-Sahara impacts	13.3 (-21%)	10.9 (-22%)
Filter with sub-Sahara impacts	6.1 (-64%)	5.0 (-65%)

ARB should revise its iLUC emissions for various biofuels to account for the Babcock/Iqbal analysis. The reasons why emissions are lower with application of their analysis are not new – they are related to multiple cropping in certain regions, the use of idle or fallow land, and the improvement in harvested versus planted land, which are all related to higher prices for commodities. None of these items is currently included in the GTAP model that ARB is using. LCFS 46-108 cont.

Other Comments on the Workshop

Price-Yield Elasticity

As indicated earlier, ARB has stated its intent to use its current price elasticity range, with an average elasticity of 0.19. The Purdue estimate is 0.25, and it does not account for double-cropping or other intensification measures used by the agriculture industry. We have been recommending a price-yield elasticity range of 0.2-0.5, with an average of 0.28, slightly higher than the Purdue best estimate, to account for some multiple cropping. After reviewing the Babcock/Iqbal analysis, we think the best way to account for multiple cropping in the short term is by applying the Babcock/Iqbal filter. Therefore, if ARB were to utilize the Babcock/Iqbal filter on its results, the price-yield range should be modified to have an average of 0.25 at the Purdue best estimate. We do not support ARB's current range, because the lower end of the range is based on very short-term price-yield studies, and GTAP is a medium to long-term model. LCFS 46-109

Conservation Reserve Program Land (CRP) in the US

We have submitted comments showing that a large amount of ex-CRP land appears to have come into production in the US in the last 7 years (see page 5 in Attachment 3).[32] The GTAP model is capable of accessing this land, but in the ARB version of the model the option to access this land within GTAP has been turned off. It is very straightforward to turn this option on. The Babcock/Iqbal study also identifies ex-CRP land as a factor in confirming that there has been no forest or pasture transformations to cropland in the US (see pages 29-30 of the study). Implementation of the CRP land option in GTAP reduces emissions for the ARB average case from 17.22 gCO2/MJ to 16.35 g CO2e/MJ. LCFS 46-110

If ARB decides to use the Babcock/Iqbal study as a filter to determine regions with forest to crop and pasture to crop transitions, then there is no need to modify GTAP to access CRP lands. However, if ARB decides not to use the Babcock/Iqbal study as a filter, then the GTAP modeling used by ARB should allow the model to access CRP land, because that is what has already happened.

Cropland/Pasture Elasticity (PAEL)

In its modeling scenarios, ARB is only examining cropland/pasture elasticity values of 0.2/0.1 (US/Brazil) and 0.4/0.2. The 0.4/0.2 levels are Purdue's default or best LCFS 46-111

[32] "Comments on ARB's March 11 Workshop on The Low Carbon Fuel Standard, Air Improvement Resource Inc., April 6, 2014 (provided in Attachment 4).

estimate. So, ARB is examining the Purdue best estimate and one-half that level (lower levels increase the iLUC emissions).

We indicated in our comments on the September 29 workshop and also in the November 20 workshop, that ARB should estimate emissions for three PAEL levels for the US and Brazil. Two of the levels are the same as the ARB's current levels, the third one is 0.6/0.3. ARB had previously planned on using the 0.6/0.3 values. In response to our question as to why PAEL levels of 0.6/0.3 were dropped from the analysis, ARB indicated that there was a problem with the run, and promised further information on this. To date, we have not seen that information.

LCFS 46-111 cont.

We therefore ran the 0.6/0.3 case using the ARB average price yield elasticity of 0.19 and the baseline ETA value. We encountered no problems with the run, and obtained emissions of 15.55 gCO_2e/MJ (as compared to 17.22 g/MJ for the ARB average case using PAEL levels of 0.3/0.15). We therefore recommend that ARB re-instate the 0.6/0.3 PAEL case in its scenario runs, or explain in detail what its concerns are with this case.

Longer-Term Items

ARB appears to have only 4 items on its agenda for longer-term study (see page 29 of the November 20 workshop handout):

- Address forestry issue in the model
- Account for fertilizer, livestock, and paddy rice emissions
- Include analysis for cellulosic feedstocks
- Develop and validate dynamic GTAP model

Notably absent from this list are all the items which Babcock/Iqbal identify as primary drivers of less Forest-to-Crop and Pasture-to-Crop transitions (and thus the overall iLUC emissions of biofuels) in many regions of the world, such as (1) multiple cropping (double- and even triple-cropping), (2) use of temporary fallow/idle land, (3) less land that is planted and not harvested, and (4) the use of CRP land in the US. In addition, stakeholders reviewing ARB's iLUC estimates have made numerous comments about multiple cropping, the use of CRP, idle land, etc. Many of these items were identified 4-5 years ago by various stakeholders. None should be deferred from action in the current rulemaking, if ARB's intent is to use the best available scientific information and analysis, as A.B. 32 requires.

LCFS 46-112

The amount of temporary or fallow land can actually be computed from the GTAP land cover. In GTAP there are two layers of information on cropland; land cover and harvested area. Any land which has been cultivated in the past is included in the cropland category under the land cover header. This category of land includes all types of cropland (cultivated and idled land such as planted but not harvested, cropland-pasture, CRP, or fallow). The cropland area is generally not divided into different types (except partially

LCFS 46-113

for the US and Brazil). The second layer is harvested area. Harvested area refers to the cropland that is harvested in the base year (i.e. 2004). LCFS 46-113 cont.

The version of GTAP used by CARB has cropland-pasture for the US and Brazil and CRP area for the United States added to the harvested land layer. The model does not allow conversion of CRP land to crop production (the model keeps it under the conservation program). However, cropland-pasture which is used for grassing tasks can be converted back to crop production. Cropland-pasture in the other regions of the world and fallow land (either deliberately not planted or having a harvest failure) are not included in the harvested land layer. The model currently has no capability of accessing this land for increased crop production even though it is probably the most likely land to respond to higher crop demand and is land that could be brought into production without any land use change. LCFS 46-114

In some areas of the world two or more crops can be harvested from the same land in a given year. In these areas, the harvested land may be greater than the cropland area. While some regions may have both fallow land and double-cropped land from this data we can only show the net fallow land (i.e., net cropland not in crops) and the net double-cropped land. A summary of these lands by model region is shown in Table 6.[33]

[33] Darlington, Kahlbaum, O'Connor, and Mueller, "Land Use Change Greenhouse Gas Emissions of European Biofuel Policies Utilizing the Global Trade Analysis Project Model, August 30,2013.

Table 6. GTAP Land Summary (Ha)

In addition, ARB currently assumes that cropland-pasture that is converted to cropland experiences 50% of the emissions of conversion of permanent pasture. This is strictly an assumption. Purdue currently estimates conversion of cropland-pasture has the same emissions as crop-to-crop conversions. This should also be a focus of future research.

LCFS 46-114 cont.

46_OP_LCFS_GE Responses (Page 55 – 90)

409. Comment: **LCFS 46-78**

The comment contends that the iLUC value for corn ethanol is too high.

Agency Response: ARB staff does not agree with comment that the iLUC value for corn ethanol is too high. The current iLUC values were estimated for all 6 biofuels after the consideration of the best available data and science. (See ISOR and ISOR App. I.) Furthermore, by not accounting for additional emissions from the increased use of fertilizers, staff believes that our approach potentially presents a conservative estimate for iLUC for all the 6 biofuels. See response to **LCFS 8-1**.

Regarding fuel shuffling, see response to **LCFS 46-40**.

410. Comment: **LCFS 46-79**

The comment argues that ARB staff should reevaluate their method for including price-yield values in estimating the iLUC emissions of corn ethanol.

1. Agency Response: The approach used by staff to include a range of YPE values between 0.05 and 0.35 is justified. Justification for this approach is provided in response to **LCFS 8-9**.

2. Notwithstanding the conclusion by Dr. Rocke that the data provided by Juan Francisco Rosas Perez did not support the 0.29 value for YPE, ARB considered this value in the range of YPE values used in the current analysis. This was to account for a range of likely values for YPE based on different published studies (list provided in Appendix I, Attachment 1of the ISOR).

3. The commenter's dismissal of Prof. Rocke's statistical analysis as "sketchy" without further explanation is not a convincing reason for ARB to re-calculate the YPE value.

4. Justification for using the entire range of YPE values has been provided in response **LCFS 8-9**. ARB therefore, does not concur with commenter's suggestion to eliminate the lowest two price-yield values and adjust iLUC values accordingly.

See also response to **LCFS 46-86**.

411. Comment: **LCFS 46-80**

The comment recommends using their suggested values and additional modifications in the GTAP model, to account for multiple cropping.

Agency Response: The methods offered by the commenter to 'adjust' model outputs to reflect effects of double cropping are arbitrary. The GTAP model is a complicated economic model that includes interactions of various sectors in the global economy. Every parameter and input value has the potential to have significant impacts on outputs, many of which may not be substantiated by 'realistic' model behavior. The suggestions offered by the commenter do not conform to accepted principles and procedures used by GTAP modelers in instituting methodologies in such complex general equilibrium models. See responses to **LCFS 8-3**, **LCFS 8-5**, **LCFS 8-9**, and **LCFS 8-10**.

412. Comment: **LCFS 46-81**

The comment makes recommendations for updates to the GTAP model to include the effects of Conservation Reserve Program land.

Agency Response: ARB staff recognizes that Conservation Reserve Program (CRP) land is included in the current GTAP model as an option for future analysis. See response to **LCFS 46-110**.

413. Comment: **LCFS 46-82**

The comment states that the GTAP model does not consider reductions from reduced livestock herds and rice cultivation.

Agency Response: An initial review of fertilizer, livestock, and paddy rice emissions revealed that these impacts could increase iLUC emissions could be higher by up to 10 g/MJ. There was, however, an inconsistency between the approaches used to estimate direct (CA-GREET model) and indirect emissions (GTAP/AEZ-EF models) related to fertilizer, livestock and paddy rice emissions. To eliminate the possibility of double counting such emissions, ARB staff has not yet included these emissions in the present analysis. In the future, when appropriate adjustments can be made to avoid double counting, emissions from these sources will be included.

414. Comment: **LCFS 46-83**

The comment expresses concern that the GTAP model has shortcomings which will affect land use practices.

Agency Response: The GTAP 2004, base data used by ARB, contains all production and economic activities occurring for that year. The claim that idle/fallow land should be accessed by the GTAP land pool is questionable. Stakeholders have not shown any evidence that the trends for fallow or idle land practices have been altered noticeably in recent years. There are reasons why idle/fallow land has remained idle or fallow for many years, perhaps due to lower productivity; degraded soil; salinization; and lack of access to capital, irrigation, or infrastructure.

415. Comment: **LCFS 46-84**

The comment indicates that the GTAP model should include the cropland-pasture land use category.

Agency Response: After review of available data, Purdue and ARB staff updated the GTAP model to include the cropland/pasture land category in the U.S. and Brazil. Since no such data are available for other regions, this category of land cover was not included in the GTAP model for the remaining 17 regions. If data becomes available to inform staff that this land category is active in other regions, appropriate elements could be used to update the model at a future date.

416. Comment: **LCFS 46-85**

The comment argues that the AEZ-EF model is not superior to the CCLUB model.

Agency Response: The AEZ-EF model is a peer-reviewed carbon emissions model that uses the best available science, data, and methodology to estimate carbon release (or sequester) when land is converted from one use to another. CCLUB has numerous problematic assumptions and due to the reasons detailed in **LCFS 46-16**, inconsistencies arise when elements of the CCLUB model are integrated into the GTAP model. Therefore, the potential impacts as presented by the commenter cannot be compared to the iLUC analysis presented by ARB staff.

417. Comment: **LCFS 46-86**

The comment expresses concern about the GTAP model. It goes on to disagree with the low price-yield elasticity range chosen by ARB.

Agency Response: There is no discussion of Yield Price Elasticity (YPE) in Ray and Foley and they have no recommendation in this regard. From this paper, it cannot be concluded that YPE, as a result of multiple cropping, should increase. In fact, Ray and Foley argue that in some cases multiple cropping may lead to lower YPE in the long run. They argue:

> "While increasing the cropland harvesting frequency can, in the short run, increase the net annual production of agricultural crops per hectare of land, it can also lead to the long-term deterioration of soil, water resources, and the agricultural land base itself."[24]

With regard to the commenter's concerns with the GTAP model and the YPE value chosen by ARB staff, see responses to **LCFS 8-2, LCFS 8-3, LCFS 8-5, LCFS 8-9, LCFS 8-10, and 46-9**.

418. Comment: **LCFS 46-87**

The comment seeks an explanation on why ARB staff chose ETL1 and ETL2 values, and what is the basis for choosing them.

Agency Response: The differences in the land transformation elasticities (including ETL1 and ETL2) used by ARB staff and those that appear in the Applied Sciences paper are related to updates in the Applied Sciences paper that was done for the ARB. Taheripour and Tyner developed the elasticity values used in the current analysis. For ARB staff's analysis, Taheripour corrected shortcomings of the Applied Sciences paper where the older model produced results such as reforestation in places where reforestation did not occur.

419. Comment: **LCFS 46-88**

The comment recommends updates for the GTAP.

Agency Response: The Expert Working Group (EWG) recommended "separating the CET nest of forestland from the one

[24] Deepak K Ray and Jonathan A Foley 2013 Increasing global crop harvest frequency: recent trends and future directions *Environ. Res. Lett.* **8** 044041, (Page 6)

for pasture and cropland" and ARB staff has updated the model transformation tree structure accordingly. In the new model tree structure, forestland is in one category and cropland and pasture land in another as recommended by the EWG. Furthermore, cropland is divided into two subcategories of irrigated and rain-fed land, each of which has its own crop categories.

420. Comment: **LCFS 46-89**

The comment recommends that ARB staff include cropland/pasture land use category in the GTAP model.

Agency Response: See response to **LCFS 46-84**.

421. Comment: **LCFS 46-90**

The comment recommends that the GTAP model should be run to access CRP land in the US before converting forests or pastured to cropland.

Agency Response: See response to **LCFS 46-110**.

422. Comment: **LCFS 46-91**

The comment states that AEZ-EF model should include carbon stocks for only accessible forests.

Agency Response: It is true that the carbon data used in the AEZ-EF model includes both accessible and inaccessible forests, and this is broader than those represented in GTAP-BIO model. This would tend to underestimate emissions slightly. The main reason for this is that the GTAP data offer only hectares of managed/accessible forest, not locations, and ARB staff do not have any spatial data distinguishing these. Since the carbon stocks are produced based on spatial data, staff would need to know which areas to include or exclude in our analysis. Also, if GTAP were modified to allow conversion of natural forests, staff would want to assign distinct emission factors to the different forest conversions. Since it does not allow this, all conversion of forest is accompanied by a reduction in timber supply, which incentivizes afforestation elsewhere.

423. Comment: **LCFS 46-92**

The comment recommends that ARB staff account for wood biomass used for fuel during forest clearing as it replaces fossil fuels.

Agency Response: ARB staff does not believe that it is appropriate to account for CO_2 credits from hardwood products (HWP) biomass use since it is our understanding that most of the waste wood is used to produce energy that is used in the processing of the wood itself. Therefore, if the wood weren't harvested, no fossil energy would be needed to be replaced by biomass energy.

In principle, the quantity of biomass energy that displaces fossil energy of the system boundaries should be accounted for. The question isn't answered by looking at the quantity of waste wood combusted for energy; the analysis must determine how much of this energy displaces specific fossil fuels so that the carbon offset can be calculated.

424. Comment: **LCFS 46-93**

The comment recommends that ARB staff use the CCLUB model.

Agency Response: See response to **LCFS 46-16**.

425. Comment: **LCFS 46-94**

The commenter provides quantitative information for the estimated impact of iLUC emissions of corn ethanol if three parameters are changed as discussed previously.

Agency Response: The commenter is providing a quantitative assessment of the impact of changing three parameters; ARB's ETL1 and ETL2 values, the model nesting structure, and the price yield value. As clarified in responses to comments **LCFS 8-9**, **LCFS 46-86**, **LCFS 46-90**, **LCFS 46-92**, and **LCFS 46-110**, ARB staff does not agree with the rationale for the changes. Also, staff notes that the commenter references results and analysis based on an outdated 2013 version of the model. ARB staff has modified the 2013 GTAP model and a new version used to perform the staff's analysis is available to the public. The ETL1 and ETL2 values and the model nesting structures have been changed to reflect the latest Purdue University work. The Ray and Foley study cited does not include any recommendation for changing YPE in the model. For responses to additional comments, see the table below.

Comment	Response
Accounting for CO_2 credits from forest wood	**LCFS 46-92**
Price-Yield Range	**LCFS 8-9** and **LCFS 46-86**
CRP land conversions	**LCFS 46-90** and **LCFS 46-110**

426. Comment: **LCFS 46-95**

The comment states that the use of CI “bins” would severely limit continued innovation in biofuel facilities. The comment also states that the application processes for biofuel facilities should be streamlined and there should be no limits to the number of pathways a facility can apply for.

Agency Response: Staff notes that this comment is counter to their claims (in comment LCFS **46-37**) that past CI improvements due to the LCFS from corn ethanol facilities have not occurred and have all been merely “paperwork exercises”. This commenter goes on to state that significant future optimization opportunities and declines in CIs from corn-starch ethanol is unlikely (see comment **LCFS 46-43**). These prior comments are directly at odds with the request in this comment for continued continuity along the dimension of CI in the program, rather than creation of CI bins, to allow for “*continued* innovation*”* [emphasis added] to be recognized.

Staff agrees that continued innovation and incremental CI reduction is possible from corn ethanol as well as in the lifecycle of other low carbon fuels. Based on this belief, and feedback staff received from the commenter and other stakeholders, staff rejected the proposed bin concept. The bin method was replaced with the two-tiered framework approach described in the Initial Statement of Reasons.

With respect to concerns about limits on the number of pathways a facility can apply for, Staff’s proposal does not include such a limitation.

427. Comment: **LCFS 46-96**

The comment contends that the bin method is problematic no matter how it is designed.

Agency Response: See response to **LCFS 46-95.**

428. Comment: **LCFS 46-97**

The comment contends that the bin method is inconsistent with the proposed method for refineries.

Agency Response: See response to **LCFS 46-95**.

429. Comment: **LCFS 46-98**

The comment requests clarification on how ARB identifies areas with constrained irrigation.

Agency Response: ARB staff utilized two reports developed by the World Resources Institute (WRI) used to generate criteria for water constraints in the GTAP model available at: http://www.arb.ca.gov/fuels/lcfs/lcfs_meetings/lcfs_meetings.htm . Using these reports, WRI generated a matrix of regions/AEZ which identified water-stressed regions/AEZ combinations. The methodology used was discussed in a workshop on September 29, 2014, and the information posted to the LCFS website on December 31, 2014.

The commenter did not provide details of parameter values and modeling constraints used in their analysis and therefore, ARB staff cannot determine the validity of the results shown in Table 1 of the comment and staff cannot comment on the differences detailed between unconstrained and constrained irrigation as presented. However, a review indicates that the results appear to be influenced by Ydel (interchangeably used as YPE), Cropland Pasture Elasticity (PAEL), and elasticity of crop yields with respect to area expansion (ETA) parameters. Discussion on YPE, PAEL, and ETA can be found in Appendix I of the ISOR. Details of identifying water constrained regions is provided in the two reports cited above.

430. Comment: **LCFS 46-99**

The comment requests justification for why ARB staff did not update land supply structure and different land transformation elasticities for forest and pasture, as directed by the commenter.

Agency Response: The document was prepared by the commenter in response to an ARB staff analysis presented in March 2014, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB addresses the comments as follows:

Since the comments are related to an older version of GTAP that is not used in the current analysis, they are irrelevant because the current analysis uses the approach in line with the commenter.

431. Comment: **LCFS 46-100**

The comment recommends that ARB use their recommended land conversion elasticity values.

Agency Response: The document was prepared by commenter in response to ARB analysis presented in March 2014, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

The values used in ARB staff's current analysis correspond to the values suggested by the commenter.

432. Comment: **LCFS 46-101**

The comment seeks justification for values chosen by ARB staff, for yield price elasticity (YPE) and yield elasticity with respect to crop area expansion (ETA).

Agency Response: ARB staff's approach is based on a comprehensive review of literature and a detailed analysis of available studies. ARB staff has used the best scientific approach for YPE. To specifically address YPE, see response to **LCFS 8-9**.

ETA values used by ARB staff are based on the best analysis of productivity of new cropland. Baseline values for ETA, which represents productivity of new cropland relative to existing cropland, were developed by Purdue researchers for each region and AEZ using data from the TEM model. The scenario approach was used to account for the likelihood of variability in values of the critical parameters in the GTAP model. For YPE, published data allowed staff to consider a range between 0.05 and 0.35 (see discussion above). For ETA, however, lack of published data required ARB staff to use values that were 120 percent and 80 percent of baseline as the best estimate to account for variability in ETA.

433. Comment: **LCFS 46-102**

The comment recommends lower values for the yield price elasticity range used by ARB staff. The comment goes on to direct staff to justify their choice.

Agency Response: YPE values used in ARB staff's analysis represent the likely range of values for this parameter and therefore are appropriate. Justification for the selection of the YPE values is provided in responses to **LCFS 8-1**, **LCFS 8-3**, **LCFS 8-5, LCFS 8-9**, **LCFS 46-15**, **LCFS 46-81**, **LCFS 46-83**, and **LCFS 46-86**.

434. Comment: **LCFS 46-103**

The comment recommends running three PAEL values for a sensitivity analysis. The commenter directs ARB staff to justify their choice.

Agency Response: See response to **LCFS 38-33**.

435. Comment: **LCFS 46-104**

The comment recommends a set of values for Ydel, PAEL, and ETA which results in the commenter's preferred iLUC value for corn ethanol. The commenter directs ARB staff to justify their decision.

Agency Response: ARB staff does not agree with the approach suggested by the commenter to use an average of input parameter elasticities to estimate iLUC emissions which is then compared to the average of the 30 scenario runs used in the current analysis. For a given set of elasticities for the three parameters (YPE, ETA, and PAEL), the GTAP output represents a unique solution utilizing complex interactions between various sectors, regions, resources, etc. ARB staff's approach uses 30 different sets of input elasticities (for the three parameters identified above) and uses an average of these runs to estimate iLUC emissions for a biofuel. The average iLUC value estimated by ARB staff is not likely to be the same as the iLUC value estimated by using a single set of elasticity values representing the average of the range used by ARB. This is because the interactions between the various elements within the model are different for each set of input values and is unlikely to be linear. Therefore, values presented in Tables 3 and 4 representing the outputs from 'average' inputs cannot be compared meaningfully to the significantly more rigorous average of the 30 scenario runs. In addition, it is unclear to ARB staff why the commenter refers to 45 runs when the initial comments refer to the 30 scenario runs used in the current analysis. To address the commenter's recommendation to use a value for YPE of 0.28, see responses to **LCFS 8-3**, **LCFS 8-5, LCFS 8-9**, **LCFS 46-15**, and **LCFS 46-101** for ARB staff's justification for YPE values used in the current analysis.

436. Comment: **LCFS 46-105**

The comment lends support to the adoption of Approach B in GTAP modeling by ARB.

Agency Response: ARB staff acknowledges the commenter's support for using Approach B for the current analysis. Staff does not agree with commenter that 'very little new information' was provided at the November 20 workshop. ARB staff provided the following:

- Updates to the AEZ-EF model;
- Indicated that the land transformation parameter would use Approach B;
- Detailed the iLUC value for palm biodiesel; and
- Complete details of the 30 scenario runs that were used to estimate iLUC analysis for the six biofuels.

437. Comment: **LCFS 46-106**

The comment requests that the two lowest price yield values be eliminated.

Agency Response: Justification for using the entire range of YPE values has been provided in response **LCFS 8-9**. ARB staff, therefore, does not concur with the commenter's suggestion to eliminate the lowest two price-yield values and adjust iLUC values accordingly.

See response to **LCFS 46-12** for a discussion of the inclusion of the UC Davis study. See also responses to **LCFS 46-79** and **LCFS 46-86**.

438. Comment: **LCFS 46-107**

The comment requests ARB staff to consider the recent findings in an Iowa State University report on iLUC emissions of biofuels.

Agency Response: See responses to **LCFS 8-3** and **LCFS 8-5**.

439. Comment: **LCFS 46-108**

The comment argues that increases in biofuel crop prices in response to increased biofuel demand do not translate into extensive land conversion. Hence the commenter directs ARB staff to revise its iLUC values for biofuels based on the Babcock and Iqbal analysis.

Agency Response: ARB staff does not agree with the comment that current analysis significantly overestimates pasture and forestland conversion. The database used in the GTAP model includes double cropping data for appropriate regions of the world where double cropping was practiced. Therefore, outputs from the model implicitly include impacts from double cropping though staff does not explicitly disaggregate contributions from such effects. A preliminary review of U.S. agricultural data has concluded that double cropping is small and not expected to contribute significantly to 'intensification effects' as mentioned in the Babcock paper. As for other regions of the world, significant work has to be completed to collect and disaggregate data to provide accurate information on double cropping across the world. Beyond using a baseline that includes double cropping, there is no good methodological approach that would allow model adjustments to account for the evaluation of double cropping. For this, land in different locations needs to be separated into double-cropped vs. non-double cropped land and such data are not currently available. When detailed data becomes available, staff will consider updates to the modeling structure to explicitly account for double cropping in the analysis. It should also be noted that double cropping benefits are offset by increased use of fertilizers and pesticides and these impacts also need to be accounted in the analysis (not included in the current analysis).

ARB staff does not agree with commenter that land conversion as a result of market response to higher prices should be similar for any sector. Land cover changes resulting from increased biofuel production, increased consumption of beef, and decreased supply from drought could be directionally similar but are not expected to be the same for every location/region. The work by Babcock/Iqbal uses the totality of the effect of all factors in the global marketplace to support their conclusions. For ARB's work, however, staff is estimating land cover changes resulting only from the increased production of biofuels, and the results are not expected to mirror the changes from all sectors and all other events in the world.

The GTAP base data used by ARB staff contains all production and economic activities occurring for that year. The claim that idle/fallow land should be accessed by the GTAP land pool is questionable. Stakeholders have not shown any evidence that the trends for fallow or idle land practices have been altered noticeably in recent years especially during the period 2004-2010. There are reasons why idle/fallow land has remained idle or fallow for many years, perhaps due to lower productivity; degraded soil; salinization; and lack of access to capital, irrigation, or infrastructure. Staff will evaluate this land type in its parts, for agronomic and economic viability, yield potential and soil emission estimates, and whether marginal change in land use for this land type occurred since 2004, and will adjust the effects for each AEZ/region together with the resultant changes in yield, agricultural inputs and other relevant factors.

Harvested-to-planted ratio varies from year to year by crop, region, and AEZ. There is no detailed data available for all crops by region and AEZ. When detailed data becomes available, ARB staff will evaluate the potential to include this in the GTAP modeling framework.

ARB staff has not completed a detailed review of the studies provided to support the conclusion that higher world prices are not transmitted to growers in many African countries. It is expected that since the products studied are international commodities, prices will be affected across all markets. As part of the work to consider the inclusion of food security and prices in the iLUC analysis[25], ARB staff reviewed several studies and reports that concluded the biofuel expansion in developed countries was a factor in price increases leading to increased starvation and poverty in developing countries, including African countries. Different conclusions on this issue by various authors and reports led to ARB staff's decision to defer the inclusion of food versus fuel for the current proposal. When additional reports and data become available and a comprehensive analysis has been completed, ARB staff will evaluate the impacts in the future.

The analysis, results, and comparison presented are not relevant since it does not use the current version of the GTAP-AEZ-EF models. For comments related to the inclusion of several issues considered in the Babcock/Iqbal analysis, see responses to **LCFS T25-4**, **LCFS 46-83**, **LCFS 46-102**, **LCFS 46-107**, **LCFS 46-110**, **LCFS 46-113**, **LCFS 8-3**, **LCFS 8-5**, and **LCFS 8-6**.

[25] Since the analysis was not completed at the time of publishing the ISOR, no detailed analysis was available for publication.

440. Comment: **LCFS 46-109**

The comment alleges ARB staff's price yield elasticity values primarily are based on short-term price yield studies.

Agency Response: See response to **LCFS 46-101** and **LCFS 46-102**.

441. Comment: **LCFS 46-110**

The comment suggests ARB staff should run the GTAP model by turning on the option to access CRP land.

Agency Response: ARB staff does not agree with the comment that inclusion of CRP land will necessarily reduce iLUC emissions. Inclusion of a new land cover in the GTAP requires detailed economic data for the conversion to cropland. It also requires information about carbon stock and dynamics to model carbon emissions released when such land is converted to cropland. ARB staff recognizes that CRP land is included in the current GTAP model as an option for future analysis. However, for a type of land to be considered in the GTAP model, a set of data for each region is needed to make that land a viable part of the model's economic decision-making. Unfortunately, detailed data (by AEZ) required to model the economics of conversion and attendant carbon release is currently not available for CRP land. When data for CRP land conversion combined with the economics of conversion are available, ARB staff will include this land cover into the analysis. Also, associated emission factors disaggregated spatially will be included when such data becomes available.

Regarding the comment related to the Babcock study see response to **LCFS 8-5**.

See also responses to **LCFS 46-15**, **LCFS 46-90** and **LCFS 46-118**.

442. Comment: **LCFS 46-111**

The comment recommends that ARB run the GTAP model with higher PAEL.

Agency Response: See responses to **LCFS 38-33** and **LCFS 46-103**.

443. Comment: **LCFS 46-112**

The comment suggests that ARB staff's agenda for longer-term study is limited and should include more items.

Agency Response: The iLUC analysis as currently proposed by ARB staff is based on the latest and best available scientific and economic information. Staff continues to develop greater refinements such that the remaining items to be address represent a smaller and smaller impact.

ARB staff acknowledges that double cropping or multiple cropping is practiced in some regions of the world, but detailed data by region, AEZ, and crop are not available at the present time for inclusion in the analysis. For CRP land and fallow land, detailed economic data and carbon emissions data by region and AEZ are not available. As data becomes available for these topics, staff will consider including them into the modeling framework. See also responses to **LCFS 46-81**, **LCFS 46-108**, **LCFS 46-90**, **LCFS 46-110**, **LCFS 8-5**, and **LCFS 8-10**.

444. Comment: **LCFS 46-113**

The comment points out that the size of temporary or fallow land for biofuel production can be derived from the GTAP land cover.

Agency Response: ARB staff does not agree with the commenter that the amount of temporary or fallow land can be computed from the GTAP land cover data. It is true that the GTAP landcover includes harvested area and total cropland area. Total cropland area includes harvested area, CRP (for U.S. only), planted but not harvested area, land fallowed, etc. It does not disaggregate the amount of fallow land.

The claim that idle/fallow land should be accessed by the GTAP land pool is questionable. Stakeholders have not provided clear evidence that the trends for fallow or idle land practices have been altered noticeably in recent years. There are reasons why idle/fallow land has remained idle or fallow for many years, perhaps due to lower productivity; degraded soil; salinization; and lack of access to capital, irrigation, or infrastructure. When detailed data become available, ARB staff will evaluate this land type for agronomic and economic viability, yield potential and soil emissions estimates, and will consider the inclusion of fallow land into the modeling framework. See also responses to **LCFS 8-5**,

LCFS 46-81, **LCFS 46-83**, **LCFS 46-90**, **LCFS 46-102**, **LCFS 46-110**, and **LCFS 46-114**.

445. Comment: **LCFS 46-114**

The comment suggests that several areas which the commenter wishes to be investigated as part of ARB's future study.

Agency Response: To specifically address comment related to CRP land, see response to **LCFS 46-110**.

After review of available data, Purdue and ARB staff updated the GTAP model to include cropland/pasture land category in the U.S. and Brazil. Since no such data are available for other regions, this category of land cover was not included in the GTAP model for the remaining 17 regions. If data becomes available to inform that this land category is active in other regions, appropriate elements could be used to update the model at a future date. The same approach will be considered for fallow land for which data are currently not available.

The GTAP model uses harvested area to estimate additional land requirements and the base data in 2004 implicitly includes double-cropping information. Therefore, outputs from the model implicitly include impacts from double cropping though ARB staff does not explicitly disaggregate contributions from such effects. Staff recognizes that there are regions in the world which use double cropping. However, significant work has to be completed to collect and disaggregate data to provide accurate information on double cropping for all crops by region and AEZ and to integrate it into the GTAP framework. When detailed data becomes available, staff will consider updates to the modeling structure to explicitly account for double cropping in the analysis. It should also be noted that double cropping benefits are offset by increased use of fertilizers and pesticides and these impacts also need to be accounted in the analysis (not included in the current analysis). The same approach will be considered for fallow land for which data are currently not available.

Cropland pasture refers to land that was previously in cropping but has been fallowed in the recent past. The actual land-use history of the converted cropland-pasture strongly determines conversion emissions: land recently in crops will have very low emissions, while lands taken out of crop production long ago will have high emissions. Since there is no detailed data available for land-use history and corresponding carbon stock in cropland pasture for the

U.S. and Brazil, ARB staff assumed that emissions from conversion of this land cover type are 50 percent of emissions from conversion of pasture. When detailed data becomes available, ARB staff will evaluate carbon emissions from cropland pasture and consider updating the current methodology.

See also responses to **LCFS 8-5**, **LCFS 8-10**, **LCFS 46-81**, **LCFS 46-83**, **LCFS 46-90**, and **LCFS 46-102**.

Appendix B

Comments on the CA-GREET 2.0 Model
February 10, 2014

ARB staff released a draft report comparing GREET1.8b, GREET12013, and CA-GREET 2.0 on October 10. In addition, staff released the GREET 2.0 model for comment. AIR has reviewed some aspects of this model, and offers comments in the following areas:

- GREET2014
- Denaturant Modifications for Ethanol
- DGS Reduced Enteric Emissions Credit

In addition to the above, Professors Bruce Dale and Seungdo Kim reviewed the agricultural chemical and ethanol plant chemical emissions for both corn and cellulose ethanol. Their comments are included in Attachment 1 to this document.

Our combined reviews indicate that ARB has overestimated the direct emissions of both corn ethanol and ethanol made from stover. The implications of overestimating the lifecycle emissions for corn and stover ethanol are that it could lead to shuffling of fuels without any reduction in greenhouse gases and increased costs of compliance with the LCFS. LCFS 46-115

GREET2014

The CA-GREET 2.0 model is based on the GREET1-2013 model from Argonne. GREET2014 was released by Argonne on October 3, 2014. ARB should examine GREET2014 to determine improvements that should be made to CA-GREET 2.0. LCFS 46-116

Denaturant Modifications for Ethanol

The amount of denaturant assumed in CA-GREET1.8b was 2.0%. However, in CA-GREET-2.0 the amount of non-ethanol material in ethanol was increased to 5.4%. The 5.4% is assumed to be 2.4% denaturant, at most 1 percent water, at most 0.5 percent methanol, and at most 1.4 percent "other." The 2.9% combination of water, methanol, and "other", is assumed to have the same carbon intensity of CARBOB, so the net effect of this assumption is the same as assuming 5.4% CARBOB in ethanol. The CI of CARBOB is higher than most ethanol pathways, so increasing the denaturant from 2% to 5.4% in effect raises the CI of ethanol (and doubles the denaturant effect). LCFS 46-117

It is very clear that water does not have the CI of CARBOB. It is also highly unlikely that methanol and "other", whatever the other is, would have the same CI as CARBOB. AIR believes increasing the denaturant to 5.4% is a mistake that unfairly penalizes ethanol. AIR recommends that the denaturant percentage be set to 2.4% in CA-GREET 2.0. LCFS 46-117 cont.

DGS Reduced Enteric Emissions Credit

GREET2013 contains a distiller grains (DGs) credit for the coproduct due to reduced enteric fermentation from livestock from feeding with DGs. Staff is proposing no DGs reduced enteric emissions credit "due to the feeding of animals not being considered in the LCFS pathway LCA system boundary." Staff goes on to say that "...including the feeding of animals in the LCA would require significant analysis and would not only include the enteric emissions or change thereof from business as usual, e.g., other emissions would need to be considered and feed markets would need to be analyzed and updated."

Staff's arguments for not including the enteric emissions credit due to feeding of DGs are weak. First, Staff expands the system boundaries in arbitrary ways already. The Staff has included indirect land use system emissions (iLUC), which cannot be measured, and can only be estimated with a combination of economic modeling and estimates of the carbon released during specific land use changes (i.e., the emission factors of each land use change). Staff has spent a great deal of time and effort on this indirect effect. So, other indirect effects such as reduced enteric fermentation should also be included in Staff's analysis. Second, Argonne has already estimated this effect, and has included it in GREET1-2013. LCFS 46-118

Staff has no specific criticisms of the effect as estimated in GREET1-2013. Staff say, however, that the primary driver of reduced enteric emissions are shortened lifespan of livestock. Staff is concerned that if feeding DGs increases livestock throughput, then enteric emissions could increase. They also cite studies that show feeding defatted DGs compared to grain feeding causes an increase in N2O emissions from finishing beef cattle, which could reduce the enteric credit.

We recommend that Staff include the DG enteric credit in CA-GREET2.0. It is already included in GREET2013. If Staff have concerns with the effect, then they should develop a better estimate of the effect after finalizing CA-GREET2.0 with the current effect, in much the same way as Staff adopted an iLUC effect in 2009 and have spent some effort in the last 1.5 years attempting to improve it.

We note that there is another very significant effect of enteric fermentation. The economic models show that increasing biofuels requires additional cropland, and much additional cropland comes from pasture and cropland/pasture. This raises livestock prices, thereby reducing total livestock herds and total enteric fermentation emissions. The EPA included this effect in the RFS four years ago. We have repeatedly commented to ARB that the Staff should include this effect as well in its analysis, and Staff has pushed this off to the future. Clearly, there are very significant effects of biofuels on enteric fermentation emissions in two areas – the LCFS 46-119

DGs effect and the price effect – and ARB has ignored these effects in this analysis. These are very serious shortcomings in the current ARB analysis. LCFS 46-119 cont.

Additional Comments by Bruce Dale and Seungdo Kim

Attachment 1 contains additional comments by Ca-GREET2.0 by Kim/Dale. These comments cover a number of items for both corn ethanol and ethanol made from corn stover.

Table 1 summarizes the Kim/Dale comments and their impacts on CaGREET emissions for both corn ethanol and corn stover.

Table 1. Impacts of the Kim/Dale Recommendations on CaGREET Corn Ethanol and Stover Ethanol Emissions		
Corrections	Corn dry mill pathway [gCO_2/MJ]	Corn stover pathway [gCO_2/MJ]

Attachment 1

Review of lifecycle GHG calculations for corn ethanol and corn stover ethanol in the

CA-GREET2.0 model

November 6, 2014

Bruce E. Dale and Seungdo Kim

Department of Chemical Engineering and Materials Science

Michigan State University

3815 Technology Boulevard, Lansing, MI 48910

The authors reviewed farming nutrient emission rates and the emission rates of chemicals used in corn ethanol production in the CA-GREET 2.0 model. We have a number of comments, which are detailed in this document.

The table below summarizes the emission impacts of our comments.

Summary of suggested numerical corrections to the CARB values

Corrections	Corn dry mill pathway [gCO_2/MJ]	Corn wet mill pathway [gCO_2/MJ]	Corn stover pathway [gCO_2/MJ]
1.1. Current fertilizer rates	-0.67	-0.66	
1.2. CO_2 emissions from limestone	-0.83 ~ -2.18	-0.82 ~ -2.14	
1.3. Nutrient contents in fertilizers	-0.06	-0.06	-0.05
1.5. Soil N_2O emissions from corn stover in corn ethanol	-0.21	-0.21	
1.6. Supplement nutrients in corn stover ethanol			-7.98
2.2. Lifecycle GHG emissions of sulfuric acid	-0.47	-0.46	-0.92
2.3. Cellulase enzyme loading in corn stover ethanol			-1.32 ~ -1.79
2.4. Marginal electricity in corn stover ethanol			-8.07
Total	-2.24 ~ -3.59	-2.22 ~ -3.57	-26.4~ -26.9

Our comments are presented in the next two sections. The first section details comments on agricultural chemicals, and the second section deals with chemicals used in corn ethanol plants.

1. Feedstock production (corn grain and corn stover)

1.1. Fertilizer rates in corn grain production

The fertilizer application rates per bushel of corn in the CA-GREET2.0 model (in cells: Inputs!F281:F283) do not reflect the current corn culture practices in the US. LCFS 46-120

The CA-GREET2.0 supporting document provides a reference[1] for the fertilizer application rates given in the CA-GREET2.0 model. These values are probably based on available data up to 2005. Unfortunately, the timeframe for the fertilizer application rates was not clearly stated in the reference so we are unable to determine how these California values were generated. Furthermore, newer fertilizer application rates for corn culture practices in 2010 are available and should be used in preference to any earlier values. Thus in this report we have used USDA statistics[2] to estimate the US average 2010 fertilizer application rates per bushel of corn—the most recent time period available. These USDA data are summarized in Table 1. The fertilizer rates in the NASS (USDA study) are slightly lower than those in the CA-GREET2.0 model due to higher corn yields. The NASS fertilizer application rates are 4 – 20% less than the rates in the CA-GREET2.0 model.

LCFS 46-120 cont.

Table 1 Fertilizer application rate per bushel of corn produced [2]

	NASS¶	CA-GREET2.0 (in cells: Inputs!F281:F283)
N (gram per bushel)	400.84	415.33
P_2O_5 (gram per bushel)	138.42	147.77
K_2O (gram per bushel)	143.36	172.11

Fertilizer consumption to produce corn silage is excluded from these data.

[1] Wang, Michael Q., Jeongwoo Han, Zia Haq, Wallace E. Tyner, May Wu, and Amgad Elgowainy. "Energy and greenhouse gas emission effects of corn and cellulosic ethanol with technology improvements and land use changes." Biomass and Bioenergy 35, no. 5 (2011): 1885-1896
[2] National Agricultural Statistics Service. http://www.nass.usda.gov/

Using the current fertilizer application rates per bushel of corn from the NASS data summarized in Table 1 reduces the GHG of corn ethanol by 0.67 (0.66) g/MJ in the dry (wet) mill pathway. The detailed calculations are as follows:

The calculations are done in the CA-GREET2.0 spreadsheet model. Replace the fertilizer rates in the CA-GREET2.0 model (in cells: Inputs!F281:F283) by the NASS values in Table 1. Results are summarized in Table 2.

Table 2 Calculations for fertilizer application rates

	Rates from NASS	CA-GREET2.0
GHG associated with fertilizers [gram/MJ] (EtOH!D429)	14.28	14.81
N_2O emissions [gram/MJ] (EtOH!E429)	14.93	15.32
GHG credit of co-products [gram/MJ] (EtOH!G429)	13.21	13.47
GHG of corn ethanol [gram/MJ] (EtOH!Y429)	76.11	76.78

LCFS 46-120 cont.

The USDA/NASS statistics[2] also show that fertilizer application rates per bushel (i.e., N, P_2O_5, K_2O applied per bushel of corn produced) have been steadily declining with time. (See Figure 1) Even though total amount of fertilizer applied nationally has increased, the application rate per bushel has actually declined due to higher corn yields. Assuming the trends summarized in Figure 1 have continued, even less total fertilizer use per bushel of corn produced is projected after 2010.

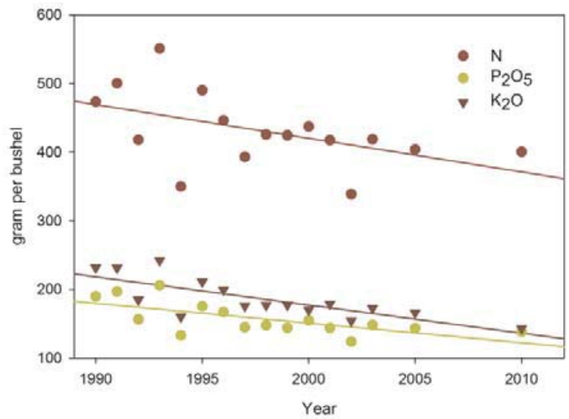

Figure 1 Fertilizer application rates in the US [data source: NASS[2]]

LCFS 46-120 cont.

1.2. CO_2 emissions from limestone

Limestone ($CaCO_3$) is the primary agricultural lime used in the US in 2011[3], accounting for about 93% of the total lime applied. The rest is dolomite ($MgCa(CO_3)_2$). The CA-GREET2.0 model incorrectly assumes that 100% of the carbon in limestone that is applied to soil is released to the air as carbon dioxide and fails to account for various soil, water and atmospheric processes that are very relevant. In contrast, a USDA report[4] based on actual, physical processes occurring in soil, water and the atmosphere finds that two-thirds of the carbon in limestone remains in long-term carbon sinks and only one-third of the carbon in limestone is actually released as carbon dioxide.

LCFS 46-121

[3] United States Environmental Protection Agency (2013) U.S. greenhouse gas inventory report: Inventory of U.S. greenhouse gas emissions and sinks: 1990-2011. United States Environmental Protection Agency, Washington, DC.

[4] USDA (2014) Quantifying Greenhouse Gas Fluxes in Agriculture and Forestry: Methods for Entity-Scale Inventory. , Washington, DC.

For example, dissolved CO_2 resulting from root and microbial respiration exists in equilibrium in soil water with H_2CO_3. This slightly acidic H_2CO_3 reacts with limestone[5] as described below in Equations (1) and (2).

$CO_2 + H_2O \rightarrow H_2CO_3$

(1)

$CaCO_3 + H_2CO_3 \rightarrow Ca^{2+} + 2HCO_3^-$

(2)

Dissolved HCO_3^- is stable and is transported to the ocean by rivers and streams. In the ocean, this carbon is sequestered for time periods of decades to centuries[4].

In a separate study, West and McBride[6] also estimate the carbon dioxide emission factors for limestone applied by accounting for leaching and transport by rivers to the ocean. The carbon dioxide emission factors for limestone applied to agricultural land given in their study are 0.059 kg C/kg limestone applied for limestone and 0.064 kg C/kg dolomite applied for dolomite. These are the emission values currently used in the U.S. National GHG Inventory[3]. However, they do not include the entire range of biophysical processes covered by the USDA report[4].

CA-GREET2.0 should use the most comprehensive, scientifically-valid calculations available to estimate the GHG emissions of agricultural lime application. We believe

LCFS 46-121 cont.

[6] West TO, McBride AC (2005) The contribution of agricultural lime to carbon dioxide emissions in the United States: dissolution, transport, and net emissions. Agr Ecosyst Environ 108:145–154

those are the values given by the USDA report[4]. The carbon dioxide emission factors for agricultural limestone applied are summarized in Table 3 below.

Table 3 Carbon dioxide emission factors for agricultural limestone application

	Carbon dioxide emission from Limestone [kg CO_2/kg]
CA-GREET2.0	0.44
USDA[4]	-0.15
GREET2014[7] & West and McBride[6]	0.216

LCFS 46-121 cont.

Using the carbon dioxide emission factors from the USDA process-based report[4] and the GREET2014 model[7] reduces the GHG of corn ethanol by 0.83 and 2.18 (0.82 and 2.14) g/MJ in the dry (wet) mill pathway, respectively. The detailed calculations are as follows:

Replace the carbon dioxide emission factors in the CA-GREET2.0 model (in cells: EtOH!F380, 44/100) by the factors in Table 3. Results are summarized in Table 4.

Table 4 Calculations for lime application

	Factor from USDA report[4]	Factor from GREET2014[7]	CA-GREET2.0

1.3. Nutrient contents in N and P_2O_5 fertilizers

The CA-GREET2.0 model assumes that N fertilizer consists of ammonia, urea, ammonium nitrate, urea-ammonium nitrate solution, mono-ammonium phosphate, and di-ammonium phosphate, and P fertilizer consists of mono-ammonium phosphate, and di-ammonium phosphate as summarized in Table 5. However, the nutrient contents in some of these fertilizers are not given correctly in the CA-GREET2.0 model. The nitrogen content in di-ammonium phosphates is 18%[8], not 16% as given in the CA-GREET2.0 model. The P_2O_5 contents in mono- and di-ammonium phosphates are 48 -61% (the most common value is 52%) and 46%[8], respectively.

LCFS 46-122

Table 5 Fraction and nutrient content of N and P_2O_5 fertilizers in CA-GREET2.0 [basis: N for N fertilizer, P_2O_5 for P fertilizer]

N fertilizer	Ammonia	Urea	Ammonium Nitrate	Urea-Ammonium Nitrate Solution	Mono-ammonium Phosphate	Di-ammonium Phosphate
Fraction	0.31	0.23	0.04	0.32	0.04	0.06
N content (%)	82.4%	46.7%	35.0%	-	11.0%	16.0% (Ag_Inputs!AC74)

[8] Penn State Extension, Nitrogen Fertilizers. http://extension.psu.edu/agronomy-guide/cm/tables/table-1-2-11

P_2O_5 fertilizer		Mono-ammonium Phosphate	Di-ammonium Phosphate
Fraction		0.5	0.5
P_2O_5 content (%)		48.0% (Ag_Inputs!AE74)	48.0% (Ag_Inputs!AF74)

Using the correct nutrient contents reduces the GHG of corn ethanol by 0.06 (0.06) g/MJ in the dry (wet) mill pathway and reduces the GHG of corn stover ethanol by 0.05 g/MJ. The detailed calculations are as follows:

Replace the nutrient content in the CA-GREET2.0 model (in cells: Ag_Inputs!AC74, Ag_Inputs!AE74, Ag_Inputs!AF74) by the corrected values (18% for Ag_Inputs!AC74; 52% for Ag_Inputs!AE74; 46% for Ag_Inputs!AF74). Results are summarized in Table 6.

LCFS 46-122 cont.

1.4. Emissions of N and P_2O_5 fertilizers

Mono- and di-ammonium phosphate fertilizers contain both N and P_2O_5 nutrients. Therefore, the CA-GREET2.0 model probably uses allocation factors to assign emissions to either N or P_2O_5. However, there is no background information given in the CA-GREET2.0 model to describe and define how these putative allocation factors were chosen. The choice of allocation factors should be transparent and readily available through the CA-GREET2.0 model.

The amounts of N and P_2O_5 fertilizers applied based on the fractions of each fertilizer used in agriculture and their respective nutrient contents as given by CA-GREET2.0 are not equal to those of N and P_2O_5 fertilizers used in corn grain production as seen in Table 7. Emissions of N and P_2O_5 fertilizers (in cells: EtOH!D365:E379) are associated with using 439.8 g of N fertilizer and 284.2 g of P_2O_5 fertilizer, not 415.33 g of N fertilizer and 147.77 g of P_2O_5 fertilizer. Therefore, emissions of N and P_2O_5 fertilizers (in cells: EtOH!D365:E379) do not represent emissions associated with the actual amounts of N (415.33 gram/bushel) and P_2O_5

LCFS 46-123

(147.77 gram/bushel) used in corn grain production and should be recalculated to be consistent with current actual corn grain production practice.

Total P_2O_5	142.1 + 138.4 =284.2			

1.5. Soil N_2O emissions from corn stover due to corn ethanol production

LCFS 46-124

The CA-GREET2.0 model uses the emission factor (1.325%) for N_2O according to the IPCC guidelines[9], which include direct and indirect N_2O emissions. The CA-GREET2.0 model applies this emission factor to both inorganic fertilizer and corn stover. However, the IPCC guideline[9]

does not include volatile nitrogen loss from crop residues. This volatile nitrogen is lost to the air and is thus not available for soil microbes to convert it to N_2O. Thus, the N_2O emission factor for corn stover should be reduced to 1.225%. The data surrounding this correction to the CA-GREET2.0 calculations are summarized in Table 8. Box 1 below quotes the relevant procedures for calculating indirect N_2O emissions as given in the IPCC guideline[9].

LCFS 46-124 cont.

Box 1. Indirect N_2O calculations (quoted from the IPCC guideline[9])

Volatilization, $N_2O(ATD)$

N_2O FROM ATMOSPHERIC DEPOSITION OF N VOLATILISED FROM MANAGED SOILS (TIER 1)

$$N_2O(ATD)\text{–}N = [(FSN \bullet FracGASF) + ((FON + FPRP) \bullet FracGASM)] \bullet EF4$$

Where:

$N_2O(ATD)$–N = annual amount of N_2O–N produced from atmospheric deposition of N volatilized from managed soils, kg N_2O–N yr^{-1}

FSN = annual amount of synthetic fertilizer N applied to soils, kg N yr^{-1}

FracGASF = fraction of synthetic fertilizer N that volatilizes as NH_3 and NOx, kg N volatilized (kg of N applied) $^{-1}$

FON = annual amount of managed animal manure, compost, sewage sludge and other organic N additions applied to soils, kg N yr^{-1}

FPRP = annual amount of urine and dung N deposited by grazing animals on pasture, range and paddock, kg N yr^{-1}

FracGASM = fraction of applied organic N fertilizer materials (FON) and of urine and dung N deposited by grazing animals (FPRP) that volatilizes as NH_3 and NOx, kg N volatilized (kg of N applied or deposited) $^{-1}$) EF4 = emission factor for N_2O emissions from atmospheric deposition of N on soils and water surfaces, [kg N– N_2O (kg NH_3–N + NOx–N volatilized) $^{-1}$]

This correction reduces the GHG of corn ethanol by 0.21 (0.21) g/MJ in the dry (wet) mill pathway. The detailed calculations are as follows:

Replace the emission factor for corn stover in the CA-GREET2.0 model (in cells: EtOH!D382) by the IPCC emission factor given in Table 8 above. Results are summarized in Table 9.

LCFS 46-124 cont.

Table 9 Calculations for nutrient content

GHG of corn ethanol [gram/MJ] (EtOH!Y429)	76.56	76.78

1.6. Supplemental nutrients in corn stover ethanol production

LCFS 46-125

In the CA-GREET2.0 model, supplemental nutrients (i.e., N, P_2O_5, K_2O) are added in the subsequent growing season to replace nutrients that are assumed to be lost when corn stover is collected to produce corn ethanol. The amount of the supplement nutrients required is assumed to be exactly equal to the nutrient content of the corn stover removed. However, the supplemental nutrients required depend on actual crop management practices used in the subsequent growing season. According to USDA statistics[10], only 33% of cornfields function as cornfields ("corn on corn") in the subsequent growing season, while about 48% of cornfields are used to grow soybeans in the subsequent growing season. Approximately 2.4% of cornfields are converted to developed land, open water or left fallow in the subsequent growing season. This information is summarized in Figure 2.

LCFS 46-125 cont.

Supplemental N nutrients in the following growing season are therefore not necessary for croplands used to produce soybeans even though the nitrogen content in corn stover was removed. Furthermore, supplemental nutrients are not necessary for lands converted to developed land, open water or left fallow. Therefore, supplemental N nutrients are needed in only 49% (=100% - 48% (soybean) - 2.4% (fallow, etc.)) of corn-producing croplands next year, and the supplemental P and K nutrients are needed in only 98 % (100% – 2.4% (fallow, etc.)) of croplands from cornfields next year. By accounting properly for the actual use of corn land in the subsequent growing season, the GHG of corn stover ethanol is reduced by 7.98 g/MJ. The detailed calculations are as follows:

[10] USDA, CropScape - Cropland Data Layer. http://nassgeodata.gmu.edu/CropScape/

Multiply the fertilizer used in the CA-GREET2.0 model (in cells: EtOH!H20:H22) by 0.49 for N, and 0.98 for P_2O_5 and K_2O, respectively. Results are summarized in Table 10 below.

LCFS 46-125 cont.

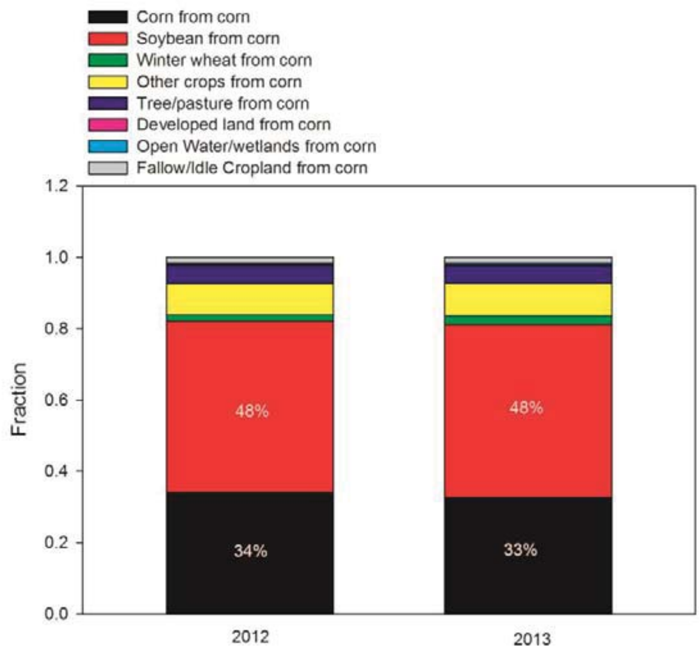

Figure 2 Land use changes in corn cultivation [data source: USDA[10]]

2. Ethanol production (dry mill and cellulosic biorefinery)

2.1. CO_2 emissions from urea displaced by DDGS

Enzymes from bacteria in cattle rumen, specifically urease, break down urea to CO_2 and ammonia, and CO_2 is released. Displacing urea by DDGS avoids those CO_2 emissions. However, the CA-GREET2.0 does not include a credit for CO_2 emissions from urea displaced by DDGS. Even though this value is very small, it should be included in the model for completeness. LCFS 46-126

2.2. Lifecycle GHG emissions of sulfuric acid in corn stover ethanol LCFS 46-127

About 250 grams of sulfuric acid (EtOH!CR361) are used to produce one gallon of corn stover ethanol. A plant producing sulfuric acid generally exports thermal energy (steam) and electricity, and therefore its net energy use is negative[11, 12]. However, the CA-GREET2.0 model does not include the correct energy credits for the exported energy in calculating lifecycle emissions of sulfuric acid. Assuming that 2.1 MMBTU per ton of sulfuric acid[11] is exported from a sulfuric acid plant, the GHG of corn ethanol is reduced by 0.47 (0.46) g/MJ in the dry (wet) mill pathway, and the GHG of corn stover ethanol is reduced by 0.92 g/MJ. The detailed calculations are as follows:

Add an energy credit (2.1 MMBTU/ton) in the cell Ag_Inputs!R26 in the CA-GREET2.0 model. Results are summarized in Table 11. In the CA-GREET2.0 model, sulfuric acid is used to manufacture the phosphorus-containing fertilizers.

The lifecycle GHG of sulfuric acid also affects lifecycle GHG of mono- and di-ammonium phosphates. Correcting the lifecycle GHG of sulfuric acid also changes the GHG of corn ethanol.

2.3. Cellulase enzyme loading in corn stover ethanol

Recent authoritative studies[13, 14] show that current cellulase enzyme loadings range from 17.5 - 19.9 mg per g of cellulose for dilute acid pretreatment of corn stover followed by enzymatic hydrolysis and fermentation of the sugars to ethanol. This enzyme application rate is equivalent to about 72 – 83 g enzyme per gallon of

LCFS 46-128

[13] Humbird D, Davis R, Tao L, Kinchin C, Hsu D, Aden A, Schoen P et al. Process design and economics for biochemical conversion of lignocellulosic biomass to ethanol: Dilute-acid pretreatment and enzymatic hydrolysis of corn stover. Colorado: National Renewable Energy Laboratory; 2011.

New Orleans, LA: 34th Symposium on Biotechnology for Fuels and Chemicals; 2012.

ethanol. However, the enzyme loading used the CA-GREET2.0 model (cells EtOH!CR359) is 113.4 g per gallon of ethanol, which is higher than the current enzyme technologies actually require. Applying current enzyme technologies as summarized in the 2011 National Renewable Energy Laboratory study reduces emissions by 1.32 – 1.79 g/MJ. The detailed calculations are as follows:

Replace the enzyme loading rate in the CA-GREET2.0 model (cells EtOH!CR359) by new enzyme loading values. Results are summarized in Table 12.

2.4. Marginal electricity in corn stover ethanol

The CA-GREET2.0 model assumes that excess electricity from a cellulosic biorefinery displaces US average electricity demand. However, it is more reasonable to assume that excess electricity would displace marginal electricity, not US average electricity, which consists of electricity from many different energy sources (i.e.,

LCFS 46-129

fossil fuel, nuclear, renewable energy sources, and hydro). Excess electricity from a cellulosic biorefinery will likely displace electricity from a coal or natural gas-fired power plant, not electricity from nuclear power plant. A nuclear power plant must keep its electricity production level constant at all times. In contrast, marginal electricity is electricity from a power plant which can be brought on line quickly so that the power plant can respond to changing demand for electricity. Nuclear plants and hydroelectric stations are thus ruled out as suppliers of marginal electricity—they can only satisfy base load electricity demand. Electricity from renewable energy sources such as wind and solar are also excluded as sources of marginal electricity because of renewable energy certificates.

Therefore, the marginal electricity replaced by excess electricity from a cellulosic biorefinery would be marginal electricity derived from burning fossil fuels (i.e., coal, petroleum, natural gas). The fuel mix used for marginal electricity production is 64% coal, 34% natural gas and 2% petroleum. These percentages are based on electricity fuel mixes given in the CA-GREET2.0 model. When marginal electricity generated from these fossil fuels is displaced by excess electricity from a cellulosic biorefinery, the GHG of corn stover ethanol is reduced by 8.07 g/MJ. The detailed calculations are as follows:

LCFS 46-129 cont.

Create new sheet for marginal electricity in the CA-GREET2.0 model. The new sheet is named “marginal elec”. Replace the electricity fuel mixes in the cells (marginal elec!C56:C72) by marginal fuel mixes - coal (64%), natural gas (34%), petroleum

(2%), others (0). Replace emissions associated with electricity (EtOH!CS371:CS379) by emissions of marginal electricity. Results are summarized in Table 13.

LCFS 46-129 cont.

46_OP_LCFS_GE Responses (Page 91 – 117)

446. Comment: **LCFS 46-115**

The comment argues that ARB has overestimated the direct emissions of corn ethanol and corn stover ethanol and that this overestimation could lead to shuffling of fuels without any reduction in greenhouse gases and increased costs of compliance with the LCFS.

Agency Response: ARB staff has already addressed many of the comments and questions regarding corn grain and corn stover ethanol CI estimations. Staff believes that GREET1 2013, as the base model for CA-GREET 2.0, provided an adequate starting point for modeling these pathways. Nevertheless, staff, in consultation with Argonne National Laboratory (ANL), further modified many parameters for these pathways and others to be more in-line with many scientific considerations and to work within the LCFS LCA system boundaries. ARB staff made some of these changes prior to the release of the ISOR, but the commenter references the October 10, 2014, CA-GREET 2.0 model and report (supplemental document or ISOR Appendix C), which refers to an earlier version of CA-GREET 2.0. An example of some of the changes made to the corn grain and corn stover pathways is staff's reduction of the nitrous oxide emission factors for feedstocks (corn grain) and agricultural residues (corn stover) from what they are in GREET1 2013 and GREET1 2014 (See "Background:" in response to comment, **LCFS 46-125**, and Appendix C from the ISOR). Another example of how CA-GREET 2.0 was modified from GREET1 2013 is the change of using 100 percent CO_2 emissions from agricultural lime application ($CaCO_3$) to 49 percent, which was updated in GREET1 2014 as well (See response to **LCFS 46-122** and Appendix C from the ISOR). With respect to fuel shuffling see **LCFS 46-40.**

447. Comment: **LCFS 46-116**

The comment argues that the CA-GREET 2.0 model should be updated to reflect the changes made in the GREET2014 model.

Agency Response: The commenter references the October 10, 2014, release of a draft report accompanying CA-GREET 2.0 as an introduction to their comments (**LCFS 46-116** and **LCFS 46-117**), and also references pre-ISOR feedback submitted by Professors Bruce Dale and Segundo Kim, which were included again with Growth Energy's 45-day public comments on the ISOR. The commenter states that the CA-GREET 2.0 model is based on GREET1-2013 from Argonne, and due to Argonne's release of GREET2014, ARB staff should analyze the new model and determine what improvements should be made to CA-GREET 2.0. In actuality, ARB staff did adapt and update many parameters used in CA-GREET 2.0 with GREET1 2014 parameters prior to release of the ISOR. These changes (and the reasons why some parameters were not changed) are explained in the responses to ISOR comments, 15-day change package, and the CA-GREET 2.0 model released with the 15-day changes.

448. Comment: **LCFS 46-117**

The comment recommends that "the denaturant percentage be set to 2.4% in CA-GREET 2.0."

Agency Response: See response to **LCFS 8-12**.

449. Comment: **LCFS 46-118**

The comment encourages ARB to include the credits from enteric methane reductions.

Agency Response: See responses to **LCFS 8-13** and **LCFS 30-3**.

450. Comment: **LCFS 46-119**

The comment argues that the ARB analysis has serious shortcomings in that it allegedly ignores what commenter believes will be a reduction in enteric emissions.

Agency Response: ARB staff disagrees that is it a foregone conclusion that increased biofuel production shifts land use from livestock pasture to cropland, causing a rise in livestock prices, thereby reducing total livestock herds and total enteric fermentation emissions. All of the following would need to be true:

1. Livestock prices increase because of pastureland being used to produce biofuels

2. Rising livestock prices lead to reduced demand for specific livestock (i.e., livestock for the purpose of discussing reduced enteric emissions credit are likely to be feedlot cattle) rather than displacement between various uses of pastureland.

3. Reduced herd sizes result from reduced demand.

4. An overall reduction of emissions occur from reduced heard sizes (see Appendix C: cattle lifetime, N_2O emissions, herd size, etc.)

Additionally, other questions, not limited to the following, would be raised if the price effect above was somehow added to the iLUC modelling. These issues need to be resolved before staff would be comfortable recommending a DGS/enteric fermentation credit to a particular pathway.

1. Where is the DGS going if the livestock market is experiencing reduced demand due to higher costs, but DGS production is not changed for a particular pathway (or is increasing globally with increased biofuel production)?

2. Does DGS production reduce livestock feeding costs and create a counteracting price effect from biofuel production? How should this be treated, for individual pathways or across all pathways with DGS?

For additional information regarding enteric fermentation emissions please see the response to comment **LCFS 8-13**.

451. Comment: **LCFS 46-120**

The comment argues that the CA-GREET 2.0 model does not reflect the current practices for fertilizer use for corn production.

Agency Response: As referenced in Appendix C of the ISOR, ARB staff adopted the agricultural fertilizer input values that Argonne National Laboratory (ANL) used in the release of GREET1 2014. The commenter references a pre-ISOR set of parameters used in CA-GREET 2.0, which were originally used in GREET1 2013 (also cited in Appendix C of the ISOR). When ANL released GREET1 2014, staff reviewed the model and updated CA-GREET 2.0 as applicable. Staff adopted the actual values used in GREET1 2014[26] (as referenced in Appendix C of the ISOR), not the rounded values reported in the ANL report.[21]

Regarding the allocation of agricultural inputs emissions comment: The CA-GREET 2.0 model applies the same allocation factors for these inputs that are used in GREET1 2013 to assign emissions to either N or P_2O_5, which are transparent in CA-GREET 2.0 and

[26] Argonne National Laboratory, GREET 1 2014 spreadsheet, Obtained on 03-OCT-2014 from https://greet.es.anl.gov/greet_1_series

GREET1 2013. The comment states that the incorrect agricultural inputs are used (grams/btu of fertilizer) in CA-GREET 2.0, but this comment, also addressed above, refers to fertilizer application rates that were used in GREET1 2013 and pre-ISOR CA-GREET 2.0 models.

Furthermore, regarding the concentrations of the multi-component fertilizers: Staff is using GREET1 2013 (also GREET1 2014) parameters for nitrogen and phosphorous concentrations in multi-component fertilizers and the resulting emissions. ANL was asked about their choice regarding the nitrogen content of diammonium phosphate (DAP) and the phosphorus content of monoammonium phosphate (MAP) and DAP. In ANL's publication[27] on page 433, section "2.2.2 Ammonium Phosphate", the authors' state, "…referring to the weight percentages of nutrients in the product, N–P_2O_5–K_2O DAP is normally produced as 18–46–0 or 16–48–0, while MAP is 11-51-0, 11-48-0, or 13-52-0 [11]."

ANL communicated to ARB staff that the reason for selecting the 16 percent rather than 18 percent nitrogen content is based upon the more conservative (lower nitrogen content) case.

ANL communicated to ARB staff that the reason for assuming 48 percent P_2O_5 is, "ANL understands that P_2O_5 concentration typically ranges from 46% to 48% for DAP, and from 48% to 52% for MAP for fertilizer application. Without more details on the most common values, ANL is keeping these assumptions." ANL cites, "J. Glauser, Ammonium phosphates, Chemical Economics Handbook, SRI Consulting, Menlo Park, CA, 2010.", which is citation [11] as quoted above regarding MAP and DAP concentrations.

Staff agrees with ANL in selecting the more conservative, lower nitrogen concentration of DAP so all pathways using this fertilizer will not undercount emissions if the lower nitrogen content (DAP) is utilized and therefore requiring greater application than if the higher concentration were used. Similarly, staff agrees with ANL's selection of phosphorous concentrations. In the absence of verified individual producers' agricultural inputs, selecting the more conservative (lower concentration and higher emissions) is appropriate.

[27] Johnson, Michael C., Ignasi Palou-Rivera, and Edward D. Frank. "Energy consumption during the manufacture of nutrients for algae cultivation." *Algal Research* 2, no. 4 (2013): 426-436, http://www.sciencedirect.com/science/article/pii/S2211926413000854

452. Comment: **LCFS 46-121**

The comment suggests replacing the current emission factors for lime application in the CA-GREET 2.0 model with those recommended by the commenter.

Agency Response: ARB staff updated this emission factor from GREET1 2013, based on GREET1 2014 updates, with the release of the ISOR (see CA-GREET 2.0 model and Appendix C from the ISOR). The comment refers to a pre-ISOR CA-GREET 2.0 model, which used the GREET1 2013 parameter. Argonne National Laboratory (ANL) adopted the 2014 U.S. EPA Inventory approach as explained in their technical report.[28] Staff agrees with ANL's selection between the USDA 2014 and U.S. EPA 2014 reports on this matter, as stated in the conclusion of their published technical report quoted as follows:

> "We decided to take the EPA's approach to estimate the CO_2 emission factor from agricultural liming as the EPA has explained in their 2014 GHG emission inventory that the lime dissolution rate was based on liming occurring in the Mississippi River basin, where the vast majority of all U.S. liming takes place. U.S. liming that does not occur in the Mississippi River basin tends to occur under similar soil and rainfall regimes, and thus the emission factor is appropriate for use across the United States (US EPA 2014). On the other hand, the USDA approach lacks resolution at the farm scale, because the method of estimation is based on stream-gauge data that are collected at the watershed scale (U.S. Department of Agriculture 2014). Besides, the USDA does not clarify the scientific basis that supports their assumption on the relative magnitudes of limestone that is acidified to CO_2 emissions to bicarbonate, which has a direct impact on the estimated overall CO_2 emissions from agricultural liming. With the EPA's approach, we updated the CO_2 emission factor from agricultural liming

[28] Hao Cai, Michael Wang, and Jeongwoo Han, Argonne National Laboratory, "Update of the CO2 Emission Factor from Agricultural Liming" October 2014. https://greet.es.anl.gov/publication-co2-lming

from previous 0.44 g CO_2/g $CaCO_3$ to 0.216 g CO_2/g $CaCO_3$ in GREET1_2014[29]."

453. Comment: **LCFS 46-122**

The comment suggests replacing the current nutrient content values of N and P_2O_5 fertilizers in the CA-GREET 2.0 model with those recommended by the commenter.

Agency Response: See response **LCFS 46-120**.

454. Comment: **LCFS 46-123**

The comment argues that emissions from N and P_2O_5 fertilizers in the CA-GREET model 2.0 do not match the amounts of N and P_2O_5 used.

Agency Response: See response **LCFS 46-120**.

455. Comment: **LCFS 46-124**

The comment suggests replacing the current emission factor for N_2O in the CA-GREET 2.0 model with the IPCC emission factor.

Agency Response: ARB staff agrees that N_2O from crop residue should be calculated using the IPCC Tier 1 default emission factor of 1.225 percent rather than the 1.325 percent applied to synthetic nitrogen fertilizer. The CA-GREET 2.0 model has been updated to reflect this change.

Staff concurs with the commenter that N_2O emissions are influenced by soil type, precipitation, topography, temperature, and other factors. Staff further agrees that the CA-GREET model will underestimate the N_2O emissions for some crops and regions of the world, and overestimate the N_2O emissions for others. While there remains a high degree of uncertainty in modeling of N_2O emissions, IPCC Tier 2 methodology should ideally be used to more accurately estimate N_2O emissions; however, until ARB staff is able to develop a robust protocol for verification of applicant-specific agricultural-phase parameters, the IPCC Tier 1 default emission factors will

[29] Hao Cai, Michael Wang, and Jeongwoo Han, Argonne National Laboratory, "Update of the CO2 Emission Factor from Agricultural Liming" October 2014. https://greet.es.anl.gov/publication-co2-lming

continue to be applied uniformly to all feedstocks in the CA-GREET model.

Additional Background: Staff started working with the GREET1 2013 model that uses N in N_2O as percent of N in N fertilizer and biomass for all feedstocks as 1.525 percent, except for sugarcane at 1.220 percent (see comparison in ISOR Appendix C). Staff notes that GREET1 2014 maintains these emission factors except sugarcane is now also 1.525 percent. Staff has discussed the choice of these parameters used in GREET1 2013 and GREET1 2014 with ANL, and the change for CA-GREET 2.0. Staff initially changed all of these factors to the known and widely-accepted IPCC factor of 1.325 percent. Upon subsequent feedback from stakeholders (pre-ISOR), staff again modified CA-GREET 2.0 (post-ISOR, due to time constraints) to more appropriately use the IPCC Tier 1 emission factor for agricultural residues, which is 1.225 percent.

456. Comment: **LCFS 46-125**

The comment recommends that ARB adjust the supplemental nutrients requirements for N, P_2O_5, and K_2O fertilizers since soybean can provide additional nutrients and about 2.4 % of corn fields are converted to developed land or left fallow in the subsequent growing season.

Agency Response: ARB staff agrees with the commenter that actual practices involving stover removal and the next crop after stover harvest influence the amount and types of supplemental nutrients required for a specific field. GREET1 2013, GREET1 2014, and CA-GREET 2.0 rely upon average application rates for any feedstock or make-up application for harvested residue. Staff is not able to review the practices for each field used in a specific pathway, the specific inputs, and subsequent practices going forward annually or for the life of the LCFS pathway. Until better verification and monitoring programs are in-place for LCFS pathways, average input values must be used to prevent undercounting of GHG impacts based upon inputs or removal of residues. Staff recommends this method of analysis for many agricultural practices that cannot be monitored or verified on an ongoing basis.

457. Comment: **LCFS 46-126**

The comment recommends that ARB incorporate CO_2 due to animal waste urea into the CA-GREET 2.0 model.

Agency Response: The comment refers to a pre-ISOR release of the CA-GREET 2.0 model and Appendix C. The release of the ISOR CA-GREET 2.0 model provides a default DGS credit for Tier 1 pathways of 0.781 lb corn, 0.307 lb soybean meal, and 0.023 lb urea for 1 lb DGS. Urea is included as part of the displacement for DGS. These values are based upon Argonne National Laboratory research (referred to in Appendix C), and is the aggregated displacement ratio for U.S. and export markets, which is available in GREET1 2013 and GREET1 2014. The aggregated displacement for U.S. and export markets is the necessary average displacement to use due to staff not being able to monitor the fluctuating U.S. and international DGS markets for the lifetime of LCFS fuel pathways.

458. Comment: **LCFS 46-127**

The comment recommends that ARB consider CO_2 credits associated with excess heat and electricity production in the CA-GREET 2.0 model.

Agency Response: ARB staff reviewed the sulfuric acid production lifecycle assessment (LCA) modeling that Argonne National Laboratory (ANL) used for GREET1 2013, which was used as the base model for CA-GREET 2.0. ANL also employs this same modeling in GREET1 2014. The paper, Johnson, et. al.[30], describes how the sulfuric acid plants energy use is modeled in GREET1 2013. The parameters used in CA-GREET 2.0 and GREET1 2013 are presented in the Johnson paper including a suggested value for net steam export (Johnson et. al., pg. 433, Table 12). However, the steam export credit was not selected for use in GREET1 2013. ANL stated, “ANL is aware that the sulfuric acid plants have an excess heat export of about 3.0 MJ/kg H_2SO_4 (see ANL 2013 paper by Johnson et al.). However, ANL decided not to credit this heat without clear evidence showing that there is always a stable demand from nearby facilities for the excess heat.” Staff agrees with the more conservative approach with modeling sulfuric acid production because there may be sulfuric acid producers that supply sulfuric acid to LCFS pathways, but do not recover the potentially recoverable heat. Staff cannot currently monitor and verify sources of sulfuric acid for all LCFS pathways in order to ensure this heat

[30] Johnson, Michael C., Ignasi Palou-Rivera, and Edward D. Frank. "Energy consumption during the manufacture of nutrients for algae cultivation." Algal Research 2, no. 4 (2013): 426-436. http://www.sciencedirect.com/science/article/pii/S2211926413000854

recovery credit is warranted on an ongoing basis for the lifetime of the LCFS pathway.

459. Comment: **LCFS 46-128**

The comment argues that the current enzyme loading rate in the CA-GREET model is high and suggests ARB to use a lower loading rate.

Agency Response: ARB staff understands the comment to be applicable if enzyme loading were a default parameter in CA-GREET 2.0. However, enzyme loading and many other inputs within the LCFS pathway are user defined, not default. Staff may ask for verification of quantities of enzymes used and receipts documenting these purchases, but the amount of cellulase used is defined by the LCFS fuel pathway applicant based upon the actual use. As such, the enzyme loading cited by the commenter related to the 2011 National Renewable Energy Laboratory (NREL) report is a potential input that an LCFS pathway applicant may claim if that is accurate for their process, but if they use more or less they would report and justify that amount.

460. Comment: **LCFS 46-129**

The comment argues that excess electricity from a cellulosic biorefinery displaces marginal electricity.

Agency Response: ARB staff will require the use of average electricity resource mixes for both grid power consumption and for displacement credit for generated power for pathways submitted under CA-GREET 2.0. See the response to comment **LCFS 18-3.**

EXECUTIVE SUMMARY

The California Air Resources Board (Board/ARB) is proposing to re-adopt the Low Carbon Fuel Standard (LCFS) regulation and to include updates and revisions compared to the previous regulation. The ARB staff will bring a new LCFS regulation to the Board for consideration in February 2015. The proposed LCFS regulation will contain revisions to the 2010 LCFS as well as new provisions designed to foster investments in the production of the low-CI fuels, offer additional flexibility to regulated parties, update critical technical information, simplify and streamline program operations, and enhance enforcement.

To address these issues with fuel pathway certifications, staff is proposing a two-tiered system in which conventionally produced first-generation fuels, such as starch- and sugar-based ethanol, would fall into the first tier. Next-generation fuels, such as cellulosic alcohols, would fall into the second tier.

ARB has stated that the Tier 1 process simplifies and expedites the certification process by providing applicants with a streamlined CI calculator that computes pathway CIs using a base set of input parameters needed to determine a Tier 1 pathway CI. This method will use the CA-GREET 2.0 model. This model is a California version of the GREET1 2013 model.

Scope of Work

This work reviews the sugarcane ethanol pathways in the new CA GREET model to ensure that they function properly and utilize the best available science. The review has considered the following questions.

Are the pathways consistent?

It is important that the model uses the same basic approach, including system boundaries and assumptions for all of the ethanol pathways and ideally all of the fuel pathways.

Does the model ask for the key input parameters?

The model will use a combination of default values and user defined inputs to model specific plants. It will be important that all of the important parameters that change from one plant configuration to another are user defined inputs and are not default values.

Does the model reflect the actual practices?

The model must include all of the actual steps in the production process for it to be useful. If it doesn't, some plants will not be able to generate accurate values.

Does the model have the correct background data and are the calculations correct?

Finally it is important that the model contains the best available background data and that the model functions properly. Background data would include the default values, biomass and fuel characteristics, and other inputs.

A significant number of issues were identified. Most of the issues results in the model returning values that are lower than what would be returned if the issues were addressed properly.

Sugar Cane Farming Summary

The CA GREET model does not apply different energy use factors to sugar cane farming even though the two scenarios with mechanical harvesting require almost twice the energy of a manual harvest system. A mechanical harvest system with 100% of the energy supplied by diesel fuel will have GHG emissions of 7.54 g CO_2eq/MJ.

There is evidence that the crop residues that are left on the field are reducing the synthetic nitrogen that is required. The proportion of nitrogen from fertilizer and from crop residue should vary depending on whether or not there is straw burning. The CA GREET model is assuming that there is no difference in nitrogen requirements between burned and unburned fields, an unlikely scenario.

Although there is significant uncertainty regarding the appropriate N_2O emission factor for sugar cane production, the best information in the peer reviewed literature would suggest that the 1% EF1 factor used by CARB is too low. The impact of increasing this to 1.5% is an increase in sugar cane N_2O emissions of 2.83 g CO_2eq/MJ.

Straw Burning Summary

The straw burning emissions appear to be too low by about 4.42 g CO_2eq/MJ as a result of using the IPCC emission factors for Ag residue burning rather than the values for grassland and savanna burning. This increase would be reduced to about 2.5 g CO_2eq/MJ if the nitrogen from the burned straw was not returned to the soil as discussed in the previous section.

Cane Transport Summary

The model should be changed so that the share of the delivery of cane by medium duty trucks and by heavy duty trucks is a user input. The truck energy requirements are the same as for corn ethanol.

Ethanol Production Summary

There are several errors in the CA GREET model related to the transfer of information from the T1 Calculator sheet to the core of the model. These include:

1. Nuclear and biomass power shares of the power generation are transposed when they are transferred to the ETOH sheet.
2. The inputs for sulphuric acid and ammonia are input into the cells for enzymes when they move from the T1 Calculator sheet to the ETOH sheet. Entering non-zero values will produce extremely high and erroneous GHG emissions.

There is also the potential for misinterpretation of the input values. The input for Residual oil is really the quantity of used lubricants that are burned in the plant and not the input of residual oil.

The quantity of biomass that is burned at the plants is hard coded in the model. Not all mills burn all of the bagasse on site; some sell a portion to other local industries. The emissions for these operations will be overestimated. The biomass from the T1 Calculator sheet is transferred to the ETOH sheet, but once it goes there it is not included in any calculations. A proper modelling would require the mills to enter the bagasse consumed and not hard code those quantities. The current model would underestimate the emissions from mills that imported bagasse from another facility or used some straw from the fields to produce more electric power for export.

Transportation Summary

There are issues with the ocean shipping calculations in GREET for many of the fuels, including sugarcane ethanol. The issues for sugar cane ethanol include:

1. The shipment size of 22,000 tons is too high and is not a user input.
2. Ethanol, uniquely of all of the fuels in CA GREET, is not charged with a backhaul.
3. The energy use for ocean shipping is calculated but the calculations underestimate the energy used by a significant amount.
4. Energy use in the model is 145 BTU/ton-mile. Data from the IMO suggests that this should be 335 BTU/ton-mile plus 283 BTU/ton-mile for the backhaul. This would increase the ocean shipping emissions by 17.0 g CO_2eq/MJ, a very significant difference.

Summary

With respect to the four questions that were investigated we find that:

1. There are inconsistencies between some aspects of the sugarcane ethanol pathway and all other pathways.
2. There are key input parameters that should be specified by the user of the model. These would include; the share of cane transported by MD and HD trucks, the ocean shipment size, and confirming that a backhaul is always provided.
3. The model does not reflect actual practice. The lack of change in the farming emissions with the different practices that are employed is problematic. The ocean shipping size is double the typical shipments.
4. The background data in the model is not accurate. Although the biggest issue is with the energy used for ocean shipping, the emission factor applied to cane burning should also be changed.

In addition, there are some programming errors in the calculator that need to be adjusted. The following two tables itemize the changes that should be made to the model.

Table ES- 1 Summary of Changes - Farming

Stage	Manual Harvest			Mechanical Harvest		
	Default	Revised	Change	Default	Revised	Change
All Diesel	4.65	5.39	0.74	4.65	5.39	0.74
Extra Diesel for Mech Harvest					7.54	2.15
Extra N Fert for manual	3.22	4.43	1.21			
N_2O from extra N	2.88	3.96	1.08			
Total			3.03			2.89

Table ES- 2 Changes to Rest of Pathway

Item	Default	Revised	Change

1. INTRODUCTION

The California Air Resources Board (Board/ARB) is proposing to re-adopt the Low Carbon Fuel Standard (LCFS) regulation and to include updates and revisions compared to the previous regulation. The ARB staff will bring a new LCFS regulation to the Board for consideration in February 2015. The proposed LCFS regulation will contain revisions to the 2010 LCFS as well as new provisions that the staff claims are designed to foster investments in the production of the low-CI fuels, to offer additional flexibility to regulated parties, to update critical technical information, and to simplify and streamline program operations, and enhance enforcement.

Based on stakeholder comments received in both the original 2009 rulemaking and the 2011 amendments, the Board directed staff in Resolutions 09-31 and 11-39 to consider revisions to the regulation in a number of specific areas, including the approval of additional fuel pathways. Additionally, staff has indicated that it has conducted internal reviews of lessons learned and has been assessing what has changed since the initial implementation of the LCFS. It is evident that evaluating fuel pathways is very resource-intensive.

Furthermore, stakeholders have expressed concerns that many of the Method 2 pathways in the Lookup Table and on the Method 2 web site are not available for wider use by regulated parties.

In order to attempt to address these issues with fuel pathway certifications, staff is proposing a two-tiered system in which conventionally produced first-generation fuels, such as starch- and sugar-based ethanol, would fall into the first tier. Next-generation fuels, such as cellulosic alcohols, would fall into the second tier.

The ARB staff has stated that the Tier 1 process simplifies and expedites the certification process by providing applicants with a streamlined CI calculator that computes pathway CIs using a base set of input parameters needed to determine a Tier 1 pathway CI. This method will use the CA-GREET 2.0 model. This model is a California version of the GREET1 2013 model.

1.1 SCOPE OF WORK

This work reviews the sugarcane ethanol pathways in the new CA GREET model to ensure that they function properly and utilize the best available science. The review has considered the following questions.

Are the pathways consistent?

It is important that the model uses the same basic approach, including system boundaries and assumptions for all of the ethanol pathways and ideally all of the fuel pathways.

Does the model ask for the key input parameters?

The model will use a combination of default values and user defined inputs to model specific plants. It will be important that all of the important parameters that change from one plant configuration to another are user defined inputs and are not default values.

Does the model reflect the actual practices?

The model must include all of the actual steps in the production process for it to be useful. If it doesn't, some plants will not be able to generate accurate values.

Does the model have the correct background data and are the calculations correct?

Finally it is important that the model contains the best available background data and that the model functions properly. Background data would include the default values, biomass and fuel characteristics, and other inputs.

The report follows the structure of the model. The following sections consider the sugarcane farming operations, straw burning, can transportation, ethanol production, and ethanol transport from Brazil to California.

The model contains four basic sugarcane ethanol pathways:

- Sugarcane Ethanol – Base Case
- Sugarcane Ethanol – with Power Export
- Sugarcane Ethanol – Mechanized Harvest
- Sugarcane Ethanol – Mechanized Harvest with Power Export.

The values that are on the T1 Calculator sheet in the user input cells are not necessarily the expected user values for those cells so there are no default values per se for the four pathways. The direct CI values in the following table are therefore indicative of differences between the four pathways. These do not include the denaturant and the ILUC values.

Table 1-1 Sugarcane Ethanol Indicative CI Values

	Base Case	Power Export	Mechanized Harvest	Mechanized Harvest with Power Export
	g CO_2eq/MJ			
Farming energy	4.65	4.65	4.65	4.65
Fertilizers	4.67	4.67	4.67	4.67
N_2O in Soil	7.48	7.48	7.48	7.48
Straw Burning	10.06	10.06	10.06	10.06
Cane Transportation	1.29	1.29	1.29	1.29
Mechanized Harvesting Credit	0.00	0.00	-10.06	-10.06
Filter Cake T&D	0.01	0.01	0.01	0.01
Plant Energy	2.30	2.30	2.30	2.30
Ethanol T&D	7.16	7.16	7.16	7.16
Power Credit	0.00	-0.72	0.00	-0.72
Total	37.62	36.90	27.56	26.84

Not all sugarcane plants will be able to use the calculator as their operations do not fit the four cases. These include fields that are burned and mechanically harvested and mechanically harvested fields that collect some of the residue to supplement the bagasse for power generation. These kinds of plants will have to follow a Tier 2 method.

CARB have also been allowing some plants that produce sugar and ethanol to reduce the sugarcane production emissions through the use of economic allocation between the sugar and the molasses that is used for the ethanol feedstock. The calculator could not be used for those plants. Economic allocation is the least preferred approach under ISO LCA guidelines. The plants that co-produce sugar and ethanol should have the available

LCFS 46-130

data on energy use in distillation and in crystallization to be able to undertake the CI calculation without any allocation.

LCFS 46-130 cont.

2. SUGAR CANE FARMING

The CA GREET model has no user inputs for farming energy, fertilizer, and N_2O emissions. Nor do these values change with the two process modifiers (mechanical harvest and power credit). This is consistent with the other biofuel pathways, where feedstock production values are fixed by the model, but there is a difference in mechanical vs. manual harvest in terms of the fuel energy used and some other parameters.

2.1 ENERGY

Farming energy in the model is supplied by diesel, LPG, gasoline, natural gas, electricity, and renewable natural gas. The default values and their contribution are summarized in the following table. While one can change the default values, they don't go anywhere in the model. The small amount of natural gas on the T1 Calculator sheet is not included in the model.

Table 2-1 Farming Energy

Fuel	Value, BTU/tonne	GHG emissions, g CO_2eq/MJ
Diesel Fuel	36,385	2.061
Gasoline	11,685	0.654
Natural Gas	20,425	0.954
LPG	17,860	0.881
Electricity	8,550	0.092
Renewable Natural gas	95	0.000
Total	95,000	4.642

The sources for the energy use in farming report the energy consumption as diesel fuel per tonne of cane, so it is not clear where the breakdown of fuel use by fuel type came from. If all of the fuel was diesel fuel, then the emissions would increase to 5.39 g CO_2eq/MJ (an increase of 0.75 CO_2eq/MJ). LCFS 46-131

The 95,000 BTU/tonne was introduced in GREET1 2011 and was about twice as high as the previous value, which used data from 2002. It was suggested by Dunn et al (2011) that the reason for the increase could be due to the increase in mechanical harvesting. A recent paper by Wang et al (2014) considered changes in the Brazilian sugarcane industry between 2010 and 2020. The diesel fuel parameters used in that study are shown in the following table.

Table 2-2 Sugar Cane Farming Parameters

	2010	2015	2020
Yield, tonnes/ha	70.5	80.0	84.0
Mechanical Harvest rate, %	50	80	100
Diesel Fuel consumption, l/ha	230	280	314
Diesel, l/tonne	3.26	3.50	3.92
Diesel, BTU/tonne	110,600	118,800	133,000

The energy use is all higher than is found in CA GREET. This data indicate that the farming energy for manual harvesting should be about 2.4 l/tonne (81,000 BTU/tonne) and for 100% mechanical harvest it should be at least 3.9 l/tonne (133,000 BTU/tonne) and not the same for both cases. This difference in farming energy should be very simple to implement in the CA GREET model. LCFS 46-131 cont.

2.2 Fertilizers

The fertilizer parameters are also set in CA GREET and are not to be adjusted by users. The default values and their impact on the GHG emissions from the manufacturing of the fertilizers are shown in the following table. The values on the T1 Calculator tab do not leave the sheet.

Table 2-3 Fertilizer Parameters

Component	Input	GHG Emissions, g CO2eq/MJ
Nitrogen, g/tonne	800.00	3.22
P_2O_5, g/tonne	300.00	0.11
K_2O, g/tonne	1,000.00	0.21
$CaCO_3$, g/tonne	5,200.00	0.71
Herbicide, g/tonne	45.00	0.39
Insecticide, g/tonne	2.50	0.02
Total		4.66

There is a range of fertilizer rates that can be found in the literature. The values used in GREET are within the range and are generally weighted to the more recent data such as the Seabra et al. 2011 report. It is obviously the nitrogen rate that has the largest impact and the earlier version of GREET, such as 1.8d used 1091.7 g/tonne of cane. LCFS 46-132

It is likely that one of the reasons for a trend to lower nitrogen inputs is the increase in mechanical harvesting and the elimination of the straw burning. This increases the nitrogen in the crop residues that are returned to the soil. The nitrogen content of the residues that are not burned during a mechanical harvest were estimated by Fortes et al (2013) to be 41 kg/ha, or 512 g/tonne at an 80 tonne/ha yield. This is consistent with the reduction N fertilizer seen over the past decade and the reduction in straw burning that accompanies the increase in mechanical harvesting.

The conclusion is that, like the farm energy, it is not appropriate to use the same fertilizer parameters for all four scenarios. There should be different parameters for the manual harvest from the mechanized harvest. The manual harvest should have higher nitrogen inputs than the average values in the model and the mechanized harvest should be lower than the current model value.

2.3 N_2O Emissions

The N_2O emissions in the CA GREET model are fixed at 7.48 g CO_2eq/MJ. None of the user inputs have an impact on this value. There are two factors that have an impact on the calculation: the total quantity of nitrogen applied, and the N_2O emission factor applied. These are discussed below. LCFS 46-133

2.3.1 Nitrogen Applied

The nitrogen applied is the sum of the synthetic nitrogen fertilizer, nitrogen applied through amendments such as vinasse application, and the above and below ground crop residues. The values in the CA GREET model are listed below.

Table 2-4 Nitrogen Additions to the System

Source	Quantity, g/tonne	CO_2eq Emissions, g/MJ
Synthetic Fertilizer	800	2.88
Crop Residue	1,036	3.73
Filtercake	36	0.13
Vinasse	205	0.74
Total	2,077	7.48

In the CA GREET model the crop residue value is independent of the type of harvest. The model assumes that the nitrogen in the crop residue is returned to the soil as ash. However the data on the fertilizer that is applied does not appear to support this. If the nitrogen in the burned residue is returned to the soil it is not likely returned to the sugarcane field but at some other land.

The proportion of nitrogen from fertilizer and from crop residue should vary depending on whether or not there is straw burning.

LCFS 46-134

2.3.2 N_2O Emission Factor

The model uses the basic IPCC Tier 1 emission factors for the synthetic nitrogen and the crop residues. This includes the direct emissions of N_2O from nitrogen and crops residues, the emissions from nitrogen that is leached from the site and run-off, and the emissions from volatilization of some of the applied nitrogen. This is a misapplication of the IPCC methodology as there should be a small difference between the emission factor for crop residues, which have no volatilization impact and the synthetic fertilizer which does have a volatilization factor. If the factor for synthetic nitrogen is 1.325%, the value for the crop residue should be 1.225%. The 1.325% is made up of:

- 1% of the nitrogen in the synthetic nitrogen and crop residues is emitted as N_2O (EF1).
- 10% of the synthetic nitrogen is volatilized and 1% of that is emitted as N_2O.
- 30% of the N applied is leached or run-off and 0.75% of that is emitted as N_2O.
- Total is 1% + 0.1*1% + 0.3*.075% = 1.325%

The larger issue is whether or not the IPCC Tier 1 default value for EF1 of 1% is appropriate for this region of the world. N_2O emissions are influenced by soil type, precipitation, topography, temperature, and other factors. The GREET model has applied some different factors for different crops but the CA GREET model has applied the same factors for all crops. This will result in underestimating the emissions for some crops and overestimating the emissions for other crops.

LCFS 46-135

2.3.2.1 *The Scientific Literature*

Sugarcane has a high need for moisture and there is evidence that the N_2O emission factor should be higher due to high levels of precipitation. Renouf et al (2010), in a study of Australian sugarcane production, use an average value of 0.04 for EF1 and report a range of 0.01 to 0.07. Thorburn et al (2010) modeled the N_2O emissions from sugarcane production systems in Australia and determined a range of N_2O emissions form 3-5% of fertilizer applied. Denmard et al (2010) measured N_2O emissions at two sites in Australia and found a range of emissions from 2.8 to 21% of nitrogen in applied fertilizer. The Australian national GHG inventory applies a value of 1.25% for EF1 but it is not clear if this is a Tier 2 value, or simply the Tier 1 value from the 1995 guidelines.

Lisboa et al (2011) looked at this issue for sugarcane production. In addition to the data from Australia they also found data for Hawaii. They determined that the average N_2O emission rate was 3.87%, however while they compare this value to the IPCC EF1 value, they are not comparable. The 3.87% is the total N_2O emissions based just on the nitrogen applied with synthetic fertilizer. It does not include the nitrogen applied from residue or other sources, nor does it include the N_2O from nitrogen leached from the site. Including these would lower the emission factor.

Although information on N_2O emissions for Brazilian sugar cane production is more limited a recent paper by Walter et al. (2014) reported:

> *Experiments in Australia comparing burnt and unburnt harvesting systems indicate that the maintenance of sugarcane straw on the field increases soil N_2O. These results have been recently corroborated by field experiments conducted in Brazil, but with an even more marked increase when vinasse is applied. Because the soil–atmosphere exchange of N_2O depends on complex interactions, more regional and site-specific data are needed to evaluate the impact of this source on the overall GHG balance of biofuels.*

LCFS 46-136

Signor et al (2013) measured the N_2O emissions from sugar cane production at two sites in Brazil. At the first site the proportion of N lost as N_2O ranged from 0.80 to 12.95%. At the second site N_2O emissions varied from 1.22 to 1.53% of added N for ammonium nitrate treatments and from 0.31 to 1.10% for urea.

Experiments reported by da Silva Paredes (2014) found the highest proportions of N emitted as N_2O were registered in the vinasse treatment, which amounted to 15 % of the N applied in the first greenhouse experiment, and 2.5 % in the field experiment, however the N_2O emission rate for just urea were considerably below the Tier 1 default value of 1%.

Vargas et al (2014) investigated the impact of soil moisture and the level of trash retained in the soil and found that N_2O emissions increase with soil moisture and the presence of trash on the soil doubled the impact of increasing soil moisture on N_2O emissions.

Although there is significant uncertainty with respect to the N_2O emission factor for sugar cane production in Brazil, the scientific literature indicates that rates are higher when the fields are not burned and the trash remains on the field. Rates are also higher when vinasse is applied to the field. More work has been done in Australia and corroborated with field experiments in Brazil, and all of that work suggests that the appropriate emission factor is greater than the 1% value for EF1 that has been used by CARB.

2.4 Sugar Cane Farming Summary

The CA GREET model does not apply different energy use factors to sugar cane farming even though the two scenarios with mechanical harvesting require almost twice the energy of a manual harvest system. A mechanical harvest system with 100% of the energy supplied by diesel fuel will have GHG emissions of 7.54 g CO_2eq/MJ.

There is evidence that the crop residues that are left on the field are reducing the synthetic nitrogen that is required. The proportion of nitrogen from fertilizer and from crop residue should vary depending on whether or not there is straw burning. The CA GREET model is assuming that there is no difference in nitrogen requirements between burned and unburned fields, an unlikely scenario. LCFS 46-137

Although there is significant uncertainty regarding the appropriate N_2O emission factor for sugar cane production, the best information in the peer reviewed literature indicates that the 1% EF1 factor used by CARB is too low. The impact of increasing this to 1.5% is an increase in sugar cane N_2O emissions of 2.83 g CO_2eq/MJ.

3. Straw Burning

For fields that are not mechanically harvested the CA GREET model assumes that the fields are burned prior to harvesting. This does result in different values for the manual versus mechanical harvested scenarios, where a credit for the burning emissions is introduced in the mechanical harvesting systems.

In the GREET model all of the nitrogen in the straw is included in the crop residue whether the straw is burned or is left on the soil. This is not likely to be the case but correcting it would result in lower emissions for fields that are burned and no change in the emissions for mechanical harvesting.

Even though the straw is biogenic the methane emissions and the N_2O emissions must still be included in the calculations of GHG emissions. The emission factors used in GREET are shown in the following table. LCFS 46-138

Table 3-1 Straw Emission Factors

	CA GREET	IPCC Grassland	IPCC Ag residue
	g/tonne		
Methane	2,700	2,300	2,700
N_2O	7	21	7

CA GREET also converts the CO and VOC emissions to CO_2eq for straw burning and then provides a credit for the carbon uptake from the atmosphere. This essentially uses the biogenic methane GWP factor of 22.25.

The IPCC values shown above are for grassland burning and for Ag residue burning, as there are no specific emission factors for sugarcane field burning. The source of the IPCC estimates is the paper by Andrea & Merlet (2001). In that paper there are over 40 references to support the grassland estimates and the note beside the Ag residue value is “Value is a best guess”.

The GHG emissions for straw burning would increase to 14.42 g CO_2eq/MJ if the IPCC Grassland values were used rather than the Ag residue values.

3.1 Straw Burning Summary

The straw burning emissions are too low by about 4.43 g CO_2eq/MJ as a result of using the IPCC emission factors for Ag residue burning rather than the values for grassland and savanna burning. This increase would be reduced to about 2.5 g CO_2eq/MJ if the nitrogen from the burned straw was not returned to the soil as discussed in the previous section. LCFS 46-139

4. CANE TRANSPORTATION

The cane transportation distance is a user input to the CA GREET model. They have modelled both a medium duty and a heavy duty truck. This is appropriate because both types of trucks can be used, although they have assigned a 100% share to both types and the share is not a user input. Either one or the other will be used, not both. The share should also be a user input.

LCFS 46-140

The same energy use is used for HD and MD trucks for all pathways in the model. Sugar cane transport it usually at lower speeds than highway travel in North America but the roads are generally dirt, so the assumption of the same energy use is probably reasonable.

The transportation distance is the user input and it is the key parameter in driving the GHG emissions.

4.1 CANE TRANSPORT SUMMARY

The model should be changed so that the share of the delivery of cane by medium duty trucks and by heavy duty trucks is a user input. The truck energy requirements are the same as for corn ethanol.

5. ETHANOL PLANT

The GHG emissions from the ethanol plant stage using the default values in the CA-GREET model amount to 2.30 g CO_2eq/MJ, or less than 10% of the lifecycle emissions for each of the 4 scenarios. The composition of the total is discussed below.

5.1 ENERGY USE

The T1 Calculator sheet asks for total energy use in the mill by type of energy. The calculator as produced only includes some residual oil use and some electric power use. It has zero for biomass use. All of the 2.30 g CO_2eq/J of emissions are energy derived.

Sugar cane mills burn a lot of bagasse to provide the power and the steam for the mills. This biomass is hardcoded into the model and is not adjusted when a user enters biomass energy into the T1 Calculator sheet. It is also not included in the energy consumption values. If a mill imported bagasse or straw to produce more electricity, the model will not produce higher emissions as a result of the higher biomass inputs.

The contribution of the default energy values to the total for this stage is shown in the following table. Even though the bagasse is biogenic the methane and N_2O emissions are still included in the calculations. LCFS 46-141

Table 5-1 Ethanol Plant Energy Related Emissions

Type	Value	Emissions
	BTU/gal	G CO_2eq/MJ
Residual oil (10% loss of lubricants)	300	0.04
Power	24.37	0.00
Bagasse	89,272	2.26
Total	89,596.37	2.30

Most of the emissions are related to methane and N_2O emissions from burning the bagasse. It is not clear on the T1 Calculator sheet that the residual oil use is related to lubricants and users will likely try and zero this value out when they use the calculator.

5.2 CHEMICALS

The two chemicals that are included in the T1 Calculator sheet are sulphuric acid and ammonia. Both are zero in the model. Seabra (2011) reports sulphuric acid consumption in the mills of 0.0074 kg/litre, 28 g/gal. The model is broken as it transfers the 28 g of sulphuric acid to cell DU 357 (Alpha Amylase) on the EtOH sheet rather than to DU 361 (Sulphuric Acid). This results in GHG emissions of 169,460 g CO_2eq/MJ for the ethanol production stage, an obvious error. The ammonia also goes to the wrong cell on the EtOH sheet. LCFS 46-142

The CA GREET model for Tier I applications doesn't apply to mills that produce sugar and ethanol. These need to be done using the Tier 2 methodology, but are still expected to be done using the CA GREET model as the base. These mills use some lime in the production process (Seabra reports 42.6 g/gal). There is no provision in CA GREET for including lime as an input to the ethanol production process. This needs to be added as user input. Lime has GHG emissions of about 1.25 g/g CAO so including this chemical would add about 0.7g CO_2/MJ to the ethanol production emissions.

5.3 POWER EXPORTS

The new CA-GREET model is using the average power mixes rather than trying to estimate the marginal power in all of the different regions that are included in the model. In the case of Brazil, this drastically lowers the credit for power exports. LCFS 46-143

There is an error in the CA-GREET model with respect to the Brazilian power mix. When the data is migrated from the T1 Calculator sheet to the ETOH sheet the values for nuclear and biomass power are transposed. The values in cells Q293 and Q294 on the ETOH sheet are therefore incorrect and lead to a slightly higher credit (~0.1 g/MJ) than should be calculated. LCFS 46-144

A larger issue is the quality of the data being used in the model for Brazil power. The power mix for Brazil that is used in CA-GREET is shown in the following table. The source identified for the data is the US DOE EIA country brief. This brief was updated in December 2014 and the results are also shown in the table. Small amounts from wind, solar, and nuclear made up the rest.

Table 5-2 GREET Brazil Power Mix

	Brazilian Mix in Model	Updated EIA Brief
Resid Oil/Fossil fuels	0.00%	4%
Natural gas	11.00%	11%
Coal	0.00%	0%
Nuclear power	2.00%	0%
Biomass	7.00%	8%
Hydroelectric	55.76%	71%
Geothermal	3.33%	0%
Wind	20.65%	0%
Solar PV	0.26%	0%
Others (purchased)	0.01%	0%
Total	100.01%	94.00%

LCFS 46-145

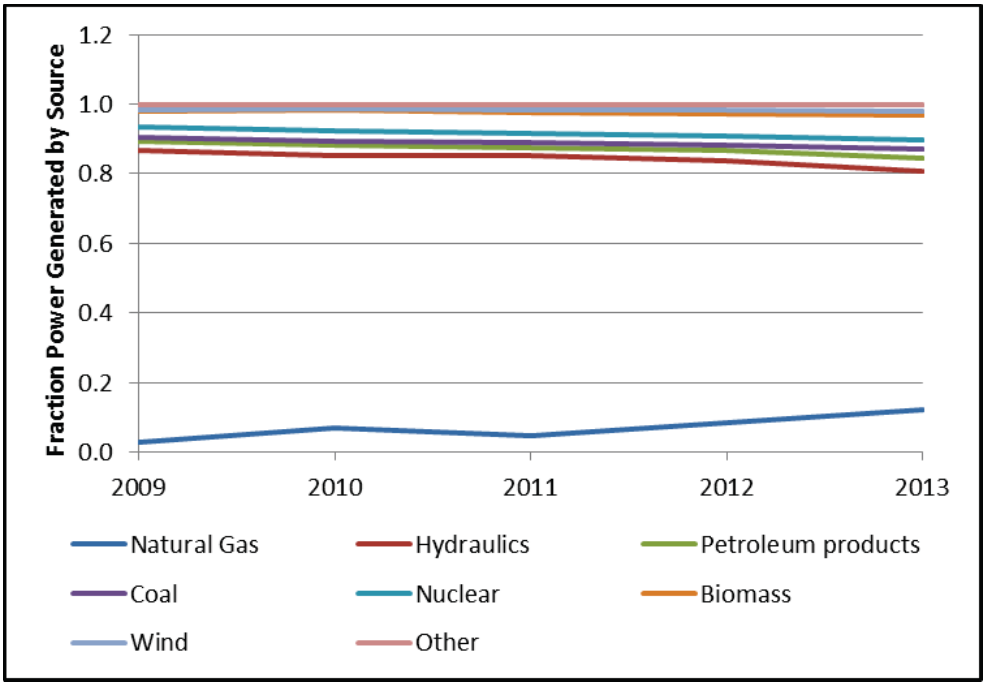
There is a better source of electrical power generation in Brazil. The Energy Research Company - EPE publishes a Statistical Review of the Electric Sector (EPE, 2014). The information from that source is shown below.

Table 5-3 Actual Brazil Power Mix

	2009	2010	2011	2012	2013
Natural Gas	2.86%	7.07%	4.72%	8.46%	12.11%
Hydro	83.87%	78.19%	80.55%	75.18%	68.59%
Petroleum products	2.73%	2.76%	2.30%	2.93%	3.88%
Coal	1.16%	1.36%	1.22%	1.52%	2.60%
Nuclear	2.78%	2.82%	2.94%	2.90%	2.57%
Biomass	4.69%	6.05%	5.95%	6.27%	6.96%
Wind	0.27%	0.42%	0.51%	0.91%	1.15%
Other	1.64%	1.34%	1.81%	1.81%	2.15%
Total	100.00%	100.00%	100.00%	100.00%	100.00%

CARB underestimates the natural gas, coal, and oil used for power generation in Brazil. Furthermore the quantity of gas being used is increasing with time as shown below. The fossil fuel fraction has increased 275% since 2009.

Figure 5-1 Power Generation Trends



Using a more accurate estimate of the Brazilian power mix will slightly increase the base emissions but also increase the power credit available for plants that export power to the grid. LCFS 46-145 cont.

5.4 Ethanol Production Summary

There are several errors in the CA GREET model related to the transfer of information from the T1 Calculator sheet to the core of the model. These include: LCFS 46-146

1. Nuclear and biomass power shares of the power generation are transposed when they are transferred to the ETOH sheet.
2. The inputs for sulphuric acid and ammonia are input into the cells for enzymes when they move from the T1 Calculator sheet to the ETOH sheet. Entering non-zero values will produce extremely high and erroneous GHG emissions.

There is also the potential for misinterpretation of the input values. The input for Residual oil is really the quantity of used lubricants that are burned in the plant and not the input of residual oil. LCFS 46-147

The quantity of biomass that is burned at the plants is hard coded in the model. Not all mills burn all of the bagasse on site; some sell a portion to other local industries. The emissions for these operations will be overestimated. The biomass from the T1 Calculator sheet is transferred to the ETOH sheet, but once it goes there it is not included in any calculations. Proper modelling should require the mills to enter the bagasse consumed and not hard code those quantities. The current model would underestimate the emissions from mills that LCFS 46-148 imported bagasse from another facility or used some straw from the fields to produce more electric power for export.

LCFS 46-148 cont.

6. ETHANOL TRANSPORTATION

Ethanol can be transported from Brazil to California by truck, rail, and pipeline in Brazil, by ocean tanker, and then by truck in California. In CA-GREET the user will select the transportation distances and the distances for each mode on the T1 Calculator sheet. The values in the calculator create emissions of 7.16 g CO_2e/MJ with only the Brazilian truck, ocean freight and the California Port to blending stations being non-zero inputs. The distance from the blending point to the service station is a non-adjustable system input for all types of ethanol; however the distance is different for sugarcane ethanol compared to corn ethanol (50 miles vs. 40 miles). They should be the same. LCFS 46-149

Table 6-1 Transportation Emissions

Mode	Distance	Emissions
Brazil Truck	130	1.01
Ocean Ship	8,758	5.06
US Truck	90	0.70
Truck to Service Station	50	0.39
Total		7.16

The Brazilian trucking distance is short but that will have to be filled in by the applicant for the specific mill.

The issue for modelling is the calculation of the ocean shipping emissions. There are three issues with the calculation which lead to an inaccurate assessment of the emissions. These are described below.

6.1 BACKHAUL

All of the ocean movements in the CA GREET model, ***except Brazilian ethanol***, have an energy charge for the primary movement and the backhaul movement. This backhaul charge is 84% of the energy of the one-way movement. There is no backhaul charge for the Brazilian ethanol. If there was, the emissions would increase by 3.43 g/MJ. The model should be revised to include backhaul as a default value whenever an applicant cannot prove that there will be no backhaul for the relevant pathway. LCFS 46-150

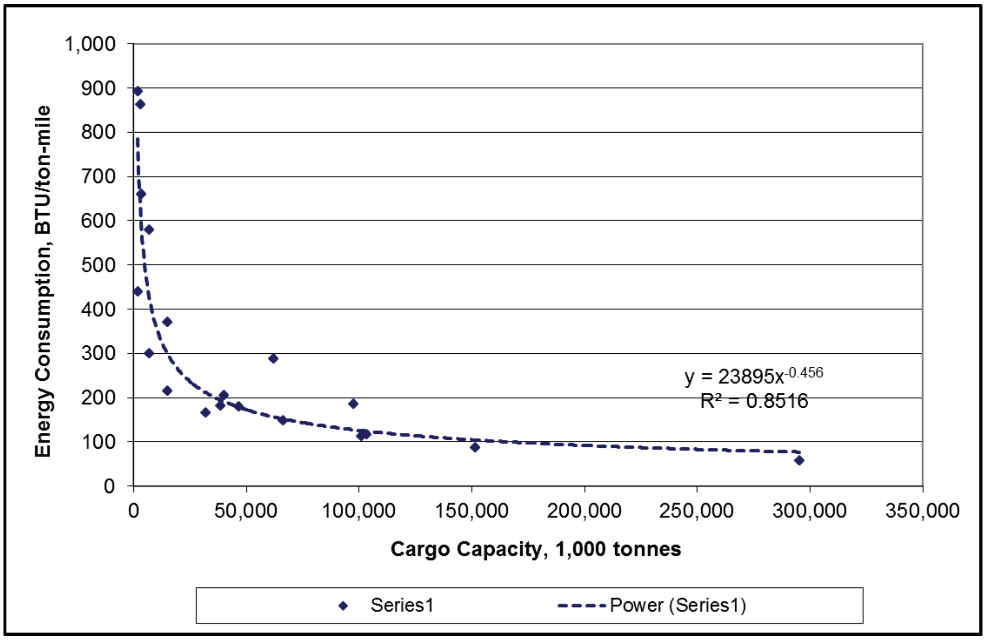
6.2 SHIPMENT SIZE

The CA GREET model assumes that the ethanol is delivered in 22,000 tons shipments. The US DOE EIA reports petroleum product imports on a company level basis. The 2014 data for the first 10 months of the year is currently available. Sugarcane ethanol from Brazil, Guatemala, and Nicaragua has been received in the US. No Brazilian ethanol has been landed in California during this time period. The average size of the shipment was 11,200 tons. This includes shipments that were delivered to more than one port as a single load of the combined capacity. This is only half of the value in the model and it will result in the energy and thus the emissions being underestimated. The model should be revised to require a verifiable shipment size as a user input. LCFS 46-151

6.3 VESSEL ENERGY REQUIREMENTS

The size of the ship has a large impact on the energy expended; larger ships require less energy to move the cargo. The International Maritime Organization (IMO, 2008) published data on the GHG emissions for various sizes of ships. The GHG emissions are easily converted to energy and the relationship for a range of chemical, petroleum product, and crude oil carriers are shown in the following figure. The energy consumption is very sensitive to vessel size, especially for the small vessels, and the energy can increase by 50% of more moving from a 22,000 ton vessel to an 11,000 ton vessel.

Figure 6-1 Energy Requirements vs. Vessel Size



The energy use for the 22,000 ton shipment in GREET is 140 BTU/ton-mile and it excludes the backhaul. The IMO estimate for an 11,000 ton shipment is 343 BTU/ton-mile. To this would be added the 84% for a back haul, for a total energy use of 631 BTU/ton-mile or 4.5 times more than the CA GREET model estimates. This would add about 17.5 g/MJ to the Brazilian sugarcane ethanol carbon intensity for pathways that cannot verify that there is no backhaul.

The calculation of energy consumption in GREET is based on theoretical calculations, includes some erroneous correlations, and underestimates the real world energy use. For example, the faster a ship travels the more power is consumed, but in GREET the energy consumption decreases with faster travel. This is because the power requirements increase as the cube of the velocity in the real world but in GREET the power requirements are independent of the speed. The energy consumed per mile is a function of the square of the speed, or power divided by speed. GREET uses the power/speed equation but doesn't account for the power being a function of the speed, so the end calculated result is incorrect. The model must be revised to correct the errors.

LCFS 46-152

6.4 TRANSPORTATION SUMMARY

There are significant issues with the ocean shipping calculations in GREET for many of the fuels, including sugarcane ethanol. The issues for sugar cane ethanol include:

LCFS 46-151 cont.

1. The shipment size of 22,000 tons is too high and is not a user input.

LCFS 46-150 cont.

2. Sugar cane Ethanol from Brazil, uniquely of all of the fuels in CA GREET, is not charged with a backhaul.

LCFS 46-152 cont.

3. The energy use for ocean shipping is calculated but the calculations underestimate the energy used by a significant amount.
4. Energy use in the model is 145 BTU/ton-mile. Data from the IMO suggests that this should be 335 BTU/ton-mile plus 283 BTU/ton-mile for the backhaul. This would increase the ocean shipping emissions by 17.0 g CO_2eq/MJ, a very significant difference.

7. DISCUSSION

The sugar cane ethanol pathway in the new CA GREET 2.0 model has been thoroughly reviewed. The review has considered the following questions.

- Are the pathways consistent?
- Does the model ask for the key input parameters?
- Does the model reflect the actual practices?
- Does the model have the correct background data and are the calculations correct?

A significant number of issues were identified. Most of the issues results in the model returning values that are lower than what would be returned if the issues were addressed properly.

7.1 SUGAR CANE FARMING SUMMARY

The CA GREET model does not apply different energy use factor to sugar cane farming even though the two scenarios with mechanical harvesting require almost twice the energy of a manual harvest system. A mechanical harvest system with 100% of the energy supplied by diesel fuel will have GHG emissions of 7.54 g CO_2eq/MJ.

There is evidence that the crop residues that are left on the field are reducing the synthetic nitrogen that is required. The proportion of nitrogen from fertilizer and from crop residue should vary depending on whether or not there is straw burning. The CA GREET model is assuming that there is no difference in nitrogen requirements between burned and unburned fields, an unlikely scenario. LCFS 46-153

Although there is significant uncertainty regarding the appropriate N_2O emission factor for sugar cane production, the best information in the peer reviewed literature indicates that the 1% EF1 factor used by CARB is too low. The impact of increasing this to 1.5% is an increase in sugar cane N_2O emissions of 2.83 g CO_2eq/MJ.

7.2 STRAW BURNING SUMMARY

The straw burning emissions are too low by about 4.36 g CO_2eq/MJ as a result of using the IPCC emission factors for Ag residue burning rather than the values for grassland and savanna burning. This increase would be reduced to about 2.5 g CO_2eq/MJ if the nitrogen from the burned straw was not returned to the soil as discussed in the previous section. LCFS 46-154

7.3 CANE TRANSPORT SUMMARY

The model should be changed so that the share of the delivery of cane by medium duty trucks and by heavy duty trucks is a user input. The truck energy requirements are the same as for corn ethanol. LCFS 46-155

7.4 ETHANOL PRODUCTION SUMMARY

There are several errors in the CA GREET model related to the transfer of information from the T1 Calculator sheet to the core of the model. These include: LCFS 46-156

1. Nuclear and biomass power shares of the power generation are transposed when they are transferred to the ETOH sheet.
2. The inputs for sulphuric acid and ammonia are input into the cells for enzymes when they move from the T1 Calculator sheet to the ETOH sheet. Entering non-zero values will produce extremely high and erroneous GHG emissions.

LCFS 46-156 cont.

There is also the potential for misinterpretation of the input values. The input for Residual oil is really the quantity of used lubricants that are burned in the plant and not the input of residual oil.

The quantity of biomass that is burned at the plants is hard coded in the model. Not all mills burn all of the bagasse on site; some sell a portion to other local industries (San Martinho, 2007). The emissions for these operations will be overestimated. The biomass from the T1 Calculator sheet is transferred to the ETOH sheet, but once it goes there it is not included in any calculations. A proper modelling would require the mills to enter the bagasse consumed and not hard code those quantities. The current model would underestimate the emissions from mills that imported bagasse from another facility or used some straw from the fields to produce more electric power for export.

LCFS 46-157

7.5 Transportation Summary

There are issues with the ocean shipping calculations in GREET for many of the fuels, including sugarcane ethanol. The issues for sugar cane ethanol include:

1. The shipment size of 22,000 tons is too high and is not a user input. LCFS 46-151 cont.
2. Ethanol, uniquely of all of the fuels in CA GREET, is not charged with a backhaul. LCFS 46-150 cont.
3. The energy use for ocean shipping is calculated but the calculations underestimate the energy used by a significant amount.
4. Energy use in the model is 145 BTU/ton-mile. Data from the IMO suggests that this should be 335 BTU/ton-mile plus 283 BTU/ton-mile for the backhaul. This would increase the ocean shipping emissions by 17.0 g CO_2eq/MJ, a very significant difference.

LCFS 46-152 cont.

7.6 Summary

With respect to the four questions that were investigated we find that:

1. There are inconsistencies between some aspects of the sugarcane ethanol pathway and all other pathways. LCFS 46-158
2. There are key input parameters that should be included in the model. These would include, the share of cane transported by MD and HD trucks, the ocean shipment size, and confirming that a backhaul is always provided. LCFS 46-159
3. The model does not reflect actual practice. The lack of change in the farming emissions with the different practices that are employed is problematic. The ocean shipping size is double the typical shipments. LCFS 46-160
4. The background data in the model is not accurate. The biggest issue is with the energy used for ocean shipping but the emission factor applied to cane burning should be changed. LCFS 46-161

In addition, there are some programming errors in the calculator that need to be adjusted. Correcting the issues in the model will increase the GHG emissions in the different scenarios. The following two tables itemize the changes that should be made to the model.

LCFS 46-162

Table 7-1 Summary of Changes - Farming

Stage	Manual Harvest			Mechanical Harvest		
	Default	Revised	Change	Default	Revised	Change
All Diesel	4.65	5.39	0.74	4.65	5.39	0.74
Extra Diesel for Mech Harvest					7.54	2.15
Extra N Fert for manual	3.22	4.43	1.21			
N_2O from extra N	2.88	3.96	1.08			
Total			3.03			2.89

46_OP_LCFS_GE Responses (Page 118 – 148)

461. Comment: **LCFS 46-130**

The comment argues that the Tier 1 calculator is not flexible enough to accommodate all sugar-cane based ethanol pathways in the CA-GREET 2.0 model.

Agency Response: The Tier 1 Calculator may not entirely be used to model complex sugarcane-based ethanol pathways where the sugarcane straw (residue of the mechanical harvesting process) is harvested, brought to the mill, and used as supplemental fuel for the biomass boilers; nor can the Tier 1 Calculator be entirely used to model ethanol fuel derived from sugarcane molasses, a by-product of the sugar production process. Staff further concurs that both of these pathways could be treated as a Tier 2 application and subject to additional scrutiny of an ARB staff person. The Tier 1 Calculator has “express” modules that would enable the applicant to expeditiously determine the GHG impacts from common pathway operations, such as agricultural farming; feedstock transport; finished fuel transport and distribution; straw burning and mechanized harvesting; and electricity cogeneration and surplus power export. These segments are common to most sugarcane-based pathways.

Staff has long since revised the pathway methodology for ethanol derived from sugarcane molasses. The market-based allocation methodology can only be used if the applicant can demonstrate the low economic value of the byproduct molasses produced from the sugar production process. The molasses in this case is a low-quality molasses that is typically sold as a livestock feed supplement. When the applicant can demonstrate that the molasses is a low-value byproduct, the full iLUC value for the crop cannot be designated to the pathway. In this case, the iLUC is apportioned based on a mass allocation of fermentable sugars.

In a recent sugarcane-based molasses-to-ethanol pathway certification,[31] the molasses produced by the sugar and ethanol producer was determined to not be a low-value byproduct, but a

[31] See Raizen Energia, S.A., Method 2B Application for Brazilian Sugarcane Molasses-based Ethanol, Carbon Intensity for Costa Pinto Mill, April 14, 2014. http://www.arb.ca.gov/fuels/lcfs/2a2b/apps/rzn-copi-041414.pdf

feedstock for ethanol production. Therefore, the pathway CI was determined using a mass basis of fermentable sugars allocated between finished sugar and molasses production, and the pathway inherited the full iLUC value designated to the crop.

462. Comment: **LCFS 46-131**

The comment questions the energy use data for sugarcane farming in the CA-GREET 2.0 model.

Agency Response: The Tier 1 calculator was meant to be an "express" calculator with minimal customization of the suggested default parameters of the baseline pathways. The intent was to prevent a change in input parameters (in agricultural chemical and fertilizer use, or agricultural farming fuel shares, for example) where the values cannot be easily corroborated, verified by staff, or usage levels enforced. The Tier 1 Calculator only permits a change in user input "yellow cells".

ARB staff has relied on research provided by ANL to support a higher energy use estimate for sugarcane farming. The higher energy use value of 95,000 Btus per tonne of cane harvested, and the corresponding fuel shares, were derived from the GREET1_2013[32] model. The value was endorsed due the higher levels of mechanized harvesting observed on applicant-owned or leased sugarcane farms, and "green harvest" protocols adopted by local governments in the State of Sao Paulo, for example. In addition, ARB staff has no empirical data yet to support projected sugarcane farming parameters in the future. As data becomes available, staff will consider factors proposed by Wang et al (2014) and stated in Table 2-2 (Appendix C) of the commenter's report.

463. Comment: **LCFS 46-132**

The comment expresses concern that the CA-GREET model 2.0 model does not allow user input values to account for different farming practices

Agency Response: ARB staff depended upon agricultural chemical and fertilizer use input parameters suggested in the GREET1_2013

[32] Argonne National Laboratories, 2013. "Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation Model (GREET Version 1), Systems Assessment Section, Center for Transportation Research, Argonne National Laboratories, October 2013.

model developed by ANL.[33] Those same factors are being proposed for adoption in CA-GREETv2.0. Staff concurs with the commenter that mechanically-harvested farms deposit straw residue on the sugarcane farms. The residue is known to contain N, P, and K nutrients which are retained in the soil to some extent, lowering the amount of fertilizer use for subsequent crop cycles. The commenter's suggestion that different fertilizer application rates for manually- and mechanically-harvested farms be used would be extremely difficult to enforce because the application rates recommended are national averages.

Staff believes that most sugarcane-based ethanol producers procure cane from both mechanically-harvested and manually-harvested farms. The fate of mechanically-harvested sugarcane residue is not exactly clear. In some instances, sugarcane straw from mechanically-harvested farms is collected and burned in a corner field. Alternately, sugarcane straw is also being recognized for its potential to produce additional fuel, either by direct combustion in a biomass boiler or by production of sugars by enzymatic hydrolysis.[34] Therefore, at some point in the future, staff may account for the removal of sugarcane straw and non-availability of nutrients for the next sugarcane crop cycle. Accidental fires, acts of nature, and sabotage also complicate the issue of pre-harvest and residue burning. Lastly, ARB staff has witnessed a tremendous increase in the number of applicants to the LCFS program using mechanized harvesting. Staff believes that this trend is likely to continue during non-drought affected years. Manually-harvested sugarcane is also being phased-out in Brazil. With all these considerations, staff recommends that the fertilizer nutrient application levels be maintained at the present level without making a distinction for manually- or mechanically-harvested sugarcane farms.

464. Comment: **LCFS 46-133**

The comment points out that the N_2O emission factor is fixed in the CA-GREET 2.0 model.

Agency Response: The commenter's assessment that the nitrous oxide emissions resulting from above ground and below ground biomass and applied nitrogen fertilizer is incorrect. The 7.48 g CO_2e/MJ value presented by the commenter does have fixed aspects as well as a variable aspect that applicants may vary in the T1 Calculator of CA-GREET 2.0. First, the fixed aspects (within the Tier 1 Calculator and application process) are including, but not limited to the nitrogenous fertilizers applied, the IPCC emission factors related to applied nitrogen fertilizer (1.325% nitrogen as N_2O as a percent of nitrogen in nitrogen fertilizer) and above and below ground biomass (1.225% nitrogen as N_2O as a percent of nitrogen in biomass), and the nitrogen content of above and below ground biomass (1,036 g/tonne for sugarcane). The variable portion of this value for all similar crops or agricultural residue based feedstocks is the yield of ethanol, which is typically represented as a volume per mass of feedstock. An increase in the ethanol yield (for example) per feedstock input would decrease this emission for corn, sorghum, sugarcane, corn stover and other similar feedstocks. Conversely, a decrease in fuel yield would result in greater emissions. For example, using the Tier 1 Calculator for sugarcane ethanol and holding all parameters constant except for the ethanol yield, a comparison can be accomplished. The typical yield of sugarcane ethanol is 21.4 gal/wet tonne (metric tons) of sugarcane, results in above ground and below ground biomass and applied nitrogen fertilizer nitrous oxide emissions of 7.20 gCO_2e/MJ. If the yield is changed to 19.0 gal/wet tonne, the emissions are 8.11 gCO_2e/MJ. If the yield is changed to 24.0 gal/wet tonne, the emissions are 6.42 gCO_2e/MJ. Due to increased fuel production per amount of feedstock, less feedstock is required; therefore, less nitrogen fertilizer is required and less above and below ground biomass results, leading to lower emissions. The opposite is true if the ethanol yield is decreased. Additionally, a review of other Tier 1 pathways (corn or sorghum) in the Tier 1 Calculator, should have cleared-up this misunderstanding or calculation error. Staff appreciates the time the commenter took to make staff aware of a potential error (no longer existing) or possibly a typical misunderstanding of how the downstream (ethanol yield) parameter affects upstream (feedstock) requirements and resulting emissions.

465. Comment: **LCFS 46-134**

The comment argues that data on fertilizer application does not support the model assumption that the nitrogen in the crop residue is returned to the soil as ash.

Agency Response: Staff believes that for manually-harvested sugarcane farms, the nitrogen in the sugarcane straw is likely to burn and be emitted as an oxide of nitrogen rather than be returned to the soil in the form of ash. At this point, staff does not have sufficient information to characterize the distinction between fertilizer inputs for manually- and mechanically-harvested sugarcane farms. Staff depended upon the fertilizer input values from ANL (see response to **LCFS 46-132** above). These values represent national averages, and most sugarcane-based ethanol producers procure cane from both mechanically- as well as manually-harvested sugarcane farms. The data represents cases where less fertilizer is applied on harvested farms where straw is left in the field, and cases where more fertilizer is applied because the straw was primarily consumed in pre-harvest burning. With manual or pre-harvest burning being phased-out in predominant sugarcane growing regions in Brazil, staff believes it may be futile to determine fertilizer application rates for each type of harvest. However, staff will continue to monitor research updates and make necessary adjustments if the application rates change significantly.

466. Comment: **LCFS 46-135**

The comment argues that there should be different N_2O emission factors for crop residues and N-fertilizers.

Agency Response: ARB staff agrees that N_2O from crop residue should be calculated using the IPCC Tier 1 default emission factor of 1.225 percent rather than the 1.325 percent applied to synthetic nitrogen fertilizer. The CA-GREET model has been updated to reflect this change.

Staff concurs with the commenter that N_2O emissions are influenced by soil type, precipitation, topography, temperature, and other factors. Staff further agrees that the CA-GREET model will underestimate the N_2O emissions for some crops and regions of the world, and overestimate the N_2O emissions for others. While there remains a high degree of uncertainty in modeling of N_2O emissions, IPCC Tier 2 methodology should ideally be used to more accurately estimate N_2O emissions; however, until ARB staff is able to develop a robust protocol for verification of applicant-specific agricultural-phase parameters, the IPCC Tier 1 default emission factors will continue to be applied uniformly to all feedstocks in the CA-GREET model.

467. Comment: **LCFS 46-136**

The comment argues that N_2O emissions factors for N fertilizers used in sugarcane farming should be high.

Agency Response: ARB staff appreciates the commenter sharing scientific literature with the ARB. Staff does not disagree with the research studies presented advocating higher N_2O emissions rates applicable to sugarcane farming in Brazil. Staff will review the research presented and discuss the merits and impacts of sugarcane straw residue retention on farms. Staff will further consider consensus opinion and derive a conclusion.

While it is important to monitor and evaluate new research, new studies assessing life cycle impacts on transportation fuel pathways, and revisions to peer-reviewed fuel carbon intensities affecting emissions factors, there is public concern over constant changes to the model parameters and a push for more stability regarding certified fuel carbon intensities. At some point, ARB staff must finalize and recommend 'closure' to the best available data. Periodically, staff will undertake an assessment of all currently available science and present an update to the life cycle analysis model, just as staff has done for CA-GREETv1.8b.

468. Comment: **LCFS 46-137**

This comment is a summary of the sugarcane farming-related comments previously made by the commenter

Agency Response: Each of these comments is addressed as follows:

1. *CA-GREET does not apply different energy use factors to sugarcane farming, even though the two scenarios with mechanical harvesting require almost twice the energy of a manual harvest system.*

   The commenter is incorrect that CA-GREET does not differentiate between burned and unburned fields. The burn-area evaluation using MODIS-based satellite imagery suggests decreased levels of pre-harvest burning on LCFS applicant owned or leased sugarcane farms in Brazil year-over-year. This leads staff to believe that manual harvesting is on the decline in pre-dominantly sugarcane growing regions of Brazil. Staff further believes that this practice will be phased-out by public and private initiatives in Brazil. As a result of increased levels of mechanized harvesting, staff did not hesitate to adopt higher farming energy usage numbers suggested by ANL. Those ethanol producers who continue to procure cane from manually harvested regions can avail of lower energy use via the Method 2/Tier 2 pathway LCFS application process.

2. *Evidence suggests crop residues left on the field reduce required synthetic nitrogen, but CA-GREET assumes there is no difference in nitrogen requirements between burned and unburned fields.*

   ARB staff disagrees; CA-GREET assumes that there may be differences between burned and unburned fields, but those differences are sometimes masked by use of national fertilizer application averages. If the national average data, upon which the present CA-GREETv2.0 fertilizer application rates are based, changes in the future, ARB may consider a CA-GREET revision.

3. *While there is significant uncertainty regarding the N_2O emission factor for sugarcane production, the best information indicates that the one percent EF1 factor used by ARB is too low.*

   ARB has chosen not to adjust the N2O emission factor until more detailed information is available.

469. Comment: **LCFS 46-138**

The comment provides the IPCC factors for grassland burning and Ag residue burning. It goes on to points out that the GHG emissions for straw burning would be higher if the IPCC value for grassland burning were used instead of Ag residue burning.

Agency Response: There is no doubt that sugarcane straw is an agricultural residue. The commenter's suggestion that IPCC-based CH_4 and N_2O factors applicable to grasslands be used for sugarcane straw residue lacks any rationale. Staff believes grassland factors are not applicable to sugarcane farm burning, but may be more suitable for indirect land use change emissions associated with land clearing, for example. Staff, however, concurs that straw-burning emissions only be based upon CH_4 and N_2O emissions. All emissions from sugarcane straw burning are determined to be biogenic; however only CH_4 and N_2O emissions will be counted because these pollutants are regulated by the IPCC. CO is assumed to rapidly oxidize to CO_2, and VOCs are assumed to be short-lived in the atmosphere. A correction for biogenic carbon uptake and elimination of VOC and CO equivalent CO_2e emissions from straw burning have been proposed as additional 15-day changes to the Regulation.

470. Comment: **LCFS 46-139**

The comment states that the current straw burning emissions are low.

Agency Response: This comment presents a summary of the sugarcane straw burning emissions presented by the commenter in the previous Comment **LCFS 46-138**. See the response to that comment.

471. Comment: **LCFS 46-140**

The comment supports the use of medium and heavy duty trucks for cane transport.

Agency Response: The commenter states that both medium-duty diesel (MDD), as well as heavy-duty diesel (HDD), trucks are employed to transport cane from the field to sugar and ethanol mills. The fuel share for each mode of transport is 100 percent because the transport modes are unique. Medium-duty diesel trucks are used to transport cane from the harvested location to a central collection location approximately two miles from the field. From the central location, the cane is then loaded onto HDD trucks for transporting the cane to the sugar and ethanol mills on paved roads. Staff, however, disagrees with the commenter that both types of trucks have the same energy intensity. The energy intensity for MDD and HDD trucks is depicted in the table below:

Energy Intensity of MD and HD Diesel Trucks Used for Sugarcane Transport

	HDD Truck	**MDD Truck**
Energy Intensity:	Btu per ton-mile	Btu per ton-mile
Origin to Destination	723	1,544
Back-Haul	723	1,544

Staff suggests that if the commenter desires, the fuel shares for MDD and HDD trucks can be changed to a user-defined input in the "T&D!" worksheet of the draft CA-GREETv2.0 spreadsheet (see Item 9: Energy Consumption and Emissions of Feedstock and Fuel Transportation, Cells GM107:GN107).

472. Comment: **LCFS 46-141**

The comment states that energy provided by bagasse does not appear in energy consumption values.

Agency Response: The yellow input cells in the T1 Calculator for sugarcane-based ethanol apply to additional energy use by the applicant during ethanol production. The GHG emissions from bagasse (the sugarcane residue left behind after the cane is crushed and juice is extracted) combustion are considered biogenic (except for CH4 and N2O emissions), and are counted with a credit for biogenic carbon uptake (see worksheet EtOH! In draft CA-GREETv2.0, Cells DU371:DU380). Additional biomass brought in and used to produce cogenerated electricity is not credited in the pathway. . All surplus cogenerated electricity is verified either by material balance or credited only to the extent supported by the ethanol production. Additionally, see response to **LCFS 46-148**.

473. Comment: **LCFS 46-142**

The comment states that there are errors in the T1 calculator sheet.

Agency Response: ARB staff concurs with the commenter that additional chemicals may be used during ethanol production. These chemicals were not identified in ARB's internal pathway for Brazilian sugarcane-based ethanol.[35] As the commenter points out, staff has confirmed that sulfuric acid is used during fermentation. The reason why it was left out was because the GHG impacts from usage of sulfuric acid were found to be extremely small (less than 0.02 g CO_2e/MJ). Similarly, staff believes that yeast is propagated onsite at most sugarcane ethanol production facilities. A yellow input cell has been provided nevertheless. Staff also concurs that an error exists and has traced the error reported by the commenter back to the GREET1_2013 model developed by ANL. The error was corrected in a 15-day change.

[35] ARB, 2009. "Detailed California-Modified GREET Pathways or Brazilian Sugarcane Ethanol: Average Brazilian Ethanol, With Mechanized Harvesting and Electricity co-Product Credit, With Electricity Co-Product Credit," Stationary Source Division, September 23, 2009, Version 2.3.

Staff also concurs with the research paper[36] cited by the commenter that lime is used in ethanol production. Staff has also assessed that if lime is used (most likely for sugarcane juice pH adjustment), then the impact at usage rates specified by the commenter is 0.66 g CO_2e/MJ to the Brazilian sugarcane-based ethanol pathway. Staff has investigated the use of this chemical and added a lime into to the Tier 1 Calculator, as well as the EtOH! Worksheet in a 15-day change. The corresponding GHG impacts of this chemical use will thus be reflected in the sugarcane-based ethanol pathway CI.

474. Comment: **LCFS 46-143**

The comment states that the use of the average electricity mix results in lower credits for power exports.

Agency Response: The new CA-GREET model uses the average power mixes rather than trying to estimate the marginal power in all the different regions. See the response to comment **LCFS 18-3.**

475. Comment: **LCFS 46-144**

The comment points out an error for the Brazilian power mix in the CA-GREET 2.0 model.

Agency Response: ARB staff concurs with the commenter on the apparent switch between biomass and nuclear energy shares in the Average electrical generating mix for the country of Brazil. The inadvertent error has been fixed in the final version of the CA-GREETv2.0 model recommended for adoption.

476. Comment: **LCFS 46-145**

The comment states that better quality data (EPE, 2014) than currently used in the model exist for the Brazilian power mix.

Agency Response: ARB staff concurs with the commenter regarding the data presented for the average portfolio of electrical generating assets in Brazil. The energy mix for electrical generation being proposed is based on data provided in the annual

[36] Seabra et al. “Life cycle assessment of Brazilian sugarcane products: GHG emissions and energy use,” Seabra, J.E.A., Macedo, I.C., Chum, H.L., Faroni, C.E., and Sarto,C.A., Biofuels, Bioproducts, & Biorefining, 5:519-532, March 7, 2011.

Brazilian Energy Balance[37] prepared by the Ministry of Mines and Energy, Government of Brazil. The correction was proposed as a 15-day change to the regulation to consider the re-adoption of an updated Low Carbon Fuel Standard (LCFS), as identified in the table below. Staff thanks the commenter for sharing the average Brazilian mix data.

Proposed 15-day Change to the Average Electrical Generation Mix for Brazil

Electric Generation Mixes: Data Table for Use in GREET (From Annual Energy Outlook 2013)	Brazilian Mix Stationary
Residual oil	3.4%
Natural gas	7.9%
Coal	1.9%
Nuclear power	2.6%
Biomass	7.0%

477. Comment: **LCFS 46-146**

This comment presents a summary of the comments presented on the life cycle impacts of ethanol production from Brazilian sugarcane.

Agency Response: This comment presents a summary of the comments presented on the life cycle impacts of ethanol production from Brazilian sugarcane. Responses to comments on this subject were presented above (see ARB staff response to **LCFS 46-142** and **LCFS 46-145**).

478. Comment: **LCFS 46-147**

The comment alleges that there is the potential for misrepresenting the used lubricant.

Agency Response: The commenter suggests that the input for residual oil under “Ethanol Production” in the T1 Calculator is actually an input being used for lubricants consumed by the ethanol

[37] The average portfolio of electrical generating assets is based upon the Brazilian Energy Balance for years 2010-2012, published by the Empresa de Pesquisa Energetica (EPE) agency of the Ministry of Mines and Energy (http://www.mme.gov.br).

plant. ARB staff concurs that is the correct assumption; it represents lubricant usage at the plant. The only way to simulate lubricant usage is by assuming that lubricants have similar properties to “Residual Oil” in worksheet Fuel_Specs!.

479. Comment: **LCFS 46-148**

The comment asserts that the emissions from bagasse burning can be over- or underestimated if the plant sells or buys some portion of the bagasse to/from other plants.

Agency Response: ARB staff believes that the commenter’s concern regarding the model’s treatment of biomass burned at the plants is largely irrelevant. Bagasse generated by the sugarcane crush is burned in the biomass boilers to produce cogenerated electricity. Most sugarcane-based ethanol plants are self-sufficient for their thermal (process steam) and electricity requirements, and even produce a surplus amount of electricity which is exported to the public grid. This exported electricity is assumed to displace the Brazilian average electricity mix. Regarding the concern that additional biomass may be brought into the facility (for example, sugarcane straw) to produce additional electricity, this should have no impact on the pathway carbon intensity, as only the modeled surplus cogeneration rate per metric tonne of sugarcane processed is credited to the pathway. Staff has relied upon Wang et al,[38] as well as material and energy balances provided by applicants, to estimate the amount of cogenerated electricity produced and surplus exported. Lastly, the bagasse combustion emissions are accounted for in ethanol production (see worksheet EtOH!), with a credit for biogenic uptake of carbon dioxide (CH_4 and N_2O emissions are counted).

480. Comment: **LCFS 46-149**

The comment argues that the transport distance between the blending point and the service station should be the same for sugarcane ethanol and corn ethanol.

Agency Response: There may be small differences in ethanol transport distance assumptions to the blending terminal between corn ethanol and sugarcane ethanol. These differences arise since

[38] Wang, 2007. “WTW Energy Use and GHG Emissions of Brazilian Sugarcane Ethanol Production Simulated by Using the GREET Model,” Wang, M., Wu, M., Huo, H., and Liu, J., Center for Transportation Research, Argonne National Laboratory, July 20, 2007.

corn ethanol arrives primarily from the Midwest by rail car and sugarcane ethanol arrives at a port terminal via ocean tanker. The corn ethanol is transported from the railyard to a bulk terminal over a suggested distance of 100 miles for blending with CARBOB gasoline. The sugarcane ethanol is transported from the port terminal to a bulk terminal over a suggested distance of 90 miles for blending with CARBOB gasoline. However, the input for this parameter in both pathways is provided as a yellow cell for the user to provide, based on actual ethanol transport operations.

481. Comment: **LCFS 46-150**

The comment states that the CA GREET model should be revised to include backhaul as a default, to prevent underestimation of emissions.

Agency Response: See response to comment **LCFS 46-21**.

482. Comment: **LCFS 46-151**

The comment states that the CA-GREET model should be revised to require a verifiable shipment size as a user input to prevent underestimation of emissions.

Agency Response: ARB staff has determined that the typical ethanol ocean tanker vessels currently calling at the Port of Santos in Brazil are Medium Range tankers, which typically carry between (33,000 – 42,700 tons). The commenter believes that shipments are about one-half the ocean tanker capacity. If this is true, then clearly there is more ethanol or other comparable product to be transported during its onward journey from a California port. Hence, a back-haul energy charge must be substantiated with more evidence. Staff will continue to investigate ethanol transport operations from Brazil to California by ocean tanker. However, the CA-GREETv2.0 transport and distribution assumptions are as accurate as possible given currently available information.

483. Comment: **LCFS 46-152**

The comment states that calculation error is introduced to the CA GREET emissions results by not taking into account an appropriate cargo capacity of the vessel and the speed at which the vessel travels.

Agency Response: ARB staff appreciates the commenter sharing their point of view on power requirements and energy use by ocean tankers for transport of ethanol from Brazilian ports to California ports. Staff will continue to investigate the logistics of ethanol transport by ocean tanker. Staff will retain the current ocean transport assumptions (capacity, energy use, and back-haul) in the CA-GREETv2.0 model until further evidence is obtained. For now, staff believes that the parameters are representative, on average, of what an ocean tanker with a cargo payload of 22,000 tons is capable of transporting:

22,000 ton x 2,000 lbs/ton x 453.4 g/lb / 2,988 g/gal Ethanol = 6.7 million gallons of ethanol.

Staff believes shipments of over 10 million gallons of ethanol are not uncommon. It is true that some smaller ethanol producers in Brazil may ship much smaller quantities, but for now the parameters suggested in draft CA-GREET appear to be representative.

484. Comment: **LCFS 46-153**

This comment is a summary of the comment on sugarcane farming emissions.

Agency Response: This comment is a summary of the comment on sugarcane farming emissions. Please see ARB staff responses to **LCFS 46-131** to **LCFS 46-137**.

485. Comment: **LCFS 46-154**

This comment is a summary of the comment on sugarcane straw burning emissions.

Agency Response: This comment is a summary of the comment on sugarcane straw burning emissions. Please see ARB staff responses to **LCFS 46-138** to **LCFS 46-139**.

486. Comment: **LCFS 46-155**

This comment is a summary of the comment on sugarcane transport.

Agency Response: This comment is a summary of the comment on sugarcane transport. Please see ARB staff response to **LCFS 46-140**.

487. Comment: **LCFS 46-156**

This comment is a summary of the comment on sugarcane-based ethanol production in Brazil.

Agency Response: This comment is a summary of the comment on sugarcane-based ethanol production in Brazil. Please see ARB staff responses to **LCFS 46-141** to **LCFS 46-148**.

488. Comment: **LCFS 46-157**

Part of this comment is a summary of the comment on the consumption of residual oil in the sugarcane-based ethanol plant in Brazil. Another part of this comment is a summary of the comment on bagasse burning.

Agency Response: See responses to **LCFS 46-147** and **LCFS 46-148**.

ARB staff would like to add that we know a sugarcane-based ethanol mill in Brazil may sell some of their bagasse to another mill. Most mills (such as Sao Martinho cited by the commenter) are producers of sugar, as well as ethanol, which leads to surplus bagasse accumulation by the mill. Staff, however, only credits bagasse combustion that can be verified by the ethanol production quantities, and the energy and material balances.

489. Comment: **LCFS 46-158**

In summary, the commenter believes that there are inconsistencies between some aspects of the sugarcane ethanol pathway and all other pathways.

Agency Response: The comment does not identify those inconsistencies or state why they should be consistent with different pathways. Accordingly it is not possible to respond. To the extent that the comment is meant merely to summarize comments **LCFS 46-130** through **LCFS 46-157**, those comments are responded to above.

490. Comment: **LCFS 46-159**

The commenter has presented a summary of key parameters that the commenter believes should be modified for sugarcane and sugarcane-based ethanol transport.

Agency Response: Issues related to sugarcane transport and identified by the commenter have previously have been addressed. See responses to **LCFS 46-140** and **LCFS 46-149** to **LCFS 46-151**.

491. Comment: **LCFS 46-160**

The commenter has presented a summary of key issues related to sugarcane farming and ethanol transport by ocean tanker.

Agency Response: See responses to **LCFS 46-131** and **LCFS 46-149** to **LCFS 46-151**.

492. Comment: **LCFS 46-161**

The commenter has presented a summary of key issues related to sugarcane farming and ethanol transport by ocean tanker.

Agency Response: See ARB staff responses to **LCFS 46-13**, and **LCFS 46-149** to **LCFS 46-151**.

493. Comment: **LCFS 46-162**

The commenter recommends the use of different factors for diesel fuel use, farming energy fuel shares, nitrogen fertilizer application rate, and N_2O emissions for manually and mechanically harvested sugarcane farms, as specified in their Table 7.1. In addition, the commenter presents a summary table of GHG impacts assessed for all other issues previously raised with regards to the CI for sugarcane-based ethanol from Brazil. Since staff has provided a response to these concerns above previously, it is not necessary to repeat staff's response here.

Agency Response: Regarding higher diesel fuel use, ARB staff has provided a response to this issue in **LCFS 46-131**. Regarding farming energy fuel shares, the commenter suggests that all fuel energy expended on the sugar farms is diesel fuel energy, whereas the CA-GREET model assumes that in addition to diesel fuel, natural gas, electricity, and LPG are also expended on sugarcane farms in Brazil. This assumption is derived from the original CA-GREETv1.8b model, and is consistent with fuel share values specified in GREET1_2013 and research papers presented on the subject.[39] Lastly, regarding nitrogen fertilizer application and N_2O

[39] Seabra, Joaquim EA, Isaias C. Macedo, Helena L. Chum, Carlos E. Faroni, and Celso A. Sarto. "Life cycle assessment of Brazilian sugarcane products: GHG emissions and energy use." *Biofuels, Bioproducts and Biorefining* 5, no. 5 (2011): 519-532.

emissions, the commenter suggests that manually-harvested farms would require more nitrogen than mechanically-harvested farms, as some of the nitrogen nutrient in sugarcane straw is lost during manual harvesting. Staff has addressed this issue in response to **LCFS 46-132**.

Appendix D

Appendix D

Compliance with the Revised LCFS Program and Associated Economic Impacts

Prepared by Edgeworth Economics

CARB's proposed changes in the LCFS regulation call for a reduction in the carbon intensity (CI) of gasoline relative to the baseline level of 99.18 by 2 percent in 2016, 5 percent in 2018, and 10 percent in 2020.[1] In theory, the strategies to achieve those reductions could include 1) displacing gasoline usage with other types of fuel with lower CI values (*e.g.*, electricity); 2) changing the current limit on the percentage of ethanol that can be blended into California gasoline below the E85 level (which is E10); 3) reducing the average CI of renewable fuel blended with gasoline under the E10 limit; and 4) deployment of credits generated from the use of renewable fuels prior to 2016 and the use of renewable fuels in diesel after 2016. CARB projects that compliance with the LCFS will rely significantly on the third method through at least 2020.[2] This Appendix to Growth Energy's comments identifies the circumstances under which the LCFS program will shift the supply of ethanol for the California market from the United States to Brazil, as a result of strategies to reduce the average CI of renewable fuels blended into gasoline under the E10 limit.

Through 2020, CARB has projected that compliance with the LCFS could be reached primarily through a shift from corn ethanol, now largely sourced from the Midwest[3] with an average CI value of about 82, to cane ethanol from Brazil, which currently has an average CI value of about 72.[4] CARB developed an "illustrative compliance scenario" which projects a reduction in corn ethanol use in California gasoline from the current (2014) level of 1,250 million gallons per year to 700 million gallons per year in 2020, with an increase in consumption of cane ethanol equal to about 64 percent of that reduction. Thus, CARB's scenario would

[1] CARB, *Staff Report: Initial Statement of Reasons for Proposed Rulemaking*, December 2014 ("ISOR"), p. ES-3.
[2] ISOR, p. B-39.
[3] The Renewable Fuels Association (RFA) lists three operating corn ethanol plants in California, with total capacity of 175 million gallons per year, representing about one percent of total U.S. ethanol production and about 14 percent of consumption in California. [RFA website at www.ethanolrfa.org/bio-refinery-locations]
[4] ISOR, p. B-39.

involve a reduction in consumption of Midwest-sourced corn ethanol of about 550 million gallons per year as of 2020, relative to today, equivalent to the entire output of about seven typical-sized ethanol plants.[5]

CARB presents the foregoing scenario as an example of how compliance could be achieved. CARB bases its analysis of the economic impacts of the LCFS on an assumption that credit prices would equal $100 from 2016 through 2020.[6] CARB also evaluates economic-impact scenarios based on assumed credit prices of $25, the current value as of January 2015, and $57, the average value from 2012 to 2013.[7]

To determine whether credit prices at those levels would, in fact, cause fuel marketers in California to switch from Midwest-based corn ethanol to Brazilian cane ethanol, Edgeworth Economics prepared an analysis of the total, delivered cost of both fuels under various assumptions about the CI for each type. Our analysis uses the following data:

- A CI range for Midwest-based corn ethanol of 81.4 to 92.4, representing a range of ratings for ethanol refineries located in the Iowa/South Dakota/Minnesota area that currently ship product to California, based on CARB's list of "Approved Physical Pathways" and information provided by Growth Energy members.
- A CI range for Brazilian cane ethanol of 72.5 (current) to 40 (as of 2016), as reported in the ISOR at p. B-39.
- Ethanol spot prices at Chicago, IL and Santos, Brazil—2014 average [source: Platts] and 2016 forecast [source: OECD-FAO, *Agricultural Outlook 2014-2023*].
- Rail freight rates from Midwest refinery locations to California, provided by Growth Energy members.
- Maritime freight rates from Brazil to California, including tariff and terminal charge [source: Odin Marine Group, *Ethanol Report*, January 2015 and Growth Energy members].

[5] The average output of operating ethanol facilities is about 76 million gallons of ethanol per year. [RFA website at www.ethanolrfa.org/pages/statistics]
[6] ISOR, p. VII-1.
[7] ISOR, pp. VII-1-2 and "Monthly LCFS Credit Transfer Activity Report for January 2015" [CARB website at www.arb.ca.gov/fuels/lcfs/credit/20150210_jancreditreport.pdf]

- D5 and D6 Renewable Identification Number (RIN) prices—2014 average [source: OPIS].

Because the delivered cost of Brazilian ethanol in California is substantially higher than the cost of Midwest corn ethanol at present, with LCFS credit levels around $25, relatively little cane ethanol is imported into California[8], while Midwest facilities with CI ratings in the low 90s continue to deliver product. At the average ethanol and RIN prices experienced in 2014, the value of an LCFS credit would need to rise to $156 in order to incentivize a switch from the highest-CI-rated Midwest sources to Brazil. The spread between prices for conventional (D6) RINs and advanced biofuel (D5) RINs has recently expanded, which provides additional incentive to import cane ethanol from Brazil. Based on the average spread in January 2015, an LCFS credit price of $105 would incentivize the same switch.

However, based on forecasts for ethanol prices in 2016, which show a narrowing of the price differential between U.S. and Brazilian ethanol, an LCFS credit price of about $36 (based on 2014 RIN spreads) would cause a switch from 92.4-CI corn ethanol to cane ethanol; and a credit price of only $77 would cause a switch from 81.4-CI corn ethanol to cane ethanol. These figures are well below CARB's estimate for LCFS credit prices of $100 in 2016. LCFS 46-163

If Brazilian cane ethanol can receive the CI ratings predicted by CARB, then the switch will occur at even lower credit prices. For example, CARB projects that Brazilian ethanol will have an average CI rating of 40.0 by 2016.[9] At that rating, LCFS credit prices as low as $14 would result in a switch away from the higher-rated facilities in the Midwest, and credit prices as low as $17 would result in a switch away from even the lower-rated Midwest facilities.[10] In this scenario, even Midwest facilities with CI ratings as low as 70, which CARB claims will be the average rating of the Midwest corn facilities still delivering product to California as of 2016[11], would be at risk. Credit prices as low as $23 would be sufficient to induce a switch to imported cane ethanol. CARB's scenario indicating a substantial decline in the use of Midwest corn ethanol in California and an increase in the use of imported cane ethanol is therefore not only

[8] CARB estimates 100 million gallons in 2014. [ISOR, p. B-39]
[9] ISOR, p. B-39.
[10] These figures are calculated using the 2016 forecast for ethanol prices and current RIN spreads.
[11] ISOR, p. B-39.

plausible, but probable if sufficient ethanol is available from Brazil, even at modest credit prices well below CARB's projected level of $100.[12]

The implications for Midwest ethanol producers in this scenario would be severe. Assuming that U.S.-wide demand for ethanol does not increase (the Energy Information Administration projects ethanol consumption will be flat through 2016[13]), then the increased imports of Brazilian ethanol would result in some combination of 1) lost production or shut-down of Midwest facilities—with total lost volumes equivalent to as many as approximately seven typical-sized plants by 2020, as noted above; or, at a minimum, 2) increased logistics costs associated with exporting corn ethanol to the nearest source of demand outside the U.S., which could be Brazil. Obviously, the latter outcome would not result in a decrease in world-wide carbon emissions.

LCFS 46-163 cont.

The economic impact of reduced production levels or complete plant closures in the Midwest can be estimated based on the characteristics of typical ethanol refineries. On average, U.S. corn ethanol facilities employ approximately 0.8 employees per million gallons of ethanol produced, or about 61 employees for a typical plant.[14] A reduction in ethanol demand of 550 million gallons per year therefore would result in a direct loss of approximately 440 jobs at ethanol refineries. In addition to these direct effects, the regions that host ethanol production facilities would experience additional reductions in economic activity stemming from reduced purchases of locally-sourced inputs (the "indirect" impact) and reduced spending by facility employees and local vendors (the "induced" impact). These additional economic impacts are generated by the "multiplier" effect, which results from the recycling of business revenues and household income within the local region. Plausible estimates for the overall multiplier effect for employment applicable to the ethanol industry range from about 2 (indicating a total impact

---

[12] This result holds even if the price differential between U.S. and Brazilian ethanol remains closer to current levels, rather than declining as indicated in the forecast described above.

[13] U.S. Energy Information Administration, *Short-Term Energy Outlook*, February 10, 2015.

[14] Based on various sources, including: John Urbanchuk, "Contribution of the Ethanol Industry to the Economy of the United States," Cardno ENTRIX, prepared for the Renewable Fuels Association, February 2, 2012; David Swenson, "Understanding Biofuels Economic Impact Claims," Iowa State University, April 2007; and various public SEC filings.

on employment equal to two times the direct employment impact) to about 7.[15] Applying a figure of 4 to the direct employment impacts calculated above implies a loss of approximately 1,760 jobs in ethanol producing regions.

Even assuming that the facilities forced out of the California market could find customers outside the U.S., there would still be substantial costs to the industry. For example, transport of ethanol from the Midwest to Brazil would entail increased logistics costs of approximately 10 cents per gallon[16], or $55 million per year, assuming sufficient demand in Brazil for all 550 million gallons of displaced corn ethanol.

Nos. 12-15131, 12-15135

UNITED STATES COURT OF APPEALS FOR THE NINTH CIRCUIT

ROCKY MOUNTAIN FARMERS UNION, *et al.*, Plaintiffs-Appellees,

v.

JAMES N. GOLDSTENE, *et al.*,Defendants-Appellants, and ENVIRONMENTAL DEFENSE FUND, *et al*.,Intervenor-Defendants-Appellants.

Appeal from the United States District Court for the Eastern District of California (D.C. Nos. 1:09-cv-02234-LJO-GSA, 1:10-cv-0013-LJO-DLB)

DECLARATION OF ERIN HEUPEL, P.E.

I, Erin Heupel, declare and state as follows:

1. I am the Director of Environment and Technology at POET LLC, a company that constructs and manages ethanol production facilities, headquartered in Sioux Falls, South Dakota. I provide this declaration in support of the opposition by Plaintiffs-Appellees ("Plaintiffs") to the motion filed by Defendants-Appellants ("Defendants") to stay the preliminary injunction and judgments in *Rocky Mountain Farmers Union, et al. v. Goldstene*, Case No. 1:09-cv-02234-

LJO-GSA (E.D. Cal., Dec. 29, 2011).[1] I am a licensed Professional Engineer in the States of Iowa and South Dakota. I make this declaration based on my professional experience and my personal knowledge of the facts set forth herein. I am willing and able to present under oath the facts set forth in this Declaration if called as a witness before the Court.

2. The purpose of this declaration is to respond to statements in the Declaration of Michael Waugh, dated January 20, 2012, and filed in this Court by Defendants on February 10, 2012, on two subjects: (i) the creation of "individualized" pathways for some corn ethanol plants under the California low-carbon fuel standard ("LCFS") regulation, and (ii) the impact of District Court's preliminary injunction on the environmental benefits that Defendants attribute to the LCFS regulation. *See* Declaration of Michael Waugh in Support of Defendants and Defendant-Intervenors' Motion to Stay Preliminary Injunction and Judgments Pending Appeal (Dkt Entry 21-7) ("Waugh Decl.") ¶¶ 5, 39-41, 52-59, *and id.* at 11:9.

3. I am in charge of the efforts of ethanol plants managed by POET LLC, to receive CARB approved individualized carbon intensity "pathways" for

[1] *See* Motion for A Stay of the District Court's Orders and Judgments Pending Appeal (Dkt Entry 22-1) ("Stay Mot.").

the plants managed by POET LLC that can qualify for such pathways.[2] My duties at POET LLC require me to have complete knowledge of the technologies, processes, and methods used for the production of corn ethanol and various co-products by the plants that POET LLC manages, including the production efficiencies and energy requirements of those plants. My responsibilities at POET LLC also require me to have substantial knowledge of the same attributes of corn ethanol plants that compete with the plants that POET LLC manages.

4. At the outset, it is important to understand that companies in the U.S. corn ethanol industry have strong commercial incentives to maximize yield from feedstock and to minimize energy usage, and thus to minimize greenhouse gas ("GHG") emissions. Corn ethanol plants cost millions of dollars to build. Midwest corn ethanol plants are carefully sited in order to have ready access to their feedstock, as well as competitively priced natural gas, electricity, or other sources of energy to run the plant. The companies that survive and prosper in this industry are those whose plants are designed from the beginning for maximum efficiency in feedstock conversion and minimum energy consumption. Next to corn costs, energy costs are the largest variable cost in producing corn ethanol.

LCFS 46-164

[2] *See* Waugh Decl. ¶¶ 52-56. The plants that POET LLC constructs and/or manages are owned by separate investor groups. *See* Declaration of Robert Whiteman (filed March 1, 2012) at note 3.

5. A number of plants managed by POET LLC have received CARB staff approval for 11 different individualized pathways for corn ethanol. I am personally familiar with the attributes of each plant awarded those pathways that the LCFS regulation treats as relevant in determining the carbon intensity of the ethanol that those plants produce. The relevant plants made no changes in production methods, feedstock, methods of transport, or any other factor relevant to the pathway application, in order to reduce the carbon intensity that would be assigned to ethanol produced at those plants. POET LLC obtained the CARB approved CI pathways for these plants by documenting the attributes of production and energy supply relevant under the LCFS regulation that those plants had adopted for commercial reasons, completely independent of the LCFS regulation and the regulation's requirements for the establishment of alternative pathways.

LCFS 46-164 cont.

6. When plants managed by POET LLC make changes in their technologies, production methods, or energy sources, and those changes reduce the carbon intensity, POET LLC seeks changes in the carbon intensity values that apply to those plants to the extent possible under the LCFS regulation. In such instances, however, the motivating factor for the change at the plant is not the LCFS regulation, but the need to remain competitive in production methods and technologies within the Midwest corn ethanol industry. In addition, to my knowledge, none of the Midwest corn ethanol plants that compete with those

managed by POET LLC have made changes in their technologies, production methods, or energy inputs in order to gain a lower carbon intensity value under the LCFS regulation; instead, those plants strive to increase efficiency and reduce energy consumption for the same commercial reasons as the plants managed by POET LLC.

7. The LCFS regulation becomes more stringent in each year after 2011. But, contrary to what appears to be the position taken in Mr. Waugh's declaration, it would not be commercially practicable for Midwest corn ethanol plants to try to keep up with the increases in the stringency of the regulation, simply in order to try to stay in business in California.[3] LCFS 46-165

8. Under the LCFS regulation, all corn ethanol plants, including those in the Midwest, must add an assigned "indirect" carbon intensity emissions factor of 30 gCO_2eq/MJ to their "direct" carbon intensity emissions factor. The "indirect" emissions factor is more than 40 percent of the total carbon intensity level assigned to the corn ethanol pathway that, according to Mr. Waugh's Declaration, has the lowest carbon intensity level recognized by the CARB staff.[4] Nothing that any LCFS 46-166

[3] *See* Waugh Decl. ¶¶ 41, 44.

[4] *See* Waugh Decl., Exh. E at 8 (pathway value of 73.21 gCO_2eq/MJ for Pathway No. ETHC0035). The pathway that Mr. Waugh's declaration identifies as the "lowest carbon intensity value approved for any ethanol," for a plant located in Kansas (Waugh Decl. ¶ 53), is a pathway for a plant that uses the combination of wheat slurry, sorghum, and corn and is not a pathway for an ethanol plant using

single corn ethanol plant or group of corn ethanol plants can do will reduce the "indirect" carbon intensity emissions factor assigned by the LCFS regulation. As a result, the impact of plant changes in improving efficiency or reducing energy consumption do not result in proportional changes in the assigned CI value. For example, the 73.21 gCO_2eq/MJ value above consists of 43.21 gCO_2eq/MJ for the production of feedstock and ethanol as well as ethanol transport and the value of 30 gCO_2eq/MJ for indirect emissions. A 10% reduction in the 43.21 gCO_2eq/MJ value to 38.89 gCO_2eq/MJ yields only a 6% reduction in the overall CI value which becomes 68.89 gCO_2eq/MJ. In addition, within the "direct" emissions factor assigned to a corn ethanol plant, the LCFS regulation attributes a substantial increment to GHG emissions attributed to the cultivation and harvesting of corn (potentially, 35.7 gCO_2eq/MJ). Ethanol plants cannot directly control and document how farmers grow and harvest corn, which the farmers grow not only to

LCFS 46-166 cont.

corn. Sufficient quantities of sorghum feedstock are not available to most corn ethanol plants, including those in the northern Great Plains that were built to serve the California market. Although the yields from converting grain sorghum to ethanol can be similar to corn, the yields of sorghum per acre are lower, making sorghum a generally less desirable crop than corn for fertile or irrigated land. Sorghum tends to be grown where the land is too marginal to support a profitable corn crop, or where moisture availability is scarce. As was the case with the fuel-grade ethanol industry prior to the implementation of the LCFS regulation, grain producers will grow crops that make the most profitable use of their land and agricultural inputs.

sell to ethanol plants, but also to other customers, on the best possible commercial terms for the farmers. LCFS 46-166 cont.

9. As indicated above, the lowest CI value for any Midwest corn ethanol pathway is 73.21 gCO_2eq/MJ and the direct CI value for that pathway is 43.21 gCO_2eq/MJ. Assuming that this lowest CI corn ethanol is blended with a gasoline blendstock assigned a carbon intensity value of 95.86 gCO_2eq/MJ (which is the value assigned to an "average" gasoline blend), LCFS compliance could only be achieved with a 15% ethanol blend ("E15") through 2015. In order for LCFS compliance to be achieved with E15 in 2016, the CI of Midwest corn ethanol would have to be reduced to 64.20, and the direct CI value to 34.20. This represents approximately a 21% reduction in the direct CI value from the lowest CI value currently documented. That same ethanol blended at 15% into the same gasoline feedstock would begin to generate deficits for the blender starting in 2017. LCFS 46-167

10. Experience in 2011 has shown that gasoline blenders in California will quickly try to stop buying and blending ethanol that does not generate a credit against the requirements of the LCFS regulation.[5] Given the "indirect" emissions factor automatically assigned to all corn ethanol plants, and the compliance schedule for LCFS regulation in the near term, even the most efficient Midwest corn ethanol plant currently recognized by the CARB staff would need to reduce LCFS 46-168

[5] *See* Declaration of James M. Lyons ¶¶ 5-7 .

its direct carbon intensity factor by more than 21% and file the necessary documentation with CARB, in order to continue in the California fuel market for one more year past the current limit of 2015. The costs incurred to reduce the carbon intensity of ethanol from the plant would have to be recovered by the end of 2016 before the gasoline blenders stopped buying that plant's ethanol and moved to an alternative fuel with a lower carbon-intensity level, for example, from Brazil or through the use of the "electricity" pathways in the LCFS regulation. LCFS 46-168 cont.

11. The upshot is that even a very efficient Midwest corn ethanol plant would have to find and implement further efficiencies or energy reduction opportunities not driven by the nationwide market and recover the costs of the necessary changes, over a very short time frame. That is not commercially practicable for corn ethanol plants managed by POET LLC or, I believe, for competitor corn ethanol plants. Rather than incur those costs, U.S. corn ethanol plants will try to compete in markets outside California. LCFS 46-169

12. In sum, I am aware of no evidence that the LCFS regulation has had any significant impact on the level of GHG emissions from corn ethanol plants located in the Midwest. A stay of the preliminary injunction will not cause the corn ethanol plants managed by POET LLC, or any competitors to those plants with whose operations I am familiar, to reduce the GHG emissions from their LCFS 46-170

operations relative to current levels. A stay of the preliminary injunction issued by the District Court therefore will not restore or continue any GHG emissions reductions during the pendency of this litigation, simply because the LCFS regulation itself has had no effect on GHG emissions attributable to corn ethanol production, nor would it have any such effect in the near term.

LCFS 46-170 cont.

Pursuant to 28 U.S.C. § 1746, I declare under penalty of perjury that the foregoing is true and correct. Executed on March 1, 2012 at Sioux Falls, South Dakota.

Erin Heupel, P.E.

Nos. 12-15131, 12-15135

UNITED STATES COURT OF APPEALS FOR THE NINTH CIRCUIT

ROCKY MOUNTAIN FARMERS UNION, *et al.*, Plaintiffs-Appellees,

v.

JAMES N. GOLDSTENE, *et al.*, Defendants-Appellants, and ENVIRONMENTAL DEFENSE FUND, *et al*., Intervenor-Defendants-Appellants.

Appeal from the United States District Court for the Eastern District of California (D.C. Nos. 1:09-cv-02234-LJO-GSA, 1:10-cv-0013-LJO-DLB)

DECLARATION OF ROBERT WHITEMAN

I, Robert Whiteman, declare and state as follows:

1. I am the Chief Financial Officer of POET Ethanol Products, LLC, d/b/a POET Ethanol Products (hereinafter "POET Ethanol Products"), a company based in Wichita, Kansas, that markets ethanol. I provide this declaration in support of the opposition by Plaintiffs-Appellees ("Plaintiffs") to the motion filed by Defendants-Appellants ("Defendants") to stay the preliminary injunction and judgments in *Rocky Mountain Farmers Union, et al. v. Goldstene*, Case No. 1:09-

cv-02234-LJO-GSA (E.D. Cal., Dec. 29, 2011).[1] I am willing and able to present under oath the facts set forth in this declaration if called as a witness before the Court.

Summary

2. In their stay motion, Defendants claim that the low-carbon fuel standard ("LCFS") regulation has had no adverse impact on what Defendants call the "domestic ethanol industry." (Stay Mot. at 31.) As explained below in the main portion of this Declaration, the U.S. corn ethanol "industry" is compromised of numerous separately-owned corn ethanol production plants, mainly located outside California near the sources of corn used to make ethanol. Long before adoption of the LCFS regulation, investors built ethanol plants in the western Great Plains area of the Midwest to serve the California market. They did so in order to obtain the "California premium" - higher prices that prevailed for corn ethanol in California, compared to other large U.S. markets, resulting from specific economic conditions in California. (*See* ¶¶ __-__ below.) The principal impact of the LCFS regulation within what Defendants define as the "domestic ethanol industry" has fallen on those Midwest producers, who served the California market before the LCFS was adopted.

---

[1] *See* Motion for A Stay of the District Court's Orders and Judgments Pending Appeal (Dkt Entry 22-1) ("Stay Mot.").

3. In its first year of implementation, the LCFS regulation forced the exit from the California market of some of those Midwest corn ethanol plants that had been built to serve California. The LCFS regulation also curtailed sales of corn ethanol by some other Midwest plants that had previously had significant sales of ethanol in California. (*See* ¶¶ __-__ below.) The preliminary injunction gives all corn ethanol producers the ability to try to compete again in California as they could before the LCFS regulation took effect.[2]

4. Defendants also claim that the preliminary injunction is jeopardizing reductions in greenhouse gas ("GHG") emissions that were being provided by the LCFS regulation, or that would be provided by the regulation during the pendency of the litigation. (*See*, *e.g.*, Stay Mot. at 28.) That claim ignores the fact that in 2011, and currently and for the foreseeable future, corn ethanol that cannot be sold in California as a result of the LCFS is still being produced and is being sold in other markets. (*See* ¶¶ __-__ below.) The preliminary injunction is not jeopardizing reductions in GHG emissions from the corn ethanol production sector, because there is no evidence that such reductions occurred as a result of the LCFS regulation. Indeed, the LCFS regulation did not affect, and in the near term will

LCFS 46-171

[2] The exclusion of some producers from the California market and those producers' loss of the "California premium" does not mean that the LCFS regulation has lowered ethanol prices in California. *See* ¶ __ below.

not affect, methods of production or output of that sector, which are determined by macroeconomic factors unaffected by the regulation.

LCFS 46-171 cont.

5. This declaration is based on my personal knowledge of the ethanol industry gained in the course of my employment at POET Ethanol Products. I have worked in the transportation fuels industry for more than 17 years, and in the corn ethanol marketing business for more than a decade.[3] My duties at POET Ethanol Products require me to have direct, first-hand knowledge of sales of ethanol by all the production facilities for which we market ethanol. My duties also require me to have a full and current understanding of the methods of ethanol production and delivery throughout the U.S. corn ethanol industry, as well as corn ethanol marketing practices and factors affecting competitive conditions within the

---

[3] POET Ethanol Products currently markets ethanol from 35 ethanol producers, located in Colorado, South Dakota, Nebraska, Kansas, Missouri, Iowa, Minnesota, Indiana, Ohio, and Michigan.

Some of the ethanol plants for which POET Ethanol Products markets ethanol have management contracts with POET LLC, an ethanol plant construction and management firm based in Sioux Falls, South Dakota. The U.S. Environmental Protection Agency has sometimes referred to "POET Biorefining" as a single ethanol production or marketing entity. (*See*, *e.g.*, Renewable Fuels Standard Program (RFS2) Regulatory Impact Analysis (Feb. 2010) 97, *available at* http://nepis.epa.gov/Exe/ZyPURL.cgi?Dockey=P1006DXP.txt. In point of fact, nearly every ethanol plant having management contracts with POET LLC is owned by a separate group of investors, which typically include a large number of investors from the farming communities near the ethanol plant, who often sell their grain to the local plant managed by POET LLC to make ethanol.

corn ethanol industry, including the impact of regulations like the LCFS regulation on corn ethanol markets.

6. The balance of my declaration is divided into two parts. Part I provides necessary background on the U.S. corn ethanol industry and the California corn ethanol market. Part II explains how the LCFS regulation affected the U.S. corn ethanol industry in 2011, and would continue to affect that industry in the absence of a preliminary injunction.

I. The Corn Ethanol Industry and the California Energy Market

7. Ethanol is used as an additive in gasoline. It has high octane ratings, and can also be used as an oxygenate to help reduce automotive air pollution. Corn ethanol produced at plants located in the Midwest historically provided about 95 percent of California's requirements for oxygenates for blending into gasoline.

8. All ethanol sold in the United States for use in motor fuel has the same physical and chemical composition, regardless of the method of production or the material from which the ethanol is produced (called the "feedstock").[4] Prior to implementation of the LCFS regulation, ethanol for use in gasoline could be sold as a fungible commodity. The market for corn ethanol for use in gasoline was highly competitive. A successful business plan for a corn ethanol plant required

[4] In the case of ethanol made from corn starch, the type of corn used is "No. 2" corn, the hard corn grown as animal feed, and not so-called "sweet corn" sold in grocery stores for human consumption.

proximity to the corn feedstock, access to competitively priced energy needed in the production process, efficient production technology and methods, and good transport logistics to get the ethanol from the plant to the customers' locations.

9. Transport logistics are particularly important for corn ethanol plants that intend to serve distant energy markets, sometimes located more than a thousand miles from the plant. Plants that produce ethanol for shipment over long distances use railways as a mode of transport, preferably in dedicated "unit trains" of tanker cars that can be loaded at sidings within or adjacent to the ethanol plant's fence line.[5]

10. California is the single largest state market for corn ethanol in the United States, historically consuming about ten percent of total U.S. corn ethanol production. Companies that market gasoline in California blend ethanol into base gasoline, called "California Reformulated Gasoline Blendstock for Oxygenate Blending," or "CARBOB." Publicly available price data show that historically, the California gasoline blenders have paid higher prices on average than could be obtained for ethanol sold in other parts of the United States. While many factors can affect the price paid for ethanol, one factor that likely accounts for the higher prices available in California is that the refineries that produce CARBOB tend to

[5] A photograph showing the integration of an ethanol plant with its rail connection is attached as Exhibit 1 to the Declaration of Russ Newman, being filed today by Plaintiffs. (*See* [ECF #], Exh. 1.)

have higher average total production costs than refineries outside California. Even after accounting for the costs of shipping ethanol over the Rocky Mountains, Midwest ethanol producers who could obtain a customer base in California obtained over time a higher "net-back" per gallon (*i.e.*, price per gallon to the customer, net of freight costs) than they could obtain in other markets. For example, in the three years prior to implementation of the LCFS regulation at the end of 2010, for example, the average California "net-back" price for a gallon of ethanol was 3.65 cents per gallon ("cpg") higher than the Chicago market, and 4.17 cpg over prices at New York Harbor.[6]

11. To compete in the California ethanol market, investors in Midwest corn ethanol plants have for many years sited their plants in locations with the best possible rail access to California. Those producers are located west of the Mississippi River, often in North and South Dakota, Minnesota, Iowa, Kansas and Nebraska. Their plants are designed at the outset to be "single line" shippers to California, meaning that they can ship their product on either the BNSF or Union Pacific systems, without changing freight lines and having to pay more than one freight bill.

---

[6] Based on Platts Fuel Price Service daily reports, Jan. 1, 2008 to Dec. 31, 2010, for Chicago spot prices, New York Harbor 5- to 15-day barge prices, and Southern California rail prices, less average estimates of freight from the Midwest.

II. Impacts of the LCFS Regulation

12. The basic features of the LCFS regulation, as it existed in the summer of 2010 prior to implementation, were described in the District Court's decision denying Defendants' motion to dismiss this case. (*See Rocky Mountain Farmers Union, et al. v. Goldstene*, 719 F.Supp. 2d 1170, 1177-79 (E.D. Cal. 2010).) As first adopted, and in its current form, the LCFS regulation assigns to each gallon of ethanol sold in California a "carbon intensity" (or "CI") score based on the "pathway" assigned to the plant where it is produced. The "pathway" for ethanol is in turn defined by the location where the ethanol is produced, the feedstock used (in the case of corn ethanol, No. 2 Corn), the production method, the consumption of ethanol in a vehicle's engine, and other factors. Carbon intensity is quantified in units of grams of carbon-dioxide-equivalent emissions per megajoule ("g/mj") of energy that the LCFS regulation attributes to each pathway. (*See* 719 F.Supp. 2d at 1178-79, 1197.)

13. The stated goal of the LCFS regulation is to produce reductions in the average carbon intensity of transportation fuels sold at the retail level in California, on a year-by-year basis, starting in 2011, until 2020 when that average carbon intensity is required to be 10 percent lower than before the regulation took effect. For example, the LCFS regulation's carbon intensity reduction schedule for gasoline calls for an average carbon intensity in 2011 of 95.61 g/mj (a reduction of

0.25 percent from a 2006 baseline); by 2020, the average carbon intensity level must be 86.27 g/mj. (10 percent below the 2006 baseline). A gasoline blender achieving a lower level of average carbon intensity than 95.61 g/mj in 2011 would generate a credit against the compliance schedule set by the regulation. A gasoline blender whose blended product exceeded 95.61 g/mj in 2011 would generate a deficit. LCFS credits have an indefinite lifetime. Deficits, however, must be made up by the end of the year following the year in which they were created.

14. From a marketing perspective, the simplest example of how the LCFS regulation works is to start with the fact that the LCFS regulation assigns a CI value of 95.85 g/mj for a baseline gasoline and a CI value of 95.86 to CARBOB. In 2011, the LCFS regulation set a target for the average CI of finished gasoline products at 95.61 g/mj -- a value that is 0.25% lower than the baseline gasoline CI value. An oil company blending CARBOB with ethanol having a CI value greater than 95.86 g/mj would increase, not decrease, the carbon intensity of the final gasoline product it is selling -- which is not what the regulation is trying to accomplish. As such, it would generate a deficit, rather than a credit. For ethanol assigned a CI value lower than 95.86 g/mj, the ethanol product will enable, to some extent, a reduction in the carbon intensity of the final, blended gasoline product. The lower the CI value assigned to a given ethanol pathway, the more valuable the

ethanol is to a gasoline blender trying to reduce the carbon intensity of its final product.[7]

15. As first approved by CARB in 2009, the LCFS regulation assigned a CI value of 98.40 g/mj to the Midwest corn ethanol pathway that represented the majority of Midwest plants, including most members of Growth Energy, one of the Plaintiffs in this action. An oil company blending ethanol from that most typical Midwest pathway would therefore have increased, not reduced, the carbon intensity of its finished gasoline product. At POET Ethanol Products, we saw a shift in the buying preferences of our California customers after the LCFS regulation was adopted. A number of our customers would pay a higher price for ethanol that had lower CI values, and to the extent they would buy ethanol with CI values above the CI level assigned to CARBOB, they would only purchase the ethanol at lower prices. That fact is borne out in one of the Declarations signed by Mr. Michael Waugh and filed in support of Defendants' stay motion, which states that "[w]ith the exception of a few isolated days, spot prices for ethanol with a

[7] Federal regulations limit the maximum amount of ethanol that can be blended into gasoline, and commercial gasoline blenders do not always decide to blend the highest levels of ethanol allowed by law. At a blend level of 10 percent, as explained in an accompanying declaration, the blended gasoline could not begin to generate any credit for a gasoline blender against the LCFS regulation in 2011 unless it was assigned a CI value below 95.61 g/mj. *See* Declaration of James M. Lyons ¶ __.

carbon intensity value of 90.1 [g/mj.] were at least $0.01/gal higher than with a carbon intensity of 98.4 [g/mj.], during all of 2011."[8]

16. As Mr. Waugh also notes, a number of Midwest corn ethanol producers were able to obtain adjustments in the CI levels assigned to their ethanol, after the LCFS regulation was first approved. (*See* Waugh Decl. ¶¶ 52-59.) Thus, some plants whose ethanol would have been assigned the 98.4 g/mj. carbon intensity level under the original, 2009 version of the LCFS regulation have been able to obtain lower pathways. As explained in an accompanying Declaration, those plants obtained their specific lower carbon intensity pathways by documenting the production technologies, processes, methods, and energy inputs that were already in place and which they would have used in the absence of the LCFS regulation, which the CARB staff then decided would warrant a lower-CI pathway.[9]

17. Neither Mr. Waugh nor any of Defendants' other declarants addresses the fact that, while some Midwest producers were able to provide documentation to

[8] Declaration of Michael Waugh in Support of Defendants and Defendant-Intervenors' Motion to Stay Preliminary Injunction and Judgments Pending Appeal (Dkt Entry 21-7) ("Waugh Decl.") ¶ 46. Mr. Waugh calls the higher price for lower-CI ethanol a "price premium." *Id*. at 12:19. That higher price for some lower-CI ethanol is not the same as the "California premium" that obtained before the adoption of the LCFS regulation and that is described in Part I of my Declaration.

[9] *See* Declaration of Erin Heupel ¶¶ 5-6.

CARB showing that their ethanol should not be penalized in 2011 with a CI value higher than gasoline, other Midwest plants were unable to do so. Some of the plants that could not document the production technologies, processes, methods, and energy inputs that the CARB staff would reward with lower CI values had previously sold a substantial volume of ethanol in California. The LCFS regulation forced some of those plants entirely out of the California market in 2011. Several of those plants have come forward in this proceeding, and have provided Plaintiffs with declarations that explain the impact of the LCFS regulation on their business.[10] LCFS 46-172

18. The effect of the LCFS regulation has been to "de-commoditize" the corn ethanol market, for purposes of California -- *i.e.*, ethanol is no longer a fully fungible commodity in California, in which producers can prevail by offering the best commercial terms. Plants that were optimized for shipment of ethanol to California when they were built, but that can no longer sell their ethanol in California, now must find buyers outside California. On an industry-wide basis, the LCFS regulation has led to "fuel shuffling" that has likely increased the number of miles that Midwest corn ethanol had to travel in 2011 in order to get from the production facilities to customer destinations. LCFS 46-173

[10] *See* Declaration of Duane Kristensen (impact of LCFS regulation on Nebraska corn ethanol producer); Declaration of Russ Newman (impact on North Dakota producer); Declaration of Delton Strasser (on South Dakota producer).

19. Some of the Midwest plants that were excluded from the California market in 2011, especially those built to serve California, have been required to ship their product using multiple-stage freight movements, which increased the costs of delivery to the customers. Those plants have lost the ability to compete for the lucrative California market, and have also been required to incur higher costs to sell at lower prices elsewhere, as their logistics for delivery have become more complex. Defendants ignore those impacts on the producers who have been excluded from California. The preliminary injunction issued by the District Court is essential to efforts by those producers to try to re-enter the California market and to compete for sales.

LCFS 46-174

20. For all the disruptions in the California ethanol market created by the LCFS regulation, there has been no reduction in the overall amount of corn ethanol produced in the United States, or used as a motor fuel in this country or overseas. (As Mr. Waugh notes, U.S. ethanol producers have recently been shipping some ethanol overseas.) The overall production levels for corn ethanol last year, and for the foreseeable future, depend on macroeconomic factors (including demand for gasoline) that are independent of the LCFS regulation.

21. In conclusion, although Defendants claim that the "LCFS was expected to result in emissions reductions [in California] of almost one million metric tons (MTs) in 2012 and almost two million in 2013," and that "[t]hose

LCFS 46-175

targets would be achieved with a stay" of the preliminary injunction" (Stay Mot. at 28), those claims have no basis in fact. The same amount of corn ethanol would have been produced in the United States in 2011 in the absence of the LCFS regulation, and renewed enforcement of the LCFS regulation cannot be predicted to have any impact on national production of corn ethanol during the pendency of this litigation. The only effect of the LCFS is to cause ethanol "shuffling" by which some lower CI corn ethanol that would have been sold elsewhere is instead shipped to California while the higher CI corn ethanol that would have otherwise been sold in California is sold elsewhere.

LCFS 46-175 cont.

22. Finally, I note that Defendants' claim that any GHG emissions that occurred in 2011 "will be lost" in the absence of a stay. (*Id.*) Buyers in the California ethanol market typically purchase their requirements in multi-month, forward contracts. Even if one were to credit Defendants' claim (which is incorrect, for the reasons explained above) that the LCFS regulation affected production of ethanol in 2011 in a way that reduced GHG emissions, the preliminary injunction issued by the District Court on December 29, 2011, has had no impact on ethanol delivered in California under those contracts..

Pursuant to 28 U.S.C. § 1746, I declare under penalty of perjury that the foregoing is true and correct. Executed on March 1, 2012 at Wichita, Kansas.

46_OP_LCFS_GE Responses (Page 155 - 179)

495. Comment: **LCFS 46-164**

The comment states that corn ethanol producers in the Midwest are incentivized to maximize yield from feedstock and minimize energy usage, and therefore also reduce GHG emissions, due to economics rather than being incentivized to do so by the LCFS regulation.

Agency Response: Staff acknowledges that Midwest corn ethanol producers and for that matter all other fuel producers are economically incentivized to maximize yields from feedstock and to minimize energy usage (and the GHG emissions from energy usage). The LCFS is designed to work in tandem with those incentives to encourage these and other changes that reduce carbon intensity. Where efforts to reduce carbon intensity increase costs, either on a one-time or ongoing basis, additional economic incentives created by the LCFS are valuable. And those incentives will increase over times as the program becomes more stringent. See also response to comment **LCFS 46-36**.

496. Comment: **LCFS 46-165**

The comment states that Midwest corn ethanol plants are unable to keep up with the increases in stringency of the LCFS regulation in order to remain in business in California.

Agency Response: Please see response to **LCFS 46-27**. ARB does not favor one alternative transportation fuel provider over others. The requirements for application, reporting, and recordkeeping are the same across all alternative fuel providers. Staff would like to point out that one of the Midwest corn ethanol plants, POET – Chancellor, made changes to their production technologies and was approved by ARB for its new corn ethanol fuel pathways under Method 2B, with CI values significantly lower than that of conventional corn ethanol.

497. Comment: **LCFS 46-166**

The comment describes the various contributions to the CI factor for corn ethanol pathways.

Agency Response: Please see responses to **PR-27**, **LCFS 8-1**, **LCFS 46-11**, and **LCFS 46-216**.

498. Comment: **LCFS 46-167**

The comment describes changes to CI in order for Midwest corn ethanol pathways to comply with the standards that will be implemented by the LCFS.

Agency Response: Many of the CI values raised in the comment are no longer applicable under the proposed regulation. See response to **LCFS 46-42** and **LCFS 46-43**.

499. Comment: **LCFS 46-168**

The comment describes changes to CI in order for Midwest corn ethanol pathways to comply with the standards that will be implemented by the LCFS, and suggests that in the future it will be difficult to recover associated costs.

Agency Response: The LCFS program is designed to encourage reductions in the overall CI of transportation fuels used in California. Corn ethanol pathway applicants have technologically feasible ways to reduce their CIs. However, to the extent that CI improvements at certain corn ethanol facilities are not the most cost effective way to achieve the LCFS's CI reduction goals, other pathways will provide the desired reductions.

500. Comment: **LCFS 46-169**

The comment states that changes required for corn ethanol plants to meet the requirements under the LCFS program are not commercially practicable.

Agency Response: See response to **LCFS 46-28** and **46-168**.

501. Comment: **LCFS 46-170**

The comment alleges that the LCFS has had no effect on GHG emissions attributable to corn ethanol production, nor would it have any such effect in the near term.

Agency Response: This comment was made in early 2012 during litigation over the original LCFS regulation and is inapplicable here. To the extent this comment repeats the claim that the LCFS's incentives will have no effect on ethanol producers, that claim is addressed in responses to **LCFS 46-36** and **LCFS 46-40**.

502. Comment: **LCFS 46-171**

The comment alleges that the LCFS has had no effect on GHG emissions attributable to corn ethanol production, nor would it have any such effect in the near term.

Agency Response: This item is actually an unsigned declaration apparently prepared in early 2012 during litigation over the original LCFS regulation and is inapplicable here. Because it does not address the 2014 LCFS proposal, no response is necessary. To the extent this comment repeats the claim that the LCFS's incentives will have no effect on ethanol producers, that claim is addressed in responses to **LCFS 46-36** and **LCFS 46-40**.

503. Comment: **LCFS 46-172**

The comment asserts that Midwest ethanol producers should not be penalized in 2011 with CI values higher than gasoline.

Agency Response: This comment was made in early 2012 during litigation over the original LCFS regulation and is inapplicable here.

504. Comment: **LCFS 46-173**

The comment states that the LCFS regulation has de-commoditized the corn ethanol market in California, insofar as ethanol is no longer fully fungible. The comment goes on to speculate that fuel shuffling may have increased transportation distances for Midwest corn ethanol.

Agency Response: This item is actually an unsigned declaration apparently prepared in early 2012 during litigation over the original LCFS regulation and is inapplicable here. Because it does not address the 2014 LCFS proposal, no response is necessary. Nevertheless, we note that ARB agrees that the LCFS differentiates ethanol based on its CI. See response to **LCFS 46-40.**

505. Comment: **LCFS 46-174**

The comment claims that some Midwest ethanol plants have lost the ability to compete in for the lucrative California market and been required to ship their product using more costly methods due to the LCFS program which could exclude them from the California market.

Agency Response: This comment was made in early 2012 during litigation over the original LCFS regulation and is inapplicable here.

Further, a number of Midwest producers have continued to supply fuel to CA post LCFS and most have demonstrated improved production efficiency/CI reductions and reaped benefits from the CA market. See also responses to **LCFS 46-36** and **LCFS 46-40**. No fuel producer was guaranteed a market in California before the LCFS and that remains true with the LCFS in place.

506. Comment: **LCFS 46-175**

The comment asserts that the LCFS program has had no impact on national production of corn ethanol during the pendency of the litigation and the program's only effect was to cause ethanol shuffling.

Agency Response: This comment was made in early 2012 during litigation over the original LCFS regulation and is inapplicable here. To the extent this comment repeats the claim that the LCFS's incentives will have no effect on ethanol producers, that claim is addressed in responses to **LCFS 46-36**, **LCFS 46-40**, **LCFS 46-41**, **and LCFS 46-173**.

Re: Standardized Regulatory Impact Assessments for the Low-Carbon Fuel Standard and Alternative Diesel Fuel Rulemakings

Dear Dr. Asmundson and Messrs. Adams and Brieger:

Thank you for providing public access to the combined standardized regulatory impact assessments (the "CSRIA") for the low-carbon fuel standard ("LCFS") and alternative diesel fuel ("ADF") rulemakings. I write in order to present some specific questions based on Growth Energy's review of the CSRIA. The first set of questions are intended for the ARB Chief Counsel's Office, and the second set are intended for both the Department of Finance and the ARB Chief Counsel's Office. Let me state at the outset that Growth Energy appreciates the opportunity to participate in the SB 617 process for these two important rulemakings, and the consideration that the ARB staff has given to its submittals. Growth Energy regrets that more information about the goals and the estimated benefits or costs of the LCFS and ADF proposals was not available to stakeholders prior to the time when alternative proposals had to be submitted.

1. Evaluation of ADF Alternatives

Based on some recently-received information (*see* Attachment A), it appears that the ADF portion of the CSRIA does not present ARB's currently proposed regulatory approach to mitigate emissions increases that would be caused by the use of biodiesel fuels in order to comply with the LCFS regulation. As Mr. Adams confirms in Attachment A, ARB does not plan to require mitigation for any biodiesel blends below five percent ("B5"). This is contrary to what the CSRIA describes as ARB's proposal for the ADF regulation, which would require mitigation for some biodiesel blends at concentrations greater than one percent. (*See* CSRIA at 4.) Growth Energy appreciates Mr. Adams' prompt clarification of what the ARB staff is currently planning to consider as part of the ADF regulation.

In light of this clarification, Growth Energy would like to inquire whether the ARB staff plans to revise the portion of the CSRIA that discusses Growth Energy's proposed alternative to the ARB ADF 17-15 proposal. The CSRIA states at one point that the Growth Energy alternative "may achieve more emissions benefits" than ARB's proposal under some circumstances (CSRIA at 22), but then later states that the Growth Energy alternative "does not result in any more emissions reductions than the ADF proposal." (*Id.*) Those two statements appear to contradict one another.

ADF 17-15 cont.

The threshold question is whether the ARB staff intended to state that the Growth Energy proposal would, or would not, result in greater emissions reductions than the ARB proposal (as now clarified). The first quoted portion of the CSRIA refers to possible emissions reduction benefits under the Growth Energy proposal "if biodiesel were to be widely used as an additive under the ADF proposal." (CSRIA at 22.) Based on the ARB staff's projections (and treating biodiesel as "an additive"), biodiesel will certainly be "widely" used in many parts of the State and for many years. If the ARB staff disagrees, or if it meant something different when referring to the use of biodiesel as an "additive," please explain the reason for disagreeing, or clarify what "additive" means in this context.

ADF 17-16

The next question assumes that ARB did, in fact, intend to acknowledge that the Growth Energy proposal would be more protective -- provide more emissions reductions -- than the ARB proposal. On that premise, please advise whether ARB intends to revisit its position that the Growth Energy proposal would only provide "marginally more emissions benefits" than the ARB proposal, now that it is clear that ARB proposes not to require mitigation of any biodiesel blends below B5. In order for Growth Energy and others, including the Department of Finance, to understand the amount of incremental benefit that ARB would assign to the Growth Energy proposal, please also indicate how the staff has quantified that increment, and provide the inputs and assumptions on which that quantification is based.

ADF 17-17

2. Evaluation of LCFS Alternatives

The CSRIA appears to treat Growth Energy's proposed alternative to the LCFS proposal as not requiring complete assessment under the governing statute and regulations. Thus, referring to Growth Energy's proposed alternative ("this alternative") and to the CSRIA itself ("this document"), Appendix A of the CSRIA states as follows:

> ARB is required to analyze only those alternatives that are reasonable and that meet the goals of the program as required by statute. An initial assessment of the program indicates the goals of the LCFS proposal can be achieved by keeping the program '...separate of the AB 32 Cap-and-Trade system initially (at least first 10 years) in order to stimulate innovation and investment in low-GWI [global warming intensity] fuel (or transportation) technologies.' Due to the strong justifications that the Cap-and-Trade program alone generates neither the CI reductions nor fuel in the transportation sector, ***this alternative will not be assessed in this document.***

CSRIA at 27 (footnote omitted; emphasis added). The CSRIA concedes that Growth Energy's proposed alternative would "likely" achieve the same "estimated GHG emissions reductions" as the current regulation in the period up to 2020. (*Id.* at 26-27.)

LCFS 46-176

The deficiency in the Growth Energy proposal, according to the CSRIA, is not that it creates a GHG emissions reduction shortfall at any point prior to the end of the current regulatory horizon; instead, the problem is that the Growth Energy proposal does not rely on the same strategy of fuels diversification

LCFS 46-177

and achievement of GHG emissions reductions as proposed by ARB. As Appendix A of the CSRIA explains: LCFS 46-177 cont.

> Transportation in California was powered almost completely by petroleum fuels in 2010. ... Transitioning California to alternative, lower-carbon fuels requires a very focused and sustained regulatory program tailored to that goal. ... In the absence of such a program, post-2020 emissions reductions would have to come from a transportation sector that would, in all likelihood, have emerged from the 2010-2020 decade relatively unchanged. ***In the absence of an LCFS designed to begin the process of transitioning the California transportation sector to lower-carbon fuels starting in 2010, post-2020 reductions would be difficult and costly to achieve.*** This is why the primary goals of the LCFS are to reduce the carbon intensity of California fuels, and to diversify the fuel pool. A transportation sector that achieves these goals by 2020 will be much better positioned to achieve significant GHG emissions reductions post-2020.

CSRIA at 27 (emphasis added). In essence, the CSRIA is claiming that fuels diversification and carbon intensity requirements are necessary in order to make post-2020 greenhouse gas reductions less costly and less difficult to achieve. Growth Energy would submit, with the greatest respect, that the stated rationale for not providing a complete assessment of its alternative is itself deficient.[1] These are the salient points: LCFS 46-178

- The LCFS regulation does not require, and based on ARB publications is not expected to result in, the production or use of any type of alternative fuel that other regulations do not already either require or cause to be used in California. The federal renewable fuels program is intended to provide for the production and sale of cellulosic and "advanced" biofuels in the same time frame as the LCFS regulation. While the federal program does not require the use of electricity or hydrogen as a transportation fuel, the California motor vehicle emissions control and zero-emission vehicle programs do.[2] LCFS 46-179
- The long-run, post-2020 plans for greenhouse gas reductions developed by ARB calls for the phase-out of reliance on liquid biofuels.[3] Eventually, the State plans to eliminate gasoline, in LCFS 46-180

---

[1] Elsewhere, the CSRIA states that a goal of the LCFS regulation is to "create a durable regulatory framework that can be adopted by other jurisdictions." (CSRIA at 2.) ARB's authorizing legislation directs and permits the Board to adopt regulations to reduce greenhouse gas emissions. The statute does not permit the Board to impose costs on California consumers and businesses in order to export regulations to "other jurisdictions." Notably, the CSRIA does not try to claim that adoption of the LCFS program outside California will reduce costs. To the contrary, adoption of the LCFS program in other jurisdctions is likely to create supply shortages for the lowest-carbon-intensity alternative fuels, and could increase compliance costs for California consumers and businesses. LCFS 46-178 cont.

[2] *See* Attachment B (Growth Energy's proposed alternative to the LCFS regulation) at 8-11 (describing programs that will achieve the fuels diversification sought by ARB, in the absence of the LCFS regulation). LCFS 46-179 cont.

[3] *See* http://www.arb.ca.gov/planning/vision/vision.htm.

777 North Capitol Street, NE, Suite 805, Washington, D.C. 20002
PHONE 202.545.4000 FAX 202.545.4001

particular, from use in California cars and trucks and fully to replace gasoline with electricity. Putting to the side whether ARB's post-2020 strategy is meritorious, the CSRIA does not explain why ARB would seek to impose costs on California consumers and businesses to foster the use of fuels that (according to ARB) are destined for a diminishing, and no long-term, role in its greenhouse gas reduction strategy.

LCFS 46-180 cont.

- ARB's authorizing legislation does not itself require the use of regulations intended to reduce the carbon intensity of transportation fuels to achieve greenhouse gas reduction; it requires that enacted regulations achieve "the maximum technologically feasible and cost-effective reductions in greenhouse gas emissions."[4] If the CSRIA's premise is that regulation of the carbon-intensity of transportation fuels is necessary now in order to reduce the costs or difficulties of achieving greenhouse gas reductions after 2020, as the State transitions away from biofuels, then the CSRIA should have included (i) an identification of the desired reductions in greenhouse gas emissions in the transitional period, and (ii) a sufficient explanation of why the costs of achieving those reductions would be reduced if Californians paid now for compliance with an otherwise unnecessary regulatory program. On a net-present value basis, there is reason to doubt that reliance on the LCFS regulation up to 2020 is the most cost-effective way of reducing greenhouse gas emissions after 2020 -- particularly when ARB would still have authority under its authorizing legislation to adopt and enforce regulations requiring reductions in the carbon-intensity of transportation fuels after 2020.

LCFS 46-181

Appendix A of the CSRIA therefore uses unsupported speculation about future regulatory costs and strategies, and an unspecified target for a future regulation (a regulation to reduce greenhouse gas emissions resulting from the use of liquid biofuels after 2020), as reasons to not provide a complete assessment of the Growth Energy alternative. The question presented is whether the CSRIA is substantially compliant with the Government Code, as amended by SB 617, and with the Department of Finance's implementing regulations.

Section 11346.36 of the Government Code provides that standardized regulatory impact assessments must compare

LCFS 46-182

> [P]roposed regulatory alternatives with an established baseline so agencies can make analytical decisions for the adoption, amendment, or repeal of regulations necessary to determine that the proposed action is the most effective, or equally effective and less burdensome, alternative in carrying out the purpose for which the action is proposed, or the most cost-effective alternative to the economy and to affected private persons that would be equally effective in implementing the statutory policy or other provision of law.

Cal. Gov't Code § 11346.36(b)(2). The Department of Finance's SRIA regulations accordingly require among other things that agencies "should consider" including in their analyses the "assumptions" and "data" used in the evaluation of regulatory alternatives and use "an established baseline" in evaluating "feasible alternatives" to a regulatory proposal. 1 C.C.R. §§ 2003(e), (e)(5). In addition, another portion

[4] Cal. Health & Safety Code § 38562(a).

of those regulations requires agencies to consider "how the effects of the regulation are distributed over time," including costs and benefits. *Id.* at § 2003(e)(4). LCFS 46-182 cont.

The Department's regulations do not specifically provide that agencies may exclude some proposed alternatives from stakeholders from complete analysis. Whether or not the discussion of Growth Energy's proposed alternative to the LCFS proposal in Appendix A is considered as complete as the evaluation of the regulatory alternatives considered in the main text of the CSRIA, ARB's rejection of Growth Energy's alternative does not meet the requirements of the Government Code, as amended by SB 617. LCFS 46-183

The CSRIA concedes that Growth Energy's alternative is likely to achieve the same level of greenhouse gas emissions reductions as the ARB proposal within the time frame for specific emissions reductions (2010-2020) defined by the ARB proposal. The CSRIA does not identify a single alternative fuel that other regulations will not require to be produced and used in California. (*See* note 2 above.) The questions that ARB was therefore required to address are whether the Growth Energy alternative is (i) "equally effective and less burdensome in carrying out the purpose for which the action is proposed," and (ii) would be "the more cost-effective alternative." Cal. Gov't Code § 11346.36(b)(2). ARB's negative answer to those two questions posed in the statute depends on its unsupported notions about how the use of carbon intensity regulations now will ease and reduce the costs of greenhouse gas reductions after 2020. ARB has provided the Department with no basis on which to evaluate, much less to credit, its belief that imposition of the regulatory costs of the LCFS program now will reduce the costs of post-2020 greenhouse gas reductions. Without more, there is no basis to conclude that the ARB proposal is more cost-effective than the Growth Energy alternative. LCFS 46-184

The enactment of SB 617 requires ARB to employ a level of analytical rigor and transparency in the current rulemaking that may not have been required in 2009, when the Board embarked on the regulation of carbon intensity. Likewise, SB 617 requires the Department of Finance to ensure that agencies meet the requirements of SB 617, including what is now section 11346.36 of the Government Code. ARB may contend that the requirements of sections 2002 and 2003 in the Department's regulations are merely precatory, because, for example, section 2003 only lists what an agency "should" consider in the analytical process. That is a question for the Department to consider, as indicated below; regardless, under the text of the Government Code, either the CSRIA does not meet the requirements of the Department's regulations, or those regulations are themselves deficient. LCFS 46-185

Growth Energy therefore suggests that the Department of Finance and the ARB Chief Counsel's Office consider and respond independently to the following questions:

- Whether the requirements for regulatory analysis contained in sections 2002 and 2003 of the Department's regulations are mandatory for all major rulemakings; LCFS 46-186
- Whether the Department's regulations allow an agency to engage in two different levels of review and consideration of regulatory alternatives, in the manner apparently pursued by ARB in the LCFS and ADF rulemakings; LCFS 46-187
- Whether the Department has the authority, or the duty, to refuse to comment upon, or otherwise reject, a standardized regulatory impact analysis that does not contain the information and analysis required by sections 2002 and 2003 of its regulations; LCFS 46-188

- Whether the CSRIA's reliance on speculative and unquantified future (post-2020) estimated cost savings meets the requirements of SB 617 and the Department's regulations, particularly the portions of those regulations that require adequate definition of a baseline, comparative cost-effectiveness assessments, a discussion of "uncertainties associated with … estimates," and attention to how the effects of a regulation (both costs and benefits) may differ in their timing. *See* 1 C.C.R. § 2003(e), (e)(3), (e)(3)(D), (e)(4), (e)(5); and LCFS 46-189

- If the CSRIA meets the requirements of the Department's current regulations, whether those regulations should be amended in order to more effectively permit the evaluation of alternatives required inter alia by section 11346.36(b)(2) of the Government Code. LCFS 46-190

Thank you again for allowing Growth Energy to participate in the SB 617 process for these two regulations. I would appreciate it if you would advise me whether and how the Department and the ARB Chief Counsel's Office plan to respond to the specific questions presented in this letter. In addition, please let me know if you would like to discuss the issues raised here, including the questions that Growth Energy hopes you will consider and address.

Sincerely,

David Bearden

46_OP_LCFS_GE Responses (Page 180 - 186)

507. Comment: **ADF 17-15 through ADF 17-17**

Agency Response: These comments are responded to in the Alternative Diesel Regulation Final Statement of Reasons under Comment Letter **17_OP_ADF_GE**.

508. Comment: **LCFS 46-176**

The comment questions the CSRIA's decision regarding Growth Energy's proposed alternative to the LCFS proposal

Agency Response: See response to **LCFS 46-65**.

509. Comment: **LCFS 46-177**

The comment implies that CSRIA's conclusion that the Growth Energy proposal does not rely on the same strategy of fuels diversification is not adequate reason for not giving the proposal a complete assessment.

Agency Response: See response to **LCFS 46-65**.

510. Comment: **LCFS 46-178**

The comment states that CSRIA's stated rational for not providing a complete assessment of Growth Energy's alternative proposal is deficient.

Agency Response: See response to **LCFS 46-65**.

The SRIA analysis meets all the requirements of SB 617, and the alternative was not analyzed for the reasons listed in response to **LCFS 46-65**. The fuels diversification and carbon intensity requirements are necessary not solely to achieve post-2020 greenhouse gas reductions in a less costly and less difficult manner, but more importantly to achieve California's goals as described in AB 32 and Executive Orders, among other sources. See also response to **LCFS B12-5**.

511. Comment: **LCFS 46-179**

The comment states that the LCFS regulation does not require any type of alternative fuel that other regulations do not already require to be used in California.

Agency Response: The LCFS regulation will require a reduction of the CI of transportation fuels in California and is expected to have positive impacts on GHG emissions and fuel diversity. It works in conjunction with a number of other state and local programs, including the federal RFS program, and ARB's zero-emission vehicle program, as cited in the comment, as well as ARB's Cap-and-Trade Program. See response to **LCFS 46-195**.

512. Comment: **LCFS 46-180**

The comment asks why ARB fosters the use of alternative liquid biofuels when the fuels will phase-out after 2020.

Agency Response: See responses to **LCFS 46-70 and LCFS 46-71**.

513. Comment: **LCFS 46-181**

The comment states that there is reason to doubt the reliance on the LCFS regulation up to 2020 is the most cost-effective way of reducing GHG emissions after 2020.

Agency Response: See response **LCFS 46-66**.

514. Comment: **LCFS 46-182**

The commenter suggests that ARB's cost analysis is incomplete until the analysis determines more precisely the costs of future post-2020 regulations that have not been designed, proposed, subject to public comment, or adopted.

Agency Response: See response to **LCFS 46-65**.

The SRIA approach is within the requirements and spirit of SB 617 and Department of Finance regulations in meeting the goals previously mentioned. The SRIA as analyzed by the Department of Finance for compliance with SB 617, specifically included publically provided alternatives and met the following requirements:

- The data and assumptions of the modeling were clearly identified;
- The baseline was described and used for all analyses (including comparison of alternatives); and
- Outlined how the effects of the regulation, including the costs and benefits are distributed over time for all feasible alternatives.

515. Comment: **LCFS 46-183**

This comment tacitly assumes that every proposed alternative must be fully analyzed, and faults ARB for not performing a more exhaustive analysis of one particular alternative that the commenter had suggested during the SRIA process.

Agency Response: DOF regulations state that agencies must include "identification of each regulatory alternative for addressing the stated need for the proposed major regulation;" alternatives that do not meet the stated need for the proposed major regulation are not required to be analyzed. 2002(c)(8). Additionally, the regulations state that agencies should analyze "feasible alternatives…" while taking into account "an evaluation of the legal and statutory constraints that limit the selection of regulatory alternatives" 2003(e)(1). Section 11342.548 (b)5A provides a description of the alternatives agencies must analyze and Section 11342.548 (b)5C states "an agency is not required to…describe unreasonable alternatives."

516. Comment: **LCFS 46-184**

The comment states that the ARB staff does not have enough evidence to conclude that the LCFS proposal is more cost-effective than the Growth Energy alternative.

Agency Response: For the reasons set out in the SRIA and ISOR, the alternative is not equally effective nor less burdensome, nor is it the most cost-effective alternative to achieve the purpose, because it does not achieve the goals as outlined by the regulation.

517. Comment: **LCFS 46-185**

The comment is in an October 2014 letter addressed to an economist at the "Department of Finance" (DOF) and to two attorneys at the "California Air Resources Board." The paragraph suggests that in the future "ARB may contend" that certain DOF regulations are precatory, in which case "the Department" should consider whether its regulations are deficient.

Agency Response: Having set the stage for a hypothetical future dispute between two state agencies, the commenter "suggests" that DOF and ARB independently consider specific questions and render some type of advisory rulings to the commenter in October 2014. Because the letter was written in October 2014, and because this passage makes no objection or recommendation regarding the specific proposal, no response is necessary. ARB also declines to issue the type of advisory ruling requested. See also response to **LCFS 46-220**.

518. Comment: **LCFS 46-186**

The commenter asks if section 2002 and 2003 are mandatory for all major rulemakings.

Agency Response: **LCFS 46-186** to LCFS **46-190** are not objections or recommendations to the regulatory proposal. Instead, the pre-rulemaking letter "suggests that the Department of Finance and ARB Chief Counsel's Office consider and respond" to five separate legal questions. Many of these questions appear to be targeted at Department of Finance, and, in any event, ARB declines to offer the legal advice or opinions sought by the commenter. See responses to **LCFS 46-75** through **LCFS 46-77** above.

519. Comment: **LCFS 46-187**

The commenter asks if departments can engage in two levels of review for consideration of alternatives.

Agency Response: See response to **LCFS 46-186**.

520. Comment: **LCFS 46-188**

The commenter asks if the Department of Finance has the authority to reject a SRIA.

Agency Response: See response to **LCFS 46-186**.

521. Comment: **LCFS 46-189**

The commenter asks if the requirements of the SRIA process allow for estimation of future costs and benefits.

Agency Response: See response to **LCFS 46-186**.

522. Comment: **LCFS 46-190**

The commenter asks that if the LCFS SRIA meets the requirements of the Department of Finance, should the Department then amend its requirements to satisfy the commenter's agenda?

Agency Response: See response to **LCFS 46-186**.

Subject: RE: LCFS and ADF rulemakings -- SRIAs

Stuart,

The differences you point to between the biodiesel mitigation described in the SRIA and that presented at the Oct. 20 workshop reflects the progression in staff's analysis of the biodiesel NOx issue and mitigation for NOx emissions from biodiesel. You're correct that the SRIA describes a plan to require mitigation for blends from B1 and higher, while the proposal discussed at the workshop would require mitigation beginning at blends of B5 and higher. The reasons behind these changes were described at the workshop, and also on page 2 of the discussion paper that you cite.

Time constraints prevented staff from revising the SRIA to reflect staff's more recent approach. Although the SRIA was submitted to the Department of Finance on the same day that workshop materials were made available, the modeling and analysis work to prepare the SRIA was a weeks-long process. The SRIA as submitted discloses potential economic impacts from the ADF, and the economic impacts from staff's revised approach will likely be lower than stated in the SRIA. I'd also note that the issues of biodiesel NOx emissions and mitigation are still the subject of internal discussion and analysis, and consequently these provisions are subject to further changes prior to filing of the proposed regulation with the Office of Administrative Law.

The economic impact analysis for the ADF will be updated as we move forward. Regulatory concepts and proposals are often revised during their development and public review, especially at this preliminary stage. Given that, changes such as the one involving staff's evaluation of biodiesel emissions are to be expected.

Sincerely,

Steve

Subject: LCFS and ADF rulemakings -- SRIAs

Steve --

The Department of Finance yesterday provided Growth Energy and other members of the public with access to the October 17, 2014 SRIA that covers the ADF rulemaking. Thank you for helping to make that happen. I'd like to request your Office's further assistance with what appears to be a substantial problem in one portion of the SRIA. That is the portion of the SRIA that describes the staff's proposed mitigation strategy to the Department of Finance and others.

Page four of the SRIA describes the mitigation strategy for the staff's ADF proposal in relevant part as follows (emphasis added):

> "The multimedia evaluation process for biodiesels made from various feedstocks identified a NO_X significance threshold, or blend level, that will result in no significant adverse impacts. The ADF proposal seeks to mitigate NO_X impacts from biodiesel by setting a significance threshold and requiring mitigation of all non-animal biodiesel use at blends above one percent, and all animal biodiesel used at blends above five percent. *The ADF proposal identified one percent for non-animal biodiesel, rather than zero percent, because biodiesel may be used as an essential lubricity additive at one percent or less*."

I am not aware that anyone has called for mitigation when there is zero percent biodiesel in the blend. Growth Energy has proposed mitigation below the five percent level (or "B5") if the blend level was one percent or greater, as the SRIA elsewhere notes. (*See* SRIA at 22.) In any event, a fair reading of the SRIA is that the ARB decided, as of October 17, to require mitigation of all non-animal biodiesel use at blends above one percent.

LCFS 46-191

I believe there may be some material confusion about the ARB staff's position. The confusion arises because the staff appears to be saying different things in its filings with the Department of Finance and in some of its public statements. Appendix A of the ADF regulatory "discussion paper" released by the ARB staff on the same day as the SRIA (October 17) describes the staff's ADF proposal as follows:

> " Recognize biodiesel made from soy feedstocks as low saturation (i.e., B100 with cetane <56) and biodiesel made from animal feedstocks as high saturation (i.e., B100 with cetane ≥56).
>
> " Establish significance thresholds of B5 for low saturation biodiesel, and B10 for high saturation biodiesel to ensure NOx impacts associated with biodiesel use do not increase and steadily decrease. Allow 'Safe Harbor' blending below the significance threshold without the need for additional NOx mitigation."

See http://www.arb.ca.gov/fuels/diesel/altdiesel/20141017_ADF_discussion_paper.pdf. That proposal (mitigation of non-animal based, aka "low saturation" biodiesel, at B5 and higher) was discussed at the ARB staff's workshop on October 20. So, in a nutshell, the SRIA indicates that mitigation will be required for non-animal biodiesel with blend levels above one percent; by contrast, the "discussion paper" and the staff's presentation to the public at its October 20 2014 workshop, indicated that mitigation would only be required for animal-based blends at or above five percent.

LCFS 46-192

If the blend level at which the staff proposal would require mitigation is material enough to have been presented in the SRIA, then this apparent inconsistency in the relevant blend level for mitigation is also material. The SRIA advises the Department of 2inance that the staff's proposal "will result in no significant adverse impacts on public health or the environment." (SRIA at 3.) The Department might reasonably believe that the SRIA's claim in that regard was based on mitigation for animal-based biodiesel blends between one and five percent, based on the portion of the SRIA appearing on page 4 that is quoted above. The likelihood that the Department will be misled -- I assume inadvertently -- about this basic element in the staff's AD2 proposal is sufficient in itself to require correction. In addition, the inconsistency is also relevant to the reasonableness of the staff's claim in the SRIA that the Growth Energy alternative proposal "does not result in any more emissions reductions than the AD2 proposal." (SRIA at 22.) Presumably, in evaluating that claim, the Department would want to know that the staff's proposal does not require mitigation for non-animal based biodiesel at the same level as does the Growth Energy proposal.

LCFS 46-193

If I am missing something that explains why the description of the staff's AD2 proposal in the SRIA does *not* differ materially from the description in the materials that the staff has released to the public on October 17, please let me know. If the staff's proposal really is to require mitigation for non-animal blends higher than one percent (even if less than five percent), please let me know. Otherwise, Growth Energy would like to know how the staff plans to correct the SRIA, so that the Department and others will have an accurate understanding of the staff's proposal. LCFS 46-194

On the assumption that the Department has to provide its evaluation of the SRIA very soon, Growth Energy requests a response to this inquiry by the close of business on Wednesday, October 29.

Please let me know if you would like to discuss these questions, or if you don't believe that the staff will be able to respond by the close of business on October 29. Thanks, Stuart

46_OP_LCFS_GE Responses (Page 187 - 190)

523. Comment: **LCFS 46-191**

The commenter attaches an email dated October 28, 2014, two months before ARB released the proposed LCFS regulation.

Agency Response: Staff responds to the extent the email makes objections or recommendations that nevertheless pertain to the proposal. The email pointed out what it believed were different statements made by ARB staff.

The commenter suggests that because the ADF proposal changed after ARB's solicitation for alternatives, ARB did not substantially comply with SB 617. ARB fully complied with SB 617.

The ADF proposal as outlined in the SRIA, was not materially different from the final regulation as considered by ARB; SB 617 does not require a new analysis after stakeholder input is considered. After submittal of the SRIA to DOF, ARB staff continued to solicit for and incorporate feedback from stakeholders. As expressly mentioned in the SRIA submitted to DOF, "the final…regulation…to be proposed to the Air Resources Board for consideration of adoption in 2015, will be informed by continued interactions with stakeholders, external researchers, and other regulatory agencies."

Additionally, the timeline as outlined in SB 617 leaves room for additional input and should not be interpreted to indicate that a new analysis be made each time changes are proposed. There is no indication that when enacting SB 617 the legislature intended to preclude public input and the agency from making changes as required under the APA during the subsequent rulemaking process. Clearly the Legislature *added* to the rulemaking process. Preexisting APA requirements were left intact. Finally, the comments received by DOF did not indicate that there were any missing components required by SB 617.

ARB staff notes that over a period of several years there were 21 LCFS public workshops, and 26 ADF public workgroup or workshop meetings as part of developing these two related regulations. All of this work informs an evolving proposal that the public processes are intended to improve. At no point prior to the Board's final adoption of a regulation is any proposal carved in stone. At the time ARB solicited alternative proposals pursuant to SB 617, ARB staff shared its then-current thinking on the form of the proposal which had yet to be formally proposed – and by law could not yet be formally proposed under the terms of SB 617. That solicitation fulfilled the purpose of SB 617, and the input from that solicitation as well as information gathered through other normal rulemaking processes, continued to shape the proposal.

524. Comment: **LCFS 46-192**

The commenter expresses confusion over the SRIA documents and ARB's public process documents.

Agency Response: See response to **LCFS 46-191**.

525. Comment: **LCFS 46-193**

The commenter believes that ARB should resubmit the SRIA to match the current proposal.

Agency Response: See response to **LCFS 46-191**.

526. Comment: **LCFS 46-194**

The commenter asks whether the proposal will require mitigation at different levels than its alternative and when ARB plans to resubmit its SRIA to the Department of Finance.

Agency Response: See response to **LCFS 46-191**.

STATE OF CALIFORNIA

AIR RESOURCES BOARD

Response to Request for Public Input On Alternatives to the Low- Carbon Fuel Standard Regulation

Growth Energy

June 23, 2014

Executive Summary

The staff of the California Air Resources Board ("CARB") has identified the Low-Carbon Fuel Standard ("LCFS") as a "major regulation" that requires enhanced review for compliance with SB 617 (Calderon and Pavley), a 2011 amendment to the California Administrative Procedure Act (the "APA"). The California Department of Finance ("the Department") has published regulations that implement SB 617. Those regulations require rulemaking agencies like CARB to seek early public input on possible alternatives to the rules being developed by the rulemaking agencies.

Growth Energy, an association of the Nation's leading ethanol producers and other companies that serve America's need for renewable fuels, is submitting to the CARB staff a proposed alternative to the LCFS regulation that would allow the State to eliminate the LCFS program without loss of environmental benefits. Growth Energy's proposal recognizes important changes in the regulatory baseline for the control of greenhouse gas ("GHG") emissions that have occurred since 2009. In particular, the federal renewable fuels standard ("RFS") program, combined with the California cap-and-trade program and a number of California-specific vehicle- and engine-based regulations, now assure that California will receive most if not all of the direct GHG emissions reductions that can be attributed to the LCFS regulation. To the extent that CARB believes that there is still an emissions shortfall from elimination of the LCFS or that it has authority to address lifecycle GHG emissions occurring outside of California under state and federal law (which are issues not addressed in this submittal), Growth Energy proposes that CARB address those remaining issues by modifying the California GHG cap-and-trade regulations, which are now in effect in California and which apply to transportation fuels providers beginning in 2015. LCFS 46-195

Growth Energy's description of its proposed alternative to the LCFS regulation is as detailed as possible, given currently available information. In this submittal, Growth Energy urges the CARB staff to provide the additional information needed to provide further analysis of alternatives to the LCFS regulation.

Table of Contents

Growth Energy's Response to Request for Public Input
On Alternatives to the Low-Carbon Fuel Standard Regulation

Growth Energy respectfully submits this response to the request by the staff of the California Air Resources Board ("CARB") for public input on alternatives to the low-carbon fuel standard ("LCFS") regulation. The CARB staff presented its request for public comment in a notice dated May 23, 2014, and has established today as the deadline for that input.

The CARB staff is seeking public input in connection with its proposal that CARB revise and readopt the LCFS regulation at a public hearing later this year. The purpose of the LCFS regulation, which the Board first adopted in 2009, is to achieve reductions in greenhouse gas ("GHG") emissions from the California transportation sector pursuant to the Global Warming Solutions Act of 2006, commonly called AB 32. Other regulations adopted since 2008 under AB 32 to achieve the same objectives as the LCFS regulation include the "cap and trade" regulation (17 C.C.R. §§ 95801-96022), the GHG emissions standards contained in the Advanced Clean Cars (or "ACC") program (13 C.C.R. §§ 1960.1-1962.2), and a set of regulations to control GHG emissions from heavy-duty vehicles and engines.[1] LCFS 46-196

Overview

Growth Energy has organized its analysis of alternatives to the LCFS regulation in this submission into four parts.

Part I of this submission briefly outlines the statutory and regulatory framework for the CARB staff's request for input on alternatives to the LCFS regulation. As explained in Part I, regulations adopted by the California Department of Finance pursuant to a recent amendment to the APA require CARB to seek and permit effective early public input on rulemaking concerning

[1] These include California's Heavy-Duty GHG regulations now completing the rulemaking process, a second phase of regulations that are under development, and the so-called "Tractor-Trailer" GHG regulation adopted in 2008. *See* http://www.arb.ca.gov/regact/2013/hdghg2013; http://www.arb.ca.gov/cc/hdghg/hdghg.htm.

"major" regulations, including the LCFS. That amendment was contained in SB 617 (Calderon and Pavley). The LCFS rulemaking, and this stage of the LCFS rulemaking, are particularly important, because this rulemaking is one of the first CARB rulemakings governed by SB 617. *See* pp. 4-7 below.

Part II of Growth Energy's submittal addresses some of the important factors that affect a regulatory alternatives analysis undertaken under SB 617. Since 2009, there have been significant changes in the "baseline" conditions for GHG regulation relevant to the LCFS program. As explained in Part II, most of the GHG emissions reductions sought by CARB when it adopted the LCFS regulation in 2009 will be provided by a combination of the federal renewable fuels standard ("RFS") program, along with California's cap-and-trade regulation, ACC program, and regulations limiting GHG emissions from heavy-duty vehicles and engines. Given that most, if not all, of the GHG emissions reductions sought by CARB in 2009 through the LCFS regulation are now assured by those other programs, the LCFS regulation has been rendered largely superfluous from an environmental perspective, even though it imposes huge financial burdens on the regulated community and requires a large commitment of resources by CARB. As a threshold matter, CARB should therefore carefully and fully consider whether, based on regulatory and program developments related to GHG emission control since 2009, there is any continuing need for the LCFS regulation. *See* pp. 8-14 below. LCFS 46-196 cont.

Part III of this submittal explains that, to the extent that the CARB staff finds any continuing need for the LCFS regulation to control GHG emissions, that need could be met instead through a simple modification of the cap-and-trade regulation. Taking that step -- modifying the cap-and-trade regulation -- would fully eliminate any conceivable remaining need for the LCFS regulation, while doing nothing to alter CARB's overall regulatory strategy to LCFS 46-197 address GHG emissions from the California transportation sector. The GHG emissions reductions benefits of the LCFS program would be fully realized from the suite of other GHG regulations adopted federally and in California since 2009, and by the modification of the cap-and-trade program. The direct regulatory costs of the LCFS program are borne primarily by the California motor vehicle fuels marketing industry, which can to some extent pass those costs to its retail customers. Insofar as the LCFS program imposes costs on California businesses and consumers, the alternative presented here (relying on the cap-and-trade program) would not materially alter the allocation of costs and would at the same time reduce regulatory costs by eliminating an entire regulatory program (the LCFS regulation). Judging from the strong concern about the LCFS regulation expressed by oil industry stakeholders, the regulatory relief and reform proposed here warrants full consideration and further development. *See* pp. 14-20 below.

LCFS 46-197 cont.

Part IV of Growth Energy's submittal recommends specific next steps that CARB should consider, including full involvement by the Chief Counsel's Office to ensure compliance with the APA. As will be apparent throughout this submittal, Growth Energy's analysis of regulatory alternatives can be no more detailed than the publicly available information about (i) the new version of the LCFS regulation that the CARB staff is considering for proposal to the Board, and (ii) the information that the CARB staff has provided about the benefits that it is attributing to the LCFS program. Contrary to the position taken in communications to Growth Energy by CARB's Transportation Fuels Section on this subject, very little information on the new version of the LCFS regulation or its estimated benefits -- which are critical to an effective SB 617 process -- has been provided to the public to date. In order to achieve substantial compliance with the APA, the CARB staff needs to provide the public with a full picture of its proposed new

LCFS 46-198

LCFS regulation, and in particular describe any new features of the regulation intended to reduce compliance costs. The CARB staff also needs to completely identify for the public all benefits that it is attributing to the LCFS regulation that would bear on an SB 617 alternatives analysis. Then, after the public has had sufficient time to analyze the relevant information from CARB, the public should be permitted to provide updated regulatory alternative analyses, which the CARB staff should fully consider and address in the Standardized Regulatory Impact Assessment required by 1 C.C.R. § 2002. That approach would ensure compliance with the APA, without conflicting or otherwise undermining any other mandates or obligations applicable to the LCFS regulation. *See* pp. 20-24 below.

LCFS 46-198
cont.

I. The Statutory Framework for the Regulatory Alternatives Analysis under SB 617

The CARB staff is seeking submittals from the public on regulatory alternatives to the LCFS regulation because it has a legal obligation to do so. For many years, section 11346.3 of the APA has provided in part as follows:

> (a) State agencies proposing to adopt, amend, or repeal any administrative regulation shall assess the potential for adverse economic impact on California business enterprises and individuals, avoiding the imposition of unnecessary or unreasonable regulations or reporting, recordkeeping, or compliance requirements. …
>
> (2) The state agency, prior to submitting a proposal to adopt, amend, or repeal a regulation to the office, shall consider the proposal's impact on business, with consideration of industries affected including the ability of California businesses to compete with businesses in other states. For purposes of evaluating the impact on the ability of California businesses to compete with businesses in other states, an agency shall consider, but not be limited to, information supplied by interested parties.

Cal. Gov't Code § 11346.3(a)(2). Based on evidence that rulemaking agencies did not adequately consider the burdens that regulations impose on the public, in SB 617 the Legislature added a requirement that rulemaking agencies prepare a detailed assessment of the costs and benefits of any proposed major regulation, for review by the California Department of Finance ("the Department") ***before*** initiating the traditional informal rulemaking process. *See id.* § 11346.3(c). Those detailed assessments are called Standardized Regulatory Impact Assessments (or "SRIAs."). *See id.* § 11346.36. The Legislature also made it clear in SB 617 that the obligation to consider and use early public input on regulatory impacts could not be met by merely going through the formalities of seeking public input.[2]

The Department completed work on regulations to implement SB 617 in the fall of 2013. The Department's regulations require, among other steps, the following:

> The [rulemaking] agency shall also seek public input regarding alternatives from those who would be subject to or affected by the regulations ... prior to filing a notice of proposed action with OAL unless the agency is required to implement federal law and regulations which the agency has little or no discretion to vary. An agency shall document and include in the SRIA the methods by which it sought public input.

1 C.C.R. § 2001(d). As the rulemaking file for the Department's regulations implementing SB 617 shows, many state regulatory agencies, CARB not excepted, recognized that SB 617 (as implemented by the Department) would mean the end of "business as usual" in the California rulemaking process.[3]

In responding to objections from rulemaking agencies concerning the obligations created by its SB 617 regulations, the Department explained that "[i]nvolving the Department and affected parties early in the [rulemaking] process could result in the discovery of additional and

---

[2] Thus, SB 617 deleted text from section 11346.3(a)(2) of the APA that, up to 2011, had provided that the APA's public-input requirements were not "inten[ded]" to "impose additional criteria on agencies" engaged in rulemaking. *See* Stats. 2011, c.496 (SB 617), subd. (a); Cal. Office of Admin. Law, *California Rulemaking Law under the Administrative Procedure Act* (2012) 57 (legislative history of section 11346.3).

[3] Several rulemaking agencies filed sharp objections to the Department's proposed regulations to implement SB 617 on the ground that the regulations would require major changes in the timing used by the agencies to develop regulations and to obtain public input. *See, e.g.,* Dep't of Finance, *Regulations to Implement SB 617 Re Major Regulations, Responses to 45-day Comment Period (Chart A)* (hereinafter "Chart A"), available at http://www.dof.ca.gov/research/economic_research_unit/SB617_regulation/documents/Response%20to%20Comments%20Chart A.pdf. The Department dealt fully with all those objections and made no material changes in its proposed regulations to implement SB 617.

perhaps more cost-effective alternatives to [a] proposed major regulation, consistent with the intent of SB 617."[4] Similarly, when rulemaking agencies (including CARB) objected to the burdens of preparing the early regulatory analyses of costs and benefits needed for an effective SB 617 process, the Department correctly concluded that the amended APA "clearly contemplates that an agency will have considered [regulatory] alternatives prior to filing a notice of a proposed action" with the Office of Administrative Law and publication of the regulatory notice for further public comment.[5] The Department also made it clear that under the SB 617 process, the "no action" alternative to regulation -- which is an outcome seldom if ever seen in a major California rulemaking -- had to receive full and fair consideration at the beginning of the rulemaking process.[6]

In requiring significant change in the California rulemaking process, the statute and the implementing regulations are salutary. The LCFS regulation in 2009 was typical of major rulemakings affecting the motor vehicle fuels industries in California. Beginning in 2008, CARB had convened a series of public consultation meetings prior to its formal proposal for rulemaking in March 2009. Not until publication of the Initial Statement of Reasons for the LCFS regulation, however, was the public given any opportunity to review the economic analysis of costs and benefits for the proposed regulation; the written comments on economic issues were due a scant 45 days later (in April 2009), and at the Board's April 2009 public hearing, most private-sector speakers were limited to five minutes to make a presentation to

---

4 *See* Chart A at 24.

5 *Id.* at 27.

6 *Id.* at 47-48.

CARB. The public cannot have a significant role in serious economic analysis of a major regulation within such a constrained process.

Unsurprisingly, major economic assumptions and issues were not fully addressed within the time frame for written comments in March to April 2009, nor at the Board hearing. Among the assumptions and factors that could not as a practical matter be "pressure-tested" in the public comment process was the CARB staff's belief that advanced ethanol production methods would eventually drive down gasoline costs at the retail level and make the LCFS program cost-neutral for California consumers or even generate savings of up to $11 billion.[7] That assumption was unsound in 2009, and has since been disproven by experience.[8] Likewise, in the 2009 rulemaking, the CARB staff gave little attention to the ability of the federal RFS program to accomplish the same goals and purposes of the LCFS regulation, and offered largely opaque comparisons between the GHG reductions that the two programs could achieve. Now in its fifth year of implementation, the LCFS regulation has made little or no impact on the supply of lower-GHG fuels in California.[9] SB 617 and the Department's implementing regulations require the Board to improve the quality and depth of the economic analysis for major regulations like the LCFS program.

LCFS 46-199

---

[7] Air Resources Board, *Proposed Regulation to Implement the Low Carbon Fuel Standard -- Staff Report: Initial Statement of Reasons* (hereinafter "ISOR") at ES-26.

[8] As the ISOR itself noted, "Economic factors, such as tight supplies of lower-carbon-intensity fuels ... could result in overall net costs, not savings, for the LCFS." The fact that the cost savings forecast in 2009 proved ephemeral is implicit in the CARB staff's decision, less than two years after the regulation went into effect, to develop "cost reduction" features for the LCFS regulation, which would assist "regulated parties ... unable to meet their compliance obligations ... due to limited supplies of low carbon fuels or LCFS credits in the market." Air Resources Board, *Low Carbon Fuel Standard 2011 Program Review Report* (Dec. 8, 2011) (hereinafter "2011 Program Review") 16.

[9] There have been substantial increases in the efficiency of Midwest corn ethanol production facilities since CARB first embarked on the LCFS rulemaking, and those increases have reduced the lifecycle GHG emissions of those facilities under some analyses; but those reductions in GHG emissions have been caused by market forces (the need to reduce energy consumption in order to remain competitive), not by virtue of the LCFS regulation. *See* note 25 below.

II. Factors Affecting the Regulatory Alternatives Analysis

According to the CARB staff, the goal of the LCFS regulation in 2009 was, and still remains, to "reduce the carbon intensity of transportation fuels used in California by at least 10 percent by 2020 from a 2010 baseline," and also to "support the development of a diversity of cleaner fuels with other attendant co-benefits."[10] Growth Energy sought clarification of the staff's description of the goals of the regulation for purposes of its input in the SB 617 process.[11] Lacking greater specificity or clarification, Growth Energy can only turn to the 2009 rulemaking, in which CARB quantified the "10 percent" target as being a reduction of 16 million metric tons of carbon dioxide equivalent ("MMTCO2eq") GHG emissions associated with combustion of transportation fuels in California, along with a 7 MMTCO2eq reduction in "upstream" emissions, yielding a total 23 MMTCO2eq reduction in worldwide annual GHG emissions in 2020.[12] As explained below, achieving the direct GHG emissions reduction attributed to the LCFS regulation in 2009 -- the 16 MMTCO2eq -- no longer requires the existence of the LCFS regulation. LCFS 46-200

A. Changes in the Regulatory Baseline Since 2009

The most significant development in the regulatory baseline since 2009 has been the adoption and full implementation of the federal renewable fuels standard program under the Energy Independence and Security Act of 2007, pursuant to a Final Rule adopted by the U.S. LCFS 46-201

---

10 The staff identified that goal on June 5, 2014, well after the period for preparation of SB 617 public input had begun, in response to a specific request from Growth Energy. *See* Letter from D. Bearden to K. King, May 30, 2014 (included here as Attachment 1) *and* Letter from M. Waugh to D. Bearden, June 5, 2014 (included here as Attachment 2).

11 *See* Letter from D. Bearden to M. Waugh, June 11, 2014 (included here as Attachment 3). To date, no response to Mr. Bearden's letter of June 11, 2014, has been received.

12 *See* ISOR at VII-1. According to the 2009 ISOR, "These reductions account for a 10 percent reduction of the GHG emissions from the use of transportation fuel." *Id.* That 10 percent target, which the CARB staff also sometimes cites, originates in Executive Order S-01-07 of January 18, 2007. *See* Executive Order S-01-07, § 1, available at http://www.arb.ca.gov/fuels/lcfs/eos0107.pdf.

Environmental Protection Agency in 2010.[13] The federal RFS program assures an adequate supply of low-cost renewable fuel for California, *i.e.*, ethanol produced from corn starch at biorefineries located mainly in the Midwest.[14] Because ethanol produced by any method from any renewable feedstock has the same physical and chemical properties when used in motor fuel, gasoline blended with 10 percent ethanol will achieve the same reduction in exhaust or "tailpipe" GHG emissions regardless of the production process or renewable feedstock used to create the ethanol. Consequently, the portion of the 16 MMTCO2eq reduction in GHG emissions from the California transportation fleet operated on gasoline can and will be obtained by virtue of the federal RFS program.[15] Oil companies will continue to buy and blend ethanol into gasoline sold in California under the federal program even if there were no LCFS program, in order to comply with the federal RFS program. The portion of the California fleet operated on diesel fuel can also achieve its part of the 16 MMTCO2eq reduction in GHG emissions by virtue of the federal RFS

LCFS 46-201 cont.

---

[13] *See* U.S. EPA, *Regulation of Fuels and Fuel Additives: Changes to Renewable Fuel Standard Program; Final Rule*, 75 Fed. Reg. 14,669 (Mar. 26, 2010) .

[14] The RFS program, which in its early stages was effectively non-binding on ethanol usage, has begun to cause substantial increases in biofuel production. Total production of biofuels has increased steadily over the last year and a half, reaching approximately 16 billion gallons in the 12 months through April 2014. *See* http://www.epa.gov/otaq/fuels/rfsdata/.

[15] The term "fleet," as used here, includes off-road vehicles and engines in other equipment.

When the CARB staff considered the matter in 2009, it made a number of assumptions about the efficacy of the federal RFS program that need to be reconsidered. The most significant assumption, which was empirically unsupported, was that the federal program (which at the time was still under development) would provide only 30 to 40 percent of the GHG reductions that the staff predicted for the LCFS program. That assumption appears to have been based on a belief that without the LCFS regulation, only 11.3 percent of the advanced or cellulosic biofuels required nationwide by the RFS program would be consumed in California, while a substantially higher amount of those fuels would be drawn from the nationwide fuel pool to California as the result of the LCFS regulation. The advanced biofuels required by the RFS regulation that would be drawn to California by the LCFS program would have been used elsewhere in the absence of the LCFS program, leading to the same reductions in GHG emissions. To the extent that the cellulosic ethanol industry has experienced limits on achieving full commercial launch, those are national and even global economic and technical factors that the existence of the LCFS regulation has not to date, and will not in the future, be able to change or influence.

program, because the federal program results in blending biodiesel and renewable diesel into diesel fuel produced from petroleum.[16]

LCFS 46-201 cont.

As for the portion of the California fleet powered in whole or in part with electricity or hydrogen, there is similarly no continuing need for the LCFS program, owing to other changes in the regulatory baseline since 2009. The Advanced Clean Cars program now assures that electricity and hydrogen will be full participants in the California transportation fuel pool. In 2009, CARB's baseline for the alternatives analysis of the LCFS regulation included the then-current version of the Board's regulations to control GHG emissions from new motor vehicles that had been adopted in 2004, and that set GHG emission standards for 2009 to 2016 model-year new vehicles, sometimes called the "Pavley standards." In addition, the baseline also included the then-current provisions of the agency's Zero Emission Vehicle ("ZEV") standards which require manufacturers offer electric and/or hydrogen fuel cell vehicles for sale in California. CARB has now adopted new-vehicle GHG standards applicable to 2017 to 2025 model-year new vehicles and has made significant revisions to the ZEV standards as part of the ACC rulemaking in 2012.[17]

LCFS 46-202

[16] One reason why California is assured of receiving an adequate supply of ethanol is that ethanol for use in gasoline commands a higher price -- the so-called "California premium" -- in California than in other parts of the United States, as can be readily seen from data available under contract or license from the Oil Price Information Service ("OPIS"). While there are many reasons why the "California premium" exists, one major reason is that refineries producing finished gasoline products for the California retail market tend to have higher production costs than other refineries.

LCFS 46-201 cont.

[17] In its 2009 LCFS alternatives analysis, the CARB staff assumed that manufactures would sell more electric vehicles than required by the ZEV standards, as they existed in 2009. Vehicle manufacturer compliance with the ZEV, new vehicle GHG, and criteria emission standards is determined on a "fleet-average" basis. What this means is that to the extent that manufacturers sell more ZEVs than required, they can in turn sell greater numbers of less fuel efficient or higher emitting vehicles provided that they remain in compliance on average. In addition, manufacturers that over comply can sell "credits" to manufacturers that would not otherwise be in compliance. Therefore, even if the LCFS regulation might lead to greater demand and use of electric vehicles, there would be no net reduction in GHG emissions.

LCFS 46-202 cont.

CARB has also taken and is taking a number of actions to reduce GHG emissions associated with the use of diesel fuel in heavy-duty vehicles which also need to be taken into account in the baseline for the 2014 LCFS analysis. The relevant measures include California's Tractor-Trailer regulation adopted in 2008 which requires use of aerodynamic improvement devices and low-rolling resistance tires, as well as the Phase I and the soon-to-be proposed Phase II heavy-duty GHG regulations that impose specific GHG emission requirements on new heavy-duty vehicles beginning with the 2014 model-year.[18] LCFS 46-203

B. Necessary Information for Development of a Detailed Alternative Program

In addition to properly defining the baseline for the alternatives analysis, it is important to have a clear and complete picture of the revised LCFS program that the CARB staff plans to propose. In addition to full information concerning the estimated benefits of the LCFS program (both in terms of GHG reductions and in any other relevant aspect), the currently unknown elements of that program include the following:

- Updated carbon intensity values for transportation fuels that will be included in the proposed 2014 LCFS regulation. LCFS 46-204
- The detailed form of any proposed "cost-containment" provisions which could allow parties subject to the LCFS regulation to comply with the program's standards, without actually achieving the CI reductions required under the regulation.
- CARB staff's current analysis of the manner in which regulated parties will most likely attempt to comply with the proposed 2014 LCFS.

[18] In addition to ensuring that the GHG emissions reductions associated with those regulations are properly accounted for in the baseline for the 2014 LCFS, CARB staff must also ensure that they properly account for the fact that compliance with the latter regulations is determined on a manufacturer fleet average basis in order to avoid improper assignment of GHG reductions to the 2014 LCFS regulation.

- A full description of any other intended goals of the LCFS regulation, such as stimulating "fundamental" changes in the "transportation fuel pool," along with the metrics to be used to measure progress and success in meeting those other goals.[19] LCFS 46-204 cont.

Contrary to the position taken in the CARB staff's recent correspondence with Growth Energy and in related postings on the CARB website, none of those elements have been disclosed to the public at present. In addition to providing that undisclosed information concerning its analysis, the CARB staff should address the following other pertinent questions, which follow from the foregoing review of changes in the regulatory baseline since 2009: LCFS 46-205

- Does the CARB staff agree that the federal RFS program would, in the absence of an LCFS regulation, assure some level of reductions in GHG exhaust emissions from the California in-use vehicle population that is operated on gasoline? If not, why not; and if so, what would be that level of GHG emissions reductions, on an annual or some other specific basis, if the LCFS program were to be discontinued at the end of 2015? LCFS 46-206
    - Does the staff have any disagreement with the position that the federal RFS program and the "California premium" (*see* note 15 above) would cause Midwest corn ethanol producers to continue preferentially to deliver ethanol to California, and cause the California gasoline marketing sector to blend that Midwest corn ethanol into gasoline up to the current 10 percent limit, even in the absence of the LCFS regulation? If so, what are the specific reasons why the staff disagrees? LCFS 46-207
    - Does the staff believe that the LCFS regulation would result in wider usage of E85 in California than the federal RFS program would cause, and if so, what is the empirical basis for that view? LCFS 46-208
    - Would a possible need for a diesel component to an LCFS program justify an unnecessary gasoline component for an LCFS program, and if so, why? LCFS 46-209
- The 2009 regulatory analysis predicted that ultra-low-CI fuels would be available and would bring the costs of the LCFS program down to the point where the program would be cost-neutral at the consumer level, or would result in savings of up to $11 billion.[20] LCFS 46-210

[19] *See* Air Resources Board, *California's Low Carbon Fuel Standard -- Final Statement of Reasons* (hereinafter "FSOR") 24.

[20] *See* ISOR at ES-26.

Does that remain the CARB staff's position? If not, what will be the consumer costs of the staff's proposed revised LCFS regulation, predicted annually or in some other manner? What uncertainties and assumptions affect those cost estimates?

LCFS 46-210 cont.

- Are the ACC program and other vehicle-based GHG reduction programs adopted to implement AB 32 designed to obtain, and will they obtain, the maximum technologically feasible and cost effective reductions in GHG emissions from the new vehicles that are subject to those standards? (*See, e.g.*, Cal. Health & Safety Code § 38562(a).) If not, why not? With the ACC program and other non-LCFS regulations discussed above in Part II. A. now in place, would the LCFS program actually produce any incremental increase in the displacement of liquid motor vehicle fuels by electricity in ZEVs or hybrid electric vehicles or hydrogen in fuel cell vehicles? If so, what are the relevant increases, and on what assumptions do the predicted increases depend? Why would a vehicle manufacturer that over-achieved the ZEV requirement not use the credit gained from the overachievement by selling a higher-emitting conventional vehicle fleet? To what extent would the staff attribute to the LCFS program any displacement of vehicle miles traveled in conventional vehicles by vehicles powered by fuel cells, and what is the basis for that prediction?

LCFS 46-211

- The CARB staff sometimes refers to Executive Order S-07-01 as a basis for maintaining the LCFS regulation. Should the requirements of Executive Order S-07-01 be reconsidered in the current rulemaking process insofar as the Executive Order called for creation of the LCFS regulation? Does Executive Order S-07-01 limit in any way CARB's discretion in adopting and enforcing measures to implement AB 32? Does AB 32 require adoption and enforcement of the LCFS regulation, if the same GHG reductions that the LCFS regulation can achieve could be achieved by other means?

LCFS 46-212

- To the extent that the LCFS program is still intended to stimulate "fundamental changes in the transportation fuel pool" in California,[21] to what extent had the program succeeded in its first five years? Is achieving that objective consistent with the potential "cost reduction" mechanisms under consideration for a revised LCFS regulation? How should the Department and the public try to weigh that objective against the potential costs for California consumers and businesses in meeting that objective?

LCFS 46-213

Having now presented the above questions to the CARB staff, Growth Energy believes that the staff should address them in the SRIA for the Department, or concurrently in a separate submittal to the Department made available to the public, if the staff does not intend otherwise to respond to those questions. Each question bears on the need for the LCFS regulation, the costs and benefits of the LCFS regulation, or the legal authority that would limit the analysis of regulatory

LCFS 46-214

---

[21] *See* note 19 above.

alternatives. If the CARB staff does not believe that one or more of the above questions are relevant to the evaluation of regulatory alternatives, Growth Energy requests that the CARB staff explain why, with respect to each such question. LCFS 46-214 cont.

III. Regulatory Alternatives

The CARB regulations adopted since 2009 and the federal RFS program adequately provide for full control of the direct GHG emissions from the California vehicle fleet that the LCFS regulation may have been intended to control. In 2009, CARB claimed that the LCFS regulation would provide additional GHG reductions on a lifecycle basis; the "upstream" component of the GHG benefits attributed to the LCFS regulation in 2009 was 7 MMTCO2eq in 2020.[22]

Putting to one side the question whether CARB has legal authority to adopt and enforce a regulation to control GHG emissions occurring outside California, there are several reasons to question whether the LCFS regulation actually achieves any reduction in upstream emissions. As CARB has recognized, the LCFS regulation has to date caused "fuel shuffling" -- ethanol that might have been sold in California prior to the LCFS regulation is still being produced, and is sold somewhere else.[23] Ethanol production processes and pathways that have putatively higher upstream emissions have, at this point, neither terminated nor curtailed operations as a result of the LCFS regulation.[24] In addition, many Midwest corn ethanol biorefineries have qualified for LCFS 46-215

---

22 *See* ISOR at VII-1.

23 *See* FSOR at 477 ("Without the wider adoption of fuel carbon-intensity standards, fuel producers are free to ship lower-carbon-intensity fuels to areas with such standards, while shipping higher-carbon-intensity fuels elsewhere. The end result of this fuel 'shuffling' process is little or no net change in fuel carbon-intensity on a global scale.") The "wider adoption" of LCFS-type standards to which CARB referred in the 2009 FSOR has not occurred.

24 That is not to say, however, that the LCFS regulation is not injurious to the national market in ethanol, nor neutral in its impact on lifecycle GHG emissions. By causing fuel shuffling, the LCFS regulation disrupts the national market in ethanol, imposes costs, and increases transportation-related GHG emissions. Eventually, by effectively banning Midwest corn ethanol from California (if, for example, the LCFS for 2015 established in

lower-carbon-intensity LCFS "pathways" since 2009, on a scale that the CARB staff has admitted was "not expected in 2009."[25] Moreover, the estimates of upstream emissions attributed to Midwest corn ethanol in 2009 were grossly inflated: no one, including CARB, is still prepared to defend the indirect land-use change emissions factors accepted by CARB in 2009, and the current literature demonstrates that the "science" of indirect land-use change is too unreliable to be used as a basis for regulation.[26]

LCFS 46-215 cont.

LCFS 46-216

To the extent there is any remaining basis for attributing upstream GHG emissions reduction benefits to the LCFS regulation, those benefits certainly do not warrant the continuation or re-adoption of the LCFS regulation. The more efficient approach would be to adjust the cap-and-trade regulation in Title 17 of the *California Code of Regulations* to account for whatever increment of GHG emissions reductions would be forgone by eliminating the LCFS regulation.[27] To the extent necessary, modifications to the cap-and-trade regulation would be

LCFS 46-217

2009 were to be enforced), the LCFS regulation will leave California with no commercially viable method of complying with the standard; the staff appears to recognize this problem to some extent, with the currently ill-defined "cost reduction" features that it plans to propose. *See* Air Resources Board, *Low Carbon Fuel Standard Re-Adoption Concept Paper* (March 2014) at 6-7. The reduction in nationwide demand for Midwest corn ethanol will then also impose serious economic harm on the Midwest ethanol industry.

25 *See* 2011 Program Review at 169. The Midwest ethanol production facilities that have qualified for lower-carbon-intensity LCFS pathways have not done so through modifications in their production processes intended to obtain those special LCFS pathways: they have a competitive incentive to increase efficiency, and would have done increased their efficiency in the absence of the LCFS regulation. A Growth Energy member has demonstrated this point in the ongoing *Rocky Mountain* litigation involving some aspects of the LCFS regulation. *See* Declaration of Erin Heupel, P.E. (included here as Attachment 6) ¶¶ 5-6. Notably, in the *Rocky Mountain* litigation, CARB offered no competent evidence to the contrary. As Ms. Heupel also demonstrated, the specific features of the LCFS regulation will eventually force even the highest-efficiency Midwest corn production facilities out of the California market. *See id.* ¶¶ 9-11.

LCFS 46-215 cont.

26 The CARB staff has begun to revise and to reduce the indirect land-use change emission factors that were included in the 2009 LCFS regulation. *See* letter from G. Cooper to K. Sideco, April 9, 2014, available at http://www.arb.ca.gov/fuels/lcfs/regamend14/rfa_04092014.pdf. It remains Growth Energy's position that the modeling methods used by CARB to generate indirect land-use change values are too unreliable for use in a regulation intended to comply with AB 32. *See* Letter from D. Bearden to J. Goldstene, May 10, 2010 (included here as Attachment 4).

LCFS 46-216 cont.

27 In 2009, CARB received substantial comments on the relative inefficiency of the LCFS approach from one of its independent peer reviewers, who urged that CARB consider a cap-and-trade alternative. *See*, e.g., FSOR at 24 (review by Dr. John Reilly); *see also id.* (summarizing Dr. Reilly's review as stating, "The economic analysis

LCFS 46-217 cont.

simple and straightforward. Initially, CARB should determine what, if any, upstream GHG reductions should be attributable to the LCFS regulation, using a scientifically reliable process. CARB would also need an appropriate estimate of the total GHG emissions expected from the use of gasoline and diesel fuel in 2020. A CARB emissions forecast prepared in 2010[28] indicates that total GHG emissions from gasoline and diesel fuel use in California are expected to be approximately 175 million metric tons in 2020 under business as usual conditions. Assuming that the generally required 22 percent reduction in emissions in 2020 under the cap-and-trade program[29] applies to gasoline and diesel fuel use, total 2020 emissions without the LCFS program would be about 135 million metric tons.

Continuing the analysis, and by way of example, suppose that the cap-and-trade regulation had to cover the entire annual 16 MMTCO2eq of GHG emissions that the CARB staff identified as the benefit of the LCFS regulation for 2020. That level of GHG control could be achieved by amending the cap-and-trade regulations to require providers of gasoline and diesel fuel to submit 151 (135+16) million metric tons of allowances – or in other words requiring gasoline and diesel fuel suppliers to surrender 1.11 (151/136) allowances for every ton of GHG emissions they report from the fuels they supply.[30]

LCFS 46-217 cont.

[for the LCFS regulation] was done incorrectly. It does not meet [the] technical standards of economics. The baseline assumptions are mutually inconsistent, and if these assumptions were executed in a proper model it would show that the LCS was unnecessary.") CARB stated in 2009 that it would consider the role of cap-and-trade further in addressing the objectives of the LCFS program once the cap-and-trade regulations were completed. *See* FSOR at 452.

28 *See* Air Resources Board, "California GHG Emissions -- Forecast 2008-2020 (updated Oct. 28, 2010), available at http://www.arb.ca.gov/cc/inventory/data/tables/2020_ghg_emissions_forecast_2010-10-28.pdf

29 This is based on the general percentage reduction requirements established by CARB for total allowances issued. *See* Air Resources Board, "Overview of ARB Emissions Trading Program (October 2011), available at http://www.arb.ca.gov/newsrel/2011/cap_trade_overview.pdf

30 The cap-and-trade regulation already begins to take effect for the gasoline and diesel fuel marketing sector in 2015.

The modifications to the existing text of the cap-and-trade regulation would be minor and limited to section 95852(d) of the regulation.[31] Further, the CARB staff at its discretion could also create a compliance offset program in order to incentivize low- carbon intensity fuels similar to those in place which incentivize other innovative GHG reduction strategies.[32] Insofar as one goal of the APA is to eliminate unnecessary regulation, this approach would well-serve the goals

LCFS 46-218

[31] Thus, the text of section 95852(d), with the modification shown in italics, and assuming that the full 10 percent GHG emission reduction attributed to the LCFS regulation would be covered by cap-and-trade, would provide as follows:

> Suppliers of RBOB and Distillate Fuel Oils. A supplier of petroleum products covered under sections 95811(d) or 95812(d) has a compliance obligation *equal to 1.x allowances* for every metric ton CO_2e of GHG emissions included in an emissions data report that has received a positive or qualified positive emissions data verification statement or for which emissions have been assigned that would result from full combustion or oxidation of the quantities of the following fuels that are removed from the rack in California, sold to entities not licensed by the California Board of Equalization as a fuel supplier, or imported into California and not directly delivered to the bulk-transfer/terminal system as defined in section 95102 of MRR, except for products for which a final destination outside California can be demonstrated:

(1) RBOB;
(2) Distillate Fuel Oil No. 1; and
(3) Distillate Fuel Oil No. 2.

> *The value of "x" above will be established by Executive Officer by the prior October 31 for each year beginning with 2015 to ensure that actual GHG emissions from the use of RBOB and Distillate Fuel Oil No. 1 and Distillate Fuel Oil No. 2 are reduced to the level that would have been achieved had the Carbon Intensity of those fuels been reduced according to the following schedule relative to 2010.*

Required Carbon Intensity Reduction Relative to 2010	
Year	Reduction
2015	2.7%
2016	3.7%
2017	5.2%
2018	6.7%
2019	8.2%
2020	10.0%

As illustrated above for 2020, the value of "x" would be 0.11 and the compliance obligation for suppliers of gasoline and diesel fuels would be 1.11 times the number of tons of CO2e emissions reported.

[32] *See* Air Resources Board, "Climate Change Programs -- Compliance Offset Program" (updated June 11, 2014), available at http://www.arb.ca.gov/cc/capandtrade/offsets/offsets.htm

of the APA. By eliminating the LCFS regulation, CARB would also free the California transportation fuel sector from continuing uncertainty about the availability and cost of ultra-low-carbon-intensity alternative fuels necessary for future compliance with the LCFS. As the Western States Petroleum Association ("WSPA") has stated:

> The LCFS, as envisioned by Governor Schwarzenegger in his Executive Order and as developed by the ARB, is infeasible. … [S]taying the course now could result in disruptions in the transportation fuels markets. … A successful fuels policy must protect against fuel supply disruptions, severe job losses in the state's refining industry and unacceptable economic harm to California and its citizens.[33]

LCFS 46-219

While Growth Energy believes that its proposal has sufficient merit without endorsement by other organizations, the concerns expressed by WSPA are important. One benefit of the change that Growth Energy is proposing, and a benefit that is particularly important to Growth Energy and the enterprises it represents, is that elimination of the LCFS regulation would eliminate a major conflict between regulations adopted by California and the federal RFS program, a conflict that will only increase if the LCFS regulation is re-adopted.

In considering Growth Energy's proposal, and in addition to the questions presented in Part II of this submittal, the CARB staff should in the SRIA address the following questions:

- The CARB staff's May 23, 2014, notice soliciting public input for the SRIA sought "alternative LCFS approaches." (See Attachment 5.) Does the CARB staff believe the alternatives analysis for the SRIA and public submittals related to the SRIA must be confined to regulatory alternatives that include or would preserve in some form the LCFS regulation? If so, what is the basis for such a limitation?

LCFS 46-220

- Other than emissions created in generating electricity for delivery in California, does AB 32 give CARB the authority to regulate upstream emissions occurring outside California, or to account for upstream emissions occurring outside

LCFS 46-221

[33] The reference is to Executive Order S-01-07, with its "10 percent" by 2020 goal, which according to the CARB staff remains the target for the LCFS regulation. *See* Letter from G. Grey to K. Sideco, June 13, 2014 at 2, available at http://www.arb.ca.gov/fuels/lcfs/regamend14/wspa_06132014.pdf. WSPA has also stated that modification of the LCFS program through "cost reduction" provisions would "simply penalize fuel suppliers for not meeting an infeasible standard." *See* Letter from C. Reheis-Boyd to K. Sideco, April 11, 2014 at 10, available at http://www.arb.ca.gov/fuels/lcfs/regamend14/wspa_04112014.pdf.

LCFS 46-219 cont.

California in adopting regulations to meet the statewide greenhouse gas emissions limit? (*See* Cal. Health & Safety Code § 38505(m), (n); 38562(a).) If AB 32 authorizes CARB to regulate or consider out-of-state GHG emissions attributed to ethanol production, does AB 32 also authorize CARB to address those emissions through the cap-and-trade regulation? LCFS 46-221 cont.

- Can the California cap-and-trade regulations be modified to provide the same numerical reductions in GHG emissions as the LCFS regulation? If not, why not? LCFS 46-222

- If the CARB staff is concerned that the state measures to control GHG emissions and the federal RFS program might not be fully implemented and enforced at some time in the future, would adoption of a revised LCFS regulation as a "backstop" measure, to be implemented only if those other programs are not meeting defined objectives, address that concern? If not, why not? LCFS 46-223

- If the CARB staff believes some regulated parties might prefer to comply with a revised LCFS regulation rather than a modified cap-and-trade regulation, could that issue be addressed by including a revised LCFS as a part of a regulatory alternative (with appropriate opt-in provisions) that would be an option for parties that did not wish to comply with a modified cap-and-trade regulation? LCFS 46-224

- What are the current and expected future levels of resources at CARB, in terms of personnel and other resources, that are allocated to the LCFS regulation? What would be the budgetary impact for CARB if the LCFS program were eliminated? What would be the budgetary impact for CARB caused by the change in the cap-and-trade regulation proposed here? LCFS 46-225

- To the extent the CARB staff would attribute other beneficial impacts, different from GHG emissions reductions, to the LCFS regulation, to whom do those benefits accrue? With regard to those other beneficial impacts, are California consumers benefitted and, if so, how and to what extent? With regard to those other beneficial impacts, are California businesses benefitted and if so, how and to what extent? Do those other beneficial impacts justify or support continuation of the LCFS regulation, and if so, what is the basis for CARB's authority to adopt and enforce the LCFS regulation to obtain those benefits? If those other beneficial impacts include the possibility that sources for alternative fuels will be increased or diversified, are there any peer-reviewed or other studies that support such a proposition? If not, what is the staff's basis for attributing such benefits to the LCFS regulation? Could those benefits be realized through the development of a compliance offset program under the cap-and-trade regulation? LCFS 46-226

As with the questions presented in Part II, the CARB staff's responses to these questions are important in understanding its evaluation of Growth Energy's proposal. If the CARB staff does not believe that one or more of the above questions are relevant to the evaluation of LCFS 46-227 regulatory alternatives, Growth Energy requests that the CARB staff explain why, with respect to each such question. LCFS 46-227 cont.

IV. Next Steps

As noted at the outset of this submittal, Growth Energy's analysis of alternatives to the LCFS regulation can be no more detailed than the available information about the staff's intended revised LCFS regulation. If CARB does nothing further to facilitate the public input into the SB 617 process for use in the SRIA, it will not have substantially complied with the APA as amended by SB 617 and implemented in the Department's regulations. LCFS 46-228

In the CARB staff's first notice that it was ready to receive public input on regulatory alternatives, published on May 23, 2014, the staff set a deadline for that input of June 6, 2014 -- nine business days later. The staff indicated in that notice that the public should, among other things, "submit the quantities of low-CI fuels used each year" in the proposed alternative to the LCFS regulation, "as well as the associated cost and benefit information, and their sources." [34] According to the May 23 notice, that information was needed "to enable comparison of economic impacts."[35] The May 23 notice stated that the objective for public input should be to provide "alternative LCFS approaches," meaning "any approach that may yield the same or greater benefits than those associated with the proposed regulation, or that may achieve the goals at lower cost."[36] LCFS 46-229

The "proposed regulation" to which the May 23 proposal referred (i) had not been provided to the public for review as of May 23, nor (ii) has it been provided at any time since

[34] *See* Attachment 5.

[35] *Id.*

[36] *Id.*

May 23.[37] The May 23 notice was not accompanied by any information that provided the CARB staff's own prediction of "the quantities of low-CI fuels [that would be] used each year" under the CARB staff's proposed regulation, nor the benefits that the CARB staff attributed to the LCFS regulation. Growth Energy requested that the CARB staff give the public the information needed to prepare a complete SB 617 submission and requested that the public be given additional time to prepare SB 617 analyses after the necessary information was released.[38]

The CARB staff responded by extending the deadline for public submittals that would be addressed in the SRIA to June 23, 2014 (31 days after the May 23 notice), but did not provide any of the information requested by Growth Energy and needed to provide the type of input sought in the May 23 notice, and necessary under the Department's SB 617 regulations. Instead, the staff referred to the GHG emissions reductions targeted in the 2009 rulemaking, to a March 2014 "Concept Paper" that discussed the staff's approach to revision of the LCFS regulation, and to material provided to the public in connection with regulatory workshops held in ARB's offices.[39] The March 2014 Concept Paper raises more questions about the staff's approach than it answers: it included, for example, a general description of two different "cost reduction" concepts without indicating how either of them would work, how they would reduce costs, or how they would affect the GHG emissions reduction benefits of the LCFS program. If the March 2014 Concept Paper provided a basis for preparing SB 617 submittals, then there is no reason why the CARB staff should have waited until May 23 to solicit public input under the Department's regulations. Had the staff informed the public when it released the Concept Paper

LCFS 46-229 cont.

[37] The CARB staff has released some draft regulatory text for their proposed revised LCFS, but that partial text does not include, for example, the "cost reduction" feature intended for the new regulation, nor the carbon intensity values to be assigned to each alternative fuel.

[38] *See* Attachment 1.

[39] *See* Attachment 2.

and discussed the Concept Paper at one of its March 2014 regulatory workshops that the Concept Paper was intended to provide a basis for SB 617 input, Growth Energy (and perhaps other stakeholders) would have pointed out at that time that the Concept Paper was inadequate for that purpose; in that event, perhaps the CARB staff would have been able to provide the necessary information for public input into the SRIA.

LCFS 46-229 cont.

The materials provided in connection with the regulatory workshops -- including the partial regulatory text released on May 28, after the staff had launched the public input process -- likewise do not provide the necessary information for detailed public submittals consistent with SB 617 and the Department's regulations. Growth Energy has studied those materials carefully, and with the greatest respect, would challenge the CARB staff to indicate where in those materials the staff identifies GHG emissions reduction targets for a revised LCFS regulation; where the staff identifies any other putative benefits of the LCFS regulation; and where in those materials the staff provides specific and concrete information about the impact of the "cost reduction" concepts on the quantities of alternative fuels that would be used in order to comply with the revised LCFS regulation, or permits a quantification of costs and benefits of a revised LCFS regulation that includes a cost-reduction feature.

LCFS 46-230

Finally, it is important to address comments by the CARB staff at one recent workshop, which suggested that the timing of the current regulatory effort has been affected by the Board's need to comply with the mandate in litigation under the APA and the California Environmental Quality Act ("CEQA").[40] In that litigation, the Superior Court has allowed CARB all the time

LCFS 46-231

[40] The case is *POET LLC et al. v. California Air Resources Board*, Case No. 09 CE CG 04659 (Sup'r Ct., Fresno County). The Writ of Mandate in that proceeding does not require CARB to commence or conclude rulemaking by a particular date, but to proceed in good faith without delay. The Writ of Mandate was issued more than six months ago, by which time CARB presumably knew that it had to comply with the Department's SB 617 regulations.

that the Board has requested in order to comply with the mandate. If CARB needs more time in order to conduct the SB 617 process in a manner that allows sufficient time for effective public input into the preparation of an SRIA, CARB should so inform the Superior Court. (Notably, in its filings with the Superior Court, CARB has not adverted to SB 617 or the Department's implementing regulations.) In addition, the CARB staff would surely agree that even before issuance of the mandate in that litigation, it was aware that it had major program review obligations for the LCFS regulation in 2014.[41] Particularly in light of those program review obligations, the CARB staff's inability to provide more information now to the public, needed to participate fully in the SB 617 process, seems inexcusable.

LCFS 46-231 cont.

Against that backdrop, Growth Energy urges the CARB staff to reconsider its present approach to the SB 617 process, and specifically the staff's approach to obtaining public input for the SRIA. As the staff might expect, if one response to Growth Energy's proposed regulatory

LCFS 46-232

[41] In 2009, when it first adopted the LCFS regulation, the Board directed the CARB staff to conduct and to present by January 1, 2015 a "review of implementation of the LCFS program" that was to "include, at a minimum, consideration of the following areas:

"(1) The LCFS program's progress against LCFS targets;
"(2) Adjustments to the compliance schedule, if needed;
"(3) Advances in full, fuel-lifecycle assessments;
"(4) Advances in fuels and production technologies, including the feasibility and cost-effectiveness of such advances;
"(5) The availability and use of ultralow carbon fuels to achieve the LCFS standards and advisability of establishing additional mechanisms to incentivize higher volumes of these fuels to be used;
"(6) An assessment of supply availabilities and the rates of commercialization of fuels and vehicles;
"(7) The LCFS program's impact on the State's fuel supplies;
"(8) The LCFS program's impact on state revenues, consumers, and economic growth;

. . .

"(12) Significant economic issues; fuel adequacy, reliability, and supply issues; and environmental issues that have arisen; and
"(13) The advisability of harmonizing with international, federal, regional, and state LCFS and lifecycle assessments."

17 C.C.R. § 95489(a).

LCFS 46-231 cont.

alternative is that Growth Energy's proposal lacks a detailed comparison with the costs, benefits, and cost-effectiveness of the staff's proposal in the SRIA, Growth Energy will attribute its lack of specificity to the staff's failure to provide the information needed to offer a more specific regulatory analysis. Because this is one of the first major rulemakings at CARB that is required to comply with SB 617 and the Department's SB 617 regulations, it is also important for the Department to take a proactive role in providing guidance to CARB, the stakeholders, and other members of the public interested in the LCFS program.

LCFS 46-232 cont.

Respectfully submitted,

GROWTH ENERGY

46_OP_LCFS_GE Responses (Page 191 - 218)

527. Comment: **LCFS 46-195**

The comment asserts that equivalent GHG reductions can be achieved without the LCFS proposal.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, we note that for several decades, ARB has been "charged with coordinating efforts to attain and maintain ambient air quality standards, to conduct research into the causes and solutions to air pollution, and to systematically attack the serious problem caused by motor vehicles . . ." (Health & Saf. Code §39003) In recent years, greenhouse gases have been recognized as a form of air pollution, and ARB was again charged by the Legislature with developing measures to address GHG emissions. (Health & Saf. Code §38500 et seq.) Based on the agency's experience addressing air pollutants, including decades of regulating motor vehicles and fuels, sole reliance on existing programs will not achieve the carbon-intensity fuel reductions of the LCFS program. For example, California's specific vehicle and engine-based programs will result in an increase in zero-emission (electric and fuel cell) vehicles, but will not ensure the fuel for non-zero emission vehicles is cleaner. The Cap-and-Trade Program is a broad program that achieves GHG reductions across all economic sectors. Therefore, the program could not be counted on to get the same benefits from the transportation fuel sector alone, as the LCFS will.

528. Comment: **LCFS 46-196**

The comment states that other regulations currently in effect already achieve GHG reductions therefore the LCFS proposal is unnecessary.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, we note that the submitter has repeatedly mistaken GHG reductions as the sole metric to judge the need for the LCFS program and has minimized the role of the LCFS program in achieving GHG reductions. To the contrary, the LCFS program is necessary to achieve the objectives stated – reducing the CI of transportation fuels by 10 percent, achieving GHG reductions, and transforming and diversifying transportation fuel.

As discussed in response to comments **LCFS 46-179** and **LCFS 46-195**, other regulations have related but ancillary objectives. In addition, and put simply, if California were set to achieve the LCFS objectives through other regulations already adopted, then the additional costs from the LCFS regulation about which the commenter is worried will not materialize.

529. Comment: **LCFS 46-197**

The comment states that other regulations currently in effect already achieve GHG reductions therefore the LCFS proposal is unnecessary.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, we note that as explained in the response to comments **LCFS 46-173**, **LCFS 46-179**, **LCFS 46-195**, and **LCFS 46-196** the LCFS program is needed to lower the average CI of transportation fuel.

The Cap-and-Trade Program does not eliminate the need for other policies that are directly focused on promoting new technologies. The reason is that the Cap-and-Trade Program addresses a particular market failure, while technology-promoting policies address others. The Cap-and-Trade Program addresses the failure of market prices to capture the climate-change externality associated with GHG emissions. It remedies this market failure by creating a price signal for avoided emissions. Technology-promoting policies are still needed, however, to address other market failures that impede the development of new technologies. Technology-promoting policies such as California's motor vehicle regulations and the LCFS directly confront these other types of market failures. A Cap-and-Trade system does not obviate the need for such technology policies. To the contrary, it complements technology policies.

530. Comment: **LCFS 46-198**

The commenter expresses concern that the conceptual proposals circulated earlier in the rulemaking process – not the proposed regulation package itself – were not extremely detailed, thus preventing the commenter from suggesting an alternative in detail.

Agency Response: The document was prepared by commenter in June 2014, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows.

ARB staff disagrees because nothing prevented anyone from suggesting an alternative, and making it as detailed as desired. Moreover, at the time of the comment, the LCFS program had been in effect for almost five years, and many workshops and website postings had informed the public about program changes contemplated for inclusion in the eventual re-adoption proposal. As a trade group whose members have participated in and profited from the LCFS over the years, as the party or trade group representing parties who have combined brought no less than three separate lawsuits related to the LCFS, the commenter has demonstrated a deep interest in and familiarity with the program and the proposed re-adoption. ARB staff is not aware of any impediment to commenter's full participation in the pre-rulemaking or rulemaking processes.

Comment 198 goes on to instruct ARB on what it should do after June 2014, to facilitate public participation in the re-adoption process. By following its usual practices, and by complying with the APA, ARB staff successfully facilitated public input, including any economic analyses that any party wished to submit, and as evidenced in the Notice of Proposed Rulemaking and Staff Report dated December 16, 2014, the Notices of 15-day changes, and the two public hearings conducted by the Air Resources Board prior to adopting the proposal.

531. Comment: **LCFS 46-199**

The commenter criticizes ARB's 2009 Staff Report, and claims that the document contained some predictions that were not borne out, but simultaneously acknowledges that these predictions were correct, but according to the commenter happened for reasons other than those advanced in the 2009 Staff Report.

Agency Response: This comment is not pertinent to the proposed re-adoption of the LCFS in 2015, and offers no specific recommendation or objection.

532. Comment: **LCFS 46-200**

The commenter states that the goal of reducing the carbon intensity of transportation fuels by 10 percent equates to a static tonnage of GHGs and as such the LCFS is no longer required.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, we note that as the submitter states, the goal of the LCFS program is to “reduce the carbon intensity of transportation fuels used in California by at least 10 percent by, 2020 from a 2010 baseline,” as well as “support the development of a diversity of cleaner fuels with other attendant co-benefits.” That goal is clear and specific, yet the commenter incorrectly re-characterizes the goal solely in terms of the 16 MMTCO2e emission reduction, which is inaccurate. See also response to Comments **LCFS 46-173**, **LCFS 46-179**, and **LCFS 46-195**.

533. Comment: **LCFS 46-201**

The comment implies that equivalent GHG reductions will occur due to the RFS program without the LCFS proposal.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, we note that the statement ignores numerous facts and chooses to focus on downstream exhaust GHG emission reductions from 10 percent ethanol blends with gasoline, while discounting the rest of lifecycle emissions. Although tailpipe emissions with ethanol may be the same regardless of the source of the ethanol, a main tenet of the LCFS program is scientifically-based lifecycle emissions. This lifecycle assessment (LCA) examines the GHG emissions associated with the production, transportation, and use of a given fuel. The LCA includes direct emissions associated with producing, transporting, and using the fuels, as well as significant indirect effects on GHG emissions, such as changes in land use for some biofuels. Subjecting this life cycle GHG rating to a declining standard for the transportation fuel pool in California will decrease total life cycle GHG emissions from fuels used in California. The LCFS is designed to encourage the use of cleaner low-carbon fuels in California and encourage the production of those fuels through a performance-based, fuel-neutral structure. Different types of ethanol have different lifecycle emissions and ethanol blended at E10 is not the only source of gasoline credits. Other sources include E85 and advanced cellulosic ethanol, and advanced fuel innovations such as a drop-in gasoline are not referenced. All of these options achieve greater market pull from the LCFS program, thereby increasing production demand and spurring innovation. Please also see response to **LCFS 46-195.**

534. Comment: **LCFS 46-202**

The comment states that the LCFS proposal is not necessary because of the Advanced Clean Cars program.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, please see response to LCFS **46-195.** While the zero-emission vehicle (ZEV) portion of the Advanced Clean Cars program will help lower the carbon intensity of transportation fuel, the other portions of the program will not. The ZEV portion of Advanced Clean Cars pre-dates the LCFS. The Air Resources Board determined it is appropriate to have both programs in place to synergistically address emissions. It is commonplace to have complementary policies as part of an overall strategy. For example, the ZEV program also includes state incentives, high occupancy vehicle access, local preferential parking, and a variety of other regulatory and policy incentives to help achieve its goals. The ZEV program promotes electricity and hydrogen in light-duty vehicles, while the LCFS program promotes those fuels, as well as reducing carbon intensity and emissions from fuels used in vehicles that are not ZEVs.

535. Comment: **LCFS 46-203**

The comment states that the LCFS proposal is not necessary because of California's Tractor-Trailer regulation adopted in 2008.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, please see response to LCFS **46-195.** The regulations cited by the commenter work synergistically with the LCFS regulation. However, they will not have any impact on the carbon intensity of transportation fuel in California, and therefore will not help ARB achieve the primary objectives of the LCFS program and could not substitute for the LCFS.

536. Comment: **LCFS 46-204**

The commenter requests clarification of four items to establish a baseline for their alternative analysis.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. The commenter asks for information on four elements of the LCFS program, as follows:

1. *Updated carbon intensity values for transportation fuels that will be included in the proposed 2014 LCFS regulation*.

   The updated CI values are contained in sections 95484(b) and 95484(c) of the proposed regulation.

2. *The detailed form of any proposed “cost-containment” provisions which could allow parties subject to the LCFS regulation to comply with the program’s standards, without actually achieving the CI reductions required under the regulation*.

   The specific cost-containment regulatory provisions are contained in section 95485(c) of the proposed regulation. See responses to **LCFS 6-4** and **LCFS 32-9**.

3. *CARB staff’s current analysis of the manner in which regulated parties will most likely attempt to comply with the proposed 2014 LCFS*.

   Being a market-based system, there are multiple options and pathways for LCFS compliance. In fact, ARB staff would expect different companies could have drastically different compliance scenarios. However, staff prepared an illustrative scenario representing one pathway for compliance.

4. *A full description of any other intended goals of the LCFS regulation, such as stimulating “fundamental” changes in the “transportation fuel pool,” along with the metrics to be used to measure progress and success in meeting those other goals*.

   ARB staff has clearly identified the goals of the program throughout the Initial Statement of Reasons (ISOR) staff report. Specific goals include, reducing GHGs and other smog-forming and toxic air pollutants from the transportation sector; decreasing the carbon intensity of California’s transportation fuel pool; providing an increasing range of low-carbon and renewable alternatives; promoting improvements in the fuel supply chain through a full lifecycle accounting of emissions; and diversifying the fuels market in California, thereby reducing petroleum dependency and creating a sustainable and growing market for cleaner fuels.

537. Comment: **LCFS 46-205**

The commenter's June 2014 letter advised ARB to make a specific proposal together with specific analyses and projections regarding how parties are likely to comply with the proposal.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, please see response to **LCFS 46-198**. In addition, ARB made a specific proposal in the Notice of Proposed Rulemaking in December 2014, accompanied by a Staff Report analyzing the items that appear to have concerned the commenter in June and much more.

In June 2014, the commenter raised two dozen detailed questions that "CARB staff should address," also requesting an explanation of "why" for each question CARB staff deem irrelevant to alternative evaluations. Those questions do not constitute objections or recommendations regarding the December 2014 proposal. That proposal and the accompanying Staff Report addressed the topics addressed by the questions; they need not be separately addressed again here. To the extent that by re-submitting its June 2014 letter the commenter means to imply that it was improper for ARB not to provide written responses to interrogatories in the midst of a complex rulemaking process, ARB staff disagrees. Such processes are more typically part of litigation.

538. Comment: **LCFS 46-206**

The commenter asks if ARB agrees that the RFS program would assure some GHG reductions in the absence of the LCFS program.

Agency Response: See response **LCFS 46-205**.

This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nonetheless, ARB staff note that it is not uncommon for ARB to adopt synergistic programs that work in partnership with U.S. EPA's regulations – regulation of fuel and fuel additives and rules increasing the fuel economy and decreasing GHG emissions from cars and light-duty trucks are an example. Currently, the federal RFS program provides such synergistic and positive benefits with respect to alternative fuels.

539. Comment: **LCFS 46-207**

The commenter asks if RFS and the "California premium" would ensure delivery of Midwest ethanol to California in the absence of the LCFS.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. See response to **LCFS 46-205**.

540. Comment: **LCFS 46-208**

The comment questions if ARB staff believe that the LCFS regulation would result in wider usage of E85 in California and, if so, why.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nonetheless, ARB staff believes the LCFS regulation could result in wider usage of E85 in California because some ethanols may generate significant credits, though the market participants will ultimately decide which fuels are used to comply with the carbon intensity standards and other factors influence E85 usage.

See response **LCFS 46-205**.

541. Comment: **LCFS 46-209**

The comment questions whether a possible need for a diesel component in the LCFS program justifies an unnecessary gasoline component and, if so, why.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, we note that the LCFS program is necessary to achieve the stated objectives. The program provides flexibility and keeps costs down. However, in order to lower the carbon intensity of transportation fuels, achieve significant GHG reductions, and diversify the transportation pool, both a gasoline and diesel component are necessary.

See response to **LCFS 46-205**.

542. Comment: **LCFS 46-210**

The commenter asks if ARB still believes that ultra-low CI fuels will become available and bring down the cost of the program.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. See response to **LCFS 46-205**.

To the extent it pertains to the current regulatory proposal, much of the information the commenter sought in this pre-ISOR feedback was provided in the ISOR. The cost analysis, as presented in the economic chapter in the ISOR is a worst-case scenario that will likely over-estimate the costs, without monetizing many of the benefits.

For instance, the LCFS will help reduce costs associated with petroleum dependency in California, and the health and the climate change impacts of petroleum use in California's transportation sector. These benefits are not quantified in this analysis, but some studies suggest they are significant, potentially several times greater in magnitude than the direct economic costs to regulated parties.

The SRIA outlines one potential scenario of the economic impacts of the regulation using an illustrative $100 average credit price. Table F-2 in the ISOR displays the direct changes in consumer expenditures for this scenario. The consumer expenditures are based on the credit price, and the deficits and credits generated by those volumes (outlined in Table F-1). At different credit prices, volumes of lower CI fuels, and efficiency improvements, among other factors, would likely lead to lower costs to consumers.

543. Comment: **LCFS 46-211**

The commenter asks if ARB believes that the Advanced Clean Car Program and other vehicle-based programs are designed to achieve the maximum technologically feasible GHG reductions.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. See also response to **LCFS 46-205**.

544. Comment: **LCFS 46-212**

The commenter asks if Executive Order S-07-01 need to be reconsidered in the re-adoption of the LCFS.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. As noted above, ARB declines to offer the commenter legal advice or opinions. See response to **LCFS 46-205**.

545. Comment: **LCFS 46-213**

The comment questions the extent to which the LCFS program has succeeded in the last five years and how the potential cost to Californians should be weighed against the success that has been achieved.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nonetheless, staff notes that the LCFS is working as designed and intended. ARB staff notes that the LCFS program has seen real, substantiated changes to the transportation fuel in California as a result of its program – increased volumes of renewable diesel and lower-CI ethanol are two examples. To date, nearly 160 active entities have registered for reporting in the LCFS Reporting Tool, and since the regulation went into effect, regulated parties have successfully operated under the LCFS program. Furthermore, fuel producers are innovating and achieving material reductions in their fuel pathways' carbon intensity, an effect the LCFS regulation is expressly designed to encourage. This is reflected in the large number of applications submitted under the "Method 2A/2B" process. The Method 2A/2B process allows fuel producers to apply for carbon intensity values for their fuels that are lower than the default values found in the LCFS Lookup Tables. To date, more than 230 individual new or modified fuel pathways with substantially lower carbon intensities have been certified. Almost 170 biofuel facilities are registered under the LCFS as supplying low-carbon fuels to California. The fact that some Midwest biorefineries have a low CI and others are adjusting their processes to lower their CI, is a positive sign demonstrating the innovative nature of the market based program.

It is important to remember that the LCFS program is currently at one percent, and has been for a couple of years; in part, due to uncertainty associated with the program as a result of the lawsuits. Even with the standards frozen at one percent, tangible results can been seen. For example, the amount of renewable natural gas used in vehicles in California has increased by over 700 percent since the program started; renewable diesel has grown dramatically to become more than three percent of the total diesel market in California in 2013; and the average crude CI used by California refiners have remained below the 2010 baseline, meaning that the carbon footprint of the crude slate has not increased. Additionally, fuel producers are innovating and achieving material reductions in their fuel pathways' CI, an effect the LCFS regulation is expressly designed to encourage. Moving forward, ARB staff expects that the market signal provided by an increasingly stringent LCFS program will incentivize new cleaner facilities and processes that consider full life cycle emissions.

546. Comment: **LCFS 46-214**

The comment requests that ARB staff submit a new SRIA that includes responses to the series of questions they presented above.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. See also response to **LCFS 46-205.** An additional SRIA is not required, and ARB will not be submitting an additional SRIA for review to DOF. ARB staff notes that the ISOR contains additional economic analysis.

547. Comment: **LCFS 46-215**

The comment questions whether the LCFS regulation actually achieves any reductions in upstream emissions and states that the regulation has caused fuel shuffling.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. See response to **LCFS46-40** and **LCFS 46-213**.

548. Comment: **LCFS 46-216**

The commenter believes the iLUC value used for corn ethanol is too high.

Agency Response: The document was prepared by commenter in response to ARB analysis presented in 2012, and as such does not constitute an objection or recommendation regarding the proposal released in December, 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

All of the iLUC values being proposed to the Board are a result of ARB staff using the latest science and best data to estimate iLUC values for all six biofuels (including ethanol) using a consistent methodology.

See also responses to **LCFS 8-1** and **LCFS 46-165**.

549. Comment: **LCFS 46-217**

The comment states that modification of the Cap-and-Trade Program would be a more efficient way to achieve GHG reductions and makes re-adoption of the LCFS proposal unnecessary.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. See also response to **LCFS 46-205, LCFS 32-2**, **LCFS 32-7**, and **LCFS 46-226**.

550. Comment: **LCFS 46-218**

The commenter suggests that if the Cap-and-Trade Program increased the obligations it already imposed on transportation fuel suppliers, short-term greenhouse gas emission reductions equivalent to those projected to result from the LCFS could be accomplished without need for the LCFS regulation.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, please see response to **LCFS 32-2**, **LCFS 32-7**, and **LCFS 46-226**.

551. Comment: **LCFS 46-219**

The comment expresses concerns about the availability and cost of ultra-low-carbon-intensity alternative fuels and that eliminating the LCFS regulation would eliminate a major conflict with the federal RFS.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. See response to **LCFS 46-205.** The LCFS program has made a rigorous assessment of the viability of the new compliance curve (see response to **LCFS 38-1**). In addition, the LCFS program has flexibility provisions and a cost containment mechanism to allow the lowest cost options (see responses to **LCFS 32-9** and **LCFS 38-3**). Finally, for a discussion of the coordination with the RFS program, see responses to **LCFS 38-45** and **LCFS 46-26**.

552. Comment: **LCFS 46-220**

In June 2014, the commenter raised a long list of detailed questions that “CARB staff should address,” together with an explanation of why regarding each response.

Agency Response: Those questions do not constitute objections or recommendations regarding the December 2014 proposal. That proposal and the accompanying Staff Report addressed those topics; they need not be separately addressed again here. To the extent that by re-submitting its June 2014 letter the commenter means to imply that it was improper for ARB not to provide written responses to interrogatories in the midst of a complex rulemaking process, ARB disagrees. Such responses were not required. Staff notes that an unlimited number of questions were allowed, and answered, during the many public workshops ancillary to this rulemaking. The commenter was, of course, free to participate.

553. Comment: **LCFS 46-221**

The commenter asked a series of legal questions for ARB staff to address in the SRIA.

Agency Response: These June 2014 interrogatories and musings are not comments or recommendations regarding the December 30, 2015 LCFS proposal, and need no response.

554. Comment: **LCFS 46-222**

The comment questions whether the Cap-and-Trade Program could be modified to provide the same numerical reductions in GHG emissions as the LCFS.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. See also responses to **LCFS 46-205, LCFS 32-2**, **LCFS 32-7**, **LCFS 46-220**, and **LCFS 46-226**.

555. Comment: **LCFS 46-223**

The comment suggests that adoption of a revised LCFS regulation as a "backstop" measure if the federal RFS Program does not get fully implemented or enforced at some time in the future would be sufficient to meet the State's objectives.

Agency Response:

This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. See also responses to **LCFS 46-205, LCFS 38-45, 46-179, 46-195, 46-201,** and **46-220**.

556. Comment: **LCFS 46-224**

The commenter asks if a modified Cap-and-Trade program will meet the objectives of the LCFS program.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. See also response to **LCFS 46-205.** The premise of the comment is that a modified Cap-and-Trade Program is sufficient to meet the objectives of LCFS program. As explained in the response to comments **LCFS 46-173**, **LCFS 46-179**, **LCFS 46-195**, and **LCFS 46-196**, that option would not meet the objectives.

557. Comment: **LCFS 46-225**

The comment asks what level of resources the ARB has devoted to the LCFS regulation and asks what would be the impact for the ARB if the LCFS program was eliminated.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation. Nevertheless, we note that resources for the LCFS program are approximately 20 staff. If the LCFS program were eliminated, the Cap-and-Trade Program would require fundamental changes to more rigorously incorporate lifecycle emissions (as explained in the response to comments **LCFS 46-195** and **LCFS 46-201**). ARB staff would be needed to incorporate those changes and then oversee the revised program. Staff does not believe the end result would be any significant staff resource changes. Perhaps more importantly, ARB staff does not believe the State's objectives would be met by that approach. Please see responses to **LCFS 32-2**, **LCFS 46-217**, **and LCFS 46-226**.

558. Comment: **LCFS 46-226**

The commenter asks ARB what benefits other than GHG emission reductions can be attributed to the LCFS program.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the regulation proposed in December, 2014. The benefits of the regulation are addressed in the ISOR that post-dates the commenter's question. See response to **LCFS 46-220**. ARB is not obligated to answer the many interrogatories posed by commenter.

559. Comment: **LCFS 46-227**

The commenter asks ARB to explain how the questions posed in **LCFS 46-221** through **LCFS 46-226** affect the evaluation of the commenter's alternative.

Agency Response: This June 2014 submittal is not an objection or recommendation regarding the proposed regulation.

See response to **LCFS 46-220**.

560. Comment: **LCFS 46-228**

In June 2014, the commenter objected that as of that date ARB had not substantially complied with requirements to allow public input into the SB 617/SRIA process.

Agency Response: ARB staff disagrees. ARB staff solicited alternatives from the public in advance of preparing the SRIA, and then analyzed those proposals in the SRIA document. See also response to Comment **LCFS 46-198** regarding public input generally. Moreover, the SRIA process is not the public's sole avenue for participating in and commenting on economic analyses. ARB staff made public its entire proposed regulation and economic analyses in December 2014, and accepted comments for 45 days and again at two public hearings before the Air Resources Board.

561. Comment: **LCFS 46-229**

In June 2014, the commenter objected that in connection with the SB 617/SRIA process, ARB had not provided a sufficiently specific proposal.

Agency Response: ARB staff disagrees. As more fully discussed in responses to comments **LCFS 46-7**, **LCFS 46-72**, and **LCFS 46-198**, by June of 2014, (1) the LCFS program was in its fifth year of actual implementation, (2) numerous workshops related to the re-adoption had been conducted, and (3) a description and some draft language regarding new aspects to be included in the re-adoption had been released. As discussed in response to comments **LCFS 46-195**, **LCFS 46-202**, and **LCFS 46-203**, ARB staff continued to listen to public input and continued its internal research to develop the best possible proposal by the end of 2014.

562. Comment: **LCFS 46-230**

The comment questions whether ARB staff provided all the necessary information consistent with SB 617 and the Department's regulations for public review and input.

Agency Response: See response to **LCFS 46-229**.

563. Comment: **LCFS 46-231**

The comment states that ARB staff's inability to provide more information to the public so they can participate fully in the SB 617 process seems inexcusable.

Agency Response: See response to **LCFS 46-229**.

564. Comment: **LCFS 46-232**

The comment states that Growth Energy's alternative proposal only lacks a detailed comparison of the costs, benefits, and cost-effectiveness because of ARB staff's failure to provide the information needed to offer a more specific analysis.

Agency Response: See response to **LCFS 46-65** and **LCFS 46-72**. We further note that the SRIA and ISOR, including an economic analysis, were made available prior to the comment period on the proposed LCFS; nothing precluded the submitter from reading those documents and submitting comments.

Appendix G

GHG Emissions Impact of Fuel Shuffling Due to California Low Carbon Fuel Standard

AIR, Inc.

February 14, 2015

The California LCFS requires a 10% reduction in carbon intensity between 2010 and 2020 for fuels sold in California. Much of the GHG emission reductions come from biofuels that are mixed with either gasoline or diesel fuel. Biofuel production has increased in the US and elsewhere. There are two possible scenarios for where the biofuels are used. In one scenario, where the LCFS is not in effect, the carbon intensity of biofuels used is approximately the same inside and outside of California. Biofuels are generally used where they are produced, and transportation emissions for biofuels are minimized. For example, ethanol from corn is used in the US, and ethanol from Brazil is used in Brazil. In a second scenario where the LCFS is in effect, the LCFS causes lower carbon intensity biofuels to flow into California for use there. All other biofuel production, which may have slightly higher average carbon intensity than the average in California, is used outside of California. In this second case, global GHG emissions can actually increase, because the same quantity of biofuel is used in either case, but in the second case, transport GHG emissions are higher, because biofuels are not being used where they were produced. This overall concept is referred to as fuel shuffling.

The LCFS requirement causes fuel shuffling, because the regulation is expected to result in increasing amounts of cane ethanol from Brazil to be used in California. This is shown in Table B-18 below, which shows volumes of different types of ethanol that ARB expects under one of the possible compliance scenarios (see Table B-18 of Appendix B to the ISOR). In California corn and related ethanol (sorghum) declines, while other fuels, notably cane ethanol, increases. However, while corn ethanol declines in California, it does not decline elsewhere, but increases with the RFS and with exports. Thus, worldwide there is no change in GHG emissions worldwide just because corn ethanol declines in California. However, the shift from corn ethanol to cane ethanol causes an increase in ethanol transportation and distribution emissions because of the difference in transportation distances between the Midwest to California and Brazil to California.

LCFS 46-233

Table B-18. Illustrative California Reformulated Gasoline Oxygenates and Substitute Fuels through 2020							
Fuel	2014	2015	2016	2017	2018	2019	2020
Corn and related ethanol, mmg	1,400	1,350	1,250	1,175	1,000	925	875
Cane and sugar ethanol, mmg	120	170	240	290	410	460	510
Cellulosic ethanol, mmg	0	0	5	15	50	75	100
Renewable gasoline, mmg	0	0	0	0	5	15	25
Hydrogen, mmgGGE	0.03	0.4	1	2	4	5	7
Electricity for LDVs, mmgGGE	9	14	19	24	31	40	51

We first estimated the GHG emission impact of increased transportation emissions with CaGREET2.0. We used distances and modes of transportation provided in CAGREET2.0. Results are shown in Table 1 below. For this analysis we assume a 390 million gallon per year increase in cane ethanol and a corresponding decrease in corn ethanol, which is the difference in the 2020 cane ethanol value (510 million gallons per year) and the 2014 value (120 million gallons per year) in Table B-18 above. Results show a 145,000 ton per year increase in GHG emissions, which is the fuel shuffling effect, assuming GREET cane ethanol transport emissions are correct.

LCFS 46-233 cont.

Table 1. Extra Transport GHG Emissions from Brazil Sugar Cane Ethanol								
	Emission Factors (grams/MMBTU of Fuel Transported)			Emissions		Emissions, CO2e		
Pollutant	Brazil to LA/Long Beach *	Midwest to CA **	Difference	Billion Grams	GWP	Billion Grams	Short Tons	gCO2e/ MJ
VOC	5.109	1.321	3.788	0.113	3.12	0.351	387	0.0112

LCFS 46-233 cont.

A report by $(S\&T)^2$, however, shows that the CaGREET2.0 transport emissions for cane ethanol could be quite low. [1] We used the same transport distances from Table 1 and information from the $(S\&T)^2$ report to estimate emissions, both with and without a backhaul included. Results are in Table 2 (details shown in Attachment 1) and show that the fuel shuffling emissions are between 375,000 and 716,000 tons of GHG per year.

Table 2. Increase in Fuel Shuffling GHG Emissions	
Case	Extra Fuel Shuffling Emissions (GHG, tpy)
Ca GREET2.0	132,000
$(S\&T)^2$, no backhaul	375,000
$(S\&T)^2$, with backhaul	716,000

Impact of the LCFS on Global Climate

A quantitative modeling analysis was conducted to assess the impact of LCFS carbon emission reductions on global climate change.

Climate Model Summary – The effect of the LCFS ISOR estimates of CO_2 emissions reductions attributable to the proposed regulation were modeled using version 5.3 of a coupled, gas-cycle/climate model known as MAGICC (Model to Assess Greenhouse-gas Induced Climate Change). MAGICC has been the primary model used by the Intergovernmental Panel on Climate Change (IPCC) to produce projections of future global-mean temperature and sea level rise. Technical and user manuals explaining the model in more detail are publicly available.[1]

Version 5.3 is the latest version of MAGICC and was updated from version 4.1 to be consistent with the IPCC Fourth Assessment Report, Working Group 1 (AR4).[2] (Version 4.1 uses the earlier IPCC Third Assessment Report, Working Group 1 (TAR) climate couplings.) Updates reflected in MAGICC version 5.3 include: LCFS 46-234

- Climate sensitivity estimates updated based on AR4;
- Revised climate forcing values consistent with AR4;
- Updated carbon cycle modeling and CO_2 concentration stabilization scenarios;
- More realistic sea level rise projection method; and
- Minor "balancing" revision to methane and nitrous oxide budgets.

For purposes of this analysis, the updated climate sensitivity estimate from AR4 is the most noteworthy. The default climate sensitivity for a doubling of CO_2 has been upwardly revised from 2.6°C to 3.0°C in MAGICC version 5.3.

The key parameters for the MAGICC v5.3 modeling were as follows:

a) "mid"-level response for the carbon cycle model,
b) carbon cycle climate feedbacks set to "on,"
c) "mid"-level response for aerosol forcing,
d) 3.0° C sensitivity for doubled CO_2,
e) "variable" thermohaline circulation,
f) vertical oceanic diffusion coefficient set to "2.3 cm^2/s," and
g) "mid"-level ice melt sensitivity.

[1] T.M.L. Wigley, "MAGICC/SCENGEN 5.3: User Manual," National Center for Atmospheric Research, Colorado, September 2008.
[2] The IPCC released its Fifth Assessment Report (AR5), in October 2014. The MAGICC model has not yet been updated to reflect AR5.

Again the 3.0° C sensitivity to doubled CO_2 is consistent with the assumptions used in the IPCC AR4 report, which is based on the assumption that the surface temperature record accurately reflects the effect of greenhouse gas concentrations on ambient temperatures. Explanations of the other parameters are available in the above-referenced user manual.

Emission Inputs – The baseline case assumed a future in which fossil fuels will continue to be consumed in a "business as usual" manner, but with new sources of energy mixing in to supply a balance of non-carbon emitting sources. This baseline emissions case (named A1B-AIM) produces total climate forcing in 2005 that most closely approximates that in IPCC AR4 (A1B=1.596 W/m^2, AR4=1.6 W/m^2). Two different alternative scenarios were run to evaluate the potential effect of the proposed LCFS as summarized below:

1. *LCFS-CA:* This scenario applied the CARB LCFS ISOR estimated reduction in CO_2 emissions from 2020 (20.7 MMT[3] CO_2e). These reductions were held constant on a relative basis from 2020 through 2050.

2. *LCFS-US:* This second scenario assumed the reductions estimated in the LCFS ISOR would be increased by a factor of 8.9 to scale the California reductions to the entire U.S. based on California vs. entire U.S. transportation source CO_2 emission estimates published by the U.S. Energy Information Administration (EIA).

LCFS 46-234 cont.

Table 1 summarizes the baseline global fossil fuel CO_2 emissions by calendar year from the AR4-A1B-AIM reference case contained in the MAGICC v5.3 emissions scenario library. The emission units for fossil CO_2 are petagrams (10^{15} grams) as noted at the bottom of Table 1. As shown in Table 1, baseline emissions under the AR4 A1B-AIM reference case are projected to rise steadily from 1990 through 2050, with 2050 emissions roughly 2.7 times higher than those in 1990.

Table 1
Baseline Scenario
Global Fossil Fuel CO_2 Emissions (Pg C[a])

Calendar Year	Annual Emissions
1990	5.991
2000	6.896
2010	9.680
2020	12.122
2030	14.011
2040	14.945
2050	16.009

[a] Petagrams of carbon; 1 petagram = 10^{15} grams

[3] MMT = million metric tons (1 metric ton = 1,000 kilograms or 1,000,000 grams)

Emissions under the LCFS-CA and LCFS-US scenarios were calculated from these baseline estimates as follows. First, the CARB ISOR LCFS emission reductions in 2020 (20.7 MMT CO_2e) were converted to "petagram carbon" units for input into MAGICC as follows:

$$20.7\ MMTCO2e \times \frac{12.01\ g/mole\ C}{44.01\ g/mole\ CO2} \times \frac{1\ Pg}{10^3\ MMT} = 5.65 \times 10^{-3}\ Pg\ C$$

This reduction in 2020 emissions estimated in the CARB ISOR represents a 0.0047% decrease (5.65×10^{-3}/12.112 Pg C) in global fossil CO_2 emissions relative to the 2020 baseline. Since the ISOR reductions are expressed on a CO_2 equivalent basis, they were applied to the fossil fuel carbon emission estimates in MAGICC (although the model also includes emission estimates for other GHG compounds.)

In applying this LCFS reduction beyond 2020, out to 2050, two approaches were considered: 1) using the same absolute reduction (5.65×10^{-3} Pg C) for each future year; and 2) applying the same relative 2020 reduction (0.0466%) in each future year. The relative reduction approach produced nominally greater reductions (i.e., lower emissions) in future years. Thus, the relative reduction-based emissions were used in the climate modeling.

These California LCFS emission reductions were extrapolated to the second scenario representing nationwide LCFS adoption based on a scaling multiplier developed from EIA estimates of calendar year 2011 transportation sector CO_2 emissions by individual state.[4] EIA estimated 2011 transportation sector emissions of 199.3 and 1,781.9 $MMTCO_2$ in California and the entire U.S., respectively. Thus a scaling factor of 8.94 was developed from this ratio (1781.9÷199.3). This scaling factor was then used to conflate the California LCFS reductions from the ISOR to the entire U.S. For example in 2020, U.S. LCFS reductions were calculated as follows:

LCFS-CA Relative Reduction × Scaling Factor × 2020 Global Emissions, or
0.0466% × 8.94 × 12.122 Pg C = 0.051 Pg C reduction in 2020 CO_2 emissions

Table 2 presents a comparison of the resulting global emission estimates input to the MAGICC model for the baseline case and each of the two LCFS reduction analysis scenarios. Note that these values are emissions, not LCFS reductions (which are represented by the difference between the baseline and scenario emissions in the table).

LCFS 46-234 cont.

[4] U.S. Energy Information Administration (EIA), 2011 State energy-related carbon dioxide emissions by sector, http://www.eia.gov/environment/emissions/state/analysis/.

Table 2 **Comparison of Baseline and LCFS Reduction Scenario Annual Emissions (Pg C) Used in MAGICC Modeling**			
Calendar Year	Baseline (A1B-AIM)	LCFS in California	LCFS in Entire U.S.
1990	5.991	5.991	5.991
2000	6.896	6.896	6.896
2010	9.680	9.680	9.680
2020	12.122	12.116	12.071
2030	14.011	14.004	13.953
2040	14.945	14.938	14.883
2050	16.009	16.002	15.942

The highlighted cells in Table 2 denote those years and emissions that reflect LCFS reductions relative to baseline estimates.

LCFS 46-234 cont.

Climate Modeling Results – Table 3 shows modeled changes in ambient temperature from a 1990 baseline temperature for each case. As shown in the table, the baseline case produces an estimated increase of 0.9952°C in calendar year 2050 over the 1990 baseline. The addition of the LCFS standard is estimated to reduce this temperature increase by two ten-thousandths of a degree (0.0002). Assuming roughly nine times greater reductions to reflect LCFS implementation throughout the U.S., the temperature increase is reduced by 2.0 thousandths of a degree (0.0020).

Table 3 **MAGICC Version 5.3 Model Results (°C) for Calendar Year 2050**		
Scenario	Temperature Change from 1990 Baseline	Change Due to LCFS
Baseline (IPCC Case A1B)	0.9552	n.a.
Low Carbon Fuel Standard in California	0.9550	0.0002
Low Carbon Fuel Standard throughout U.S.	0.9532	0.0020

46_OP_LCFS_GE Responses (Page 224 - 229)

566. Comment: **LCFS 46-234**

This comment is an analysis commissioned by the commenter to evaluate the impact of the LCFS carbon emission reductions on global climate change using the MAGICC model.

Agency Response: This comment does not constitute an objection or suggestion to the proposed regulation. If the commenter's point is that small improvements in the environment are not worthwhile, ARB disagrees. The California Legislature has determined that GHG reductions are worth pursuing.

STATE OF CALIFORNIA

BEFORE THE AIR RESOURCES BOARD

Declaration of James M. Lyons

I, James Michael Lyons, declare as follows:

1. I make this Declaration based upon my own personal knowledge and my familiarity with the matters recited herein. It is based on my experience of nearly 30 years as a regulator, consultant, and professional in the field of emissions and air pollution control. A copy of my résumé can be found in Attachment A.

2. I am a Senior Partner of Sierra Research, Inc., an environmental consulting firm located at 1801 J Street, Sacramento, California owned by Trinity Consultants, Inc. Sierra specializes in research and regulatory matters pertaining to air pollution control, and does work for both governmental and private industry clients. I have been employed at Sierra Research since 1991. I received a B.S. degree in Chemistry from the University of California, Irvine, and a M.S. Degree in Chemical Engineering from the University of California, Los Angeles. Before joining Sierra in 1991, I was employed by the State of California at the Mobile Source Division of the California Air Resources Board (CARB).

3. During my career, I have worked on many projects related to the following areas: 1) the assessment of emissions from on- and non-road mobile sources, 2) assessment of the impacts of changes in fuel composition and alternative fuels on engine emissions including emissions of green-house gases, 3) analyses of the unintended consequences of regulatory actions, and 4) the feasibility of compliance with air quality regulations.

4. I have testified as an expert under state and federal court rules in cases involving CARB regulations for gasoline, Stage II vapor recovery systems and their design, factors affecting emissions from diesel vehicles, evaporative emission control system design and function, as well as combustion chamber system design. While at Sierra I have acted as a consultant on automobile air pollution control matters for CARB and for the United States Environmental Protection Agency. I am a member of the American Chemical Society and the Society of Automotive Engineers and have co-authored nine peer-reviewed monographs concerned with automotive emissions including greenhouse gases and their control. In addition, over the course of my career, I have conducted peer-reviews of numerous papers related to a wide variety of issues associated with pollutant emissions and air quality.

5. This Declaration summarizes the results of analyses I have performed regarding CARB staff's analysis of different aspects of the re-adoption of the Low Carbon Fuel Standard (LCFS) Regulation and Regulation on the Commercialization of Alternative Diesel Fuels (ADFs) as an independent expert for Growth Energy. If called upon to do so, I would testify in accord with the facts and opinions presented here.

6. Based on a review of the Initial Statement of Reasons (ISOR) for the LCFS regulation and the associated appendices, including the draft Environmental Analysis, it is clear that CARB staff failed to quantify the GHG emission reductions associated with the LCFS regulation itself. Rather, staff notes that the GHG reduction estimates provide are inflated as the result of the "double counting" of GHG reductions due to other regulatory programs. LCFS 46-235

7. Further, this review shows that CARB staff failed to perform a complete analysis of the potential air quality impacts associated with the LCFS regulation. More specifically, CARB staff's air quality analysis fails to quantitatively assess the impact of the LCFS and ADF on all emission sources that could be affected nor does it consider all of the pollutants for which emission changes might occur. A summary of the review is Attachment B to this declaration. LCFS 46-236

8. CARB staff rejected a proposed alternative to the LCFS regulation submitted by Growth Energy claiming that it will likely result in the same environmental benefits, but not ensure a transition to lower carbon intensity fuels that CARB staff claims is the main goal of the LCFS regulation. As discussed in detail in Attachment C to this declaration, CARB staff failed to perform any analysis of the Growth Energy Alternative and has provided no support for this finding. Because the Growth Energy Alternative provides greater environmental benefits and is expected to cost less than the LCFS regulation, it must be adopted by CARB instead of the LCFS regulation. LCFS 46-237

9. As part of the development of the ADF regulation, CARB staff examined the impacts of the proposed regulation on emissions of pollutants including oxides of nitrogen (NOx) emitted from heavy-duty diesel engines operating on blends of diesel fuel and biodiesel.

10. NOx emissions directly affect atmospheric levels of nitrogen dioxide, a compound for which a National Ambient Air Quality Standards (NAAQS) has been established. NOx emissions are also precursors to the formation of ozone and particulate matter, which are also pollutants for which NAAQS have been established. Areas of the South Coast and San Joaquin Valley air basins are in extreme and moderate non-attainment of the most recent ozone and fine particulate standards, respectively. LCFS 46-238

11. In the Initial Statement of Reasons (ISOR) for the ADF regulation and its' appendices, CARB staff summarized its analysis of increases in NOx emissions from heavy-duty diesel vehicles over the period from 2014 through 2023. The results of the staff's analysis are most clearly summarized in Table B-1 of Appendix B of the ISOR. This table shows that staff estimate that biodiesel use allowed under the ADF regulation will increase NOx emissions by 1.35 tons per day in 2014 and that the magnitude of this emission increase will drop to 0.01 ton per day by 2023. ADF 17-18

12. I have performed a review of the staff's assessment of the NOx emission impacts of biodiesel use allowed under the ADF regulation presented in ISOR and its' appendices and find it to be fundamentally flawed such that it is not reliable. First, the bases for total diesel NOx emissions inventory is not described in the ISOR or in other ADF 17-19

documents in the record. Second, CARB staff incorrectly assumes that the use of biodiesel in "New Technology Diesel Engines (NTDEs)" equipped with exhaust aftertreatment devices to lower NOx emissions will not lead to increased NOx emissions. Third, CARB staff incorrectly apply ratios of on-road vehicle travel by NTDEs from the now obsolete EMFAC2011 model to account for the amount of biodiesel used in all NTDEs including those found in non-road equipment. Fourth, to assess the overall impact of the ADF regulation on NOx emissions, CARB incorrectly subtracts NOx reductions resulting from the use of "renewable diesel fuel" from increases in NOx emissions resulting from the use of biodiesel.

ADF 17-19 cont.

13. In addition, I have performed a very conservative assessment of the NOx emission impacts of biodiesel use under the ADF that uses the latest CARB emissions models and corrects the flaws in the staff analysis, a summary of which is attached. The results of this assessment indicate that NOx increases from biodiesel will be much larger than those estimated by CARB staff and that the magnitude of the impacts will not decline over time as forecast by CARB staff. In addition, the analysis shows that the ADF regulation will lead to significant increases in NOx emissions in the South Coast and San Joaquin Valley air basins which are already in extreme non-attainment of the federal ozone NAAQS and moderate non-attainment of the federal fine particulate NAAQS. The details of both the review and revised emissions estimates are presented in Attachment D to this declaration.

ADF 17-20

14. In addition to identifying a fundamentally flawed analysis of the increases in NOx emissions from biodiesel use under the ADF, my review indicates that other elements of the staff's air quality and environmental analyses are also fundamentally flawed. These include incorrectly selecting 2014 as the baseline year for the environmental analysis, lacking documentation and using unsupported assumptions in determination of the NOx control level for biodiesel, and unnecessarily delaying the effective date for the implementation of mitigation requirements under the ADF regulation. All of these issues, which are discussed in detail in Attachment E, cause the adverse environmental impacts of the ADF regulation to be greater than purported by CARB staff.

ADF 17-21

15. Another important issue that I have identified with the ADF regulation is that it and the related LCFS and California Diesel regulations contain inconsistent and conflicting definitions and lack provisions requiring the determination, through testing, of the biodiesel content of commercial blendstocks. As a result, there is a clear potential for biodiesel blends to actually contain as much as 5% more biodiesel by volume than will be reported to CARB under the ADF regulation. A detailed discussion of the flaws in the ADF regulation that could allow this to occur is provided in Attachment F. Actual biodiesel levels above those reported under the ADF will lead to larger unmitigated increases in NOx emissions than have been estimated by either CARB staff or me.

ADF 17-22

16. CARB staff has rejected a proposed alternative to the ADF regulation submitted by Growth Energy, claiming that it will result in the same environmental benefits but be more costly than the staff proposal. As discussed in detail in Attachment G to this declaration, this finding is based on the same fundamentally flawed emissions

ADF 17-23

analysis performed by CARB staff that is discussed above. Given that the Growth Energy alternative is designed to mitigate all potential increases in NOx emissions (when assessed in light of a proper emissions analysis) due to biodiesel use under the ADF as soon as the regulation becomes effective, it yields greater and more timely environmental benefits than the staff proposal. In addition, the Growth Energy alternative would require the same mitigation techniques as the ADF regulation, but simply expands the circumstances under which they must be applied, and has an estimated cost-effectiveness equal to that of ADF regulation. Because the Growth Energy Alternative provides greater environmental benefits as cost-effectively as the ADF regulation, it must be adopted by CARB instead of the ADF regulation. ADF 17-23 cont.

I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct.

Executed this 17th day of February, 2015 at Sacramento, California.

Résumé

James Michael Lyons

Education

1985, M.S., Chemical Engineering, University of California, Los Angeles

1983, B.S., Cum Laude, Chemistry, University of California, Irvine

Professional Experience

4/91 to present — Senior Engineer/Partner/Senior Partner
Sierra Research

Primary responsibilities include oversight and execution of complex analyses of the emission benefits, costs, and cost-effectiveness of mobile source air pollution control measures. Mr. Lyons has developed particular expertise with respect to the assessment of control measures involving fuel reformulation, fuel additives, and alternative fuels, as well as accelerated vehicle/engine retirement programs, the deployment of advanced emission control systems for on- and non-road gasoline- and Diesel-powered engines, on-vehicle evaporative and refueling emission control systems, and Stage I and Stage II service station vapor recovery systems. Additional duties include assessments of the activities of federal, state, and local regulatory agencies with respect to motor vehicle emissions and reports to clients regarding those activities. Mr. Lyons has extensive litigation experience related to air quality regulations, product liability, and intellectual property issues.

7/89 to 4/91 — Senior Air Pollution Specialist
California Air Resources Board

Supervised a staff of four professionals responsible for identifying and controlling emissions of toxic air contaminants from mobile sources and determining the effects of compositional changes to gasoline and diesel fuel on emissions of regulated and unregulated pollutants. Other responsibilities included development of new test procedures and emission standards for evaporative and running loss emissions of hydrocarbons from vehicles; overseeing the development of the state plan to control toxic emissions from motor vehicles; and reducing emissions of CFCs from motor vehicles.

4/89 to 7/89 Air Pollution Research Specialist
California Air Resources Board

Responsibilities included identification of motor vehicle research needs; writing requests for proposals; preparation of technical papers and reports; as well as monitoring and overseeing research programs.

9/85 to 4/89 Associate Engineer/Engineer
California Air Resources Board

Duties included analysis of vehicle emissions data for trends and determining the effectiveness of various types of emissions control systems for both regulated and toxic emissions; determining the impact of gasoline and diesel powered vehicles on ambient levels of toxic air contaminants; participation in the development of regulations for "gray market" vehicles; and preparation of technical papers and reports.

Attachment B

Review of CARB Staff's Analysis of the GHG and Air Quality Impacts of the LCFS Regulation

In developing the proposed Low Carbon Fuel Standard (LCFS) regulation for re-adoption, CARB staff purports to have performed an analysis of the impacts that the regulation will have on emissions of both greenhouse gases and air pollutants. However, as is documented below, a review the CARB analysis demonstrates that the staff's analysis is incomplete and unsuitable for use in determining whether or not all adverse impacts have been identified and properly quantified, and all mitigation measures have been appropriately considered.

Summary of the CARB Staff Air Quality Analysis

On December 30, 2014, CARB staff released the proposed LCFS regulation language and the accompanying Initial Statement of Reasons (ISOR), Draft Environmental Analysis, and other supporting documents. Staff's analysis of the impact of the LCFS proposed for re-adoption is contained in Chapter IV of the ISOR as well as in Chapter 4.3. of the Draft Environmental Analysis. LCFS 46-239

In Table IV-2 of Chapter IV of the ISOR, CARB staff provides unsupported estimates of the reduction in GHG emissions associated with the LCFS regulation proposed for re-adoption. However, by CARB staff's own admission, the estimates presented in Table IV-2:

> …*do not include a reduction to eliminate the double counting of the Zero Emission Vehicle mandate, the federal Renewable Fuels Standard program, the Pavley standards, or the federal Corporate Average Fuel Economy program.* LCFS 46-240

Given that CARB staff has failed to estimate and report the GHG reduction benefits of the LCFS regulation proposed for re-adoption separately from other regulations that also seek to reduce GHG emissions from mobile sources, the Board and the public do not know the actual benefits expected to result from the regulation nor can alternatives to the LCFS regulation be properly evaluated by CARB staff.

Turning to the air quality analysis in Chapter IV of the ISOR, CARB staff provides a general discussion of emissions associated with transportation fuel production at California refineries, as well as ethanol, biodiesel, renewable diesel, and potential cellulosic ethanol facilities. Emission factors in, terms of pollutant emissions per year per million gallons of fuel produced, are provided for some facilities. CARB staff also provides an undocumented analysis of NOx and $PM_{2.5}$ emissions associated with "...*the movement of fuel and feedstock in heavy-duty diesel trucks and railcars*" with and LCFS 46-241 without the LCFS and ADF regulations in place. No other assessment of the air quality impacts associated with the LCFS is provided in the LCFS ISOR. LCFS 46-241 cont.

As noted above, the draft Environmental Analysis (EA) for the LCFS and ADF, which is Appendix D to both the LCFS and ADF ISORs, also addresses air quality in Chapter 4.3. Here, short term air quality impacts related to the construction of projects of various types related to the production and distribution of lower carbon intensity fuels under the LCFS are presented. There is, however, no analysis that indicates where these projects will be located within California, nor any quantitative assessment of the emission and environmental impacts beyond the following:

> *Based on typical emission rates and other parameters for abovementioned equipment and activities, construction activities could result in hundreds of pounds of daily NO_x and PM emissions, which may exceed general mass emissions limits of a local or regional air quality management district depending on the location of generation. Thus, implementation of new regulations and/or incentives could generate levels that conflict with applicable air quality plans, exceed or contribute substantially to an existing or projected exceedance of State or national ambient air quality standards, or expose sensitive receptors to substantial pollutant concentrations.*

LCFS 46-242

There is also a general discussion of potential approaches to mitigation, which CARB staff concludes are outside of the agency's authority to adopt. Ultimately, the draft EA concludes that the "short-term construction-related air quality impacts…associated with the proposed LCFS and ADF regulations would be potentially significant and unavoidable." LCFS 46-243

The draft EA also purports to assess the long-term impacts of the LCFS and ADF regulations, but addresses and attempts to quantify only potential increases in NOx emissions due to the use of biodiesel fuels, and concludes with CARB staff ultimately claiming that the long term impacts of the LCFS and ADF on air quality will be "beneficial." LCFS 46-244

Review of the CARB Staff Air Quality Analysis

As summarized above, the air quality related analyses performed by CARB staff regarding the proposed LCFS regulation are both limited and cursory. In order to demonstrate that this is in fact the case, one has to look no further than the air quality analysis CARB staff performed in 2009 to support the original LCFS rulemaking.[1] LCFS 46-245

[1] California Air Resources Board, Proposed Regulation to Implement the Low Carbon Fuel Standard, Volume I: Staff Report: Initial Statement of Reasons, March 5, 2009 and Volume II: Appendices, March 5, 2009. See in particular, Chapter VII of the ISOR and Appendix F.

The first point of note is that in the 2009 ISOR, CARB staff presents quantification of the GHG reductions expected from the LCFS occurring both in California and worldwide in Tables VII-1 and VII-2. While, those estimates have no relevance to the current rulemaking given the differences in the two regulations, fundamental changes in CARB's expectations with respect to how fuel producers will comply with a LCFS regulations, as well as the evolution of methodologies for estimating GHG emissions, provide clear evidence that the GHG emission benefits of the proposed LCFS can and should be explicitly quantified without any "double counting" of the benefits due to other regulatory programs. It should also be noted that in the 2009 ISOR, CARB staff also breaks down the GHG emission benefits expected from specific substitutes for gasoline and diesel fuel. LCFS 46-246

Turning to the air quality analysis itself, the lack of documentation provided precludes any detailed review of the accuracy of the assumptions and methodologies underlying the analysis or any effort to attempt to reproduce the staff's results. Given this lack of documentation, additional information was requested from CARB. As part of this request, Sierra Research pointed out that pursuant to the requirements of AB 1085, the agency had provided far more detailed information for other recent major rulemakings, including the Advanced Clean Cars program, than it released regarding the LCFS and ADF proposals. Unfortunately, CARB staff choose not to provide any additional information related to the analyses underlying the proposed LCFS and ADF regulations. LCFS 46-247

Another striking contrast which highlights the superficiality of the air quality analysis performed for the re-adoption of the LCFS can be seen in the treatment of potential emission impacts associated with the development of biofuel production facilities in California. These impacts are particularly important because the form of the LCFS regulation provides incentives to build biofuel production facilities in areas of California that violate federal National Ambient Air Quality standards, rather than in other states that are in compliance with those standards. The incentive for locating biofuel plants in California is to avoid GHG emissions from fuel and/or feed stock transportation which result in higher carbon intensity values. LCFS 46-248

As noted above, the air quality analysis for the re-adoption of the LCFS presented in section IV of the ISOR provides only estimates for existing California biofuel production facilities and the potential emissions of NO_x, PM_{10}, and volatile organic compounds (VOCs) associated with a hypothetical "northern California" cellulosic ethanol plant. In contrast, in the 2009 ISOR, staff provides a quantitative estimate of the overall number and types of new biofuel production facilities expected to be built in California (Table VII-6 of the 2009 ISOR) as well as a distribution of the number and type of plants expected to be built in eight of the state's air basins and a map showing expected locations. The increases in emissions of not only NO_x, PM_{10}, and VOC, but also carbon monoxide (CO) and $PM_{2.5}$ associated with these biodiesel production facilities were quantified by CARB staff (Table V11-10 of the 2009 ISOR). Again, although the data presented in the 2009 LCFS ISOR are irrelevant with respect to the current re-adoption of the LCFS regulation, the same level of detail and scope of the analysis performed by CARB staff in 2009 should have at a minimum been applied to the current LCFS air quality analysis. LCFS 46-249

Another issue noted with the air quality analysis performed for the re-adoption of the LCFS is related to emission impacts associated with "fuel and feedstock transportation and distribution." LCFS 46-250

The total impact of the LCFS and ADF on NOx and $PM_{2.5}$ emissions from these activities, which constitute a long term operational impact on air quality, are quantified in Table IV-16 of the ISOR. However, the documentation provided describing how the staff's analysis was performed is insufficient to allow one to either review or reproduce it. Further, these emissions are not addressed in the appropriate section of the draft EA. Given that staff estimates that the LCFS/ADF will increase these emissions, they should be identified and assessed as part of the draft EA, particularly given that staff has concluded that the LCFS/ADF impacts on long term air quality are beneficial without considering fuel and feedstock transportation and distribution emissions. The current analysis of these emissions also falls far short of the level of detail shown in the analysis of the same issue performed by CARB staff in the 2009 ISOR, as can be seen in Table VII-11 where impacts on VOC, CO, PM_{10}, and oxides of sulfur (SO_x) were reported by low CI fuel type. LCFS 46-250 cont.

Again, as noted above, the only issue addressed with respect to long term LCFS/ADF air quality impacts in the draft EA are potential NOx emission increases due to the use of biodiesel blends. LCFS 46-251 As discussed in detail elsewhere,[2] the analysis upon which the draft EA and its conclusions are based is fundamentally flawed. However, the air quality analysis in the draft EA is also incomplete in that it fails to address long term changes in motor vehicle emissions beyond those associated with biodiesel and renewable diesel. That such impacts should have been addressed for the current rulemaking can be seen from the CARB staff air quality analysis included in the 2009 ISOR and presentation, which included detailed estimates of motor vehicle impacts on VOC, CO, NOx, SOx, PM_{10}, and $PM_{2.5}$ (rather than just NOx and $PM_{2.5}$) as a function of vehicle and fuel type in Table VII-12. LCFS 46-252

In addition to the above, two other important issues are: 1) CARB staff's failure to even attempt to quantify construction emissions associated with biofuel production facilities in California after finding them to be potentially significant and unavoidable; and 2) to identify and quantify LCFS 46-253 potential emission increases associated with an increase in the number of tanker visits to California ports as the result of the ADF and LCFS regulations. With respect to the former, a California specific tool, CalEEmod,[3] is readily available that could have been used by CARB staff in estimating construction impacts form biofuel plants located in California. LCFS 46-254

With respect to the latter, it should be noted that although CARB staff concluded in the 2009 LCFS air quality analysis that there would be "little to no change to emissions at ports," that analysis predates the current proposal[4] regarding the assignment of CI to crude oil which are likely to encourage crude oil shuffling; as well as CARB staff assumptions regarding increases in assumed volumes of renewable diesel fuel potentially coming to California from production facilities in Asia, and the potential for direct importation of cane ethanol into California from Brazil. These factors will undoubtedly result in increased tanker operations in California waters the emission impacts of which can be estimated using the Emissions Estimation Methodology for Ocean-Going Vessels available on CARB's emission inventory website. According to this source, 1,919 visits by crude oil and petroleum product tankers are forecast for 2015 with roughly 50% percent of those trips involving southern California ports that are part of the South LCFS 46-255

---

[4] See proposed section 95489, Title 17 CCR in LCFS ISOR Appendix A.

Coast air basin. The emissions estimated by CARB to be associated with one tanker visit to California are presented in Table 1. As shown, the tanker emissions associated with a single new visit far exceed the NOx, $PM_{2.5}$ and SOx significance thresholds. Given that multiple new tanker visits are likely to result from the LCFS and ADF regulations, these values demonstrate that CARB staff has failed to identify a potentially significant source that will created adverse air quality impacts in its draft EA.

LCFS 46-255 cont.

Table 1
Comparison of Tanker Emissions During A Single Visit to California with South Coast Air Quality Management District Air Quality Significance Thresholds

Pollutant	Significance Threshold (lbs/day)	Tanker Emissions (lbs)
NOx	55	7,700
VOC	55	283
PM_{10}	150	290
$PM_{2.5}$	55	283
SOx	150	1,780
CO	550	629

Attachment C

The Growth Energy Alternative to the Proposed LCFS Regulation is the Least-Burdensome Approach that Best Achieves the Project Objectives at the Least Cost That Must be Adopted

As part of the rulemaking process leading to CARB staff's proposed re-adoption of the LCFS regulation, staff was required to solicit and consider alternatives to the proposed regulation. Growth Energy submitted such an alternative. While CARB staff acknowledged that the Growth Energy alternative could provide equivalent reductions in GHG emissions, the agency rejected it from further consideration or analysis by stating only that it was insufficient to transition California to alternative, lower carbon intensity fuels. As discussed below, CARB staff's premise for rejecting the Growth Energy alternative is incorrect. Further, given that the Growth Energy Alternative achieves the same environmental benefits through reductions in GHG emissions as the LCFS regulation, likely at the same or lower cost, it should have been analyzed by CARB staff, in which case it would have to be adopted as the least-burdensome approach the best achieves the project objectives at the least cost. LCFS 46-256

<u>Background</u>

On May 23, 2014, CARB published a "Solicitation of Alternatives for Analysis in the LCFS Standardized Regulatory Impact Assessment" which is attached. On June 5, CARB published a response to a request from Growth Energy extending the deadline for the submission of alternatives from June 5, 2014 to June 23, 2014. On June 23, 2014, Growth Energy submitted an alternative regulatory proposal for the LCFS regulation (which is attached) to CARB in response to the agency's solicitation. On December 30, 2014, CARB staff published both the ISOR for the LCFS regulation as well as a document entitled "Summary of DOF Comments to the Combined LCFS/ADF SRIA and ARB Responses," which is Appendix E to the LCFS ISOR. Appendix E discusses the Growth Energy LCFS alternative and CARB's reason for its rejection.

The staff's assessment of the Growth Energy (GE) Alternative published in Appendix E of the LCFS ISOR is as follows (emphasis added): LCFS 46-257

> *The proposed alternative assumes that the exclusive goal of the LCFS proposal is to achieve GHG emissions reductions without regard to source. If that were the case, this would be a viable alternative to the LCFS and would be assessed in this analysis. It is likely true that the estimated GHG emissions reductions appearing in the 2009 LCFS Initial Statement of Reasons (California Air Resources Board, 2009) could be achieved by the AB 32 Cap-and-Trade Program, along with the other programs cited by Sierra Research and Growth Energy. The LCFS proposal, however, was designed to address the carbon intensity of transportation*

fuels. Transportation in California was powered almost completely by petroleum fuels in 2010. Those fuels were extracted, refined, and distributed through an extensive and mature infrastructure. Transitioning California to alternative, lower-carbon fuels requires a very focused and sustained regulatory program tailored to that goal. The other regulatory schemes the alternative would rely on are comparatively "blunt instruments" less likely to yield the innovations fostered by the LCFS proposal. In the absence of such a program, post-2020 emissions reductions would have to come from a transportation sector that would, in all likelihood, have emerged from the 2010-2020 decade relatively unchanged.

In the absence of an LCFS designed to begin the process of transitioning the California transportation sector to lower-carbon fuels starting in 2010, post-2020 reductions would be difficult and costly to achieve. This is why the primary goals of the LCFS are to reduce the carbon intensity of California fuels, and to diversify the fuel pool. A transportation sector that achieves these goals by 2020 will be much better positioned to achieve significant GHG emissions reductions post 2020.

LCFS 46-257 cont.

ARB is required to analyze only those alternatives that are reasonable and that meet the goals of the program as required by statute. An initial assessment of the program indicates the goals of the LCFS proposal can be achieved by keeping the program "…separate of the AB 32 Cap-and-Trade system initially (at least first 10 years) in order to stimulate innovation and investment in low-GWI [global warming intensity] fuel (or transportation) technologies."[16] Due to the strong justifications that the Cap-and-Trade program alone generates neither the CI reductions nor fuel in the transportation sector, this alternative will not be assessed in this document.

A Low-Carbon Fuel Standard for California, Part 2: Policy Analysis – FINAL REPORT, University of California Project Managers: Alexander E. Farrell, UC Berkeley; Daniel Sperling, UC Davis. Accessed: 7-15-2015 http://www.energy.ca.gov/low_carbon_fuel_standard/

Discussion

Given that there is no analysis or other support provided by CARB staff for the assertions it makes in rejecting the Growth Energy alternative other than the one reference, which dates to 2007—before either the original LCFS or Cap-and-Trade regulation were adopted was reviewed. The discussion of interactions between a LCFS program with AB32 regulations from the reference is provided below. As can be determined by the reader, the discussion was written before the AB32 regulations were adopted, and the basic concern expressed is that the lower cost of achieving the same GHG reductions from a broader program will be lower than the cost of doing the same from the LCFS

LCFS 46-258

program. Further, the concern expressed regarding lifecycle emission under the LCFS was explicitly addressed in the Growth Energy alternative.

5.2 Interactions with AB32 regulations

RECOMMENDATION 16: The design of both the LCFS and AB32 polices must be coordinated and it is not possible to specify one without the other. However, it is clear that if the AB32 program includes a hard cap, the intensity-based LCFS must be separate or the cap will be meaningless. Including the transport sector in both the AB32 regulatory program and LCFS will provide complementary incentives and is feasible. CARB will soon be developing regulations under AB32 to control GHG emissions broadly across the economy, most likely through a cap-and-trade system plus a set of regulatory policies. Thus, emissions from electricity generation, oil production, refining, and biofuel production are likely to be regulated directly under AB32. These energy production emissions are "upstream" in a fuel's life cycle (while emissions from a vehicle are "downstream"). The recent Market Advisory Committee report recommends including all CO2 emissions from transportation, including tailpipe emissions.

LCFS 46-258

The LCFS regulates consumption emissions—the full life cycle emissions associated with products consumed in California, while it is expected that sector-specific emission caps will be imposed by AB 32 on production emissions—the emissions that are directly emitted within the borders of the state. The different types of boundaries used by these regulations causes certain upstream emissions to be double regulated under the LCFS and AB32. However, the potential for double regulation only applies to fuel production processes in the state of California or other jurisdictions where legislation similar to AB 32 also applies. We agree with the Market Advisory Committee that the LCFS and AB32 regulations will provide complementary incentives and that transportation emissions of GHGs should be included in the AB32 program.

There is no inherent conflict between the LCFS and AB32 caps; both are aimed at reducing GHG emissions and stimulating innovation in low-carbon technologies and processes. However, there are some differences. Most importantly, the LCFS is designed to stimulate technological innovation in the transportation sector specifically, while the broader AB32 program will stimulate technological innovation more broadly. The concerns associated with market failures and other barriers to technological change in the transportation sector (discussed in Section 1.3 of Part 1 and Section 2.3 of Part 2) are the motivation for adopting the sector-specific LCFS. These concerns suggest separating the LCFS from the AB32 emission caps.

The second key difference is that as a product standard using a lifecycle approach, the LCFS includes emissions that occur outside of the state such as *those associated with biofuel feedstock production and the production of imported crude oil. These emissions will not be included in the AB32 regulations.*

The third difference is in expected costs. In the absence of transaction costs and other market imperfections, economic theory suggests that a broader cap-and-trade program will be less costly than a narrower one. By allowing more sectors and more firms to participate in a market for emission reductions, one reduces the cost to achieve a given level of emission reductions -- suggesting that the LCFS be linked to the broader AB 32 regulatory system. In addition, commercially available low-carbon options exist in the electricity and other sectors, but not in transportation fuels (see Part 1 of this study, Section 1.3).

The specific regulations and market mechanisms used to implement AB32 are not yet determined, so it is not possible at this time to specify how the LCFS should interact with them. The ARB should carefully consider the differences in incentives and constraints that the combination of rules will create.

LCFS 46-258 cont.

Returning to the issue of diversification of the transportation fuel sector, CARB concerns are directly refuted by Growth Energy's submission. As noted on pages 9 and 10, ethanol will be added to California gasoline, and renewable diesel and biodiesel will be blended into California diesel fuel as the result of the federal RFS program. The range of fuels and feedstocks from which they are produced under the RFS will be diverse. For example, the following fuel/feedstock pathways, among others, are currently recognized by U.S. EPA under the RFS:[1,2,3,4,5]

- Ethanol from
  - Corn
  - Sugar cane
  - Grain sorghum
  - Celluosic materials
- Biodiesel from
  - Camelina oil
  - Soy bean oil
  - Waste oils, fats and greases
  - Corn oil
  - Canola/rapseed oil
- Renewable diesel from
  - Waste oils, fats and greases

LCFS 46-259

[2] EPA-420-F-14-045
[3] EPA-420-F-12-078
[4] EPA-420-F-11-043
[5] EPA-420-F-10-007

- Renewable gasoline from
  - Crop residue and municipal solid waste

- Renewable natural gas from
  - Landfills
  - Digesters

LCFS 46-259 cont.

As can be seen from Appendix B to the LCFS ISOR, these are many of the fuels that CARB staff also expects to be used in California under the LCFS. Similarly, electricity and hydrogen will be used as transportation fuels in California given the states regulatory mandates for the production of vehicles that operate on these fuels under the Advanced Clean Cars program. Further, in later years these fuels are expected to be required in heavy-duty vehicles as CARB adopts regulations under its proposed Sustainable Freight Transport Initiative, the purpose of which is stated by CARB staff as follows:

> *The purpose of the Strategy is to identify and prioritize actions to move California towards a sustainable freight transport system that is characterized by improved efficiency, zero or near-zero emissions, and increased competitiveness of the logistics system.*

It should also be noted that fuel providers in California will still be incentivized to provide these fuels in California under the Growth Energy alternative in order to reduce the number of GHG credits they will be required to retire under cap-and-trade program. LCFS 46-260

Finally, on pages 15 and 16, Growth Energy's proposal for addressing the loss of upstream emission benefits from the LCFS regulation is explicitly discussed.

Given that the Growth Energy alternative:

1. Provides, as determined by CARB staff, the same GHG reductions as the LCFS regulation; and

2. Is expected to result in lower costs of compliance than the LCFS.

CARB must adopt the Growth Energy alternative as it better achieves the stated project objectives in an equally cost-effective manner.

Attachment D

Review of CARB Staff Estimates of NOx Emission Increases Associated with the Use of Biodiesel in California Under the Proposed ADF Regulation

In developing the proposed Alternative Diesel Fuel (ADF) regulation, CARB staff has performed a statewide analysis of the increase in NOx emissions that is currently occurring in California due to the use of biodiesel, as well as the increases in NOx emissions that can be expected in the future due to the continued use of biodiesel in California under the proposed ADF regulation. As documented below, a review of the CARB staff analysis performed by Sierra Research demonstrates that the staff's analysis is fatally flawed and cannot be relied upon. Given this, Sierra Research has performed an analysis, also documented below, that demonstrates there will be substantial increases in NOx emissions if the ADF regulation is implemented as proposed. The significance in the NOx emissions increase associated with the use of biodiesel under the proposed ADF is clear given the dramatic reductions which CARB, the South Coast Air Quality Management District, and the San Joaquin Air Pollution Control District are seeking given their "extreme" non-compliance status with respect to the federal National Ambient Air Quality Standard for ozone.[1] This significance is also reinforced by a comparison of the estimated increase in NOx emissions from biodiesel under the proposed ADF regulation with the benefits of proposed and adopted NOx control measures intended for implementation on a statewide basis as well as in the South Coast and San Joaquin Valley air basins, respectively. ADF 17-24

<u>Review of the CARB Staff Analysis</u>

On December 30, 2014, CARB staff released the proposed ADF regulation language and the accompanying Initial Statement of Reasons (ISOR), technical and economic support information, and draft environmental analysis. Staff's analysis of the impact of the proposed ADF regulation on NOx emissions and supporting information and assumptions are contained in Chapters 6 and 7 of the ISOR, as well as Appendix B entitled "Technical Supporting Information."

The first issue that was identified with the staff's emissions analysis is that the information and data supplied by CARB staff are insufficient to determine exactly how the analysis was performed. Specifically, CARB staff provides no source for the values in Table B-1 labeled "Emission Inventory (Diesel TPD)," which are key to the analysis. As illustrated below, a clear understanding of what diesel sources (e.g., on-road heavy-duty, non-road, marine, locomotives, etc.) are included in the "inventory" is critical to assessing the accuracy of the staff's analysis. ADF 17-25

---

[1] It should be noted that the CARB statewide analysis fails to provide any estimate of the impacts of increased NOx emissions from the ADF regulation in these air basins, where the agency has stated that massive reductions in NOx emissions are required to achieve compliance with federal air quality standards.

Given the lack of documentation regarding the source of the diesel emission inventory values, additional information regarding this analysis as well as other analyses associated with the ADF and Low Carbon Fuel Standard (LCFS) rulemakings was requested. As part of this request, Sierra Research pointed out that pursuant to the requirements of AB 1085, the agency had provided far more detailed information for other recent major rulemakings, including the Advanced Clean Cars program, than it released regarding the LCFS and ADF proposals. Unfortunately, CARB staff choose not to provide any additional information related to the analyses underlying the proposed LCFS and ADF regulations.[2]

Despite the lack of all the information necessary to fully review the CARB staff analysis, it was possible to discern some key assumptions and the general methodology that was applied. The following key assumptions were identified:

1. Actual biodiesel use and the total demand for diesel fuel and substitutes in California will exactly match that forecast by CARB staff in the "illustrative compliance scenarios" developed as part the LCFS rulemaking;[3] ADF 17-26

2. Actual renewable diesel use in California will exactly match that forecast by CARB staff in the "illustrative compliance scenarios" developed as part the LCFS rulemaking;[2]

3. Forty percent of renewable diesel delivered to California will be used directly by refiners to comply with the requirements of CARB's existing diesel fuel regulations[4] while the remaining 60% will be blended into fuel that complies with the diesel fuel regulations downstream of refineries;

4. The use of biodiesel up to the B20 level in New Technology Diesel Engines[5] (NTDEs, which employ exhaust aftertreatment systems to reduce NOx emissions) will not result in any increase in NOx emissions;

5. The use of biodiesel in heavy-duty diesel engines other than NTDEs—which are referred to by CARB staff as "legacy vehicles"—will increase NOx linearly with increasing biodiesel blend content, up to a 20% increase for B100;

---

[2] See attached emails from Jim Lyons of Sierra to Lex Mitchel and other CARB staff from January 2015.
[3] These are presented in Appendix B to the LCFS ISOR.
[4] Sections 2281 to 2284, Title 13, California Code of Regulations.
[5] Proposed section 2293.3 Title 13 CCR (see Appendix A to the LCFS ISOR) defines a New Technology Diesel Engines as:

a diesel engine that meets at least one of the following criteria:

(A) Meets 2010 ARB emission standards for on-road heavy duty diesel engines under section 1956.8.
(B) Meets Tier 4 emission standards for non-road compression ignition engines under sections 2421, 2423, 2424, 2425, 2425.1, 2426, and 2427.
(C) Is equipped with or employs a Diesel Emissions Control Strategy (DECS), verified by ARB pursuant to section 2700 et seq., which uses selective catalytic reduction to control Oxides of Nitrogen (NOx).

6. The blending of renewable diesel downstream of refineries will reduce NOx emissions from legacy vehicles, with each 2.75 gallons of renewable diesel blended offsetting the emissions increase associated with each gallon of biodiesel used; and

7. During the period from 2018 to 2020, 30 million gallons of biodiesel will be blended to the B20 level for use in legacy vehicles each year, and will therefore be subject to the mitigation requirements of the proposed ADF regulation and will not cause an increase in NOx emissions. Furthermore, this volume will increase to 35 million gallons per year from 2021 to 2023.

Based on the above assumptions, CARB staff followed the methodology steps outlined below for estimating biodiesel impacts.

1. The fraction of legacy vehicles in a given year is determined by subtracting the percentage of vehicle miles traveled by on-road heavy-duty vehicles with NTDEs from 100%.

2. The fraction of legacy vehicles from Step 1 is multiplied by the total volume of biodiesel assumed to be consumed in a given year to yield the number of gallons of biodiesel used in legacy vehicles in that year.

3. For years 2018 and later, the amount of biodiesel assumed to be sold as emissions-mitigated B20 in a given year is subtracted from the total volume of biodiesel used in legacy vehicles in that year.

4. The total volume of renewable diesel assumed to be sold in a given year is multiplied by the percentage of legacy vehicles in that year and then multiplied by 0.6 to account for renewable diesel used in refineries to yield the amount of renewable diesel creating reductions in NOx emissions from legacy vehicles in that year.

5. The amount of renewable diesel used in legacy vehicles is then divided by 2.75 to determine the number of gallons of biodiesel for which NOx emissions have been offset for that year.

6. The number of gallons of biodiesel for which NOx emissions have been offset, as determined in Step 5, is then subtracted from the amount of biodiesel used in legacy vehicles, as determined in Step 3, to yield the total number of gallons of biodiesel used in legacy vehicles that cause increased NOx emissions for that given year.

7. The biodiesel volume from Step 6 is multiplied by the assumed NOx increase of 20% for B100 and then divided by the total volume of diesel fuel forecast to be used in that year to get the percentage increase in diesel emissions for that year.

ADF 17-26
cont.

8. The value from Step 7 is multiplied by the assumed Diesel Emissions inventory for that year to yield the final estimate of increased NOx emissions due to biodiesel in units of tons per day for the entire state of California.

ADF 17-26 cont.

Using the above methodology, CARB staff estimates that use of biodiesel in California led to a 1.36 ton per day increase in NOx emissions in 2014, and that the proposed ADF regulation will reduce the magnitude of that increase through 2023 down to 0.01 ton per day.[6]

The review of the staff's emission analysis identified two major issues in addition to the lack of documentation regarding how the diesel "Emission Inventory" values used by staff were developed:

1. Assuming that biodiesel use in NTDEs at levels up to B20 will not increase NOx emissions; and ADF 17-27

2. Assuming that biodiesel NOx emissions are offset by the use of renewable diesel fuel. ADF 17-28

Beginning with NTDEs, it has been demonstrated[7] that the available data indicate not only that NOx emissions from NTDEs will increase with the use of biodiesel in proportion to the amount of biodiesel present in the blend, but also that the magnitude of the increase on a percentage basis will be much greater than that observed for "legacy vehicles." At the B20 level where CARB staff assumed that there will be no NOx increase, the best current estimate is that NTDE NOx emissions will be increased by between 18% and 22%. CARB staff's failure to account for increased NOx emissions from NTDEs renders the staff's emission analysis meaningless in terms of assessing the adverse environmental impacts of the proposed ADF regulation. Another problem with CARB staff's treatment of NTDEs is that they have incorrectly assumed that the penetration of NTDEs into the on-road fleet is equal to that in the non-road fleet. NTDE penetration rates into the non-road fleet will be delayed due to the later effective date of the Tier 4 Final standards, relative to the 2010 on-road standards, and by the fact that while newer trucks dominate on-road heavy-duty vehicle operation, that effect does not occur in the non-road vehicle population.

ADF 17-27 cont.

Similarly, there are fundamental flaws with CARB staff's assumption that the use of renewable diesel will offset increased NOx emissions due to the use of biodiesel. First, it must be noted that there is nothing in either the proposed ADF regulation or the proposed LCFS regulation that mandates the use of any volume of biodiesel in California, much less the use of the exact ratio of renewable diesel to biodiesel assumed by CARB staff in its emissions analysis. Second, based on a review of the ADF and LCFS ISORs and supporting materials, there is no apparent basis for the staff's assumption that 40% of renewable diesel used in California will be used by refiners to aid in compliance with CARB's existing diesel fuel regulations, and that 60% will be blended downstream of refineries. To the extent that fuel producers choose to blend renewable diesel in California, one would expect them to do so by purchasing renewable diesel for use at their

ADF 17-28 cont.

---

[6] Table B-1, Appendix B of the ADF ISOR.
[7] "NOx Emission Impacts of Biodiesel Blends," Rincon Ranch Consulting, February 17, 2015.

refineries where they can benefit from the other desirable properties of this fuel beyond its low carbon intensity (CI) value (e.g., high cetane number and fungibility with diesel fuel at all blend levels), rather than by purchasing LCFS credits generated by downstream blenders of renewable diesel fuel.

ADF 17-28 cont.

To illustrate the magnitude of the significance of CARB's flawed assumptions regarding NTDEs and renewable diesel, if one simply and extremely conservatively assumes that NTDE NOx increases will be the same on a percentage basis as legacy vehicles and eliminates the NOx offsets assumed from renewable diesel, the NOx increases expected from biodiesel increase from 1.35 tons per day statewide in 2014 to approximately 3.44 tons per day—a factor of about 2.65. For 2023, estimated NOx emission increases due to biodiesel rise to about 0.87 tons per day, or about 100 times more than the 0.01 tons per day CARB staff estimated. However, as documented below, a more rigorous analysis indicates that far greater increases in NOx emissions are likely.

ADF 17-29

Detailed Analysis of Increases in NOx Emissions from Biodiesel Use

Given the flawed assumptions and undocumented sources of data associated with CARB staff's analysis of the emission impacts associated with biodiesel under the proposed ADF, Sierra Research undertook a detailed analysis of the same issue. The first step in this analysis was identifying the most current methods and tools for estimating NOx emissions from on- and non-road diesel engines operating in California for which biodiesel use is expected to increase NOx emissions.

ADF 17-30

On-Road Heavy-Duty Diesel Vehicles – On December 30, 2014, CARB officially released the final version of the EMFAC2014 model for estimating on-road emissions in California, which has replaced the now obsolete EMFAC2011 model that CARB staff relied upon for certain elements of its emission analysis. In releasing EMFAC2014, CARB staff noted a number of changes intended to improve the accuracy of the model relative to EMFAC2011. First, EMFAC2014 accounts for CARB's adoption of recent mobile source rules and regulations that lower future NOx emission estimates, including the Advanced Clean Cars program and the 2014 Amendments to the Truck and Bus Regulation. In addition, EMFAC2014 now estimates off-cycle emissions of SCR-equipped vehicles (i.e., NTDEs) by reflecting higher NOx emissions during low speed operation and cold starts.[8]

Given the above, Sierra selected EMFAC2014 for estimating NTDE emissions directly in this assessment. It was used to generate annual average NOx emissions, in tons per day, for the South Coast and San Joaquin Valley Air Basins, and the entire state for the years 2015, 2020, and 2023. Emission estimates were obtained for light-heavy-duty, medium-heavy-duty, and heavy-heavy-duty trucks, as well as school, urban, and transit buses. Output by "model year" was used to differentiate NOx emissions of legacy vehicles from those of NTDEs, which were defined as 2010 and later model-year vehicles consistent with the definition in proposed section 2293.2 Title 13, CCR (see Appendix A to the LCFS ISOR).

[8] Email from ARB EMFAC2014 Team, November 26, 2014.

Off-Road Diesel Equipment and Engines – The process of estimating emissions from off-road equipment and engines in California is much less straightforward than for on-road vehicles, as the most recent CARB models have been separated by equipment type and updated at various points in time as part of the rulemaking process associated with the development of regulations for different source categories.

In addition to having been developed and last updated at different points in time, some of the methodologies do not output data with sufficient detail (e.g., emissions by engine model year) to differentiate between "legacy vehicles" and NTDEs, which, in the case of off-road sources, are defined by CARB staff in proposed section 2293.2 Title 13 CCR as being compliant with Tier 4 final emission standards for non-road compression ignition (i.e., diesel) engines under sections 2421, 2423, 2424, 2425, 2425.1, 2426, and 2427 Title 13 CCR.[9] The effective dates of these standards vary as a function of engine power rating, as shown in Table 1. It should be noted that compliance with the Tier 4 Final standards by engines below 50 horsepower in general does not require the use of the SCR technology[10] that CARB has used to define "NTDEs." Therefore, all engines in this category were assumed to respond to biodiesel in the same way as legacy vehicles, despite the fact that they meet Tier 4 final standards and are technically classified as NTDEs by CARB under the ADF regulation. As discussed below, this again reduced the magnitude of the biodiesel NOx impact.

Table 1
Effective Dates of Tier 4 Final Standards

Horsepower Range	Model Year
50-75	2013
76-175	2015
176-750	2014
Over 751	2015

Table 2 summarizes current state of CARB inventory models and methodologies for off-road diesel emission sources by equipment/engine sector[11] and indicates which outputs have sufficient detail to differentiate between emissions from legacy vehicles and NTDEs. As shown, only the general off-road equipment (construction, industrial, ground support, and oil drilling equipment), cargo handling equipment, and agricultural equipment sectors could be included in the Sierra analyses for the South Coast and San Joaquin Valley Air Basins. For the statewide inventory, it was possible to include transportation refrigeration units (TRUs) as well. Given that all diesel emission categories could not be included in the Sierra analysis, it should be noted that the results of the analysis presented below are conservative in that they do not account for the full magnitude of the increase in NOx emissions related to biodiesel use in California.

[9] See ISOR Appendix A.
[10] See *http://www.arb.ca.gov/diesel/tru/tru.htm#mozTocId341892.*
[11] All models can be downloaded at *http://www.arb.ca.gov/msei/categories.htm* .

The CARB off-road emissions inventory tools were configured to include the impacts of the most recent regulatory actions in each sector, and were executed to provide estimates of annual average day NOx emissions for both legacy and NTDE vehicles for calendar years 2015, 2020, and 2023 occurring in the South Coast and San Joaquin Valley Air Basins, as well as the entire state.

Key Assumptions: The Sierra analysis of the emission impacts of biodiesel use in California relies on the following two key assumptions:

1. B5 will be in use on a statewide basis in 2015, 2020, and 2023;

2. At the B5 level, NOx emissions from legacy vehicles will be increased by 1%, and by 5% from NTDEs.

Table 2
Summary of Current California Off-Road Diesel Emission Inventory Methodologies

Category	CARB Model/Database Tool	Capable of Differentiating Legacy Vehicle and NDTE Emissions
In-Use Off-Road Equipment	2011 Inventory Model	Yes
Cargo Handling Equipment	2011 Inventory Model	Yes
Transportation Refrigeration Units	2011 TRU Emissions Inventory	Yes – but not capable of estimating emissions by air basin
Agricultural Equipment	OFFROAD2007	Yes
Stationary Engines	2010 StaComm Inventory Model	No
Locomotives	NA	No
Commercial Harborcraft	2011 CHC/CA Crew and Supply Vessel/CA Barge and Dredge Inventory Databases	No
Ocean-Going Vessels	2011 Marine Emissions Model	No

The assumption regarding B5 was based on the fact that it represents the highest blend allowed under the ADF without mitigation, at least during the summer months. That this assumption is reasonable can be seen by comparing CARB's current and previous assumptions of biodiesel use: in the current LCFS compliance scenario,[3] the staff assumes a range from about B3 in 2015 to about B4 in 2020; in 2009,[12] the staff assumed approximately B1 in 2015 and B5 in 2020; and

[12] CARB, Proposed Regulation to Implement the Low Carbon Fuel Standard, Volume II, Appendices, March 5, 2009.

in 2011,[13] approximately B10 in 2015 and B20 in 2020 were assumed. Furthermore, the Sierra results can be scaled to reflect lower or higher non-mitigated biodiesel levels by multiplying them by the ratio of the assumed biodiesel level to B5.

The assumptions of a 1% and 5% increase at B5 for legacy vehicles and NTDEs, respectively, are based on the analysis of Rincon Ranch Consulting,[7] where 5% represents the mid-point of the range of estimates.

Diesel Emission Inventory and Biodiesel Impacts

The results of the Sierra analysis for the statewide diesel inventory for 2015, 2020, and 2023 are presented in Table 3 along with the undocumented values published by CARB staff.[6] As shown, the Sierra values are lower than those used by CARB staff. This is expected to some degree given that the Sierra analysis does not include, as explained above, some diesel source categories; however, the difference cannot be reconciled given the lack of information made available by CARB staff regarding its analysis.

Table 3
Statewide Diesel Emissions tons/day

	2015	2020	2023
Sierra Analysis	621	436	277
CARB Table B-1, Appendix B ADF ISOR	863	634	496

Table 4 compares the results of Sierra's analysis with the results of the CARB staff's analysis. As shown, the differences are large and are due primarily to two factors: 1) the staff's assumption regarding biodiesel impacts on NTDE NOx emissions, which is contradicted by the available data; and 2) the differences in the assumed levels of biodiesel use. The impact of the latter difference can also be seen in the results presented in Table 4, where results from the Sierra analysis scaled to reflect the lower biodiesel use rates assumed by CARB staff are presented. Again, even with this adjustment, the results of the Sierra analysis indicate much greater NOx impacts under the proposed ADF. Finally, it should be recalled that because of limitations with CARB's emission inventory methods for off-road sources, not all sources of diesel emissions that could be impacted by biodiesel use under the ADF have been accounted for, and the actual impacts will be greater than those shown in Table 4. ADF 17-31

ADF 17-31 cont.

The results of the Sierra analysis are shown graphically in Figures 1a through c for the entire state as well as the South Coast and San Joaquin air basins, respectively. These figures also show the relative contributions of legacy vehicles and NTDEs to the total estimated for each area and year. As shown, the contributions of NTDEs to increased NOx emissions are substantial in 2015, and dominate the impacts in 2020 and 2023. Further data supporting these results are provided in Tables 6 through 8 at the end of this attachment.

Attachment D-10

As indicated above, the Sierra analysis uses the results from an assessment of existing data regarding biodiesel impacts on NOx emissions from NTDEs performed by Rincon Ranch Consulting. The key findings of that analysis are shown in Figure 2 (reproduced with permission), which establishes that the available data for biodiesel impacts on NTDE NOx emissions follow a linear relationship just as they do for legacy vehicles.

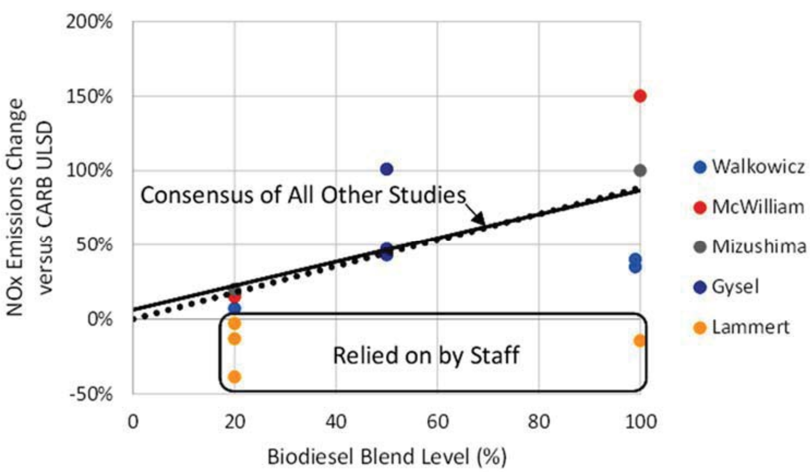
In contrast to the data upon which the Sierra analysis rests, the basis of CARB staff's assumption regarding biodiesel impacts on NTDE emissions rests on the following excerpts from the ADF ISOR:

> *Research also indicates that the use of biodiesel up to blends of B20 in NTDEs results in no detrimental NOx impacts. Therefore, the proposed regulation also includes a process for fleets and fueling stations to become exempted from the in-use requirements for biodiesel blends up to B20 as long as they can demonstrate to the satisfaction of the Executive Officer that they are fueling at least 90 percent light or medium duty vehicles or NTDEs.*
>
> *Staff proposes to take a precautionary approach and in the light of data showing there may be a NOx impact at higher biodiesel blends but not at lower biodiesel blends, staff is limiting the conclusion of no detrimental NOx impacts in NTDEs to blends of B20 and below.*

Clearly, if CARB staff were truly taking a "precautionary approach" to the issue of biodiesel impacts on NTDE NOx emissions, they would also rely on the results of the analysis summarized in Figure 2.

ADF 17-32 cont.

Figure 2
The Impact of Biodiesel on NTDE NOx Emissions



Attachment D-11

The assumption made by CARB staff regarding biodiesel impacts on NDTE NOx emissions has additional ramifications beyond those shown above by the results of the Sierra analysis. As set forth in proposed section 2293.6, Title 13 CCR (see ISOR Appendix A), the mitigation requirements for biodiesel up to the B20 level will be dropped when NTDEs account for 90% of heavy-duty vehicle miles travelled in California (expected by staff to be 2023) and use of B20 without mitigation will be allowed in all fleets of centrally fueled vehicles comprised of more than 90% NTDEs. Given this, use of unmitigated biodiesel blends of up to B20 in NTDEs may be common under the proposed ADF regulation. The potential significance of these provisions of the staff proposal with respect to the potential for NOx increases is shown in Figures 3a through 3c, which illustrate the estimated increases in NDTE NOx emissions as a function of biodiesel content up to B20 for the state, the South Coast air basin, and the San Joaquin Valley air basins, respectively, for the years 2015, 2020, and 2023.

As shown, the potential NOx increases from extensive use of higher level biodiesel blends in NTDEs is quite large. Furthermore, although the results shown in Figures 3a through 3c are maximum potential impacts, they can again be simply scaled for other cases. For example, in order to estimate statewide NOx increases from B20 use in 50% rather than 100% of NTDEs, one would simply multiply the value of 30 tons per day by 0.5 (50/100) to arrive at a 15 ton per day increase. Finally, it should be noted that the values in Figures 3a through 3c reflect both on- and off-road NTDEs as described above for the Sierra analysis of B5 impacts.

Attachment D-13

Significance of Increases in NOx Emissions Caused by Biodiesel

As illustrated above, the proposed ADF regulations are likely to lead to substantial increases in NOx emissions for the state as a whole, as well as in the South Coast and San Joaquin Valley air basins, which are in extreme nonattainment of the federal standard for ozone and experience the state's highest levels of ozone and other pollutants. The significance of the NOx increases from biodiesel can be seen by comparing those increases with air quality planning documents.

Perhaps the best initial point of reference comes from CARB's "Vision for Clean Air"[14] prepared in conjunction with the South Coast Air Quality Management District and the San Joaquin Valley Unified Air Pollution Control District. This report addresses potential control strategies that will be required to bring these extreme ozone nonattainment areas into compliance. According to the Vision report, NOx emissions will have to be reduced by 80% to 90% from 2010 levels in both the South Coast and San Joaquin Valley areas in order to achieve ozone compliance. Furthermore, in working to identify potential control strategies, the three regulatory agencies chose to focus **only** on ways to reduce NOx emissions (and not hydrocarbon emissions) because, in their words, *"NOx is the most critical pollutant for reducing regional ozone and fine particulate matter."* Given this, CARB staff's proposal to allow any NOx emission increases from the use of biodiesel is difficult to understand. ADF 17-34

CARB staff's proposal becomes even more difficult to understand when the emission increases from biodiesel are compared to the emission benefits from adopted and proposed control measures. As an illustration, the NOx reductions expected from transportation control measures in the South Coast Basin that are part of the district's Air Quality Plan[15] are compared in Table 5 to estimated NOx emission increases under the ADF based on Sierra's analysis of B5. As shown, the increases due to biodiesel are far larger than the reductions from transportation control measures and completely offset the benefits of those measures that must be implemented as the result of their being included in the Air Quality Plan. ADF 17-35

Similarly, the approximately two ton per day NOx increase estimated from the use of biodiesel in the San Joaquin Valley under the ADF can be compared to planned and implemented NOx control measures,[16,17] many of which have emission benefits on the order of two tons per day or less. Again, it should also be noted that the potential NOx emission increases allowed under the proposed ADF from extensive use of B20 in NDTEs without mitigation are far greater than the fleetwide impacts associated with the use of B5.

Attachment E

Assessment of CARB's Environmental Analysis and ADF Mitigation Requirements

In developing the proposed Alternative Diesel Fuel (ADF) regulation, CARB staff has performed an environmental analysis and included mitigation requirements intended to eliminate the adverse environmental impacts associated with increased NOx emissions resulting from the use of biodiesel under the ADF. ADF 17-36

The environmental analysis is fundamentally flawed in that staff incorrectly selected 2014 as the baseline year and performed the analysis in light of biodiesel usage levels in that year. As documented below, CARB staff has long been aware that biodiesel use leads to increases in NOx emissions, and promised but failed to act to address those emissions through enactment of an ADF regulation as early as 2009. There is no basis for an agency to use its failure to promptly act to address an environmental issue of which it was clearly aware as grounds to change the baseline for assessing its' proposed effort to address that issue. This is even more apparent given that CARB staff acknowledges that a key function of the LCFS regulation is to incent low carbon intensity fuels including biodiesel which has to date generated 13% of all credits issued by CARB under the LCFS.[1] Given this, the proper baseline for assessing the ADF regulation should be 2009 when CARB first stated it would regulate biodiesel use and when, by CARB staff's own admission, little biodiesel was used in California and NOx emissions were minimal. ADF 17-37

The mitigation requirements of the ADF regulation are equally flawed. First, they are based on CARB's staff's fundamentally flawed emission analysis, and second their implementation is unreasonably delayed until 2018—more than ten years after CARB staff was aware that biodiesel use in California would lead to increased NOx emissions. ADF 17-38

History of the ADF Regulation

Although the U.S. Environmental Protection Agency (EPA) published a report in 2002 showing that biodiesel use increases NOx emissions linearly with increasing biodiesel content,[2] the earliest document found on the CARB website indicates that agency discussions regarding the need to adopt regulations addressing NOx began at least as early as February 2004.[3] This led to the first meeting of the Biodiesel Work Group in April 2004.[4] A summary of that discussion

[1] See Page III-2 of the LCFS ISOR.
[2] See EPA, A Comprehensive Analysis of Biodiesel Impacts on Exhaust Emissions (available at http://www.epa.gov/otaq/models/analysis/biodsl/p02001.pdf).
[3] See CARB, Public Consultation Meeting Regulatory and Non-Regulatory Fuels Activities at 26-29 (Feb. 25, 2004) (available at http://www.arb.ca.gov/fuels/diesel/022504arb.pdf).
[4] See CARB Ltr. (Mar. 18, 2004) (available at http://www.arb.ca.gov/fuels/diesel/altdiesel/041204altdslwsh.pdf).

published at the time[5] it occurred indicates that topics discussed included ways to mitigate NOx emission increases associated with biodiesel use.

In 2006, CARB published a draft guidance document regarding the use of biodiesel in California,[6] at which time the agency simply decided not to address increased NOx emissions until biodiesel use became more widespread.[7] At that time, CARB instead could have ensured that there would be no NOx increases from biodiesel use by simply requiring those interested in selling biodiesel in California to demonstrate that they could formulate biodiesel blends in a way that did not increase NOx emissions, which is one of the approaches CARB is now considering.[8]

The first time CARB was scheduled to adopt regulations addressing this issue was in November 2009; this is indicated on page 12 of CARB's 2009 Rulemaking Calendar,[9] which includes the following summary:

> *Staff will propose motor vehicle fuel specifications for biodiesel and renewable diesel. These specifications are necessary for the implementation of the Low Carbon Fuel Standard regulation (to be considered at the March 2009 Hearing).*

ADF 17-39

No action was taken by CARB in 2009 and the planned adoption date was moved to June 2010; this is evidenced by CARB's 2010 Rulemaking Calendar,[10] which lists the regulatory item on page 11. This time the summary reads:

> *The staff will propose adoption of new motor vehicle fuel specifications for biodiesel and renewable diesel. These specifications are necessary to ensure that the use of these fuels will not increase emissions of criteria and toxic air pollutants when used as a motor vehicle fuel.*

Again, no action was taken by CARB in 2010 and the planned adoption date was moved to November 2011; this is evidenced by CARB's 2011 Rulemaking Calendar,[11] which lists the regulatory item on page 14. This time the summary reads:

---

[10] See CARB, 2010 Rulemaking Calendar Schedule (available at http://www.arb.ca.gov/regact/2010rulemakingcalendar.pdf).
[11] See CARB, 2011 Rulemaking Calendar Schedule (available at http://www.arb.ca.gov/regact/2011rulemakingcalendar.pdf).

The Low Carbon Fuel Standard incents the use of biodiesel and renewable diesel, for which there are no current emissions–based fuel specifications. Staff will propose fuel specifications for both of these diesel blendstocks.

Yet again, no action was taken by CARB in 2011 and the planned adoption date was moved to November 2012; this is evidenced by CARB's 2012 Rulemaking Calendar,[12] which lists the regulatory item on page 14. This time the summary reads:

Rulemaking to establish commercial fuel specifications for blends of commercial diesel fuel and neat biodiesel in amounts greater than five volume percent.

Yet again, no action was taken by CARB in 2012 and, for the fourth consecutive year, the item was scheduled to be presented to the Board—the CARB Rulemaking Calendar for 2013[13] indicates on page 8 that the Board is currently scheduled to consider adoption of amendments to the agency's Alternative Diesel Fuel Regulations in September 2013. This time the summary reads: ADF 17-39 cont.

Proposed new motor vehicle alternative diesel fuel specifications and commensurate amendments to the diesel fuel regulations.

Unlike the previous years, during 2013 CARB staff did begin to take action to actually develop a regulation that it purported would address increases in NOx emissions resulting from biodiesel use. The hearing notice[14] and Initial Statement of Reasons[15] for the proposed ADF regulation were published in October 2013, in advance of a Board hearing to be held on December 12-13, 2013. However, that hearing was postponed to until March 20, 2014,[16] and then the entire rulemaking was abandoned prior to the March 2014 hearing.[17]

History of Biodiesel Use

Although CARB does not disclose the amounts of biodiesel used in California prior to 72 million gallons estimated in 2014 in the ADF rulemaking documents (see ISOR Appendix B), data for 2005 to 2012 are available from the California Energy Commission.[18] These data are shown in Figure 1 below. As shown, biodiesel use in California increased dramatically in 2006 when CARB staff indicated that it would not regulate biodiesel, and then decreased until the LCFS

[12] See CARB, 20012 Rulemaking Calendar Schedule (available at http://www.arb.ca.gov/regact/2012rulemakingcalendar.pdf).

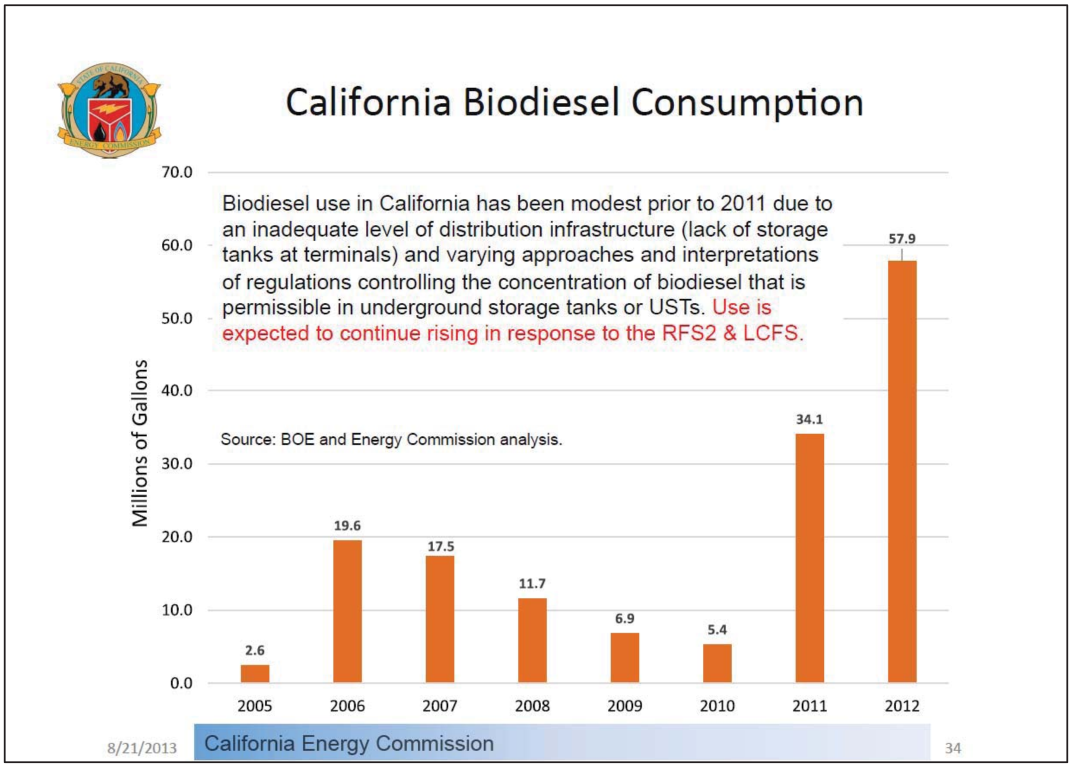
took effect in 2011 at which point it again increased dramatically. Clearly, the appropriate baseline year for analysis of the ADF regulation is 2009 or 2010 when CARB first committed to adopting a regulation to address biodiesel NOx impacts, not any later year after which substantial increases in biodiesel use occurred in response to the LCFS. ADF 17-40

Figure 1
Biodiesel Consumption in California as Reported by the California Energy Commission



The NOx increases resulting from CARB's failure to regulate biodiesel during the period from 2005 to 2014 are summarized in Table 1. The values presented are approximate and are based on the Sierra Research methodology for 2015 adjusted to account for differences in biodiesel use as well as the absence of NTDE engines in years prior to 2010. Biodiesel use for 2014 is taken from Appendix B of the ADF ISOR, and the estimated use for 2013 assumed linear growth in biodiesel use from 2012 to 2014. Significant increases in NOx emissions from 2011 to 2014 can be seen from a comparison of the values presented in Table 1 with the values presented in Table B-1 of Appendix B to the ADF ISOR. These increased NOx emissions from 2011 to 2014 total 782, 1032, and 3,463 tons for the San Joaquin Valley, South Coast, and entire state, respectively. ADF 17-41

Table 1 Estimated Increases in NOx Emissions Due to Biodiesel Use in California from 2005 to 2014 (tons per year)

Total	4225	1260	945

ADF 17-41 cont.

Proposed ADF Mitigation Requirements

Under the proposed ADF regulation,[19] mitigation is generally required for "low-saturation" biodiesel blends with diesel fuel above B5 (e.g., B6 and higher) during the summer, and above B10 (e.g., B11 and higher) during the winter, unless the fuels are used in vehicles with new technology diesel engines in which case mitigation is not required for levels up to B20. For "high-saturation" biodiesel blends with diesel fuel, mitigation is required year-round above B10 (e.g., B11 and higher) again, unless the fuels are used in vehicles with new technology diesel engines in which case mitigation is not required for levels up to B20. However, no mitigation is required for any biodiesel blend sold in California prior to January 1, 2018.

ADF 17-42

According to the ADF ISOR,[20] CARB staff selected these levels based on an "analysis" for which no detail or documentation has been provided, and that reportedly included consideration of the impacts of new technology diesel engines (NTDEs) and the use of renewable diesel as "offsetting factors." Although it is impossible to thoroughly review an analysis which is not described in detail, in this case it can still be demonstrated to be fundamentally flawed. As discussed elsewhere, CARB incorrectly assumes that NOx emissions from NTDEs are unaffected by biodiesel despite the fact that available data show statistically significant increases in NOx emissions. Further, CARB cannot rely on the use of renewable diesel as mitigation for NOx increases from biodiesel as there is nothing in the ADF or the LCFS regulation that mandates the use of any volume of renewable diesel in California, nor which links the amount of renewable diesel used to the amount of biodiesel used. Further, neither the ADF nor LCFS regulations ensure that fuel producers will use biodiesel in a manner that provides surplus

ADF 17-43

[19] Proposed section 2293.6 Title 13, CCR in ISOR Appendix A.
[20] Chapter 6, Part H.

reductions[21] in NOx emissions. Given that CARB's reliance on "offsetting factors" is fundamentally flawed, the agency's "Determination of NOx Control Level for Biodiesel" is also fundamentally flawed. Another problem with the "determination" is that CARB staff claims to have performed an "analysis" for which no detail or documentation is provided, indicating that the higher blend level threshold for mitigation that applies to "low-saturation" blends during the winter months will not result in adverse air quality impacts. Again, it is not possible to critically review an analysis which is not described in detail; further, the information provided in this analysis is so insufficient that it is not even possible to develop an appropriate set of comments.

ADF 17-43 cont.

In addition to the flaws in CARB staff's analysis of what mitigation should be applied to address the increased NOx emissions associated with biodiesel use, CARB staff is arbitrarily delaying the date on which mitigation is required by two years from the expected effective date of the ADF regulation. According to ADF ISOR, CARB staff claim the reason for this delay is:

> *ARB is also proposing the in-use requirements come into effect on January 1, 2018, as time is needed to overcome logistical and other issues in implementation of in-use requirements. For example, use of the additive Di-tert-butyl peroxide (DTBP) will require replacement of steel tanks with stainless steel tanks, permitting of hazardous substance storage, approval by local fire agencies, additional additization infrastructure, and logistical business changes to acquire the additive. All of this is expected to take around 2 years to complete. Another method of compliance is re-routing higher blends to NTDEs. Research shows that the use of biodiesel in blends up to B20 in NTDEs results in no detrimental NOx impacts. This and other methods of complying with the in-use requirements, such as certification of additional options are also expected to take 2 years or more. Because compliance with the in-use options would be infeasible during initial implementation on January 1, 2016, only recordkeeping and reporting provisions will be implemented initially. The in-use requirements are proposed to come into effect on January 1, 2018.*

ADF 17-44

It is not clear why CARB staff believes that a two year delay in the implementation of mitigation requirements is required under the ADF regulation when the maximum delay in the implementation of new requirements under the LCFS regulation, which will much more dramatically impact fuel producers than the ADF requirements, is only one year, until January 1, 2017. Further, as the biodiesel industry has been on notice that CARB intended to impose NOx mitigation requirements for over ten years, it is not clear why such measures cannot be required from the expected January 1, 2016 effective date of the proposed regulation.

The impact of the failure to immediately require Biodiesel mitigation under the ADF regulation is shown in Table 2. These values are based on the Sierra Research emissions methodology which assumes statewide use of B5. As discussed elsewhere, these impacts

[21] In order to generate surplus reductions in NOx, renewable diesel would have to be blended into diesel fuel downstream of refineries, and although CARB staff has assumed that this will occur they have provided no basis for that assumption.

are significant in that the increases are as large or larger than those sought from emission control measures implemented of under consideration by CARB and local air pollution control agencies in the South Coast and San Joaquin Valley air basins.

Table 2
Potential NOx Increases Due to CARB's Failure to Require Immediate Biodiesel Mitigation Under the ADF
(tons per year)

	Statewide	South Coast	San Joaquin Valley
2016	3405	1013	796
2017	3460	1034	815
Total	6866	2047	1612

Attachment F

Potential for Actual Biodiesel Blend Levels to Exceed Levels Purported Under the Proposed ADF Regulation

In order to properly understand and mitigate the adverse environmental impacts of biodiesel blends sold in California, it is critical that the actual amount of biodiesel present in a blend be accurately known. Despite this, the proposed ADF regulation fails to adequately ensure that the actual biodiesel content of biodiesel blends—and therefore their adverse environmental impacts—will be accurately known or appropriately mitigated. As discussed below, significant changes are required to definitions used in the proposed LCFS and ADF regulations, and new testing, recordkeeping, and reporting requirements need to be added to the ADF regulation to prevent the blending of biodiesel with fuels that already contain undisclosed amounts of biodiesel.

ADF 17-45

Background

CARB regulations at §2281 and §2282, Title 13, California Code of Regulations apply to vehicular diesel fuel sold in California and define "diesel fuel" as follows:

> *"Diesel fuel" means any fuel that is commonly or commercially known, sold or represented as diesel fuel, including any mixture of primarily liquid hydrocarbons – organic compounds consisting exclusively of the elements carbon and hydrogen – that is sold or represented as suitable for use in an internal combustion, compression-ignition engine."*[1]

The proposed LCFS regulation contains the following definitions that are relevant to biodiesel blends (See ISOR Appendix A):[2]

> *"B100" means biodiesel meeting ASTM D6751-14 (2014) (Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels), which is incorporated herein by reference.*
>
> *"Biodiesel" means a diesel fuel substitute produced from nonpetroleum renewable resources that meet the registration requirements for fuels and fuel additives established by the Environmental Protection Agency under section 211 of the Clean Air Act. It includes biodiesel meeting all the following:*

[1] 13 CCR §2281(b)(1) and §2282(b)(3)
[2] See proposed §95481, Title 17, California Code of Regulations

(A) Registered as a motor vehicle fuel or fuel additive under 40 Code of Federal Regulations (CFR) part 79;
(B) A mono-alkyl ester;
(C) Meets ASTM D6751-08 (2014), Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels, which is incorporated herein by reference;
(D) Intended for use in engines that are designed to run on conventional diesel fuel; and
(E) Derived from nonpetroleum renewable resources.

"Biodiesel Blend" means a blend of biodiesel and diesel fuel containing 6 percent (B6) to 20 percent (B20) biodiesel and meeting ASTM D7467-13 (2013), Specification for Diesel Fuel Oil, Biodiesel Blend (B6 to B20), which is incorporated herein by reference.

"Diesel Fuel" (also called conventional diesel fuel) has the same meaning as specified in California Code of Regulations, title 13, section 2281(b).

"Diesel Fuel Blend" means a blend of diesel fuel and biodiesel containing no more than 5 percent (B5) biodiesel by weight and meeting ASTM D975-14a, (2014), Standard Specification for Diesel Fuel Oils, which is incorporated herein by reference.

Finally, the proposed ADF regulation contains the following definitions that are relevant to biodiesel blends:[3]

"Alternative diesel fuel" or "ADF" means any fuel used in a compression ignition engine that is not petroleum-based, does not consist solely of hydrocarbons, and is not subject to a specification under subarticle 1 of this article.

"Biodiesel" means a fuel comprised of mono-alkyl esters of long chain fatty acids derived from vegetable oils or animal fats that is 99-100 percent biodiesel by volume (B100 or B99) and meets the specifications set forth by ASTM International in the latest version of Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels D6751 contained in the ASTM publication entitled: Annual Book of ASTM Standards, Section 5, as defined in California Code of Regulations, title 4, section 4140(a), which is hereby incorporated by reference.

"Biodiesel Blend" means biodiesel blended with petroleum-based CARB diesel fuel or non-ester renewable diesel.

[3] See proposed §2293.2(a), Title 13, California Code of Regulations

"Blend Level" means the ratio of an ADF to the CARB diesel it is blended with, expressed as a percent by volume. The blend level may also be expressed as "AXX," where "A" represents the particular ADF and "XX" represents the percent by volume that ADF is present in the blend with CARB diesel (e.g., a 20 percent by volume biodiesel/CARB diesel blend is denoted as "B20").

"B5" means a biodiesel blend containing no more than five percent biodiesel by volume.

"B20" means a biodiesel blend containing more than five and no more than 20 percent biodiesel by volume.

"CARB diesel" means a light or middle distillate fuel that may be comingled with up to five (5) volume percent biodiesel and meets the definition and requirements for "diesel fuel" or "California nonvehicular diesel fuel" as specified in California Code of Regulations, title 13, section 2281 et seq. "CARB diesel" may include: non-ester renewable diesel; gas-to-liquid fuels; Fischer-Tropsch diesel; diesel fuel produced from renewable crude; CARB diesel blended with additives specifically formulated to reduce emissions of one or more criteria or toxic air contaminants relative to reference CARB diesel; and CARB diesel specifically formulated to reduce emissions of one or more criteria or toxic air contaminants relative to reference CARB diesel.

Discussion

The first issue related to the potential for uncertainty and inaccuracy in actual biodiesel content of fuels sold in California involves the different definitions that have been proposed for the term "biodiesel" under the proposed LCFS and ADF regulations. Although the two definitions may be functionally equivalent, they should be made the same under both the LCFS and ADF regulations unless CARB staff can articulate a compelling need for the use of different definitions to describe the same thing.

More importantly, the term "Biodiesel Blend" in the proposed LCFS regulation directly conflicts with the use of the same exact term in the proposed ADF regulation: a "Biodiesel Blend" under the LCFS regulations contains at least 6% biodiesel, while a "Biodiesel Blend" under the ADF is a diesel fuel containing any biodiesel. Furthermore, the LCFS regulation defines "Diesel Fuel Blend" as a blend of diesel fuel and up to 5% biodiesel, while such a fuel would be considered "CARB diesel" under the ADF regulation. Again, this haphazard use of the same term to describe fundamentally different fuels and different terms to describe the same fuel will assuredly lead to confusion in practice regarding the actual content of biodiesel available in California.

Further confusion is created by the definitions of "Biodiesel Blend" and "Blend Level" under the proposed ADF regulation. "Biodiesel Blend" is defined as a mixture of biodiesel and an undefined fuel referred to as "petroleum-based CARB diesel." "Blend

Level" applies to blends of all fuels subject to the ADF regulation, including biodiesel, and is defined as the ratio of an "Alternative diesel fuel" mixed with "CARB diesel." However, as noted above, "CARB diesel" may already contain as much as 5% biodiesel under the proposed ADF regulation. Furthermore, the definition of "Blend Level" includes no reference to the fuel termed "petroleum-based CARB diesel" that appears in the definition of "Biodiesel Blend" under the ADF—instead, it refers to "CARB diesel," which, as noted above, may contain as much as 5% biodiesel. Obviously, the addition of biodiesel to a fuel already containing some amount of biodiesel up to 5% will cause the actual biodiesel content to be higher than the blender expects; this, in turn, will lead to more significant adverse environmental impacts than expected. It is also clear that CARB staff mean for the definition of "Blend Level" to apply to "Biodiesel Blends," as that definition uses an example based on biodiesel (B20) to demonstrate the practical meaning of "Blend Level."

Finally, under the proposed ADF regulation, "B20" is nonsensically defined as a fuel that contains between 6% and 20% biodiesel, which directly contradicts the definition of "Blend Level" in same regulation. There appears to be no need for this definition or the definition of B5 in the proposed ADF regulation.

As outlined above, the proposed CARB LCFS and ADF regulations fail completely in clearly defining the four fuels that are of fundamental importance to ensuring that the biodiesel content of a fuels sold in California—and hence the adverse environmental impacts associated with their use—is accurately known. Instead, the proposed regulations make it likely that biodiesel blenders will unknowingly use fuels that already contain an unknown amount of biodiesel (up to 5%) in blending and that the actual biodiesel content of biodiesel blends may be as much as 5% greater than that represented by the blender and reported to CARB under the ADF regulation. This is significant because, as discussed in other attachments to this declaration, the increases in NOx emissions and associated adverse environmental impacts caused by biodiesel blends become larger in direct proportion to the amount of biodiesel present.

Both the LCFS and the ADF regulation must clearly define the four fuels described below.

1. ***"Diesel fuel"*** **–** This should defined as under 13 CCR §2281(b)(1) and §2282(b)(3).

2. ***"Biodiesel"*** or "***B100"*** – It appears that this could be properly defined through changes to the definitions currently proposed in the LCFS and ADF regulations; this is what should be blended only with "diesel fuel" to create a "Biodiesel Blend."

3. ***"CARB diesel"*** – This is accurately defined under the proposed ADF regulation, but under no circumstances should it be allowed to be blended with biodiesel or any other ADF. It should be renamed to clearly differentiate it from "diesel fuel" such that no reasonable person would understand that it could be legally mixed with any ADF.

ADF 17-45 cont.

4. ***"Biodiesel Blend"*** – This should refer to the "Blend Level" and must correspond to the actual amount of "Biodiesel" or "B100" in terms of percentage by volume in the final blend with "diesel fuel."

ADF 17-45 cont.

In addition to modifying the definitions as described above, the ADF regulation must also be modified to ensure that biodiesel blenders do not intentionally or unintentionally blend biodiesel into fuels that already contain biodiesel. This can easily be achieved by adding requirements to proposed §2293.8 Title 13, CCR, to require that any "diesel fuel" to be used in blending with biodiesel be tested for the presence of biodiesel prior to blending. Similarly, that section should be modified to include reporting and record keeping requirements for biodiesel blenders that document that they have used only biodiesel-free "diesel fuel" in all of their blending operations.

Attachment G

The Growth Energy Alternative to Proposed ADF Regulation is the Least-Burdensome Approach that Best Achieves the Project Objectives at the Least Cost That Must be Adopted

As part of the rulemaking process leading to CARB staff's proposed ADF regulation, staff was required to solicit and consider alternatives to the proposed regulation. Growth Energy submitted such an alternative which CARB staff acknowledged provided equivalent or superior reductions in NOx emissions from biodiesel use but rejected as being more costly. However, as is documented in detail below, CARB staff made fundamental errors in its' assessment of the Growth Energy Alternative, which will in fact provide greater reductions in NOx emissions from biodiesel use than the staff's proposed ADF regulation but do so with equal cost-effectiveness. (Equal cost-effectiveness means that the dollars spent per unit mass of NOx emissions eliminated will be the same.) Given that the Growth Energy alternative provides greater environmental benefits, which in turn substantially lessen the ADF's significant impacts, and is equally cost-effective as the staff's proposed ADF regulation, the Growth Energy Alternative rather than the staff proposal should be adopted by CARB. ADF 17-47

Background

On July 29, 2014, CARB published a "Solicitation of Alternatives for Analysis in the Alternative Diesel Fuel Standardized Regulatory Impact Assessment" which is attached. On August 15, 2014, Growth Energy submitted an alternative regulatory proposal for the ADF regulation (which is attached) to CARB in response to the agency's solicitation. On December 30, 2014, CARB staff published both the ISOR for the ADF regulation as well as a document entitled "Summary of DOF Comments to the Combined LCFS/ADF SRIA and ARB Responses" which is Appendix E to the ADF ISOR, both of which include information related to staff's decision to reject the alternative to the ADF regulation proposed by Growth Energy.

The staff's assessment of the Growth Energy (GE) Alternative published in Appendix E of the ADF ISOR is as follows (emphasis added): ADF 17-48

> ***Benefits:***
>
> ***ARB finds that the GE alternative would meet the emissions goals of the ADF proposal and achieve roughly the same emissions benefits as the ADF proposal. The GE alternative may achieve marginally more emissions benefits if biodiesel were to be widely used as an additive under the ADF proposal. Although the GE alternative is simpler than the ADF proposal, the GE alternative is unnecessarily strict; ARB's analysis of the science does not find that there are NO_X increases with B5 animal biodiesel or biodiesel used in NTDEs, so***

requiring mitigation for these does not achieve any additional emissions benefit versus the ADF proposal.

Costs:

The GE alternative would require mitigation of more fuel than the ADF proposal; regulated parties would incur more costs to mitigate non-animal- and animal-based biodiesel similarly and setting the significance level for both at one percent. Additionally, the NTDE exemption would increase the volumes of fuels to be mitigated, further increasing the direct costs on regulated parties.

Economic Impacts:

The REMI results also indicate that the combined LCFS/ADF proposal has no discernible difference from the GE alternative. Employment, GSP, and output differ only slightly and represent a difference of less than one tenth of one percent. Given that the GE alternative has higher direct costs, the combined LCFS/ADF alternative is preferred.

Cost-Effectiveness:

The GE alternative costs more than the ADF proposal, because it requires mitigation of more biodiesel than the ADF proposal. The GE alternative does not result in any more emissions reductions than the ADF proposal and as such is less cost effective than the ADF proposal.

Reason for Rejection:

ARB rejects the GE alternative because it costs more than the ADF proposal and does not achieve additional emissions benefits*.*

The reason for rejection of the Growth Energy (GE) alternative presented in the ADF ISOR itself is as follows:

This alternative proposal retains the same biodiesel NOx mitigation options as the ADF proposal*. However, under the GE alternative, animal and non-animal biodiesel would be treated equally and require NOx mitigation for all biodiesel blends, including blends below B5.* ***ARB rejects this alternative because the costs are significantly higher than the ADF proposal and do not achieve additional emissions benefits.*** *During the development of this regulation, staff considered alternatives to the proposal and determined that the proposal represents the least-burdensome approach that best achieves the objectives at the least cost.*

Finally, it should be noted that the stated intention of the ADF regulation according to CARB staff in the ADF ISOR is as follows (emphasis added):

ADF 17-49

*The ADF regulation is intended to create a framework for these low carbon diesel fuel substitutes to enter the commercial market in California, **<u>while mitigating any potential environmental or public health impacts</u>**.*

<u>Discussion</u>

As indicated above, the stated reason why CARB staff rejected the Growth Energy alternative to the proposed ADF regulation is because CARB staff believed it would require that actions be taken to mitigate increased NOx emissions from biodiesel under circumstances where CARB staff incorrectly assumed there would no increased emissions due to biodiesel use on under the ADF. However, as is clearly demonstrated in another attachment to the declaration of James M. Lyons,[1] CARB staff's analysis and assumptions of the increases in NOx emissions that will result for the ADF regulation is fatally flawed as is CARB's basis for rejection of the Growth Energy Alternative.

ADF 17-49 cont.

As shown by the Sierra emissions analysis, once the flaws in the CARB emissions analysis are corrected, it becomes clear that the ADF regulation will allow significant and unmitigated increases in NOx emissions to occur throughout California including areas such as the South Coast and San Joaquin air basins which experience the worst air quality in the state. As CARB staff itself admits, the Growth Energy alternative would require mitigation in exactly those areas where CARB staff was lead to believe it was not required based on its flawed emissions analysis. CARB staff also admits the Growth Energy alternative is based on the same mitigation options contained in the ADF regulation, which CARB staff has already determined to be technically feasible and cost-effective. However, the Growth Energy Alternative is superior to the ADF regulation because it expands the conditions under which this mitigation has to be applied in order to eliminate the potential for any increase in NOx emissions due to biodiesel use to a less-than-significant level. The Growth Energy Alternative therefore precludes any adverse environmental impacts due to increased NOx emissions, which is exactly what CARB staff has asserted the ADF regulation is intended to do.

Given that the Growth Energy alternative:

1. Provides complete mitigation of potential NOx emission increases due to biodiesel use under the ADF and any associated adverse environmental impacts; and

2. Relies on the same mitigation strategies proposed by CARB staff which staff has found to be technically feasible and cost-effective,

ADF 17-50

CARB must adopt the Growth Energy alternative as it better achieves the stated project objectives in an equally cost-effective manner.

Appendix J

Appendix J

Additional Analysis Required Under the California Environmental Quality Act

A. <u>CARB May Not Ignore the LCFS Regulation's Pre-2015 Impacts</u>

CARB Staff initiated the environmental review process for the LCFS regulation in 2007, and circulated an Initial Statement of Reasons for the proposed regulation in 2009. As explained by the Court in *POET, LLC v. California Air Resources Board* (2013) 218 Cal.App.4th 681 ("*POET*"), CARB subsequently approved that regulation on April 24, 2009, without completing the environmental review process, and impermissibly delegated authority to complete the environmental review process to the Executive Officer. The Court found that CARB's actions violated CEQA, and directed the superior court to issue a writ enjoining enforcement of the LCFS regulation beyond 2013 levels. The writ issued by the superior court requires CARB, prior to its consideration of the LCFS regulation, to evaluate "the potential adverse environmental effect of increased NOx emissions" associated with the "project" (*i.e.*, the LCFS regulations presently being enforced). (Exhibit "1.") To this day, CARB has never performed a legally compliant review of the environmental effects of CARB's existing LCFS regulation. LCFS 46-261

Although the court in *POET* directed CARB to evaluate the effects of the LCFS regulation, the Environmental Assessment ("EA") for the LCFS regulation and the ADF regulation (the "Proposed Regulations") ignores the impacts of the LCFS regulation presently in effect, as well as any other impacts of the project prior to 2014. As a result, prior to its consideration of the LCFS regulation and the ADF regulation, CARB must substantially revise and recirculate the EA for public review to evaluate the entire project. LCFS 46-262

1. **CARB's Project Description Is Inadequate Because it is Unclear <u>Whether the Existing LCFS Regulation Is Part of the Project</u>**

"An accurate, stable and finite project description is the sine qua non of an informative and legally sufficient" environmental document. (*County of Inyo v. City of Los Angeles* (1977) 71 Cal.App.3d 185, 193.) Additionally, the ***entire project*** being proposed must be described in the EIR, and the project description must not minimize project impacts. (*City of Santee v. County of San Diego* (1989) 214 Cal.App.3d 1438, 1450.) As explained in *County of Inyo*:

> A curtailed or distorted project description may stultify the objectives of the reporting process. Only through an accurate view of the project may affected outsiders and public decision-makers balance the proposal's benefit against the environmental cost, consider mitigation measures, assess the advantage of terminating the proposal (*i.e.*, the "no project" alternative) and weigh other alternatives in the balance. LCFS 46-263

(*County of Inyo v. City of Los Angeles* (1977) 71 Cal.App.3d 185, 192-93.)

The EA violates this mandate. First, the EA is unclear as to whether CARB is treating the "Project" as including the LCFS regulation presently in effect. On the one hand, the EA's project description discusses the existing LCFS regulation; the EA recognizes that the present action is being taken in response to the decision in *POET*; and the "re-adopted" LCFS regulation is structurally nearly identical to the LCFS regulation presently being enforced. On the other hand, however, the EA does not address the environmental effects of the LCFS regulation presently being enforced, and the "carbon intensity" base year has changed from 2010 to 2014. Because it is unclear whether the "project" analyzed in the EA includes the LCFS regulation presently in effect, the project description in the EA is not stable or finite, and is thus inadequate under CEQA. LCFS 46-263 cont.

To the extent CARB intended to omit the current LCFS regulation from the project description, that action would also result in an inadequate project description because it is "inaccurate." CEQA requires the project description to include ***entire project***, not a smaller piece of the project that would have the impact of minimizing project impacts. (*City of Santee*, *supra*, 214 Cal.App.3d at 1450.) Describing only the "re-adopted" portions of the LCFS regulation also runs directly contrary to the writ issued by the superior court, which specifically requires CARB to analyze the effects of the project presently being implemented. (See Exhibit "1.") LCFS 46-264

As a result, CARB must revise the project description in the EA to specifically include the existing LCFS regulation, and analyze the impacts associated with the existing regulation. LCFS 46-265

2. <u>The Baseline Used By CARB Is Unclear</u>

Because the impacts of a project are evaluated against the environmental baseline, determining the proper baseline is critical to a meaningful discussion of the project's environmental impacts. (See *Communities for a Better Environment v. South Coast Air Quality Mgmt. Dist.* (2010) 48 Cal.4th 310, 320.) The EA here obscures the baseline used by CARB for its analysis of the impacts of the regulations because there is no definitive statement explaining what specific baseline is being used in the EA. Rather, the portion of the EA that purportedly sets forth the baseline cites to an appendix to the EA, which discusses the "Environmental and Regulatory Setting" of the Regulations. But even this appendix does not specifically state what date the EA is using as the baseline for environmental review. As a result, the EA should be revised to specifically state what baseline it is using, and recirculated for public review. LCFS 46-266

3. Ignoring Pre-2014 Impacts Results in an Improper Baseline for <u>Environmental Review</u>

Generally, the "environmental baseline" includes the environmental conditions as they exist at the time the lead agency publishes the Notice of Preparation ("NOP") for the project, or, if there is no NOP, as is the case here, "at the time the environmental analysis is commenced." (CEQA Guidelines, § 15125(a).) Although the EA does not specifically state what baseline is being used, the analysis in the EA ignores the LCFS regulation's impacts prior to 2014, and asserts that the analysis in the EA "addresses the potentially significant adverse environmental impacts resulting from implementing the proposed LCFS and ADF regulations LCFS 46-267

compared to existing conditions, **which include existing compliance with the LCFS left in place by the Court at the 2013 regulatory standards**." (EA at 3 [emphasis added].) LCFS 46-267 cont.

Omitting analysis of the project's pre-2014 impacts is improper. Here, the environmental review commenced in 2007, and the initial Staff Report/ISOR for the LCFS regulation was released in 2009. As a result, the proper baseline for environmental review under CEQA is 2007, and certainly no later than 2009. (CEQA Guidelines, § 15125(a).) LCFS 46-268

To the extent CARB intends to use a baseline of 2014, that baseline is also impermissible because it is "misleading" and obscures the impacts of the Regulations. (See, e.g., *Neighbors for Smart Rail v. Exposition Metro Line Construction* (2013) 57 Cal.4th 439.) Specifically, NOx emissions caused by the existing LCFS regulation from 2011 through 2014 from the San Joaquin Valley, the South Coast air basin, and the entire state, respectively, total 782, 1,032, and 3,463 tons per year. (Decl. Lyons at E-4.) Because a 2014 baseline has the effect of essentially sweeping prior NOx emissions under the rug, it is misleading, and a more accurate baseline should be used. LCFS 46-269

The fact that the emissions occurred in the past does not excuse CARB from analyzing the effects of those emissions, as CARB still has the ability to mitigate these emissions, or modify the LCFS regulation in response to its analysis. In *Bakersfield Citizens for Local Control*, for example, the court set aside an EIR for a large commercial development, including a Wal-Mart. The trial court enjoined the construction of the Wal-Mart, but let the remainder of the construction proceed, and those businesses were operating at the time the court of appeal heard the case. The agency asserted the environmental review for the other businesses was moot because those businesses were operational. The Fifth District Court of Appeal disagreed, finding:

> [E]ven at this late juncture full CEQA compliance would not be a meaningless exercise of form over substance. The City possesses discretion to reject either or both of the shopping centers after further environmental study and weighing of the projects' benefits versus their environmental, economic and social costs. As conditions of reapproval, the City may compel additional mitigation measures or require the projects to be modified, reconfigured or reduced. The City can require completed portions of the projects to be modified or removed and it can compel restoration of the project sites to their original condition. LCFS 46-270

(*Bakersfield Citizens for Local Control v. City of Bakersfield* (2004) 124 Cal.App.4th 1184, 1204.) In other words, "[a]s a matter of public policy and basic equity, developers should not be permitted to effectively defeat a CEQA suit merely by building out a portion of a disputed project during litigation . . . ." (*Id.* at 1203.) By ignoring pre-2014 NOx emissions, CARB is seeking to do just that.[1]

---

[1] CARB also cannot rely upon the rule that the baseline for a previously-reviewed project assumes the previously-approved project exists. (See Remy, Thomas, Moose & Manley, *Guide to CEQA* (11th ed. 2007) at 207.) This is because the Court in *POET, LLC v. California Air Resources Board* invalidated CARB's environmental document for the original LCFS regulation.

Because the EA employs the wrong baseline, the EA should be revised, and recirculated for public review. LCFS 46-271

4. By Failing to Address Pre-2014 NOx Emissions, the EA Is Deficient <u>Because it Does Not Analyze Cumulative Impacts</u>

Even if CARB could argue the existing LCFS regulation was a different "project" under CEQA, CARB in its EA would still need to address the impacts of that regulation as "cumulative impacts." This is because CEQA requires that the environmental document discuss the cumulative effect on the environment of the subject project in conjunction with other closely-related ***past***, present, and reasonably foreseeable probable future projects. (See, e.g., Pub. Resources Code, § 21083, subd. (b).) "The purpose of this requirement is obvious: consideration of the effects of a project or projects as if no others existed would encourage the piecemeal approval of several projects that, taken together, could overwhelm the natural environment and disastrously overburden the man-made infrastructure and vital community services. This would effectively defeat CEQA's mandate to review the actual effect of the projects upon the environment." (*Citizens to Preserve the Ojai v. County of Ventura* (1985) 176 Cal.App.3d 421, 432.) Thus, regardless of whether the original LCFS regulation and the proposed LCFS regulation constituted different projects, CARB cannot avoid analyzing pre-2014 impacts as cumulative impacts. LCFS 46-272

5. CARB's Failure to Analyze Pre-2014 Impacts Constitutes Improper <u>Segmentation/Piecemealing</u>

Ignoring the impacts of the existing regulation also impermissibly piecemeals the analysis of the impacts of the LCFS regulation. CEQA prohibits a lead agency from piecemealing – or segmenting – the environmental review of a project; in other words, a lead agency may not break up an action into several small "projects" that would have the effect of minimizing environmental review. "The requirements of CEQA cannot be avoided by piecemeal review which results from "chopping a large project into many little ones-each with a minimal potential impact on the environment-which cumulatively may have disastrous consequences." (*Lighthouse Field Beach Rescue v. City of Santa Cruz* (2005) 131 Cal.App.4th 1170, 1208-09 [quoting *Bozung v. LAFCo* (1975) 13 Cal.3d 263, 283-84]; see also *Environmental Protection Info. Ctr. v. Calif. Dept. of Forestry & Fire Prot.* (2008) 44 Cal.4th 549, 503.) In other words, where "an individual project is a necessary precedent for action on a larger project," the environmental review performed by the public agency "***must*** address itself to the scope of the larger project." (Cal. Code Regs., § 15165 [emphasis added].) LCFS 46-273

As explained previously, NOx emissions caused by the LCFS regulation from 2011 through 2014 from the San Joaquin Valley, the South Coast air basin, and the entire state, respectively, total 782, 1,032, and 3,463 tons per year. (Decl. Lyons at E-4.) These past emissions – caused directly by the LCFS regulation that remains in effect – are troubling, due to among other things the U.S. EPA's recent redesignation of the San Joaquin Valley as an "extreme" non-attainment area for NOx. (75 Fed. Reg. 24409.) Estimated NOx emissions in the San Joaquin Valley caused by the existing version of the LCFS regulation total approximately 2.39 tons per day (or 872.35 tons per year) in 2020. (Decl. Lyons at D-10 [Figure 1c], F-18 [Table 8].) This is far higher than the San Joaquin Valley Air Pollution Control District's (the "District") adopted threshold of significance for NOx, which explain that a "project" under

CEQA is considered to have a significant impact on air quality if it would cause NOx emissions to exceed 10 tons per year.[2]

LCFS 46-273 cont.

The EA makes no mention of these past increases, despite the fact that under the proposed LCFS regulation considered for "re-adoption" and the ADF regulation, statewide NOx emissions from biodiesel are projected to increase. (ADF ISOR at 42.) To fully consider and evaluate the potential significant impacts of the LCFS regulation and the ADF regulation, CARB may not look at the post-2014 emissions in isolation. Rather, by "chopping" the LCFS regulation into two smaller pieces, and obscuring the environmental impacts of the Regulations in the process, CARB is seeking to impermissibly piecemeal environmental review of the project. (*Lighthouse Field*, *supra*, 131 Cal.App.4th at 1208-09.)

B. The EA's Analysis of Criteria Pollutant Emissions, Including NOx, Is <u>Incomplete</u>

LCFS 46-274

NOx is one of the most important smog-forming emissions from man-made sources in some areas of California, including the San Joaquin Valley. Progress in reducing smog depends largely upon reductions of NOx, or "oxides of nitrogen," which are considered "major contributors to smog formation and acid deposition." (17 C.C.R., § 93118(d)(19).) NOx contributes to the formation of ground-level ozone (smog) in the San Joaquin Valley, particularly during the summer months. (*Calif. Building Indus. Ass'n v. San Joaquin Valley Air Pollution Control Dist.* (2009) 178 Cal.App.4th 120, 126 ["*CBIA*"].) The San Joaquin Valley air basin does not meet the federal ozone standard required under the Clean Air Act; the area has thus been designated by EPA as "extreme non-attainment" for ozone under the federal National Ambient Air Quality standards ("NAAQs"). (75 Fed. Reg. 24409.)

1. The EA Fails to Analyze or Discuss Criteria Pollutants Other than <u>NOx</u>

LCFS 46-275

The EA contains only a minimal discussion of impacts associated with criteria pollutants. (See EA at 51-52.) The EA only quantifies the emissions associated with one criteria pollutant: NOx. There is no discussion of other criteria pollutants, including particulate matter (PM), volatile organic compounds (VOCs), and reactive organic gases (ROG).

Whether CARB believes these impacts are insignificant is irrelevant. CEQA places the burden of environmental investigation on government rather than the public," and a lead agency "should not be allowed to hide behind its own failure to gather data." (See, e.g., *Sundstrom v. County of Mendocino* (1988) 202 Cal.App.3d 296, 311.) By failing to analyze the impacts of the proposed "re-adopted" LCFS regulation and the ADF regulation on criteria pollutants, other than NOx, the EA does not comply with CEQA.

[2] San Joaquin Valley Air Pollution Control Dist., Guide for Assessing and Mitigating Air Quality Impacts (1998; Jan. 2002 rev.) § 4, Table 4-1, p. 26 (the "SJVAPD Guide"), *available at* http://www.valleyair.org/transportation/CEQA%20Rules/GAMAQI%20Jan%202002%20Rev.pdf

2. The Project Will have Significant Impacts Associated With NOx Emissions, Even Using CARB's Own Analyses

Although the EA estimates that NOx emissions will decrease over time, CARB itself estimates that increased use of biodiesel associated with the ADF regulation and the "re-adopted" LCFS regulation will result in additional NOx emissions of 1.29 tons per day [or 470.85 tons per year] in 2015. (ADF ISOR, Table B-1.) Although CARB's estimated increases in NOx are inaccurate, and drastically understate NOx emissions, as explained *infra*, an increase in NOx emissions of 470.85 tons per year is in itself significant, and CARB cannot plausibly claim the Projects' impacts will have "beneficial" impacts on operational criteria pollutant emissions. LCFS 46-276

Any attempt by the EA to offset, or mitigate, biodiesel NOx emissions with the use of renewable diesel fuel is erroneous. There is "nothing in either the proposed ADF regulation or the proposed LCFS regulation that mandates the use of any volume of biodiesel in California, much less the use of the exact ratio of renewable diesel to biodiesel assumed by CARB staff in its emissions analysis." (Decl. Lyons, at D-4.) Despite this, the EA does not include any analysis of the possibility that renewable diesels will not displace biodiesels at the rate contemplated in the ISOR. Thus, any alleged off-set is speculative, and does not excuse CARB's failure to analyze NOx increases associated with biodiesel, or to mitigate the 470.85 tons per year in emissions increased use of biodiesel will generate. LCFS 46-277

Moreover, none of the documents made available for public review by CARB (including the EA, the two ISORs, or the supporting materials) support staff's assertion "that 40% of renewable diesel used in California will be used by refiners to aid in compliance with CARB's existing diesel fuel regulations and that 60% will be blended downstream of refineries." (*Id.*) Indeed, this result defies common sense; to the extent fuel producers choose to blend renewable diesel in California, it would be far more logical for "them to do so by purchasing renewable diesel for use at their refineries where they can benefit from the other desirable properties of this fuel beyond its low carbon intensity (CI) value (e.g., high cetane number and fungibility with diesel fuel at all blend levels)," as opposed to "purchasing LCFS credits generated by downstream blenders of renewable diesel fuel." (*Id.*) LCFS 46-278

The Regulations will have significant impacts resulting from the emission of NOx caused by increase biodiesel usage. As a result, the EA's finding that the Regulations would have a "beneficial" effect to criteria pollutant emissions is erroneous, and not supported by substantial evidence. LCFS 46-279

3. The Analysis of NOx Impacts Is Flawed and Incomplete, and Omits Known Sources of Emissions

The EA's analysis significantly understates the true impacts associated with operational NOx emissions. CARB staff's calculation of NOx emissions associated with increased biodiesel usage was based on the erroneous assumption that biodiesel use in "New Technology Diesel Engines" (NTDEs) at levels up to B20 will not increase NOx emissions. As explained in the Declaration of James M. Lyons, the available data demonstrate "not only that NOx emissions from NTDEs will increase with the use of biodiesel in proportion to the amount LCFS 46-280 of biodiesel present in the blend, but also that the magnitude of the increase on a percentage basis will be much greater than that observed for 'legacy vehicles.'" (Decl. Lyons, at D-4.)

Specifically, "if one simply and extremely conservatively assumes that NTDE NOx increases will be the same on a percentage basis as legacy vehicles and eliminates the NOx offsets assumed from renewable diesel, the NOx increases expected from biodiesel increase from 1.36 tons per day statewide in 2014 to approximately 3.44 tons per day—a factor of about 2.65." (Decl. Lyons, at D-4; see also ADF ISOR, Table B-1.) "For 2023, estimated NOx emission increases due to biodiesel rise to about 0.87 tons per day . . . ." (*Id.* at D-4, D-5.) Thus, accounting for NOx emissions associated with NTDEs alone, projected NOx emissions are far greater than those calculated by CARB staff.

LCFS 46-280 cont.

By performing a detailed and comprehensive – yet conservative – analysis of NOx increases using generally accepted techniques, Sierra Research has concluded that NOx emissions are far more severe, and could total as much as 9.73 tons per day statewide in 2020, and 2.39 tons per day (or 872.35 tons per year) in 2020 in the San Joaquin Valley air basin alone. (Decl. Lyons at D-10 [Figure 1c], D-18 [Table 8].) This figure is vastly higher than the 10 tons per year threshold of significant adopted by the San Joaquin Valley Air Pollution Control District for projects under CEQA. (See SJVAPD Guide, § 4, Table 4-1, p. 26.)

4. The EA Fails to Quantify Impacts Associated With the Construction <u>Of New Facilities</u>

The EA posits that the Regulations would result in the construction of new or modified fuel production facilities to meet demand for fuels created by the Regulations, including processing plants for agriculture-based ethanol, cellulosic ethanol, and biomethane. Without quantifying the potential impacts of these facilities, the EA makes the bare conclusion that several of the impacts associated with these facilities would be "significant and unavoidable."

LCFS 46-281

An environmental document, including a functional equivalent document, however, cannot simply label an impact "significant and unavoidable" without first providing a discussion and analysis. Such a backwards approach "allows the agency to travel the legally impermissible easy road to CEQA compliance." (*Berkeley Keep Jets Over the Bay Comm. v. Bd. of Port Comm'rs* (2001) 91 Cal.App.4th 1344, 1370.) Rather, the lead agency must quantify the impact, and consider feasible mitigation based on that analysis. (See, e.g., *Sundstrom*, *supra*, 202 Cal.App.3d at 311 ["CEQA places the burden of environmental investigation on government rather than the public," and a lead agency "should not be allowed to hide behind its own failure to gather data."].)

The potential impacts associated with the development of new or modified facilities *can* be quantified. As explained in the Declaration of James M. Lyons, CARB attempted to quantify emissions from such facilities in its 2009 rulemaking. (Decl. Lyons at B-3.)

LCFS 46-282

Moreover, by declining to quantify impacts associated with new facilities, the EA essentially forecloses any and all mitigation measures. For example, if potential criteria pollutant emissions were quantified, CARB could modify the proposed regulation, enact another regulation, or otherwise develop mitigation to reduce such impacts. CARB could also reconfigure the Regulations, create performance standards for new California biodiesel facilities, or otherwise create disincentives to develop new facilities within California. Instead, however, the EA merely provides a laundry list of *potential* mitigation measures, without actually requiring that those mitigation measures be implemented, or analyzing whether those mitigation measures would reduce the impacts to a less-than-significant level. LCFS 46-282 cont.

5. The Increased NOx Emissions Under the Regulations Violate AB32

NOx emissions caused by the Regulations also violate AB 32. Health and Safety Code Section 38570, subdivision (b), requires CARB, "***[p]rior to*** the inclusion of any market-based compliance mechanism in the regulations," to "(1) [c]onsider the potential for direct, indirect, and cumulative emission impacts from these mechanisms, including localized impacts in communities that are already adversely impacted by air pollution," and "(2) [d]esign any market-based compliance mechanism *to* ***prevent any increase*** in the emissions of toxic air contaminants or criteria air pollutants." (Health & Saf. Code § 38570, subd. (b) [emphasis added]. In addition, for any regulation adopted under AB32 like the LCFS regulation, the Board must "***ensure*** . . . activities undertaken pursuant to the regulations do not interfere with . . . efforts to achieve and maintain federal and state ambient air quality standards" (*Id.* § 38562(b)(4); emphasis added)].) Because the Regulations would ***increase*** NOx emissions from biodiesel, the Regulations are unlawful. LCFS 46-283

C. The Mitigation Measures Proposed in the EA Inadequate Under CEQA

The Mitigation Measures specified in the EA are also inadequate under CEQA. The EA finds that several potential impacts of the Regulations would be "significant and unavoidable," resulting from the construction of new or modified facilities to meet demand for fuels created by the Regulations, including processing plants for agriculture-based ethanol, cellulosic ethanol, and biomethane. Rather than including enforceable mitigation, however, the EA merely sets forth "recognized practices" that are "routinely required" to avoid or minimize impacts, without requiring the implementation of any specific measure, or even evaluating whether any such measures – if incorporated – would actually reduce or minimize the impact. This is improper under CEQA for several reasons. LCFS 46-284

First, mitigation must be enforceable. (Pub. Resources Code, § 21081.6, subd. (b); CEQA Guidelines, § 15126.4(a)(2).) The EA, however, does not require any particular measure. Rather, the EA just sets forth a potential mitigation measures that local land use authorities *could* implement if they choose to do so. Because none of the mitigation measures identified in the EA are enforceable, they are inadequate under CEQA. LCFS 46-285

Mitigation must also be effective, and an agency must identify mitigation measures that will minimize the project's significant impacts by reducing or avoiding them. (See, e.g., Pub. Resources Code, §§ 21001, 21100.) The EA, however, does not discuss *how* any of the proposed mitigation measures – if implemented – would reduce or avoid the potential impacts of the Regulation, and if so, to what degree. LCFS 46-286

Nor may CARB permissibly defer the formulation of specific mitigation. To defer mitigation, a lead agency must still (1) "evaluate[] the potentially significant impacts of the LCFS 46-287 project," (2) "identif[y] measures that will mitigate those impacts," (3) "commit[] to the mitigating the significant impacts of the project," and (4) "specify performance standards which would mitigate the significant effect of the project" to govern the subsequent mitigation. (*California Native Plant Soc'y v. City of Rancho Cordova* (2009) 172 Cal.App.4th 603, 621.) Here, in contrast, the EA does not specifically identify the potential impacts, require the mitigation of significant impacts, or "specify performance standards which would mitigate the significant effect of the" Regulations. (See *id.*) LCFS 46-287 cont.

As a result, CARB must revise the EA to further analyze potential mitigation measures, and include enforceable mitigation to minimize the recognized potentially significant impacts of the Regulations, and recirculate the revised EA for public review. LCFS 46-288

D. <u>The EA Fails to Analyze Impacts Associated With Fuel Shuffling</u>

Since its enactment in 2009, the LCFS regulation has led to a phenomenon called "fuel shuffling," in which lower-CI fuels are shipped from around the world to California and higher-CI fuels must be sent for sale elsewhere. (Decl. Lyons at B-4.) CARB has admitted that fuel shuffling will occur. (See, e.g., December 2009, Final Statement of Reasons at 241.) There is no environmental advantage to fuel shuffling, for the same fuels are still produced and consumed, and the same GHGs are still emitted from those processes. Rather, because the LCFS regulation encourages the shipment of fuels to alternative locations that are further from origin facilities, fuel shuffling actually causes emissions of GHGs to increase.[3]

These increases in emissions are potentially significant, but discussed nowhere in the EA. For example, even using CARB's direct emissions model (GREET), GHG emissions associated with shuffling would be significant. For example, the LCFS regulation will likely result in higher amounts of Brazilian cane ethanol being shipped to California, with more traditional fuels being shipped from California to Brazil and other destinations by ship. Additional shipping corn- and sugarcane-based ethanol by ship to and from destinations such as Brazil alone would result in an additional 150,000 tons per year of CO2 equivalent emissions. (Appendix G) Using more accurate direct emission models, increase CO2 equivalent emissions would be between 385,000-735,000 tons per year – or nearly 4.5% of the total emissions benefits CARB assets the Regulations would allegedly cause. (Appendix G) Notably, these figures do not include increases in emissions associated with fuel shuffling of crude oils, or the increases in the transport of ethanol by rail as part of fuel shuffling. (Appendix G) LCFS 46-289

The EA likewise does not evaluate whether fuel shuffling caused by the Regulations would result in additional increases in criteria pollutant emissions. Because transportation of fuels by rail, truck, and sea indisputably create emissions of criteria pollutants, both inside and outside[4] California, the EA must analyze those potential impacts to determine LCFS 46-290

[3] Because the LCFS regulation will not achieve any benefits as to climate change, CARB cannot base any statement of overriding considerations on this assertion.

[4] CARB must analyze both in-state and out-of-state impacts caused by the Regulation. CEQA defines "environment" to include "the physical conditions that exist within the area which will be affected by a proposed project, including land, air, water, minerals, flora, fauna, noise, or objects of historic or aesthetic significance." (Public Resources Code, § 21060.5.) That definition includes no geographic limitation. We also understand CARB has considered out-of-state impacts in previous rulemakings.

whether they are significant. (See, e.g., *Sundstrom*, *supra*, 202 Cal.App.3d at 311 ["CEQA places the burden of environmental investigation on government rather than the public," and a lead agency "should not be allowed to hide behind its own failure to gather data."].) LCFS 46-290 cont.

Thus, to accurately identify and analyze the impacts of the Regulations, the EA must be revised to address impacts associated with fuel shuffling, and recirculate the EA for public review. LCFS 46-291

E. <u>The EA's Discussion of the Growth Energy Alternative Is Insufficient</u>

The requirement that environmental documents identify and discuss alternatives to the project stems from the fundamental statutory policy that public agencies should require the implementation of feasible alternatives or mitigation measures to reduce the project's significant impacts. (See, e.g., Pub. Resources Code, § 21002.) The lead agency must focus on alternatives that can avoid or substantially lessen a project's significant environmental effects. (See *id.*) The EA here impermissibly rejects discussion of the Growth Energy Alternative, and does not include any discussion of a Cap and Trade Alternative. These alternatives are discussed in greater detail below. The CEQA Guidelines specifically recognize that comments raised by members of the public on an environmental document are particularly helpful if they suggest "additional specific alternatives . . . that would provide better ways to avoid or mitigate the significant environmental effects." (CEQA Guidelines, § 15204.) LCFS 46-292

The Growth Energy Alterative contemplates an adjustment to the cap and trade regulation in Title 17 of the California Code of Regulations to account for whatever increment of GHG emissions reductions would be foregone by eliminating the LCFS regulation. CARB concedes the Growth Energy Alternative would achieve the same emissions reductions contemplated under the Regulations. (See Standardized Regulatory Impact Assessment at 26-27.) LCFS 46-293

The Growth Energy Alternative also would not result in fuel shuffling, or the construction of numerous fuel production plants in California. (See Decl. Lyons at B-4.) Because the only impacts found to be "significant and unavoidable" under the EA result from the construction of new and modified fuel production facilities, the Growth Energy Alternative would likely eliminate ***all*** of the Regulations' significant and unavoidable impacts. Because the Growth Energy Alternative would lessen the "significant and unavoidable" effects of the Regulations, it should be included as an alternative in a recirculated EA. (Pub. Resources Code, § 21002.) LCFS 46-294

Despite these benefits, the EA rejects the Growth Energy Alternative to the Regulations because it would allegedly require that actions be taken to mitigate increased NOx emissions from biodiesel under circumstances where CARB staff incorrectly assumed there would be no increased emissions due to biodiesel use under the ADF. These assumptions are flawed. LCFS 46-295

As demonstrated by Sierra Research, the ADF regulation will result in significant and unmitigated increases in NOx emissions throughout California, including significant impacts within the San Joaquin Valley and South Coast air basins. (Decl. Lyons ¶ 15.) The EA concedes the mitigation proposed under the Growth Energy Alternative would require "mitigation in exactly those areas where CARB staff was lead to believe it was not required based on its flawed emissions analysis." (Decl. Lyons at G-3.) Because of this, and the fact that the Growth Energy Alternative expands the conditions under which this mitigation has to be applied in order to eliminate the potential for any increase in NOx emissions due to biodiesel use, the Growth Energy Alternative is environmentally superior to the ADF regulation. (*Id.*) LCFS 46-295 cont.

To the extent CARB argues the Growth Energy Alternative does not meet the objective of "greater innovation and development of cleaner fuels," this is not a valid reason to reject discussion of the alternative. First, as explained in the Declaration of James M. Lyons, the Growth Energy Alternative would also foster greater innovation and development of cleaner fuels in California because most of the same fuels will be blended into California fuels as a result of the federal RFS program. (Decl. Lyons at C-4.)

But even if the Growth Energy Alternative would not meet this project objective, (see ISOR at E-40, E-41), CARB may not simply reject discussion of an alternative simply because it does not meet one of several project objectives. Rather, a feasible alternative that would substantially reduce the project's significant impacts should not be excluded from the analysis simply because it would not fully achieve the project's objectives. (See *Habitat & Watershed Caretakers v. City of Santa Cruz* (2013) 213 Cal.App.4th 1277, 1304.) Here, as discussed above, the Growth Energy Alternative would essentially eliminate all of the "significant and unavoidable" impacts of the Regulations. LCFS 46-296

Further, to the extent CARB relies upon this objective to reject mere analysis of the Growth Energy Alternative, this is improper because it would essentially limit the range of alternatives described to regulations that are nearly identical to the Regulations. Because agencies may not "give a project's purpose an artificially narrow definition," (*In re Bay-Delta Programmatic Envt'l Report Coordinated Proceedings* (2008) 43 Cal.4th 1143, 1166), and CARB has previously demonstrated a pattern of prejudging the LCFS regulation prior to completing the environmental review process, (see *POET, LLC v. California Air Resources Board* (2013) 218 Cal.App.4th 681), CARB should not artificially tailor its objectives to limit the range of alternatives to the LCFS regulation itself. LCFS 46-297

In short, the Growth Energy Alternative better achieves the project objectives than the Regulations, and is environmentally superior to the Regulations. As a result, the EA must analyze the Growth Energy Alternative, and CARB must recirculate the EA for public comment. LCFS 46-298

F. CARB Must Substantially Revise the LCFS Regulation, the ADF Regulation, And the EA, Due to Material Inconsistencies Between the Two Regulations

As explained in detail in the Declaration of James M. Lyons, the LCFS regulation and the ADF regulation "contain inconsistent and conflicting definitions," and lack "provisions requiring the determination, through testing, of the biodiesel content of commercial blendstocks." (Decl. Lyons ¶ 17.) These inconsistencies include that: (1) the Regulations contain different definitions for the term "biodiesel"; (2) the term "Biodiesel Blend" under the LCFS regulations contains at least 6% biodiesel, while a "Biodiesel Blend" under the ADF is a diesel fuel containing any biodiesel; (3) the LCFS regulation defines "Diesel Fuel Blend" as a blend of diesel fuel and up to 5% biodiesel, while such a fuel would be considered "CARB diesel" under the ADF regulation; and (4) under the proposed ADF regulation, "B20" is LCFS 46-299 nonsensically defined as a fuel that contains between 6% and 20% biodiesel, which directly contradicts the definition of "Blend Level" in same regulation. (See Decl. Lyon at H-3, H-4.)

In addition, the term "Biodiesel Blend" is defined in the ADF regulation as a mixture of biodiesel and an undefined fuel referred to as "petroleum-based CARB diesel." "Blend Level" applies to blends of all fuels subject to the ADF regulation, including biodiesel, and is defined as the ratio of an "Alternative diesel fuel" mixed with "CARB diesel." As noted above, however, "CARB diesel" may already contain as much as 5% biodiesel under the proposed ADF regulation. The addition of biodiesel to a fuel already containing some amount of biodiesel up to 5% will cause the actual biodiesel content to be higher than the blender expects, which in turn will result in increased NOx emissions. (See Decl. Lyons at F-3, F-4.) These potential NOx emissions are not discussed in the EA.

LCFS 46-299 cont.

The internal inconsistencies between the LCFS regulation and the ADF regulation also render the project description defective. "An accurate, stable and finite project description is the sine qua non of an informative and legally sufficient EIR." (*County of Inyo v. City of Los Angeles* (1977) 71 Cal.App.3d 185, 193.) Because the LCFS regulation and the ADF regulation contain material, conflicting terms, the project description is not accurate or stable, and must be revised.

Due to these material inconsistencies, the EA is legally flawed. Both the proposed regulations and the EA must be revised significantly, and recirculated for public review.

FILED
FEB 10 2014
FRESNO SUPERIOR COURT
By________ DEPT. 402 - DEPUTY

SUPERIOR COURT OF CALIFORNIA, COUNTY OF FRESNO

CENTRAL DIVISION

POET, LLC and JAMES M. LYONS Petitioners and Plaintiffs, vs. CALIFORNIA AIR RESOURCES BOARD; JAMES N. GOLDSTENE, in his official capacity as Executive Officer of the California Air Resources Board; LORI ANDREONI, in her official capacity as a Manager of the California Air Resources Board; and ELLEN PETER, in her official capacity as Chief Counsel of the California Air Resources Board, Respondents and Defendants.	Case No. 09 CE CG 04659 **[redacted] PEREMPTORY WRIT OF MANDATE** Department: 402 Honorable Jeffrey Y. Hamilton, Jr. Action Filed: December 23, 2009

Judgment having been entered in this proceeding, ordering that a peremptory writ of mandate be issued from this Court,

IT IS ORDERED that, immediately on service of this writ:

1. Respondent and Defendant California Air Resources Board ("ARB") set aside its approval of the Low-Carbon Fuel Standard ("LCFS") regulations, including Board Resolution 09-31, dated April 23, 2009; Executive Order R-09-014, dated November 25, 2009; Executive Order R-10-003, dated March 4, 2013; and ARB's decision to defer the formulation of mitigation measures relating to NOx emission from biodiesel.

2. ARB shall (a) select a decision maker, (b) take such action as may be necessary to assure that the decision maker has full authority to approve or disapprove the proposed LCFS regulations and to complete the environmental review, and (c) take such action as may be necessary to assure the decision maker does not approve the proposed LCFS regulations until after the decision maker has completed the environmental review.

3. ARB shall address whether the project will have a significant adverse effect on the environment as a result of increased NOx emissions, make findings (supported by substantial evidence) regarding the potential adverse environmental effect of increased NOx emissions, and adopt mitigation measures in the event the environmental effects are found to be significant.

4. ARB shall allow public comments for a period of at least 45 days on all issues related to the approval of the proposed LCFS regulations (which shall include, without limitation, issues concerning (a) the carbon intensity values attributed to land use changes, (b) the application of the GTAP model, and (c) any new material in any supplemental staff report prepared in connection with the proposed LCFS regulations) and respond to those comments before approving the proposed LCFS regulations.

5. ARB shall [redacted] include in its rulemaking file [redacted] the four emails referenced in the July 15, 2013, Opinion of the Fifth District Court of Appeal, case number F064045, at pages 61 through 80.

6. ARB shall preserve the status quo by continuing to adhere to the LCFS regulations standards in effect for 2013 until the corrective action is completed. Notwithstanding the directive herein that ARB set aside its prior approvals of the LCFS regulations and related resolutions and orders, the LCFS regulations shall remain in operation and shall be enforceable unless its operation is suspended as provided below.

7. Pursuant to Public Resources Code Section 21168.9(c), the Court does not direct ARB to exercise its lawful discretion in any particular way.

8. Pursuant to Public Resources Code Section 21168.9(c), the Court shall retain jurisdiction over ARB's proceedings by way of a return to this peremptory writ of mandate until the Court has determined that ARB has fully complied with the provisions of CEQA.

9. ARB shall file an initial return no later than 30 days after issuance of this writ. The initial return shall explain what action ARB will take to satisfy the writ's requirements; this explanation shall include a schedule and shall identify who will act as the decision maker.

10. Within 15 days of the filing of the initial return, Plaintiffs POET, LLC, and James M. Lyons ("Plaintiffs") may file a response, which shall include Plaintiffs' objections to matter addressed in the initial return. If Plaintiffs file a response, ARB's reply shall be due no later than 15 days after the response.

11. ARB shall proceed in good faith without delay. In the event ARB fails to proceed in good faith with diligence, this Court immediately shall vacate Paragraph 6 of this writ, which preserves the status quo, and shall direct ARB to set aside the LCFS regulations (i.e., suspend the operation and enforcement of the regulations).

IT IS SO ORDERED.

DATED: 2/10/14

Honorable Jeffrey Y. Hamilton, Jr.
Judge of the Superior Court

Submitted on this 23rd day of December 2013, by:

Timothy Jones
John P. Kinsey
Daren A. Stemwedel
Attorneys for Petitioners and Plaintiffs
POET, LLC and James M. Lyons

PROOF OF SERVICE

My business address is 265 E. River Park Circle, Suite 310, Post Office Box 28340, Fresno, California 93720. I am employed in Fresno County, California. I am over the age of 18 years and am not a party to this case.

On the date indicated below, I served the foregoing document(s) described as **[PROPOSED] PEREMPTORY WRIT OF MANDATE** on all interested parties in this action by placing a true copy thereof enclosed in sealed envelopes addressed as follows:

SEE ATTACHED SERVICE LIST

_____ **(BY MAIL)** I am readily familiar with the business' practice for collection and processing of correspondence for mailing, and that correspondence, with postage thereon fully prepaid, will be deposited with the United States Postal Service on the date noted below in the ordinary course of business, at Fresno, California.

_____ (BY PERSONAL SERVICE) I caused delivery of such envelope(s), by hand, to the office(s) of the addressee(s).

_____ (BY ELECTRONIC MAIL) I caused such documents to be scanned into PDF format and sent via electronic mail to the electronic mail addressee(s) of the addressee(s) designated.

_____ (BY FACSIMILE) I caused the above-referenced document to be delivered by facsimile to the facsimile number(s) of the addressee(s).

__X__ (BY OVERNIGHT COURIER) I caused the above-referenced envelope(s) to be delivered to an overnight courier service for delivery to the addressee(s).

EXECUTED ON December 23, 2013, at Fresno, California.

__X__ **(STATE)** I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct.

Comment List: lcfs2015

Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento CA, 95814

Dear Chairman Nichols and Board Members:

Kern Oil & Refining Co. (Kern) is providing comments on the California Air Resources Board's (ARB) Proposed Re-Adoption of the Low Carbon Fuel Standard (LCFS). Specifically, Kern is providing comments in support of the following: (1) Low-Complexity/Low-Energy Use (LC/LU) Refinery Provision; (2) Refinery-specific Incremental Deficit Option; (3) Refinery Investment Credit; and (4) Modification of Compliance Curves for Gasoline and Diesel Standards.

Kern is an independently owned, small refinery located in the Southern San Joaquin Valley, just outside Bakersfield, California. From the inception of LCFS, Kern has been acutely aware of the potential inequalities that result from methodologies adopted to effectuate program goals in a manageable manner for CARB. The loss of granularity and reliance upon averages to effectuate program goals is understandable from a management standpoint; however, it can have detrimental impacts on stakeholders like Kern who do not fit the average mold. In California, the crude oil capacity of transportation fuel producing refineries ranges from approximately 26,000 to 343,800 barrels per day, with a rough average of 142,000.[1] At a crude oil capacity of 26,000 barrels per day, Kern is literally the smallest refinery currently producing transportation fuels. In certain circumstances, specifically the vast discrepancy in facility size and complexity in the refining sector, a more robust/complicated methodology is required to insure the program is being effectuated in a credible and equitable manner. Kern is gratified that the Board has

[1] See California Energy Commission, California Energy Almanac, California Oil Refineries, Information as of November 2014, http://energyalmanac.ca.gov/petroleum/refineries.html and considering Tesoro-Carson / Tesoro Refining & Marketing Company, Wilmington Refinery as a single facility.

previously acknowledged and directed Staff to consider these inequalities and that the LCFS Re-Adoption is incorporating provisions that recognize and take steps to mitigate the inequalities inherent in the broader LCFS "average refinery" implementation methodologies.

Low-Complexity/Low-Energy Use (LC/LU) Refinery Provision

Kern strongly supports ARB's inclusion of a provision issuing a credit for Low-Complexity/Low-Energy Use (LC/LU) refineries in recognition of the inherent lower carbon intensities (CI) of transportation fuels produced at these facilities. The credit helps address the unfair subsidization of higher than average energy-use refiners that results from the current regulation's reliance upon the "average refinery" in determining CI values for finished transportation fuels. Kern greatly appreciates the extensive work performed by CARB staff in calculating the demonstrable lower CI of the transportation fuels produced by LC/LU refineries, which serves as the strong scientific and technical basis for the credit consideration being given to those refineries.

During the initial program adoption during April of 2009, Kern raised concerns regarding the disproportionate impact of the LCFS on low-complexity, lower-energy use refineries like Kern as a result of the program's use of the "average refinery" in calculating CI and emissions targets. On December 16, 2011, the Board formally acknowledged and echoed Kern's concerns – directing the Executive Officer in Resolution 11-39 to consider provisions to the LCFS to address low-energy-use refining processes. As acknowledged in the Staff Report: Initial Statement of Reasons for Proposed Re-Adoption of the Low Carbon Fuel Standard ("ISOR"),[2] Resolution 11-39 was meant to address the lower energy inherently embedded into the transportation fuels from refineries that use simple processes to refine transportation fuels. LCFS 52-1

Over the next three years, staff performed extensive analysis of refinery data submitted through the robust Mandatory Reporting Regulation which unequivocally demonstrated that LC/LU refineries, in fact, embed less carbon intensity into the fuels they produce. In line with the Board's direction, Staff also considered and has adopted clear, justifiable metrics defining LC/LU refineries in relation to a refinery's modified Nelson Complexity and Total Annual Energy Use. Staff's analysis across the refining sector demonstrated a clear break between LC/LU refineries versus their larger, more-complex peers at a Modified Nelson Complexity of less than or equal to 5 and a Total Annual Energy Use of 5 million MMBtu per year.[3] Staff's analysis further demonstrated that the identified LC/LU refineries have demonstrably lower CIs for produced gasoline and diesel – 5.53 gCO2e/MJ below the complex refineries' CI for gasoline and 4.79 gCO2e/MJ below the complex refineries' CI for diesel.[4] After a robust public process, which included multiple workshops, extensive stakeholder collaboration and consideration of no less than seven alternatives,[5] Staff is proposing to credit the LC/LU refineries 5 gCO2e/MJ for

CARBOB and diesel. Kern strongly supports the credit proposal and is grateful to staff for the years of work, analysis and stakeholder collaboration that have ultimately culminated in the current proposal. LCFS 52-1 cont.

Refinery-specific Incremental Deficit Option

Kern continues to be encouraged by ARB's acknowledgement that low volume refineries are disadvantaged by the current California Average Approach, in that they can be affected by the incremental deficit but cannot affect the sector-wide annual crude average CI. ARB is proposing a one-time opportunity for Low-Complexity/Low-Energy Use (LC/LU) refineries to opt out of the California Average Approach, and instead have their incremental deficits determined through a comparison of the facility's annual average crude CI and its 2010 baseline crude CI. Kern has some concerns about the potential for LC/LU refineries to be locked into too low of a CI baseline, but is generally supportive of the option proposed.

Kern, however, does believe that ARB should revise the option as relates to the use of a default CI for crude oils that do not have a specific CI assigned in the regulation. As proposed, any crude without a specific assigned CI would get assigned the California average CI of 12.71 gCO_2e/MJ. ARB should assign LC/LU refineries opting into the incremental deficit option their own average default crude CI based on their 2010 baseline CI. Given that LC/LU refiners will likely have 2010 Baseline CIs much lower than the California Average, and that ARB only intends to update the CI lookup table with new crudes on a three year cycle, assigning a California Average default crude CI to all new crudes will unnecessarily limit or even prevent LC/LU refineries from running new crudes without incurring incremental deficits. A LC/LU's default CI for new crudes should also be its individual 2010 Baseline CI as opposed to the California Average because a LC/LU's individual 2010 Baseline CI is more representative of that facility's historic performance as opposed to the State's historic performance. Kern also believes that ARB should consider an implementation schedule for the Refinery-specific Incremental Deficit Option similar to the three-year rolling phase-in approach as proposed in the California Average method for transitioning from the 2010 Crude CI Lookup Table to the 2012 Crude CI Lookup Table. LCFS 52-2

Modification of Compliance Curves for Gasoline and Diesel Standards

Given, the two year delay resulting from the *Poet* decision and the required re-adoption of the LCFS, Kern agrees with ARB that some adjustment must be made to the compliance curves to prevent imposition of a sudden dramatic reduction that would negatively affect the market and regulated parties' ability to comply. Kern understands that ARB has conducted in-depth analyses of projected fuels availabilities and evaluated the impact on compliance goals from separate proposed changes to the LCFS in order to develop the proposed compliance curves. To that end, Kern supports ARB smoothing out the curve to 2020 to ensure that reductions are required in a ratable and smooth manner. LCFS 52-3

GHG Emissions Reductions at Refineries

Kern is cautiously optimistic with regard to ARB's proposal to reward refiners for projects resulting in demonstrable emission reductions at a stationary source facility. As Kern LCFS 52-4 understands it, refiners would earn program credits in consideration of those reductions, consistent with full life cycle analyses demonstrating lower resultant CI of fuels produced. ARB's proposal describes an application process where the refinery's baseline transportation fuel CI would be calculated and compared to the new, post-project calculated transportation fuel CI. Specifically, credits would be generated based on the difference between these two CIs, but only for qualifying projects where a reduction of greater than 0.1 gCO2e/MJ is achieved. Kern understands that Staff's intention is to allow for a project to be implemented in multiple phases over an approved period of time in order to achieve the threshold 0.1 gCO2e/MJ and recommends additional language be added to the proposed regulatory text to clarify Staff's intent. As a small refinery, Kern has limited resources and must utilize its efforts, resources and investments with a high degree of efficiency. Allowing flexibility on the timing of a project is critical because it is not always financially feasible to carry out a substantial project all at once.

LCFS 52-4 cont.

In conclusion, Kern appreciates ARB's consideration of Kern's comments. As always, Kern is committed to working with Staff throughout this regulatory process.

Sincerely,

Melinda L. Hicks

52_OP_LCFS_Kern Responses

583. Comment: **LCFS 52-1**

Agency Response: ARB staff appreciates the support for the proposed Low Complexity/Low Energy Use provision.

584. Comment: **LCFS 52-2**

The commenter requests that ARB revise the use of average CIs for crude oils that don't have a specific CI.

Agency Response: ARB staff agrees that refineries opting for refinery-specific incremental deficit accounting should be assigned their refinery 2010 Baseline carbon intensity (CI) as a default for new crudes. Staff included this revision as part of the 15-day change package. Staff disagrees, however, with the suggestion to use a three-year rolling transition into the refinery-specific accounting. The California Average approach was initially implemented in 2012, and therefore a three-year rolling transition is appropriate. If adopted, the refinery-specific option will start in 2016 with assessment of the 2015 refinery crude slate. Refinery crude slates for previous years are not relevant to the refinery-specific option as these were assessed under the California Average approach for years 2013 and 2014.

585. Comment: **LCFS 52-3**

Agency Response: ARB staff appreciates the support for the compliance curves.

586. Comment: **LCFS 52-4**

The commenter requests that ARB staff add additional language to allow for projects to be implemented over multiple phases over an approved period of time.

Agency Response: ARB staff does not agree that additional language is necessary to address the concerns expressed by Kern. A refinery applying for a Refinery Investment Credit may define the length and the scope of the project as it wishes in its application for the Refinery Investment Credit. All portions of the project will be subject to the post-January 1st, 2016 authority-to-construct permit approval deadline. The project shall not start generating credits until it has achieved a reduction of 0.1 gCO_2e/MJ or more from the comparison baseline.

Re: Public Health Support for Low Carbon Fuel Standard

Dear Chairman Nichols:

On behalf of the undersigned organizations and individuals dedicated to improving the health and medical well-being of Californians, we write in support of the re-adoption of the Low Carbon Fuel Standard (LCFS) to advance California's leadership in moving beyond petroleum and promoting a healthier mix of transportation fuels to keep Californians moving. Since its original adoption, public health and medical groups have supported the LCFS as a key strategy for cleaning our air and ensuring California meets its landmark AB 32 climate targets for 2020. This policy will also be critical to help meet Governor Brown's health-protective goal to cut petroleum usage in California by 50 percent by 2035. LCFS 53-1

California's current dependence on petroleum fuels generates nearly half of our climate pollution, 80 percent of smog-forming NOx emissions and 95 percent of cancer causing diesel particulates[1]. Approximately 40 percent of Californians live close enough to major roadways[2] to experience higher health risks caused by traffic pollution. These pollutants cause billions in health and economic costs and contribute to public health burdens including: respiratory and cardiac illnesses, hospitalizations and deaths as well as the growing health impacts of climate change. California must stay the course with the LCFS regulation to ensure fuels are at least 10% cleaner by 2020, and plan for continued reductions beyond 2020. We appreciate the inclusion of strengthening amendments, such as the provision designed to spur more investment in cleaning up local refinery facilities and produce health and community benefits. We also support the inclusion of safeguards as proposed by staff to ensure that any biofuels used to meet the standard maintain progress toward both criteria air pollution and greenhouse gas reduction goals. LCFS 53-2

Our comments support continuing forward progress with the LCFS to protect the health and well-being of all Californians, and especially those most impacted by dirty fuels, as more alternatives come online to combat climate change. LCFS 53-3

The Low Carbon Fuel Standard promotes a cleaner, healthier fuel mix. The LCFS moves California forward toward the cleanest, most sustainable, low carbon fuels. Each year the LCFS will promote a cleaner mix of fuels and support the implementation of important regulations like the Zero Emission Vehicle Regulation. The CARB analysis demonstrates that the LCFS will provide substantial health benefits by reducing pollution that cuts lives short. In 2020, CARB estimates that nearly 100 lives will be saved by displacing harmful fuels with cleaner, healthier choices.[3] These findings complement recent Lung Association research demonstrating over 400 lives will be saved with the LCFS and Cap and Trade programs' implementation, avoiding over $23 billion in societal damages, including $8.3 billion in respiratory health impacts, by 2025.[4] CARB should move forward to finalize these health-protective policies. LCFS 53-4

CARB should both maintain the 2020 LCFS target and plan additional emission reductions beyond 2020. California's health and medical community strongly support the proposal to re-adopt the LCFS with the original target for a 10 percent carbon reduction by 2020. This goal is vital to cutting the health harms caused by our transportation fuels by incentivizing ever-cleaner choices for Californians. In the first years of the program, the equivalent of taking nearly 2 million vehicles off the road was achieved through the modest requirements to reduce carbon – a number projected to equal removing over 7 million vehicles as the program moves on between 2016 and 2020[5,6]. We believe that after the LCFS is re-adopted, that CARB must turn quickly to the next phase of the program and determine an ambitious course beyond 2020 and evaluate efforts to strengthen the regional programs developing along the West Coast. LCFS 53-5

Refinery Investment provisions support environmental justice and local air quality. We applaud the development of the refinery investment provision as a positive incentive to cut greenhouse LCFS 53-6

gases, toxics and other air pollutants in communities burdened by refinery emissions. While this program is aimed at reducing petroleum consumption, we must also support incentives to clean up local pollution sources and improve community health as the LCFS moves forward. We are especially supportive of CARB precluding refinery investment projects that would cut carbon but increase criteria air pollutants or air toxics from receiving credits. LCFS 53-6 cont.

Biorefinery Siting Guidance needs update to incorporate new information on disadvantaged communities. Given the focus in many AB 32 discussions on the need to protect and improve health and air quality in California's most disadvantaged communities, CARB should provide more clear direction to staff on the timing to update the *Siting Guidance for Biorefineries in California* section on cumulative impacts. Specifically, the guidance document should be updated to reflect the development and widespread use of CalEPA's CalEnviroScreen tool for identifying communities most disadvantaged by local pollution. LCFS 53-7

Expanded electric transportation credits support clean air. Our organizations support the expanded role for electrification of transportation in the LCFS. The proposal to allow transit agencies to opt-in to the LCFS for fixed guideway systems (light rail, street cars, trolleys, etc.) encourages cleaner transit that cuts carbon pollution, cleans up neighborhood traffic pollution and supports sustainable communities as envisioned under Senate Bill 375. We support the provisions to more clearly account for the sustainability benefits of California's growing electric bus fleet. These expanded electric transportation credits provide local air quality benefits, encourage the development of more ultra-low carbon transportation options[7] and support healthier, sustainable communities. LCFS 53-8

Ensure low carbon fuels support clean air progress. California needs to continue to focus on promoting the cleanest, most sustainable fuels over the long term. The LCFS regulation must ensure that any alternative fuels used to meet LCFS requirements in the short term contribute to both criteria pollutant and climate benefits without any unintended consequences. We believe that staff's proposal to re-adopt the Low Carbon Fuel Standard along with separate proposals being considered to protect against criteria emissions backsliding is an appropriate pathway forward. LCFS 53-9

In closing, our organizations strongly support the re-adoption of the LCFS to cut petroleum use, air pollution and climate change impacts as California moves forward to a low carbon economy. Further, the LCFS is a crucial component of climate leadership on the West Coast because it provides a strong model for national and international action to clean up transportation fuels and promote improved health and sustainability. We urge the California Air Resources Board to continue its leadership and advance the Low Carbon Fuel Standard to benefit all Californians. LCFS 53-10

53_OP_LCFS_CAHealth Responses

587. Comment: **LCFS 53-1**

The comment expresses support for the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

588. Comment: **LCFS 53-2**

The comment expresses support for the compliance curves and refinery investment provision.

Agency Response: ARB staff appreciates the support for the compliance curves and the proposed refinery investment provision.

589. Comment: **LCFS 53-3**

The comment expresses support for the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

590. Comment: **LCFS 53-4**

The comment expresses support for the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support of the human health benefits of the re-adoption of the LCFS regulation.

591. Comment: **LCFS 53-5**

The comment stresses the importance of maintaining the target of a 10 percent carbon reduction by 2020.

Agency Response: The regulation approved by the Board retains the requirement for a 10 percent carbon intensity reduction in 2020.

592. Comment: **LCFS 53-6**

The comment supports the refinery investment provision and the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the proposed refinery investment provision.

593. Comment: **LCFS 53-7**

The comment requests ARB staff to provide more clear direction on the timing to update the *Siting Guidance for Biorefineries in California* section.

Agency Response: See response to **LCFS 42-17**.

594. Comment: **LCFS 53-8**

The comment expresses support for the expanded electric transportation credits of the LCFS proposal.

Agency Response: ARB staff appreciates the support for the proposed electricity provision.

595. Comment: **LCFS 53-9**

The comment lends support for the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

596. Comment: **LCFS 53-10**

The comment lends support for the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

California Air Resources Board

Proposed Re-Adoption of the Low Carbon Fuel Standard

Comments Submitted by the Energy Future Coalition and the Urban Air Initiative
February 17, 2015

The Energy Future Coalition and Urban Air Initiative commend CARB for its groundbreaking work in the area of low carbon transportation fuels, and we appreciate this opportunity to comment on ways to further improve on the efficacy of California's Low Carbon Fuel Standard (LCFS). CARB has the opportunity with this rulemaking, in reducing the carbon footprint of the California transportation sector, to take steps that will not only help address the threat of global climate change, but also mitigate serious impacts on public health.

As summarized here and developed more fully in the appendices, these comments argue that:

1. Automakers who continue to use internal combustion engines must increase engine efficiency to meet LCFS standards and reduce GHGs.
2. Displacing aromatics now used for octane in gasoline would produce substantial benefits for public health.
3. Increased use of domestically produced renewable ethanol is essential to both objectives and would have additional co-benefits.
4. The LCFS should fully reflect the latest research on the value of mid-level ethanol blends to reduce GHGs and benefit public health and the environment through the displacement of aromatics. LCFS 54-1

About the Energy Future Coalition and the Urban Air Initiative

The Energy Future Coalition is a broad-based, non-partisan public policy initiative, co-located with the United Nations Foundation in Washington, DC. The Coalition seeks to bridge the differences among stakeholder groups and identify domestic energy policy options that can find broad political support and accelerate the transition to a clean energy economy. Since the Coalition's founding in 2002, one of its principal areas of interest has been the potential of clean renewable fuels to reduce the nation's dependence on oil. This has led to a focus on the public health consequences of the use of aromatic compounds to enhance octane in gasoline. On two occasions, most recently last year, the Coalition co-hosted workshops on this topic with the National Institute of Environmental Health Sciences (NIEHS).

The Urban Air Initiative is a non-profit entity dedicated to research and education in the area of fuel quality and its relationship to mobile source emissions, especially in urban areas. The climate and public health impacts of mobile source (traffic) pollution—in the U.S. and globally—are of great importance to policymakers, industries, and the billions of people that are regularly exposed to harmful pollutants in their homes, schools, and vehicles. Among the most vulnerable are infants and children. The Urban Air Initiative believes that protecting our children's health and well-being is the most important investment society can make to build a better future.

Toward that end, in recent years our two organizations have analyzed dozens if not hundreds of peer-reviewed studies supported and/or conducted by the U.S. Environmental Protection Agency (EPA), the Health Effects Institute (HEI), NIEHS, the U.S. Department of Energy (DOE), the National Oceanographic and Atmospheric Administration (NOAA), numerous federal laboratories (e.g., Argonne, Oak Ridge, NREL, Pacific Northwest, etc.), the California Air Resources Board (CARB), academic institutions, auto companies, and many others.

Context of the LCFS Rulemaking

For many years, California has been a global trend-setter in transportation fuels regulatory policy. The state is one of the world's largest consumers of gasoline, and it has more gasoline-powered light duty vehicles (LDVs) than most nations. Consequently, CARB has led the way in addressing the serious health and climate threats from gasoline combustion by-products. By law, California has special status—relative to other states—in terms of establishing fuel quality standards under the Clean Air Act. CARB's experts recognize that fuel composition is just as important as vehicle control technologies in reducing emissions of carbon and other harmful pollutants.

The December 2014 CARB staff report on the LCFS, "Initial Statement of Reasons for Proposed Rulemaking," notes in the Executive Summary that "the production, transport, and use of traditional fuels are responsible for nearly half of the state's greenhouse gas (GHG) emissions" and states: "The primary goal of the LCFS regulation is to reduce the carbon intensity of transportation fuels used in California by at least ten percent by 2020 from a 2010 baseline." It goes on to say, "The LCFS is a key part of a comprehensive set of programs in California to reduce GHG emissions and other smog-forming and toxic air pollutants from the transportation sector."

These comments are intended to show the link between reducing "GHG emissions and other smog-forming and toxic air pollutants from the transportation sector" and to "encourage the use of cleaner low-carbon fuels in California, encourage the production of those fuels, and, therefore, reduce GHG emissions."

Statement of the Case

1. **Automakers who continue to use internal combustion engines must increase engine efficiency to meet LCFS standards and reduce greenhouse gas emissions.**

Meeting the California LCFS standards by 2020, the EPA's ambitious fuel economy standards of 54.5 miles per gallon by 2025, and the "more aggressive targets for 2030" forecast for California in the current rulemaking will require a fleet-wide transition to light-duty vehicle technologies capable of much greater efficiency. While electric vehicles are gaining traction, they are not expected to achieve substantial market penetration in that time, nor are hydrogen fuel cell vehicles likely to be commercially viable at scale. Even in 2040, according to the U.S. Energy Information Administration, cars with gas- and diesel-powered engines will still represent some 95% of the international car market. Continued evolution of today's internal combustion engines, on the other hand, can achieve the fuel economy targets at an affordable cost. Highly efficient high-compression engines offer the cheapest and most certain path to the GHG and fuel economy standards of the future. The limiting factor is not scalable vehicle technology, but fuel—specifically its octane rating.

The efficiency of an internal combustion engine increases as a factor of its compression ratio – which reflects the amount of fuel burned in a single piston stroke. Higher-octane fuels are needed to enable higher compression ratios – they can withstand a greater rise in temperature during the compression stroke without igniting, thus allowing more power to be extracted. (Uncontrolled combustion, or knock, is harmful to an engine and would render a vehicle unmarketable.)

Thus, to perform adequately, high-compression engines require higher-octane fuel than today's regular-grade gasoline. Premium gasoline can deliver more octane at a higher cost but is currently produced by the addition of a blend of toxic aromatic hydrocarbons, implicated in a range of serious health effects. Clean-burning alcohol fuels such as ethanol, on the other hand, are inherently high in octane. These fuels – which, unlike gasoline, can be produced from a variety of feedstocks, including cellulosic biomass, municipal waste, and even natural gas – can enable greater fuel economy while providing substantial environmental benefits and dramatically reducing oil dependence in the next decade, at a price that mainstream Americans can afford.

Automakers have asked EPA for higher-octane gasoline to comply with the new fuel efficiency-carbon reduction rules.[1] Higher-octane gasoline would enable a compression ratio increase of approximately 2 numbers, significantly increasing fuel efficiency while reducing the most harmful emissions. To do that, automakers need an octane pool of 94 AKI (100 RON) gasoline, as compared with today's U.S. market standard of 87 AKI.

Ethanol has superior octane enhancement properties compared to other alternatives. Technically, economically, and legally (because the Clean Air Act limits the amount of aromatics in reformulated gasoline), the best and perhaps only way to make 94 AKI gasoline available nationwide is with mid-level ethanol blends (discussed here as E30). These blends have been shown in tests by automakers and Oak Ridge National Laboratory to have superior performance and emissions characteristics – mid-level ethanol blends have been called by Oak Ridge a "renewable super premium" fuel.

[1] *See, e.g.*, Cynthia Williams, Ford Motor Company, Comments on Proposed Tier 3 Rule, EPA-HQ-OAR-2011-0135-4349, at 3 (July 1, 2013) ("strongly recommend[ing] that EPA pursue regulations . . . to facilitate the introduction of higher octane rating market fuels," noting that they "offer the potential for the introduction of more efficient vehicles").

Recalling that the "primary goal of the LCFS regulation is to reduce the carbon intensity of transportation fuels used in California," ethanol has the following significant carbon-reducing effects compared to gasoline:

1. Argonne National Laboratory has devoted 20 years of research and analysis to the life-cycle greenhouse gas impacts of transportation fuels. As a 2012 Argonne paper summarized, "advances in technology and the resulting improved productivity in corn and sugarcane farming and ethanol conversion … have increased the energy and greenhouse gas (GHG) benefits of using bioethanol." Compared to regular gasoline, it showed a "well-to-wheels" reduction in GHG emissions from corn-based ethanol of 44% and from cellulosic ethanol of 89-95%.[2]

   To be sure, as agricultural production increases to support ethanol production, concerns about land use and indirect GHG effects must also be considered. A widely circulated and globally influential paper by Timothy Searchinger concluded that those effects are so negative as to overwhelm ethanol's GHG benefits. However, this paper has since been shown to be simplistic in its approach and wrong in its conclusion. Several peer-reviewed analyses have been published, most notably by Argonne, that show the indirect land use impacts hypothesized by Searchinger were overestimated by an order of magnitude. Including the recalculated indirect land use effects in the analysis cited above still results in a <u>reduction of GHG emissions from corn-based ethanol of 34% and from cellulosic ethanol of 88-108% compared to gasoline</u>.

2. That same Argonne research gives no credit for corn's ability to fix carbon in soil permanently. Recent research is showing that modern, high-yield continuous corn grown using conservation or no-till practices is in fact sequestering and rebuilding the carbon content of soil in the Midwest. Argonne is beginning a new study of soil carbon fixation, as well as NOx emissions related to fertilizer use, with regard to its GHG estimates for corn ethanol. Current EPA and CARB life-cycle analysis models similarly underestimate corn's superior ability as a highly efficient C4 plant in sequestering carbon, and should be updated accordingly.[3]

3. Gasoline itself is increasing in carbon intensity as oil from energy-intensive operations, such as heavy crudes from the Alberta tar sands and North Dakota fracking operations in the Bakken field, come to market.

LCFS 54-1 cont.

[2] M. Wang *et al.*, "Well-to-wheels energy use and greenhouse gas emissions of ethanol from corn, sugarcane and cellulosic biomass for US use," 2012 Environ. Res. Lett. 7 045905 (http://iopscience.iop.org/1748-9326/7/4/045905).

[3] See Alverson, "Re-thinking the Carbon Reduction Value of Corn Ethanol Fuel" (attachment).

4. Aromatics require the most energy to produce in the already energy-intensive oil refining process. An E30 blend would reduce refinery CO_2 emissions by 10%.[4]

5. Because of their chemical structure, aromatics are among the most carbon-rich components of gasoline. A recent report by a Health Effects Institute panel noted that aromatics "represent one of the heaviest fractions in gasoline" and said: "The aromatic content of gasoline has a direct effect on tailpipe carbon dioxide emissions. The EPEFE study[5] demonstrated a linear relationship between CO_2 emissions and aromatic content. A reduction of aromatics from 50 to 20% was found to decrease CO_2 emissions by 5%."[6]

LCFS
54-1 cont.

2. Displacing aromatics now used for octane in gasoline would produce substantial benefits for public health.

Aromatic hydrocarbons have been known for a long time to be toxic in their own right. California has limited the amount of aromatics in diesel fuel since 1988, and the Clean Air Act Amendments of 1990 limited the permissible amount of aromatics in reformulated gasoline. Yet the BETX group of chemicals (i.e., benzene, ethylbenzene, toluene, and xylene) still comprises 25-30% of the average gallon of gas. Benzene is a proven human carcinogen that can cause leukemia in exposed persons, and the other aromatics (mainly toluene and xylene) are neurotoxins. Combustion of these aromatics can lead to the formation of benzene in the exhaust gas. According to the HEI report just cited, "It is estimated that about 50% of the benzene produced in the exhaust is the result of decomposition of aromatic hydrocarbons in the fuel." The same report also noted, "Lower levels of aromatics enable a reduction in catalyst light-off time for all vehicles. Research indicates that combustion chamber deposits can form from the heavier hydrocarbon molecules found in the aromatic hydrocarbon portion of the gasoline. These deposits can increase tailpipe emissions, including carbon dioxide, hydrocarbons and NOx."

Of even greater concern, aromatics' emission products are transformed in the atmosphere into secondary organic aerosol (SOA). An important study from the Harvard Center for Risk Analysis, which focused specifically on the public health impacts of secondary particulate formation from aromatic hydrocarbons in gasoline, reported: "Evidence is growing that aromatics in gasoline exhaust are among the most efficient secondary organic matter precursors. … For example, a source apportionment study of SOA formation during a severe photochemical smog event in Los Angeles found that gasoline engines represented the single-

[4] See the 2014 MathPro – GM/Ford/Chrysler linear program study, "Refining Economics of U.S. Gasoline: Octane Ratings and Ethanol Content" (attachment).

Fuel Composition Changes Related To Emission Controls" in Special Report 17, "Traffic-Related Air Pollution: A Critical Review of the Literature on Emissions, Exposure, and Health Effects," Chapter 2. Emissions from Motor Vehicles. 2010. http://pubs.healtheffects.org/getfile.php?u=555

largest anthropogenic source of SOA. … Source-specific speciation of total VOC in the 2005 National Emissions Inventory reveals that the U.S. emissions of single-ring aromatic hydrocarbons are 3.6 million tons per year, of which 69% are from gasoline-powered vehicles."[7] The Harvard study predicted 3,800 premature mortalities per year due to aromatics.

Among the toxic SOA emission products from partial combustion of the aromatics in gasoline are polycyclic aromatic hydrocarbons (PAHs). At an EPA Workshop on Ultrafine Particles on February 11, Michael Kleeman of the University of California presented new results from the California Teachers Study by B. Ostro et al., accepted for publication in *Environmental Health Perspectives*. Initial epidemiological results show a hazard ratio of 1.25 for ischemic heart disease from anthropogenic SOA. Research by Verma et al. has found that "photochemical transformations of primary emissions with atmospheric aging enhance the toxicological potency of primary particles in terms of generating oxidative stress and leading to subsequent damage in cells"[8] and that "the oxidative potential was strongly correlated with organic carbon and PAHs."[9]

Delfino et al. strongly linked PAHs with mobile sources: "Indoor and outdoor PAHs (low-, medium-, and high-molecular-weight PAHs), followed by hopanes (vehicle emissions tracer), were positively associated with biomarkers, but other organic components and transition metals were not. … Vehicular emission sources estimated from chemical mass balance models were strongly correlated with PAHs (R = 0.71). … Traffic emission sources of organic chemicals represented by PAHs are associated with increased systemic inflammation and explain associations with quasi-ultrafine particle mass."[10]

How do PAHs created during combustion of aromatic hydrocarbons undergo long-range transport? Zelenyuk et al. found that they are trapped inside highly viscous semisolid OA particles and thus prevented from evaporation and shielded from oxidation. "In contrast, surface-adsorbed PAHs rapidly evaporate leaving no trace. The data show the assumptions of instantaneous reversible gas-particle equilibrium for PAHs and SOA are fundamentally flawed, providing an explanation for the persistent discrepancy between observed and predicted particle-bound PAHs."[11]

PAHs have been summarized by one leading researcher as: "carcinogenic, immunotoxic, neurotoxic, mutagenic, and endocrine disruptors."[12] Prenatal exposure to low levels of PAHs from ambient air pollution has been associated with multiple adverse effects, including developmental delay at age 3, reduced IQ at age 5 (effects similar to lead), symptoms of anxiety/depression and attention problems at ages 6–7, and ADHD behavior problems in children.[13] At a time when the rising incidence of autism is increasingly linked to disruption by environmental factors, and when the mutagenic effect of PAHs is well established, reducing exposure to PAHs should be a high public health priority.

3. **Increased use of domestically produced renewable ethanol is essential to both objectives and would have additional co-benefits.**

Ethanol's value for octane is not a new discovery. In fact, it was only the competition from tetraethyl lead that knocked ethanol out of that role a century ago. When lead was phased out, however, ethanol was not available in sufficient supply to provide a substitute. That is no longer true today. U.S. ethanol production has risen to roughly 15 billion gallons per year, and almost all gasoline sold today contains 10 percent ethanol. A phased increase to supply an E30 market, sufficient to supply the octane needed for higher-compression engines – reducing aromatics by 60%[14] – is entirely achievable.

Renewable ethanol can be produced from multiple agricultural feedstocks; corn starch has been the principal source in the U.S. and sugar cane in Brazil. Decades of federal investment in research has made possible the conversion of cellulose – widely abundant material that gives plants their structural stability – and major new cellulosic ethanol facilities, representing billions of dollars of private investment, are now going into production from POET-DSM, Abengoa Bioenergy, and DuPont Danisco, using corn stover and other "waste" biomass feedstocks.

The demand for farmland to produce corn for ethanol has been mitigated by continuing increases in yield and by the diversion of the protein in corn to supply animal field. Increased use of conservation tillage has reduced soil erosion and water runoff while saving labor and fuel.

4. **The LCFS should fully reflect the latest research on the value of mid-level ethanol blends to reduce GHGs and benefit public health and the environment through the displacement of aromatics.**

[13] F. Perera et al., "Early-Life Exposure to Polycyclic Aromatic Hydrocarbons and ADHD Behavior Problems," PLOS ONE, November 5, 2014, DOI:10.1371/journal.pone.0111670. http://journals.plos.org/plosone/article?id=10.1371/journal.pone.0111670
[14] See the 2014 MathPro – GM/Ford/Chrysler linear program study, "Refining Economics of U.S. Gasoline: Octane Ratings and Ethanol Content" (attachment).

The Energy Future Coalition and the Urban Air Initiative respectfully urge CARB to consider the role that mid-level ethanol blends could play in delivering a nationwide low carbon, high octane transportation fuels system.

- As a renewable fuel, reflecting its production and land use, ethanol offers substantial GHG reduction benefits relative to gasoline and particularly to aromatics. CARB should incorporate the latest values from Argonne's life-cycle analysis into its calculations. LCFS 54-1 cont.

- In the fall of 2013, the World Health Organization's International Agency for Research on Cancer (IARC) published its findings that traffic-related particulate matter emissions represented a Group 1 carcinogenicity threat to humans. WHO noted that in 2010, 223,000 worldwide deaths from lung cancer alone were attributable to air pollution, and singled out particulate matter and transportation-related pollution as a major source.

- Advanced GDI (gasoline direct injection) systems could make particle number (PN) emissions <u>worse</u> unless fuel composition is improved by reducing aromatic content. Mid-level ethanol blends have been shown to reduce particulate and black carbon emissions by 45 to 80% in direct injection and port fuel injection engines, respectively. Some have argued for the use of particulate filters on gasoline engines; however, the much smaller particles in gasoline exhaust (compared to diesel exhaust) elude capture by such filters, which also will interfere with, possibly even reverse, important fuel efficiency and carbon reduction gains.

The most important fuel quality improvement to achieve reductions in both carbon and particle-borne toxics emissions would be to substantially reduce aromatic hydrocarbons in gasoline. The need for octane can easily be supplied by cleaner-burning ethanol blends. They would:

1. Facilitate automaker compliance with tighter fuel efficiency and carbon reduction requirements.
2. Improve vehicle performance and reduce costs to the consumer.
3. Reduce harmful urban particulate matter, black carbon, and toxics emissions.
4. Provide market-based demand signals to meet national biofuels targets in a cost-effective manner.
5. Provide an alternative to ineffective and costly gasoline particulate filters.
6. Generate billions of dollars annually in carbon reduction and health savings co-benefits.
7. Reduce refinery crude oil usage and diversify the transportation sector away from reliance on crude oil.
8. Stimulate the rural economy and create new jobs.
9. Provide a more stable investment climate for next-generation biofuel technologies.
10. Simplify California's path to low carbon fuels.

54_OP_LCFS_EFC Responses

597. Comment: **LCFS 54-1**

The comment states that the LCFS should fully reflect the latest research on the value of ethanol to reduce GHGs and benefit public health and the environment through the displacement of aromatics. The comment also states that Argonne, EPA and CARB life-cycle analysis models all neglect to account for corn's ability to fix carbon in soil permanently and should be revised.

Agency Response: Staff recognizes that some crops under certain conditions and management practices can incrementally increase soil carbon content over time; however, soil carbon accumulation does not qualify as carbon sequestration under current AB 32 regulations. Once appropriate audit and certification systems are in place for agricultural systems, reduced tillage regimes may yield CI reductions indirectly in the form of reduced on-farm energy use and other such co-benefits of cultivation practices which enhance soil quality, but such systems are not yet in place.

2. Vehicle technology advances must be optimized with gasoline quality improvements

On June 3, 2014, in Washington, DC, the Energy Future Coalition held a workshop to bring together leading experts and policymakers to discuss fuel and filter technology options for avoiding or controlling particulate pollution from aromatic hydrocarbons in gasoline and the toxic substances that can accompany them, especially polycyclic aromatic hydrocarbons (PAHs). The event featured a panel of experts from the automobile, clean fuels, and filter technology sectors.

The four excellent presentations can be accessed at the following link:
http://www.energyfuturecoalition.org/What-Were-Doing/Eliminating-Aromatics-Gasoline/Technical-and-Policy-Responses-Health-Risks-Ultrafine
The experts agreed that improvements in gasoline quality were a critically important policy tool for optimizing vehicle technology advances required to meet stricter fuel efficiency and carbon reduction rules.

An important take away from Woebkenberg (Mercedes-Benz), Splitter (Oak Ridge National Labs), and Vander Griend (ICM, Inc.) was that the next generation of vehicles would benefit significantly from higher octane gasoline, preferably in the 94 AKI range. This would allow engine designers to optimize for higher efficiency and reduced emissions, primarily by downsizing and increasing compression ratios. However, the experts all agreed that using aromatic compounds to increase octane to this level would result in substantial increases in PM emissions, especially UFPs and their associated toxics. In contrast, Mercedes confirmed substantial reductions in PN emissions (e.g., 50% or more) with mid-level ethanol blends (AKA E30). In answer to a question about what would happen if E30 were widely available, Woebkenberg replied that the effect would be "magic" in terms of increased engine efficiency accompanied by significant reductions in carbon and particle-borne toxics emissions.

Dr. Derek Splitter of ORNL reported that ethanol's superior octane properties are not fully understood, but involve a combination of octane sensitivity, heat of vaporization, flame speed, pressure sensitivity, and ethanol-specific kinetics. Referring to E30 as "Renewable Super Premium," Splitter said that compared to regular gasoline, it enables much more aggressive downsizing and downspeeding, enabling higher fuel economy despite ethanol's lower energy density. Oak Ridge research has confirmed that ethanol shows diminishing octane returns on blends above E50. He concluded that widespread use of E30 blends would offer a cost effective way to achieve a number of national policies simultaneously: RFS2, GHG – CAFE, and Tier 3.

Steve Vander Griend of ICM provided data to underline the importance of "splash-blending" additional ethanol to E10 to make E30, as opposed to "match-blending", where other components—especially aromatic compounds—are artificially added to shape the blend's distillation curve. Woebkenberg and Splitter agreed that given ethanol's superior octane properties, it makes no sense to add more aromatics when producing an E30, RSP blend.

3. Substantial climate and health co-benefits would be achieved by using ethanol's clean octane to improve gasoline quality

Replacing carbon intensive aromatic compounds with less carbon-intensive ethanol to increase gasoline octane levels has been shown by Oak Ridge and other experts to have the potential of substantially reducing the carbon footprint of the U.S. LDV fleet. E30 "clean octane" would also help reduce the transportation sector's carbon footprint in other ways. LCFS 55-1

In recent years, misinformed sources have contended that the increase in corn ethanol production has contributed to undesirable land use changes, and exacerbated carbon releases to the atmosphere. The empirical evidence shows that this is not true, as farmers have largely shifted some soybean acres to corn, with substantial benefits to soil fertility, carbon sequestration, and feed/food supplies, as explained below.

Shifting soybean acres to corn acres has not reduced the feed ration supplies, but it has increased soil fertility and carbon sequestration and soil organic matter buildup. After processing in an ethanol plant, an acre of corn yields as much protein as an acre of soybeans. Because it is a photo-synthetically superior C4 plant, corn has an extraordinary ability to sequester carbon, and help to move fertilizer nutrients back to the surface for plant growth rather than polluting ground water. Corn's extensive deep root system makes it one of the few plants with this important capability that makes crop production sustainable.

A multi-year USDA research project recently confirmed that no-till corn equaled switch grass in SOC (soil organic carbon) formation, and that over half the increase in SOC was below one foot depth. The researchers estimated that deep soil SOC sequestration benefits of corn have been understated by 60 – 100% in modeling done to date.[1]

Even Michael Pollan, a frequent critic of the current agricultural system, has singled out corn's efficiency compared to other crops. In his book, "Omnivore's Dilemma", Pollan noted: "Few plants can manufacture quite as much organic matter (and calories) from the same quantities of sunlight and water and basic elements as corn." Pollan goes on to praise corn's ability to extract carbon from the air. "The C-4 trick represents an important economy for a plant, giving it an advantage…By recruiting extra atoms of carbon during each instance of photosynthesis, the corn plant is able to limit its loss of

[1] U.S. Department of Agriculture, Agricultural Research Service, "A Surprising Supply of Deep Soil Carbon," February 2014. http://www.ars.usda.gov/is/AR/archive/feb14/soil0214.htm

water and "fix"—that is take from the atmosphere and link in a useful molecule—significantly more carbon than other plants."

98% of U.S. corn is not directly consumed by people (less than one bushel per person per year, out of a 14 billion bushel crop), but instead used as livestock feed and for other purposes. Importantly, when the starch portion of an acre of corn is converted to ethanol, what remains is as much protein and other equivalent high -value feed products as found in an acre of soybeans.

Since corn yields are nearly four times greater than soybean yields, and corn rebuilds SOC much more efficiently than soybeans, the economically and environmentally smart thing to do is to first process the corn to ethanol, and replace the starch with other low-value substitutes. Doing so results in the same amount of protein and feed co-product equivalents offered by an acre of soybeans, increases soil fertility and captured carbon, and offers the added bonus of the corn ethanol industry's job creation, health cost savings, oil import reduction, and environmental (aromatic substitution) benefits.

In the future, as corn yields increase with genetic engineering advances and other improved technologies, corn's ability to simultaneously supply high octane fuel components, feed/food, and carbon sequestration benefits will also increase. As grain output increases, so too does the output of the valuable corn stover residue which has value as a rebuilder of SOC, a feed ration component that can be mixed with ethanol's high protein co-products to replace starch, and a feedstock for cellulosic ethanol production. In summary, more corn, not less, is good for the environment (health and carbon co-benefits), the soil, the food supply, and the economy.

4. Substantial reductions are possible in urban black carbon emissions with clean octane gasoline

Scientists and regulators have identified soot (also known as black carbon, or BC) as a major contributor to climate change and harmful global warming, accountable for as much as 30-40 percent of the rise in global temperatures. Nations are proposing aggressive remediation measures such as installing filters on diesel engines. http://www.nytimes.com/2012/02/18/opinion/a-second-front-in-the-climate-war.html?_r=2&nl=todaysheadlines&emc=tha211

In addition to its global warming effects, press reports have identified BC as "perhaps the most deadly widespread air pollutant".
http://www.washingtonpost.com/national/health-science/epa-to-tighten-national-soot-standards/2012/06/14/gJQABYsPdV_story.html

New real-time measurements suggest that black carbon emissions from light-duty gasoline vehicles are significantly underestimated, as found by Liggio et al:[2]

"Unlike the results for gasoline vehicles, the measured BC emission factor for heavy-duty diesel vehicles was in reasonable agreement with previous measurements. This suggests, the team concluded, that greater attention needs to be paid to black carbon from gasoline engines to obtain a full understanding of the impact of black carbon on air quality and climate and to devise appropriate mitigation strategies.

"The present results also have implications for BC measurements, modeling, and emission regulations. ... The gap between BC mass emissions of HDDV and LDGV is likely to shrink further as regulations for HDDV continue to take effect and alternate technologies for fuel delivery in gasoline vehicles (i.e., gasoline direct injection; GDI) become more popular. BC emissions from GDI engines have been observed to be significantly higher than those from conventional engines. The present results suggest that further dynamometer and on-road measurements of BC from gasoline vehicles are required in order to corroborate our findings and to improve emissions inventories in support of modeling, national and international policies, and estimates of impacts on health, the environment, and climate."

A recent Ford Motor study (2012 Ford/Maricq, cited above) found that gasoline direct injection (GDI) vehicle exhaust PM is dominated by EC/BC, rather than organic carbon (OC), contrary to what EPA concluded in its 2008 Kansas City study, which found that OC accounted for 80% of PM emissions. Ford said this discrepancy stems from the differences between port fuel injection (PFI) and GDI engine technologies. Ford found that GDI vehicles fueled by E0 (gasoline with no ethanol) emit an approximate range of from 8 – 15 x 10^{12} per mile (vs. cubic meter). E30+ blends reduce BC emissions by 45%. Consequently, a nationwide clean octane program could achieve a significant, if not predominant, share of the EPA's targeted emissions of urban BC in a cost-effective, technologically proven, and consumer-friendly manner.

Numerous experts have concluded that spark ignition gasoline-powered engines are a larger source of urban BC emissions than diesel engines (96% of the U.S. vehicle fleet is gasoline powered). In one recent study based upon CalTrans vehicle data, SI gasoline emissions were a factor of 8 to 10 greater than heavy duty diesel emissions. http://aaqr.org/VOL10_No1_February2010/6_AAQR-09-05-IR-0036_43-58.pdf, Table 1, p. 46

[2] J. Liggio et al., "Are Emissions of Black Carbon from Gasoline Vehicles Underestimated? Insights from Near and On-Road Measurements." *Environmental Science & Technology*, 2012. doi: 10.1021/es2033845

In a December 2011 PM study for its LEV III rule, CARB stated that "recent studies show that gasoline engines also play a key role" in PM emissions, and that EC/BC "dominates PM". http://www.arb.ca.gov/regact/2012/leviiighg2012/levappp.pdf, p. 88, p. 11, Fig. 4

"Contrary to the perception diesel vehicles are the main vehicular source of PAHs, light-duty gasoline vehicles have been found to be the most important source of PAH emissions in some urban areas." BC has high porosity and a large surface area, and thus easily adsorbs the carcinogenic and mutagenic PAHs, and transports them to the lungs and organs. http://earthjustice.org/sites/default/files/black-carbon/jiang-et-al-2005-mexico-city.pdf, p. 3378

Honda researchers (2010 Honda study, cited above) noted that gasoline engines are responsible for a significant share of urban particulate emissions. Honda warned that in order to reduce both harmful global warming emissions, as well as health-threatening PN/PAH emissions, gasoline fuel quality must be improved to complement advances in vehicle hardware.

Comments Submitted by the Energy Future Coalition and the Urban Air Initiative

Appendix II. Displacing aromatics now used for octane in gasoline would produce substantial benefits for public health.

1. **Gasoline aromatic compounds are a primary cause of the most dangerous urban pollutants**

Aromatic compounds constitute 20-30% of U.S. gasoline, which means that more than 40 billion gallons are combusted each year in U.S. light-duty vehicles. Their physico-chemical properties make them very difficult to combust efficiently. The higher distillation aromatics (high molecular weight, HMW), have higher double-bond equivalents (DBEs), and are particularly important contributors to urban ultrafine particles (UFPs) and polycyclic aromatic hydrocarbon (PAH) emissions. In the 1990 Clean Air Act Amendments, Congress instructed the EPA to achieve the "greatest reduction possible" in gasoline aromatics and the lethal air toxics they produce.

EPA has called ambient particulate matter (PM) one of the nation's greatest health threats, but it regulates only particle mass (vs. particle number), in the form of $PM_{2.5}$ (2.5 to 0.1 micrometers in aerodynamic diameter). Unfortunately, the much smaller UFPs (.1 micrometer, or 100 nanometers and smaller) are the most toxic, most bio-available, and the most effective carriers of the carcinogenic and mutagenic PAHs to the human body.
http://www.particleandfibretoxicology.com/content/6/1/24/ref

PAHs are semi-volatile organic compounds (SVOCs) found in both gaseous and particle form. They comprise the largest mass fraction of UFPs, the primary urban source of which is also gasoline aromatics. Gasoline PAHs are carcinogenic, mutagenic, and genotoxic.
http://aaqr.org/VOL10_No1_February2010/6_AAQR-09-05-IR-0036_43-58.pdf

UFPs have orders of magnitude higher number counts, and much larger surface mass with which to attract and carry the PAHs. For example, PM of 2.0 micrometer per cubic meter ($2\mu/m^3$) would have 2 particles per ml of air, and a surface area of $30\mu/m^2$ per ml of air. In contrast, a UFP of 0.02 μ/m^3 (20 nanometers, or 20 one-billionth of a meter) would have 2,390,000 particles in each ml of air, and a surface area of 3,000 μ/m^2 per ml of air. See slide 4 on link below. https://www.aqmd.gov/tao/ConferencesWorkshops/AircraftForum/FroinesSlides.pdf

Particle-borne PAHs can persist for days in the environment, and can carry long distances after their emission from the tailpipe. SOAs and UFPs insulate and preserve PAHs, which are able to penetrate indoors, and have been found 1.5 miles from congested roadways.
http://www.ph.ucla..edu/pr/newsitem061009.html

Gasoline PAHs are high molecular weight (4 – 6 rings), as opposed to diesel PAHs, which are low molecular weight. HMW PAHs are more toxic, and more persistent than LMW PAHs. In the U.S., approximately 250 million light duty vehicles consume more than 130 billion gallons of gasoline each year, and have historically accounted for more than 90% of transportation sector emissions. Thus, contrary to conventional wisdom, since gasoline PAHs are more abundant and ubiquitous, much smaller than diesel PAHs (extremely difficult and costly to trap), and more toxic, gasoline exhaust poses a much greater health threat to humans than does diesel exhaust. For example, a 2012 University of Colorado – Boulder study found that 80+% of PM2.5 secondary organic aerosols in Los Angeles originated from gasoline, as opposed to diesel, exhaust. http://www.colorado.edu/news/releases/2012/03/02/gasoline-worse-diesel-when-itcomes-

PAHs are considered to be one of the most ubiquitous endocrine disruptor compounds (EDCs) in urban environments. EDCs mimic natural hormones in the body, and experts warn that they are especially damaging to the fetus and young children, and can disrupt genetic structures, causing serious damage that transfers throughout generations. PAHs have been linked to a wide range of disorders, including cancers, heart disease, asthma and other respiratory disorders, premature births, autism, and obesity.
http://ehp03.niehs.nih.gov/article/info%3Adoi%2F10.1289%2Fehp.1104056

The California Office of Environmental Health Hazard Assessment has placed PAHs in Tier 1 on its toxic air contaminants list, in part due to the fact prenatal exposure to PAHs results in "serious and irreversible effects in the fetus".
http://www.oehha.ca.gov/public_info/pdf/GasOEHHA.pdf

Water quality regulators are reporting increasing deposition of PAHs in the nation's waterways, as gasoline exhaust is washed from roadways into rivers, lake, and estuaries. The PAHs are then ingested by fish and other seafood, and can then enter the human food chain.
http://calcium25.com/PAHs-Water-Air-Pollution-0707.pdfhttp://www.greencarcongress.com/2005/08/toxic_metals_de.html

2. **Gasoline aromatic compounds are the predominant precursors to urban secondary organic aerosols (SOAs)**

The Harvard Center for Risk Analysis found that up to $50 billion per year in social costs are attributable to gasoline aromatics. The Harvard study considered only premature mortalities (as opposed to morbidity) caused by PM2.5 secondary organic aerosols (SOAs). In other words, Harvard did not attempt to quantify the even greater health costs associated with particle-borne PAHs, including the increasing evidence of the damage they do to infants and developing children. http://www.ehjournal.net/content/12/1/19/abstract

- Excerpts:

  "Modeled aromatic SOA concentrations from CMAQ fall short of ambient measurements by approximately a factor of two nationwide...Assuming that the contribution of SOA precursors originating from aromatic hydrocarbons in gasoline is higher in urban areas increases these estimates to 5100 predicted premature mortalities nationwide...associated with total social costs of $37.9B".

"...particulates from vehicular emissions of aromatic hydrocarbons demonstrate a sizeable public health burden. The results provide a baseline from which to evaluate potential public health impacts of changes in gasoline composition."

"Evidence is growing that aromatics in gasoline exhaust are among the most efficient secondary organic matter precursors. In general, air quality models do not adequately capture these increased yields or potential interactions, although improvements have been made."

"In the United States, gasoline-powered vehicles are the largest source of aromatic hydrocarbons to the atmosphere...Therefore, it has been suggested that removal of aromatics could reduce SOA concentrations and yield a substantial public health benefit...a number of studies have noted that gas-phase vehicle emissions lead to a substantial fraction of observed SOA. For example, a source apportionment study of SOA formation during a severe photochemical smog event in Los Angeles found that gasoline engines represented the single-largest anthropogenic source of SOA."

"Although CMAQv5.0 contains updated...processes for predicting SOA formation, evidence suggests that the model may still underestimate secondary PM2.5 concentrations."

"Source-specific speciation reveals that the U.S. emissions of aromatic hydrocarbons are 3.6 million tons per year, of which 69% are from gasoline-powered vehicles as shown in Table 3."

"In addition to premature mortality, which dominates monetized estimates of total social cost, exposures to SOA from aromatics in gasoline are associated with other health outcomes, including exacerbation of asthma, upper respiratory symptoms, lost work days, and hospital emergency room visits."

"A recent study in Los Angeles found that gasoline emissions dominated SOA formation, accounting for nearly 90% of total aerosol formation, and the ratio of SOA to primary organic aerosol was approximately a factor of three...Anthropogenic SOA have been shown to enhance biogenic SOA formation."

3. SOAs and PAHs synergistically bind together, enabling long-range transport, increased aging, and greater persistence/penetration indoors

Zelenyuk et al. contend that conventional predictive models of SOAs and PAHs transport and persistence are fundamentally flawed. In its Tier 3 rule, EPA said that PAHs have a half-life of less than an hour, and that they dissipate within 300 feet of emission source. Here, DOE's PNNL confirms that the PAHs undergo LRT and persist for weeks or longer due to their insulation from atmospheric evaporation by the SOAs. This LRT and persistence has enormous implications for the much greater magnitude of the human health threat predicted by EPA assumptions vs. reality. http://www.ncbi.nlm.nih.gov/pubmed/23098132

"[B]ased on current understanding of gas-particle partitioning and atmospheric degradation of PAHs some species, like benzo[α]pyrene and fluoranthene, should not undergo LRT at all yet are found in the Arctic at concentrations similar to those in Europe. In general, existing gas-particle partitioning models severely underpredict observed LRT of particle-bound PAHs, highlighting large knowledge gaps in kinetic partitioning models."

An article describing the PNNL work noted: "The results also show that the particles that envelop pollutants also benefit from this arrangement. The new study shows that the airborne particles last longer with PAHs packed inside." http://www.greencarcongress.com/2012/11/pah-20121117.html#more

As the study put it: "Perhaps the most surprising finding is the observed synergetic relationship between PAHs and SOA. The presence of even a small amount of hydrophobic organics inside SOA significantly decreases the SOA evaporation rate and amplifies the effect of aging, thus creating conditions that ensure efficient LRT of both SOA particles and PAHs, consistent with observations. This synergy between PAHs and SOA particles has important implications not only for human health but also for climate change."

Using advanced instrumentation, PNNL scientists found that the potent PAHs are trapped within the semisolid SOAs (secondary organic aerosols) during particle formation and thus shielded from oxidation and preserved for extended periods of time. This is why CARB and others are now reporting UFP-borne PAHs as far away as 2,500 meters (not 300 feet, as EPA contended in its Tier 3 rule) from their source.

This PNNL research is very important. It helps explain some of the confusion amongst experts about the differences between concentrations of PAHs in gas-phase partitioning (which can be orders of magnitude lower) compared to the much higher concentrations of particle-bound PAHs. The PNNL scientists proved that the SOAs synergistically bond with the PAHs and serve as the "insulation and preservative" for the PAHs that enables their perpetuation and LRT (and vice versa).

4. Gasoline vehicles are the principal source of SOAs and toxics from aromatics

- Excerpts from Bahreini et al. (2012), "Gasoline emissions dominate over diesel in formation of secondary organic aerosol mass", Geophysical Research Letters, Vol. 39: http://onlinelibrary.wiley.com/doi/10.1029/2011GL050718/abstract

  Air-borne and ground-based measurements of OA in Los Angeles Basin indicated that "the contribution from diesel emissions to SOA formation is zero within our certainties. Therefore, substantial reductions of SOA mass on local to global scales will be achieved by reducing gasoline vehicle emissions."

"Consistent with previous studies, this indicates that gasoline vehicles are the dominant source of CO and light, single-ring aromatic VOCs including benzene and toluene."

"Because diesel emissions contribute to POA, but not detectably to SOA, as photochemical processing and SOA formation proceeds, the contribution of diesel emissions to total OA decreases."

"…for more accurate modeling of SOA formation in urban areas, future research should be directed at identifying specific species in the exhaust of gasoline engines that are responsible for SOA formation."

"Assuming that production of SOA relative to POA from gasoline exhaust follows the same trend as in LA…we estimate that within a day of processing, SOA from gasoline exhaust may reach 4 Tg/yr, which is 16% of recent global estimates of biogenic SOA. Our observations suggest that a decrease in the emission of organic species from gasoline engines may significant reduce SOA concentrations on local and global scales."

- Excerpts from Nordin et al. (2013), "Secondary organic aerosol formation from idling gasoline passenger vehicle emissions investigated in a smog chamber," Atmos. Chem. Phys., 13, 1601-6116: http://www.atmos-chem-phys.net/13/6101/2013/acp-13-6101-2013.html

"Gasoline vehicles have recently been pointed out as potentially the main source of anthropogenic secondary organic aerosol (SOA) in megacities."

"Gasoline exhaust readily forms oxidized organic aerosols that commonly dominates the organic aerosol mass spectra downwind of urban areas. … Classical C6 – C9 light aromatic precursors were responsible for up to 60% of the formed SOA, which is significantly higher than for diesel exhaust. Important candidates for additional precursors are higher-order aromatic compounds such as C10 and C11 light aromatics, naphthalene and methyl-napththalenes. We conclude that approaches using only light aromatic precursors given an incomplete picture of the magnitude of SOA formation and the SOA composition from gasoline exhaust."

"Photo-oxidation of gasoline exhaust forms SOA and ammonium nitrate. At the end of the experiments the formed SOA is 9-500 times higher than the emitted POA, which is in sharp contrast to diesel exhaust where the contribution of primary PM often dominates over secondary PM."

"The benzene concentration is strongly elevated in these idling experiments compared to the fuel content (benzene is regulated to less than 1% by volume in gasoline in Europe), most likely due to formation of benzene from other light aromatic compounds in the catalyst. … The enrichment of benzene in the exhaust is also found in road tunnel emission measurements."

"Since gasoline exhaust SOA is a more complex mixture than SOA from pure precursors, it can be expected that gasoline SOA resembles atmospheric observations better than SOA from pure precursors."

"This implies that relatively low concentrations of PAHs can give a significant contribution to SOA formation."

"As shown in this study, gasoline exhaust readily forms secondary organic aerosol with a signature aerosol mass spectrum with similarities to the oxidized organic aerosol that commonly dominates the OA mass spectra in and downwind of urban areas. This substantiates recent claims that gasoline SOA is a dominating source to SOA in and downwind of large metropolitan areas."

- Excerpts from Delfino et al., "Association of biomarkers of systemic inflammation with organic components and source tracers in quasi-ultrafine particles," 2010. Environ Health Perspect 118:756–762: http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2898850/

"Indoor and outdoor PAHs (low-, medium-, and high-molecular-weight PAHs), followed by hopanes (vehicle emissions tracer), were positively associated with biomarkers, but other organic components and transition metals were not. Vehicular emission sources estimated from chemical mass balance models were strongly correlated with PAHs (R = 0.71)".

"Traffic emission sources of organic chemicals represented by PAHs are associated with increased systemic inflammation and explain associations with quasi-ultrafine particle mass."

"To our knowledge, this is the first report from a panel cohort study to show associations of circulating biomarkers of response in human subjects to specific PM organic compound classes. The measured chemicals serve as indicators and tracers for air pollutant sources and for classes of chemicals with the potential for redox activity in the body. In the present analysis, we found the strongest biomarker associations with air pollutant variables for all molecular weight classes of PAHs and specific source markers of vehicular emissions (hopanes) measured in $PM_{0.25}$ with GC/MS. Furthermore, two-pollutant models of the relation between the biomarkers of systemic inflammation and both total PAHs and $PM_{0.25}$ mass showed that mass associations were completely explained by PAHs."

"In the Los Angeles Basin, most outdoor PAHs in $PM_{0.25}$ are expected to be from mobile sources (Schauer et al. 1996), and the CMB exposure correlations are consistent with this expectation. PAHs were also correlated with source markers of vehicular emissions (hopanes). Hopanes are the most unambiguous source marker of traffic emissions."

"Overall, the associations of biomarkers with PAHs and hopanes suggest that our previous findings of positive associations of biomarkers with PM2.5, EC, and primary OC (Delfino et al. 2009) were due to PM of mobile-source origin. PAHs are found in greater concentrations in the quasi-UFP range compared with larger particles (Ntziachristos et al. 2007), and this has been hypothesized to explain enhanced prooxidative and proinflammatory effects of urban UFPs in the lungs and peripheral target organs of rodents (Araujo et al. 2008). The increased biological potency of UFPs may be related to the content of organic chemicals that have the capacity to reduce oxygen, such as quinones and nitro-PAHs, for which PAHs may act, in part, as a surrogate (Ntziachristos et al. 2007) or as a source after biotransformation. From the present results we infer that, although PAHs may have an effect by themselves, they are also likely surrogates for other causal species we did not measure that are emitted from the same (traffic) sources."

"Finding positive associations of biomarkers with both indoor and outdoor PAHs and hopanes along with the indoor/outdoor ratios of these organic components being close to 1.0 suggests that, even though people spend most of their time indoors, indoor air quality and PM exposures are strongly influenced by PM of outdoor origin. These findings are consistent with our previous analysis for the first half of this panel showing that CMB-estimated indoor PM of outdoor origin (particle number, EC, and primary OC) were associated with the biomarkers to a similar degree as outdoor PM (Delfino et al. 2008)."

5. **Heavy molecular weight (HMW) PAHs from gasoline are far more potent than LMW PAHs from diesel**

- California Office of Environmental Health Hazards Assessment report: Gasoline PAHs are heavy molecular weight (HMW), bear many similarities to cigarette smoke PAHs, and are ubiquitous in urban environments, especially adjacent to roadways. http://www.oehha.ca.gov/public_info/pdf/GasOEHHA.pdf.

- Prioritization of Toxic Air Contaminants – Children's Environmental Health Protection Act", October 2001: http://www.oehha.ca.gov/air/toxic_contaminants/pdf_zip/PAHs_Final.pdf

"Prenatal exposure to PAHs results in serious or irreversible effects in the fetus…For instance, PAHs are transplacental carcinogens…There is greater exposure of children to environmental PAHs compared to adults…Biomarkers for direct impacts associated with adverse health outcomes, such as DNA adducts, are increased in children exposed to environmental pollution by PAHs and related POM components. In view of this range of evidence for differential sensitivity of the fetus, infants, and children to health effects induced by POM components such as PAHs, and for greater exposure of children to POM, OEHHA has placed POM in Tier 1 of the priority list."

- Excerpt from Riddle et al., "Large PAHs detected in fine particulate matter emitted from light-duty gasoline vehicles," Atmospheric Environment, Volume 41, Issue 38, December 2007, Pages 8658‑8668: http://www.sciencedirect.com/science/article/pii/S1352231007006553

  "Emission factors of large PAHs with 6–8 aromatic rings with molecular weights (MW) of 300–374 were measured from 16 light-duty gasoline-powered vehicles (LDGV) and one heavy-duty diesel-powered vehicle (HDDV) operated under realistic driving conditions. LDGVs emitted PAH isomers of MW 302, 326, 350, and 374, while the HDDV did not emit these compounds. This suggests that large PAHs may be useful tracers for the source apportionment of gasoline-powered motor vehicle exhaust in the atmosphere. Large PAHs made up 24% of the total LEV PAH emissions and 39% of the TWC PAH emissions released from gasoline-powered motor vehicles. Recent studies have shown certain large PAH isomers have greater toxicity than benzo[a]pyrene. Even though the specific toxicity measurements on PAHs with MW >302 have yet to be performed, the detection of significant amounts of MW 326 and 350 PAHs in motor vehicle exhaust in the current study suggests that these compounds may pose a significant public health risk."

- MW 302+ PAHs are especially toxic, see slides 16 and 17 on Relative Potency Factors, 2012 Simonich/OSU deck. http://www.niehs.nih.gov/research/supported/assets/docs/r_s/what_goes_around_comes_around_chasing_polycyclic_aromatic_hydrocarbons_from_the_beijing_olympics_to_the_us_west_coast.pdf

- Abstract of a study by Y. Jia, "Estimated Reduction in Cancer Risk due to PAH Exposures If Source Control Measures during the 2008 Beijing Olympics Were Sustained," *Environ Health Perspect*. 2011 Jun; 119(6): 815–820: http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3114816/

  "The 2008 Beijing Olympic Games provided a unique case study to investigate the effect of source control measures on the reduction in air pollution, and associated inhalation cancer risk, in a Chinese megacity.

  "We measured 17 carcinogenic polycyclic aromatic hydrocarbons (PAHs) and estimated the lifetime excess inhalation cancer risk during different periods of the Beijing Olympic Games, to assess the effectiveness of source control measures in reducing PAH-induced inhalation cancer risks.

  "We estimated the number of lifetime excess cancer cases due to exposure to the 17 carcinogenic PAHs [12 priority pollutant PAHs and five high-molecular-weight (302 Da) PAHs (MW 302 PAHs)] to range from 6.5 to 518 per million people for the source control period concentrations and from 12.2 to 964 per million people for the nonsource control period concentrations. This would correspond to a 46% reduction in estimated inhalation cancer risk due to source control measures, if these measures were sustained over time. Benzo[b]fluoranthene, dibenz[a,h]anthracene, benzo[a]pyrene, and dibenzo[a,l]pyrene were the most carcinogenic PAH species evaluated. Total excess inhalation cancer risk would be underestimated by 23% if we did not include the five MW 302 PAHs in the risk calculation.

"Source control measures, such as those imposed during the 2008 Beijing Olympics, can significantly reduce the inhalation cancer risk associated with PAH exposure in Chinese megacities similar to Beijing. MW 302 PAHs are a significant contributor to the estimated overall inhalation cancer risk."

6. Particle filters are not an adequate solution

Advanced GDI (gasoline direct injection) systems could make particle number (PN) emissions worse unless fuel composition is improved by reducing aromatic content. Mid-level ethanol blends have been shown to reduce particulate and black carbon emissions by 45 to 80% in direct injection and port fuel injection engines, respectively. Some have argued for the use of particulate filters on gasoline engines; however, the much smaller particles in gasoline exhaust (compared to diesel exhaust) elude capture by such filters, which also will interfere with, possibly even reverse, important fuel efficiency and carbon reduction gains.

_BGA

February 17, 2015

Mary Nichols, Chairman
California Air Resources Board
1001 I Street, PO Box 2815
Sacramento, CA 95812

Dear Chairman Nichols and Members of the Board:

The Natural Resources Defense Council and BlueGreen Alliance join to thank you and CARB staff for your efforts to improve and readopt the Low Carbon Fuel Standard (LCFS). We remain strong supporters of AB 32 and the LCFS, which is transforming the fuel industry by reducing the carbon intensity of our transportation fuels.

We share in the mission to address today's environmental challenges in ways that can create, maintain and secure quality jobs and a stronger, fairer economy. We are guided by the principle that Californians deserve both environmental sustainability and economic prosperity. We believe the Low Carbon Fuel Standard advances our mission. To that end, we support efforts in the LCFS that establish a cost containment provision and pathways for refinery improvements.

Over the past three years, the Natural Resources Defense Council and the BlueGreen Alliance, have worked together to meet with ARB and provide recommendations to the California Air Resources Board on the Low Carbon Fuel Standard. On July 10th, 2014, the organizations jointly submitted comments to the agency on ways to enhance the standard. In particular, these include recommendations to add a cost containment mechanism and expand the program's flexibility to encourage GHG emission reduction projects that lower carbon pollution, including energy efficiency and combined heat and power, at both petroleum refineries and crude oil production facilities.

We thank ARB for considering the recommendations, developing the concepts further over the past year, and proposing them for adoption. We support the Board moving forward to adopt those provisions.

By providing a maximum compliance cost or "safety valve," ARB's proposed cost containment provision creates more certainty for all parties while preserving the signal to continue to invest in emission reductions. Allowing regulated parties to make up shortfalls through an additional credit clearance period the following year, providing up to an additional five years to make up credits in the event of a true lack of credits, together with a five percent annual interest applied to deficits will enhance

LCFS 57-1

certainty, encourage future compliance with the LCFS, while maintain the environmental benefits of the standard. LCFS 57-1 cont.

We strongly support credits for GHG emission reductions from refinery improvement projects. Credits for refinery improvements represent a significant opportunity to spur additional investment to improve the environmental performance at refineries and create secure refinery jobs, while reducing the carbon intensity of transportation fuels and fostering additional benefits such as reductions in criteria pollution. To that end, we support the Board adopting staff's proposal for crediting refinery improvements and the provisions that ensure these projects are beyond business as usual. These include the requirements that the projects:

- Represent actual capital investments to reduce carbon emissions (as opposed to simply shutting down units) or expand refineries' use of renewable energy
- Create net reductions in carbon intensity
- Be limited to projects undertaken to help comply with the standards that are not business as usual.
- Demonstrate that associated toxic and criteria air pollutants will not lead to net increases or be lower over the life of the project

LCFS 57-2

We also support awarding LCFS credits to producers and project developers that invest to reduce emissions from crude oil production processes. Implementing innovative technologies, such as carbon capture and storage (CCS), solar thermal and other renewable inputs, can create good, secure jobs and reduce carbon intensity of petroleum directly. In light of petroleum's more than 90% share of the transportation fuels market, improvements such as these could have far reaching positive effects. LCFS 57-3

We believe offering LCFS credits to refineries and producers for these improvements could create significant incentives and make projects that will reduce GHG emissions more attractive while creating, maintaining and securing quality jobs.

Again, we thank ARB staff for their hard work on the LCFS re-adoption and leadership to help address climate change. We look forward to working together on the successful and smooth implementation of the LCFS.

Sincerely,

Simon C. Mui

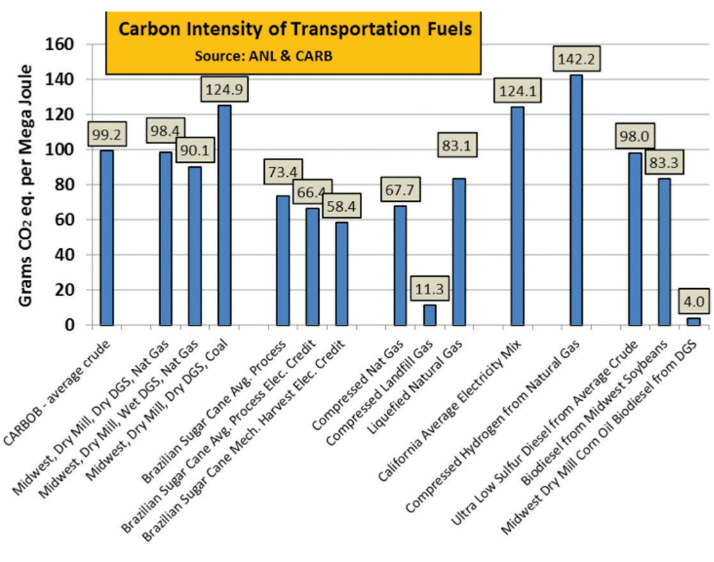
Re-thinking the Carbon Reduction Value of Corn Ethanol Fuel

ETHANOL ACROSS AMERICA

An Ethanol Across America White Paper | Winter 2015

It has been seven years since Argonne National Labs (ANL), as part of the Energy Security and Independence Act requirements, first determined the Life Cycle Carbon Intensity of mid-west corn ethanol fuel. ANL, using their **G**reenhouse gases, **R**egulated **E**missions, and **E**nergy use in **T**ransportation (GREET) model determined that Mid-West average corn ethanol fuel had a CI score of 98 grams CO_2 eq. emissions per mega joule of energy production. In the subsequent years, ANL has provided several updates to this greenhouse gas accounting that have significantly reduced the CI of corn ethanol fuel. However, low carbon fuel market regulators, such as the U.S. EPA and the California Air Resource Board (CARB) have yet to acknowledge these improvements and update their models with this new science. Because fossil fuel CI is trending higher and corn ethanol fuel CI is trending lower, failure to account for and acknowledge these trends erodes public support for biofuels and unfairly penalizes biofuels in low carbon fuel markets. Conversely, recognizing these new realities would provide us with a home grown advanced biofuel that meets a range of health and public policy objectives.

Carbon Intensity Modeling of Transportation Fuels



Using the GREET model, ANL and regulators such as CARB and the U.S. EPA, have determined the CI of all current and potentially significant transportation fuels used in the U.S.

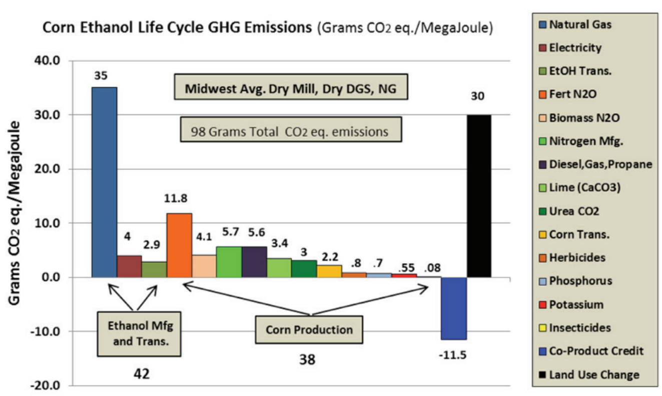
In 2013, California used Corn and Sugar Cane ethanol (62%), Biodiesel (27%), and Natural Gas (9%) for their Low Carbon Fuel Standard (LCFS) compliance.

Ron Alverson

For the past 40 years, Ron, a farmer, has raised corn and soybeans near Chester, South Dakota. Mr. Alverson was a founding member (1987) and past president of the South Dakota Corn Grower's Association, and past board member of the National Corn Grower's Association. Ron was also a founder and is a current board member of Lake Area Corn Processors LLC (Dakota Ethanol), a 60 million gallon per year ethanol production plant at Wentworth, SD, where he is involved with low carbon pathway applications for low carbon fuel markets. He also currently serves as President of the American Coalition for Ethanol's Board of Directors and is a member of the South Dakota State University Foundation Board of Trustees. Ron holds a BS degree in Agronomy/Soil Science from South Dakota State University.

Midwest Average Corn Ethanol Fuel Carbon Intensity

Even though ANL has issued several updates to GREET, CARB Scientists continue to use ANL's GREET 1.8b model (2008) to determine midwest avg. corn ethanol fuel CI. Chart below lists the measurement/modeling points and GHG emissions from corn ethanol fuel.



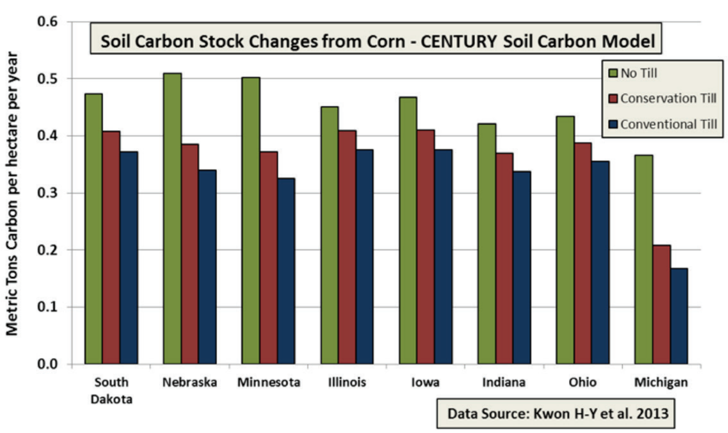
Continued

In addition to the direct GHG emissions from energy used in ethanol mfg. and corn production, modelers adjust total life cycle carbon intensity for co-product credits and soil carbon emissions from estimated **L**and **U**se **C**hanges (LUC).

To their credit, CARB has allowed individual ethanol production facilities to prove reduced carbon pathways. To date more than 100 ethanol production facilities have documented significant reductions in energy use. These production facilities average 86 CI.

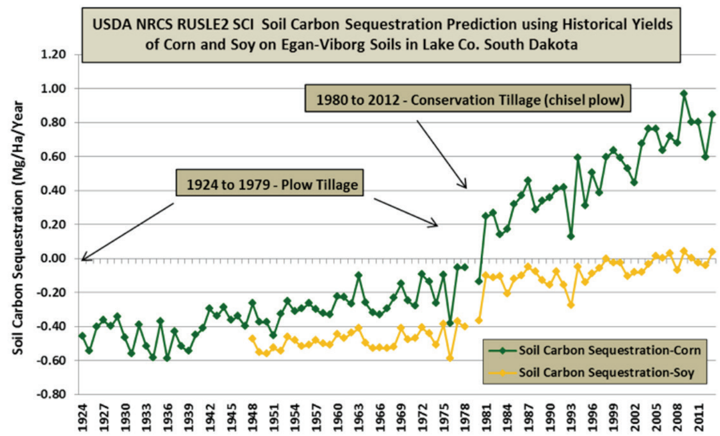
Reductions in Corn Ethanol Fuel Carbon Intensity since 2008

ANL, Agricultural Scientists, Environmental Scientists, and Ethanol Production Companies have documented significant reductions in corn ethanol fuel CI since 2008. ANL Scientists recently determined (GREET version 2.0, 2013) that average ethanol mfg. energy use has decreased 25%, corn farming energy use decreased 24%, corn fertilizer and chemical use decreased by 3%, and that ethanol manufactures are extracting 3% more ethanol from each bushel of corn. ANL affiliated scientists have also updated their Land Use Change calculations (Dunn et al. 2013)[1] with recent data and now estimate that soil carbon emissions from LUC are 7.6 grams CI, a 75% reduction from the widely used estimate of 30 grams CI. A significant portion of this reduction resulted from CENTURY (Kwon H-Y et al. 2013) and CCLUB (**C**arbon **C**alculator for **L**and **U**se Change from **B**iofuels Production) soil carbon modeling that predicts significant soil carbon sequestration from corn. Kwon H-Y et al. results are in the following chart:



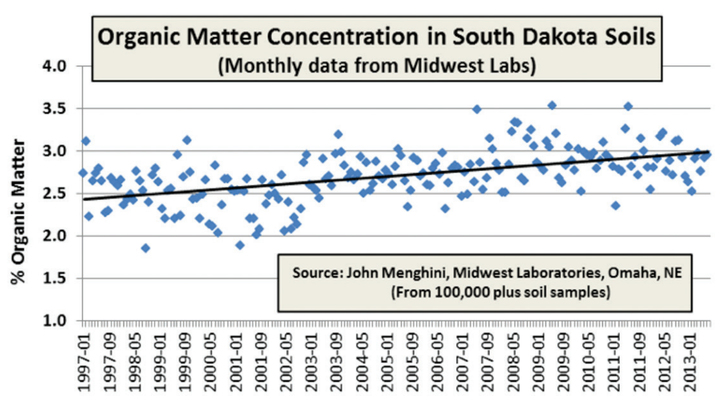
Corn crops that sequester .5 metric tons per hectare of atmospheric carbon annually in soil reduce overall corn ethanol CI by 20 grams.

This modeling is supported by U.S.D.A. National Resource Conservation Service (NRCS) soil carbon modelers. Modelers charted the effect of crop, increasing yield, and reduced tillage practices on soil carbon sequestration. Below are modeling results for Lake County, South Dakota:



The RUSLE2 SCI soil carbon model is calibrated with in-field measurement of actual long term soil carbon stock changes. Calibration data can be found on page 22 of an NRCS publication titled *"Using the Soil Conditioning Index to Assess the Management effects on Soil Carbon"* www.usda.nrcs.gov.

Regional soil testing laboratories (SDSU Soil Testing Laboratory, AGVISE Labs, and Mid-West Labs) have also contributed data indicating gains in soil carbon stocks. Below is a chart generated with soil organic matter data from Mid-West Labs in Omaha, Nebraska:



Organic matter concentration in South Dakota soils has increased about six tenths of 1% in the past fifteen years. Although this may seem like a very small change, this represents significant carbon sequestration in soil and is equivalent to 19 grams CI. The soil samples these data represent came from fields representing all crops grown in South Dakota. Had only corn fields been sampled, soil organic matter increases would very likely have been significantly higher.

1 *Land-use change and greenhouse gas emissions from corn and cellulosic ethanol*. Dunn et al., 2013

2 *Modeling state-level soil carbon emission factors under various scenarios for direct land use change associated with United States biofuel feedstock production.* Kwon H-Y et al., 2013

Dr. David Clay, along with a team of SDSU soil scientists (Clay et al. 2012)[3] merged soil carbon modeling with soil testing lab data to produce a paper titled "Corn Yields and No-tillage Affects Carbon Sequestration and Carbon Footprints"

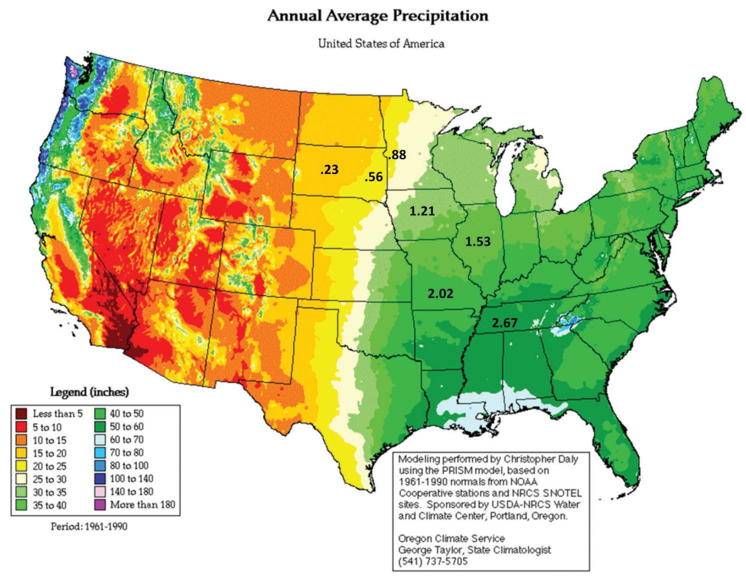
Of equal or greater impact on Land Use Change calculations, is the recently completed work (Babcock and Iqbal., 2014)[4] that tested first generation LUC model assumptions. These scientists have determined that little or no forest land has been converted to cropland in the U.S. as a result of biofuel production. Since 43% of the 30 CI LUC emission penalty is from estimated U.S. forest conversions, LUC is overestimated by more than 13 grams CI. As these and more data are accumulated it appears likely that corn ethanol fuel will eventually receive a LUC emission credit. Indeed, U.S.D.A. Agriculture Research Service Scientists (Follet et al., 2012)[5] have documented annual soil (full rooting profile) carbon sequestration in no-till corn exceeding .9 tons per year. This amount of atmospheric carbon sequestration in soil is equivalent to 80 grams CI! (*http://www.ars.usda.gov/is/AR/archive/feb14/soil0214.htm*)

Corn Production N_2O Emissions

Soil and crop scientists are also re-examining assumptions made in GHG models regarding Nitrous Oxide (N_2O) emissions from Nitrogen (N) fertilizer use and biomass N in corn production. N_2O is by far the largest component of corn production GHG emissions and comprise approximately 50% of all corn production CI.

Current N_2O emission calculations assume that about 1.5% of applied N fertilizer is converted to N_2O. But corn farmers are responding to market signals (N fertilizer prices are up 3–4X over the past 15 years) and have rapidly adopted precision application technology and employed Enhanced Efficiency Fertilizers (EEFs) in order to reduce N application rates, increase N use efficiency and reduce N losses to the air and water. Reviews of Scientific Literature indicate that these actions can reduce N_2O emissions by up to 50%. N losses and N_2O emissions are also greatly impacted by precipitation. Higher rainfall areas have higher N losses and N_2O emissions. European Soil and Environmental Scientists (Lesschen et al., 2012),[6] have developed a "precipitation adjustment factor" to estimate N induced N_2O emissions. These scientists calibrated this factor based on a global review of 352 N_2O emission measurements from fields. Using the Lesschen et al. "precipitation adjustment factor" scientists have estimated N to N2O conversion rates across the U.S. Midwest. See following map.

Precipitation adjusted Fertilizer N-to-N_2O Conversion Rates



As an example, average N_2O emissions from corn produced in Eastern Nebraska are expected to be only 50% of Central Illinois grown corn based on differences in precipitation.

Given the geographic location of U.S. corn ethanol production, these data suggest that using a uniform N-to-N_2O conversion rate across the U.S. Corn Belt does not properly account for the actual N_2O emissions from U.S. corn used for ethanol. A weighted average (ethanol production by precipitation zone) indicates a 10% reduction in Mid-West average N_2O emissions is warranted using this approach. This work is supported by a comparison of the Wang et al. 2012[7] field measurements of N_2O and the Wang et al. data adjusted with the Lesschen et al. precipitation factor. See chart on the following page. N_2O emissions increase when annual precipitation increases.

The GREET model also assumes that the N in corn residues has the same N-to-N_2O conversion rate as fertilizer N. This assumption is not in agreement with Scientific Literature. Research indicates that the N-to-N_2O conversion rate of the N in corn residues is only 20% of fertilizer N conversion rates. Corn residues have a very high carbon to nitrogen ratio, and because of this, N is immobilized by bacteria as this high carbon residue is decomposed. Lesschen et al.[6] discuss this research and support this reduced N-to-N_2O emission factor for corn residue in their research paper. Since 25% (4 CI) of corn ethanol fuel N_2O emissions are the result of corn biomass N, a 3 CI reduction is warranted.

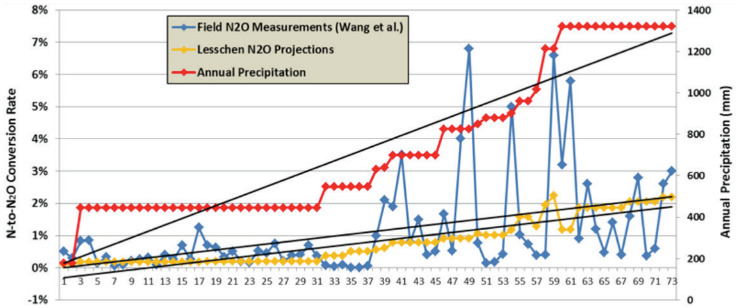
3 *Corn Yields and No-Tillage affects Carbon Sequestration and Carbon Footprints.* Clay et al., 2012.

4 *Using Recent Land Use Changes to Validate Land Use Change Models.* Bruce A. Babcock and Zabid Iqbal, 2014.

5 *Soil Carbon Sequestration by Switch grass and No-Till Maize Grown for Bioenergy.* Follet et al., 2014.

6 *Differentiation of nitrous oxide emission factors for agricultural soils.* Lesschen et al., 2011.

7 *Supporting Information For Well-to-Wheels Energy Use and Greenhouse Gas Emissions of Ethanol from Corn, Sugarcane, and Cellulosic Biomass for U.S. Use*. Wang et al., 2012.



Precision N management practices and increased use of enhanced efficiency N fertilizers have resulted in lower N_2O emissions in corn fields. Acknowledging an ethanol plant location precipitation adjusted weighted average N-to-N_2O conversion factor to determine Mid-West average, and recent science regarding N-to-N_2O conversion factors of fertilizer N and corn biomass N is clearly more scientifically defensible modeling. Corn ethanol N_2O emission factors in GHG models should be adjusted and N_2O emissions should be reduced a minimum of 6 CI. When corn ethanol is produced in areas where precipitation is reasonably balanced with corn crop evapotranspiration, N_2O emissions are likely less than 50% of the current Mid-West average.

Co-Product Credit

For use in the California LCFS, CARB modifies the GREET 1.8b model to reduce the co-product credit for distillers grains and assumes 1 lb. of distillers displaces only 1 lb. of corn in feed markets. Corn ethanol distillers grains are significantly more nutrient dense than corn, containing three times the protein, oil, minerals, and vitamins. None of these high value feed/food components are lost in the corn ethanol fermentation process. Peer reviewed University feeding trials have indicated that distillers grains displace 1.2 to 1.4 lbs of corn in cattle rations. ANL's GREET 1.8b model assumes one pound of distillers grains displace the equivalent of 1.27 lbs. corn. The failure of CARB to acknowledge this science raises corn ethanol CI 2.5 grams in that low carbon fuel market.

When high corn starch diets are used in cattle feed lots and dairies, significant methane emissions occur (enteric fermentation). ANL tabulates a CI credit for a reduction in enteric fermentation because distillers grains has replaced corn in cattle diets. CARB does not acknowledge this science, and has zeroed out this credit in the GREET 1.8b model. This raises corn ethanol CI 3.5 grams in California's LCFS market.

Many dry mill corn ethanol plants have added an additional co-product, corn oil. Each acre of corn produces about 10 gallons. This provides a significant amount of energy in feed rations and or biodiesel markets. Modelers have not accounted for this additional co-product in the same manner as the distillers grain co-product (unlike distillers grains, no feed, food or energy credit has been accrued to the corn ethanol life cycle for corn oil). Rather, modelers have tabulated an exceedingly low life cycle CI for corn oil biodiesel because they have assigned no portion of the GHG emissions from corn production to the corn oil. This distorts the CI of corn oil biodiesel downward at the expense of corn ethanol fuel CI. Corn ethanol gets all the gasses and corn oil biodiesel gets all the glory.

Summary

If greenhouse gas modeling of transportation fuels are to maintain integrity and achieve their desired outcome, it is essential that modeling is done consistently and that modeling assumptions are periodically reviewed and updated with the latest science. U.S. corn ethanol fuel production has experienced significant energy use and greenhouse gas emission reductions over the course of the last few years. Since 2008, innovation in energy use and conversion technology at ethanol production facilities, innovation in enhanced efficiency fertilizers and in corn production management, and improved accuracy of GHG modeling assumptions have reduced current corn ethanol fuel CI by more than 50%. The future is bright for corn ethanol blends to provide significant reductions in U.S. transportation fuel CI. Long term trends are biofuel's friends…fossil fuel CIs are increasing and biofuel CIs are being reduced. Corn provides high per acre production of feed/food, high octane fuel, and low GHGs. The wait is over…the advanced biofuel of tomorrow has arrived!

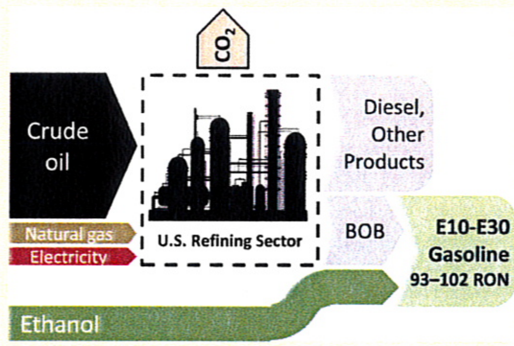
Supporting Information



ABSTRACT: Increasing the octane rating of the U.S. gasoline pool (currently ~93 Research Octane Number (RON)) would enable higher engine efficiency for light-duty vehicles (e.g., through higher compression ratio), facilitating compliance with federal fuel economy and greenhouse gas (GHG) emissions standards. The federal Renewable Fuels Standard calls for increased renewable fuel use in U.S. gasoline, primarily ethanol, a high-octane gasoline component. Linear programming modeling of the U.S. refining sector was used to assess the effects on refining economics, CO_2 emissions, and crude oil use of increasing average octane rating by increasing (i) the octane rating of refinery-produced hydrocarbon blendstocks for oxygenate blending (BOBs) and (ii) the volume fraction (Exx) of ethanol in finished gasoline. The analysis indicated the refining sector could produce BOBs yielding finished E20 and E30 gasolines with higher octane ratings at modest additional refining cost, for example, ~1¢/gal for 95-RON E20 or 97-RON E30, and 3–5¢/gal for 95-RON E10, 98-RON E20, or 100-RON E30. Reduced BOB volume (from displacement by ethanol) and lower BOB octane could (i) lower refinery CO_2 emissions (e.g., ~ 3% for 98-RON E20, ~ 10% for 100-RON E30) and (ii) reduce crude oil use (e.g., ~ 3% for 98-RON E20, ~ 8% for 100-RON E30).

INTRODUCTION

Octane rating specifications for standard grades of U.S. gasoline (regular, midgrade, and premium) have not changed since the 1970s, when leaded gasoline was phased out, leading to reductions in gasoline antiknock index (AKI) and compression ratios (CR) for naturally aspirated engines. AKI is the average of research octane number (RON) and motor octane number (MON)). But, since the 1970s, there have been great changes in technologies, standards, and regulations applicable to vehicles, oil refining, and fuels.

Auto manufacturers have improved performance and complied with higher fuel economy standards for new U.S. car and light-duty trucks using a variety of design changes, including gradually increasing engine CR. Higher CRs have been enabled by new engine technologies (adaptive spark control, variable valve timing, and fuel injection) and by new combustion chamber designs featuring high turbulence, central spark plug location, and optimized cooling. New vehicle technologies have also contributed (hybridization, turbocharging, downsizing, lightweight materials, and improved aerodynamic drag and rolling resistance).

Over the same time period, refineries have increased energy efficiency, reduced operating costs, met more stringent fuel standards (e.g., low-sulfur gasoline and diesel fuel), accommodated increasing volumes of ethanol in the gasoline pool,

Received: May 2, 2014
Revised: August 20, 2014
Accepted: August 21, 2014
Published: August 21, 2014

and are now reducing the gasoline/distillate ratio of the U.S. refined product slate in response to changes in demand. U.S. gasoline now meets stringent regulations for volatility (as measured by Reid Vapor Pressure (RVP)), sulfur content, and benzene content.

The U.S. Renewable Fuel Standard (RFS2) mandates[1] have triggered large increases in ethanol use; essentially all U.S. gasoline is now E10. RFS2 calls for further annual increases in ethanol use through 2022, although it is not clear how additional ethanol volumes will be accommodated in the gasoline pool, given current regulations governing gasoline and the limited compatibility of the refueling infrastructure and the light-duty vehicle fleet with ethanol content greater than E10.

More change is coming as the automotive industry gears up to meet new federal corporate average fuel economy (CAFE) and GHG standards.[2] The new standards become more stringent each year, reaching a fleet average of 54.5 mpg in 2025 (about double the current standard). Meeting these standards will require advanced vehicle and engine technologies and, possibly, new fuels.

One approach under consideration is to further increase gasoline engine CRs to achieve higher thermal efficiency and therefore higher vehicle fuel economy and lower GHG emissions. For example, increasing the CR from 10:1 to 12:1 could increase efficiency by 5−7%, or by 6−9% for 13:1, depending on attributes of the vehicle, engine, fuel, and drive cycle.[3,4] However, higher CRs require higher-octane fuel to prevent knocking at high load. Increasing CR by 1 number (e.g., from 10:1 to 11:1) requires an increase of 2.5 to 6 RON in the fuel (e.g., from 92 RON to 94.5−98 RON),[3−5] depending on cylinder displacement and geometry and engine technology (e.g., direct injected or port fuel injected, turbocharged or naturally aspirated).

As ethanol use has increased in the past decade, the U.S. refining industry has reduced the average octane rating of the hydrocarbon portion of gasoline (the BOB) by approximately 2−2.5 AKI to take advantage of ethanol's high octane rating while meeting the minimum octane standards for the finished gasoline.[5]

The potential for realizing higher gasoline octane ratings depends on refining techno-economics and federal and state standards on gasoline properties and composition. However, significantly higher gasoline octane ratings can be achieved by (i) increasing the octane rating of hydrocarbon gasoline to the extent feasible (e.g., to values typical 10 years ago) and (ii) increasing ethanol content from the current 10 vol % to 20−30 vol % (assuming federal regulations were modified to allow such fuels). Ethanol has a high volumetric blending octane value in gasoline: ~115−135 RON, depending on the ethanol concentration and BOB RON and composition (Supporting Information (SI) Section 4.6).[6,7]

Ethanol also has a high latent heat of vaporization and high sensitivity (RON minus MON), contributing to improvements in knock resistance in direct-injection and turbo-charged engines, allowing further increases in CR.[3,4] Ethanol can also increase efficiency in part-load operation, regardless of engine architecture.[8,9]

Finally, increasing the ethanol content in gasoline blends could reduce the "well-to-wheels" (WTW), life-cycle GHG emissions from light-duty vehicles, with the magnitude depending on the carbon footprint of ethanol production, fuel properties (e.g., carbon content), and engine efficiency benefits.

The use of high-RON gasolines would contribute to the vehicle industry's ability to meet future CAFE and GHG standards, but the production of such fuels would impose costs on the refining industry. Older WTW studies are outdated, do not consider GHG implications in the U.S. setting, and do not consider ethanol use at present or projected U.S. levels. The 1970s oil embargo and lead phase-out spurred studies[10,11] of optimal octane ratings for unleaded U.S. gasoline, considering both refining sector effects and vehicle efficiency. Reviewing these studies, the U.S. Environmental Protection Agency (EPA) concluded[12] that "the current rating of 91 RON/83 MON for unleaded gasoline does not appear strictly appropriate on a permanent basis." In the 1980s, a European oil industry study[13] evaluated gasoline octane ratings in light of their lead phase-out. In that study, oil consumption was the key metric and neither GHG emissions nor ethanol as a high-octane blending component were considered. A more recent European analysis[14] considered cases with 100-RON gasoline and E20 gasoline, reporting higher refinery CO_2 emissions and cost in the former case and lower CO_2 emissions and cost in the latter. In 2005, a Japanese auto-oil industry research group concluded that increasing the RON of Japanese gasoline from 90 to 95 could provide a WTW CO_2 emissions reduction and that ethanol blending had greater potential than refinery changes.[15] However, that study considered vehicles designed for the Japanese market, Japanese refineries and fuels, and ethanol content was limited to 3 vol %.

A recent paper by Speth et al.[16] addressed economic and GHG implications of increasing U.S. gasoline RON from regular- to premium-grade in the context of future CAFE standards and reported significant associated reductions in WTW CO_2 emissions and cost. Further addressing the lack of relevant analysis, this paper examines the implications for the U.S. refining industry of increasing the octane rating and/or the ethanol content of U.S. gasoline. It assesses the investment requirements, refining cost, and other consequences in the U.S. refining sector of producing a national gasoline pool meeting minimum RON standards from 93.2 (the approximate current average) to 102, with ethanol concentrations from 10 to 30 vol %, both as nationwide midlevel blends (E10 to E30) and as combinations of E85 and E10. Fuel properties are estimated to enable WTW assessments of the associated GHG emissions.

METHODS

The analysis employed regional refinery linear programming (LP) modeling to estimate the effects on the U.S. refining sector of producing a single future national gasoline that (i) meets a uniform minimum octane rating (RON) standard, (ii) contains ≤10 ppm sulfur (the new national Tier 3 standard),[17] and (iii) satisfies existing federal, California, and industry gasoline standards. Linear programming has long been the preferred method for analyzing technical and economic aspects of refining operations.[18,19] A refinery LP model yields an optimal value for an economic objective function, subject to a set of constraints denoting product demands, crude oil availability, refinery process capacities and capabilities, and energy and material balances.

In this study, the objective function to be minimized was total refining cost (the sum of direct operating costs and capital charges for new investments) incurred in producing the same slate of primary refined products with specified properties including octane rating. In this product slate, the volumes of all primary refined products were fixed in all cases (as required for

dx.doi.org/10.1021/es5021668 | Environ. Sci. Technol. 2014, 48, 11064−11071

cost minimization). (See SI Section 4.5.) The methodology for estimating capital charges associated with installing new refining process capacity is discussed in SI Section 4.8 and is similar to that used in the U.S. Department of Energy's Liquid Fuels Market Model.[20]

The analysis assessed refining operations in a future year (2017) for each of three regional refining aggregates, defined in terms of U.S. Petroleum Administration for Defense Districts (PADDs, SI Section 1). PADDs 1−3 were treated together because of their similar refinery characteristics; PADDs 4 and 5 were treated individually because their refining operations and economics differ significantly. Regional results (presented in SI Section 5.3) were aggregated to a national level.

Model Cases. Table 1 shows the scenarios in the analysis, each consisting of a combination of current gasoline octane

[a]RON of the E10 portion is the same as the Reference cases.

ratings or prospective national RON standard (95 to 102 RON), ethanol concentration (10, 20, or 30 vol %), and RVP waiver assumption. Two additional scenarios representing joint production of E10 and E85 with total ethanol volumes matching that required for national E20 and E30.

Calibration cases validated the regional refining models by demonstrating that their outputs closely match reported data on refining sector performance in 2010, including retail gasoline property data.[21] (See SI Section 4.1).

Reference cases represented production of projected refined product volumes in the study year (2017) assuming nationwide E10, E20, or E30 with *unchanged octane ratings*, and subject to all other fuel regulations and industry standards currently in place or scheduled to be in place by 2017, including the Tier 3 gasoline sulfur limit (10 ppm average).[17] The Reference cases embody octane ratings corresponding to the current average for the U.S. gasoline pool: 87.6 AKI, corresponding to 93.2 RON. For PADD 4, the baseline includes an AKI of 85 (not 87) for Regular-grade gasoline.

Study cases assessed the techno-economic refining sector effects, relative to the corresponding Reference cases, of meeting higher national RON standards with specified ethanol concentrations and blending approaches (as nationwide E10, E20 or E30 or as E10/E85). In the E10/E85 cases, ethanol constituted 20 vol % or 30 vol % of the U.S. gasoline pool, but with the ethanol blended in combinations of E10 and E85 in amounts to provide equal total delivered energy. The ethanol content of E85 was 74 vol %[22] and RVP was 8.0 psi for both winter and summer, with light naphtha as hydrocarbon blendstock.

Model Assumptions. Consistent with federal, state, and industry standards for E10,[23] finished gasoline in all Reference and Study cases also met the following property limits: MON > 82, sulfur <10 ppm average, summer RVP (7 psi in California and federal RFG areas; 9 psi elsewhere), Driveability Index <1250, and benzene <0.62 vol %, average.

Uncertainty in future RVP regulations was considered. Under the federal Clean Air Act,[24] E10 is allowed a 1 psi RVP waiver, relaxing the applicable summer RVP standard by 1 psi, in regions not otherwise subject to lower RVP standards. This waiver reduces refining costs. Higher ethanol blends including E20 and E30 are ineligible for the RVP waiver and were modeled accordingly. The E10 cases were modeled both with and without the RVP waiver; the former to represent current regulations and the latter to avoid conflating the refining cost of summer RVP control with that of producing high-RON fuels.

All Reference and Study cases reflect (i) regional refined product volumes for 2017 estimated from national projections from the U.S. Energy Information Administration (EIA), (ii) an average crude oil price of $96/b, and (iii) an average natural gas price of $5.19/Mcf, all drawn from EIA's Annual Energy Outlook 2011.[22] Reference cases for each refining region maintain approximately constant domestic gasoline output in terms of *energy delivered* (BTU/year) across *all* ethanol concentrations. The total annual volume of finished gasoline increases with increasing ethanol content, reflecting ethanol's lower energy content relative to hydrocarbon gasoline. The Study cases corresponding to each Exx Reference case maintained the same finished gasoline volume.

In all cases, the regional refining models represented refinery production of gasoline blendstocks for oxygenate blending (BOBs). A BOB (SI Section 1) is a gasoline blendstock purpose-produced for blending with ethanol in specified proportions (downstream of the refinery). The resulting finished gasoline meets the specified octane rating standard and all other specifications.

The refinery LP models incorporate ethanol's octane contribution estimated using the molar concentration blending method,[6,7] expressed as volumetric blending octane values that decrease with increasing RON of the finished gasoline blend (SI Table S6). This method provides a conservative representation of ethanol's blending value in typical U.S. gasoline.[7] The blending RVP for ethanol was incorporated as a declining function of ethanol content from E10 to E30[25] (SI Section 4.6).

Model Outputs. The estimated refining sector effects (relative to the appropriate Reference case) for each Study case include the required RON and MON of the BOBs, industry-wide average annual additional refining cost (ARC), per-gallon ARC, refining industry investment, crude oil input to the refining sector, natural gas and electricity use, refining sector CO_2 emissions, average operating severity and total throughput of refinery reformer units, refinery sales of distressed blendstocks, resulting effects on BOB properties (aromatics content, density, energy content), and consumer savings associated with energy density. Reported refining cost and refinery CO_2 emissions results are average national full-year *differences* between values for Study cases and their corresponding Reference cases.

The methodology for computing refining sector CO_2 emissions (described in SI Sections 2 and 3) was as in a

dx.doi.org/10.1021/es5021668 | Environ. Sci. Technol. 2014, 48, 11064−11071

prior study by Hirshfeld and Kolb.[18] The estimated CO_2 emissions apply only to the refining sector; they *do not* represent complete life cycle emissions for fuels (e.g., natural gas) purchased by refineries and used to provide refinery energy.

The estimated changes in refining costs apply only to BOB production and do not depend on the price of ethanol, because ethanol use is constant across the Reference case and Study cases *within* a given ethanol blending scenario (E10, E20, or E30).

The higher ethanol concentration cases assume that implementation barriers are managed; total U.S. ethanol supply (from all sources) increases to support nationwide demand; federal and state regulations governing ethanol/gasoline blends are modified to allow such concentrations; and vehicle fleet and infrastructure capability are in place. Likewise, the E10/E85 cases assume sufficient ethanol supply, numbers of flexible fuel vehicles (FFVs), and E85 fueling stations, and a regulatory framework to support energy parity (or better) retail E85 pricing.

■ RESULTS

Key results, presented here, include refining economics, CO_2 emissions, petroleum consumption, and BOB properties. Additional and more detailed results are given in SI Section 5 and SI Appendix C.

Refining Economics. The estimated average additional refining costs (ARC, ¢/gal of BOB)—*relative to the corresponding Reference case*—of producing gasoline BOBs for each case are shown in Figure 1. These estimated costs are

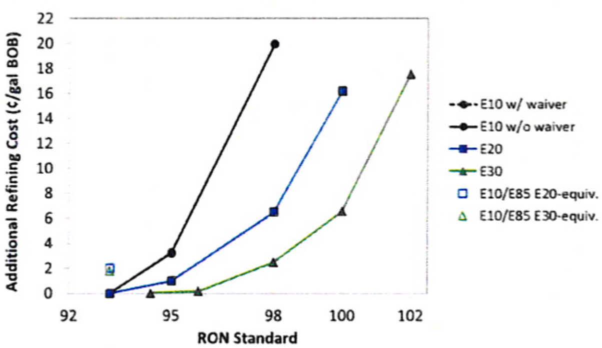

Figure 1. Estimated additional refining cost (¢/gal BOB) for different finished gasoline RON standards, total U.S. year-round average, relative to the respective Reference cases.

independent of ethanol price. They are volume-weighted national averages for the refining regions analyzed and include changes in investment costs and annual operating costs. For a given ethanol content, the refining cost increases with increasing RON standard at an accelerating rate. However, for a given RON standard, the associated ARC decreases with increasing ethanol content. These trends exist for every refining region.

The highest point shown on each curve represents the maximum RON considered feasible for production as the primary gasoline throughout the U.S., using only ethanol and refinery-produced gasoline blendstocks (i.e., with no purchased high-octane blendstocks). These limits come primarily from limitations in U.S. refineries' existing octane-generating capacity needed to produce high-octane BOBs. However, the *maximum* RON standards likely to be attainable nationwide increase with available ethanol content, namely 98-RON E10, 100-RON E20, and 102-RON E30.

The analysis suggests that the refining sector could produce BOBs for national 95-RON E20 or 97-RON E30 gasoline pools at an ARC of approximately 1¢/gal of BOB. This small cost increase reflects the fact that these BOBs have octane ratings similar to that of the BOB currently used for Regular-grade E10. The refining sector could produce national BOB pools for (i) 95-RON E10, 97-RON E20, or 100-RON E30 gasoline pools at ARCs of approximately 5¢/gal, and (ii) 96-RON E10, 99-RON E20, or 101-RON E30 gasoline pools at an ARCs of approximately 10¢/gal.

The cost estimates incorporate both volume and octane rating effects on refining costs. Increasing the *ethanol content* in finished gasoline at constant octane (e.g., E10 95 RON → E20 95 RON) reduces refining costs through two effects. The required octane rating of the BOB declines (Figure 2), reducing

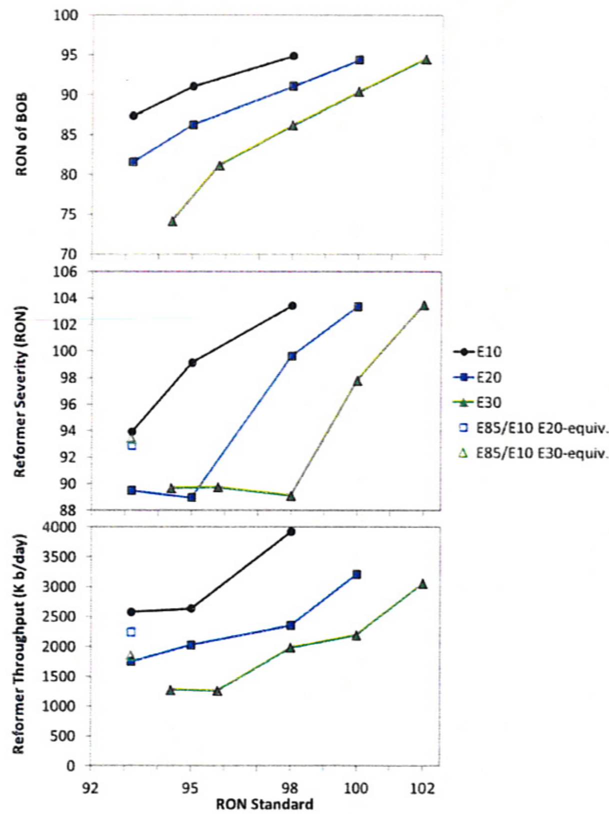

Figure 2. Estimated RON of gasoline BOBs and U.S. total reformer throughput and average severity as functions of RON standard and ethanol content.

the refining cost, and the necessary volume of the gasoline BOB declines (to accommodate the additional ethanol). Increasing the *octane rating* of gasoline at constant ethanol content (e.g., E20 95 RON → E20 98 RON) increases refining costs, likewise through two effects. The required BOB octane rating and associated refining cost increase, while the volume of BOB declines slightly, because its energy density increases with increasing RON. Additional details are provided in SI Section 5.2.

[a]All cases are without RVP waiver unless indicated otherwise. [b]Amounts are relative to the corresponding reference case (~93 RON) with the same ethanol content. [c]Amounts are ¢/gal of finished gasoline. [d]E10 and E10 BOB octane ratings are the same as the E10-only case w/o RVP waiver. The BOB for E85 is assumed to be light naphtha with approximately 71 RON and 70 MON.

Figure 2 shows the estimated BOB RON, average reformer severity, and total reformer throughput as functions of the finished gasoline RON and ethanol content. For a given ethanol content, the BOB octane rating is increased mainly by increasing the concentration of reformate, leading to greater aromatic hydrocarbon content (SI Table S15), higher crude oil consumption, and higher refinery energy use and CO_2 emissions.

(The estimation of BOB RON values using the linear molar blending method,[6] as described in SI Section 4.6, gives a conservative estimate of BOB RON. However, different BOB compositions can have second-order effects yielding higher RON than predicted by this approach.[7,26] Combining the synergistic ethanol blending effects reported by Anderson et al.[7] with the BOB RON values in Figure 2 yields higher finished gasoline RON values for all fuels in the study, with larger effects for E20 and E30 fuels than for E10. A key implication is that higher-octane blends would be more attractive than shown here, because they would require lower-RON BOBs).

The increases in ARC in most of the higher-RON cases are partially offset by the value of the gasoline's increased energy density (Table 2), stemming mainly from increases in aromatic hydrocarbon content. Increased energy density increases vehicle fuel economy and reduces the fuel volume consumed.

Table 2 includes a summary of key refining economics results, reported in terms of annual national values. Costs in Table 2 are incremental changes relative to each Reference case; Reference case costs are provided in SI Table SI−C1.

Estimated refinery investment required increases rapidly with RON standard for each ethanol content but decreases with increasing ethanol content for each RON standard. Most of the indicated investment goes to increase octane-generating capacity, mainly in reforming and pentane/hexane isomerization (the latter an octane-enhancing process that isomerizes *n*-paraffins to *i*-paraffins). Large increases in investments for the highest RON cases—more than $25 billion for E10 and $15 billion for E20 and E30, respectively—indicate that further increases in the RON standard (beyond those shown in Figure 1) would likely be infeasible with existing refining technology.

Estimated annual refining costs are the sum of capital and fixed charges for refinery investments and additional refining operational costs. The latter includes costs from increasing reformer severity and throughput, other octane-yielding refining operations, and loss in revenue associated with rejected low-octane refinery streams sold at a distress price (SI Section 4.5). The estimated annual refining costs and ARCs (¢/gal) exhibit the same trends as refinery investments with respect to RON standard and ethanol content.

Comparison of the refining economics for the E10/E85 Study cases with their corresponding E20 and E30 Reference cases indicates that average U.S. refining costs would be about 1.6¢/gal and 1.2¢/gal (of finished gasoline) higher if ethanol was blended in combinations of E10 and E85 rather than in national E20 or E30, respectively, with the *Reference case octane rating*. These incremental costs are approximately equal to that for producing nationwide 95-RON E20 and 97-RON E30, respectively.

The additional refining costs in the E10/E85 cases stem from "octane give-away" in E85: E85's octane rating is higher than that required by applicable fuel specifications, while it could be fully utilized for E20 or E30. (Current FFVs cannot fully utilize E85's high octane rating, because they must also function well using Regular-grade gasoline. Future vehicles optimized for E85 might realize greater benefit.) Refiners generally take full advantage of ethanol's octane value in the production of suboctane BOBs for E10; in the Reference cases it is assumed that they would follow the same practice in producing E20 or E30.

As a sensitivity analysis, the effect on estimated refining costs of changes in the assumed prices of crude oil and natural gas was determined. As discussed in SI Section 5.5, the ARC would be increased by increasing crude oil price due to increased crude oil demand. In contrast, the ARC would be decreased by increasing natural gas price because of increased production of low-value refinery streams used as refinery fuel instead of natural gas, and increased reformer production of hydrogen, displacing hydrogen produced from natural gas. Also, incremental costs of finished gasoline, assuming a given ethanol price, are provided in SI Table S16. Not surprisingly, higher ethanol price increases the incremental cost of finished gasoline production, in step with increasing ethanol content.

Refining Sector Crude Oil Use. Estimated changes in total refinery crude oil throughput, relative to the E10 Reference case, are shown in Figure 3. The E20 and E30 cases indicate

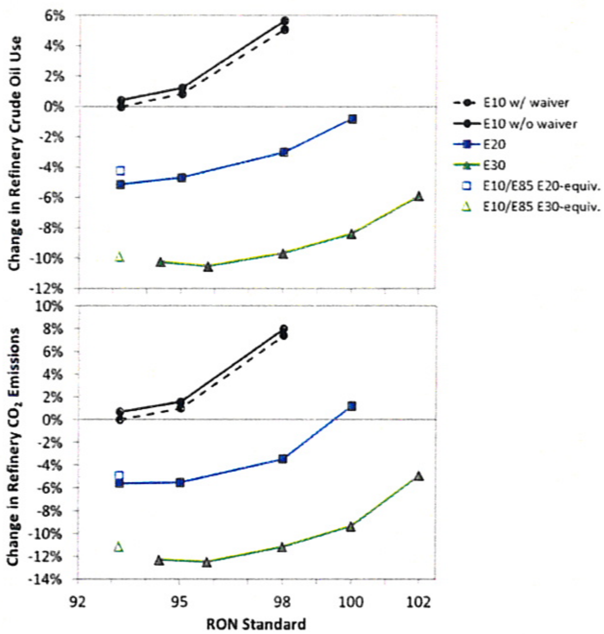

Figure 3. Estimated percent change in total U.S. refinery crude oil use (top) and CO_2 emissions (bottom) relative to E10 Reference case with RVP waiver, year-round average.

reductions of about 5% and 10%, respectively, in crude oil use. Reduced refinery demand for crude oil generally provides a net WTW reduction in oil use, because gasoline production consumes more oil than production of most alternative fuels.[27] These percentage changes are higher if attributed solely to the change in gasoline BOB production (i.e., by a factor of approximately 2, the ratio of total refinery product divided by gasoline BOB quantity).

Crude oil use increases with increasing RON (for a given ethanol content) because this requires higher RON for the corresponding BOBs, typically accomplished through increased reformer throughput and/or severity, both of which increase crude oil consumption. The additional consumption is negligible in Study cases with reformer throughput and severity comparable to their corresponding Reference case (Figure 2). Specifically, 95-RON E20 and 98-RON E30 involve increases in crude oil use of approximately 0.5%, and 1%, respectively, relative to their Reference cases (which have lower RON). Production of higher-RON BOBs calls for larger increases in crude throughput.

Refining Sector CO_2 Emissions. Changes in estimated annual refinery CO_2 emissions relative to the E10 Reference case are shown in Figure 3. Refinery CO_2 emissions decrease with increasing ethanol content in the finished gasoline pool. Conversely, at constant ethanol content, refinery CO_2 emissions increase with increasing RON of the finished gasoline pool, primarily reflecting increased refinery energy use to increase the RON of the BOB pool.

The analysis indicates that the refining sector could produce national BOB pools for 95-RON E10, E20, or E30 finished gasoline with increases in refinery CO_2 emissions $\leq 1\%$ relative to their Reference case octane ratings. Producing national BOB pools for 98-RON E20 or E30 would entail increases in refinery CO_2 emissions of 2.3% and 1.3%, respectively. To yield a net reduction in WTW CO_2 emissions, these increases in refinery CO_2 emissions would have to be more than offset by vehicle CO_2 emissions reductions from higher engine efficiency enabled by these fuels.

Finished Gasoline Pool Properties. To conduct a complete WTW analysis for CO_2 emissions, changes in finished fuel properties are needed, including carbon/hydrogen (C/H) ratio, energy content (lower (net) heating value), and density. Fuel properties were estimated from results returned by the LP models (SI Section 4.7) and are given in SI Table S18 for both gasoline BOB and finished gasoline pools. In general, the C/H ratio and lower heating value of finished gasoline increase with increasing finished gasoline RON (at constant ethanol content) and decrease with increasing ethanol content (at constant finished gasoline RON). Density increases with RON whether accomplished through increased content of aromatic hydrocarbons or ethanol.

Vehicle tailpipe CO_2 emissions (assuming constant engine efficiency) are proportional to a fuel's energy-based carbon content (gC/MJ, Figure 4), calculated from carbon weight

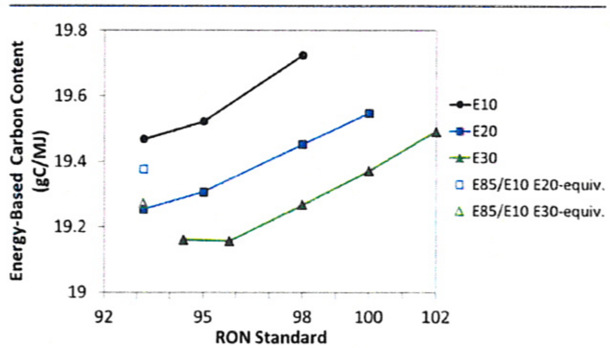

Figure 4. Energy-based carbon content of finished fuel pools (with no RVP waiver), defined as the ratio of carbon weight fraction and energy content on a lower-heating value basis. (Values for E85/E10 scenarios are weighted averages of E10 and E85 in the total fuel pool).

fraction and energy content (MJ/kg). This parameter increases with RON (for a given ethanol content) and decreases with ethanol content (for a given RON). For example, compared with the E10 Reference case, the energy-based carbon content of 98-RON E10 is 1.2% higher and that of 95-RON E30 is 1.6% lower. These differences reflect the greater energy-based carbon content of aromatic hydrocarbons relative to nonaromatic hydrocarbons and ethanol.

DISCUSSION

Increasing the octane rating of U.S. gasoline would enable higher engine efficiency, facilitating compliance with federal fuel economy and greenhouse gas (GHG) emissions standards for light-duty vehicles. It would also have significant implications for the U.S. refining sector, whether the higher octane ratings were achieved through more severe refining operations, increased use of ethanol, or both.

This analysis applied linear programming modeling of the U.S. refining sector to assess the effects on refining economics, crude oil use, CO_2 emissions, and gasoline pool properties of increasing the average octane of the U.S. gasoline pool (currently ~87.5 AKI, corresponding to 93.2 RON) to as high as 102 RON by increasing the octane rating of refinery-produced BOBs and/or the ethanol content in finished gasoline.

This analysis concludes that the U.S. refining sector could produce national BOB pools for 95-RON E20 and 97-RON E30 finished gasoline pools with < $1 billion of investment in additional refining capability and at an ARC of ~1¢/gal (including return on investment). The ARC for these BOBs is low because they would have octane ratings (~92 RON) close to that of the current U.S. E10 BOB pool. Similarly, the U.S. refining sector could produce national BOB pools for 95-RON E10, 98-RON E20, or 100-RON E30 gasoline pools with ~$4–$6 billion of investment and at an ARC of ~3–5¢/gal. Achieving still higher octane ratings for finished gasoline would incur progressively higher investment and ARC until practical limits of refining capability were reached. The price of ethanol relative to gasoline and crude oil are key determinants of the relative costs of the various finished fuels (SI Tables S16 and S17).

Producing E20 and E30 gasoline pools would incur somewhat lower refining costs, petroleum use, and CO_2 emissions than using the corresponding volumes of ethanol in combinations of E10 and E85. The difference stems from the "octane give-away" associated with E85 (whose octane rating is higher than that required by fuel specifications), whereas ethanol's octane can be fully utilized in producing BOBs for E20 or E30.

The study considered higher-RON E10 blends produced with and without the 1 psi waiver for summer RVP currently allowed for most U.S. gasoline (other than reformulated gasoline). Eliminating the RVP waiver would call for a compensating reduction of ~1 psi in the RVP of the affected E10 BOBs. In a given refinery, the ARC of this additional RVP control could be significant. However, on a year-round, national basis, the ARC of this additional RVP control would be small, because (i) it would be required only in the summer gasoline season and (ii) the RVP waiver is not available for federal and California reformulated gasoline (which account for more than one-third of the U.S. gasoline pool).

The analysis showed that, for a given ethanol content, refinery CO_2 emissions and crude oil use increase with finished gasoline RON, reflecting higher refinery energy use and higher reformer severity and throughput needed to produce a BOB pool with higher RON. For a given RON, refinery CO_2 emissions and crude oil use decrease with increasing ethanol content in the gasoline pool, due primarily to the reduction in BOB volume and RON.

The analysis did not include the option to utilize certain high-octane gasoline blendstocks not used now in the U.S., though some have been in the past, including hydrocarbons (iso-octane, iso-octene), alcohols (methanol, iso-butanol), and ethers (MTBE, ETBE, TAME), all with RON of 100 or more.[28,29] A national high-RON gasoline standard (coupled with increased supplies of natural gas liquids resulting from the expansion of U.S. natural gas production) could call out supplies of these high-octane blendstocks, which in turn could improve the economics of the high-RON gasoline standards, with or without additional ethanol use.

The cost estimates for E20 and E30 blends include neither additional costs that would be incurred in the distribution system, refinery to pump, to accommodate higher ethanol content fuels (e.g., replacement of tanks, lines, and pumps at terminals and filling stations) nor savings that might be realized because a national RON standard would reduce the number of gasoline grades in commerce. Nor do these estimates reflect any assessment of market conditions, such as supply/demand balances, that might influence retail gasoline prices in a given period.

Producing national E20 and E30 gasoline pools would require (i) changes in the regulatory framework governing ethanol use to allow such midlevel ethanol blends, (ii) sufficient additional ethanol production to support nation-wide production of these blends, (iii) changes in the distribution infrastructure to handle midlevel ethanol blends, and (iv) a vehicle fleet capable of using these fuels.

For vehicle manufacturers to optimize engine designs to use the combustion advantages of higher-RON, higher-ethanol content fuels, these fuels would have to be readily available nationwide and competitively priced with other liquid fuel alternatives, particularly during a transition to a national high-RON E20 or E30 standard. The transition would require concerted actions by multiple stakeholders, including fuel producers, fuel distributors and retailers, vehicle manufacturers, and government agencies. However, such transitions have been accomplished in the past to realize longer-term, system-wide benefits (e.g., transition to unleaded gasoline).

Understanding the implications for the refining sector is fundamental to assessing the feasibility and potential of future U.S. gasoline with higher octane ratings and/or higher ethanol content. This study provides a techno-economic assessment of this subject to address the lack of such information in the open literature. Higher-octane (95 RON) E10 gasoline was determined to be technically feasible, without considerable additional cost, CO_2 emissions, or petroleum consumption for refineries. Higher ethanol content (E20, E30) could provide a viable path to fuel with still higher octane ratings (98 RON) with reduced petroleum consumption and lower refinery CO_2 emissions. Considering the significant efficiency increases demonstrated for higher-CR engines,[3,4] these results suggest that further consideration (e.g., WTW life-cycle analyses[16]) of higher-octane gasoline in the U.S. is warranted.

CENTER for BIOLOGICAL DIVERSITY Because life is good.

February 17, 2015

Via electronic submission

Mary Nichols, Chair
California Air Resources Board
1001 I Street, PO Box 2815
Sacramento, CA 95812

Dear Chair Nichols and Members of the Air Resources Board:

This letter is submitted on behalf of the Center for Biological Diversity ("Center") regarding the California Air Resources Board's ("ARB") proposed adoption of the Low Carbon Fuel Standard, or LCFS, and the associated Draft Environmental Impact Report ("EIR"). The Center for Biological Diversity strongly supports the LCFS as a crucial tool in addressing the large proportion of California's greenhouse gas emissions and other air pollutants that comes from the production, transport, refining, and combustion of transportation fuels.

The Center appreciates ARB's continuing work on the LCFS and other measures to address pollution from transportation fuels. The extraction, refining, transport, and combustion of transportation fuels is the source of nearly half of California's annual greenhouse gas emissions, and the equivalent of more than 217 million metric tons of carbon dioxide (CO2e). This category of greenhouse gas emissions is accompanied by large amounts of nitrogen oxides and ozone pollution: 80 percent of California's total emissions of nitrogen oxides of nitrogen (NOx), and 95 percent of diesel particulate matter (PM) emissions. These pollutants are major contributors to the dangerously poor air quality that affects many communities in our state. Without a doubt, California must pursue every option and opportunity to reduce emissions from transportation fuels.

These comments identify specific opportunities to strengthen the proposed rule with respect to hydraulic fracturing and forest-sourced biofuels, and to strengthen the EIR's treatment of impacts to food prices and availability. Some of the noted issues exist in the previously adopted rule but warrant additional consideration in the proposed rule. In all cases, the Center believes there are real solutions for addressing these issues and enacting a strong LCFS that best serves California.

I. The Carbon Intensities Must Account for Energy Inputs and Greenhouse Gas Emissions Specific to Hydraulic Fracturing and other Carbon-Intensive Oil Recovery Methods.

LCFS 60-1

The LCFS uses carbon intensity values generated via the Oil Production Greenhouse Gas Emissions Estimator (OPGEE) Version 1.1 Draft D, to provide average carbon intensities for

Alaska . Arizona . California . Florida . Minnesota . Nevada . New Mexico . New York . Oregon . Vermont . Washington, DC
P.O. Box 191122 . Sacramento, CA 95819 tel: (916) 201.6938 www.BiologicalDiversity.org

crude supplies by country or U.S. state, often specific to individual oil fields (including more than 150 different crudes in California). However, OPGEE Version 1.1, included by reference in the proposed rule, does not explicitly address fracking as a distinct category of crude production. As a result, it does not account for energy inputs and greenhouse gas emissions associated with many components of fracking and other enhanced oil recovery, such as: the pumping and transport of freshwater used in fracking fluid, manufacture and transport of constituent chemicals and fracking fluids, the manufacture and transport of frac sand, flowback emissions, and disposal of fracking fluids. These omissions are evident in the table of input categories for the OPGEE model, which lists input categories in some detail, and which is extensive for many oil production activities.[1] This oversight is also directly stated in the documentation for the OPGEE model.[2]

> Some techniques are not built in the current version of OPGEE, including CO2 flooding and hydraulic fracturing (also known as "fracking"). These modules will be added in the future.[3]
>
> Because waste treatment emissions only occur sporadically, they are likely to be small when amortized over the producing life of an oil field. For this reason, emissions from waste treatment are considered below the significance cutoff in OPGEE v1.1 Draft D. Possible exceptions could be the treatment and disposal of fracturing fluids and fracturing flow-back water, due to the large volumes produced. Future versions of the model may include these factors.[4]

LCFS 60-1 cont.

The undercounting of emissions and energy inputs specific to fracking raises concerns regarding the impacts associated with high carbon-intensity crudes (addressed in more detail in the next section). In addition, this undercounting undermines the ability of LCFS to effectively achieve its target reductions. Fracking and acidizing are major components of operations in many oil fields in California, North Dakota, and elsewhere. Correctly accounting for the emissions and energy inputs specific to fracking would significantly change both the carbon intensity values for many individual crudes as well as the state average crude carbon intensity used by the large refineries.

Furthermore, the inputs and calculations behind the carbon intensity lookup table indicate heavy use of standard default values instead of field-specific inputs.[5] For example, all California oil fields are given a default flaring-to-oil ratio of 13 scf/bbl oil, and a default pipeline transport distance of 100 miles. Similarly, the three oil fields listed for North Dakota all use the same default inputs for all values, resulting in identical carbon intensities, the relatively low 10.18. In

[4] OPGEE v1.1 Draft D, User Guide & Technical Documentation, page 83.

[5] OPGEE Version 1.1 Draft Lookup Table MCON Inputs, http://www.arb.ca.gov/fuels/lcfs/lcfs_meetings/draft_lookup_table_mcon_inputs_opgee_v1_1_102914.xlsx

all of these cases, the LCFS is significantly underestimating carbon intensities for individual oil fields with heavy use of fracking and other high energy-intensity operations. The calculation documentation acknowledges as much with respect to many crudes, including the North Dakota crudes: "OPGEE does not account for emissions from fracking so the CI estimate will likely be low."[6]

We understand that ARB is currently developing these components--water pumping and transport, manufacture and transport of fracking fluid and acid constituents, the manufacture and transport of frac sand, flowback emissions, disposal of fracking fluids and flowback wastewater--to be included in future revisions to the LCFS. In the meantime, these emissions and energy inputs are either being undercounted or not counted at all in the carbon intensity value. Nonetheless, the proposed rule would explicitly include these faulty carbon intensity values, and incorporate the model inputs by reference. While the proposed rule states that ARB intends to update the LCFS at three year intervals, these low carbon intensity values would be in place until the LCFS is amended in the future.

The Center strongly supports ARB's development of a model to assign values to the carbon impacts of fracking and other carbon intensive enhanced oil recovery methods. Correctly accounting for the carbon impacts associated with fracking is critical to demonstrating that the LCFS has successfully reduced fuel carbon intensities by 10% by 2020 and achieved the projected reductions expected from this sector under AB 32. The results of modeling the carbon impacts associated with fracking may lead to retroactive correction of baseline and compliance schedules. One approach, in the interim, would be to apply an additional default value to the standard carbon intensity for crudes produced in oil fields where fracking is common, until the model for estimating emissions associated with fracking is completed and the carbon intensity values can be corrected.

LCFS 60-1 cont.

II. ARB Should Consider Additional Measures to Directly Discourage the Development and Production of High Carbon Intensity Crude Oils Under the LCFS.

In the years since the LCFS was first adopted, the greenhouse gas pollution from the production of transportation fuels has become a much more important and visible issue in California and nationwide. The import of high carbon-intensity crude into California from the expansive hydraulic fracturing operations in the Bakken oil play in North Dakota has increased from essentially zero in 2009, to millions of barrels a year by 2014.[7] This has raised concerns not only over the greenhouse gas impacts but also over the dangers associated with transporting crude by railroad through our state and our communities. Over that same period, California has become increasingly aware of the extensive use and rapid expansion in high-intensity extraction methods such as hydraulic fracturing (fracking) and acidizing. Furthermore, California is now receiving imports of crude from the Alberta tar sands that are the focus of international opposition due to their tremendous damage to the people, land, waters, and wildlife of Alberta and their immense implications for the global climate.

LCFS 60-2

[6] OPGEE v. 1.1 Lookup Table Inputs, USA-North Dakota.

[7] Energy Almanac by CEC, http://energyalmanac.ca.gov/petroleum/statistics/2014_crude_by_rail.html, and the LCFS, Appendix H: 2014 Mid-Year Crude Average CI Estimate.

In 2014, there were five crudes that were not in the 2010 slate, with a production and transport carbon intensity greater than 15 gCO_2e/MJ, for a total of 61.[8] There are 17 crude sources (i.e. oil fields) in California that surpass this carbon intensity, and five with production and transport carbon intensity values greater than 30 gCO_2e/MJ. While some of these high carbon-intensity crudes are relatively small components of the state's domestic crude supply, this still amounts to hundreds of thousands of barrels per field. For example, Placerita crude has a production and transport carbon intensity of 41.72 gCO_2e/MJ and produced 447,209 barrels in the first six months of 2014.

Other high carbon intensity fields are relatively large components of California's domestic crude supply. Coalinga produced 2.9 million barrels in the first half of 2014, with a carbon intensity of 32.82 gCO_2e/MJ; Cymric, 7.6 million at 21.48; Kern Front, 1.5 million at 29.65; McKittrick, 7.6 million at 28.72; Midway-Sunset, 14.4 million at 29.27; Poso Creek, 1.7 million at 32.09; Round Mountain, 2.1 million at 27.77; San Ardo, 3.5 million at 31.48.[9] All of these crudes have production and transport carbon intensity values greater than 15 gCO_2e/MJ even without accounting for many of the greenhouse gas emissions and energy inputs associated with high-intensity production methods such as fracking, an issue raised in the previous section. LCFS 60-2 cont.

The initial LCFS regulation in 2009 included a "bright line" approach to high carbon-intensity crude oil ("HCICO"), in which HCICOs were treated as a distinct category separate from non-HCICO gasoline and diesel; the carbon intensities of the HCICOs were calculated separately and oil suppliers had to report the associated deficits compared to the baseline. The initial LCFS rule also required refinery-specific accounting of crude slates. This approach would have applied penalties specifically to refineries for crude oils that were above a "bright line" of 15 grams CO2 per mega joule and that were not part of the original 2006 crude oil slate.

When ARB amended the LCFS in 2012, the final regulation eliminated the bright line approach to HCICOs and replaced refinery-specific accounting with a statewide average crude carbon intensity. Although the amended rule did include provisions to require reporting of the carbon intensity of fuels by crude source, the current LCFS and the proposed rule were specifically designed to be "fuel-neutral" with respect to all crudes, including HCICOs.[10] Under this approach, an increase in carbon intensity at one refinery is not assigned to the responsible refinery, but is instead spread across the entire sector statewide, and refineries selling higher-carbon products to California will be debited only if the statewide carbon-intensity of all California refineries and importers increases over time. Such a system dilutes both the incentives for parties refining high-intensity crude to change their crude slates and any incentive

[8] Access Western Blend, Canada; Premium Albian Synthetic, Canada; Hamaca, Venezuela; Burrell, California; and Chico-Martinez, California. 2014 Mid-Year Crude Average CI Estimate.

[9] LCFS, Appendix H: 2014 Mid-Year Crude Average CI Estimate.

[10] "The LCFS is designed to encourage the use of cleaner low-carbon fuels in California, encourage the production of those fuels, and, therefore, reduce GHG emissions. The LCFS is performance-based and fuel-neutral, allowing the market to determine how the carbon intensity of California's transportation fuels will be reduced." ISOR at ES-2.

for refineries that may be maintaining or reducing the carbon-intensity of their crude oil slates to avoid higher-carbon crudes.

We urge the Air Resources Board to consider additional measures to directly discourage the development and production of high carbon-intensity crudes, such as the bright line approach to HCICOs and refinery-specific reporting.

LCFS 60-2 cont.

III. The CA-GREET pathway for cellulosic ethanol from "forest waste" does not account for the carbon impacts associated with generating forest-sourced feedstock.

The CA-GREET "Pathway for Cellulosic Ethanol from Forest Waste" does not account for fuels or energy inputs associated with the forest management activities that generate woody biomass feedstock (e.g. harvest, limbing, piling).[11] The "Forest Waste" pathway apparently considers all forest-sourced feedstock to be "residue" from some existing forest management activity, and the CA-GREET model accounts for inputs and emissions starting at the point of collection of the feedstock material, such as from a slash pile. The Forest Waste pathway also does not account for forest carbon impacts (i.e., loss of forest carbon stores and foregone carbon sequestration) from the harvest activities that generate the residue materials.

There is an obvious, if implicit, assumption that all forest-sourced feedstock is waste from forest management activities that had already occurred or would have otherwise occurred. This assumption is not explicated or supported. The Forest Waste pathway defines forest waste generally as " treetops, branches, small-diameter wood, stumps, leaves, dead wood and even poorly-formed whole trees, as well as undergrowth and low-value [tree] species."[12] This definition includes virtually every forest carbon pool other than soil and the boles of large, commercially-valuable saw timber, and there are no criteria with respect to demonstrating that these feedstock materials are the residue of some otherwise occurring forest management activity, rather than the primary driver for a logging project. LCFS 60-3

If forest projects are planned, in whole or in part, in response to economic incentives created by the LCFS (for example, the availability of a nearby biofuels facility that makes forest projects more economically feasible than they would have been in its absence), the CA-GREET life cycle analysis would need to account for the carbon impacts associated with the forest management and harvest of those biofuels feedstocks. Such a scenario is already occurring in

[11] Detailed California-Modified GREET Pathway for Cellulosic Ethanol from Forest Waste, 2009. Available at http://www.arb.ca.gov/fuels/lcfs/022709lcfs_forestw.pdf

[12] "Forest waste typically refer to those parts of trees unsuitable for sawlogs such as treetops, branches, small-diameter wood, stumps, leaves, dead wood and even poorly-formed whole trees, as well as undergrowth and low-value species. Nearly 20 billion cubic feet of wood is removed on an annual basis from lands in the United States. Of that volume, 16 percent is classified as logging waste, according to U.S. Department of Agriculture (USDA). This material is mainly tree tops and small branches that have been considered uneconomical to harvest. The USDA Forest Service Inventory and Analysis program estimates that in 2001, 61 million dry tons of residuals are available annually from harvesting and fuel reduction activities. A recovery system, which would follow behind a conventional logging operation, could recover 60 percent or 40 million dry tons of this waste for potential bioenergy and bio-based product markets." CA-GREET Pathway for Cellulosic Ethanol from Forest Waste, at 2.

the southeastern United States, where the export of wood pellets to Europe to replace coal for electricity generation and residential heating under the European Commission's climate and energy package doubled in 2013, to 3.2 million metric tons annually.[13] Traditionally manufactured from mill waste, wood pellets can also be produced from unprocessed harvested wood, and may constitute a new and growing demand on forest resources.

Because the CA-GREET model does not include emissions and carbon impacts associated with land use and land use change, a separate methodology (the Detailed Analysis of Indirect Land Use Change, or iLUC) was developed to account for indirect land-use change impacts associated with biofuels.[14] This methodology primarily addresses the carbon impacts associated with the conversion of agricultural land from food crops to biofuel feedstocks, and with the clearing of land to plant agricultural feedstock.[15] With respect to forests, the land-use change component addresses only the potential carbon impacts of forest loss to agricultural development. As a result, it does not consider any forest carbon impacts associated with the generation of forest-sourced feedstock in the Forest Waste pathway or elsewhere. These impacts include but are not limited to reduction in forest carbon stocks and lost future sequestration resulting from harvest of trees that otherwise would have continued growing and sequestering carbon, regardless of whether they are considered "poorly-formed" or "low-value." In short, even if forest remains forest, the increased removal of materials for cellulosic ethanol production may affect both terrestrial carbon stocks and atmospheric CO2 concentrations. A model that considers only change from one type of land use to another will not capture these relevant effects.

LCFS 60-3 cont.

In 2009, the ARB Board directed ARB staff to establish a LCFS Sustainability Workgroup charged with developing criteria for each biofuel feedstock category in order to limit the effects of biofuels on carbon stores, GHG emissions, food supplies, and ecological values. However, the Workgroup has not yet proposed any such standards with respect to forest-sourced biofuels, and the LCFS otherwise contains no guidance specific to forest-sourced feedstocks or biofuels.

---

[13] US Energy Information Administration, "U.S. wood pellet exports double in 2013 in response to growing European demand. May 22, 2014. Available at http://www.eia.gov/todayinenergy/detail.cfm?id=16391

[14] LCFS, Appendix I: Detailed Analysis for Indirect Land Use Change.

[15] "Carbon intensities are calculated under the LCFS on a full life cycle basis. This means that the CI value assigned to each fuel reflects the GHG emissions associated with that fuel's production, transport, storage, and use. The CA-GREET model accounts only for such direct effects. In addition to these direct effects, some fuel production processes generate GHGs indirectly, via intermediate market mechanisms. To date, ARB staff has identified an indirect effect that has a measurable impact on GHG emissions: land use change. A land use change effect occurs when demand for a crop-based biofuel brings non-agricultural lands into production. When new land is converted, such conversions release the carbon sequestered in soils and vegetation. The resulting carbon emissions constitute the "indirect" land use change (iLUC) impact of increased biofuel production. For the LCFS, iLUC emissions are attributable to biofuels produced from crops." ISOR, at ES-5.

We urge ARB to ensure that the energy inputs and forest carbon impacts associated with forest-sourced feedstock are fully accounted for before a CA-GREET pathway for cellulosic ethanol from forest waste, or any other biofuel from forest-sourced feedstock, is certified. In addition, we strongly urge ARB to complete the work of the LCFS Sustainability Workgroup, and to adopt standards specific to forest-sourced feedstocks before certifying any related CA-GREET pathways.

LCFS 60-3 cont.

IV. The EIR Fails to Mitigate the Project's Foreseeable Impacts on Food Availability and Hunger among "the World's Poorest People."

The EIR indicates that increasing demand for biofuels can displace production of food crops in favor of biofuel feedstock crops.[16] The Detailed Analysis for the Indirect Land Use Change states that the economic model used to evaluate land use change impacts indicates that the LCFS will result in higher food prices, with some alarming outcomes.

> The LCFS, together with biofuel production mandates in the U.S. and Europe, will result in the diversion of agricultural land from food production to biofuel feedstock production. This diversion of agricultural land to biofuel production will exert an upward pressure on food commodity prices, and potentially lead to food shortages, increasing food price volatility, and inability of the world's poorest people to purchase adequate quantities of food. GTAP analysis predicts that price increases resulting from the additional demand for biofuels will result in reduced crop production, leading to lower food consumption.[17]

LCFS 60-4

In short, the iLUC analysis predicts that the LCFS can exacerbate hunger and food shortages for "the world's poorest people." The Analysis cites Tenenbaum (2008) for references to these impacts.[18] More recently, a Word Resources Institute working paper by Searchinger and Hemilch (2014) found that "bioenergy that entails the dedicated use of land to grow the energy feedstock will undercut efforts to combat climate change and to achieve a sustainable food future."[19] The working paper concludes that "[p]hasing out the dedicated use of land to generate bioenergy, particularly biofuels, would reduce the food gap and, perhaps even more importantly, keep it from greatly expanding."[20]

---

[16] "As discussed above, as demand for biofuel crops increases, it could displace production of food crops, resulting in conversion of both fallow and cultivated lands to biofuel feedstock crop production." Draft EIR, at 33.

[17] Appendix 1: Detailed Analysis for Indirect Land Use Change, at I-21.

[18] D. J. Tenenbaum , "Food vs. Fuel: Diversion of Crops Could Cause More Hunger.", Environmental Perspectives 116(6): A254-257, (2008).

[19] Searchinger, T. and R. Heimlich. 2015. "Avoiding Bioenergy Competition for Food Crops and Land." Working Paper, Installment 9 of *Creating a Sustainable Food Future*. Washington, DC: World Resources Institute, at 1. Available at http://www.worldresourcesreport.org.

[20] Searchinger and Heimlich (2015), at 28.

Currently, the LCFS includes no mechanism, either as part of the carbon intensity value or elsewhere, to account for these impacts. The Detailed Analysis for Indirect Land Use Change determines that the land use change model is incapable of modeling these impacts, and proposes to address the problem "in future updates."[21] Ultimately, the EIR finds that because ARB has no land use authority, it is not within ARB's authority to mitigate these impacts.[22] LCFS 60-5

Exercising land use authority is not the only possible approach to reducing these impacts, and ARB may not point to its lack of land use authority as a reason for implementing no mitigation measures. That is, an agency may not claim that mitigation is infeasible unless that agency truly lacks any authority to implement any feasible mitigation measures. (*See, generally, City of Marina v. Board of Trustees* (2006) 39 Cal.4th 341.) ARB must instead consider all feasible options to mitigate or avoid any significant land use change effects identified. ARB is designing the program that creates the incentives that are producing the impacts, and is thus responsible under CEQA for analyzing and mitigating those impacts. (*Cf. California Unions for Reliable Energy v. Mojave Desert AQMD* (2009) 178 Cal. App. 4th 1225.) Nor may ARB avoid its responsibility to disclose and analyze these impacts by simply declaring that mitigation is infeasible and the impacts unavoidable. "An agency may not "travel the legally impermissible easy route to CEQA compliance" by making a significance determination without fully analyzing a project's effects. (*Berkeley Keep Jets Over the Bay Comm. v. Bd. of Port Comm'rs* (2001) 91 Cal.App.4th 1344, 1371). LCFS 60-6

Accordingly, ARB is responsible not only for providing all the information it reasonably can about these indirect impacts, but also for considering whether there are any possible changes to the program itself (such as limitations on eligibility of particular feedstocks, eligibility requirements for biofuels, including a provision in the life cycle analysis that accounts for the potential of displacing food crops, or verification and certification requirements) that could change the incentives driving land use change and reduce the associated impacts. We urge ARB to take up every option for addressing this important issue. LCFS 60-7

V. Conclusion

The Center for Biological Diversity strongly supports the LCFS as a crucial tool in addressing the large proportion of California's greenhouse gas emissions and other air pollutants LCFS 60-8

---

[21] Some stakeholders maintain that global changes in food consumption are not a direct consequence of biofuel production and staff should not consider food impacts in the modeling of iLUC while others argue that reductions in food consumption would require an assessment of the calorific content of finished food products in the GTAP-BIO model. The model as currently structured, is not capable of modeling any changes in food consumption driven by calorific content. Staff is therefore, proposing to address this issue in future updates. Appendix 1: Detailed analysis for Indirect Land Use Change, at I-21.

[22] "Potential agricultural and forest resource impacts could be reduced to a less-than-significant level by mitigation measures prescribed by local, State, federal, or other land use or permitting agencies (either in the United States or abroad) with approval authority over the particular development projects. However, because ARB has no land use authority, mitigation is not within its purview to reduce potentially significant impacts to less-than-significant levels." Draft EIR, at 47.

that comes from the production, transport, refining, and combustion of transportation fuels. The Center supports ARB's development of a model to assign values to the carbon impacts of fracking and other carbon intensive enhanced oil recovery methods, and the Center encourages the LCFS Sustainability Workgroup's to develop standards specific to forest-sourced feedstocks. LCFS 60-8 cont.

We urge ARB to strengthen the proposed rule with respect to hydraulic fracturing and forest-sourced biofuels, and to strengthen the EIR's treatment of impacts to food prices and availability. For those issues that may take longer than ARB is currently contemplating for adoption of this rule--such as additional measures to directly discourage the development and production of high carbon-intensity crudes, and mitigating impacts to food prices and availability--we urge ARB to initiate the process of developing these measures, in the resolution adopting the revised LCFS. LCFS 60-9

Thank you for your consideration of these comments. Please contact me with any questions or concerns.

17 February 2015

Clerk of the Board, Air Resources Board
ATTN: Mary Nichols, Chairman
1001 I Street, PO Box 2815
Sacramento, California 95812

Re: Notice of Public Hearing to Consider a Low Carbon Fuel Standard

Dear Chair Nichols and Air Resource Board Members:

Thank you for the opportunity to provide comments to the California Air Resources Board (CARB) regarding its re-adoption of the Low Carbon Fuel Standard (LCFS). Neste Oil US, Inc. respectfully presents the following comments for consideration.

Neste Oil continues its successful strategy of focusing on the production of cleaner traffic fuels and has a long history in providing clean fuels to California that have been refined from traditional petroleum products. Consistent with our vision to be the preferred partner for cleaner traffic fuel solutions, Neste Oil has expanded into the production of transportation fuels from renewable feedstocks and is now the leader and largest producer world-wide of renewable hydrocarbon diesel produced at locations in Porvoo, Finland; Singapore; and Rotterdam, The Netherlands. Neste Oil uses a wide variety of sustainably produced vegetable oil feedstocks including soybean oil, palm oil, rapeseed oil, camelina oil, and various biogenic waste oils and residues including animal tallow, technical corn oil, and other triglyceride oils and free fatty acids usually produced as wastes or residues from various industrial processes.

Neste Oil's renewable hydrocarbon diesel (NEXBTL) meets the ASTM D975 specification for diesel fuel; qualifies as CARB diesel; and is a fully fungible, drop-in fuel that can be used in existing diesel engines without a blend wall and which can utilize existing infrastructure. This renewable hydrocarbon diesel has significantly lower carbon intensity as compared to petroleum diesel and is almost free from aromatics and sulfur, whilst reducing NOx, particulate, and hydrocarbon tailpipe emissions.

Neste Oil supports California's commitment to reducing the greenhouse gas emissions associated with transportation fuel and has incorporated this demand for low-carbon fuels into our business plans. Specifically, Neste Oil has delivered, and plans to continue to deliver, commercial volumes of renewable hydrocarbon diesel (NEXBTL), which qualifies as a low carbon fuel, to numerous customers in California.

Stable Program Necessary to Support Capital Investments LCFS 60-1

LFCS 61-1

Neste Oil, along with many other low-carbon fuel producers, have made significant capital investments in response to the LCFS implementing a demand for renewable or low-carbon transportation fuels. Changing the course or significantly altering the goals of the program at this late stage will have a severe chilling effect on any future potential investments as participants, investors, and capital markets will lose confidence in California's commitment to follow through with its policy goals. Accordingly, re-adoption of a stable LCFS is a necessary next step to fulfil the commitment California made to those producers, to support those investments, and realize true change in the air quality resulting from California's

Neste Oil – Houston

1800 West Loop South, Suite 1700
Houston, Texas 77027
Tel. 713.407.4400 Telefax. 713.407.4480

transportation fuels. Implementation of a stable Low Carbon Fuel Standard in California will send the proper signals to fuel producers like Neste Oil and will provide a significant driver to draw low-carbon fuels to the State in adequate volumes to comply with the target of 10% carbon intensity reduction by 2020.

In addition to stabilization, ARB should use the re-adoption as a springboard to begin to formulate and implement longer-term targets. Producers cannot recoup large capital investments in a short economic cycle. To further support the investments and growth in the production of low-carbon fuels, the market will require signals that the program will remain effective and robust beyond the 2020 timeframe currently at issue. LFCS 61-1 cont.

Proper Implementation is Key to Success

Opponents of the re-adoption efforts may cite concerns about a potential future lack of credit availability. Neste Oil has confidence that a properly implemented Low Carbon Fuel Standard would stabilize the economic drivers and would be an adequate market signal driving continued volumes of low-carbon fuels to California.

Accordingly, proper implementation of the program – both during the re-adoption transition and under the new program – is paramount to the success LCFS. Neste Oil sees staff's inability to timely process and approve otherwise complete pathway applications as an obstacle to additional volumes of low-carbon fuels to be available for consumption in California.

The simple economic model shows that fuels with a lower carbon intensity yield a higher return. However, absent the confirmed CI determination, a producer might reduce fuel production or instead send the fuel to more economical markets outside of California. The removal of those otherwise credit-generating fuels from the California transportation fuel pool could create a shortage – not because of the failure of the market or program design, but as a failure of implementation. LFCS 61-2

With the addition of more approved low-carbon pathways, Neste Oil hopes to significantly increase the volume of low-carbon renewable diesel that it will deliver to its California customers. Neste Oil proposes that the ARB direct staff to implement more robust procedures to ensure that fuel producers are not limited from participation in the California market because of gaps in staff resources.

As a supplement to the pathway application processes proposed, Neste Oil reiterates its recommendation that CARB authorize third-party verifiers, who are unrelated to the applicant, to perform due diligence on the proposed pathway and verify the CI modeling and calculations. The role of CARB staff would then be focused on oversight and verification of Method 1 pathway applications and Tier 1 pathway applications, leaving Tier 2 for more specific staff review, if desired. This methodology is in place in jurisdictions of British Columbia, Alberta, and Ontario and is functioning well. Additionally, the European Union's Renewable Energy Directive (RED) similarly allows producers to calculate actual production values and then be confirmed by an independent third-party verifier.

ILUC Considerations

As a part of the re-adoption proposal, staff has included the use of indirect land use change (ILUC) values for crop-based feedstocks. Staff have made considerable efforts to update the indirect ILUC values of corn ethanol and sugarcane ethanol as well as soy biodiesel, revising these values for all of LFCS 61-3 these pathways downward by 10 to 30 g CO_2/MJ points. These revisions are a result of robust scientific review and stakeholder engagement. However not all of the proposed ILUC values for crop-based fuels have completed the same degree of review to provide adequate confidence. Neste Oil expresses concern regarding some the methodologies used and submits a more detailed analysis and more specific recommendations in the enclosed Attachment A. We look forward to working the staff to refine the ILUC component of the program and modifying the proposal to provide a better result of the indirect land use effects associated with the ever-evolving fuels market. LFCS 61-3 cont.

Renewable Hydrocarbon Diesel Definition

As part of ARB's efforts in the re-adoption of the LCFS regulations, staff identified renewable hydrocarbon diesel as a potential low carbon fuel. The proposed regulation properly describes renewable hydrocarbon diesel as an alternative fuel subject to the LCFS regulations and a biomass-based diesel fuel made from biogenic feedstock sources.

Unfortunately, the proposed definition is less accurate than necessary to describe the various types of fuel available on the market. The proposed LCFS regulation uses the term "renewable diesel". [Of note, staff in the Transportation Fuels Branch have proposed an alternative term and definition for the same product as a part of the Alternative Diesel Fuel Regulation that uses the term "non-ester renewable diesel". At a minimum, we would encourage all programs under ARB to have unified definitions.] While that was a term used in the early commercialization of the fuel, it is not the most accurate term given the wide variety of fuels and different uses of the term. Specifically, some jurisdictions (like Ontario, Canada) use the term "renewable diesel" broadly to include both oxygenated biofuels (fatty acid methyl ester biodiesels or "FAME") along with fungible renewable hydrocarbon diesel (RHD).

Confusion may exist in the market regarding fuels that are not fungible with conventional diesel and are not fully de-oxygenated but are nonetheless called "renewable diesel". As such, that term is not ideal for use by the ARB in its regulations. The commonly understood product available in California and described in the ISOR and proposed regulations is a hydrocarbon oil. The definition should reflect that fuel as accurately as possible. LFCS 61-4

We propose that the term "renewable diesel" be replaced with the term "renewable <u>hydrocarbon</u> diesel" (including references in the definition of "biomass-based diesel" and in section 95486(b)(1) [energy density table]). We further propose that staff consult with the Oil and Gas and GHG Mitigation Branch and with the Department of Measurement Standards to align the nomenclature ("renewable <u>hydrocarbon</u> diesel") within the various regulations that touch and regulate this fuel.

In order to further align the LCFS definition with those in the Proposed ADF Regulations and the LCFS definition of "biomass-based diesel", we propose including language indicating that the fuel is intended for use in a compression ignition engine and that it must comply with ASTM D975-14a (2014). A uniform definition throughout the various ARB regulations will help reinforce a consistent nomenclature and description, accurately describe the fuel with adequate specificity, as well as avoid unnecessary confusion within the agency.

The proposes definition uses "derived from nonpetroleum renewable resources" as descriptive language. This is less useful for the regulations purposes in that is uses the word 'renewable' in the definition of 'renewable diesel' (potentially sloppy drafting), and attempts to define the fuel using a negative by what it is <u>NOT</u> rather than what it <u>IS</u>. A clearer definition would include the phrase "derived from biomass." This is further supported by the fact that the term "biomass" (which is defined in the LCFS regulation) would be clear and adequate.

Accordingly, we propose the following definition (to be used in both ADF and LCFS regulation):

LFCS 61-4 cont.

"Renewable Hydrocarbon Diesel" means:

a) a hydrocarbon oil meant for combustion in compression ignition engines;
b) derived from biomass;
c) not a mono-alkyl ester;
d) registered as a motor vehicle fuel or fuel additive under 40 CFR part 79; and
e) complies with ASTM D975-14a, (2014) *Specification for Diesel Fuel Oils*

CONCLUSION

Neste Oil appreciates the opportunity to comment on the re-adoption proposals. Like California, Neste Oil is proud of its continued leadership in producing clean transportation fuel. While no one producer or type of low-carbon fuel will be able to satisfy the State's carbon reduction and air quality improvement goals in the near term, Neste Oil believes its efforts, along with others like it, can contribute to the continued success of the Low Carbon Fuel Standard.

We look forward to continued participation in the California fuel market and the continued success of the Low Carbon Fuel Standard. Please do not hesitate to contact me if at 713.407.4415 or Dayne.Delahoussaye@nesteoil.com if you have any questions regarding the foregoing.

Respectfully submitted,

NESTE OIL US, INC.

Dayne Delahoussaye

61_OP_LCFS_NESTE Responses

605. Comment: **LCFS 61-1**

The comment states that re-adoption of the LCFS program is needed to fulfil the commitment California made to producers and realize true change in air quality. The comment also states that re-adoption should be used as a springboard to formulate longer-term target goals.

Agency Response: See response to **LCFS 5-2**.

606. Comment: **LCFS 61-2**

The comment expresses concern that untimely processing fuel pathway applications will limit producers' participation in the California market. The comment suggests the use of third-party verifiers to help accommodate the excess workload.

Agency Response: ARB does not agree that implementation cannot succeed without formally adding third-party verification to speed pathway reviews. Prior to the re-adoption effort, ARB staff was able to process full pathway applications in a timely manner. With the diversion of existing staff resources to the re-adoption effort, pathway application processing times increased significantly. If the Board approves the proposed regulation, ARB staff will need to simultaneously process new pathway applications and re-certify existing applications. ARB will devote the necessary resources to these vital functions. Moreover, without changing the LCFS proposal, ARB can develop an improved internal process, in some cases involving a verification step, similar to that proposed by the commenter.

607. Comment: **LCFS 61-3**

The comment states that some of the proposed iLUC values for crop-based fuels have undergone insufficient review.

Agency Response: The update of the iLUC analysis has been a rigorous and transparent process. The scenario runs use the same parameter values and modeling methodology for all six biofuels assigned an iLUC value. All of the iLUC values being proposed to the Board are a result of ARB staff using the latest science and best data available to estimate iLUC values for all six biofuels using a consistent methodology.

See also responses to **LCFS 8-1**.

608. Comment: **LCFS 61-4**

The comment states that the definition for renewable hydrocarbon diesel does not cover all the types that are available on the market. The commenter suggests new definitions.

Agency Response: ARB staff agrees that it is important to have a uniform definition throughout the various ARB regulations to avoid unnecessary confusion. However, different regulations can have different purposes and as such it is sometimes necessary to have definitions which are specific to a regulation. Staff made every effort to make definitions consistent to avoid confusion as long as it did not compromise the intent of each specific regulation.

Staff has responded to the comment by modifying and clarifying the regulation as part of the 15-day changes. Staff replaced the term "*non-ester renewable*" with the term "*renewable hydrocarbon diesel"*.

Katrina Sideco
(916) 323-1082
ksideco@arb.ca.gov

Reference: **Comments on the Treatment of Nitrogen Fixation in Soybeans**

Dear Ms. Sideco,

Life Cycle Associates would like to take this opportunity to provide comments and insight to the recently released California GREET2.0 model. The comments herein address the analysis and treatment of N_2O emissions from soybean farming and time impacts on biofuel pathways. These comments are a continuation of comments submitted on 10/28/2014 addressing the same issue, which has not been addressed in the new release. CA_GREET2.0 estimates the releases of N_2O due to fertilizer application, crop residue, volatilization, and the secondary effects from leaching as per the IPCC methods. GREET does not include emissions from nitrogen fixation in legumes. The emissions from the nitrogen fixed in the plants are a major contributor to lifecycle greenhouse gas emissions from soybeans, which affects soy bio- and renewable diesel pathways as well as co-product credits for other pathways. Table 1 shows the impacts of addressing N_2O fixation on the CA_GREET2.0 soy biodiesel and corn ethanol fuel pathways. The effect of the N fixation on the corn ethanol pathway is due to the higher DGS co-product credit obtained for displacing the higher emissions soybean meal animal feed.

Table 1. N_2O fixation Impact on corn ethanol and soy biodiesel fuel pathways.

	GHG Emissions (g CO_2e/MJ_{Fuel})	
Model	**Soy Biodiesel**	**Corn Ethanol**
CA_GREET2.0	1.6	18.3
CA_GREET2.0, N Fixation	6.8	15.3
Difference in Pathway	**5.2**	**-3.0**

LCFS 62-1

GHG Impacts of Nitrogen Fixation in Legumes

The emissions from soybean production have been examined in many fuel LCA models and the latest research from the JRC's GNOC model as well as other studies shows that the emissions from nitrogen fixation are significant. The effect is well described by Venkat, 2010:

> "IPCC (2006) does not include biological nitrogen fixation as a direct source of N_2O, instead relying solely on the nitrogen inputs from crop residues (above and below ground) to account for all legume N_2O emissions. The problem with this is that the IPCC crop residue model does not seem to capture the magnitude of N_2O emissions in the late-growth stages of soybeans (this is the one crop that I have looked at in detail; others may have a similar problem). There is in fact almost an order of magnitude difference between the worst-case (high) N_2O emissions from crop residue and the conservative (low) N_2O emissions in the late-growth stages (crop residue emissions are smaller by a factor of 5 to 10)."

These comments address the N_2O release from soybean farming in GREET and CA_GREET2.0 and compare the results to the EPA RIA analysis, the EU GNOC (Global Nitrous Oxide Calculator) and the 2013 JRC WTT report. Results from these studies suggest that the GREET inputs underestimate the N_2O emissions from soybean production, which affects soy biodiesel, renewable diesel, and corn ethanol pathways with soy displacing corn. Figure 1 shows the N_2O

Stefan Unnasch
1. 650.461.9048 direct

Portola Valley, CA 94028 USA

contribution to the total GHG emissions of the finished fuel produced, based on data from GREET and the various leading studies addressed in these comments.

ARB should evaluate these studies and re-examine the GREET methodology and values to ensure that the treatment of corn and soy is commensurate to the N_2O emissions generated.

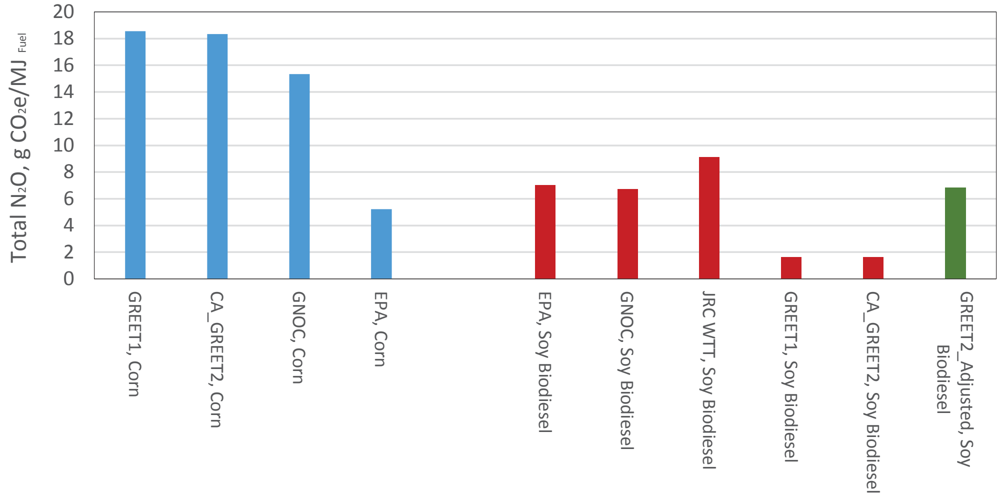

Figure 1. N_2O contribution to GHG emissions from corn and soy crops.
[a] Emissions are calculated from GREET data and data in the EU and EPA studies, crop yields are based on 2014 NASS data for corn and soy.

LCFS 62-1 cont.

EPA RIA N_2O Emissions Analysis

The EPA evaluated the nitrous oxide emissions for soy and corn biomass as part of the RIA analysis (EPA, 2013). Figure 2 shows the N_2O emissions from bioenergy crops in the U.S as presented in the EPA RIA. The N_2O emissions attributed to the crop residue and leaching from soy and corn bioenergy crops account for approximately 40% and 25% of the total N_2O emissions.

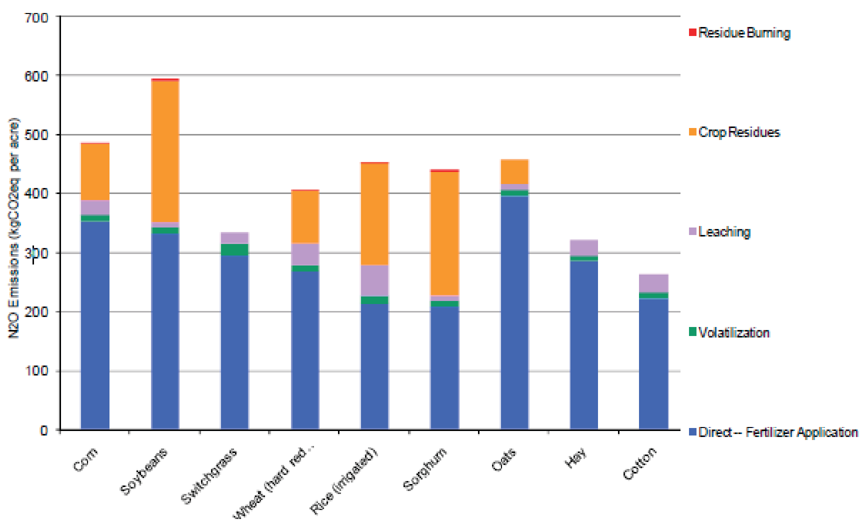

Figure 2. EPA RIA N_2O emissions form bioenergy crops

Stefan Unnasch
1. 650.461.9048 direct
1.484.313.9504 facsímile
unnasch@LifeCycleAssociates.com

Portola Valley, CA 94028 USA

Table 2 shows the N_2O emissions from the biomass fixation and leaching and also the contribution of these emissions to the total GHG emissions of the finished fuel produced, based on the EPA RIA. NASS average crop yields for 2014 is assumed for calculation of the total N_2O emissions (kg/ha).

Table 2. EPA RIA Nitrous Oxide Emissions from Soybean and Corn Farming

EPA RIA Result	Corn	Soybean
Fertilizer and Leaching	2.98	2.82
Crop Residue	0.83	19.9
Total N_2O, g/bu	3.81	22.7
Total N_2O, kg/ha*	1.8	2.2
g CO_2e/MJ_{Fuel}	**5.2**	**7.0**

*NASS 2014 Average crop yield assumed for conversion to kg/ha.

JRC GNOC N_2O Emissions Analysis

The European JRC GNOC (Global Nitrous Oxide Calculator) (Köble, 2014) calculates N_2O emissions based on the 2006 IPCC guidelines (Eggleston, 2006) combining TIER1 and TIER2. The IPCC guidelines distinguishes different pathways (direct, indirect) and different nitrogen sources (e.g. mineral fertilizer, manure, crop residues, and drained organic soils). For the indirect pathways (leaching/runoff and volatilization) the GNOC follows the IPCC TIER1 approach for all nitrogen sources. The same holds for direct emissions from crop residues and drained organic soils.

Table 3 shows the GNOC and the JRC WTT study (CONCAWE, 2013) N_2O emissions from soy and corn farming and also the contribution of these emissions to the total GHG emissions of the finished fuel produced.

LCFS 62-1 cont.

Table 3. JRC GNOC Nitrous Oxide Emissions from Soybean and Corn Farming

N_2O result	GNOC, Corn	GNOC, Soybean	JRC WTT
Region	Iowa	Iowa	EU
Crop	Corn	Soybean	Soybean
Crop Yield, kg/ha	23,827	5,291	--
Chemical N, kg/ha	198	3.05	--
Manure N, kg N/ha	0	0	--
Total N_2O, g/bu	9.16	21.57	29.53
Total N_2O, kg/ha	4.36	2.13	2.92
g CO_2e/MJ_{Fuel}	12.6	6.7	9.1

GREET N_2O Emissions Analysis

Table 4 shows the GREET N_2O emissions from soybean and corn farming and the contribution of these emissions to the total GHG emissions of the finished fuel produced. Table 4 also shows the GREET2 soybean results if a constant for N fixation in the biomass consistent with the GNOC results was applied. A constant for the corn analysis can also be applied (not shown here).

GREET does not include biological nitrogen fixation as a direct source of N_2O, instead relying on the nitrogen inputs from crop residues to account for total N_2O emissions. As previously stated by Venkat, 2010, this analysis does not accurately capture the magnitude of N_2O emissions in the late-growth stages of soybeans. The omission of nitrogen fixation leads to a misrepresentation of

62_OP_LCFS_LCA Responses

609. Comment: **LCFS 62-1**

The comment claims that the soil N2O emission factor for soy-based fuels should account for biological nitrogen fixation (BNF).

Agency Response: ARB staff relies on Intergovernmental Panel on Climate Change (IPCC) 2006 GHG Inventory Guidelines to determine Soil N_2O emissions. IPCC specifically reviewed biological nitrogen fixation (BNF) and excluded it as a contributor to N_2O emissions. N_2O emissions from soybeans are accounted for based on the nitrogen content of the residual biomass and the quantity of nitrogen fertilizer applied, using IPCC 2006 Tier 1 default emission factors. Staff recognizes soil N_2O emissions as an evolving and uncertain area of science, and will continue to review emerging studies and monitor progress on this topic.

February 10, 2015

Introduction and Summary

This analysis supports the Comments of Neste Oil concerning the ARB ISOR posted Dec. 30, 2014 and specifically the document Appendix I: Detailed Analysis for Indirect Land Use Change which can be found here: http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15appi.pdf

Neste believes that in many key areas, ARB staff have employed extremely conservative data and analytical approaches that collectively produce a substantial overestimation of the ILUC effect of fuels derived from palm oil.

List of Comments

1. CI comparison. The CI savings of future biofuels is the sum of the direct and indirect emissions compared to the emissions of the appropriate fossil fuel counterpart. This implies that a similar analysis for the fossil fuel counterpart including both the direct and indirect emissions produced in the same period as the biofuel should be conducted. Comparing the emissions for a biofuel produced in the future to that of the fossil fuel counterpart produced today is not valid. The comparison should be for the marginal or new fossil fuel production. The mix of crudes used in refineries is changing and the value for a future "average crude" should be estimated in a similar manner to that of a "future feedstock" for biofuel production. LCFS 63-1

Proposed improvement: That ARB model future marginal oil production and use the fossil fuel counterpart result as the CI comparator for future biofuels.

2. Additional indirect effects. The ISOR states that ARB staff have only identified one indirect effect that has a measurable impact on GHG emissions (Appendix I, paragraph 1, line 8). This statement illustrates the authors have not fully appreciated all of the effects of the biofuels' industry requirement for a GHG reduction in the agricultural as well as other sectors. Other indirect effects as a direct consequence of the biofuel industry are taking place already today. One very clear and important example of this is the indirect effect concerning biogas (methane) capture and avoidance outside of / in addition to what is happening within the biofuel industry. LCFS 63-2

Methane is a powerful greenhouse gas and significant amounts are released during the milling of oil palm fresh fruit bunches into crude palm oil. The capture and use of this biogas is a direct consequence of the biofuels' GHG reduction requirements. As such, when the methane is captured and used, this CI effect is attributed to the oil palm pathway as a direct effect. But in addition to this biofuel sector methane captue, the GHG reduction mechanism is spreading to the agro and oleochemicals sector. GHG reduction is not a requirement in the food or oleochemicals sectors. That the current economic models have failed to capture this effect clearly illustrates an area which should be explored further. (See Annex I for a further description.) LCFS 63-2 cont.

Proposed improvement: ARB model the GHG reduction effects of methane capture in oil palm mills outside of the biofuel sector and include these in the oil palm GHG net emissions reduction calculation

3. Over-simplification of ILUC analysis. ARB staff state:

> *A land use change effect is initially triggered when an increase in demand for a crop-based biofuel begins to drive up prices for the necessary feedstock crop. This price increase causes farmers to devote a larger proportion of their cultivated acreage to that feedstock crop.*

There is in fact a wide range of options and alternatives to farmers and their decisions are much more complex than this simple analysis implies. One of the major considerations is soil suitability as well as weather and climate issues. In addition, farmers consider the cost for additional fertilizers and of switching to new plant varieties etc.

LCFS 63-3

Concerning biofuels and the effect of increased demand on feedstock prices, the facts do not at all coincide with the model. Vegetable oil prices have been decreasing as biofuel volumes have been ramped up. See for example: http://www.nesteoil.com/default.asp?path=1,41,538,2035,14053

There is thus a correlation between biofuel production and decreasing of vegetable oil prices. This should then trigger, by the ARB staff's logic above, that land is taken out of production and by doing this, the biofuels have in fact caused carbon sequestration.

Obviously, there are a number of other factors which come into play when farmers expand or reduce production and it is an over-simplification to focus on commodity prices.

Proposed improvement: ARB continue to work with GTAP modelers in order to validate and calibrate the model to better reflect current reality

4. Peat emissions. On attachment 2-25 of Appendix I, it states:

> *the most robust current estimate of peat CO_2 emissions is 86 Mg CO_{2e} ha^{-1} y^{-1} assuming 50-year annualization; annualized over 30 years, the value is 95 Mg CO_{2e} ha^{-1} y^{-1}. We adopt this 30-year value in AEZ-EF.*

The basis upon which this value has been derived is from a series of papers by Page et al. (*see* list of references at bottom of the page 2-25). That this value is robust is highly questionable. There is in fact a large body of literature and full agreement that the long term emissions from drained peat forest are in the 60 to 70 t CO_2 / hectare / year depending on depth of drainage and peat type. The rule of thumb is that emissions are 1 ton CO2 for each centimeter of drainage with drainage levels of 60 to 70 cm. The depth of peat drainage here is the key issue as a more shallow drain exposes less peat to the air and thus less oxidation (references to this effect can be supplied later). Staff analysis correctly states that of the two techniques used for determining peat loss, that the direct gas flux measurements is subject to difficulties in factoring out respiration of roots but neglects to acknowledge that the subsidence method has major uncertainties with the extent of peat oxidation in the first few years. Page et al repeatedly state that a high subsidence of 75 cm occurs in the first year and that by peat density measurements they attribute a high-level oxidation to occur during this period and further that: LCFS 63-4

> *Bulk density profiles indicate that consolidation contributes only 7 % to total subsidence, in the first year after drainage, and that the role of compaction is also reduced quickly and becomes negligible fter 5 years. Over 18 years after drainage, 92 % of cumulative subsidence was caused by peat oxidation[1].*

This assumption on high levels of oxidation during the first year then increases the time averaged emissions from the lower commonly accepted values of 60 to 70 t CO_2 / hectare / year to the value adopted in the analysis of 95 t CO_2 / hectare / year. Running the GTAP-BIO model with this lower value has a significant effect on the final results.

The only evidence that Page present for the high oxidation rates are the differences in peat density. They do not seem to be aware that during plantation establishment, a deep drain occurs and soil compaction is carried out in order to provide a good base for the palm trees. Obvious examples can

[1] REVIEW OF PEAT SURFACE GREENHOUSE GAS EMISSIONS FROM OIL PALM PLANTATIONS IN SOUTHEAST ASIA Page, S. E., Morrison, R., Malins, C., Hooijer, A., Rieley, J. O. & Jauhiainen, J. www.theicct.org White Paper Number 15 | September 2011

be seen in the region where this practice is not carried out to a sufficiently high degree where palm trees lean over.

LCFS 63-4 cont.

Proposed improvement: ARB use the IPCC value in the model of 73 Mg CO2/hr/yr for peat emissions and solicit expert opinions on the percentage of oxidation during the initial subsidence.

5. Expansion onto peat. ARB states that of the oil palm expansion in Malaysia and Indonesia that one-third (33%) of oil palm expansion in Mala_Indo occurs on peatland (Edwards, Mulligan et al. 2010, Appendix III). It is interesting that ARB has not been able to find a more recent reference. It is highly questionable that the situation concerning expansion has not changed in the past 6 years as the reference to Edwards uses data from 2009. The analysis on expansion by Edwards is given in Appendix III of staff's report. For Malaysia, they state:

> *Tropical Peat Research Institute [TPRI 2009] (quoted in "Status of Peatlands in Malaysia" July 2009 report by Wetland International), displayed a conference poster showing that that the area of oil palm on peatlands in Malaysia increased by roughly 200 kha between 2003 and 2008. The Malaysian Palm Oil Board report that the total area of oil palm in Malaysia increased by roughly 600 kha in the same period. So according to this source, roughly* ***one third*** *of those new plantations are on peat.*

LCFS 63-5

So, for Malaysia, we see that the basis for the data was a conference poster from 2009. Neste Oil strongly suggests that due to the importance of this issue in the ARB ILUC analysis, staff use more than mere conference posters as the source of the basis of the analysis.

With respect to Indonesia, Edwards used the following source:

> *In Indonesia, palm oil is mostly grown in Sumatra, and some in Papua. [Hooijer 2006] superimposed maps of concessions granted for palm oil plantations in these areas, on maps of peatland (table 4 in [Hooijer 2006]), and found that 25% of concessions were on peatland.*
>
> *[Hooijer 2006] argues that the % oil-palm on peat is likely to rise in future, and estimates that probably more than 50% of future palm oil plantations will be on peat.*
>
> ***Conclusion: at least 33% of new plantations in Indonesia and Malaysia are likely to be on peat.***

In this case, a much older reference was used. We understand that Hoojier, who is a peat scientist and is very concerned about peat conversion to estates and the emissions that occur, is not an expert on estate expansion in the region.

In fact other authors reached different conclusions: ***Spatial Modeling of Future Oil Palm Expansion in Indonesia, 2000 to 2022*** *Nancy Harris, Sean Grimland and Timothy Pearson;* Report submitted to EPA July 2011

> *3.4.2 Expansion by Soil Type*
>
> *The area of predicted palm oil expansion between 2000 and 2022 per soil type is important primarily for determining how much expansion occurs on histosols. In both the FAO soil classification and the USA soil taxonomy, a histosol is an organic soil with an organic carbon content by weight of 12 percent or more. Histosols are sometimes referred to as organosols. When palm oil is cultivated on a histosolic soil, the water must be drained as part of site preparation activities and results in significant GHG emissions. Approximately 9% (531,366 ha) of palm oil expansion are predicted to occur in histosol soils with an additional 4,894 ha in the palm only model.*

LCFS 63-5 cont.

The following table illustrates the value that EPA used in their analysis based on a detailed investigation of soil types and land suitability etc.

TABLE II–6—PERCENT OF PALM OIL PLANTATIONS ON PEAT SOIL, HISTORICAL AND PROJECTED

Year	Indonesia %	Malaysia %
2009 (Historical) ...	22	13
2022 (Projected) ...	15	10
2022 (Projected Incremental Expansion)	13	9

RSPO commissioned the following report, which is on the TROPENBOS website: **HISTORICAL CO2 EMISSIONS FROM LAND USE AND LAND USE CHANGE FROM THE OIL PALM INDUSTRY IN INDONESIA, MALAYSIA AND PAPUA NEW GUINEA**[2]

Table 2. Oil palm development in Indonesia and Malaysia on peatland and mineral soils (million hectares).

Country, soil	1990	2000	2005	2010
Indonesia	1.34	3.68	5.16	7.72
Peat	0.27	0.72	1.05	1.70
Mineral	1.07	2.95	4.10	6.02
Malaysia	2.08	3.53	4.59	5.38
Peat	0.15	0.28	0.40	0.72
Mineral	1.93	3.25	4.19	4.66

LCFS 63-5 cont.

Proposed improvement: That ARB use a value in the range 15- 20% expansion onto peat OR alternatively perform a more detailed analysis of the current situation.

6. GTAP-BIO model constraints In the analysis on palm oil, the model has been constrained assuming that all future palm oil would be coming from Malaysia and Indonesia. Neste Oil disagrees with this approach and feels that the constrain is not warranted.

For example, 1.5 million hectares of land have been approved for palm oil development in Liberia, Cameroon and Gabon alone.[3]

LCFS 63-6

[2] http://www.tropenbos.org/publications/historical+co2+emissions+from+land+use+and+land+use+change+from+the+oil+palm+industry+in+indonesia,+malaysia+and+papua+new+guinea

[3] http://www.sustainablepalmoil.org/palm-oil-by-region/africa/#sthash.Q0jnJsao.dpuf

In early 2011, Ghana was the first country in Africa to have its National Interpretation (NI) of the Roundtable on Sustainable Palm Oil (RSPO) Principles and Criteria for sustainable palm oil approved. Ghana has 336,000 hectares planted with oil palm; it is a net importer to meet its demands for palm oil.

Proposed improvement: Neste Oil therefore feels that the constraint of all future palm oil coming from Malaysia and Indonesia is not valid.

LCFS 63-6 cont.

7. AEZEF model YieldTable sheet. All references to palmf have a value of 0. Neste Oil cannot understand what staff have used in the model for the accumulated time averaged biomass for oil palm plantations.

Proposed improvement: Include values for the dry fraction, AGB C- factor etc. for palm trees.

LCFS 63-7

8. AEZEF model forest types for Mala_Indo ARB uses the following forest types for the region

4	Tropical	Sub-humid	Tropical-Sub-humid
5	Tropical	Humid	Tropical-Humid
6	Tropical	Humid (year round)	Tropical-Humid (year round)

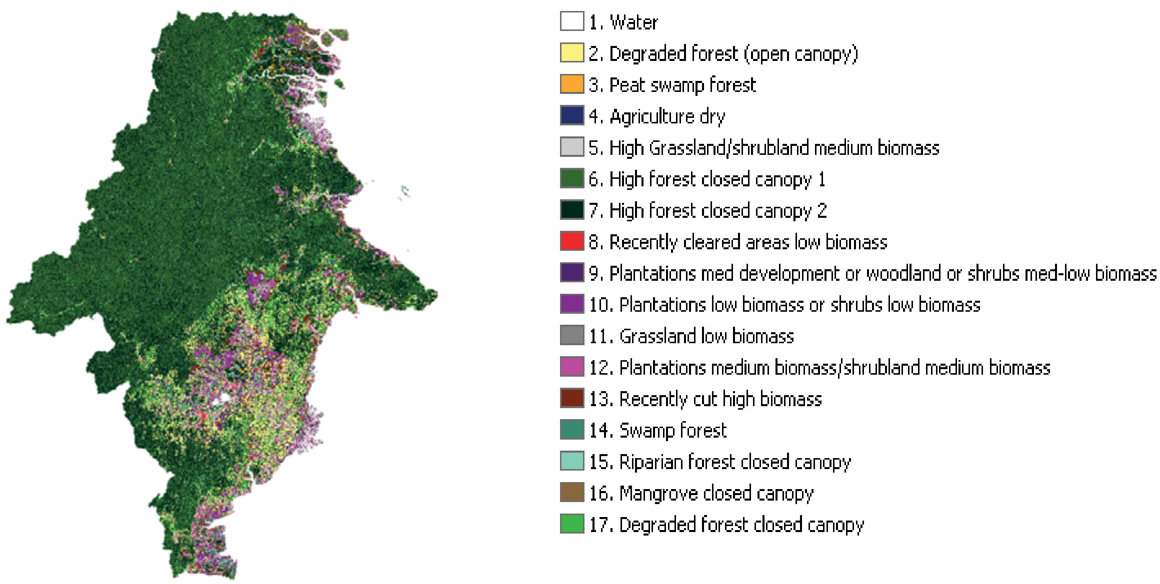
It is unclear from this analysis what classification degraded forests or logged over forests would be given. For example the below map for North-East Kalimantan indicates land cover types. A very large part of the region is covered by degraded forest.

LCFS 63-8

Steven Gust 10 February 2015

Also see this reference for land types:

http://www.isric.org/isric/webdocs/docs/ISRIC_Report_2007_01_web.pdf



LCFS 63-8 cont.

Large areas of grassland and scrub land have also been converted for plantations, especially in Kalimantan. These areas were typically once forested but gave way to scrub and grassland after the large-scale el Niño fires in 1982-1983 and 1997-1998.

According to an article in Geoderma 149 (2009) 76–83*:*

> *… in Indonesia, forests are under increasing pressure of population growth, illegal logging, forest fire, and land use change for agriculture, transmigration and estate crops such as timber and oil palm.*
>
> *Imperata grasslands in Indonesia cover 8.5 million ha, or about 4.5% of Indonesia's total land area. In Kalimantan alone, Imperata grasslands cover an estimated 2.2 million ha (Garrity et al., 1997). Imperata grasslands are seen as a final stage of land degradation and are very difficult recover for more valuable land uses (Murniati, 2002). Regeneration*

of grassland areas is becoming increasingly important, not only to create new secondary forest, but also to recover the original biodiversity. LCFS 63-8 cont.

Conclusions from Neste Oil Analysis

Based on the above comments we suggest that ARB use a 20% peat conversion estimate for the new oil palm estates with a 73 Mg CO2/hr/yr for peat emissions. According to our knowledge, this would produce a value of around 33.6 g CO_2/MJ_{fuel}

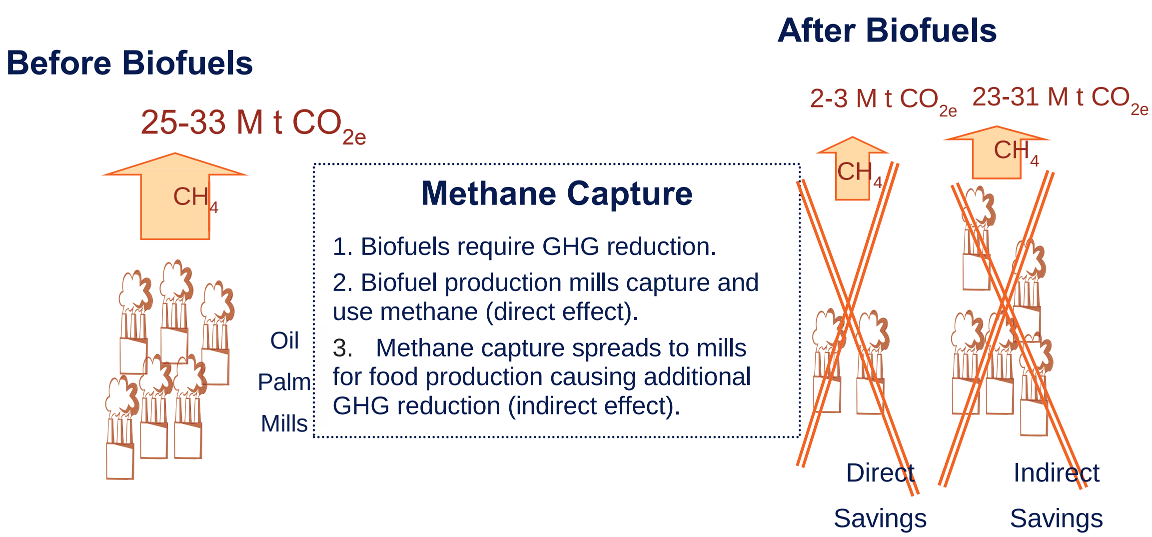
iLUC Emissions for Alternative Scenarios	
Scenario	iLUC, gCO2/MJ
CARB Scenario 8	65.2
20% peat conversion estimate	42.0
73 Mg CO2/hr/yr for peat emissions	51.4
20% peat and 73 Mg CO2/ha/a	33.6

LCFS 63-9

*****

Annex I

At palm oil mills, the GHG reduction strategy with the largest and most immediate beneficial effect is methane capture and utilization. This has long been recognized as a major GHG source in the oil palm pathway but only recently, has there been much progress. There are approximately 1000 palm oil mills in Malaysia and Indonesia. These mills are self-sufficient in energy, using the fiber and shell from the palm oil fruit to produce the electricity and process steam they require. The process generates a wastewater known as POME (palm oil mill effluent), which contains about 5 percent organic materials. For most mills, approximately 3 tons of POME are generated per ton of crude palm oil (CPO). POME is fed into a series of cooling ponds and digestion ponds where the organic material is digested, producing biogas (a 50:50 mixture of methane and carbon dioxide). The digestion proceeds until the discharged water achieves a sufficiently low biological and chemical oxygen demand.



NESTE OIL

Steven Gust 10 February 2015

An example of the indirect savings is:

In the milling process, there is on average 3 $\pm$ 0.2 tons of POME per ton of crude palm oil. Each ton of POME generates 28 cubic meters (varies from 25 to 45) of biogas or about 14-16 cubic meters of methane 14-16 m^3 CH4 x 0.7 kg CH_4 /m^3 = 10 - 11 kg CH_4/t POME. At an CPO yield of 3.7- 4 t CPO/ha x 3 $\pm$ 0.2 t POME/ t CPO x 10-11 kg CH_4/t POME = 110 – 140 kg CH_4/ha. Using a greenhouse gas factor of 21 for methane this becomes 2.3 - 3 t CO_{2e}/ha. In Malaysia and Indonesia there are roughly 11 M ha of mature or producing hectares or 25 -33 M t CO_{2e}.

63_OP_LCFS_NESTE Responses

610. Comment: **LCFS 63-1**

The comment contends that future marginal oil production should use the fossil fuel counterpart result as the CI comparator for future biofuels.

Agency Response: The commenter's request to perform 'marginal' analysis is not relevant since the methodology used for both fossil fuels and biofuels represent an 'average' value for both groups. The LCFS baseline carbon intensity (CI) represents a weighted average of the various crudes used in California and was first established in 2010. This crude CI is updated periodically to reflect the different mix of crudes during each year. In the modeling of indirect effects of biofuels, staff used incremental volumes of biofuels (produced in the period 2004-2010) to estimate indirect Land Use Change (iLUC) values. For biofuels, GHG emissions as they occurred at one time are amortized over 30 years to estimate iLUC values. It is in effect an 'average' iLUC value for the biofuel and is expected to be used over a period of 30 years. Updates to iLUC values represent changes to reflect updated land use science and data for the period 2004-2010. The Global Trade Analysis Project (GTAP)/Agro-Ecological Zone-Emissions Factor (AEZ-EF) models do not calculate new values to reflect changing volumes of biofuels every year.

611. Comment: **LCFS 63-2**

The comment requests ARB staff to model the GHG reductions effects of methane capture in oil palm mills outside of the biofuel sector and include these in the oil palm GHG net emissions reduction calculation.

Agency Response: Currently, only a limited number of mills capture biomethane. For situations where palm mills capture methane and where palm oil is used as a transportation fuel feedstock, an appropriate emissions credit for biomethane capture can be considered under Method 2 of the direct analysis.

612. Comment: **LCFS 63-3**

The comment states that focusing on commodity prices is an over-simplification and requests that ARB continue to work with GTAP modelers to validate and calibrate the model to better reflect current reality.

Agency Response: ARB staff disagrees that the GTAP model is overly simple. In fact, the structure of the GTAP model is complex and includes various elements (i.e., calibrated elasticity parameters, trade relationships, land rents, use of fertilizers, soil quality, new plants and seed varieties, etc.) implicitly designed to account for many of the economic decisions that farmers make when responding to a market demand.

Correlating increases in biofuel availability to lower prices of vegetable oil is not within the scope of the analysis conducted by ARB staff. The adopted modeling methodology only looks at the impacts related to 'additional' production of biofuels and attributes increased demand for biofuels to have a direct relationship to higher prices for the feedstock. Thus, the analysis conducted by staff represents only the effects from increased biofuel production and does not consider all of the global forces that dictate cultivation of oilseeds. In the global marketplace, prices for commodities such as vegetable oils are a result of many complex factors. However, as the commenter suggests, ARB staff will continue to work with GTAP modelers to further validate and calibrate the model.

613. Comment: **LCFS 63-4**

The comment argues for the use of IPCC values for peat emissions.

Agency Response: The ARB emission factor of 95 gCO2e/ha/yr was developed from Page et al. (2011) in their review of studies on peat GHG emissions from palm oil plantations in Southeast Asia. These studies were conducted on deep, organic-rich peatlands with low mineral content typical of peatlands in Southeast Asia that have been converted to palm oil plantations. The GHG emissions estimated are representative of the average peatland emissions in the region. The Page et al. study has been peer reviewed and published in a respected scientific journal. ARB staff believes that this is the most appropriate emissions factor for peatlands for use in our lifecycle analysis of palm oil biodiesel. It should also be noted that the ARB emission factor included the pulse of emissions during the first years following drainage amortized over a 30 year period.

Furthermore, the ARB emission factor may still be a conservative representation of the net effect on GHG emissions from draining peat soils since it does not include emissions due to burning of drained peat during land clearing or via accidental fires. While such emissions are episodic and thus difficult to estimate, peat fires have been estimated to emit around 1,000 tCO_2/ha per event, with very large variability (Couwenberg et al., 2010). The ARB emission factor also does not consider emissions that may occur on inadvertently drained peatlands adjacent to drained palm oil plantations.

The studies reviewed by Page account for emissions from draining and compaction of peat soil prior to palm planting. The commenter has not provided detailed information to identify differences, if any, between the drain and compaction process in representative peat soils and the one cited in the comment.

614. Comment: **LCFS 63-5**

The comment questions the validity of the percentage of oil palm expansion in Malaysia and Indonesia that occurs on peatland.

Agency Response: ARB staff believes that the 33 percent value used for expansion into peatland is appropriate for the following reasons:

- The Edwards study accounted for expansion of land for palm plantations over the period 2003-2008, which matches reasonably well with the 2004-2010 time period considered for the iLUC analysis. In addition, the data was provided by the Malaysian Oil Palm Board, the trade group representing palm oil suppliers.

- The Hoojier paper concluded that greater than 50 percent of expansion was likely on peatland. However, ARB staff used a value of 33 percent as a conservative number to represent expansion on peatland.

- The analysis conducted by Harris et al. for the U.S. Environmental Protection Agency (U.S. EPA) estimated palm expansion through 2022 and does not represent the time period used by ARB staff in the iLUC analysis (i.e., 2004-2010). Utilizing projections for 2022 is therefore not representative of the predicted expansion into peatland in Malaysia and Indonesia for the period 2004-2010.

- Peatland conversion in Malaysia/Indonesia for the period 2005-2010 as reported in Table 2 of the comment is significantly higher than the estimates for such land conversion from the iLUC analysis. Therefore, it appears that the iLUC analysis may have under estimated peatland conversion. ARB staff will review this information and make appropriate revisions in the future.

615. Comment: **LCFS 63-6**

The commenter asserts that the model constraint that all future palm oil will come from Malaysia and Indonesia is not valid.

Agency Response: The modeling timeframe used in the analysis is for the period 2004-2010, and ARB staff used Food and Agriculture Organization of the United Nations (FAO) data for palm oil production and exports for this time period. The FAO data showed that close to 90 percent of palm oil was produced in Malaysia and Indonesia. Only these two countries produced surplus quantities of palm oil that have been exported beyond domestic consumption. All other countries that produced the remaining 10 percent of palm oil were not capable of exporting palm oil in quantities required to produce 400 million gallons of biodiesel.

The commenter cites Ghana, even with 336,000 hectares of palm plantation, is a net importer of palm oil to meet internal demand. Since the ARB analysis is for the time period 2004-2010, export of palm oil by other regions in the future is not applicable for the current analysis.

616. Comment: **LCFS 63-7**

The commenter asserts that the model constraint that all future palm oil will come from Malaysia and Indonesia is not valid.

Agency Response: In the Agro-Ecological Zone–Emissions Factor (AEZ-EF) model, biomass factors for crops are computed based on yield, harvest index (fraction of biomass removed in harvest), moisture content, and carbon fraction. This approach does not apply to Oil Palm whose fruit is harvested. Therefore, in the AEZ-EF sheet, cells that include biomass factors for Oil Palm are set to zero. Biomass factors for Oil Palm have been included in a separate area of the model (rows 69-70 of the Factors Tab in the AEZ-EF model.)

617. Comment: **LCFS 63-8**

The comment states that it is unclear from the model analysis what classification degraded forests or logged over forests would be given.

Agency Response: The model used by ARB staff does not include separate land categories for degraded or logged-over forests. This is because currently there are no data on these land categories (i.e., land rents and other economic data). When data becomes available, staff will consider the inclusion of such transitions into the GTAP modeling framework.

The efforts to create new secondary forests, recover original biodiversity, etc. are not related to the expansion of palm for the production of palm oil and not applicable to the current iLUC analysis. The commenter cites an article from Geoderma 149 (2009) pages 76-83, which concludes that grasslands (e.g., termed Imperata) resulting from destruction of forests by wildfire represent the final stage of land degradation and are not suitable for cultivation (or other useful and valuable purpose). This article does not provide data related to the conversion of grasslands to palm plantations. ARB staff acknowledges that efforts could be directed by governments in these regions to create new secondary forests, recover original biodiversity, etc. but is not applicable to the current analysis.

618. Comment: **LCFS 63-9**

The comment suggests that ARB staff use the commenter's number for peat conversion estimate for new oil palm estates rather than the current model values.

Agency Response: See responses to **LCFS 63-4** and **LCFS 63-5**. Based on responses to these two comments, the consideration of 20 percent peat conversion and the palm emissions factor value of 73 Mg CO_2/ha/yr is not appropriate. Accordingly, any adjustments to the iLUC value for palm oil biodiesel are not justified at this time.

Fulcrum BIOENERGY

February 17, 2015

Clerk of the Board
Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: CARB Low Carbon Fuel Standard Re-Adoption

Dear Chairwoman Nichols and Honorable Board Members:

Fulcrum BioEnergy, Inc. ("Fulcrum") strongly supports the California Low Carbon Fuel Standard ("LCFS") and we appreciate the opportunity to provide comments to the California Air Resources Board ("CARB") regarding the implementation of this important policy.

Fulcrum BioEnergy Overview

Fulcrum is a leading developer and owner of low carbon fuel projects that convert post-recycled municipal solid waste ("MSW") into drop-in fuels such as syncrude, diesel and jet fuel. We are entering construction on our first commercial project – the Sierra BioFuels Plant ("Sierra") located near Reno, NV – that will convert approximately 200,000 tons of MSW into nearly 12 million gallons of low carbon fuels. Beyond Sierra, Fulcrum has already contracted for long-term supplies of MSW feedstock that supports the development of several more projects collectively capable of generating nearly 400 million gallons per year of low carbon fuels.

Fulcrum has the capability of producing at least three different fuels for sale into the transportation market. Fulcrum's syncrude is an excellent replacement for crude oil, which can be sold directly to petroleum refineries for further refining into diesel and gasoline. Fulcrum can also further refine its own syncrude to make either diesel or jet fuel. Both Fulcrum's diesel and jet fuels are "drop-in" fuels that meet already established ASTM standards for use in vehicles and aircraft, respectively.

Environmental Benefits of MSW-to-Fuels

Fulcrum's projects reduce greenhouse gas emissions on a lifecycle basis by more than 80% when compared to petroleum-based fuels. Fulcrum has carefully integrated its projects into the waste management hierarchy, such that we only utilize MSW that would otherwise be landfilled, after all available recycling and composting activities. Fulcrum further enhances recycling

fulcrum-bioenergy.com

4900 Hopyard Road, Suite 220 | Pleasanton, CA 94588 | 925.730.0150 PHONE | 925.730.0157 FAX

activities by recovering an additional ten percent of landfilled waste for recycling, which incrementally increases a community's recycling rates. Additionally, Fulcrum converts more than 50% of landfilled waste into low carbon fuels. Between its enhanced recycling activities and the conversion of landfilled MSW into low carbon fuels, Fulcrum will divert a significant portion of waste from landfills.

Moreover, Fulcrum's process does not compete with other waste conversion solutions, such as anaerobic digestion, which are complementary to Fulcrum's efforts because they target wet organics for conversion to biogas.

Credits for Producing Crudes Using Innovative Methods

Fulcrum welcomes CARB's creation of an Innovative Crude pathway that incentivizes the production and sale of lower carbon crudes into California. Fulcrum's projects produce a syncrude, which is an excellent replacement for crude oil and can be refined into transportation fuels at a conventional petroleum refinery. The production of syncrude from waste feedstocks such as post-recycled MSW has several key advantages. It leverages existing infrastructure, reduces the capital costs of emerging biorefineries, minimizes biorefinery emissions and displaces crude oil purchased by a refinery – ultimately reducing the amount of crude oil sold into California.

LCFS 64-1

In reviewing the Innovative Crude requirements in the Proposed Regulation Order, it appears that CARB has focused on several methods to produce conventional crude oil with lower carbon methods (e.g. solar, wind and carbon capture). While these methods have sound GHG benefits, Fulcrum respectfully asks that CARB be open to other forms of innovative crude production – particularly those that directly produce low carbon syncrude and displace actual crude oil. The LCFS program is unique in welcoming innovative and technology-neutral approaches to reducing the carbon intensity of the transportation sector and we hope that the same technology-neutral approach is applied to this section.

Refinery Investment Credit

Fulcrum sees significant opportunity to provide renewable feedstocks directly to a refinery for the production of CARBOB or diesel fuel. As described above, Fulcrum can produce a syncrude from post-recycled MSW feedstock that can be upgraded at a conventional petroleum refinery along with other crude oils. We welcome CARB's inclusion of these renewable feedstocks to generate credit under the Refinery Investment Credit provisions. However, we didn't understand the reason for the 10% minimum requirement to replace fossil based feedstocks. A typical refinery processes well in excess of 100,000 barrels per day and most advanced biofuel refineries will not produce 10,000 to 20,000 barrels of biofuel per day – which would be necessary to meet the minimum threshold for this standard. In fact, many of the advanced biofuel projects that will be built in the coming years will produce 1,000 to 5,000

LCFS 64-2

4900 Hopyard Road, Suite 220 | Pleasanton, CA 94588 | 925.730.0150 PHONE | 925.730.0157 FAX

barrels per day, well short of the proposed 10% displacement requirement. We encourage CARB to focus instead on the overall Carbon Intensity ("CI") benefit that such a renewable feedstock strategy provides the refinery under this Refinery Investment Credit provision, which would be consistent with how other projects are evaluated under this section. If the focus is instead on CI reduction, then this provision will encourage innovative ways to supply refineries with low carbon feedstocks that reduce the overall carbon intensity of a refineries' fuels – consistent with the intent of the LCFS. LCFS 64-2 cont.

In summary, Fulcrum strongly supports the re-adoption of the California LCFS and continues to work every day towards developing and building projects that will serve this important market. We thank CARB Board Members and Staff for their hard work and dedication in addressing GHG emissions in the transportation fuels sector. LCFS 64-3

Respectfully,

FULCRUM BIOENERGY, INC.

64_OP_LCFS_FBE Responses

619. Comment: **LCFS 64-1**

The commenter recommends that technologies that produce low carbon syncrude be included under the innovative crude production method provision.

Agency Response: ARB staff believes that technologies that convert municipal solid waste to finished transportation fuels are most appropriately evaluated under the Method 2 application process for alternative fuels and not under the innovative crude provision, as the emissions benefits of such technologies are only captured through a complete well-to-wheels assessment. Staff encourages the commenter to explore the Method 2 process.

620. Comment: **LCFS 64-2**

The comment asserts that the 10 percent biofuel displacement threshold is too high and should be replaced with a carbon intensity reduction threshold.

Agency Response: See response to **LCFS 38-13**. ARB staff determined that renewable feedstocks are better handled under a Method 2A/2B pathway and thus have removed the renewable feedstock provision from the Refinery Investment Credit Provision.

621. Comment: **LCFS 64-3**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

Reference: **Electricity Mix in CA GREET**

Dear Ms. Sideco,

Life Cycle Associates would provide insight to the choice of electricity mix in CA_GREET. The choice of electricity mix affects the consumed power for fuel production facilities as well as exported power. Both input power and export power are treated symmetrically in the GREET model. Exported power is treated as a co-product using the substitution method.

The question of electricity mix is most important for fuel pathways using or exporting the most electricity. The pathways involving the most power and the amount of power used/exported are shown below.

Hydrogen, water electrolysis	+ 50 kWh/kg H_2
Electricity	+ 33 kWh/gasoline equivalent gallon
Cellulosic ethanol with power export	- 3 kWh/gal ethanol
Sugarcane ethanol with power export.	- 3 kWh/gal ethanol

These pathways use/export the most power of any fuel pathway. The export power from cellulosic ethanol and sugarcane ethanol represent 13.4% of the output product, while the power is 100% and 150% of the input for the electricity and hydrogen pathways. In contrast, the 0.55 kWh/gal of corn ethanol represents only 2.4% of the energy in this pathway. Consequently, understanding the environmental impact of the power in the above 4 pathways is of the highest priority.

Purpose of LCA

The objective of the LCA for the LCFS is to identify the impact of the change to the use of an alternative fuel on global emissions. ARB has embraced this objective in the analysis of indirect land use. The consequential impact of biofuel use reflects the net global impact of feedstock demand on the agricultural system. ARB calculates the marginal land use for each biofuel.

LCFS 65-1

Similarly, ARB has embraced the marginal approach in the estimation of emissions from alternative fuels, specifically electric vehicles (Unnasch 2001) and hydrogen vehicles (Unnasch, 2005). The analysis conducted as part of ARB fuel cycle studies and the California Hydrogen Highway Blueprint Plan concluded that the marginal resource for electric power corresponds to permanent and sustainable load growth. This concept has the following implications:

- Average emissions are not an appropriate indicator of future emissions
- Minute by minute dispatch does not predict permanent changes in resource mix
- Nuclear power is always base loaded and never on the margin
- Marginal power in California is best represented by a mix of new combined cycle natural gas power plants and non-fossil renewables that correspond to the Renewable Portfolio Standard Requirement.

This approach for marginal emissions was applied to the California Energy Commission's AB1007 Full Fuel Cycle Analysis (Unnasch, 2007), which resulted in the first GREET model used to represent California specific emission impacts. The inputs for this model provided that basis for CA_GREET 1.8b.

Marginal Resource Mix

The choice of marginal resource mix has remained challenging. For example the Midwest mix used on CA_GREET 1.8b was based on a Midwest mix without nuclear power. Unfortunately, the changes in the power market with the grown in natural gas is more complicated. ARB has chosen to use and average resource mix for all regions in the US and globally. This approach simplifies the selection of electric resource mix in that the method is well defined. Unfortunately the average resource approach does not accurately reflect the impact on the environment for the fuels with the greatest electric power impacts. These include EV's charged in California as well as cellulosic ethanol and sugarcane ethanol from Brazil. Since these fuel pathways use the most electric power, ARB should develop a marginal approach for these pathways. As more information is understood in other regions, a marginal resource mix could be applied as the analysis progresses.

LCFS 65-1 cont.

Table 1 shows the marginal resource mix for California and Brazil, which are the regions affected most by the power assumption. The prior CA_GREET1.8b assumption on marginal power is appropriate. Alternatively, ARB could revise the marginal assumption to correspond to the prevailing RPS requirement. Similarly, the Brazilian marginal mix can be calculated from the annual resource mix in Table 2. Clearly fossil fuels are growing on the margin and hydroelectric and nuclear power do not correspond to resource growth.

Table 1. Marginal resource mix for fuel pathways involving the most electric power.

Region:	CA Marginal	Brazil Marginal
Residual oil	0.0%	19.7%
Natural gas	78.7%	61.1%
Coal	0.0%	13.1%
Nuclear	0.0%	0.0%
Biomass	0.0%	0.0%
Other (renewables)	21.3%	6%

In the Brazilian situation, bagasse power is derived from the sugarcane ethanol plants, so this power that is being produced by the plant should not be treated as the power that is displaced by the ethanol plant.

Table 2. Generation Resources in Brazil

Type	Source	2009	2010	2011	2012	2013	2013 part. % (per source)	2013 part. % (per type)
Hydro	Hydro	390.988	403.290	428.333	415.342	390.992	68,6	68,6
Fossil	Natural gas	13.332	36.476	25.095	46.760	69.003	12,1	18,6
	Petroleum	12.724	14.216	12.239	16.214	22.090	3,9	
	Coal	5.429	6.992	6.485	8.422	14.801	2,6	
Biomass	Bagasse, wood and others	21.851	31.209	31.633	34.662	39.679	7,0	7,0
Nuclear	Uranium	12.957	14.523	15.659	16.038	14.640	2,6	2,6
Wind	Wind	1.238	2.177	2.705	5.050	6.576	1,2	1,2
Others	Recoveries, secondary gases	7.640	6.916	9.609	10.010	12.244	2,1	2,1
Total		466.158	515.799	531.758	552.498	570.025	100,0	100,0

LCFS 65-1 cont.

The choice of average power for California does not accurately affect the criteria pollutant impacts. Criteria pollutants shown in the Appendix include many generation resources that are not on the margin, providing the incorrect impression that EV and hydrogen vehicle emissions are higher than they actually are.

Therefore, the most appropriate resource mix for Brazil and California would be marginal resources defined in here.

Best Regards,

Stefan Unnasch

VIA ELECTRONIC MAIL

John Courtis
Manager, Alternative Fuels Section
California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: UNICA's Comments on California Air Resources Board's (CARB) Staff Report: Initial Statement of Reasons.

Dear Mr. Courtis:

The Brazilian Sugarcane Industry Association ("UNICA") appreciates the opportunity to provide comments on the California Air Resources Board's CARB) Staff Report: Initial Statement of Reasons, which was posted for comments on December 31st, 2014.

UNICA is the largest representative of Brazil's sugar, ethanol, and bioelectricity producers. Its members are responsible for more than 50% of Brazil's ethanol production and 60% of Brazil's sugar production. UNICA's priorities include serving as a source for credible scientific data about the competitiveness and sustainability of sugarcane biofuels. UNICA also works to encourage the continuous advancement of sustainability throughout the sugarcane industry and to promote ethanol as a clean, reliable alternative to fossil fuels. Sugarcane ethanol production uses less than 1.5% of Brazil's arable land and reduces lifecycle greenhouse gas (GHG) emissions by up to 90% on average, compared to conventional gasoline. Thanks to our innovative use of ethanol in transportation and biomass for power cogeneration, sugarcane is now a leading source of renewable energy in Brazil, representing over 15% of the country's total energy needs. The industry is expanding existing production of other renewable products, and with the help of innovative companies here in the United States and elsewhere, is beginning to offer bio-based hydrocarbons to replace carbon-intensive fossil fuels and chemicals.

UNICA recognizes the amount of work CARB staff has done throughout 2014 culminating with the issuance of this report, and we continue to support your work LCFS B1-1

Brazilian Sugarcane Industry Association (UNICA) • 1156 15th Street, NW Suite 800 • Washington, DC 20005
Phone +1 (202) 506-5299 • Fax +1 (202) 747-5836 • washington@unica.com.br • www.unica.com.br/EN

improving the Low Carbon Fuel Standard by requesting input and welcoming the cooperation of stakeholders like UNICA. For the purpose of this letter, we would like to comment on two specific appendix of the study: A) Appendix C Comparison of CA-GREET 1.8B, GREET1 2013, and CA-GREET 2.0; and B) Appendix I Detailed Analysis for Indirect Land Use Change. LCFS B1-1 cont.

A) Appendix C: Comparison of CA-GREET 1.8B, GREET1 2013

We were disappointed to see CARB staff's decision to opt for using average electricity mix instead of the marginal mix in Brazil's sugarcane ethanol production for a few reasons. As per your report, the reason for this change is to provide better accuracy for power plants in the U.S. to find their region-specific electricity resource mix and calculate the carbon intensity (CI) of their electricity use. In order to do that, CARB adopted the U.S. Environmental Protection Agency's (EPA) Emissions & Generation Resource Integrated Database (eGRID), 9th edition Version 1.0 for the different regions in the U.S., and included Brazil as the only international eGRID region (Region 29). The more we analyze this proposal, the more it does not make sense for Brazilian industry. Perhaps the average mix approach may make sense for U.S. power plants because the plants take energy from the grid, but this situation is very different compared to the Brazilian model. During the harvest season, sugarcane mills in Brazil are 100% self-sufficient in electricity, so mills consume nothing from the general electricity grid. On the contrary, the electricity unused by the mills is sold into the national grid, contributing as a clean source of power to the grid by displacing the marginal increase of dirtier sources. According to the Brazilian Agriculture Ministry, in December 2013 there were 389 sugarcane mills in Brazil, all of them producing energy for self-consumption and we estimate that about 170 of these mills sell excess electricity into the grid. LCFS B1-2

The Brazilian electrical system (National Interconnected System - SIN) is 98.3% interlinked, so virtually all the production and transmission of electricity in Brazil happens on one main grid closely monitored by the National Electric System Operator (ONS), a federal agency responsible for coordinating and controlling operation of the electricity generation and transmission facilities in the SIN under the supervision and regulation of the National Electric Energy Agency (ANEEL). This unique system adopted by the country creates certainty as to what sources contribute to the marginal generation of power. Sugarcane biomass-based electricity in Brazil receives a fixed income to deliver a "package" of energy per year to the grid. Sugarcane biomass receives this fixed income for the energy it produces and declares its Unit Variable Cost (UVC) equal to zero, since co-generation of sugarcane biomass electricity occurs in order to meet the demand of the sugar and ethanol production in the mill. Wind and solar sources also have a UVC equal to zero. In this way, all the electrical energy these sources produce are made available to the national grid (since the government already paid a fixed income for it).

The process is different for thermo-gas sources. On top of the fixed income they receive to be on stand by, their UVC is greater then zero, meaning if and when the ONS utilizes them, they receive payment for their fuel cost and the operation. In fact, since sugarcane biomass is classified with a unit variable cost equal to zero, the ONS adopts the so-called merit order, where thermal plants from lower to higher operating costs are dispatched in order to meet demand. The ones with lower UVC are the first to be called to meet domestic demand. Since biomass plants have unit variable cost equal to zero, when available (during the sugarcane harvest season), they are the first to be dispached to the system, without the need of an order from the ONS. Differently from sources like coal, diesel, and natural gas, the generation of energy of sugarcane biomass sources is controlled and dictated by the industrial process itself instead of by order of the national operator.

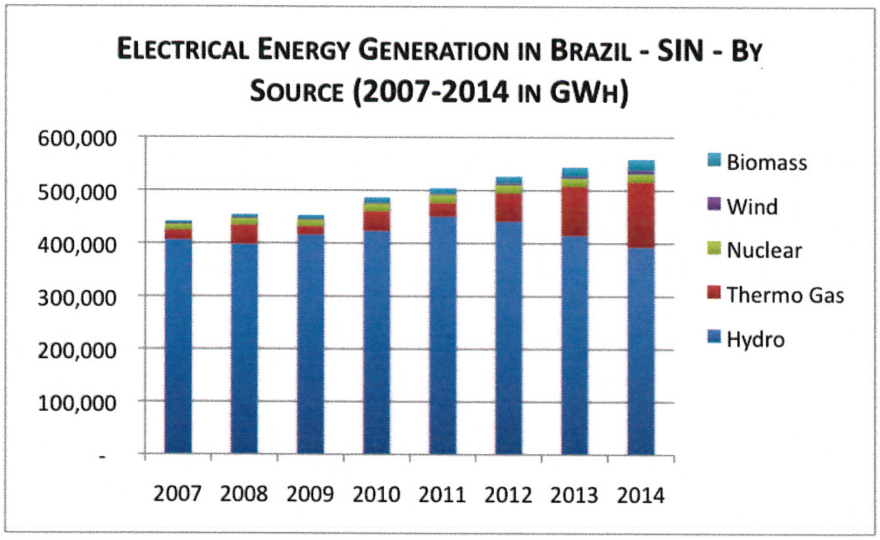
Another important point to remember is during the dry season, when Brazil's reservoirs are at their lowest level, the system is heavily relient on thermo-gas sources, in order to guarantee the security of the system. This is when sugarcane harvesting season and co-generation is at peak, so given the lower operational cost of biomass electricity, this source substitutes for natural gas at the margin.

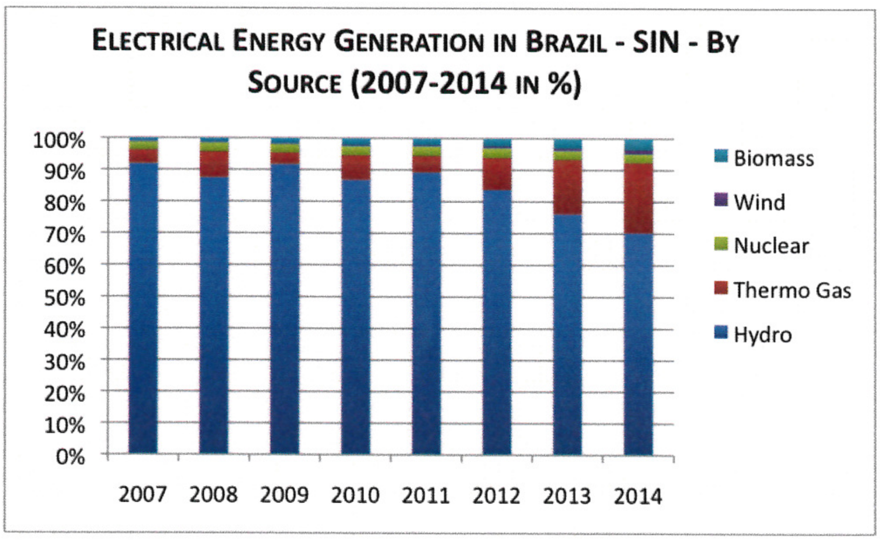
LCFS B1-2 cont.

The graphs below show from 2007 to 2014, the share of hydropower in Brazil decreased significantly, mainly due to droughts that have significantly impacted reservoirs and due to the reduction of the multiannual regulating capacity of the hydroelectric reservoirs, since the most recent hydropower projects in Brazil are composed of "thread-of-water" mills, mills that are only able to hold water for a few hours or days.[1] According to the Brazilian Ministry of Mines and Energy's (MME) 10-year Energy Expansion Plan (PDE 2023), this decreasing trend is predicted to continue, and Brazil has relied (and will rely) especially heavily on thermo-gas sources to provide the marginal power it needs, and to guarantee the security of the electrical system in the country[2]. Since sugarcane mills operate on a fixed revenue basis described above with zero Unit Variable Cost (UVC), we know bagasse-burning electricity cogeneration goes straight into the grid, to substitute the marginal increase of energy. If we look at the marginal sources that have increased over the last few years, we see natural gas has the largest share in the system. Given the operational cost differential between biomass and thermo-gas sources, the seasonality of hydro and biomass energy generation and the fact that hydro mills have a decreased capacity of holding water, we know bagasse electricity cogeneration is displacing fossil fuel sources of power in Brazil, in the daily operation system.

[1] The Brazilian Ministry of Mines and Energy published in 2014 the Brazil 10-year Energy Expansion 2023 Plan (Plano Decenal de Expansão de Energia 2023 –PDE) , available in Portuguese at: http://bit.ly/1F5IlaW, for more information on reservoir capacity see pages 84 and 85.

[2] PDE 2023 page 396.





Notes: Source (Hydro, Wind, Nuclear and Thermo Gas): ONS 2015 available online at http://bit.ly/1zPCNDr
Biomass from 2007-2009: Data from the National Energy Balance for corresponding year – Ministry of Mines and Energy.
Biomass from 2010-2014: Source CCEE (2015) available online at http://bit.ly/1EhnDq0

We urge CARB to continue to adopt the marginal source of electricity for sugarcane pathways. By adopting energy average mix, CARB is not only taking the wrong approach, but is also turning its back on one of the greatest environmental benefits of sugarcane pathways. There is no doubt in our minds that such a position by CARB would discourage carbon mitigation behavior in Brazil and elsewhere.

LCFS B1-2 cont.

Another very important point for consideration is that CARB adopted the U.S. Energy Information Administration's (EIA) data for Brazil's 2011 electricity generation, while the government of Brazil publically displays its data on electricity generation by fuel type on a very up-to-date fashion. As the graphs above show, Brazil's energy matrix includes significantly less hydro today than in 2011, and we believe this decreasing trend will prevail for years to come. The current reality for renewable and fossil sources of energy in the Brazilian energy matrix is very different from the one pictured by EIA, and regardless of the position CARB adopts, this average mix of electricity data should to be updated with the most current numbers available. LCFS B1-2 cont.

B) Appendix I: Detailed Analysis for Indirect Land Use Change

We were glad to see the iLUC penalty number reduced for sugarcane ethanol, as we believe this reflects the effort of CARB staff throughout the years in improving iLUC modeling under the LCFS. We believe some changes adopted by staff, like the new land supply structure for GTAP ("Approach B"), allow us to improve the iLUC analysis by identifying with much more accuracy how pastures and forests respond to cropland expansion, an important improvement for regions with large stocks of pastureland and forests like Brazil.

Despite these positive changes, UNICA would like to once again stress the urgent need for CARB staff to capture crop production expansion based on double-crop systems (soy-corn and soy-cotton, in Brazil's case). During the September 29, 2014 seminar, CARB staff indicated crop and region-specific YPE is the possible solution for representing double cropping within GTAP, but once again CARB ran scenarios of equal values for the different regions of GTAP. We sympathize with CARB staff on the difficulty finding accurate double-cropping data for all regions of the world, however, Brazil has compiled this data for some time and UNICA has provided this information to CARB in previous correspondences. As mentioned in our October 15, 2014 letter, UNICA has run scenarios using a YPE value of 0.35 with encouraging results: less area allocated to crops (due to higher yields) and higher share of cropland expansion in Brazil (cropland expansion is a consequence of the shock on ethanol production). UNICA urges CARB to set a YPE value of 0.35 for soy and corn in Brazil in order to capture the effects of double cropping and improve iLUC analysis even further. We maintain that CARB needs to incorporate this tropical land-saving practice occurring in Brazil in its iLUC analysis. We remain at staff's disposal to provide available data and make necessary introductions to Brazil's government and academia for better explanation and confirmation of this phenomenon to CARB. LCFS B1-3

We appreciate the opportunity to submit these comments, and as we have done in the past, will continue to engage with CARB staff to provide additional input and feedback on the LCFS. We are pleased to see CARB continuing to improve the LCFS and we are glad to be part of this process by cooperating with the agency and serving as a LCFS B1-4 credible source of information about the Brazilian biofuels industry. We remain committed to continue our collaboration with CARB and we look forward to the opportunity to discuss these comments in detail with you. LCFS B1-4 cont.

1_B_LCFS_Unica Responses

623. Comment: **LCFS B1-1**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

624. Comment: **LCFS B1-2**

The comment urges ARB staff to use the marginal electricity mix when modeling Brazil's sugarcane ethanol production.

Agency Response: With regards to the comment on the incorrect mix of electrical generating assets specified in the draft CA-GREETv2.0 life cycle analysis model, ARB staff concurs with the commenter that the proposed mix had incorrectly grouped several fossil-fueled generating resources with natural gas generation. The table as proposed would have resulted in an applicant using the draft CA-GREETv2.0 model underestimating the GHG impacts as a result of grid-based electrical energy use applicable to a Brazilian fuel pathway. Conversely, the applicant would have also received a lower co-product credit for displacing surplus cogenerated electricity exported to the public electrical grid.

A 15-day change is based on data provided in the annual Brazilian Energy Balance[53] prepared by the Ministry of Mines and Energy, Government of Brazil. Staff thanks the applicant for sharing the average Brazilian mix data.

[53] The average portfolio of electrical generating assets is based upon the Brazilian Energy Balance for years 2010-2012, published by the Empresa de Pesquisa Energetica (EPE) agency of the Ministry of Mines and Energy (http://www.mme.gov.br).

15-day Change to the Average Electrical Generation Mix for Brazil

Electric Generation Mixes: Data Table for Use in GREET (From Annual Energy Outlook 2013)	Brazilian Mix Stationary
Residual oil	3.4%
Natural gas	7.9%
Coal	1.9%
Nuclear power	2.6%
Biomass	7.0%

With respect to the question of marginal vs. average grid emission assumptions, please see response to comment **LCFS 18-3**.

625. Comment: **LCFS B1-3**

The comment requests that ARB staff set a preferred YPE value for soy and corn in Brazil in order to capture the effects of double cropping and improve iLUC analysis.

Agency Response: While ARB staff recognizes that double cropping occurs in Brazil, the structure of the Global Trade Analysis Project (GTAP) model does not allow explicit modeling of double cropping effects. When staff presented the GTAP model with disaggregated Yield Price Elasticity (YPE) by crop and region, it was designed to facilitate the use of crop and region-specific values. However, lack of data did not allow the use of specific values for YPE by crop and region. Academics at Purdue University who developed the GTAP model were also not in favor of using region-specific values until detailed data for each region and crop was available to conduct comprehensive testing of model responses. Given the absence of data, staff did not utilize the crop and region-specific YPE values for the analysis.

Lacking data for all crops and regions, ARB staff used the same value of YPE for all regions and crops for each scenario analysis. The scenario runs used by staff utilized a range of likely values for critical parameters based on literature or expert judgement. A value of 0.35, as suggested by the commenter, was in fact used as one of the values for YPE in the scenario analysis conducted by staff. When region-specific cropping data becomes available for various regions of the world, staff will evaluate the applicability of using these values to test model response. See response to **LCFS 46-14**.

626. Comment: **LCFS B1-4**

The commenter thanks ARB and offers to continue assisting by providing information.

Agency Response: ARB staff appreciates the support.

Re: Comments on the Re-adoption of the Low Carbon Fuel Standard

Dear Madams and Sirs:

We appreciate this opportunity to comment on the Air Resources Board's ("ARB") proposed re-adoption of and amendments to the Low Carbon Fuel Standard ("LCFS").

Sutherland Asbill & Brennan LLP ("Sutherland") represents various importing, blending, and trading companies in matters related to ARB's LCFS. Among Sutherland's clients are domestic trading companies, fuel suppliers, renewable fuel producers, importers, exporters as well as LCFS credit traders and owners. Many of these companies have participated actively in the regulatory and policy development process underlying ARB's LCFS.

We would like to express our concern over the proposed new requirement in section 95491(c) of the LCFS that would require all product transfer documents ("PTDs") to contain Environmental Protection Agency ("EPA") company and facility identification numbers of the fuel producer as registered under the Renewable Fuel Standard and other EPA fuel regulatory programs.

While requiring this information in PTDs for transfers of biofuels may be reasonable given the diversity of pathways, feedstock, and carbon intensities for such fuels, we believe that the burdens and costs of requiring such information on PTDs for standard carbon intensity ("CI") CARBOB and diesel transfers outweigh the benefits that this requirement would afford.

LCFS B2-1

This requirement would eliminate the possibility of creating a standard PTD for CARBOB and diesel transfers, because each different party transferring such products would have to create its own PTD to provide for its specific company or facility identification numbers. Standardized PTDs for gasoline and diesel are the industry standard at this time, and the time and paperwork necessary to meet this proposed requirement would be substantial.

While providing the specific identification numbers on PTDs for transfers of biofuels may be useful to assist in distinguishing biofuels based on their varying pathways, feedstock, and CIs, this designation for CARBOB and diesel with standard pathways, feedstock, and CIs would provide no additional benefit. Standard gasoline and diesel can be tested so as to ensure that it conforms to applicable ASTM standards and thereby has the standardized CI value. Requiring identification numbers would disrupt automated tracking and inventory systems, resulting in the potential for issues with compliance and tracking the chain of title. Accordingly, requiring facility and company identification numbers on each PTD for standard CI CARBOB and diesel would be burdensome and at the same time would inure few regulatory benefits or value. Furthermore, there are substantially more transfers of CARBOB and diesel than of biofuels, such that this requirement would have a disproportionate impact on CARBOB and diesel transfers.

LCFS B2-1 cont.

We are available to answer any questions that ARB may have on these comments.

Respectfully submitted,

Susan Lafferty (SW)

Susan G. Lafferty
David M. McCullough

2_B_LCFS_Sutherland Responses

627. Comment: **LCFS B2-1**

The commenter requests that the requirement for all product transfer documents to contain EPA company and facility identification numbers of the fuel producer for CARBOB and CARB diesel be eliminated.

Agency Response: ARB staff acknowledges the recommendation and made the necessary regulation amendments as 15-day changes. Staff will propose a revision that will exclude recording U.S. Environmental Protection Agency (U.S. EPA) company and facility identification on product transfer documents (PTDS) for California Reformulated Gasoline Blendstock for Oxygenate Blending (CARBOB) and ultra-low sulfur diesel (ULSD) transfers.

To the California Air Resources Board

At the Public Hearing to Consider
California's Low Carbon Fuel Standard
February 19, 2015

Dear Chairman Nichols and Members of the Board:

Thank you for the opportunity to present Consumers Union's views on California's Low Carbon Fuel Standard (LCFS). We strongly support reauthorization of the LCFS due to its benefits to California's citizens, economy, and environment.

Since our inception in 1936, auto safety and value have been a paramount concern. Consumer Reports tests about 75 new vehicles every year at our test track, where we assess such attributes as fuel economy, ownership costs, reliability, safety, and performance. We do not accept outside advertising, and we have more than 8 million subscribers to all our products and services.

As a national consumer organization with subscribers and activists in every state, we care deeply about the cost of fuel to power our vehicles, and actively promote measures that provide consumers with cleaner, more efficient choices. Working towards this goal, we have supported federal and state fuel economy and greenhouse gas (GHG) emissions standards for vehicles, as well as state initiatives to enhance customer choice for vehicles and fuels.

LCFS B4-1

The California Air Resources Board (CARB) has been successfully implementing the LCFS since it first issued proposed regulations in 2009. CARB's efforts have stimulated the production of alternative fuels. This has increased consumer choice at the pump, and decreased GHG emissions across the state.

Oil prices are volatile. While today gas prices are dramatically low, all forecasts indicate that they will increase again soon. When prices are too low, production slows, demand and supply sync up, and prices increase again. We also recognize that depending on unconventional sources for oil, where production costs are much larger (e.g. hydraulic fracturing and horizontal drilling), will drive prices upward.

So what is the best long-term strategy to hedge our transportation bets and lessen uncertainty at the pump? In two words: competition and diversification. Introducing competition from cleaner fuels will encourage innovation and exert downward pressure on gasoline prices. Diversifying the fuel supply both decreases demand for oil and gives consumers more transportation fuel choices, which are especially valuable when oil prices rise. By increasing consumer choice, the LCFS has helped increase the elasticity of demand, providing protection from fuel price increases.

It is more important now than ever to prepare for our long-term energy future. We don't have to wait for oil prices to go up again to invest in clean fuel technologies. While improvements are being made, oil's near monopoly over transportation infrastructure stymies investment in alternative, and competing, products. The LCFS helps diversify transportation fuels and foster a market for clean fuels by providing greater certainty for bringing these alternatives to market.

LCFS B4-1 cont.

Finally, programs such as LCFS bring numerous other benefits. Burning less fuel, compounded by that fuel being cleaner, improves air quality and progresses public health. These enhancements lead to fewer consumer expenses on health care and missed work days as well.

Consumers Union believes the LCFS will continue to boost fuel choice, incentivize innovation, and decrease consumer costs in the long run. We thank you for your time and support and urge the Board to move forward with this important program.

Sincerely,

Shannon M. Baker-Branstetter

Hand Delivered at Board Meeting

February 19, 2015

Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Subject: Comments on the LCLE Provisions in the Proposed LCFS Regulation

Alon USA Energy (Alon) respectfully submits these comments on the proposed regulatory provisions for the readoption of California's Low Carbon Fuel Standard (LCFS or regulation) for Low Complexity – Low Energy Use Refiners (LCLE Refiners). Alon and the Board have been discussing the concept of a LCLE refiner provision since 2011. **Alon strongly supports the LCLE concept as the policy and technical basis for the provision are sound.** But Alon requests ARB also ensure its language includes the entire population of smaller, lower complexity, lower CI refineries located in California for which the policy was intended.

The LCLE provision is an important policy acknowledgment by the Board that there are refineries in California that produce transportation fuels while consuming substantially less energy per finished gallon. These refineries are very limited in numbers, have historically been acknowledged by the regulators that they operate at a market disadvantage, and are by their very design smaller and less complex. Alon owns three such refineries, including one in Bakersfield that seems to be forgotten in this regulatory process. Alon strongly supports the LCLE as policy position, but we have grave concerns over its proposed implementation by staff, specifically the complete omission, or mis-categorization of our Kern County facility.

Though Alon's Bakersfield refinery is currently operating in a very limited mode, and hasn't been in full operation since January 2009, Alon is actively working to bring production back to 2008 levels. The Kern County Board of supervisors have approved an Environmental Impact Report to allow Alon to reconfigure the Refinery and Alon is beginning the engineering work. The impacts of the LCFS and the potential mitigating effects of the LCLE refiner provisions are significant economic considerations for the facility.

Because the CI of the Bakersfield facility is substantially lower than the average California refinery, when operating, the fuels produced by the facility would save approximately 350,000 metric tons of GHG emissions annually over what would otherwise be emitted by an average in-state refinery. The question ARB needs to be asking is "Do we want to encourage or discourage lower CI fuel production in California?". Establishing an appropriate LCLE eligibly criteria is critical to answering this question. This includes addressing LCLE status for the Bakersfield facility. As Attachment A shows, the Bakersfield refinery is most certainly NOT in the group of California's larger, more complex refineries. LCFS B5-1

The Board has an opportunity now to make the LCFS's LCLE provisions work for all refineries in California. Alon cannot wait multiple years for the next scheduled LCFS revision with only the possibility that CARB will amend the LCLE provision. The regulation needs to be adjusted prior to finalizing this package. A summary of Alon's position is a follows:

- Alon supports inclusion of a Low Complexity – Low Energy Use Refinery provision;
- Alon supports the staff proposal of a 5 gCO2e/MJ adjustment, for both gasoline and diesel, at the reporting tool level;
- Alon recommends eligibility metrics for the LCLE refinery category to be at 7 million mmbtu/year and 7 Modified Nelson Index.

Inclusion of the LCLE Refiner provision correctly recognizes that the carbon intensity (CI) associated with the refining portion of a California's fuels is not uniform. Along with other specific refiners, the Bakersfield facility is lower in complexity and energy input than the majority of the in-state fuel producing facilities. The challenge over these past few years has been how to define these separate groups in a manner that is publicly transparent, technically defensible, and provides the necessary eligibility "bright line" between the two. The issue was how to define the eligibility metrics, but it has never been in question that Bakersfield's refinery CI will be significantly lower than the statewide average.

LCFS B5-1 cont.

Alon has demonstrated that the CI of the Bakersfield facility is very low for gasoline and diesel production. This is the metric that should matter the most in the LCFS, the fact that the facility is currently not in full operation, should not impact the eligibility criteria *that will be in effect when the facility comes back into more normal operations.* The fuels produced in Bakersfield will have a lower carbon intensity than the average of the larger, more complex refiners in the state, therefore inclusion into the LCLE category is consistent with the underlying policy and excluding the facility is inconsistent and would lead to increased GHG emissions associated with fuel produced in California.

The proposed eligibility metrics are Total Annual Energy Use and a Modified Nelson Complexity Index. Alon supports the use of these metrics, but rejects the notion that the proposed eligibility levels of 5 million MMBTU/year and a modified Nelson Index complexity below 5 are the right level. This "5/5" level isn't reflective of the entire category of refineries that the LCLE policy is trying to recognize. Alon has been and continues to recommend an eligibility criteria of "7/7". This recommended amendment would not have any ripple impacts throughout the remaining LCFS language, it truly is a stand-alone change. Additionally, this modification would not impact any other refinery in the state, larger or smaller than Alon Bakersfield.

Alon recommends the following actual language amendments:

§ 95481. Definitions and Acronyms.

(55) "Low-Complexity/Low-Energy-Use Refinery" means a refinery that meets both of the following criteria:

(A) A Modified Nelson Complexity Score equal to or less than ~~5~~ 7 as calculated in section 95489(e)(1)(A).

(B) Total annual energy use equal to or less than ~~5~~ 7 million MMBtu as calculated in section 95489(e)(1)(B).

LCFS B5-1 cont.

In summary, the proposed LCLE provisions are technically sound, and convey the right policy, but the LCLE definition (eligibility threshold levels) of "5/5" level isn't reflective of the complete category of refineries that fit its important policy goal. Alon has been and continues to recommend an eligibility criterion of "7/7". Such a level would not allow any existing California refiners to be eligible for the LCLE provisions, but would recognize Alon's lower CI values, assist the facility in producing lower CI fuels while advancing the goals of the LCFS.

We look forward to working through this issue in the coming months. If you have any questions on these comments please contact Gary Grimes at 562-531-2060 (ggrimes@ppcla.com).

5_B_LCFS_Alon Responses

630. Comment: **LCFS B5-1**

The commenter recommends that the eligibility metric for the LC/LE provision should be increased to 7 million MMBtu/year and a 7 modified Nelson Index.

Agency Response: ARB staff has analyzed the possibility of changing the Low-Complexity/Low-Energy-Use Refinery (LC/LE refinery) eligibility requirements to total annual energy use equal to or less than 7 million MMBtu and a Modified Nelson Complexity Score equal to or less than 7 (7/7) to accommodate Alon in the LC/LE provisions. Staff has determined that Alon's configuration and expected operation is more similar to other complex refineries than it is to LC/LE refineries. Also, a 7/7 eligibility requirement could potentially allow some of the simpler complex refineries to make modifications and also qualify under the LC/LE provision contrary to the objective of the proposal. In addition, Alon is not currently operational. ARB staff used actual refinery and emission data to design and calculate the LC/LE provision. Alon is asking ARB staff to revise the qualification standards based on projected data provided by Alon. However, it is not appropriate to use projected data to change the qualification standard or recalculate the credit generated. Staff maintains that a 5 million MMBtu per year and 5 Modified Nelson Index score are appropriate eligibility requirements for the LC/LE provision.

Comments to the California Air Resources Board by the Clean Air Task Force

CLEAN AIR TASK FORCE

On the Proposed Re-Adoption of the Low Carbon Fuel Standard

February 19, 2015

SUMMARY

The Clean Air Task Force (CATF) appreciates this opportunity to comment to the California Air Resources Board on the Low Carbon Fuel Standard (LCFS). CATF is a nonprofit organization that works to help safeguard against the worst impacts of climate change by catalyzing the rapid global development and deployment of low carbon energy and other climate-protecting technologies through research and analysis, public advocacy leadership, and partnership with the private sector.

Our comments focus on the following points:

- ARB should readopt the LCFS through 2020. Achieving compliance with the 2020 target will be difficult, but the LCFS remains the most promising policy tool available for reducing the climate impacts of the transportation sector.
- The LCFS's promise is undermined by the proposed adjustment to the lifecycle emissions for corn ethanol, and by the likelihood that regulated entities will increase their reliance on corn ethanol to meet LCFS targets.
- The proposed adjustment to corn ethanol's lifecycle emissions score rewards corn for its negative impact on global food security. ARB must acknowledge and address this issue before it erodes the legitimacy of the LCFS program.
- The prospects for deep reductions in transportation sector GHG emissions are likely to improve significantly after 2020, particularly if liquid ammonia's potential as an affordable low-carbon fuel is proven out.

READOPTION OF THE LCFS

Consistent with an order issued by the California Court of Appeals in *POET, LLC v. California Air Resources Board*, 218 Cal.App.4th 681 (2013), ARB staff has reviewed and revised the LCFS, and is now

> proposing that the Board re-adopt the LCFS, replacing the current LCFS regulation in its entirety. The proposed LCFS regulation will maintain the basic framework of the current LCFS regulation, including: declining carbon intensity targets; use of life cycle analyses; inclusion of indirect land use change effects; quarterly and annual reporting requirements; and credit generation and trading.[1]

[1] California ARB, *Staff Report-Initial Statement of Reasons* (December 30, 2014) at ES-3.

CATF urges the Board to readopt the LCFS. California's LCFS is the country's most promising public policy for bringing low-C fuels into the transportation market. It has several key attributes, all of which positively differentiate it from the federal Renewable Fuel Standard (RFS):

- Dynamic requirements: Increasingly stringent annual reduction requirements dissuade regulated entities from investing in marginally effective compliance strategies.
- Dynamic analyses: There are important ongoing debates about the performance of lifecycle GHG analyses—both with respect to specific technologies and their overall effectiveness. Regular reanalysis of compliance strategies prevents "lock-in" of outdated analyses and ineffectual technologies.
- No grandfathering: Under the LCFS, compliance options are measured according to their performance. Under the RFS, corn ethanol—which is largely exempt from the program's GHG reduction requirements—accounted for 83% of the overall volume mandate finalized by the Environmental Protection Agency (EPA) in 2013, the most recent year in which final renewable volume obligations were issued by EPA. LCFS B7-1
- Not limited to biofuels: Climate change mitigation depends on strategies that are scalable. That poses a problem for biofuels: the climate benefits of conventional biofuels typically diminish as production scales up, and advanced biofuels tend to be difficult (or impossible) to produce at a large scale.
- Clear focus on GHG reductions: The LCFS cannot blind itself to critically important non-climate impacts, especially the effect that increased consumption of biofuels can have on food prices and global food security. With appropriate safeguards in place, however, ARB can pursue the program's singular goal of GHG reductions without having to accommodate related-but-different objectives like price support for the agricultural sector or energy security.

A strong, stringent, flexible, intellectually honest LCFS creates a forum in which to consider new, truly low-carbon fuels, and a key market in which to commercialize them. It needs to succeed. However, that success must be achieved in terms of real GHG reductions, not merely on paper. CATF is concerned that a short-term reliance on conventional biofuels—especially corn ethanol—could pull the LCFS in the wrong direction, and imperil its prospects for long term success.

NET GHG EMISSIONS FROM CORN ETHANOL

When assessing a biofuel's net GHG emissions in the context of a given policy, an important—and complicated—component is the carbon release associated with land use changes. Of particular concern is indirect land use change (ILUC), or the amount of land use change that occurs as agricultural markets accommodate new policy-driven demand for biofuel feedstocks, and the amount of soil and plant-carbon that is released into the atmosphere as a consequence of those changes. LCFS B7-2

As supply margins for corn and other crops tighten in the face of competition from policy-driven demand for biofuels, the price of foodstuffs increases. The increase in food prices encourages farmers around the world to cultivate previously unfarmed land—a process that results in substantial losses of soil- and plant-carbon to the atmosphere. Accordingly, a biofuel must "pay back" this "carbon debt" (via CO_2 sequestration by subsequent energy crop growth) before it can be credited with any net climate benefits as compared to petroleum-based fuels (which have comparatively insignificant land use-related carbon impacts).

LCFS B7-2 cont.

ARB staff have proposed that the ILUC score for corn ethanol should be reduced from the current score of 30 gCO_2/MJ. Adopting the proposed reduction would be wrong, both as a matter of emissions accounting and as a matter of climate mitigation policy. The proposed reduction would make corn ethanol a more viable LCFS compliance strategy. Heavier reliance on corn ethanol would limit the near- and long-term GHG reductions that can be achieved by the LCFS and would undermine the program's innovation-forcing objective—despite corn ethanol's status as an outmoded technology, the significant uncertainty about whether corn delivers any climate benefits, and the concerns about the non-climate environmental damage associated with its production.

Reducing the ILUC score for corn would be wrong from an emissions accounting perspective because it ignores a host of relevant factors that ARB has not yet been able to effectively quantify in CA GTAP-BIO, but which it knows will raise the ILUC score if/when the factors are correctly incorporated into the model. These factors have been identified by ARB staff[2] and in comments submitted by CATF and other stakeholders.[3] They include:

LCFS B7-3

- The effect of water scarcity constraints on projected crop expansion. Researchers from Purdue University who used GTAP to examine the likely role of water scarcity on crop expansion found that earlier ILUC analyses "likely underestimated induced land use emissions due to ethanol production by more than one quarter."[4] As discussed below, ARB has not yet succeeded in sensitizing CA GTAP-BIO to water constraints, so the effect that such constraints have on LUC patterns and resulting emissions are not fully accounted for.
- GTAP's inability to differentiate commercial forest from non-commercial forests, which means that the model wrongly assumes that markets respond to the conversion of both land types in the same way.
- The yield improvement assumptions in GTAP overlook important differences among crops and growing regions, they fail to incorporate new research on future corn yields in the Midwest United States, and they do not adequately address the climate impact associated with the increased use of nitrogen-based fertilizers to sustain yield growth.

These issues are described more fully in the appended comments that CATF submitted to ARB in May 2014.

[4] Farzad Taheripour, Thomas W. Hertel and Jing Liu. 2013. The Role of Irrigation in Determining the Global Land Use Impacts of Biofuels. ENERGY, SUSTAINABILITY AND SOCIETY.

Even if the fundamental concerns described above are put aside for a moment, the proposed ILUC reduction for corn ethanol is problematic because the materials prepared by ARB staff appear to consider two different reduced scores. The first—19.8 gCO_2/MJ—is the unweighted average of the thirty different production scenarios run on CA GTAP-BIO.[5] ARB's potential reliance on this value implies that it believes all thirty scenarios are equally plausible—a position that ARB has not, and cannot, justify. The second score—21.8 gCO_2/MJ—was derived by performing a Monte Carlo simulation (MCS). ARB's Expert Working Group has urged the use of MCS because of its "ability to represent arbitrary input and output distributions, ... perform global sensitivity analysis (e.g., contribution to variance) to identify which input parameters contribute most to the variance in the output, and ... represent parameter correlations."[6] As between the two scores, the value that was derived from the Monte Carlo simulation—*i.e.*, 21.8 gCO_2/MJ—is superior.

A recent paper by Bruce Babcock and Zabid Iqbal of Iowa State University asserts that ILUC models utilized by ARB and EPA have overestimated land use changes by "attribut[ing] all supply response[s] not captured by increased crop yields to land use conversion on the extensive margin."[7] The paper argues for the use of lower ILUC scores by attempting to prove that "the primary land use change response of the world's farmers from 2004 to 2012 has been to use available land resources more efficiently rather than to expand the amount of land brought into production."[8] The paper has several shortcomings, however:

- Babcock and Iqbal only consider intensification techniques such as double cropping rather than analyzing yield increases over this time period.
- The paper dismisses data on extensive land use changes in Africa on the grounds that the linkage between global food prices and those in rural Africa is weak (implying that biofuel policies in the US and EU have little effect on African food prices and land use change)—even though the authors note a correlation between global food prices and food prices in urban Africa.
- The paper makes overly generous assumptions about the extensiveness of double cropping. As Jeremy Martin of the Union of Concerned Scientists wrote in recent comments to ARB, double cropping is not widely used in Southeast Asia where palm oil plantations have moved into formerly uncultivated areas. Nor is double cropping widely adopted in parts of the Midwest where most U.S. biofuels feedstocks—primarily corn and soybeans—are grown. The Babcock and Iqbal paper also fails to account for increased GHG emissions from increased fertilizer usage where it does assume the use of additional double cropping in response to higher crop prices.
- Finally, the authors assume the "only net contributor to US cropland from 2007 to 2010 was a reduction in [Conservation Reserve Program (CRP)] land," but this too is an inappropriate assumption, because several studies (from South Dakota State University and even U.S. Department of Agriculture Economic Research Service, Farm

8 *Id.*

Service Agency, and Natural Resources Conservation Service data) show that cropland conversions exceeded acres exiting CRP, with huge impacts on GHG emissions.[9]

Reducing the ILUC score for corn ethanol would also be a mistake in terms of climate mitigation policy. The use of highly complex models like CA GTAP-BIO to determine the net emissions associated with biofuels produces values that have the veneer of objective validity. But the modeling outputs are enormously dependent on the data that are fed into the system and on the system's assumptions about how those data affect physical and economic processes.

A recently published paper examines the extent to which subjective decisions about incorporating different assumptions and data into a lifecycle model can affect the outcome.[10] Plevin *et al.* used a Monte Carlo simulation to characterize the parametric uncertainty associated with the two components of the lifecycle analysis that California used to evaluate biofuels: "an economic modeling component that propagates market-mediated changes in commodity production and land use induced by increased demand for biofuel globally, and a carbon accounting component that calculates the GHG emissions associated with (some) of these induced changes."[11]

LCFS B7-5

The authors found that three parameters have particularly strong influences on the uncertainty importance for ILUC emissions intensity:

- Elasticity of crop yield with respect to price (YDEL) (in the economic model);
- Relative productivity of newly converted cropland (in the economic model); and
- Ratio of emissions from cropland-pasture to cropland, as compared to the ratio from converting standard pasture (in the emissions factor model).[12]

Among these factors, "[b]y far, the greatest contributor to variance in the estimate of ILUC emissions was YDEL, the elasticity of crop yield to price;" in fact, in ILUC analyses for corn ethanol, YDEL accounts for "nearly 50%"of the variance among possible modeling results.[13] ARB currently uses a YDEL value of 0.25 in GTAP-BIO—a subjective decision that is

[12] *Id.*

[13] *Id.*

increasingly difficult to justify in light of separate analyses conducted for ARB by Steven Berry and David Locke. Berry reviewed a collection of studies on yield price elasticity (YPE) and, according to an ARB staff report, "concluded that YPE was mostly zero and the largest value that could be used was 0.1."[14] Locke ran a statistical analysis of a similar set of studies and found "that based on methodologically sound analyses, yield price elasticities are generally small to zero."[15] ARB has nonetheless chosen to include YPE values up 0.35 in its ILUC analyses.[16] [[Id. at Attachment 1-6]]

Developing the relevant data and determining which datasets to use (and which to exclude) are highly subjective exercises, as are the processes of choosing and programming the relational assumptions that drive the model. Viewed in this context, the proposal to reduce the corn ethanol ILUC score can be more appropriately understood as the product of a subjective process—one that reflects the current availability of certain data and analyses that would contribute to a lower ILUC score, but fails to account for a host of countervailing factors that ARB does not yet understand how to model.

LCFS B7-5 cont.

The Board should recognize these limitations, as well as the necessary role that it and ARB staff play in interpreting and acting upon modeling results. The Board should exercise its best judgment in light of the overarching policy objective of the LCFS, which CATF understands to be a meaningful reduction in GHG emissions from the transportation sector. Because corn ethanol's lifecycle GHG emissions are—at best—only slightly lower than those from gasoline, and because increased reliance on corn ethanol would frustrate the development of more innovative and effective compliance options, the proposal to reduce the ILUC score for corn ethanol undermines the objectives of the LCFS. Accordingly, CATF urges the Board to table the proposal.

CORN ETHANOL'S IMPACT ON FOOD SECURITY

Another critically important way in which ILUC estimates are the product of subjective decisions (and not just objective calculations) relates to the treatment of food price increases associated with policy-induced demand for biofuels. As Plevin *et al.* (2015) write, "ILUC emission estimates depend on various modeling choices, such as whether a reduction of food consumption resulting from biofuel expansion is treated as a climate benefit."[17] ARB currently chooses to count GHG reductions that result from reduced food consumption when analyzing the lifecycle emissions of biofuels, but that—again—is a subjective decision. (Moreover, doing so implies that ARB assumes that national governments would not subsidize food consumption in the face of rising food prices.)

LCFS B7-6

If instead ARB chose to assume that society would limit the extent to which food consumption would decline (especially taking into consideration a growing world population demanding significantly more calories and protein), its ILUC analysis would produce different results. For

[14] California ARB, *Staff Report-Appendix I: Detailed Analysis for Indirect Land Use Change* (December 30, 2014) at Attachment 1-2.
[15] *Id.* at Attachment 1-5.
[16] *Id.* at Attachment 1-6.
[17] Plevin *et al.* (2015), *supra.*

example, Thomas Hertel *et al.* (2010) found that if food consumption were held constant in GTAP, the estimated emissions from biofuel expansion would increase by 41%.[18]

Similarly, Plevin *et al.* (2015) examine the effect of food consumption assumptions by comparing three model outputs for corn ethanol and other biofuels: the ILUC emissions factor; the non-CO_2 emission factor (*i.e.*, methane and nitrous oxide); and the total emission factor, which sums the ILUC factor and the non-CO_2 factor on a trial-by-trial basis.[19] When food consumption is held constant (or fixed) in non-Annex I countries, ILUC emissions for corn ethanol increase by more than 5 gCO_2/MJ as compared to a scenario in which food consumption is not fixed.[20] Total emissions from corn ethanol under a "food fixed" scenario increase by approximately 10 gCO_2/MJ (from roughly 35 gCO_2/MJ to roughly 45 gCO_2/MJ), while the upper limit of the confidence interval for the total emission factor reaches approximately 70 gCO_2/MJ.[21]

LCFS B7-6 cont.

As with the other factors discussed above, the problematic and highly subjective treatment of reduced food consumption reinforces the point that ARB is not obligated to reduce the ILUC score for corn ethanol on the basis of the most recent—but highly incomplete—modeling results.

More generally, CATF urges ARB to reconsider how it accounts for reduced food consumption within the LCFS context, before the issues erodes the legitimacy of the LCFS program.

EMISSION REDUCTION OPPORTUNITIES POST-2020

ARB is appropriately interested in using the LCFS to achieve deep, long-term reductions.

> Although post-2020 goals for the LCFS are not part of this proposed rulemaking, continuing these policies beyond 2020 will ensure that fuel carbon intensity continues to decline and that low-carbon alternatives to petroleum are available in sufficient quantities in the long term. Achieving California's mid and long-term greenhouse gas and air quality goals will require a renewable portfolio of transportation fuels—including electricity and hydrogen—well beyond the current policy trajectories. Accordingly, ARB, in a future rulemaking, will consider extending the LCFS with more aggressive targets for 2030.[22]

An unwarranted reduction to the corn ethanol ILUC score would do more than undermine the actual climate benefits that the LCFS can achieve through 2020; it would lower the ceiling on the long-term effectiveness of the program by extending the period in which marginally beneficial technologies can compete with the far better options that will be available to California after 2020. Chief among these better options may be ammonia, a hydrogen-based energy carrier that CATF has previously discussed with ARB management and staff.

22 California ARB, *Staff Report-Initial Statement of Reasons* (December 30, 2014) at ES-1.

The potential benefits associated with ammonia fuel ammonia are enormous, both for the environment and for the prospects of the LCFS:

- Zero-carbon ammonia can be produced using air, water, and electricity generated by renewable or nuclear power plants, or by fossil fuel-based generating stations equipped with carbon capture and storage systems.
- A wide range of engines and fuel cells can use ammonia to generate electricity or to power vehicles, and can do so without emitting CO_2.
- Substantial global ammonia production and transport infrastructure is already in place. At 150 million metric tons per year, it is the third largest chemical produced globally.
- At $3.27 per gallon (on an energy equivalent basis to gasoline, at current prices) and $1.78 per gallon (when compared against gasoline's 10-year average price), ammonia is affordable. And as a liquid, it can be more easily transported and stored than hydrogen and natural gas.

The steps that need to be taken before a widespread transition to ammonia fuel can occur are significant—but not insurmountable. These include:

- Building awareness among industry, regulators, and other stakeholders about the economic and environmental advantages of using ammonia fuel for power generation and transportation (especially, at the outset, rail and long-haul truck fleets).
- Helping innovators and investors identify small volume/high profit projects to jumpstart the ammonia energy industry.
- Highlighting opportunities to shift ammonia production to zero-carbon processes (e.g., using stranded or otherwise underutilized wind power assets for ammonia synthesis).
- Detailing ammonia's toxicity risk (which is similar to that of LPG), describing how that risk is managed by farmers globally, and outlining protocols for how it can be managed in the power and transportation sectors.
- Developing a long-term roadmap for building up ammonia production and distribution capacity to the scale of a global energy commodity.

LCFS B7-7 cont.

Since CATF briefed ARB on ammonia in July 2014, research in Texas (on ammonia-gasoline blending in internal combustion engines), Toronto (on the use of ammonia to fuel locomotives), and California have continued to validate the concept and develop demonstration projects.

The California project—which involves the University of California at Los Angeles (UCLA), California Energy Commission, and South Coast Air Quality Management District (SCAQMD)—is among the most interesting efforts to date. UCLA is spearheading a comprehensive program to utilize advanced engines from Sturman Industries for a multifuel (gas and ammonia), low NO_x combined-heat-and-power system. The system will be designed, installed, and optimized at a metals foundry in Los Angeles called California Metal-X (CMX). The project goal is to provide power at $0.097/kwh compared to a current base load cost of $0.18/kwh and peak power costs ranging from $0.20-$0.50/kwh from the grid. These cost savings come along with the potential to prove out an ammonia-based, scalable power source that meets the stringent air quality requirements implemented by SCAQMD.

The system will be designed to run in a wide range of modes including pure ammonia as a peak fuel and a variety of combined heat/power modes depending on power pricing, air quality standards, process efficiency, and power export profitability. UCLA, Sturman Industries, and other project partners will instrument the system to test and optimize ammonia engines, emissions, costs, maintenance, safety and other aspects of these types of operations in the real world. This project is being designed to provide a robust prototype for low cost, clean electricity across the California economy. If successful, the project will provide a technology and engineering basis for installing ammonia power in various markets around the world. LCFS B7-7 cont.

CONCLUSION

CATF urges ARB to readopt the LCFS through 2020. Although significant challenges remain, the LCFS is the most promising policy tool available for reducing the climate impacts of the transportation sector. LCFS B7-8

However, that promise is undermined by the proposed adjustment to the lifecycle emissions for corn ethanol, and by the likelihood that regulated entities will increase their reliance on corn ethanol to meet LCFS targets. The proposed adjustment to corn ethanol's lifecycle emissions score rewards corn for its negative impact on global food security. ARB must acknowledge and address this issue before it erodes the legitimacy of the LCFS program. LCFS B7-9

An unwarranted reduction to the corn ethanol ILUC score would also lower the ceiling on the long-term effectiveness of the program by extending the period in which marginally beneficial technologies can compete with the far better options that will be available to California after 2020. The prospects for deep reductions in transportation sector GHG emissions are likely to improve significantly after 2020, particularly if liquid ammonia's potential as an affordable low-carbon fuel is proven out. Estimating Indirect Land Use Change Emissions from Biofuels

CLEAN AIR TASK FORCE

Comments by Clean Air Task Force to California Air Resources Board

On the ILUC emissions estimate discussed in ARB's presentation "iLUC Analysis for the Low Carbon Fuel Standard (Update)" (March 11, 2014)

May 19, 2014

Overview

The Clean Air Task Force (CATF) is a non-profit environmental organization that works to protect the earth's atmosphere by improving air quality and reducing global climate change through scientific research, public advocacy, technological innovation, and private sector collaboration. CATF is pleased to submit the following comments to the California Air Resources Board concerning ARB's review of the indirect land use change (ILUC) emissions associated with biofuels and how those emissions are accounted for within the state's Low Carbon Fuel Standard (LCFS).

Although research into the effect that biofuels have on climate change is marked by uncertainty and controversy, it is increasingly evident that the production and consumption of some types of biofuels are undermining efforts to reduce greenhouse gas (GHG) emissions. As compared to other policies being used to promote biofuels—most notably, the federal Renewable Fuel Standard—the LCFS represents a significantly better platform for evaluating net GHG emissions and rewarding the fuels with the lowest carbon intensities. CATF is therefore committed to helping ARB ensure that the best and most current research is used to inform its assessments of the carbon intensities of different fuels, especially biofuels. LCFS B7-11

These comments highlight three factors that ARB should take into account as it evaluates the ILUC emissions estimate used to calculate the carbon intensity of biofuels in the LCFS context:

- Studies that supposedly demonstrate a trend toward lower ILUC emissions estimates—including versions of the Global Trade Analysis Project (GTAP) model that ARB relies upon to implement the LCFS—typically ignore how water scarcity constraints will impact crop expansion. A recent analysis that takes water scarcity into account finds that earlier studies "likely underestimated induced land use emissions due to ethanol production by more than one quarter." LCFS B7-12
- GTAP's inability to differentiate commercial forest from non-commercial forests means that the model wrongly assumes that markets respond to the conversion of both land types in the same way. LCFS B7-13
- The yield improvement assumptions in GTAP overlook important differences among crops and growing regions, they fail to incorporate new research on future corn yields LCFS B7-14

in the Midwest United States, and they do not adequately address the climate impact associated with the increased use of nitrogen-based fertilizers to sustain yield growth. LCFS B7-14 cont.

Each of these factors separately suggest that the GTAP model is currently under-counting ILUC emissions. Taken together, they indicate that a reduction to the ILUC emissions estimate discussed in ARB's March 11, 2014, presentation, "iLUC Analysis for the Low Carbon Fuel Standard (Update),"[1] would not be appropriate. CATF therefore urges ARB to keep the ILUC estimate at its current level until ARB can more fully account for the issues raised here and at the March workshop. LCFS B7-15

[I] The "Trend" Toward Lower ILUC Emission Estimates Is Illusory

In California (as in Washington DC), the ethanol industry has aggressively promoted the idea that ILUC emissions estimates for corn ethanol are steadily trending downward as new lifecycle analyses are published. The industry places particularly high value on particular publications by Purdue researchers Wally Tyner and Farzad Taheripour that point toward relatively low estimates of ILUC emissions, e.g., a 2012 paper that reduces the estimated land requirements for US ethanol production by 25%.[2] The cited studies have important shortcomings, however—a problem that is exemplified by the way in which the studies have ignored real-world constraints on the amount of water available for new agriculture.

In fact, more recent work by Taheripour is intended to correct this oversight. In a 2013 study he co-authored by Thomas Hertel and Jing Liu, two other researchers from Purdue, he writes: "[I]n contrast to the recent trend in such studies, incorporating explicit modeling of irrigation, and associated constraints, *significantly raises the land-based emissions associated with biofuel expansion*."[3] LCFS B7-16

Taheripour *et al.* (2013) opens with two key points. First, water availability is essential to understanding the land use impact of biofuel expansion, especially with water availability projected to decrease over the next two decades.

> [T]he question of whether expansion of global cropland cover involves irrigated or rainfed lands make a significant difference in terms of how much new land will be required to provide the additional production called for in the presence of biofuels ... [I]f the expansion of irrigated land is constrained, either due to insufficient water or due to insufficient pumping capacity, then it is likely that more cropland area will be required to meet the additional global demand induced by ethanol production.[4]

The authors cite recent studies that predict large water deficits, including an analysis by McKinsey which estimates that by 2030 water demand will exceed water supply by 40%. "In summary," Taheripour *et al.* write, "it appears that water for agricultural irrigation will become much more expensive in the future – no doubt spurring considerable efficiency gains, but also raising the cost of production and therefore limiting the amount of land on which irrigated crops can be economically grown."[5]

Second, refining land use change models to account for real-world constraints on water availability reveals a greater likelihood that biofuels expansion will drive displaced agricultural LCFS B7-17 production into areas that are rainfed. "These regions tend to be more carbon rich and therefore exhibit higher ILUC emission factors," write Taheripour *et al.* "Therefore, earlier models which ignore the role of irrigation in crop expansion tend to underestimate the ILUC emissions due to biofuel expansion."[6]

LCFS B7-17 cont.

One such model is GTAP-BIO, which Taheripour and Tyner used in the earlier 2012 study to assess the land use impacts of the 2015 ethanol mandate in the US Renewable Fuel Standard.[7] (GTAP-BIO, of course, is used to generate the emissions estimates for biofuels that ARB relies upon to implement the LCFS.) The enhancements that Taherpour *et al.* make to GTAP in the 2013 study allow the model to recognize water scarcity constraints and distinguish between rain-fed and irrigated land. Figures 3 and 6 from Taheripour *et al.* (2013) illustrate the extent to which the intensity of global land use change can differ when models are programmed to distinguish between irrigated crops and rainfed crops, and when constraints on water availability are introduced:

LCFS B7-18

Fig. 3 from Taheripour et al. (2013)

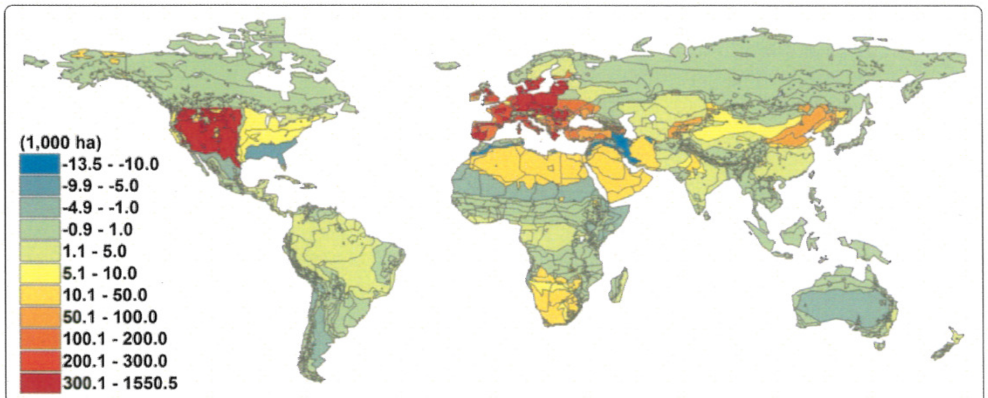

Figure 3 Irrigated cropland cover change, without irrigation constraint.

Fig. 6 from Taheripour et al. (2013)

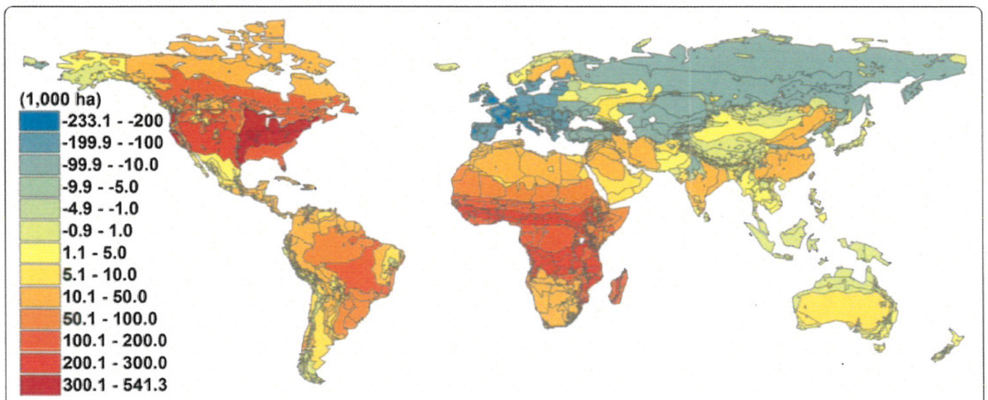

Figure 6 Rainfed cropland cover change, with irrigation constraint. Figures 3, 4, 5, 6 represent change in harvested areas.

By sensitizing the model to these factors, the 2013 study finds that ILUC emissions are likely to be substantially higher than prior estimates:

> [I]ncreasing US ethanol production from its 2001 level to 56.78 billion liters causes about 35.6 g CO2e/MJ emissions if there is no irrigation constraint across the world. Factoring in the physical limitations on irrigation expansion increases the land-based emissions to 45.4 g CO_2e/MJ. This means that the physical water scarcity adds 27.5% to the emissions due to land use changes induced by ethanol expansion. As shown in Table 5 [excerpted below], the constrained case also generates 27.5% more emissions compared to the case wherein we ignore irrigation altogether. This means that earlier studies, which failed to distinguish rainfed from irrigated lands, likely underestimated induced land use emissions due to ethanol production by more than one quarter.[8]

LCFS B7-18 cont.

Table 5 from Taheripour et al. (2013)

Table 5 Land use emissions due to US ethanol production

Simulations	Ethanol production (billion liters)	Annualized ILUC emissions	
		(g CO_2e/MJ)	Deviation from no-irrigation (%)
Unconstrained	50.08	35.6	−0.05
No-irrigation	50.08	35.6	0.0
Constrained	50.08	45.4	27.5

An additional point worth noting in this context is that both of the values cited in the 2013 study for corn ethanol—35.6 and 45.4 g CO_2e/MJ—are higher than the central values that ARB presented at the March 11 workshop (30.0 and 23.2 g CO_2e/MJ).[9]

In its March 2014 presentation, ARB staff notified the Board that the current version of GTAP fails to differentiate between the irrigated and rain-fed land and assumes that the water availability (or, rather, the unavailability of water) does not affect the model's estimates concerning the conversion of new land for crop production. Staff flagged two of the problems connected with this assumption—water is not an unlimited resource, and it cost money to irrigate newly converted cropland—and pointed out that, "Crop expansion and crop switching decisions will require availability of water resource and may change model predictions."[10] According to the presentation, staff plans to collect data on water availability, productivity differences, and land elasticity, and integrate those data into a revised GTAP model within the next few months.[11]

LCFS B7-19

This effort to incorporate water-related restrictions on biofuel demand-driven cropland expansion is likely to materially affect ARB's estimate of the net GHG emissions associated with the LCFS. The 2013 study by Taheripour *et al.* indicates that ignoring the role of irrigation in cropland expansion "introduces systematic biases in the measurement of the size and pattern of global land use changes and therefore the land use emissions due to production of biofuels."[12]

We therefore encourage ARB to ensure that water constraints are accounted for in the lifecycle emissions analyses used to assess the treatment of biofuels within the LCFS.

[II] GTAP's Treatment of Forest Conversion Artificially Suppresses ILUC Emissions

Currently GTAP represents three land-use classes: forestry, pasture, and cropland. These are economic uses of land, however, not land-cover types. That is, GTAP does not represent forests generally; it represents economically productive timberland. As a result, the model assumes that any conversion of forestry land causes a reduction in timber supply, which in turn creates upward pressure on timber prices. This assumption has two effects that are likely to produce lower projected ILUC emissions.

First, the opportunity cost of converting commercial forestry land is greater than the opportunity cost of converting forestland that is not in economic use. The assumption within GTAP that all forestland is commercially managed therefore exaggerates the economic limits on non-commercial forest conversion. Consequently, the model likely projects less overall forest conversion than it would if it differentiated between commercial and non-commercial forests and made both types available for conversion.

Second, once commercial forestland is converted, there is an *afforestation* response elsewhere that makes up some portion of the lost timber supply. GTAP fails to appreciate that the conversion of non-commercial forestland would not produce a similar afforestation response. LCFS B7-20

Notably, other models used to estimate land-use change emissions—including IFPRI's MIRAGE, MIT's EPPA, and PNNL's GCAM—allow for the conversion of non-commercial forestland.

ARB staff referenced these concerns in their presentation for the March 2014 workshop, explaining that GTAP's inability to differentiate between forest categories "creates unrealistic deficit from wood products in the forestry sector."[13] A temporary fix involving adjustments to the Land Transformation Elasticity (ETL) values was proposed, with a completion target of April 2014.[14] It is not clear from ARB's website whether this fix has been executed or how the adjustment impacts the ILUC estimate. CATF cannot specifically comment on the proposed fix until we have reviewed the results of the ETL adjustment, but we are encouraged that ARB has identified this problem and is committed to addressing it. We urge ARB to ensure that its ILUC determination is based on land use modeling that effectively differentiates between commercial and non-commerical forestland.

[III] Aspects of GTAP's Treatment of Yield Problematically Affect ILUC Analysis

Several of the ways in which GTAP treats future crop yields are suppressing the model's ILUC emission projections. These include the model's assumption that price-induced yield improvements for all crops in all regions will match the improvement rate projected for Midwestern US corn, the model's current failure to accommodate new research suggesting that future corn yield improvements in the Midwest US could decelerate, and model's ongoing failure to adequately address the climate impact associated with the increased use of nitrogen-based fertilizers to sustain yield growth. LCFS B7-21

[A] GTAP's Handling of Yield Price Elasticity Suppresses ILUC Estimates

Yield price elasticity is perhaps the most controversial parameter in the GTAP model. GTAP utilizes a single number which determines how much yields—of all crops, in all regions—increase in response to price increases. Most arguments about price-induced yield improvements have focused on the "correct" value for this parameter, while failing to recognize that no such parameter exists in the real world: no single value can properly capture the substantial variability across crop types, climatic conditions, and economic conditions.

In practice, nearly all of the discussion about this parameter is informed by studies of one crop grown in one region—*i.e.*, corn grown in the US Corn Belt. There is little reason to expect that the yield effects measured for corn in the Midwest, a growing region characterized by fertile soil and readily available capital, to be representative of the effect that minor price increases have on, say, rice yield in developing regions. LCFS B7-22

When setting a range of values to consider for yield price elasticity within GTAP, ARB must treat this parameter as representing the *average* yield elasticity for all crops, in all regions, which is likely to be lower than what has been achieved by corn growers in the United States. The high values suggested for the US corn should be treated as the maximum obtainable. If GTAP assumed (appropriately) that not all crops grown around the world will achieve the same level of yield price elasticity as US corn, estimated ILUC emissions would likely increase.

[B] GTAP Does Not Incorporate New Research on Future Corn Yields

The assumptions made in GTAP about future crop yields do not yet take into account important new research by David Lobell and others on the impact that future drought conditions will have on Midwest US corn yields over the next 50 years. According to the study—Lobell *et al.*, "Greater Sensitivity to Drought Accompanies Maize Yield Increase in the U.S. Midwest," SCIENCE (May 2, 2014)—a greater incidence of midsummer drought conditions will slow the steady improvement in corn yields that farmers have historically achieved by increasing their cropping density. Assuming that finding is corroborated, it should be incorporated into GTAP's assumptions about future yield improvement.

According to the study, a handful of factors have allowed farmers to increase the density at which they plant corn and soy—e.g., no-till agricultural, higher ambient CO_2 concentrations, and genetic enhancements. Increased density has contributed to yield improvements, but it also "can be detrimental under drought conditions because of excessive stress exposure for individual plants."[15] The authors examined how corn and soy respond to various environmental stresses to determine "the net effect of recent genetic, agronomic, and environmental changes on drought sensitivity." They find that corn yields are particularly sensitive to increases in daytime vapor pressure deficit (VPD), "a widely used measure of atmospheric water demand that depends on air temperature and humidity." VDP increases appear to be especially impactful when they occur 2-3 months after a corn crop is sowed.[16] As Figure 4(B) from Lobell *et al.* shows, VDP during that timeframe (July, approximately) is expected to climb significantly over the next forty years: LCFS B7-23

Fig. 4 from Lobell et al. (2014)

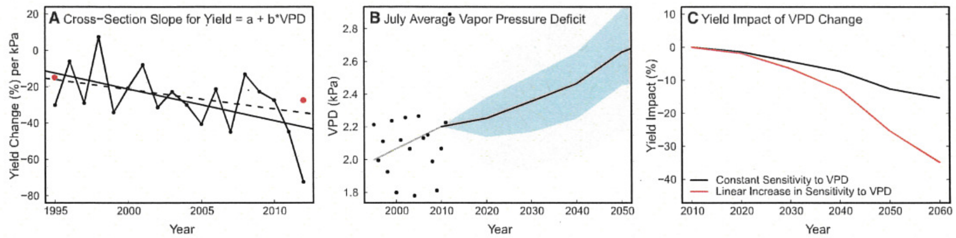

Fig. 4. Changes in vapor pressure deficit and its impacts. **(A)** Estimates of maize yield sensitivity to VPD 61 to 90 days after sowing from a cross-sectional regression for each year in the study period, along with best-fit trend lines with (solid) or without (dashed) including 2012 for computing the trend. Red dots indicate sensitivity estimates from APSIM simulations with sowing densities corresponding to the start and end of the study period. **(B)** Average July VPD in the study region for historical and projected periods. Dots show individual year observations, gray line shows linear trend for 1995 to 2012, black line shows mean VPD projected using 29 climate models, blue shading indicates 25th to 75th percentile of model projections, and gray shading indicates 5th to 95th percentiles. **(C)** Estimated impact of mean VPD projections on average maize yields using either constant yield sensitivity of −27.5% per kPa or a linear increase in sensitivity at the historical rate of 7% per kPa per decade.

The study concludes that if corn-growing regions continue to experience hotter and drier Julys, current projections for corn yield improvements are unlikely to be met: LCFS B7-23 cont.

> One implication is that climate change effects may be more severe than predicted by models that assume current crop genetics and management. Climate model projections indicate that July VPD for this region will become more severe, with an expected increase in average VPD of roughly 20% over the next 50 years (Fig. 4B), driven both by higher temperatures and reduced relative humidity. At current VPD sensitivity, these VPD trends would reduce yields by about 15% over the next 50 years. If maize yields continue to become increasingly sensitive to VPD, then yield losses from VPD trends could be as much as 30% (Fig. 4C).[17]

In addition to casting doubt on long-term yield projections for corn (the feedstock used to produce more than 80% of the biofuel consumed in the United States in 2013), Lobell *et al.*'s findings support the point made above that ARB should not use a yield price elasticity value for corn as a proxy for the elasticity of other crops' yields. Lobell *et al.* demonstrate that there are important physical constraints on corn yields that farmers may not be able to overcome through the commitment of additional resources. Accordingly, the study suggests that GTAP's yield price elasticity value for corn may not be appropriate for corn, much less for other crops.

Consequently, ARB should ensure that the new work by Lobell *et al.* informs future yield projections and the effect those projections have on ILUC estimates.

[C] ARB's Modeling Framework Undercounts N_2O Emissions

The modeling framework used by ARB assumes that yields for a wide range of crops will climb in response to increased demand for biofuel feedstocks, but it does not adequately account for the extra emissions associated with the farming techniques that will be utilized to achieve those higher yields. The likely result of ARB's approach is that ILUC emissions are undercounted. LCFS B7-24

Adding fertilizer, for example, results in additional emissions of nitrous oxide (N_2O), a potent greenhouse gas. ARB's modeling framework currently accounts only for the N_2O emissions that result from fertilization of the feedstock crops used to produce biofuels. This approach ignores the additional use of fertilizer for other crops, even when that additional usage is tied to an overall rise in crop prices brought about by new demand for energy crops. Under the existing modeling framework, therefore, the benefit of price-induced yield increases are counted, while the cost to climate of achieving those increases is not. If ARB accounts for both sides of the equation—*i.e.*, improved yields *and* higher N_2O emissions—as it should, estimated ILUC emissions are likely to increase. LCFS B7-24 cont.

In the March 2014 presentation, ARB staff acknowledged that both crop intensification and crop extensification associated with increased biofuel demand could result in additional N_2O emissions.[18] We urge ARB to fully account for these emissions when estimating ILUC emissions.

[D] GTAP's Treatment of Marginal Crop Yields Increases Uncertainty

One of the recent changes to GTAP that contributed to the proposed reduction in ILUC emissions relates to how the model represents yield on newly converted cropland. GTAP previously relied on a single value of 0.66 to represent the relative productivity of newly converted land,[19] until Taheripour *et al.* (2012) used the Terrestrial Ecosystem Model (TEM) to estimate relative yields on a regional basis.[20] The shift to regionalized estimates is an improvement conceptually, but the implementation of this change creates additional uncertainty—leaving in doubt whether this change produces a better representation of reality.

To implement this change, Taheripour *et al.* estimated the average net primary productivity (NPP) of a single crop—based on corn grown in the US Corn Belt—for land not currently used for crop production in each Region-AEZ combination, and the average NPP of land currently in crop production in that Region-AEZ.[21] The ratio of these NPP values—truncated to a maximum value of 1.0[22]—is used as a proxy for the relative yield of newly converted cropland.[23] This approach implicitly incorporates the following assumptions:

- *That Iowa's 1996 corn season is an appropriate proxy for all crops grown around the world.* (TEM is parameterized using data for corn grown in 1996 in Iowa, one of the world's most productive corn producing regions.) LCFS B7-25
- *That NPP is a good proxy for yield, and the difference in yield between these two land-use classes is best represented as a constant ratio (A/B) rather than, say, a constant difference (A-B).*
- *That TEM's estimate of NPP is correct.* (Pan *et al.* (1996) performed sensitivity analysis on the TEM model (version 4.0), showing that estimated NPP is sensitive to different assumptions about soil texture, temperature, precipitation, and radiation—all of which may vary within a given Region-AEZ.[24])
- *That the average NPP of all land not in crop production is a good approximation of NPP on the land actually converted.* (This assumption holds true only when land selection is random or there is little variability of NPP across land in the Region-AEZ. Neither of these are claimed to be the case in the study.)
- *That truncating some of the NPP ratios to 1.0 produces a valid estimate of marginal yield.* (Taheripour *et al.* make this adjustment in their 2012 study as a way of recognizing the unlikelihood that yields are better on land not being used for production. It remains unclear, however, why this adjustment is necessary if the basic method of computing

NPP and using the ratio is valid. In other words, if the method produces values that are believed to be unrealistically high in some cases, what basis is there to believe that the other values produced by TEM (*i.e.*, those <1.0) are not likewise too high?)

LCFS B7-25 cont.

In principle, regionalized estimates of marginal yield can produce more accurate model results. Whether this is true in practice, however, depends on how the regionalized values are determined. It is unclear whether the present implementation brings GTAP results closer to reality or further from it.

Conclusion

CATF believes that California's LCFS can play a globally important role in identifying and promoting fuels that can meaningfully reduce GHG emissions from transportation. We therefore appreciate the opportunity to help ARB ensure that the best and most current research is used to assess the carbon intensities of different fuels, particularly biofuels.

LCFS B7-26

In order to develop a more reliable ILUC estimate, CATF urges ARB should ensure that its model fully appreciates the extent to which water scarcity will constrain future crop expansion, effectively differentiates commercial forest from non-commercial forests, and utilizes the most comprehensive and up-to-date data on yield improvements.

LCFS B7-27

Sincerely,

Jonathan F. Lewis

7_B_LCFS_CATF Responses

632. Comment: **LCFS B7-2, LCFS B7-3, LCFS B7-6, LCFS B7-9, LCFS B7-10, and LCFS B7-12**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

633. Comment: **LCFS B7-1**

The comment requests that the Board to re-adopt the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

634. Comment: **LCFS B7-4**

The comment expresses concern about the proposed iLUC reduction for corn ethanol.

Agency Response: See response to **LCFS 29-2**, **LCFS 29-3**, and **LCFS 29-5** to **LCFS 29-11**.

635. Comment: **LCFS B7-5**

The comment states that reducing the iLUC score for corn ethanol could be counter to climate mitigation policy.

Agency Response: ARB staff disagrees and believes that we have used the best science. See response to **LCFS 29-2**, **LCFS 29-3**, and **LCFS 29-5** to **LCFS 29-11**.

636. Comment: **LCFS B7-7**

The comment states that the reduced iLUC score for corn ethanol would lower the ceiling on the long-term effectiveness of the program.

Agency Response: See response to **LCFS 29-2**, **LCFS 29-3**, and **LCFS 29-5** to **LCFS 29-11**.

637. Comment: **LCFS B7-8**

The comment supports the re-adoption of the LCFS program through 2020.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS.

638. Comment: **LCFS B7-11**

The comment states that the LCFS program represents a valuable platform for evaluating net GHG emissions and rewarding the fuels with the lowest carbon intensities.

Agency Response: ARB staff welcomes the stakeholders' commitment to offer assistance on lifecycle analyses of transportation fuels.

639. Comment: **LCFS B7-13**

The comment states that GTAP's inability to differentiate commercial forest and non-commercial forests should be taken into account as ARB staff evaluate iLUC emissions estimates.

Agency Response: See response to **LCFS 29-6**.

640. Comment: **LCFS B7-14**

The comment states that the yield improvement assumptions in GTAP overlook several factors.

Agency Response: See response to **LCFS 29-7** and **LCFS 8-9**.

641. Comment: **LCFS B7-15**

The comment states that the GTAP model is currently under-counting iLUC emission.

Agency Response: ARB staff does not agree with commenter that the current analysis under-counts iLUC emissions. The current analysis takes into account updates to data and land use science and represents the best estimate of iLUC emissions. Staff remains committed, however, to monitor new data and updates to land-use change science, and to revise the iLUC analysis when supported by science and data. See also responses to **LCFS 29-5 to LCFS 29-7**.

642. Comment: **LCFS B7-16**

The comment states that past studies have not properly accounted for water availability issues.

Agency Response: ARB staff acknowledges the concern expressed by the commenter related to the need to account for water constraints in agriculture. ARB's Global Trade Analysis Project (GTAP) model was modified in 2014 to disaggregate cropland into rain-fed and irrigated areas to account for the issues highlighted by the commenter. The current ARB GTAP model uses the latest data for irrigation water availability (obtained from the World Resources Institute, WRI) and includes methodology to limit expansion into irrigated cropland if constrained by water scarcity. The McKinsey report cited in the work of Taheripour and Tyner estimates water scarcity for 2030; whereas WRI modeling of water scarcity uses data from 2004-2010 to estimate water scarcity constraints which is the period of interest for the current analysis. See also response to **LCFS 29-5**.

643. Comment: **LCFS B7-17**

This comment states that refining land use change models to account for real-world constraints on water availability reveals a greater likelihood that biofuel expansion will drive displaced agricultural production in areas that are rainfed, and that models which do not account for this tend to underestimate iLUC emissions due to biofuel expansion.

Agency Response: In the current analysis, cropland was disaggregated into rainfed and irrigated areas in the GTAP model. The current ARB GTAP model uses the latest data on irrigation water availability (obtained from the World Resources Institute) and includes methodology to limit expansion into irrigated cropland if constrained by water scarcity. The current ARB analysis allows expansion into rain-fed regions where it is necessary. However, there is no detailed data for carbon stocks by agro-ecological zone (AEZ) and region to distinguish differences in stored carbon between rainfed and irrigated cropland. When data becomes available, ARB staff will include these parameters into the model and update iLUC analysis in the future. See also response to **LCFS 29-5**.

644. Comment: **LCFS B7-18**

The comment presents information that ethanol production emissions are likely to be higher than the LCFS regulation estimates.

Agency Response: Rain-fed and irrigated crop sectors were included in the GTAP model after the March 2014 workshop. In the analysis by Taheripour et al., as reported by the commenter, the authors used an older (2001) database and an older model different than the current ARB model. Also, in their analysis, assumptions related to rainfed and irrigated lands are outdated. Furthermore, the older model used by Taheripour et al. does not include current elasticity structures and does not disaggregate crops. Given that the Taheripour et al. work relies on a model that is different from ARB's version, the iLUC values listed in their work are also different from the iLUC estimates from ARB's model. See also responses to **LCFS B7-16** and **LCFS 29-5**.

645. Comment: **LCFS B7-19**

The comment encourages ARB staff to ensure that water constraints are accounted for in the lifecycle emissions analyses.

Agency Response: ARB staff addressed the concerns expressed by the commenter by including rain-fed and irrigated crop sectors in the GTAP model. The current ARB GTAP model accounts for water availability throughout the biofuels production system and uses the latest water scarcity data from the World Resources Institute. See also responses to **LCFS B7-16**, **LCFS B7-18** and **LCFS 29-5**.

646. Comment: **LCFS B7-20**

The comment urges ARB staff to ensure that the iLUC values are based on land use modeling that differentiates between commercial and non-commercial forestland.

Agency Response: It is true that the current version of the GTAP model does not differentiate between commercially-managed forest and non-commercial forest by region and AEZ. As a result, it is necessary to use the same market response to land conversion both for commercial and non-commercial forests until pertinent data is available because ARB staff cannot predict if inclusion of the non-commercial forest category in the GTAP model leads to higher forest conversion. See also response to **LCFS 29-6**.

ARB staff recognizes the potential for 'afforestation' resulting from deficits in wood products. When additional data differentiating the two categories of forests and the corresponding market responses is available, staff will modify the model to incorporate commercially-managed forest and non-commercial forest by region and AEZ.

Due to the scarcity of data, the current model structure and methodology do not allow for the inclusion of non-commercial forestland into the GTAP model. There is just one forest category in the model. Data will be collected and the methodology adjusted accordingly to account for the conversion of commercial and non-commercial forests in future model updates.

To address the issue related to deficit from wood products in the forestry sector, ARB staff worked collaboratively with researchers at Purdue to calibrate land transformation elasticity values to mitigate such effects. The final set of values for land transformation elasticities are provided in Table I-3 in Appendix I of the ISOR.

647. Comment: **LCFS B7-21**

The commenter states that GTAP's treatment of crop yields fails to accommodate new research that suggests corn yield improvements in the Midwest could decelerate in the future and that the model continues to fail to address the related climate impact from increased use of fertilizers to sustain yield growth.

Agency Response: The commenter states that GTAP's treatment of crop yields fails to accommodate new research that suggests corn yield improvements in the Midwest could decelerate in the future and that the model continues to fail to address the related climate impact from increased use of fertilizers to sustain yield growth. Staff has committed to incorporate data that differentiates yield improvements of different corps for different growing regions in future model updates. Regarding the effects of nitrogen-based fertilizers, current ARB methodology accounts for the increased emissions of nitrogen-based fertilizer in the direct analysis of carbon intensity (CI) for biofuels feedstock. When data becomes available for all other crops, ARB staff will evaluate these impacts in future model updates. See also response to **LCFS 29-7**.

648. Comment: **LCFS B7-22**

The comment questions the current method for determining the yield price elasticity parameter in GTAP.

Agency Response: The GTAP model includes elements that capture critical drivers impacting agricultural and other sectors of the economy. Yield Price Elasticity (YPE) is a parameter in the model to account for price-induced yield changes in agricultural crops. There are other elements in the model such as disaggregation by

AEZ which captures climatic conditions, calibrated parameters to capture economic decisions, etc. See also response to **LCFS 8-9**.

649. Comment: **LCFS B7-23**

The comment requests ARB staff to ensure that the latest work is used to inform future yield projections and the effect those projections has on iLUC estimates.

Agency Response: The commenter's request that ARB staff account for decreases in yields based on the published article by David Lobell is outside the scope of the present analysis. Future work that may consider expanding the LCFS targets beyond 2020 could potentially address the issues related to decreases in yield due to local atmospheric conditions and other factors.

650. Comment: **LCFS B7-24**

The comment requests that ARB staff take into account that crop intensification and crop extensification associated with increased biofuel demand when developing estimated iLUC emissions.

Agency Response: Current ARB methodology accounts for increased N_2O emissions from nitrogen-based fertilizers in the direct analysis of carbon intensity (CI) values for various biofuel feedstocks. ARB staff acknowledges, however, that additional N_2O emissions are likely a result of intensification and extensification associated with increased biofuel demand, but the data for other crops and regions are insufficient to separate the effects of direct analysis from the effects related to land-use changes within the GTAP framework. To avoid the potential for double-counting, ARB staff decided to take a conservative approach and did not include emissions from intensification-extensification. When data becomes available for all crops and regions, staff will evaluate these impacts and include them in future model updates. See also response to **LCFS B7-22**.

651. Comment: **LCFS B7-25**

The comment questions the change from using a single value to represent relative productivity of newly converted land to using the Terrestrial Ecosystem Model (TEM).

Agency Response: ARB staff disagrees that changes to the GTAP model to account for regionalized productivity are less representative of reality. The Terrestrial Ecosystem Model (TEM) approach using average net primary productivity (NPP) as a surrogate for yield estimates for newly converted land provides the best approximation to crop yields on newly converted land in relation to yields on existing cropland. Researchers at Purdue used data for C4 and C3 crops (not exclusively corn as stated by the commenter) to estimate the relative productivity of newly converted land. The following addresses the bulleted list of assumptions regarding NPP that were identified by the commenter:

- The TEM does not use Iowa's 1996 corn season as a proxy for all crops grown around the world. The model, in fact, uses inputs for various crops.

- Taking the difference in yield between land not currently used for production and the average NPP of land currently in crop production does not represent any more meaningful use of these outputs from the TEM model compared to the use of a ratio of the two values. Ratios allow for the consideration of relative productivity of the two types of lands being modeled using the TEM model.

- ARB staff acknowledges that model outputs are sensitive to assumptions about soil texture, temperature, etc. However, if the two sets of runs (i.e., NPP for existing cropland and NPP for newly converted land) use the same inputs, then use of ratios ensures that outputs from both cases are scaled appropriately to ensure ratios remain similar (i.e., varying inputs could generate different inputs but ratios of outputs are likely similar within acceptable variability of input values).

- NPP by AEZ is actually a weighted average of gridded cells used in the modeling and therefore represents a reasonable estimate of average for an AEZ in a region.

Land currently in production usually has the highest productivity among all land available locally. New land that comes into production is expected to have lower productivity. Researchers at Purdue used this reasoning to justify limiting the maximum estimated productivity of new cropland to be no higher than existing cropland (by truncating NPP ratios to 1.0). To assess the impacts of non-truncation for values lower than 1.0, ARB staff conducted a Monte Carlo analysis using a range of potential variables in the NPP values. The Monte Carlo analysis did not indicate that variability in NPP was a significant contributor to the overall variability of iLUC values. ARB staff, however, recognizes that there may be other approaches to improve estimates of new converted land. ARB staff will re-evaluate the productivity of newly converted land when data and new methodologies become available for use in future updates.

652. Comment: **LCFS B7-26**

The comment states appreciation for the opportunity to help ARB staff ensure that the best and most current research is used to assess the carbon intensities of different fuels.

Agency Response: See response to **LCFS B7-11**.

653. Comment: **LCFS B7-27**

The comment requests ARB staff to ensure that its model fully incorporates the effects of water scarcity, effectively differentiates commercial and non-commercial forests, and uses the most up-to-date data on yield improvements.

Agency Response: See responses to **LCFS B7-13**, **LCFS B7-14, LCFS B7-16** to **LCFS B7-18**, and **LCFS B7-23**.

San Francisco, CA 94104

Chair Mary Nichols
California Air Resources Board
1001 I St.
Sacramento CA, 95814

Dear Chair Nichols:

On behalf of NextGen Climate, I would like to thank the Air Resources Board for the opportunity to comment on the proposed re-adoption of the Low Carbon Fuel Standard. NextGen Climate America is dedicated to preventing climate disaster and enabling American prosperity. We recognize the critical role transportation plays in climate policy and we strongly support extending California's Low Carbon Fuel Standard (LCFS). Fuel carbon policies, like the LCFS, are a critical element in a comprehensive climate policy and provide an essential incentive for bringing advanced low-carbon technologies into commercial deployment as economies transition to long-term sustainability.

California's s Low Carbon Fuel Standard Shows Leadership on a Key Climate Issue

LCFS B8-1

Transportation accounted for approximately 37% of California's greenhouse gas (GHG) emissions[1]. The share of emissions from transportation is generally expected to go up over the next decade in western U.S. states due to reductions in emissions from non-transportation sectors of the economy. Recognizing the critical need for carbon reduction policies California joined Oregon, Washington and British Columbia in agreeing to groundbreaking climate policy through participation in the Pacific Coast Collaborative (PCC). The success of the PCC efforts towards sustainable fuels policy is a direct result of the leadership the Air Resources Board showed in implementing the first-of-its-kind Low Carbon Fuel Standard. Low carbon fuels policy is necessary element in achieving long term climate sustainability. If the emissions from transportation are not substantially reduced, it is virtually impossible for any state to meet its climate goals. California can set an example the rest of the world can follow by continuing this groundbreaking policy.

Low Carbon Fuel Standards Enable a Smooth Transition to a Sustainable Future

LCFS B8-2

Low carbon fuel policies achieve two goals: direct reduction of carbon emissions and incentivizing commercial deployment of advanced technologies. The latter goal is a niche that few other options in the policy toolkit can address in as direct, efficient and timely a fashion. By creating a market-based incentive structure that provides greater rewards for

[1] CARB (2014) *California's Greenhouse Gas Emission Inventory* http://www.arb.ca.gov/cc/inventory/inventory_current.htm

fuels which yield greater carbon reductions, the Low Carbon Fuel Standard would help the most advanced technologies reach market sooner, so that future, bigger reductions can be attained in a cost effective manner. Without technology-promoting policies like a Low Carbon Fuel Standard, there is a risk that highly efficient technology will not develop quickly enough to meet long term goals. LCFS B8-2 cont.

Recent Research Has Demonstrated that California's Targets Can be Met with Likely Fuel Supplies

Several recent research reports, including the *Pacific Coast Collaborative Low Carbon Fuel Availability Study* from the International Council on Clean Transportation and E4tech, and from Promotum have demonstrated that there are a variety of technological and supply pathways which can meet California's low-carbon fuel demands in a cost-effective manner[2,3]. Already, electric vehicles, including plug-in hybrids, are demonstrating that they are cost-competitive and commercially attractive options in the passenger vehicle market. Existing biofuel production facilities are reducing their carbon emissions through efficiency enhancements and greater use of renewable energy. The first two advanced cellulosic ethanol production facilities in the U.S. came online in the last quarter of 2014, with other projects in various stages of demonstration or commercialization, including in California[4]. There are many combinations of fuels and technologies which would allow California to meet its goals under the proposed Low Carbon Fuel Standard. This flexibility will help minimize cost by allowing fuel markets to find the lowest cost pathways for decarbonization. LCFS B8-3

Cost Containment through a Credit Clearance Market Will Mitigate the Effect of Price Spikes

While there is a growing body of evidence to indicate that the LCFS credit market is appropriately regulated and balanced[5], we recognize that there is value in providing additional levels of cost containment. In order to protect California consumers and businesses, we support the creation of a Credit Clearance Market, to effectively cap the LCFS credit prices in times of excessive demand. LCFS B8-4

A Credit Floor Price Would Give Needed Certainty to Prospective Advanced Low-Carbon Fuel Producers

While the fundamental nature of the LCFS provides a critical incentive for advanced fuels (e.g. cellulosic biofuels, renewable diesel or hydrogen) to enter the market, this incentive often lacks the certainty required for prospective fuel producers to access capital markets LCFS B8-5

and build commercial-scale production facilities. Part of this uncertainty revolves around the value of LCFS credits. Credit values have been relatively low for most of the program's history and the best projections indicate an over-supply of credits for the next 2-3 years[6]. This over-supply could risk a decline in credit prices during this period. At the same time, it is critical that advanced, low-carbon fuel producers expand production capacity during this time in order to meet stricter targets in the 2019-2020 timeframe.

Creating a floor price on LCFS credits can help create this certainty and bring more advanced fuel producers into commercial production. This would not only help the LCFS program meet its goals, but would create a more robust and liquid market for low carbon fuels, which would protect California's consumers and businesses from supply-related price increases in the future.

LCFS B8-5 cont.

Carbon Intensities Need to be Regularly Re-Evaluated

Low carbon fuel production is still an emerging field, particularly as it relates to advanced biofuels. Scientific understanding of biofuel production processes is rapidly improving, as are the tools for conducting objective and accurate life cycle analyses. It is very likely that as our understanding of these systems, and our tools for evaluation improve, existing Carbon Intensity (CI) values will be revised. We urge the board to include a regular review process and procedure for modifying existing carbon intensities as better information emerges. We recognize the need to provide long term certainty to fuel providers regarding the value of their fuels and urge the board to find a balanced solution that allows for appropriate revision of CI numbers with a sufficient lead-in or phase-in time to allow producers to compensate for any changes and react appropriately.

LCFS B8-6

Soil Carbon Changes May be Insufficiently Addresses by Current CI Calculations

Agricultural residues are thought to be a critical feedstock for biofuel or bioenergy production[7]. Emerging science is starting to question the assumption that agricultural residues can be removed for biofuel use without impacting soil characteristics, such as stored soil carbon[8,9]. While there is still substantial research ongoing, depleting soil carbon as a result of residue removal can result in fuels which offer limited value towards carbon reduction and may even be worse than the fuels they replace[10]. Given the critical importance of California's LCFS in setting standards for similar policies on the West Coast and beyond, it is absolutely essential that this determination be made with the greatest level of scientific certainty. Please review Attachment 1[11], research which aggregates data from several existing

studies of the effect of corn stover removal on soil carbon levels, which finds evidence of significant soil carbon loss even at moderate levels of corn stover removal. This research is not, by itself, definitive on the subject but it indicates that there is a substantial risk here, which has not been adequately addressed by existing models or agricultural practice. We urge the board to exercise extreme caution when determining CI values for residue-derived fuels where the residues would previously have been returned to the soil. We also urge the Board to regularly review research on this subject and revise CI values promptly when sufficient evidence exists to justify such.

LCFS B8-7 cont.

The LCFS is a Strong Policy Which Should be Re-Adopted

The current LCFS has, according to the overwhelming preponderance of evidence, achieved its goals and when the benefits to public health and energy security are considered, it has been a strong investment for the state. Already, tens of thousands of Californians are employed by jobs related to sustainable transportation in the state[12] The California Air Resources Board now has the opportunity to extend this success to 2020 and beyond and cement the state's leadership in this critical area of climate policy.

We would be happy to discuss any of these issues with the Board at your convenience. Please do not hesitate to contact us if there is anything else we can add.

Sincerely,

Colin W. Murphy

Chapter 4: Analysis of Soil Organic Carbon Changes from Corn Stover Harvest

4.1 Introduction

Biofuels are thought to be a promising technology for reducing greenhouse gas (GHG) emissions from the transportation sector. The U.S. Revised Renewable Fuel Standard (RFS2) calls for a substantial increase in biofuel utilization over the next 10 years. At least 16 billion gallons (61 billion liters) of biofuels made from lignocellulosic feedstocks ("cellulosic biofuels") are specifically mandated by RFS2 (Renewable Fuels Association, 2010). Cellulosic biofuels have the potential to meet RFS2 GHG reduction goals (Bracmort, 2012; Farrell et al., 2006; C. Murphy & Kendall, n.d.; Tao & Aden, 2009; Viikari et al., 2012), but substantial uncertainty remains, particularly surrounding soil organic carbon (SOC) changes from producing and harvesting lignocellulosic feedstocks (Anderson-Teixeira et al., 2009; Lemke et al., 2010; P. Smith, 2007). In fertile soils, organic matter from root growth and above-ground litter is incorporated into the soil over time. Some of this carbon remains in the soil for long periods of time (Humberto Blanco-Canqui & Lal, 2009; J. M.-F. Johnson, Barbour, & Weyers, 2007). When undisturbed, carbon content in soils often reaches equilibrium, where the amount of soil carbon being added approximately equals that being lost (Buyanovsky & Wagner, 1997).

Disturbing these pools of SOC through changes in land coverage or agronomic management, such as removing large amounts of biomass for biofuel production, can alter soil carbon balances. This is of particular interest to biofuel analysts and policy makers, since the magnitude of these changes can be quite significant (Fargione et al., 2008). Cultivating feedstock crops for cellulosic biofuels typically requires a substantial change in management since, at present, virtually no cellulosic biofuel capacity is operating in the U.S. (Advanced Ethanol Council, 2013). Even where specific agronomic practices for biofuel crops are similar to food ones, biomass harvest removes much more biomass from the field than food harvest.

Corn stover, the above-ground, non-grain part of the corn plant, is thought to be a promising feedstock for biofuel production because substantial acreage of corn is already cultivated in the U.S. and stover is typically left on the field as residue (Graham et al., 2007). If harvesting stover causes a loss of soil organic carbon, through oxidation or reduction and volatilization to CO_2 or CH_4, then the life-cycle GHG impact of stover-based biofuels would increase. SOC changes are affected by local soil and climatic conditions as well as the type of organic matter in the soil, some forms, such as lignin, are typically much more recalcitrant than others. Understanding the SOC change is, therefore, an important element in accurate life-cycle assessment of biofuels.

This paper focuses on the following question: Does removing some part of the corn stover from corn fields reduce SOC? If so, under what conditions and by how much is it reduced? To answer this, we collect data from 21 studies of corn stover removal and SOC changes. 17 of these studies were from peer-reviewed publications, two were unpublished data from authors which had published in this field before (and which are intended for publication in the future), one was a M.S. thesis and one a PhD Dissertation.

4.2 Methodology

4.2.1 Data Collection

A literature search was conducted of studies quantifying changes in SOC from the harvest of corn stover. Google Scholar and ISI Web of Science were searched using the keywords "soil carbon" and "corn stover". This returned several hundred results, so a set of criteria was established to limit the inclusion to papers which would most directly reflect the effects of corn stover removal on SOC. These criteria were:

- Inclusion of at least two levels of stover removal, including zero.
- Corn must be grown continuously or must represent at least 50% of any crop rotation.
- Sampling depth must be at least 5 cm.

- Agronomic parameters including soil classification, tillage and nitrogen (N) fertilization must be reported or obtainable through other sources.
- Must be unique data; literature reviews and meta-analyses were used to identify potential studies, though all data in the dataset was copied from the original publication.

Only studies reporting empirical data were selected for this analysis; a comparison between measured and modeled studies is planned for future work. The 5cm sampling depth was picked to minimize the transient effects of surface litter. The crop rotation condition was set to allow corn-soy rotations, which are common. When a paper met these criteria, the relevant data were extracted to a MS-Excel data file (Microsoft, 2006). Additional papers were discovered by examining the works citing and cited by papers which were included in the study, as well as several literature reviews on the subject (Anderson-Teixeira et al., 2009; Humberto Blanco-Canqui, Lal, Post, Izaurralde, & Owens, 2006; Powlson, Glendining, Coleman, & Whitmore, 2011; W W Wilhelm, Johnson, Hatfield, Voorhees, & Linden, 2004; Zanatta, Bayer, Dieckow, Vieira, & Mielniczuk, 2007). When many sampling depths were reported in the same study and field, no more than two were included in this study, to avoid overrepresentation of any single study.

21 suitable studies were identified, which included data from 22 experimental fields (Appendix 8.2). These studies identified several factors thought to impact SOC changes from stover removal: soil clay content, biomass removal rate, initial SOC content, crop rotation practice, N fertilization, tillage practice, sampling depth, soil bulk density and duration of the study. Values for these parameters were extracted from the papers in the study. Where data were not reported, study authors were contacted to attempt to fill in gaps. If this failed, values were estimated from other sources, such as companion studies or earlier or later work from the same research plots. Soil conditions, such as bulk density and clay content were estimated by referencing the soil series and study location in the USDA Web Soil Survey (Soil Survey Staff, 2013).

Residue removal rates were given in the constituent papers, however not all were given as the fraction of above-ground biomass; some were based on surface area measurements or on the percent of mechanically-harvested stover, which excludes a stubble under the cutting height of a harvester. These were converted to mass fractions based on the 1:1 relationship between cut height and stover mass reported in Wilhelm, et al. (2010) and the average "Low-Cut" height for mechanical silage harvesters reported by Wu and Roth (Z. Wu & Roth, n.d.). Where corn height was unavailable, it was assumed to be equal to that of the average in the nearest test field reported in Wilhelm, et al. (Wally W. Wilhelm et al., 2010).

SOC is typically reported in one of two forms, as a mass fraction (g SOC/kg soil, or % SOC) or as a mass-per-area (typically Mg SOC/ha). The mass fraction form was used as the functional unit for our analysis, which reduces covariance between SOC levels and sampling depth. Where mass fractions were not available, the following relationship was used to convert between the two:

$$SOC_m \ \left(\frac{Mg}{ha}\right) = 10{,}000\frac{m^2}{ha} \times SD\ (m) \times BD\left(\frac{Mg}{m^3}\right) \times SOC_f\left(\frac{kg_{SOC}}{kg_{soil}}\right) \qquad (1)$$

where SOC_m is SOC mass per area, SD is sampling depth, BD is soil bulk density and SOC_f is SOC mass fraction.

Tillage practices were grouped into three classes: (1) conventional tillage (CT - which includes continuous tillage using moldboard plow); (2) reduced tillage (RT - which includes conservation tillage; chisel plow; strip tillage; mulch tillage; ridge tillage); and (3) No tillage (NT). Conventional tillage has been widely reported as contributing to SOC loss; several studies find that tillage has a greater affect on SOC than residue removal (Clapp et al., 2000; Dick et al., 1998; Reicosky & Evans, 2002). This effect varies with soil depth, since tillage induces mixing of soils and rapidly moves stover carbon downwards, as well as reducing particle size (Anderson-Teixeira et al., 2009; Dolan, Clapp, Allmaras, Baker, & Molina, 2006). We control for the different tillage classes using indicator variables for which tillage method was used on a field.

Nitrogen fertilization may have an effect on SOC concentrations; this is examined in this study. The effect of nitrogen fertilizer on soil microbial activity and carbon dynamics will depend strongly on biogeochemical conditions, including the amount of available nitrogen in the soil prior to fertilization. Previous literature has been mixed and uncertain regarding the effect of nitrogen on SOC levels (Dolan et al., 2006). There is relatively little variation in nitrogen treatment rates, so it is uncertain whether treating this as a continuous parameter will identify any meaningful effects. Accordingly, two specifications are presented, one with nitrogen treated as a binary qualitative variable and one as a numeric rate (Specifications 4 and 5, respectively).

Soil classes are grouped into 7 categories, corresponding with USDA soil textural classes (Soil Conservation Service, 1987); not every class was observed in this dataset. Indicators for each class and type are included in regressions with appropriate exclusions to avoid perfect multicollinearity.

4.2.2 Analytical Methods and Identification

A reduced form regression approach was used to study the effect of various factors on SOC content in soil. The approach allows for flexible control of a number of factors which may affect SOC. In addition, cluster robust standard errors, clustered at the study level, were used to construct confidence intervals which account for idiosyncratic differences across studies as well as correlation in observations over time within studies (Cameron & Trivedi, 2005). In order to produce results that are relevant for prospective modeling of SOC changes, two types of SOC change are considered. In some cases, the important characteristic is the net gain or loss of SOC after a period of corn stover recovery. This "Within-Field" (WF) change is estimated using a differences-in-differences regression, where the dependent variable is the initial SOC and the initial SOC is controlled for as an explanatory variable.

Sometimes the critical characteristic for models is the difference between SOC in a field in which stover is collected and a hypothetical *status quo*. In the case of corn stover, the *status quo* is assumed to be corn production with stover left on the field, as it is in over 95% of all U.S. corn fields(U.S. EPA, 2013a). This "Between-Field" (BF) change is analyzed using a differences estimation. The basic regression used takes the form

$$y_{it} = h(x'_{it}\beta) + \epsilon_{it} \qquad (2)$$

where y_{it} is the final SOC percentage for field i in time t and x_{it} are explanatory variables including percent biomass removal, initial percent SOC, nitrogen treatment, tillage practice, clay content, sampling depth, and study duration. β is the coefficient estimated by regression, ϵ is the error term and h is the functional form of the parameter, which can be non-linear, such as quadratic or logarithmic. The purpose of the regression is to identify the causal relationship between x_{it} and final SOC. This requires a number of assumptions.

The data collected represent averages across a number of replications such that

$$\overline{y_{it}} = \frac{1}{n_j}\sum_{j=1}^{n_j} y_{ijt} \qquad (3)$$

where j is the number of replications on field i. In order to be able to identify the relationship of interest, the estimates must have linear parameters. To see this, note that the average change in y_i from a change in variable x_i is given by

$$\Delta\,\overline{y_i} = \frac{1}{n_j}\sum_{j=1}^{n_j} \Delta y_{ij} = \frac{1}{n_j}\sum_{j=1}^{n_j} h(\Delta x'_{ij}\beta) \qquad (4)$$

So long as $h(\cdot)$ is linear in the parameters, then

$$\Delta \bar{y}_j = \beta \frac{1}{n_j} \sum_{j=1}^{n_j} h(\Delta x_{ij}) \qquad (5)$$

Note that $h(x_{ij})$ can be a non-linear in the variables x_{ij}, so the assumption is not unduly restrictive.

A second key assumption to identify the causal relationship is that the conditional expectation of the errors is zero. The assumption would be violated if important explanatory variables are omitted, which correlate with an explanatory variable x_{ij} and affect final SOC percent, known as omitted variable bias. The condition may also be violated if the functional form is mis-specified. The robustness of the estimated effects to the inclusion of a number of control variables and specifications is checked to test the sensitivity of our results to potential omitted variable bias.

A last concern relates to the nature of the dependent variable. The SOC content in fields, as a percentage of mass, is constrained to be within the interval (0,1). Linear regressions do not restrict predictions to be between (0,1) and could lead to biased results (Kieschnick & McCullough, 2003). A popular approach to dealing with this is to use a logistic transformation of the dependent variable given by

$$\ln\left(\frac{y_{jt}}{1-y_{jt}}\right) = h(\boldsymbol{x'}_{it}\beta) + e_{jt} \qquad (6)$$

If the errors follow an additive logistic normal distribution, then e_{it} will follow a normal distribution and standard Gaussian statistical inference applies. All proceeding results were run under both a linear model and a logistic model. In general, the logistic model had limited if any advantage over the linear model, and the linear model allowed for more precise estimates because of its assumption of linear marginal effects.

4.3 Results

Variable	Mean	Std. Dev	Min	Max	N
Final Soil Organic Content (kg/kg)	0.0202	0.0064	0.0072	0.0473	251
Initial Soil Organic Content (kg/kg)	0.0233	0.0082	0.0091	0.0544	185
Biomass Removed (fraction of total)	0.4735	0.4187	-0.1800	1	251
Tilling Practice (Categorical Variable)	1.7540	0.6850	1	3	212
Clay Content (kg/kg)	0.2156	0.1002	0.0580	0.4370	251
Sampling Depth (cm)	23.4821	13.4621	5	60	251
Study Duration (years)	10.075	9.99	2	34	251

Table 4-1 - Summary Statistics for Corn Stover Removal Dataset. 81% of plots in the study were treated with nitrogen fertilizer.

Table 4-1 presents the summary statistics of the key variables of interest. As can be seen, final SOC is slightly lower than our initial observed SOC; however, directly comparing differences in means can be misleading for a number of reasons. First, we do not observe initial SOC for 47 of our observations. Second, as can be seen from the summary statistics, there is substantial heterogeneity across studies such as the type of tilling practice, the soil class, sampling depth, soil density and the duration of study.

Direct evaluation of WF and BF changes may lead to incorrect inference if there are other factors which led to changes in SOC in addition to biomass removal. Using a regression approach, we measure WF and BF changes flexibly, controlling for a number of factors which may also determine final SOC percentage. Included in our analysis are nitrogen application rates, duration of the study, clay content, sampling depth, and tillage practices. The effect of different parameters and combinations of parameters are checked in several forms, or "specifications" of the linear regression model.

Study and field effects are also considered, since agronomic practices, as well as local soil and climate conditions would be strongly correlated with the study they are reported in. If different studies are associated with different methodologies which are not captured in the dependent variables of interest, our results may be biased. These are controlled for in the same way as the qualitative variables above. Namely, for some specifications we include indicators for each study, with appropriate exclusion restrictions. In these regressions, identification is based on within-study variation as including indicator variables for each study effectively demeans all variables by their respective within-study or within-field means. By checking for study effects, the effect of variation within a study or field is lost, so this approach can identify whether there are systematic differences between studies, but cannot simultaneously identify the effects of other parameters.

The first three specifications for each model, [1-3] and [6-8], check for the presence of bias introduced by study-specific or field-specific effects. Table 4-2 shows the result for the linear difference estimator (BF SOC changes). Specification [1] presents the basic BF effect with no control variables. If the experiments were properly randomized, the estimated effect should be unbiased. Results including study fixed effects are shown in specification [2]. Control for the effects of the experimental field, rather than the study in which results were reported, was done using the same methods and shown in specification [3]. Similar analyses are done for WF SOC change in specifications 6-8. The relatively similar coefficients generated for each of these specifications, combined with clear statistical significance for all, indicates that there are no significant biases introduced by study or field effects.

Table 4-2 Difference Estimators (BF SOC changes) for Linear Regression of SOC concentration (%) as dependent variable. Asterisks indicate significance, *: $p<0.1$, **: $p<0.05$, ***: $p<0.01$. Standard errors are in parenthesis.

All of the linear models with more complete sets of parameters, specifications [4], [5], [9] and [10], indicate a very consistent effect of SOC removal; every 1% of additional residue removal leads to a 0.0013% reduction in SOC, with all other factors being held equal. All SOC change values are significant to $p<0.01$. While this SOC reduction appears small, when one considers that the average corn field in this study had 57 Mg/ha at the start of residue removal treatments, this implies a loss of around 50 kg C per hectare for every percent of residue removal. The duration term has a negative sign under both linear (not shown) and logarithmic forms, which indicates that continuing treatment also tends to reduce SOC.

All specifications show a significant negative effect at the 1 percent level of residue removal on SOC. Importantly, this effect does not vary substantially between specifications. The stability in the point estimate indicates that biomass removal treatment was well randomized and was not correlated with other important determinants of final SOC. Few other parameters reach statistical significance in the

Table 4-3 - Difference-in-Difference Estimators (WF SOC changes) for Linear Regression of SOC concentration (%) as dependent variable. Asterisks indicate significance, *: p<0.1, **: p<0.05, ***: p<0.01. Standard errors are in parenthesis.

specifications, however, which generally supports the common impression in literature on the subject: that SOC in corn production systems is variable and uncertain. The signs of most parameters agree with other studies. Sampling depth and study duration are negative, which is to be expected, since both treatment duration and the mass of soil sampled would be expected to correlate with the magnitude of effects noticed; repeated corn cultivation is generally associated with declining SOC (D. L. L. Karlen et al., 1994; W. Smith & Grant, 2012). Clay content has a positive sign, indicating that increasing clay content generally reduces SOC loss, as reported by multiple studies (e.g., 29).

Table 3 shows the difference-in-difference estimator, which controls for initial levels of SOC and describes WF changes If removal treatments were not randomly assigned and there were important differences between treated and untreated fields which affect final SOC levels, the differences regression may lead to biased point estimates. The difference-in-differences estimator is robust for these concerns. Like the difference estimator discussed above, the effect of biomass removal is significant and negative, and does not substantially vary when alternative control variables are included. Unsurprisingly, the parameter with the greatest effect on final SOC concentration is initial SOC concentration. Parameters are generally of similar magnitude, sign and significance as in the BF analysis discussed above, suggesting the studies properly randomized treatment.

For most of the complete specifications (numbers [4], [5], [9], [10]), the results indicate each additional percent of biomass removal results in SOC decreasing an average of 0.0013% with a standard error of approximately 0.0004%, which yields a 95% confidence interval of approximately 0.0005 to 0.002% decrease. We tested for the presence of nonlinear effects using both the logistic model as well as quadratic terms in the linear model; however, the nonlinearities across biomass removal rates were not found to be statistically significant. The result is likely driven by lack of heterogeneity in removal rates across studies. Most studies reported removal rates only for no or near complete removal of biomass, and few had intermediate removal levels. As a result, the estimates are best thought of as an average effect of biomass removal.

Very few parameters besides biomass removal, initial SOC and the model coefficient (which is omitted in favor of tillage practice dummy variables in several specifications) achieve statistical significance, however those parameters are significant to $p<0.01$ certainty. Nitrogen treatment rate is significant on the WF model, but not on the BF model. Several of the non-significant parameters have been identified by other studies, or theoretical understanding of SOC dynamics, as affecting SOC changes. It is uncertain whether the results here are merely artifacts of this experimental design or call into question previous results.

4.4 Discussion

The results demonstrated above show a loss of 0.0005% to 0.002% in SOC per year for every 1% of residue removed. Using equation (1) and assuming a removal rate of 30%, which has been proposed by several sources in literature as a sustainable rate of stover removal (e.g. 41, 42), over a sampling depth of 30 cm and soil density equal to 1.31 (the average found from this dataset), this equates to a loss of 197-786 kg SOC/ha*year, which if emitted entirely as CO_2 yields 0.72 to 2.9 Mg CO_2/ha*year. In the context of life cycle analysis, this CO_2 emission is highly significant. Assuming an approximately 4 dry tonne/ha yield of stover and 292 liter/tonne conversion efficiency, this adds approximately 30 grams of CO_2e per megajoule (MJ) of delivered fuel. The RFS2 requires fuels that achieve the "cellulosic" designation achieve 50% reductions in life cycle GHG intensity compared to the petroleum fuels they displace. This implies targets of around 50 grams CO_2e/MJ for cellulosic biofuels, depending on the fuel being evaluated and the life cycle analysis methodology. The results of this study indicate that for stover based fuels, SOC change alone accounts for most of the allowable GHG emissions.

One area where substantial uncertainty remains is temporal effects. The treatment duration term was highly uncertain (the estimate was much smaller than the standard error) for both linear and logarithmic transformations of duration (Table 4-2 and Table 4-3, specifications 4, 5, 9, 10. Linear parameters were estimated, but not shown). Under commonly accepted models of soil dynamics, SOC concentrations in a field under a positive or negative SOC flux, such as residue removal, will come to an equilibrium over time (Anderson-Teixeira et al., 2013; Buyanovsky & Wagner, 1997). The lack of significance in this parameter may be a result of incorrect model specification, omission of other factors which affect SOC (such as total biomass production on the field), of a misunderstanding regarding the nature of SOC equilibria

SOC changes from stover harvest is a critical issue for determining the life-cycle GHG footprint of biofuels and bioproducts in the U.S. The U.S. grew over 34 million ha (84 million acres) of corn in 2011; which produces over a hundred million tonnes of residue as well. This residue could potentially be used for a wide range of bioprocesses and since it is currently left on the field on over 95% of farms. If SOC decreases from moderate levels of stover harvest are as high as earlier studies predict (Anderson-Teixeira et al., 2009), any bioprocess using corn stover is likely to be a significant net emitter of GHGs.

The results from the regressions above clearly show a significant and robust negative correlation between residue removal and SOC concentration. This matches the expected behavior of systems according to current understanding of SOC dynamics (Anderson-Teixeira et al., 2013; Humberto Blanco-Canqui, Lal, Post, Izaurralde, et al., 2006; Hooker et al., 2005), which strongly implies that the statistical correlation, in fact, reflects a causal relationship. By aggregating the results of many studies, the analysis presented above was able to overcome some of the statistical uncertainty described by previous authors in the field.

Few other parameters achieve statistical significance, which confirms the common conclusion in literature that SOC dynamics are highly uncertain. For WF changes, initial SOC was significantly correlated with final SOC, which is to be expected, since SOC changes are incremental increases or decreases upon previously existing SOC pools. The WF analysis also showed a significant relationship between nitrogen fertilization rate and SOC change. Previous research has been divided on the subject of the relationship between N fertilization and SOC (Dolan et al., 2006; Pikul, Johnson, Schumacher, Vigil, & Riedell, 2008).

One finding of this analysis contradicts well-established opinion in this field. For both WF and BF changes, SOC did not significantly differ between different tillage practices (CT, RT and NT were within a range less than any of their standard errors). Multiple previous studies have concluded that tillage, particularly conventional tillage (CT in this study), are strongly associated with reductions in SOC (e.g. 27, 38, 39). Further analysis is required to determine whether this is an artifact of the regression parameters used in this study, or whether tillage effects are more uncertain than previous literature indicated.

It is possible that the current model does not effectively capture differences in biomass production between fields. Of the parameters considered, only nitrogen fertilization is strongly associated with more biomass being produced. Changes in SOC levels are determined by the balance between inputs to soil, largely from plant matter, and flows out, from erosion and microbial metabolism. Rapid plant growth can increase SOC in two ways, by facilitating rapid root growth and creating a larger pool of above ground biomass, some of which may be incorporated into the soil. If the model, as currently formulated, is insensitive to the total biomass production of corn plants, then the categorical variables for tillage may be absorbing some unintended effects. Additionally, in areas with very high biomass production, tillage is sometimes required to minimize the insulating effects of surface residue, which can slow soil warming in spring and retard germination (Nielsen, 2010). This may imply an interaction between biomass production effects and tillage which is not captured in the current model.

Understanding SOC changes within the framework of life cycle analysis is complicated because accurate estimation of these changes is typically based on a consequential assessment framework. That is to say, the characteristic of interest is what changes a proposed production system would cause on the world. So, for a stover based production system the absolute magnitude of emissions from SOC change must be evaluated in a context which also considers any emissions from SOC change that would occur had the stover not been removed. This is usually done by a comparison between systems in which stover is harvested and the *status quo* in which it is generally not harvested. The analysis presented in this paper can help future analysts by presenting models for WF and BF changes. In general, the BF case better matches the needs of consequential LCA. BF comparison evaluates the difference between fields in which stover is removed and those in which it is retained on the soil. The WF comparison, on the other hand, may be less vulnerable to uncertainty stemming from soil conditions or measurement practices. BF comparisons in this study implicitly assume that all fields in a study have approximately equal SOC concentrations at the start of the study, which is not always the case, as is demonstrated by some of the studies in this review (Clapp et al., 2000; Wilts, Reicosky, Allmaras, & Clapp, 2004). Since initial SOC levels clearly affect SOC dynamics under residue removal, this means that BF comparisons suffer from at least one source of uncertainty that WF would likely avoid.

There are several areas of uncertainty which may affect the conclusions of this analysis. Climate conditions and the cultivars grown substantially affect total biomass production, which is the maximum amount of biomass that could be returned to the soil. Not all studies quantify total biomass returned, future work will attempt to evaluate whether mass of carbon entering the soil is more strongly correlated with maintaining SOC levels than residue removal rates.

While many studies have reviewed the impact of crop residue removal on SOC (Anderson-Teixeira et al., 2009; Humberto Blanco-Canqui, Lal, Post, Izaurralde, et al., 2006; Powlson et al., 2011; W W Wilhelm et al., 2004; Zanatta et al., 2007) most have not looked at agricultural management strategies that can help offset SOC lost due to crop residue removal. Blanco-Canqui (2013) recently reviewed the potential of several agricultural practices to counteract the SOC lost due to residue removal. No-till cover crops or applying C-rich substances such as manure, compost or the solid byproduct of cellulosic ethanol production (e.g. lignin cake or biochar) can all have beneficial impacts on SOC levels in soils from which lignocellulosic biomass is harvested.

The substantial uncertainty surrounding the SOC effects of sustained stover collection clearly demonstrate the need for further research in this area. LCA of biofuel production shows the critical importance of providing relatively low-GHG feedstocks for biofuel production systems. Likely near-term technology can achieve the goals of climate change mitigation policies, like RFS2, but they do not clear the GHG target thresholds for advanced biofuels by much; if feedstock production results in SOC loss at the higher end of its uncertainty range, there is virtually no chance for biofuels to achieve their GHG reduction targets and, in fact, at the high ranges of SOC loss, biofuels may be worse than the petroleum fuels they hope to replace.

Further study is needed to answer these critical questions. Most pressingly, there needs to be more empirical studies of SOC change under a variety of management conditions. Already, there is a multi-center research effort, coordinated by the USDA under the Sungrant program to directly address this research need (D. L. Karlen, Varvel, et al., 2011; Stott, Jin, & Ducey, n.d.). Additionally, better guidance regarding the most relevant methods for quantifying SOC change and measurement standards would help facilitate meaningful comparisons between studies.

8_B_LCFS_NGC Responses

654. Comment: **LCFS B8-1**

The comment states that the LCFS regulation is a necessary element in achieving long-term climate sustainability.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

655. Comment: **LCFS B8-2**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

656. Comment: **LCFS B8-3**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

657. Comment: **LCFS B8-4**

The comment supports the re-adoption of the LCFS regulation and the cost containment provision.

Agency Response: ARB staff appreciates the support for the proposed cost containment provision.

658. Comment: **LCFS B8-5**

The comment suggests the creation of a price floor for LCFS credits.

Agency Response: See response to **LCFS 6-5**.

659. Comment: **LCFS B8-6**

The comment requests that the Board to include a regular review process and procedure for modifying existing carbon intensities as better information emerges.

Agency Response: ARB staff agrees that the scientific understanding of biofuel production processes is continuing to improve, as are the tools for conducting life cycle analyses. See response to **LCFS 24-5**.

660. Comment: **LCFS B8-7**

ARB staff appreciates the commenter's concern regarding the use of harvested agricultural residues as biofuel feedstock and its net effect on stored soil carbon.

Agency Response: ARB staff appreciates the commenter's concern regarding the use of harvested agricultural residues as biofuel feedstock and its net effect on stored soil carbon. Staff acknowledges the importance of sustainable harvesting practices and the complex nature of soil organic carbon modeling and empirical analysis.

Staff agrees that soil carbon is affected by many parameters and these variables should be evaluated for specific regions, conditions, and practices for individual and specific LCFS fuel pathways. Furthermore, because soil organic carbon levels are dynamic, verification and monitoring for fuel pathways is critical to ensure LCFS credit market integrity. Staff has already gained some experience processing and approving agricultural residue feedstocks for biofuel production in the LCFS program. The fuel pathway reviews conducted to date include operating conditions that require sustainable harvesting and collecting of agricultural residues. Staff is committed to track new developments in research on soil carbon changes from use of agricultural residues for biofuel production. Staff will continue to review research on this subject and propose revisions to CI values when sufficient evidence exists to justify a change. Staff appreciates the ongoing feedback, comments, and other useful information provided by stakeholders on soil organic carbon changes from agricultural residue harvesting, which is an evolving and complex area of study.

RE: Comment of Low Carbon Fuels Coalition Regarding the Proposed Re-adoption of an Updated Low Carbon Fuel Standard

Dear Chairwoman Mary Nichols and Members of the Board,

Thank you for the opportunity to provide comments regarding the proposed re-adoption of California's Low Carbon Fuel Standard ("LCFS"). This letter provides the comments of the Low Carbon Fuels Coalition. The Coalition represents a broad range of low carbon fuel providers including producers and developers of biodiesel, ethanol, renewable natural gas, waste-derived fuels, and retail low carbon fuel providers. The Low Carbon Fuels Coalition tracks regulations and legislation, advocates for policies that benefit the entire low carbon fuels industry, and facilitates industry success through consensus and coalition building.

We strongly support the re-adoption of the Updated LCFS as proposed. We applaud the Air Resources Board's continued work to implement and improve the LCFS. As a direct result of the LCFS, California is leading the world in reducing greenhouse gas ("GHG") emissions from vehicles, and diversifying the transportation sector. We look forward to the LCFS program's continued success and are committed to assisting you in this endeavor.

California's first three years of LCFS experience have strengthened rather than weakened the state's economy and accelerated the growth of California's Clean Economy. The LCFS is driving tangible and valuable business activities by incentivizing technological innovations that reduce carbon intensity ("CI"). Companies are developing new CI fuels and technologies, investing in infrastructure to expand the availability of low CI fuels and

LOW CARBON
FUELS COALITION
980 Ninth Street, 16th Floor
Sacramento, CA 95814
(916)668-4636
www.lcfcoalition.com

technologies, and making investments to reduce the CI of conventional petroleum fuels and biofuels.

The LCFS is also providing the collateral benefit of reducing the US trade deficit. While domestic production has expanded substantially in recent years, the US still imports approximately half of its crude oil requirements, resulting in a net export of about $500 million per day to foreign coffers.[1] By diversifying the California transportation market, the LCFS enables the expansion of low CI fuels derived from US biomass and waste materials, as well as other US based low carbon fuel technologies. It has been determined that ethanol production in 2013 added more than 87,000 direct jobs across the country, increased the gross domestic product by $44 billion, and contributed $30.7 billion in new household income.[2] By 2022, the advanced biofuels industry is expected to produce $150 billion of economic output and support 800,000 jobs in the U.S.[3]

While we support the program as a whole, we would like to highlight several key aspects of the proposed regulation that have received significant attention and emphasize our support for these program components.

1. Compliance Curve- We strongly support ARB's proposal to maintain the original LCFS CI reduction at 10% by 2020. The entire US fuels market is watching California's progress and will benefit from California's aggressive leadership given the increasing severity of climate change. The low carbon fuels industry is committed to supplying California's low carbon fuel requirements and confident that it can produce more than sufficient quantities of fuel. LCFS B9-1

---

[1] The US is a massive net importer of crude oil at a monthly value that ranged from 20-25 billion dollars per month during 2013. A small portion of this trade deficit is offset by finished petroleum product exports which ranged from 1-7 billion dollars per month during the same period. See US Energy Information Administration, Monthly Crude Oil Trade and Monthly Petroleum Products Trade, http://www.eia.gov/todayinenergy/detail.cfm?id=15151#tabs_SpotPriceSlider-2 (last viewed November 1, 2014).

[2] See 2014 Ethanol Industry Outlook, Renewable Fuels Association, http://ethanolrfa.3cdn.net/2704ddcafa38cadd54_mlblcbx7o.pdf (last viewed February 11, 2015).

[3] See Energy Fact Check, American Council on Renewable Energy, http://www.energyfactcheck.org/featured-fact-checks/ (last viewed February 11, 2015.)

LOW CARBON
FUELS COALITION
980 Ninth Street, 16th Floor
Sacramento, CA 95814
(916)668-4636
www.lcfcoalition.com

2. Price Cap- We support the transparent and predictable market rules in the Updated LCFS to ensure that temporary shortages in the supply of low CI fuels or LCFS credits do not disrupt the market. Adoption of a Credit Clearance Market will protect markets in the event of a lack of liquidity. We support the proposed figure of $200/ton as the price that triggers the credit clearance mechanism. LCFS B9-2

3. Enforcement provisions- We support the expanded and clarified enforcement provisions that ARB has proposed to respond to fraudulent credit trades or other invalid activities are discovered in the market. The clearly defined rules dictating culpable parties and penalties will help market participants to behave within acceptable compliance boundaries. Due to the complex and novel nature of environmental attribute markets, regulators and enforcement officials must exert concerted efforts to maintain the integrity of credits and respect for the overall program. We support ARB's vesting of the Executive Officer with discretionary authority to intervene in the market to investigate suspect credits as well as the provisions providing interested parties the opportunity to respond and to submit evidence in the proceedings. LCFS B9-3

We look forward to working with you as you continue to strengthen and improve the LCFS. Please let me know if any clarification of these comments would be helpful. LCFS B8-1

Sincerely,

Graham Noyes
Acting Executive Director
Low Carbon Fuels Coalition

Mary D. Nichols, Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95812

Re: SUPPORT FOR LCFS READOPTION AND ADF REGULATION ADOPTION at February 19-20, California Air Resources Board Hearing – Items: 15-2-3 & 15-2-4

Dear Chair Nichols,

I am very supportive of both the re-adoption of the Low Carbon Fuel Standard ("LCFS") and the adoption of the Alternative Diesel Fuel ("ADF") regulation. I would like to thank ARB leadership and staff for all their hard work on these issues, which are vitally important to Californians. I would also like to commend you on implementing a program that has inspired other carbon reduction plans on the west coast and around the country and North America. LCFS B10-1

Driven by my intense concern over global climate change, I've spent nearly 15 years committed to education, fleet transition and implementation of biodiesel in California, and have watched it grow from a fledgling idea of a few pioneering environmentalists, scientists and engineers into a robust and growing industry that has created hundreds of high paying green California jobs in some of the most disadvantaged communities around the state.

Today the California biodiesel industry is capable of reducing over 610,000 metric tons of carbon emissions from our atmosphere, which is equivalent to removing almost 140,000 cars from California roads. But these metrics took on important and measurable meaning when ARB put them into the context of the Low Carbon Fuel Standard. This groundbreaking, critical policy demonstrates California's commitment to environmental and energy sustainability while simultaneously sending a strong and stable signal to the business community that will encourage investment and innovation, which will, in turn, help to further the state's carbon reduction goals.

The development of the ADF regulation has been a challenging process but ARB has been very mindful of all stakeholder interests and I am very appreciative of that effort. The California biodiesel industry is made up of independent producers, marketers, feedstock suppliers and other interested companies of all sizes. The challenge has been to be inclusive and ARB staff has been attentive to our needs and demonstrated their willingness to work with our industry to help develop a variety of compliance options.

I am confident that working together with ARB, the California biodiesel industry can build on its success. Last year biodiesel was responsible for generating 16% of all LCFS credits while contributing approximately $350 million in economic activity to California's economy. We look forward to doing even more to reduce carbon, lower emissions, displace petroleum and create good, high paying jobs in disadvantaged California communities.

Respectfully submitted,

Joe Gershen
Biodiesel industry veteran
CBA Vice-Chair

COMMUNITY FUELS™ It makes sense.

February 11, 2015

The Honorable Chairwoman Mary Nichols
California Air Resources Board
PO Box 2815
Sacramento, CA 95812

RE: Low Carbon Fuel Standard Re-adoption

The Honorable Chairwoman Nichols:

The California Low Carbon Fuel Standard (LCFS) has made a positive impact by reducing harmful emissions and stimulating the California economy. Community Fuels designed, built and operates an advanced biorefinery at the Port of Stockton. When I co-founded the company 10 years ago, our team was confident that the public would continue to support clean, renewable energy and that state and federal policies would be implemented to incentivize the further development and integration of clean fuels.

Community Fuels produces biodiesel, an advanced biofuel as defined by the U.S. EPA. **Biodiesel is the nation's first commercially-available advanced biofuel**; U.S. production has exceeded 1 billion gallons per year for the past three years. Biodiesel is an important component to the Low Carbon Fuel Standard because it is a proven, reliable, and commercially-available low carbon fuel that can be integrated into the existing diesel infrastructure (i.e. tanks, pumps and engines).

Biodiesel continues to have strong public and bipartisan support due to its many benefits.

1. **Performance Benefits**
   - Biodiesel is a superior diesel fuel with high lubricity and detergent properties. This results in smoother and cleaner running engines and contributes to reduced wear and tear and lower maintenance costs.
   - Biodiesel (used in a 5% or lower blend ratio) may be used in all diesel engines; diesel engines are 20 to 30% more efficient than gasoline engines.

2. **Environmental & Health Benefits**
   - Biodiesel is nontoxic, biodegradable and reduces harmful emissions including carbon dioxide, particulate matter, carbon monoxide, hydrocarbons, sulfates, and PAH; reducing these emissions improves human health.
   - Biodiesel is produced from a wide variety of fats and oils that are co-products of other industries; fats and oils are plentiful due to the high global demand for proteins.
   - Biodiesel has a strong energy balance; for every unit of fossil energy it takes to produce biodiesel on a lifecycle basis, over 5.5 units of renewable energy are returned.

3. **Economic Benefits**
   - When biodiesel is produced in California, it generates significant economic benefits including jobs, revenues and taxes.
   - In-state biodiesel production creates new advanced manufacturing jobs; manufacturing jobs have the highest multiplier effect of all the industries surveyed by the U.S. Bureau of Economic Analysis.
   - Biodiesel diversifies our State's energy sources which increases energy security and reduces price and supply volatility.

The U.S. biodiesel industry has over 3 billion gallons of production capacity registered with the EPA. This existing production capacity is over 5 times higher than the entire biomass based diesel (biodiesel and renewable diesel) categories included in the 2020 illustrative compliance scenario published by the California Air Resources Board (CARB). Californians do not need to rely on fuels imported from other countries - the U.S. biodiesel industry is ready to deliver. Also, when Californians import energy, we give up many of the economic opportunities associated with the LCFS program. **Let's keep the economic opportunities within California by minimizing imported energy and maximizing in-state production.**

Community Fuels biodiesel is primarily sold to regulated parties, which include petroleum refiners, pipeline shippers and importers. Regulated parties purchase our fuel in order to meet compliance obligations under the U.S. Renewable Fuel Standard, the CA LCFS, and the CA Cap and Trade program. Every gallon of biodiesel that is purchased displaces a gallon of diesel fuel and therefore reduces the market share of regulated parties. **Without strong and stable policies requiring the use of clean, renewable fuels, regulated parties would not purchase our fuel.**

We appreciate the efforts made by CARB staff to further improve the LCFS program by reducing indirect land use change penalties, improving the integrity of fuel pathways, and strengthening the reporting and enforcement provisions to reduce fraud risk. We request that CARB staff sunset the alternative diesel fuel rulemaking at the earliest possible date in order to remove obstacles to broader use of biodiesel throughout the state. **Community Fuels strongly supports the re-adoption of the California Low Carbon Fuel Standard.** The continued success of this regulation is critical to the viability of our California business. Please contact me with any questions at (760)942-9306 or lisa@communityfuels.com. LCFS B11-1

With enthusiastic support of renewable fuels, clean air and a strong economy,

Lisa Mortenson

COMMUNITY FUELS™

Community Fuels. A proven advanced biofuel producer.

- **Empowering Communities**
with regional production of cost-effective renewable energy.
- **Supporting Regional Economies**
by enabling easier access to clean energy and developing diversified feedstock supplies.
- **Producing High Performance Fuels**
that improve lubricity and reduce engine wear.
- **Supplying Advanced Biofuels**
that help clean the air and meet the requirements of the US Renewable Fuel Standard.
- **Meeting Market Demand**
efficiently with our proprietary process technology.
- **Supplying Western Markets**
with a renewable fuel that meets the rigorous quality requirements of multiple major oil companies.

Why Community Fuels?

- **Proven:** Community Fuels is a proven producer - We have been in continuous operation since 2008 and have fulfilled over 5000 bulk orders of fuel.
- **Low Risk:** Our fuel exceeds the ASTM standard and meets the requirements of multiple major oil companies and pipeline operators. We perform proactive testing on all fuel to ensure high quality.
- **Marketable Credits:** The marketplace is comfortable with Community Fuels' product, our RINS, and our CI credits - it takes years to build market confidence.
- **Operational Excellence:** Our rigorous operational procedures in production, quality assurance, and accounting makes our customers' jobs easier. We provide comprehensive documentation and proof of compliance with every load.

Contact Community Fuels now to establish a relationship for reliable supply of high quality biodiesel fuels. **Call (760)942-9306 or email sales@communityfuels.com now!**

665. Comment: **LCFS B11-1**

The comment strongly supports re-adoption of the LCFS program and states that the continued success of this regulation is critical to the viability of their California business.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

Re: Petition to Amend the Low-Carbon Fuel Standard Regulation Pursuant to Cal. Gov't Code § 11340.6

Dear Mr. Goldstene:

On behalf of Growth Energy, an association of the nation's leading ethanol manufacturers and other companies who serve the nation's need for alternative fuels, I respectfully petition for amendments to the California low-carbon fuel standard ("LCFS") regulation published in title 17 of the *California Code of Regulations* at 17 C.C.R. §§ 9548-95490. That regulation was approved by the California Air Resources Board ("CARB" or "the Board") in April 2009, and you took final action with respect to the relevant provisions of the LCFS regulation in November 2009. This petition is submitted pursuant to section 11340.6 of the California Government Code. It is based upon data and analysis that has become available to Growth Energy within the last two weeks.[1]

The specific amendments to the LCFS regulation proposed by Growth Energy are as follows:

1. An amendment to the LCFS regulation that would take effect no later than December 31, 2010, that would eliminate the "Land Use or Other Indirect Effect" carbon intensity values assigned to the corn ethanol pathways in Table 6 in section 95486 ("Table 6") for corn ethanol used to comply with the LCFS regulation in 2011 and 2012. LCFS B12-1

[1] The relevant new developments are also discussed in a letter to ARB from the Renewable Fuels Association ("RFA") dated April 28, 2010, which, while not formally requesting action under the Government Code, also recommends an immediate change in the LCFS regulation. The RFA letter is included as an attachment to this petition.

2. As an alternative to the amendment presented above in paragraph 1, an amendment to the LCFS regulation that would take effect no later than December 31, 2010, and that would replace the 30 gram of carbon dioxide-equivalent emissions per megajoule ("g/mj") value in Table 6 for corn ethanol pathways with 15.1 or 13.9 g/mj, for corn ethanol used to comply with the LCFS regulation in 2011 and 2012. LCFS B12-2

3. If the amendment presented in paragraph 1 is not adopted, then in addition to the amendment presented in paragraph 2, an amendment to the LCFS regulation that would take effect no later than September 30, 2010, and that would require the Executive Officer to take final action on a Method 2A or Method 2B submittal under section 95486 within 90 days of his receipt of a complete submittal pursuant to Method 2A or Method 2B. LCFS B12-3

The change in paragraph 1 above would be effected by replacing "30" in the indirect emissions values for corn ethanol in Table 6 with "0." Changes in regulatory text sought in paragraphs 2 and 3 of the petition are shown in Exhibit 1. The balance of this letter and the attached exhibits provide the rest of the information required by section 11340.6 of the Government Code. LCFS B12-4

I. Authority to Amend the LCFS Regulation and Requirements of the Government Code

Sections 39600-39601 of the Health & Safety Code empower the Board to adopt regulations in accordance with the California Administrative Procedure Act ("the APA"). The power to adopt regulations brings with it the power to amend regulations. Except when the right to do so is otherwise restricted, section 11340.6 of the Government Code permits any interested person to seek amendment to rules adopted by the Board. There is no statutory impediment to consideration of this petition on its merits. A response is therefore required in the manner described in your recent response to another petition under section 11340.6 of the Government Code, in which you stated as follows:

> Under Government Code section 11340.7, the State agency within 30 days may grant or deny the petition in part, and may grant any other relief or take any other action as it may determine to be warranted by the petition. It must also indicate why the agency has reached its decision in writing and if it grants the petition, it must schedule the matter for public hearing in accordance with the notice and hearing requirements of the APA.

Letter to M. Steele from J. Goldstene, Feb. 11, 2010 at 1 n.1 (*see* Exhibit 2). If you determine that you lack authority under sections 39515 and 39516 to consider and to grant any aspect of this petition, Growth Energy requests that (i) you refer this petition to the Board, and (ii) the Board grant this petition. LCFS B12-5

II. Grounds for Amendment of the LCFS Regulation.

The Board adopted the LCFS regulation as an early-action measure to implement the Global Warming Solutions Act of 2006, codified at sections 38500-38599 of the Health & Safety Code (the "2006 Act"). The Legislature directed ARB to use the "best available economic and scientific information" when adopting regulations to implement the 2006 Act. Health & Safety Code § 38652 (e).

During the LCFS rulemaking, ARB selected models developed by the Global Trade Analysis Project ("GTAP") to estimate the indirect emissions impact of the use of corn ethanol to comply with the LCFS regulation. As you explained in announcing the use of GTAP at the start of the LCFS rulemaking:

> To assess the emissions from land use changes, staff used the Global Trade Analysis Project (GTAP) [model] to estimate [greenhouse gas, or "GHG"] emissions impact. ... In general, the [GTAP] model evaluates the worldwide land use conversion associated with the production of crops for fuel production. Different types of land use have different rates of storing carbon. In general, multiplying the changes in land use times an emission factor per land conversion type results in an estimate of the GHG emissions impacts of land conversions.

Notice of Public Hearing to Consider Adoption of a Proposed Regulation to Implement the Low Carbon Fuel Standard (dated Feb. 24, 2009) at 8. The suite of the GTAP models used in last year's LCFS regulation is specified in the regulation at 17 C.C.R. §95481(a)(20.5), and is called in the regulation the "February 2009" version of GTAP.

LCFS B12-6

The GTAP modeling system was developed by the faculty and staff of the Department of Agricultural Economics at Purdue University. It should be noted in this regard that at least one GTAP expert at Purdue (Dr. Thomas Hertel) advised the Board at the inception of the regulatory process that the use of GTAP to select single-point carbon intensity values might be less defensible than other uses of the GTAP system and could be considered arbitrary. Last month researchers at Purdue led by Professor Wallace E. Tyner reported the development of a new and, in their opinion, improved version of the GTAP modeling system, called GTAP-BIO-ADV. Their research was partially funded by the Argonne National Laboratory. A final report summarizing the changes made in the GTAP modeling system has been prepared and is attached to this petition as Exhibit 3. Consistent with Dr. Hertel's advice during the rulemaking process, the new GTAP report presents a range of indirect land-use emissions values for corn ethanol, and invites the reader to evaluate the range of outputs and the assumptions that produce the different outputs.[2]

As indicated in the new report from the GTAP researchers at Purdue, the indirect emissions impact that Table 6 attributes to corn ethanol (which is based on the February 2009 version of GTAP) is significantly overstated, based on the results of GTAP-BIO-ADV. Table 6 assigns an indirect carbon intensity value to corn ethanol of **30 g/mj**. Based on certain assumptions about growth in yield and population, the average indirect land-use emissions that can properly be attributed to corn ethanol using the updated GTAP modeling system is **13.9 g/mj**, or less than half the level used in Table 6, measured in g/mj of carbon intensity. The marginal carbon intensity value that the new analysis based on GTAP-BIO-ADV would attribute to corn ethanol's indirect effects under those same assumptions about yield and

LCFS B12-7

[2] It should be noted that Growth Energy does not agree with some of the fundamental assumptions made in indirect land-use change ("ILUC") theory applied in the LCFS rulemaking, and that Growth Energy believes that the final LCFS regulation failed to comply with the 2006 Act and other legal requirements, even before publication of the new work on GTAP discussed in this petition.

LCFS B12-6 cont.

population growth is **15.1 g/mj.** The Board should not overlook this important change in the results that are produced by the GTAP modeling system using updated data, which was not available to the Board when it approved the LCFS regulation, nor available to the public during the post-hearing review process last summer and fall. LCFS B12-7 cont.

Growth Energy does not believe that the economic and scientific bases for attribution of indirect emissions impacts to corn ethanol usage are adequate, as explained in comments submitted to ARB last year. Putting that disagreement with the Board's overall approach to the side, however, it should be clear that ARB must reconsider Table 6 before the LCFS regulation takes full effect at the start of 2011. Discussing the carbon intensity values developed last year, one consultant for ARB testified as follows at the April 2009 Board hearing:

> [I]f we make a mistake in one direction in estimating these numbers, we'll use too much of a biofuel that's actually higher carbon [than] we thought and will therefore increase global warming. And if we use numbers that are too low, then we'll use too little of a biofuel that's lower carbon than we thought and will therefore increase global warming.

See April 2009 Hearing Transcript, *available at* http://www.arb.ca.gov/board/mt/2009/mt042309.pdf, at 73-74. As the same witness pointed out, "the cost to the world of being wrong in both directions is fairly symmetrical," and "there's no obvious conservative direction" to take in order to minimize the risks and costs of error. *Id.* at 74. LCFS B12-8

There is debate today about how to conduct a full lifecycle emissions analysis of transportation fuels. At this point, however, it should be clear that the GTAP modeling framework as adapted to a lifecycle analysis for corn ethanol has changed significantly since 2009. Moreover, the results produced by the GTAP systems are highly dependant on some assumptions that (in the latest report from Purdue) are not fully documented or explained. For example, it is far from clear whether what the new report calls the "yield effect" on food consumption is consistent with historical data. The selection of a population growth rate in the new iteration of the model is also not fully explained, and the new model appears to continue the assumption in the old model that forest land is converted in roughly the same proportion to all other land types. The new model is therefore likely to overstate the impact of corn ethanol usage on greenhouse gas emissions, accepting all other assumptions made in the ILUC theory. The new GTAP system may be an improvement over the February 2009 version, but the risk of error that punishes corn ethanol without a proper scientific basis remains great. LCFS B12-9

Given the risk of error, Growth Energy believes that the best course would be to eliminate any indirect emissions penalty for ethanol, and perhaps for all other biofuels, for at least the first two years of the LCFS compliance period (2011 and 2012), so that the science can catch up with regulatory process. Such a deferral of indirect emissions assessments will give the Board's external expert working groups time to formulate and present recommendations for full lifecycle analysis to the Board. A decision to defer ILUC-based emissions penalties in Table 6 for a full two years should be made now, so that the regulated parties can develop initial compliance plans with the LCFS regulation that are not based on clearly mistaken ILUC-based penalties. Assuming that the expert working groups can report to the Board by the end of the current year and recommend appropriate reforms in lifecycle emissions assessments at LCFS B12-10 that time, and that the Board can act on those recommendations in early 2011, then revised carbon intensity values could be included in Table 6 in early 2011 to take effect in 2013. LCFS B12-10 cont.

Even if ARB maintains the view (not shared by Growth Energy) that there is surely some indirect emissions impact from corn ethanol use, and that the indirect emissions value must be "greater than zero," there should be no disagreement that the February 2009 verison of the GTAP modeling system on which the LCFS regulation is currently based is now obsolete. When the GTAP modeling system is updated with what the new Purdue report calls "model improvements" and with a 2006 data base, there is a substantial reduction in the carbon intensity values that the Purdue team believes can credibly be assigned to corn ethanol. (*See, e.g.*, Exhibit 3, Table 20 at p. 46.) The use of a 2006 data base seems itself to be questionable, but the availability of that data set certainly shows that the older data set used in the February 2009 version of the GTAP modeling system is no longer the "best available economic and scientific information." Health & Safety Code § 38652 (e). Surely, those who believe that some "non-zero" value needs to be assigned to indirect emissions from the use of biofuels would agree that the 30 g/mj value in Table 6 is not the correct or most reliable "non-zero" value, and must be changed in order to avoid a serious mistake. LCFS B12-11

Based on the new work at Purdue (but without agreeing with the premise that corn ethanol must be assigned some indirect land-use change emissions impact), if the Board believes that a "non-zero" value for indirect emissions must remain in Table 6, Growth Energy believes that consistency with the "best available" science requirement of the 2006 Act mandates the replacement of the 30 g/mj value with either 13.9 or 15.1 g/mj, depending on whether ARB decides to use average or marginal emissions values. Such a change should be made now, with the expectation that the expert working group and the Board will be able to revisit the issue in time to make any necessary further changes for biofuels usage after 2012. If such a change is not made now, the LCFS regulation will take full effect in a few months' time using carbon intensity values that are simply no longer credible.[3] LCFS B12-12

In the event that ARB decides not to establish a two-year moratorium on the use of indirect emissions impacts for corn ethanol, Growth Energy requests two further regulatory changes in addition to the reduction in the indirect emissions values assigned to corn ethanol in 2011 and 2012. First, given the importance of prompt action on revisions to the carbon intensity values assigned to alternative fuels, LCFS B12-13 Growth Energy also requests that section 95486 be revised to include a 90-day deadline for action on Method 2A and Method 2B applications. Second, in light of the rapid pace of developments in the GTAP modeling structure, Growth Energy believes it would be appropriate to amend the LCFS regulation to make it clear that the Executive Officer should permit the use of updated versions of the GTAP models in the Method 2A and Method 2B procedures for determining carbon intensity. LCFS B12-14

---

[3] During the rulemaking process that Growth Energy seeks, it is possible that other interested parties could come forward with data and analysis to support changes in the indirect land-use change values assigned to ethanol produced from sugar cane. To avoid proliferation of proceedings, Growth Energy recommends that any such changes sought in the indirect emissions values assigned to ethanol produced from sugar cane be presented without delay pursuant to Government Code § 11340.6. Growth Energy would vigorously oppose any action with respect to such a petition concerning sugar cane ethanol that might result in a delay in consideration of amendments sought in this petition. LCFS B12-12 cont.

The dates specified for final action to amend the current regulation presented on pages one and two of this letter (by December 31, 2010, for the amendments to Table 6, and by September 20, 2010 for the Method 2A/2B amendments) are critical to the objectives of this petition. Any delay from those dates will therefore mean effective denial of the petition. ARB should proceed with the publication of a notice for a public hearing to consider the changes requested here as soon as possible, and certainly no later than the 30-day period allowed by the Government Code for action on petitions of this type. LCFS B12-15

* * * *

Thank you for considering this petition. Please contact me at 605-965-2375 if you have any questions, or if further steps are required for consideration of this petition by you or by the Board.

Sincerely,

David Bearden

David Bearden
General Counsel

12_B_LCFS_GE Responses (Page 1 – 8)

666. Comment: **LCFS B12-1**

The comment suggests eliminating the "Land Use or Other Indirect Effect" carbon intensity values assigned to corn ethanol pathways.

Agency Response: Eliminating the "land-uses or other indirect effect" carbon intensity values would be inconsistent with a key objection of the LCFS program; to lower the CI of transportation fuels through an accurate lifecycle assessment. See also responses to **LCFS 8-1**, **LCFS 8-4**, **LCFS 46-166**, **LCFS 46-216**, **LCFS T25-1**, and **LCFS B12-4**.

667. Comment: **LCFS B12-2**

The comment suggests an amendment to the LCFS program that would impose a different iLUC value for corn ethanol.

Agency Response: This document was prepared by the commenter in response to ARB analysis presented in 2009 where the value of 30.0 g/MJ appears, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

The comments are not relevant since it requested reductions in the iLUC value for corn ethanol for 2011 and 2012. The current analysis has updated the iLUC value for corn ethanol to 19.8 g/MJ, and this value will be used starting in 2016 upon Board approval in 2015.

668. Comment: **LCFS B12-3**

The comment suggested a 2010 amendment to the LCFS regulation to require the Executive Officer to take final action on a Method 2A or Method 2B submittal within 90 days of submittal of the complete package.

Agency Response: The 2010 document is not directed at the current LCFS proposal. Staff responds to the extent the 2010 letter makes objections or recommendations that nevertheless could pertain to the proposal. ARB does not think it is wise to require an absolute time limit for processing applications, given that every application is different in terms of complexity, and given the fact that available staff resources fluctuate depending on the State's annual budget. In approving the LCFS regulation, the Board considered the need for an expeditious process for reviewing a Method 2A or 2B submittal and weighed that need against the public interest in being able to review the submittal in an open process. While ARB staff expects most submittals to be reviewed relatively quickly, in some cases, the complexity of a submittal may warrant a staff review that exceeds 90 days. Therefore, the Board determined that the most appropriate balance of these considerations is reflected in the public review and final action provisions contained in section 95486(f). Staff believes the existing-process in the regulation provides a necessary and appropriate balance between these two considerations and has therefore determined that commenter-requested amendment would be inappropriate.

669. Comment: **LCFS B12-4**

Agency Response: This document was prepared by the commenter in response to an ARB analysis presented in 2009, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

ARB staff disagrees with the commenter's proposal to amend the LCFS regulation to eliminate "Land Use or Other Indirect Effect" carbon intensity values assigned to corn ethanol by replacing the proposed iLUC value with "0". See response to **LCFS B12-1**.

670. Comment: **LCFS B12-5**

The commenter argues that "any regulation adopted by the Board must be consistent with and reasonably necessary to accomplish the purposes of AB 32."

Agency Response: The commenter asserts that the proposal falls short of that standard for three separate reasons, addressed as (1), (2), and (3) below.

Before addressing those points, ARB staff notes that the commenter has made an implicit – and incorrect – assumption, namely that the LCFS is founded solely on AB 32. Before AB 32 was enacted in 2006, ARB promulgated regulations under other authority for almost 40 years. During those decades, ARB's authority grew steadily. The LCFS proposal is based in part on ARB's pre-AB 32 authority, and need not serve only AB 32 goals. For example, ARB relied upon its broad authority to regulate motor vehicles, motor vehicle fuels, and to attack the problem caused by motor vehicle emissions systematically. (See, e.g., Health & Saf. Code §§39003, 39600, 39601.) Moreover, it is the policy of the State of California to reduce the State's dependence on petroleum. (Pub. Res. Code §25000.5) ARB has also been charged with reducing toxic air contaminants. (Health & Saf. Code §39650 et seq.)

Insofar as AB 32 also authorizes ARB to adopt an LCFS, the proposal, by stimulating innovative fuels and incentivizing the use of existing low-carbon fuels such as electricity, will help accomplish the purposes of AB 32.

1. *The commenter points out that AB 32 implementation measures "must not 'interfere with . . . efforts to achieve and maintain federal and state ambient air quality standards' to the extent feasible.*"

   The LCFS does not interfere, and in fact furthers California's systematic efforts to reduce motor vehicle pollution. The LCFS incentivizes fuels that are currently understood to be cleaner than gasoline and diesel, such as low carbon ethanol, electricity, hydrogen, biodiesel, and renewable diesel.

2. *GHG reductions must be "real, permanent, quantifiable, verifiable, and enforceable."*

   Based on quarterly and annual reports showing what fuels have been provided for use in California, ARB will be able to demonstrate the applicability of those five objectives.

3. *The Board is required to rely on the best available economic and scientific information available when adopting AB 32 regulations*.

   As set forth in the Initial Statement of Reasons, and its appendices and references, ARB staff has relied on the best available economic and scientific.

671. Comment: **LCFS B12-6**

The comment questions whether the GTAP model provides accurate estimates for the indirect emissions impact of corn ethanol pathways.

Agency Response: The document was prepared by the commenter in response to ARB analysis presented in 2009, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

1. ARB staff disagrees with the commenter that the use of a point estimate value for carbon intensity is arbitrary. Although the regulation adopted in 2009 requires the use of a point value for iLUC emissions, it reflects the average of iLUC estimates from several scenarios for each biofuel. The scenarios were designed to capture variability in parameters that impact the model outputs. To improve upon the analysis completed in 2009, ARB staff developed a Monte Carlo framework with assistance from UC Berkeley. The Monte Carlo analysis uses outputs from hundreds of simulations and is able to isolate parameters in the GTAP and AEZ-EF models that have the largest impact on model outputs. These parameters were used to develop a set of 30 scenarios by utilizing a range of discrete values for each of the parameters (variations were based on literature review and expert opinion) identified from the Monte Carlo screening analysis. For the proposed regulation, the iLUC estimate, a single point estimate for each biofuel reflects the average of the 30 scenario runs. Furthermore, the mean value estimated from the hundreds of Monte Carlo simulations was used to corroborate the average value calculated from the scenario runs. To be noted is that the mean estimated from the uncertainty analysis is similar to the average calculated from the scenario runs for all of the six biofuels. See also response to **LCFS 38-32**.

2. The updates to the model being referenced are for the time period 2010-2012. All applicable updates to the GTAP database, methodology, and structure have been included in the current version of the GTAP model. Only areas for which there was lack of data were not included in the current analysis.

3. Commenter's footnote (written in 2010 about the adoption of an earlier regulation) are not objections or recommendations regarding the current proposal and do not need a response. As to comments related to the incorporation of iLUC emissions into the regulation, the ISOR describes support below for the inclusion of iLUC estimates for biofuels.

The analysis conducted in 2009 used available data and understanding of land use science to develop the best estimate of iLUC emissions. The current analysis has refined the 2009 iLUC analysis to account for the latest data and updated land use change science. All of the iLUC values being proposed to the Board are a result of ARB staff using the latest science and best data to estimate iLUC values for all six biofuels.

See also responses to **LCFS 8-1**, **LCFS 46-166** and **LCFS 46-216**.

672. Comment: **LCFS B12-7**

The comment states that the indirect emissions impact attributed to corn ethanol is significantly overstated based on the results of GTAP-BIO-ADV.

Agency Response: The document prepared by the commenter is dated May 10, 2010, and is in response to ARB analysis presented in 2009, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014.

See also responses to **LCFS 46-216** and **LCFS B12-13**.

673. Comment: **LCFS B12-8**

The comment states that the economic and scientific basis for determining the value for indirect emission impacts of corn ethanol usage are inadequate.

Agency Response: The document was prepared by commenter in response to ARB analysis presented in 2009 where the value of 30.0 g/MJ appears, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

ARB staff does not agree with comments that the economic and scientific bases for attribution of indirect emissions to corn ethanol are inadequate. ARB staff used GTAP, which is an economic model that captures the most significant economic effects related to modeling the impacts of biofuel expansion. The GTAP model is also a peer-reviewed model based on sound scientific principles. A peer review of iLUC emissions in 2009 concluded that the model was scientifically appropriate to estimate iLUC emissions.

The 2010 letter is irrelevant because it refers to updates to the GTAP model implemented by Purdue after the Board Hearing in 2009. ARB staff, per the Board's directive, had committed to update the iLUC analysis only after completing a comprehensive review of the science of land use change. Between 2009 and December 2014, ARB staff utilized published information by Purdue and other researchers and available data to refine the 2009 version of the model. Empirical data, real-world observations, updated modeling methodology, and improved assessment methods have all been considered in the current methodology to estimate iLUC emissions. Many of the suggestions presented by the commenter have been incorporated into the current analysis. Some recommendations that were not considered for the current analysis were either due to lack of detailed data or because the modeling structure did not allow for the inclusion of such effects. In the future, when data becomes available, staff will incorporate appropriate modeling structures and parameters to account for other effects not considered for the current rulemaking

Details of the 30 scenario runs and the uncertainty analysis using the Monte Carlo approach are provided in Appendix I of the ISOR. The uncertainty analysis concluded that the mean of the likely values was not significantly different from the average of the 30 scenario runs. ARB staff's approach therefore limits the likelihood of risks and costs related to erroneous values for iLUC emissions. See response to **LCFS 8-1** for support using the Monte Carlo. See also responses to **LCFS B12-6** and **LCFS B12-19**.

674. Comment: **LCFS B12-9**

The comment expresses concern that the GTAP model needs further improvement and currently runs the risk of error that punishes corn ethanol without a proper scientific basis.

Agency Response: The 2010 letter is irrelevant because it refers to updates to the older version of the GTAP model implemented by Purdue after the Board Hearing in 2009. See responses to **LCFS B12-8** and **LCFS B12-27**.

675. Comment: **LCFS B12-10**

The comment suggests eliminating any indirect emissions penalty for ethanol, and possibly all other biofuels, for at least the first two years of the LCFS compliance period.

Agency Response: The document was prepared by the commenter in response to ARB analysis presented in 2009 and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

ARB staff does not agree with the commenter that the iLUC values as should be eliminated for the first two years of the program. Although it should be noted that those first two years (2011 and 2012) have passed with no adverse impact identified to the ethanol industry.

See also responses to **LCFS 8-1**, **LCFS 8-4**, **LCFS 46-166**, **LCFS 46-216**, **LCFS B12-4**, **LCFS T25-1**, and **LCFS B12-16**.

676. Comment: **LCFS B12-11**

The comment states that the 2009 version of GTAP is obsolete.

Agency Response: See response to **LCFS B12-7**.

677. Comment: **LCFS B12-12**

The comment states that the indirect land-use change emissions impact for corn ethanol should be changed.

Agency Response: The document was prepared by the commenter in response to ARB analysis presented in 2009 where the value of 30.0 g/MJ appears, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

The current ARB proposal is a significant change from the 2009 proposal and includes results based on the latest data and improved version of GTAP modeling and the latest information on parameters influencing the model and emission factors. ARB staff, per the Board's directive, had committed to update the iLUC analysis only after completing a comprehensive review of the science of land use change.

See also responses to **LCFS B12-8**, **LCFS B12-9, LCFS B12-1**, **LCFS B12-4**, **LCFS B12-17**, **LCFS B12-26**, and **LCFS B12-27**.

678. Comment: **LCFS B12-13**

The comment implies that a two-year moratorium should be placed on the use of indirect emissions impact for corn ethanol.

Agency Response: This document was prepared by the commenter in response to ARB analysis presented in 2009, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments in responses to **LCFS 46-216**, **LCFS B12-7**, and **LCFS B12-10**.

679. Comment: **LCFS B12-14**

The comment requests a 90 day deadline for action on the Method 2A and Method 2B applications and an amendment to the LCFS regulation to make it clear that the Executive Officer should permit the use of updated versions of the GTAP models in the Method 2A and Method 2B procedures.

Agency Response: Please see response **LCFS B12-3**. With regard to the suggestion to use an updated version of GTAP, we note that such an updated version is part of the readopted LCFS.

680. Comment: **LCFS B12-15**

In 2010, the commenter believed that there was available evidence of certain land changes that were not accounted for in the GTAP model incorporated into the 2009 proposal.

Agency Response: The comment is not directed at the 2014 LCFS proposal and does not need a response.

(c) *Method 2A – Customized Lookup Table Values (Modified Method 1).*

Under Method 2A, the regulated party may propose, for the Executive Officer's written approval pursuant to section 95486(f), modifications to the GTAP Model or to one or more inputs to the CA-GREET model used to generate the carbon intensity values in the Method 1 Lookup Table.

For any of its transportation fuels subject to the LCFS regulation, a regulated party may propose the use of Method 2A to determine the fuel's carbon intensity, as provided in this section 95486(c). For each fuel subject to a proposed Method 2A, the regulated party must obtain written approval from the Executive Officer for its proposed Method 2A before the regulated party may use Method 2A for determining the carbon intensity of the fuel. The Executive Officer's written approval may include more than one of a regulated party's fuels under Method 2A.

The Executive Officer may not approve a proposed Method 2A unless the regulated party and its proposed Method 2A meet the scientific defensibility, "5-10" substantiality, and data submittal requirements specified in section 95486(e)(1) through (3) and the following requirements:

(1) The proposed modified GTAP Model or CA-GREET inputs must accurately reflect the conditions specific to the regulated party's production and distribution process;

(2) The proposed Method 2A uses only the inputs that are already incorporated in CA-GREET and does not add any new inputs (e.g., refinery efficiency); and

(3) In lieu of use of the GTAP Model or a modified GTAP Model, the ~~The~~ regulated party ~~must~~ may request the Executive Officer to conduct an analysis or modeling to determine the new pathway's impact on total carbon intensity due to indirect effects, including land-use changes, as the Executive Officer deems appropriate. ~~The Executive Officer will use the GTAP Model (February 2009), which is incorporated by reference, or other model determined by the Executive Officer to be at least equivalent to the GTAP Model (February 2009).~~

(d) *Method 2B – New Pathway Generated by California-Modified GREET (v.1.8b).* Under Method 2B, the regulated party proposes for the Executive Officer's written approval the generation of a new pathway using the CA-GREET model as provided for in this provision and the GTAP Model or a modified GTAP model. The Executive Officer's approval is subject to the requirements as specified in section 95486(f) and the following requirements:

(1) For purposes of this provision, "new pathway" means the proposed full fuel-cycle (well-to-wheel) pathway is not already in the ARB Lookup

Table specified in section 95486(b)(1), as determined by the Executive Officer;

(2) The regulated party must demonstrate to the Executive Officer's satisfaction that the CA-GREET can be modified successfully to generate the proposed new pathway. If the Executive Officer determines that the CA-GREET model cannot successfully generate the proposed new pathway, the proponent-regulated party must use either Method 1 or Method 2A to determine its fuel's carbon intensity;

(3) The regulated party must identify all modified parameters for use in the CA-GREET for generating the new pathway;

(4) The CA-GREET inputs used to generate the new pathway must accurately reflect the conditions specific to the regulated party's production and marketing process; and

(5) In lieu of use of the GTAP Model or a modified GTAP Model, the ~~The~~ regulated party ~~must~~ may request the Executive Officer to conduct an analysis or modeling to determine the new pathway's impact on total carbon intensity due to indirect effects, including land-use changes, as the Executive Officer deems appropriate. ~~The Executive Officer will use the GTAP Model (February 2009), which is incorporated by reference, or other model determined by the Executive Officer to be at least equivalent to the GTAP Model (February 2009).~~

(e) *Scientific Defensibility, Burden of Proof, Substantiality, and Data Submittal Requirements and Procedure for Approval of Method 2A or 2B.* For a proposed Method 2A or 2B to be approved by the Executive Officer, the regulated party must demonstrate that the method is both scientifically defensible and, for Method 2A, meets the substantiality requirement, as specified below:

(1) *Scientific Defensibility and Burden of Proof.* This requirement applies to both Method 2A and 2B. A regulated party that proposes to use Method 2A or 2B bears the sole burden of demonstrating to the Executive Officer's satisfaction, that the proposed method is scientifically defensible.

(A) For purposes of this regulation, "scientifically defensible" means the method has been demonstrated to the Executive Officer as being at least as valid and robust as Method 1 for calculating the fuel's carbon intensity.

(B) Proof that a proposed method is scientifically defensible may rely on, but is not limited to, publication of the proposed Method 2A or 2B in a major, well-established and peer-reviewed scientific journal (e.g., Science, Nature, Journal of the Air and Waste Management Association, Proceedings of the National Academies of Science).

(2) *"5-10" Substantiality Requirement.* This requirement applies only to a proposed use of Method 2A, as provided in section 95486(c). For each of its transportation fuels for which a regulated party is proposing to use Method 2A, the regulated party must demonstrate, to the Executive Officer's satisfaction, that the proposed Method 2A meets both of the following substantiality requirements:

(A) The source-to-tank carbon intensity for the fuel under the proposed Method 2A is at least 5.00 grams CO2-eq/MJ less than the source to-tank carbon intensity for the fuel as calculated under Method 1. "Source-to-tank" means all the steps involved in the growing/extraction, production and transport of the fuel to California, but it does not include the carbon intensity due to the vehicle's use of the fuel; "source-to-tank" may also be referred to as "well-to-tank" or "field-to-tank."

(B) The regulated party can and is expected to provide in California more than 10 million gasoline gallon equivalents per year (1,156 MJ) of the regulated fuel. This requirement applies to a transportation fuel only if the total amount of the fuel sold in California from all providers of that fuel exceeds 10 million gasoline gallon equivalents per year.

(3) *Data Submittal.* This requirement applies to both Method 2A and 2B. A regulated party proposing Method 2A or 2B for a fuel's carbon intensity value must meet all the following requirements:

(A) Submit to the Executive Officer all supporting data, calculations, and other documentation, including but not limited to, flow diagrams, flow rates, CA-GREET calculations, equipment description, maps, and other information that the Executive Officer determines is necessary to verify the proposed fuel pathway and how the carbon intensity value proposed for that pathway was derived;

(B) All relevant data, calculations, and other documentation in (A) above must be submitted electronically, such as via email or an online web-based interface, whenever possible;

(C) The regulated party must specifically identify all information submitted pursuant to this provision that is a trade secret; "trade secret" has the same meaning as defined in Government Code section 6254.7; and

<u>(D)</u> The regulated party must not convert spreadsheets in CA-GREET containing formulas into other file formats.

~~(D)~~ (f) The Executive Officer shall take final action a request for modification of a fuel's carbon intensity value using Method 2A or Method 2B within 90 days of a complete submittal of such a request. The Executive Officer shall notify a party making a submittal using Method 2A or Method 2B within 15 days of receipt of such a submittal whether he has found the submittal to be complete.

Re: Response to January 11, 2010, Petition Filed by Associated General Contractors of America

Dear Mr. Steel:

I am writing in response to the petition filed pursuant to the Administrative Procedure Act (APA), Government Code section 11340.6, by the Associated General Contractors of America (AGC or petitioner) dated January 11, 2010.[1] The petition requests that the Air Resources Board (ARB or Board) adopt an emergency amendment to delay the fleet average target dates of the In-Use Off-Road Diesel-Fueled Fleets Regulation (regulation)[2] for two years. The petition also requests that ARB ask the United States Environmental Protection Agency (U.S. EPA) to postpone consideration of California's request for authorization of the regulation that ARB submitted pursuant to section 209(e)(2) of the federal Clean Air Act (CAA) until such time that ARB has resolved the issues underlying the petition.

After careful consideration of all of the facts associated with the petitioner's request, pursuant to Government Code section 11340.7(b), I am granting the following relief and finding that the following actions are warranted:

---

[1] The petition is available from ARB upon request. Under the APA, any interested person may petition a State agency requesting the adoption, amendment, or repeal of a regulation as provided in Government Code section 11340.6. The petition must clearly and concisely state the substance or nature of the regulation, the requested amendment or repeal, the reason for the request, and the reference to the authority of the State agency to take the action requested. Under Government Code section 11340.7, the State agency within 30 days may grant or deny the petition in part, and may grant any other relief or take any other action as it may determine to be warranted by the petition. It must also indicate why the agency has reached its decision in writing and if it grants the petition, it must schedule the matter for public hearing in accordance with the notice and hearing requirements of the APA.

The energy challenge facing California is real. Every Californian needs to take immediate action to reduce energy consumption For a list of simple ways you can reduce demand and cut your energy costs, see our website: http://www.arb.ca.gov

California Environmental Protection Agency

Printed on Recycled Paper

(1) ARB will issue an advisory notifying all stakeholders subject to the regulation that ARB will take no enforcement action regarding compliance with the regulation's emission standards or other emission related requirements before ARB receives authorization from U.S. EPA; and

(2) a hearing will be held in Sacramento on March 11, 2010, before the Executive Officer to take testimony and other relevant information on the need for further amendments to the regulation to address the economic recession confronting the State and the adverse impacts that the recession has caused to the construction and other industries that operate off-road vehicles. As the Board has already directed staff to provide an update on the regulation at its April 2010 meeting, any information and testimony collected at this hearing shall be compiled and included as part of that update.

This relief, coupled with statutory and regulatory relief already provided by Assembly Bill 8 2X (AB 8 2X or bill), will ensure no stakeholders will be in violation with the regulation's March 1, 2010 emission standards or other emission related requirements. Therefore, I have concluded that an emergency does not exist. I am also taking no action on the petitioner's request that ARB request U.S. EPA to delay issuance of the authorization, because the request is outside the scope of the APA petition process.

Summary of January 11, 2010 Petition

The petitioner's request that ARB delay implementation of the regulation can be summarized as follows: since the Board's approval and adoption of the regulation in 2007-2008, changed circumstances in the economy and its impact on construction activity in California have affected the financial ability of construction fleets to comply with the regulation's requirements while concurrently resulting in fewer emissions from construction vehicles. In claiming that a two-year moratorium in implementing the initial compliance requirements is urgently necessary, the petition argues that, without such immediate relief, California construction contractors will suffer immediate and irreparable harm because the regulation as it currently exists will force fleets to either downsize or have to purchase and install expensive and unreliable emission control devices or repower their equipment in order to meet the 2010 and 2011 fleet average requirements.[3] In making this claim, AGC asserts that the relief provided by AB 8 2X signed by the Governor on February 20, 2009, provides insufficient relief with "some relief to some contractors, but not to others, and certainly not to all [a]nd even those relieved of the initial burdens will find that that [sic] their relief is fleeting. . . ."[4]

[3] Petition at p. 6.
[4] *Id.*

AGC further argues that current economic conditions in the construction industry will not improve over the next two years,[5] and that reduced emissions resulting from the current economy gives the Board flexibility to delay the regulation and thereby reduce the financial burdens that it will impose, while still meeting the goals of the State Implementation Plan.[6]

<u>Background of the Regulation</u>

The Board approved the regulation for adoption on July 26, 2007, and formally adopted it on April 4, 2008. In adopting the regulation the Board specifically found that the regulation was necessary, technically feasible, and cost effective.[7] In finding that the regulations were necessary, the Board determined that in-use off-road diesel-fueled vehicles are significant contributors of emissions of oxides of nitrogen (NOx), particulate matter (PM), including PM2.5, and diesel exhaust, the last of which has been identified as a toxic air contaminant. The Board further found that the regulation would result in reductions in emissions that would prevent approximately 4,000 premature deaths and other harmful health impacts and would help California meet National Ambient Air Quality Standards (NAAQS) for ozone and PM2.5.

Subsequently, California, the nation, and the international community, in general, experienced a serious economic recession that has undisputedly impacted California businesses, including the State's construction industry. In response, as part of the 2009-2010 State budget, the California Legislature passed, and the Governor signed, AB 8 2X. Codified in Health and Safety Code section 43018.2, ARB was directed to amend the regulation to provide specified relief to affected stakeholders who have been negatively impacted by the State recession. Specifically, the legislation directed the Board to modify the NOx and PM credit provisions of the regulation to reflect vehicle retirements that reduce total fleet horsepower between March 1, 2006 and March 1, 2010, and reduced fleet activity between March 1, 2007, and March 1, 2010. It further directed the Board to amend the total cumulative NOx turnover and PM retrofit requirements for the years 2011 through 2013, to provide fleets with greater compliance flexibility with the regulation's requirements over the next three years.

Pursuant to the legislation's directives, the Board approved amendments to the regulation on July 23, 2009, with the amendments formally adopted and operative on December 3, 2009.

After adoption of the regulation in 2008, but before the enactment of AB 8 2X, AGC filed on December 15, 2008, the first of its two petitions, and requested that ARB amend and/or repeal the regulation. ARB and AGC agreed on February 4, 2009, to hold the

---

[5] *Id.*, at p. 7.
[6] *Id*, at p. 5.
[7] Resolution 07-19, a copy of which is attached as Attachment 1.

petition in abeyance as the parties evaluate data to determine the recession's impacts on construction fleets. With notice from either party, the petition could once again be activated and require an ARB response. To date, neither party has sought to activate the first petition.

On December 3, 2009, AGC presented ARB staff with its 2009 emissions inventory modeling analysis using the Diesel Off-Road On-Line Reporting System (DOORS)[8] data collected by ARB staff. The analysis was subsequently sent to the Board and made a part of the record of the December 11, 2009, Board hearing. At the hearing, the Board directed staff to return at its April and July 2010 Board hearings with an assessment of how the recession has impacted stakeholders subject to the regulation, using such information that is available, including the most recent fleet data that fleets are required to report no later than April 1, 2010.

<u>Response to Petition</u>

A. Actions Warranted by the Petition

Pursuant to the authority provided under Government Code section 11340.7, I am granting the following relief and finding the actions described below to be warranted.

1. Enforcement Advisory

I have determined that issuance of an enforcement advisory is warranted. The advisory will notify all stakeholders affected by the regulation that ARB will not take any enforcement action for noncompliance with the regulation's emission standards or other emission related requirements before ARB receives authorization from U.S. EPA.

2. Hearing before the Executive Officer to Determine Need for Further Relief from the Impacts of the Recession

I am scheduling a hearing to be held on March 11, 2010 before the Executive Officer for the purpose of receiving testimony and other relevant information on the question of whether the regulation needs to be further amended to provide additional mitigation for stakeholders that have been adversely impacted by the recession and for whom the compliance relief provided by the AB 8 2X amendments has not been adequate. At the hearing, the petitioner and affected stakeholders will be provided the opportunity to fully present information on the effects of the recession on the construction industry and other industrial sectors of the economy, in general, and off-road fleets in particular. They will also be able to present testimony and information on how the recession has

[8] DOORS is an online reporting tool designed to help fleet owners report their off-road diesel vehicle inventories and actions taken to reduce vehicle emissions to ARB, as required by the regulation.

affected emissions in the State, and why further delay of the regulation's compliance schedule is necessary and will not affect California's continuing efforts to improve air quality within its borders. I am also requesting that AGC and other stakeholders provide concrete and verifiable information to support any claims that the economy, in general, and the construction industry, specifically, will not have sufficiently rebounded from the recession by 2013.[9] The collected information will assist ARB staff in determining whether additional amendments to the regulation beyond those already adopted should be proposed to the Board.

In holding the hearing, I recognize that the present recession is the deepest recession since the Great Depression of the 1930s, that it has adversely impacted many fleets covered by the regulation, and that recovery from this recession is taking longer than many expected. I also recognize that the recession has resulted in reduced activity for many fleets and that, as a consequence, emissions are lower than forecasted in 2007, when the regulation was initially approved. However, what must be determined is the adequacy of the amendments already in place. The Executive Officer hearing will provide the best means of collecting information to make that determination.

In directing that an Executive Officer hearing be held, I have determined immediate Board action is not necessary since no emergency exists. The petition argues that the regulation must be immediately delayed by two years to prevent immediate and irreparable harm to fleets, in large part because the fleets have been adversely impacted by the current severe recession.[10] There is no dispute that a severe recession exists and that fleets have been negatively impacted. However, the AB 8 2X amendments, which became operative on December 3, 2009, have averted the need for immediate emergency action. The amendments adopted by the Board address the petition's concerns by providing a two-year delay, except for the largest fleets that were able to sustain revenues at pre-recession 2007 levels. Any fleet that has reduced its horsepower through retirement of vehicles between March 1, 2006 and March 1, 2010 will receive compliance credit for that horsepower reduction. Similarly, any fleet that has reduced its operational activity over the last several years (i.e., the difference in fleet activity between calendar year 2007 and the 12-month period bounded by March 1, 2009 to February 28, 2010) will also receive compliance credit. This effectively provides immediate compliance relief in the first years of the regulation's implementation for most fleets that have been adversely affected by the recession. For example, any fleet that has reduced its horsepower through retirements or reduced the amount that it operates by 32 percent or more will be COMPLETELY exempt from any compliance actions in 2010 or 2011 (i.e., will not be required to turn over any vehicles or install any retrofits). Fleets that have been more modestly impacted by the recession will be able to offset some of their 2010 and 2011 compliance requirements.

---

[9] See Petition at pages 4 and 6
[10] Petition at page 6

The AB 8 2X amendments also allow all fleets, even those unaffected by the recession, to postpone much of the compliance actions originally required for 2011 and 2012 until 2013. Fleets whose business has not been adversely impacted should financially be in position to meet the regulation's immediate 2010 requirements.[11] Moreover, it is reasonable to assume that at least some of these fleets will take advantage of the regulation's early action credit provisions.[12] This relief along with the compliance relief provided in the above-referenced advisory preclude my finding that an emergency exists. For these reasons, I cannot accept AGC's characterization that most, if not all, fleets need immediate further relief to avoid irreparable harm.[13]

Immediate action is also not required even though the AB 8 2X amendments do not address the fleet average requirements of the regulation. The petition essentially argues that the remedy provided in AB 8 2X is insufficient in that it does not address the fleet average requirements of the regulation.[14] The argument is unsupportable because AB 8 2X specifically provides relief to fleets from the regulation's best available control technology (BACT) requirements, which are a compliance alternative to the fleet average requirements. Thus, to the extent that fleets achieve compliance by meeting the regulation's BACT requirements through credits for vehicle retirements and fleet inactivity, they are under no obligation to meet the fleet average requirements. Consequently, the AB 8 2X relief effectively addresses all of the regulation's performance requirements.

B. No Action is Warranted for ARB to Request that U.S. EPA Delay Issuing California an Authorization for the Regulation

The petition requests that ARB inform U.S. EPA that it should not issue the authorization that California has requested for the regulation. I have determined that such a request is outside of the scope of the APA petitioning process, which is directed at requests for adoption, amendment, or repeal of a regulation.[15] Accordingly, no action on the request is warranted.

C. Conclusion

In conclusion, for the foregoing reasons, I am granting the following relief: ARB will issue an advisory no later than February 28, 2010, notifying stakeholders that ARB will not take any enforcement action for noncompliance with the regulation's March 1, 2010 emission standards or other emission related requirements before it receives authorization from U.S. EPA. I have further determined that an Executive Officer

[11] See e.g., title 13, Cal. Code Regs., §§ 2449(d)(1), 2449.1(a)(2)(A)2., and 2449.2(a)(2)(A)2.

[15] Govt. Code § 11340.7.

hearing to take testimony and receive information on the question of whether further amendments to the regulation, beyond those that have been adopted to date, is warranted. At the hearing, AGC and other stakeholders will have the opportunity to present testimony and documentation on the recession's impact and what additional relief stakeholders need to address those impacts.

If you have questions regarding the decision on this petition or would like to discuss the regulation, please contact Mr. Erik White, Chief, Heavy-duty Diesel In-Use Strategies Branch, at (916) 322-1017 or ewhite@arb.ca.gov or Mr. Michael Terris, Senior Staff Counsel, Office of Legal Affairs, at (916) 445-9815 or mterris@arb.ca.gov.

Sincerely,

James N. Goldstene
Executive Officer

FINAL REPORT

* The research underlying this report was partially funded by Argonne National Laboratory. We are deeply indebted to Dr. Michael Wang for his many contributions to this research. Throughout the process, he has consistently posed excellent questions that have stimulated more thinking and modifications on our part. Also, for this final paper, he provided an excellent set of insightful suggestions and comments that have improved the paper significantly. Of course, the authors are solely responsible for the content of and any errors in the report.

Executive Summary

The basic objective of this research was to estimate land use changes associated with US corn ethanol production up to the 15 billion gallon Renewable Fuel Standard level implied by the Energy Independence and Security Act of 2007. We also used the estimated land use changes to calculate Greenhouse Gas Emissions associated with the corn ethanol production.

The main model that was used for the analysis is a special version of the Global Trade Analysis Project (GTAP) model. It is a computable general equilibrium model that is global in scope. The version used for this analysis has up to 87 world regions and 57 economic sectors plus the biofuel sectors that were added for this analysis. There are many different versions of the GTAP model. It is used by thousands of economists around the world for analysis of trade, energy, climate change, and environmental policy issues. The model is publically available with documentation of the model and data base at www.gtap.org. The version used in this analysis contains energy and GHG emissions (GTAP-E) and also has land use (GTAP-AEZ). The name for the special version created for this work is GTAP-BIO-ADV and encompasses many changes to improve the analysis of corn ethanol:

- The three major biofuels have been incorporated into the model: corn ethanol, sugarcane ethanol, and biodiesel.
- Cropland pasture in the US and Brazil and Conservation Reserve Program lands have been added to the model.
- The energy sector demand and supply elasticities have been re-estimated and calibrated to the 2006 reality. Current demand responses are more inelastic than previously.
- Corn ethanol co-product (DDGS) has been added to the model. The treatment of production, consumption, and trade of DDGS is significantly improved.
- The structure of the livestock sector has been modified to better reflect the functioning of this important sector.
- Corn yield response to higher corn prices has been estimated econometrically and included in the model.
- The method of treating the productivity of marginal cropland has been changed so that it is now based on the ratio of net primary productivity of new cropland to existing cropland in each country and AEZ.

There are many other changes both in data and model structure, which are detailed in the report, but these are the major model and data modifications.

To evaluate the land use implications of US ethanol production we develop three groups of simulations. In the first group we calculate the land use implications of US ethanol production off of the 2001 database. This approach isolates impacts of US ethanol production from other changes which shape the world economy. In the second group of simulations, we first construct a baseline which represents changes in the world economy during the time period of 2001-2006. Then we calculate the land use impact of the US ethanol production off of the updated 2006 database, while we follow the principles of the first group of simulations for the time period of 2006-20015. Finally, in the third group of simulations we use the updated 2006 database obtained from the second group of simulations but we assume that during the time period of 2006-2015 population and crop yields will continue to grow.

In this summary, we will first report the land use changes for the third group of simulations. Then we present emissions obtained for the three groups of simulations. Tables 1 and 2 provide the estimated land use changes broken down by US and rest of world (Table.1) and the forest pasture split (Table 2). On average 28% of the land use change occurs in the US, and 72% in the rest of the world. Forest reduction accounts for 35% of the change and pasture 65%. On average 0.12 hectares of land are needed to produce 1000 gallons of ethanol.

Table1. Simulated global land use changes due to the US ethanol production: with yield and population growth after 2006

Changes in US corn ethanol production	Land use changes (hectares)			Distribution of Land Use changes (%)			Hectares per 1000 Gallons
	Within US	Other Regions	World	Within US	Other Regions	World	
3.085 BG (2001 to 2006)	119281	320068	439349	27.1	72.9	100.0	0.14
2.145 BG (2006 to 7 BG)	58799	150754	209553	28.1	71.9	100.0	0.10
2.000 BG (7 to 9 BG)	58167	134225	192392	30.2	69.8	100.0	0.10
2.000 BG (9 to 11 BG)	60919	141118	202038	30.2	69.8	100.0	0.10

*The difference between the changes in cropland and the sum of forest and grassland is due to rounding

We now consider estimated emissions induced by US ethanol production. Table 3 summarizes the emissions results from the three sets of simulations, and Table 4 provides the estimated ethanol and gasoline emissions in grams per gallon of gasoline equivalent.

Table 3. Estimated land use change emissions due to U.S. ethanol production (Figures are annual CO_2 emissions in grams per gallon of ethanol)

GTAP results off of 2001 database	Average emissions	1676
	Marginal emissions	1846
GTAP results off of 2006 database	Average emissions	1407
	Marginal emissions	1446
GTAP results off of 2006 plus population & yield growth	Average emissions	1116
	Marginal emissions	1217

Table 4. Estimated well-to-wheel ethanol and gasoline emissions for average land use changes (emissions are in grams per gallon of gasoline equivalent)

Description	Ethanol Emissions	Gasoline Emissions	Ethanol GHGs vs Gasoline (percent)
Simulations Off of 2001	10342	11428	90.5
Simulations Off of 2006	9933	11428	86.9
Simulations Off of 2006 Plus population & yield growth	9490	11428	83.0

Land use change and the associated GHG emissions is a very controversial topic. Some argue it is impossible to measure such changes. Others argue that failure to measure the land use changes and the consequent GHG emissions would lead us to incorrect policy conclusions. After working on this topic for over two years, we come out between these extremes. First, with almost a third of the US corn crop today going to ethanol, it is simply not credible to argue that there are no land use change implications of corn ethanol. The valid question to ask is to what extent land use changes would occur. Second, our experience with modeling, data, and parameter estimation and assumptions leads us to conclude that one cannot escape the conclusion that modeling land use change is quite uncertain. Of course, all economic modeling is uncertain, but it is important to point out that we are dealing with a relatively wide range of estimation differences.

In some cases, the results are fairly stable regardless of the simulation. For example, the percentage of land that comes from forest ranges between 25 and 35 percent depending on the model and assumptions being used. Similarly, the fraction of land use change that occurs in the U.S. ranges between 25 and 34 percent. However, the land needed to meet the ethanol mandate ranges between 0.12 and 0.22 hectares/1000 gallons, which is a fairly wide range. The land use ethanol CO_2 emissions per gallon range between 1116 and 1676, also a fairly large range. Total ethanol CO_2 emissions due to production and consumption of gasoline (including land use) range between 77.5 g/MJ and 84.4 g/MJ. Ethanol emissions as a fraction of gasoline emissions range between 83.0 and 90.5 percent. From these results, we feel confident that corn ethanol would meet a 10 percent savings standard. On the other hand the results suggest that corn ethanol would not meet a 20 percent emissions reduction standard. However, we cannot say that corn ethanol would not meet a 20 percent standard given the inherent uncertainty in the analysis, and potential improvement in direct emissions associated with corn farming and ethanol production.

Analysis such as that undertaken here is very complex and is limited by data availability, validity of parameters, and other modeling constraints. Economic models, like other models, are abstractions from reality. They can never perfectly depict all the forces and drivers of changes in an economy. However, the basic model used for this analysis, GTAP, has withstood the test of time and peer review. Hundreds of peer reviewed articles have been published using the GTAP data base and analytical framework. In this project, we have made many changes in the model and data base to improve its usefulness for evaluating the land use change impacts of large scale biofuels programs. Yet, uncertainties remain. In this paper, we have described the evolution of the modeling and analysis and present openly the evolution of the results. We believe quite strongly that analysis of this type must be done with models and data bases that are available to others. Replicability and innovation are critical factors for progress in science. They also are important for credibility in policy analysis.

List of Figures

1. Introduction

US ethanol production has increased sharply from 1.7 billion gallons (BGs) in 2001 to about 10 BGs in 2009. According to the Renewable Fuel Standard (RFS) in the US Energy Independence and Security Act of 2007 (CRS RL34294), 2007, US corn ethanol production will reach 15 BGs in 2015. This level of ethanol production will affect agricultural activities within the US and around the world. In particular, it can cause land use changes anywhere in the world, and the implications of land use changes are complex and controversial. A sizeable ethanol production program has the potential to increase corn price, corn yield per unit of land, affect corn consumption, change corn trade, and encourage livestock producers to use byproducts of ethanol production in their animal feed rations. Land use changes associated with increased corn ethanol production are important because the land use changes can affect the CO_2 emissions associated with ethanol production and consumption.

Argonne National Laboratory (ANL) (Wang 1999, Wang et al. 1999, and 2005) has developed a life cycle model (GREET) which estimates the emissions of greenhouse gases (GHGs, including CO2, CH4, and N2O) of corn ethanol production. The GREET model classifies GHG emissions into three categories: 1) feedstock production; 2) fuel production - corn to ethanol in this case; and 3) vehicle operation. The total emissions associated with the ethanol supply chain are then compared with the analogous calculations for gasoline. At present, there is limited data on GHG emissions from direct land use changes due to biofuel production included in the GREET model. The land use consequences of biofuel production and their corresponding emissions were highlighted in the literature. The early papers published in this area show that biofuel production could have extraordinary land use implications (Searchinger et al. 2008[1], Fargione et al. 2008). Because the land use emissions were claimed to be so large, it was deemed important to get different assessments of the possible land use changes and associated emissions. Argonne and Purdue agreed that Purdue would conduct such an analysis using the Global Trade Analysis Project (GTAP) modeling framework and data base. In order to do this analysis with GTAP, several model and data base modifications were required, and these are described in this report.

This report aims to evaluate land use changes and CO_2 emissions induced by US corn ethanol production for several alternative configurations and assumptions. The results of this paper provide information on land use related emissions due to ethanol production that can be combined with the emissions calculated in GREET to produce total green house gas (GHG) emissions associated with corn ethanol production and use. This total can then be compared with gasoline to determine the net gain/loss for corn ethanol production and use compared with gasoline.

To achieve this goal we use three major components. First, we use a computational general equilibrium (CGE) model to assess the economic impacts of ethanol production and its land use implications for the world under alternative sets of assumptions. The CGE model is a special version of the Global Trade Analysis Project (GTAP) model (Hertel, 1997) of the global economy which was recently developed by Taheripour, Hertel, and Tyner (2009) to evaluate impacts of biofuel production for the global livestock industry.

The second component consists of a module which converts land use changes estimated in GTAP to the associated CO_2 emissions. This module generates CO_2 emissions factors which we use to convert land use changes into CO_2 emissions based on the Woods Hole Research Center data set on the soil and land cover carbon profiles. The Woods Hole data set divides the

[1] We will henceforth refer to this paper as SEA

whole world into 10 regions and provides data on the soil and land cover carbon profiles for each region[2].

Finally, we convert the land use related emissions calculated in module two to emissions per gallon of 100% ethanol and add those emissions to those calculated in GREET to get total emissions. This can be done either within the GREET model or by direct calculations. For this paper we have done the calculations directly.

In this report rather than using the terms direct and indirect emissions, as is commonly reported in the literature, we categorize the emissions as those calculated in GREET and associated with use of corn for producing and consuming ethanol and emissions associated with land use changes. By some definitions of the term indirect, these would be labeled indirect emissions, but to avoid confusion we label them emissions associated with induced land use changes.

We should from the outset acknowledge that land use change is a complicated process. It is driven by many factors and varies through time. There are social as well as economic factors involved in the complicated process of evolving land use. The factors vary by culture, region, and economy.[3] Obviously neither this analysis nor any analysis can capture all the factors involved in land use change. What we have attempted to do is to isolate the impacts of a substantial increase in US corn based biofuels production. Since corn is a globally produced and consumed commodity, these impacts will be of necessity global. The impacts will be driven to a

---

[2] In our earlier report (Tyner, Taheripour, and Baldos, 2009) we applied the IPCC data set as well. The IPCC data set provides data on the soil and land cover carbon profiles at a global scale with no specification of geographical distribution. The IPCC land use emissions factors are much larger than the regional emissions factors derived from the Woods Hole data set. In this report we only apply the land use emissions factors obtained from the Woods Hole data set. The IPCC data set is too aggregate to be useful in this analysis. Since our results are down to the AEZ and country level, we took advantage of the greater disaggregation in the Woods Hole data.

[3] We are indebted to Gbadebo Oladosu and Keith Kline of Oak Ridge National Laboratory for providing data and useful perspectives on the land use change process.

significant degree by changes in global supply and demand of feed grains. Thus, we have used a global general equilibrium model which can capture many of these market mediated effects.

The rest of this paper is organized as follows. We first introduce the GTAP model and modifications which are made in this model to make it suitable for analyzing economic and environmental consequences of biofuels. Then we explain our simulations and assumptions behind them along with the land use results from these simulations. After that we introduce the land use CO_2 emission factors which we use to convert land use changes into CO_2 emissions. Finally, we present CO_2 emissions induced by US ethanol production due to land use changes and compare these results with results from other studies.

2. Land use changes due to US ethanol production: GTAP model

To evaluate the impacts of the US corn ethanol production on global land use we need a model which is global in scope, and which links global production, consumption and trade. In addition, the model should properly link energy, biofuel, and agricultural markets. Since biofuel, crop, and livestock industries compete through the land market, the model should link these activities through the land market as well. Furthermore, biofuels byproducts, which can be used in animal feedstuffs, bridge these industries through a triangular relationship which alters the nature of competition among these industries. All of this has led us to use a special purpose version of the Global Trade Analysis Project (GTAP) model and its database. GTAP is a computable general equilibrium (CGE) model which considers production, consumption, and trade of goods and services by region and at a global scale. Figure 1 represents an illustrative overview of the GTAP model.

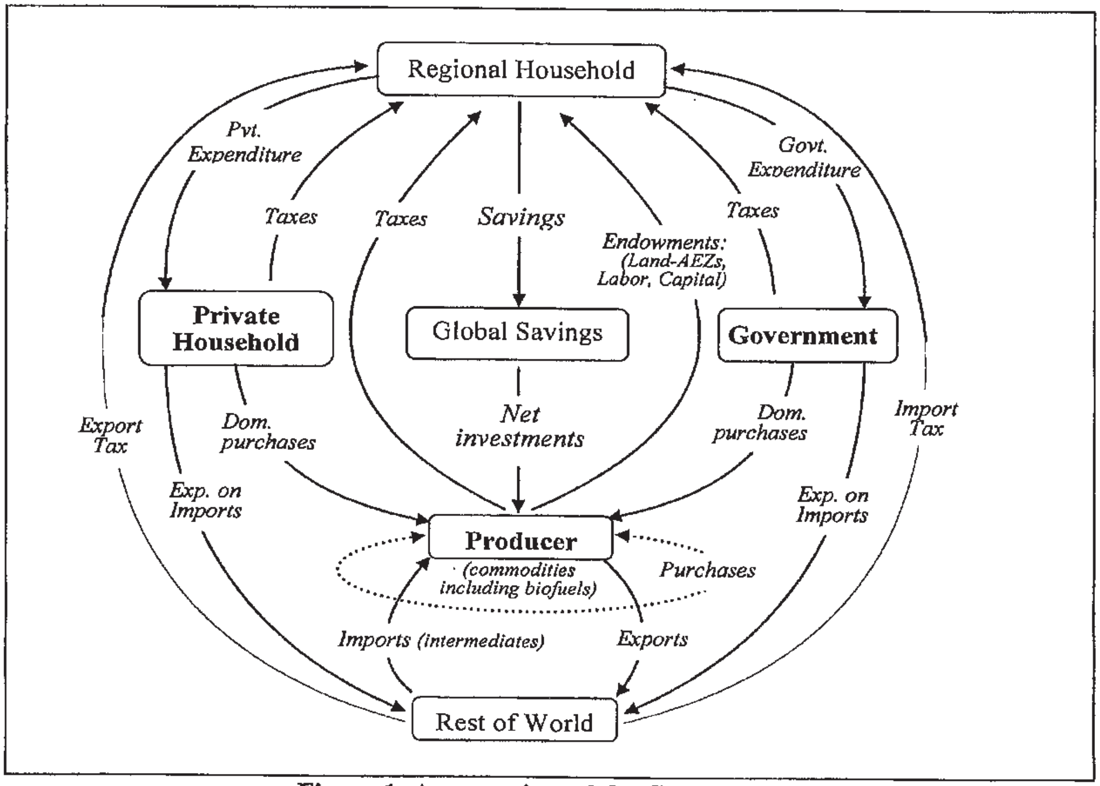

Figure 1. An overview of the GTAP model

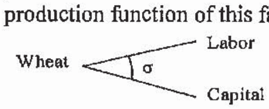
In GTAP each country or composite region is represented by a regional household which collects all incomes generated by the economy and allocates them among three components of the final demand: Private Household, Government, and Savings (for details see Brockmeier (1996)). In this model households (consumers) maximize their utilities according to their budget constraints and producers minimize their production costs subject to resource constraints. The model determines demands for and supplies of goods and services according to consumer and producer behaviors. Resources are labor, capital, land, and natural resources, and they owned by consumers. In GTAP, markets are competitive, consumers and producers are price takers, and utility and production functions usually follow the constant elasticity of substitution (CES) functional forms[4]. We will introduce the production and consumption structures of GTAP later in this report.

The GTAP model simulates the world economy using a global database which contains input-output tables for almost all countries. These tables provide detailed information on production and consumption of commodities and services along with investment and bilateral trade among regions. This database also includes payments to labor, capital, and land (for details see Dimaranan (2006)). GTAP data come from a multitude of sources. The country input-output tables are generally provided by contributors in the countries who have access to national statistics data. Trade data come from UN sources and USDA. Protection data come from several sources, but CEPII in France is the major source. Energy data come from the IEA in Paris. There are other sources as well. The GTAP staff at Purdue set the standards for data and assure quality and consistency. The database also includes the most updated global land cover and land uses database by region disaggregated into 18 Agro Ecological Zones (AEZs). These AEZs share common climate, precipitation and moisture conditions. The land cover and land use database is based on the Center for Sustainability and Global Environment (SAGE) database (for more information on the land use database see Lee et al. (2005)). The land use data base provides information on global crop yields as well. Note that the land use database excludes inaccessible forests. The version 6 of the GTAP data base covers 57 groups of commodities and services for

[4] Here, we use a simple graphical example to explain a constant elasticity of substitution functional form. Consider a producer which can use labor (L) and capital (k) to produce wheat (W). The following simple figure depicts the production function of this farmer:



In this graph σ represent the elasticity of substitution between labor and capital. If the farmer can only use labor and capital in a fixed proportion, then $\sigma=0$. However, if the farmer can reduce number of work hours and increase the amount of capital (say due to an increase in wage rate) to achieve its production goal, then σ is a number greater than zero. In general, σ can take any number between zero and infinity when we consider substitution among inputs or among consumption of goods and services.

87 countries and regions. Version 6 is based on 2001 data, and was the starting point for the biofuels analysis reported in this paper.

The GTAP model and its data base have been frequently modified and improved in the past three years to develop an improved tool for examining the economic and environmental consequences of the global biofuel production. In this process Taheripour et al. (2007) have explicitly introduced three biofuel commodities (including ethanol from food grains, ethanol from sugarcane, and biodiesel from oilseeds) into the GTAP data base version 6.

Birur, Hertel, and Tyner (2008) have incorporated biofuels into the GTAP-E model[5]. They augment the model by adding the possibility for substitutability between biofuels and petroleum products. We will henceforth refer to this model as GTAP-BIO-ADV (advanced GTAP-BIO model). Figures 2 and 3 represent the structure of consumption and production sides of this model. In these figures CES means constant elasticity of substitution (as explained in footnote 4 above) and CDE stands for constant difference elasticity and is the means of expressing household preferences in GTAP.

[5] GTAP-E was originally developed by Burniaux and Truong (2002) to incorporate energy into the GTAP framework, and recently modified by McDougall and Golub (2007).

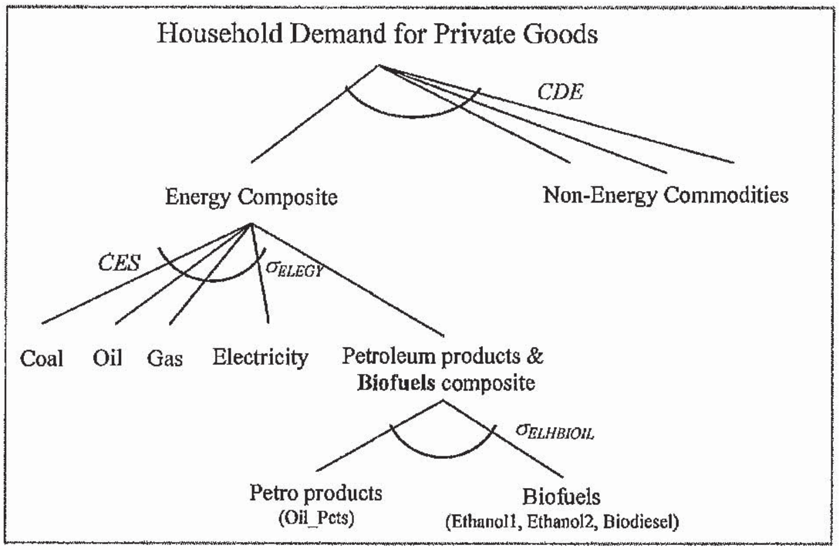


Figure 2. Structure of consumption side of the GTAP-BIO-ADV model

Figure 2 indicates that households could use biofuel as a substitute for petroleum products in GTAP-BIO-ADV. On the other hand, Figure 3 shows that at the bottom-most level of the production side biofuels are a compliment to petroleum products in the production process. It should be noted here that in a general equilibrium model like GTAP, all the equations are solved simultaneously, so it is not a stepwise solution process.

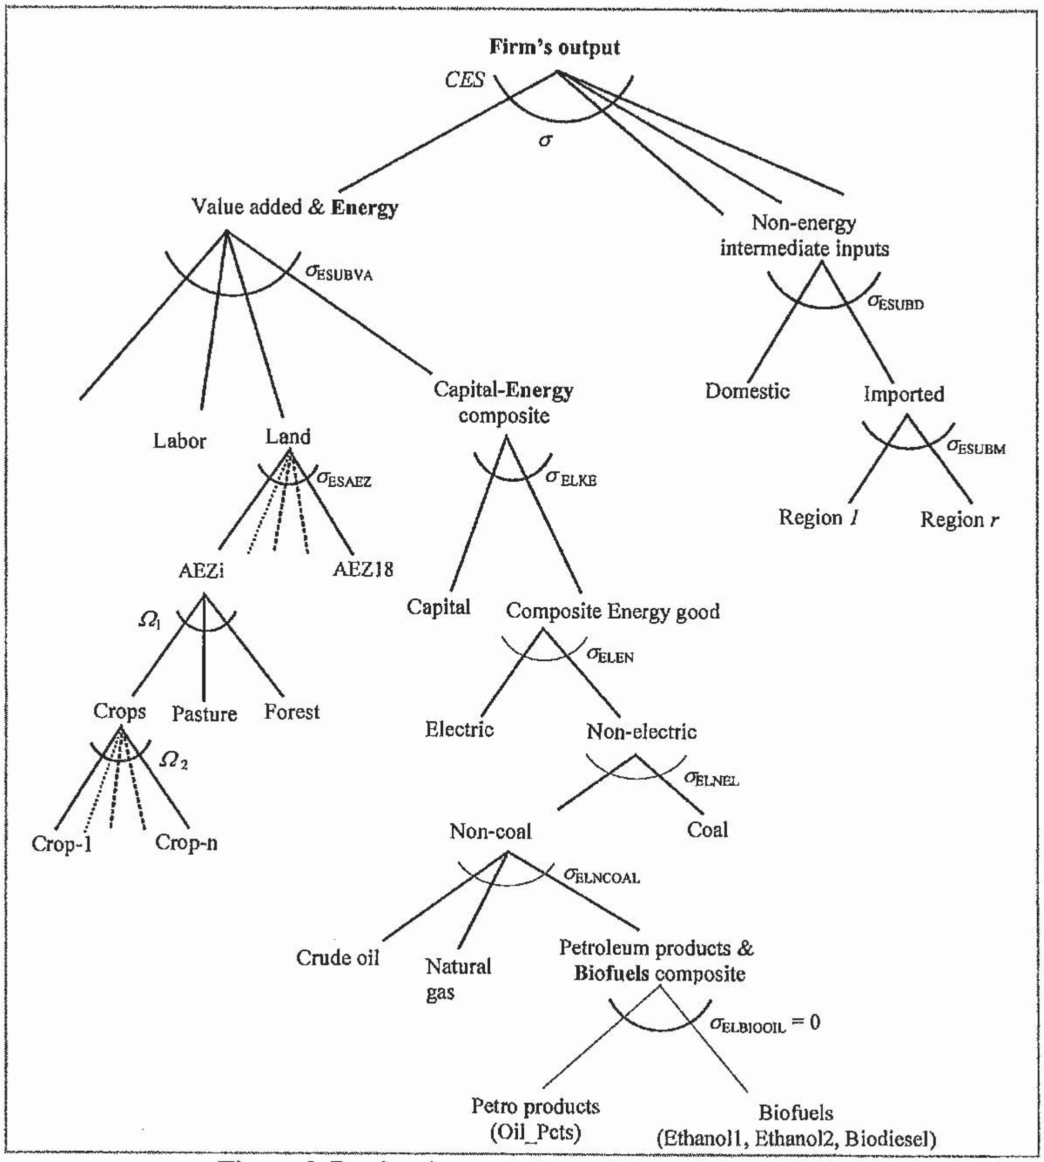

Figure 3. Production structure of GTAP-BIO-ADV

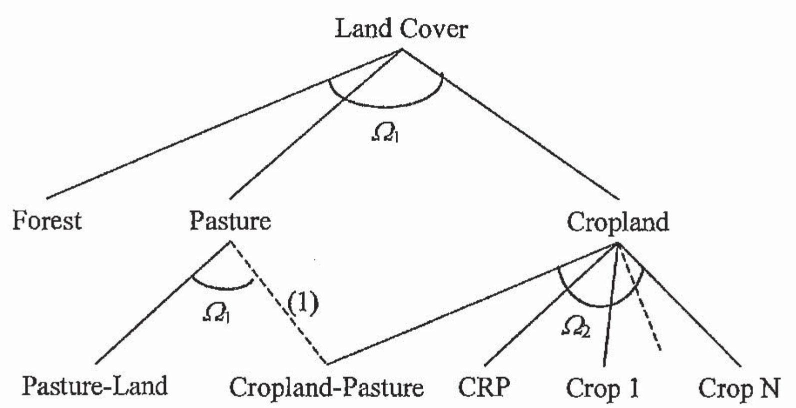
Hertel, Tyner, and Birur (2008) have recently augmented this model with a land use module to better depict the global competition for land among land use sectors. The land use module traces changes in the demand for land across the world at the AEZ level and thereby captures the potential for real competition between alternative land uses. In this module land does not move across AEZs. However, distribution of land across its alternative uses can change within each AEZ. Alternative uses of land are: forest, grassland, and cropland. In this module livestock producers compete to use grassland, and there is competition among agricultural activities to use croplands. Corn is in the coarse grains category along with sorghum, oats, and barley. However, in the US, that grouping is mostly corn. For example, in 2009, corn constituted 95.4% of the coarse grains production (by weight). Most of the rest was sorghum, which also could be used for biofuels. There is no need to separate corn from the other coarse grains.

Recently, Birur (2010) has added two new land categories of cropland-pasture and unused cropland (e.g. retired cropland under the US Conservation Reserve Program (CRP)) into supply of land. Figure 4 represents the new structure of land supply in the modified model.



(1) To create this link we introduced an industry into the GTAP framework which uses only cropland-pasture as an input and sells its output (land) to the livestock industry.

Figure 4. Land cover and land use activities in the GTAP-BIO-ADV

In the new land supply tree cropland pasture and unused cropland (mainly CRP) are explicitly defined as components of cropland. CRP land mainly generates environmental benefits. Hence, this type of land is introduced as an input into the sector which provides these services (i.e. Oth_Ind_Se). Cropland-pasture is an input into livestock industry. To facilitate transition of cropland-pasture from livestock industry to crop production and vice versa, an industry is added to the model which uses cropland-pasture as an input and sells its output (cropland-pasture) to the livestock industry. This industry competes in the land market with crops. Finally, the livestock industry combines cropland-pasture with pasture land in its production function as shown in Figure 5. This figure indicates that the livestock industry combines pasture land with cropland-pasture in the value added nest and uses feed and non-feed inputs in its production function.

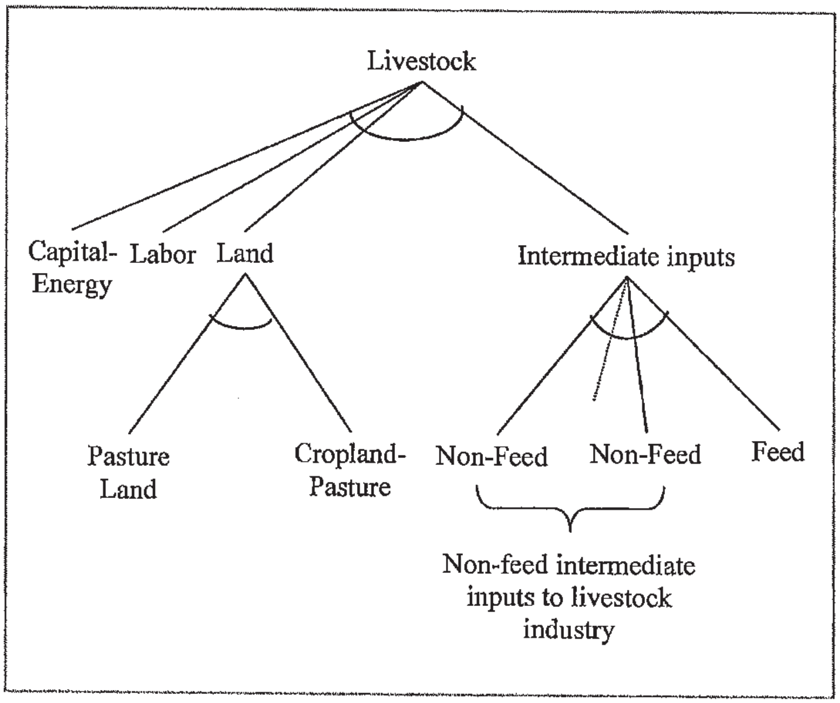


Figure 5. Production structure of the livestock industry

The land use module determines expansion of cropland and its distribution among agricultural activities according to two important parameters: price elasticity of yield and ratio of productivities of marginal and average lands. The price elasticity of yield measures changes in crop yield due to the changes in crop price. In the simulations reported in this report we assumed that the price elasticity of yield is equal to 0.25. Keeney and Hertel (2008) have provided a detailed discussion on this parameter along with econometric evidence behind it.

The ratio of marginal and average productivities measures the productivity of new cropland versus the productivity of existing cropland. We will henceforth refer to this ratio as ETA. In our earlier work we were assumed that ETA=0.66 all across the world. In this report we use a set of regional ETAs at the AEZ level which is obtained from a bio-process-based biogeochemistry model (Terrestrial Ecosystem Model (TEM): Zhuang et al., 2003) along with spatially referenced information on climate, elevation, soils, and vegetation land use data. The new regional ETAs vary across the world and among AEZs. Appendix A represents these ETAs along with more details on their calculation processes. The new estimated ETA values are now included in the model by country and AEZ.

A major attempt has been made to introduce production, consumption, and trade of biofuel byproducts into the GTAP modeling framework. Taheripour et al. (2010) and Taheripour, Hertel, and Tyner (2009) represent the latest modifications in this area. These papers extend the original GTAP-BIO database (Taheripour et al. 2007) in several directions to properly trace the links among biofuel, vegetable oil, food, feed, and livestock industries. Unlike the initial database these papers distinguish between feedstock of the US and EU ethanol industries. In the modified GTAP-BIO database, the US uses corn and EU uses wheat in ethanol production. Following the original work, the ethanol industry also produces distillers dried grains with solubles (DDGS). They also split the "other food products" industry into two distinct industries: processed food and processed feed. In addition, they split the vegetable oil sector into two distinct industries: crude vegetable oil and refined vegetable oil. The crude vegetable oil sector uses oilseeds and produces crude vegetable oil (as the main product) and oilseed meal (as the byproduct). Unlike the original GTAP-BIO database which directly converts oilseeds to biodiesel, they introduce a biodiesel production technology which uses crude vegetable oil and other inputs to produce biodiesel.

In addition, the latter paper uses a three level nesting structure for the demand for animal feedstuffs in the livestock industry which brings more flexibility into this part of the model. Figure 6 depicts this nesting structure. At the lower level of this nesting structure DDGS and coarse grains are combined to create an energy feed. At this level oilseeds and oilseed meals are combined to create a protein feed as well for countries that use oilseeds directly as feed. At a higher level the protein and energy feed ingredients are combined. At this level other crops also are bundled together. The livestock industry receives some inputs from processed livestock industry as well, and these materials are bundled together at the second level too. Finally, all feed ingredients are combined to create the feed composite.

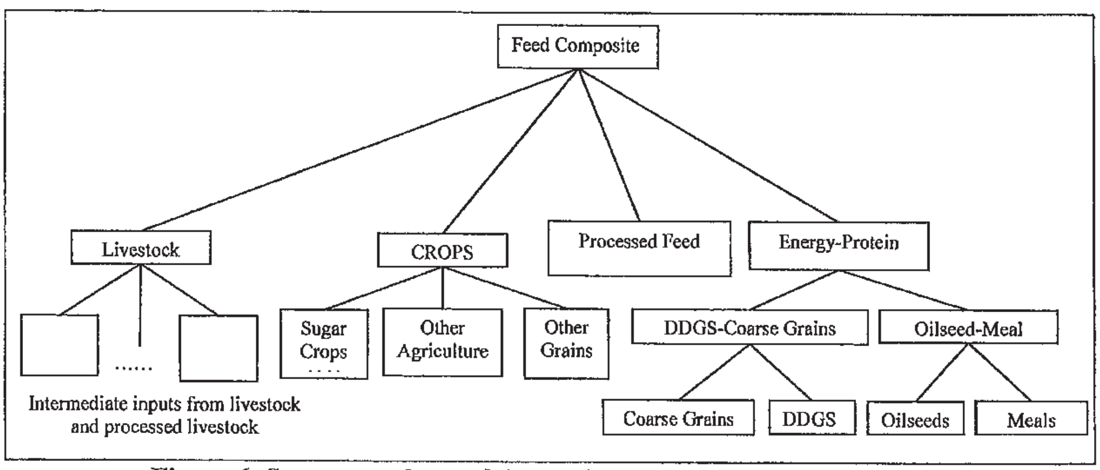

Figure 6. Structure of nested demand for feed in livestock industry

They assigned elasticities of substitution to the different components of the demand for feed to replicate changes in the prices of DDGS and meals in the US and EU during the time period of 2001-2006. In addition, they did several experimental simulations and sensitivity tests to reach displacement ratios between DDGS, grains, oilseeds, and oilseed meals according to the literature in this area. Since oilseeds and oilseed meals are good substitutes in some regions, they applied a relatively high elasticity of substitution, 20, between these two feed materials for all types of animal species. Following the literature, they used values of 25, 30, and 20 for the elasticities of substitution between coarse grains and DDGS in the dairy farms, other ruminant, and non-ruminant feed structure, respectively. They also applied a non zero and small value, 0.3, for the elasticity of substitution between the energy and protein feedstuffs because DDGS could displace a portion of meals in some feed rations, as shown in Arora, Wu, and Wang (2008) and Fabiosa (2009). In the composite of other crops and composite of processed livestock inputs they applied elasticities of substitution of 1.5 for all types of livestock industry. Finally, following Keeney and Hertel (2005) they used 0.9 for the elasticity of substitution at the higher level of the feed demand nest.

Here we use some GTAP simulation results to show how these elasticities shape the cost structure of the livestock industry. To accomplish this task we use the results obtained from the simulations introduced in the next section of this report. In particular, we use the results of the first simulation of the second group of experiments. This particular simulation replicates transition of the global economy from 2001 to 2006. The results of this simulation predict that the cost shares of coarse grain, other crops, and meals in the US livestock industries declined during the time period of 2001-2006, while the cost share of DDGS increased. The largest substitution is DDGS for coarse grains, but there is also substitution for other crops and oilseed meals, depending on the livestock species. Note that we dropped processed feed from the list of animal feeds to highlight the changes in the shares of crops, DDGS, and meals in this time period (Table 1).

Table 1. Cost shares of major feed items in the US livestock industries in 2001 and 2006*

Feed Items	2001			2006		
	Dairy	Meat Ruminant	Non-Ruminant	Dairy	Meat Ruminant	Non-Ruminant
Coarse Grains	67.6	68.4	82.9	64.9	63.8	83.0
Other crops	6.4	10.4	2.9	6.0	9.7	2.7
DDGS	5.6	6.4	1.1	9.2	11.5	1.6
Oilseeds meals	20.3	14.9	13.1	19.9	14.9	12.6

*Processed feed is dropped from this table to highlight shares of items listed in the table.

To evaluate the land use implications of US ethanol production we use a new model which includes all modifications and improvements which have been made in the GTAP-BIO-ADV model and its data base described above and in the associated references. In short this model has the following specifications:

1) It covers production, consumption, and trade of three types of biofuels: ethanol from crops, ethanol from sugarcane, and biodiesel from crude vegetable oil.
2) By products are DDGS and oilseeds meals.
3) The crude vegetable oil industry uses oilseeds and produces crude vegetable oil and oilseed meals.
4) The biodiesel industry uses crude vegetable oil to produce biodiesel.
5) The demand for feedstuffs follows a three level nesting structure.
6) The land module handles two new land categories of unused cropland and cropland pasture. While the model could trace changes in these two groups of land across the world, we have data on cropland pasture for the US and Brazil and data on CRP only for the US.

7) We have calibrated ETA for each AEZ and region instead of using the globally fixed ETA parameter as in the past.
8) Energy demand and supply elasticities have been re-calibrated for this version.
9) In this report we divide the world economy into 19 regions, 34 groups of commodities and services, 32 industries, and 5 groups of endowments. The list of regions, commodities, industries and endowments are shown in Appendix B.
10) In this report when we shock US ethanol, we hold production of other biofuels constant.

3. GTAP simulations and their results

To evaluate the land use implications of US ethanol production we develop three groups of simulations. In the first group we follow the approach that we used in our earlier report (Tyner, Taheripour, and Baldos, 2009). In this approach, we calculate the land use implications of US ethanol production off of the 2001 database. This approach isolates impacts of US ethanol production from other changes which shape the world economy. This method assumes that other factors such as population growth, yield improvement, and economic growth do not affect the land use implications of producing more ethanol from agricultural resources. Hertel et al. (2010) provide more insights on this approach. While this approach uses the 2001 starting point, it is different from our January 2009 draft results in that all the model changes described above have been included in this first set of simulations.

In the second group of simulations, we first construct a baseline which represents changes in the world economy during the time period of 2001-2006. Then we calculate the land use impact of the US ethanol production off of the updated 2006 database, while we follow the principles of the first group of simulations for the time period of 2006-2015. Finally, in the third group of simulations we use the updated 2006 database obtained from the second group of simulations, but we assume that during the time period of 2006-2015 population and crop yields will continue to grow. These are two important factors which could alter the land use impacts of ethanol production in the future. These three groups of simulations and their results are described in the rest of this section.

Group 1: Simulations with no economic and yield growth and 2001 base

We calculate the land use implications of the US ethanol production for the following 6 time segments:

- Ethanol production from 2001 to 2006 level.
- Ethanol production from 2006 level to 7 B gallons,
- Ethanol production from 7 B to 15 B gallons by increments of 2 B gallons.

The global biofuel industry has followed a rapid growth path during the time period of 2001-2006. The historical observations from this time period have been used to calibrate the biofuel-parameters of the model (Hertel, Tyner, and Birur, 2008). Then we consider gradual increases in the production of US ethanol after 2006 to evaluate marginal impacts of ethanol production. For this purpose we first increase the US ethanol production from its 2006 level (4.855 BG) to 7 B gallons. Thereafter we increase ethanol production by increments of 2 B gallons to achieve the goal of 15 B gallons of ethanol in 2015.

The detailed global land use changes obtained from the first group of simulations are shown in Appendix C. Table 2 summarizes these results. These results indicate that producing 13.23 BGs of ethanol (from the 2001 production level to 15 BGs) requires about 2.96 million hectares of additional land, of which 1.01 million hectares (34%) are expected to be in the US, with the reminder (1.95 million hectares) in other regions (66%). This result suggests that the land use changes due to US ethanol production will mainly take place outside the US. Results from this group of simulations also indicate that the size of required land to achieve the 15 BGs ethanol production is much smaller than the land use changes suggested by a simple calculation which ignores important factors that could mitigate land use impacts of ethanol production[6]. Several factors mitigate the land use consequences of ethanol production. Among them are: less corn consumption in the livestock industry due to using more DDGS in the livestock industry, reductions in output of the livestock industry, reallocation of croplands across the world among alternative crops, and higher yields in crop production due to higher prices. Hertel et al. 2010 have decomposed contributions of these factors in mitigating the land use impacts of ethanol production.

Table 2. Global land use changes due to the US ethanol production: Off of 2001 database

Changes in US corn ethanol production	Land use changes (hectares)			Distribution of land use changes (%)			Hectares per 1000 gallons
	Within US	Other Regions	World	Within US	Other Regions	World	
3.085 BG (2001 to 2006)	227982	382394	610376	37.4	62.6	100.0	0.20
2.145 BG (2006 to 7 BG)	162558	297766	460324	35.3	64.7	100.0	0.21
2.000 BG (7 to 9 BG)	152990	295051	448041	34.1	65.9	100.0	0.22
2.000 BG (9 to 11 BG)	154018	310639	464657	33.1	66.9	100.0	0.23
2.000 BG (11 to 13 BG)	154706	325639	480345	32.2	67.8	100.0	0.24
2.000 BG (13 to 15 BG)	155000	340311	495311	31.3	68.7	100.0	0.25
13.23 BG (2001 to 15 BG)	1007253	1951800	2959053	34.0	66.0	100.0	0.22

The magnitude of land requirement to increase US ethanol production from its 2001 level to 15 BG obtained from these simulations is smaller than its corresponding value in our earlier report (Tyner, Taheripour, and Baldos, 2009) by about 16.7% (i.e. 2.96 million hectares versus 3.55 million hectares). Two major modifications in the GTAP model contribute to this reduction.

[6] One can determine land use changes due to the US ethanol production by multiplying corn yield (370 bushels per hectare of land) by a corn to ethanol conversion factor (e.g. 2.7 gallons per bushel of corn). This simple approach leads to 1000 gallons of ethanol per hectare of land. Hence, based on this simple calculation, increasing ethanol production from its 2001 level (1.77 BG) to 15 BG needs about 13 million hectares of land.

A portion of this reduction is associated with the land conversion factors. As noted earlier in this report we apply a set of regional land conversion factors at the AEZ level. These land conversion factors in several AEZs are higher than the single conversion factor of 0.66 which we used in our earlier work (see Appendix A).

Introducing the new land categories (cropland pasture and unused land[7]) into the model also contributes to the reduction in land requirement. In particular, in the US and Brazil in the presence of cropland pasture farmers convert a portion of this type of land to crop production. For example, an increase in US ethanol production from its 2001 level to 15 BG brings about 1.2 million hectares of cropland pastures into crop production, but not only to corn production. Indeed, a portion of this land conversion prevents sharp reductions in production of other crops. It is important to note that the competition between crop and livestock industry prevents full conversion of cropland pasture to crop production.

These two modifications not only reduce the land requirement of ethanol production. They also alleviate the adverse impact of ethanol production on the prices and consumption of crops.

Table 2 also indicates that the required land for producing 1000 gallons of ethanol grows as we move to higher levels of ethanol production. For example, for the 2001 to 2006 simulation, an additional 3.085 B gallons of ethanol triggers global land use changes of roughly 610,376 hectares. This is equal to 0.20 hectares per 1000 gallons of ethanol. However, for the 13 BGs to the 15 BGs simulation, an additional 1000 gallons of ethanol requires 0.25 hectares of land. To increase ethanol production from the 2001 level to 15 BGs, we need an average of 0.22 hectares of land per 1000 gallons of ethanol. The marginal level (0.25) is higher than the average (0.22),

[7] In these simulations we hold the area of US CRP land constant.

which would be expected because as more land comes into production, the yields on the incremental area would be lower.

Table 3 depicts another aspect of the land use implications of US ethanol production. This table shows the distribution of land use changes between forest and grassland. About 24.7% of the required croplands which are needed to increase ethanol production from its 2001 level to 15 BGs come from forest, and the rest (75.3%) come from grasslands. Table 3 also indicates that as we move to higher levels of ethanol production the portion of forests in the converted land into crop production increases very slightly (from 23.5 % in 2001 to 25.1% at the 15 BGs ethanol production.

Table 3. Global land use changes due to the US ethanol production: Off of 2001 database

Changes in US corn ethanol output	Land use changes (hectares)			Distribution of land use changes (%)		
	Forest	Grassland	Crop*	Forest	Grassland	Total*
3.085 BG (2001 to 2006)	-143716	-466652	610376	23.5	76.5	100.0
2.145 BG (2006 to 7 BG)	-114409	-345912	460324	24.9	75.1	100.0
2.000 BG (7 BG to 9 BG)	-112330	-335712	448041	25.1	74.9	100.0
2.000 BG (9 BG to 11 BG)	-116795	-347864	464657	25.1	74.9	100.0
2.000 BG (11 BG to 13 BG)	-120688	-359650	480345	25.1	74.9	100.0
2.000 BG (13 BG to 15 BG)	-124151	-371156	495311	25.1	74.9	100.0
13.23 BG (2001 to 15 BG)	-732089	-2226946	2959053	24.7	75.3	100.0

*The difference between the changes in cropland and the sum of forest and grassland is due to rounding. Cropland pasture is included in cropland.

In the absence of crop yield growth, the increasing global land use change given equal increments of US ethanol production is explained by the differences in the productivity of available lands. Productive lands are employed first before marginal lands, which have lower productivity and lower yields. At low levels of production, more productive lands are available; hence, less land is required to produce additional ethanol. However, at high levels of production, most of the productive land is already being used, and only marginal land is available. Given this, more marginal land is required to produce the same increment of US corn ethanol production.

Group 2: Simulations with updated baseline for the time period of 2001-2006

The global economy changed significantly over the 2001-2006 period. Countries followed different economic growth paths, population increased everywhere at different rates, land productivity rapidly increased in many regions (with some exceptions), and technology has improved in many areas. These are important factors which could alter the land use implications of biofuels. In the second group of simulations we take these factors into account.

To accomplish this task we developed a database which includes data on: crop production, harvested area, forest areas, gross capital formation, labor force (skilled and unskilled), gross domestic product, and population for the whole world at the country level. Then we used this data set to generate a baseline which replicates transition of the global economy from 2001 to 2006, while we targeted global biofuel production during this time period in the presence of population, income, and yield growths. In building the baseline we guide the model to replicate the historical paths of changes in harvested area across the world as well. Furthermore, we trace changes in global forest area to match our land use results with the historical changes in forest areas during the time period of 2001-2006. We adjusted rates of technological improvements to trace changes in cropland and forest areas.

Data sources

To construct the baseline the following data items were collected:

1- Population: World population figures by country were obtained from the UN website for 2001-2006. Then the population figures by region were calculated for our GTAP aggregation[8]. Finally, the percentage change in population between 2001 and 2006 was calculated for each region (see table 4).

2- GDP: Real GDP figures by country were obtained from the World Development Index (WDI) database for 2001-2006. Then the GDP figures by region were calculated for our GTAP aggregation. Finally, the percentage change in GDP between 2001 and 2006 was calculated for each region (see table 4).

3- Capital: Real capital formation figures by country were obtained from the WDI database for 2001-2006. Then the capital formation figures by region were calculated for our GTAP aggregation. Finally, the percentage change in capital formation between 2001 and 2006 was calculated for each region (see table 4).

4- Labor: Labor force figures by country were obtained from the WDI database for 2001-2006. Then the labor force figures by region were calculated for our GTAP aggregation. Finally, the percentage change in labor force between 2001 and 2006 was calculated for each region (see table 4). We followed Walmsley, Dimaranan, and McDougall (2000) to split labor force into groups of skilled labor and unskilled labor.

5- Crop production: Crop production figures by crop type and by country were obtained from the FAO website for 2001-2006. Then crop production figures by region were calculated for our GTAP aggregation for 2001-2006.

6- Harvested Area: Harvested areas by crop type and by country were obtained from the FAO website for 2001-2006. Then the harvested areas by region were calculated for our GTAP aggregation for 2001-2006.

[8] The aggregation schedule is shown in Appendix B, Table B-2.

7- Yield: Yields were calculated by region and by crop using items 5 and 6 introduced above. Since yield fluctuates over time, annual percentage changes in yields were calculated. Then we obtained the average of percentage changes in yield over the time period of 2001-2006 for each crop within each region. Table 5 reports the cumulative yield change for each region and crop category over the five years. Thus these percentages are roughly five times the annual growth rates.

8- Global forest export price - Values and quantities of exports of forestry products were obtained from the FAO website for 2001-2006. These figures were used in defining a global price index for forest products to shape technological progress in forest industry.

9- Finally, we used the FAO assessment of changes in global forest areas to track changes in the global forest areas (FAO, 2006). The FAO assessment covers the time period of 2000-2005, while we need changes in 2001-2006. So we assumed that changes in forest areas within the period of 2000-2005 are similar to the changes in the time period of 2001-2006.

To generate the 2006 baseline, we shock major macroeconomic variables according to the historical observations for the time period of 2001-2006. In particular, we shocked GDP, gross capital formation, labor force, and population at the regional level. We also introduced shocks to increase global biofuels outputs according to actual observations for the same time period. In addition to these shocks, we guide the model to replicate observed improvement in yield over the time period of 2001 to 2006 by crop and by region. Finally, we introduced technological changes in input output ratios to replicate regional changes in harvested area during the time period of 2001-2006. Furthermore we guide the model to trace changes in forest area during the baseline time period. Appendix D shows the list of implemented shocks. This experiment provides us a new database which represents the world economy in 2006 in the presence of changes in the major derivers of the world economy. To separate out the impacts of the US ethanol program from other derivers of the world economy we repeat this experiment without the US ethanol shock. The difference between the land use implications of these two simulations gives us the impact of the US ethanol program for the time period of 2001-2006.

Then we used the updated 2006 database to evaluate the land use impacts of increasing US ethanol from its 2006 level to 15 BG incrementally. The global land use implications obtained from the second group of simulations are shown in Appendix C. Table 6 summarizes these results.

Table 6. Simulated global land use changes due to the US ethanol production: Off of updated baseline

Changes in US corn ethanol production	Land use changes (hectares)			Distribution of Land Use changes (%)			Hectares per 1000 gallons
	Within US	Other Regions	World	Within US	Other Regions	World	
3.085 BG (2001 to 2006)	119281	320068	439349	27.1	72.9	100.0	0.14
2.145 BG (2006 to 7 BG)	76003	225500	301503	25.2	74.8	100.0	0.14
2.000 BG (7 to 9 BG)	71207	217720	288927	24.6	75.4	100.0	0.14
2.000 BG (9 to 11 BG)	71783	223877	295660	24.3	75.7	100.0	0.15
2.000 BG (11 to 13 BG)	72547	228732	301279	24.1	75.9	100.0	0.15
2.000 BG (13 to 15 BG)	73459	233064	306524	24.0	76.0	100.0	0.15
13.23 BG (2001 to 15 BG)	484280	1448962	1933242	25.1	74.9	100.0	0.15

The results obtained from the second group of simulations indicate that we need 1.93 million hectares of cropland to increase ethanol production from the 2001 level to 15 BGs. This figure is smaller than its corresponding figure obtained from the first group of simulations by 34.7%. Two main factors contribute to this reduction. During the time period of 2001-2006 crop yields are growing faster than the demands for crops globally. This reduces the size of land use changes in this period. Then when we calculate the land use implications of US ethanol for the time period of 2006-2015 from the updated database of 2006, we get smaller land use changes because crop yields are higher in the updated database.

In the second group of simulations cropland pasture moves to crop production faster than in the first group of the simulations as well. In the presence of economic growth about 3.9 million hectares of cropland pasture will move to crop production.

Table 7 represents distributions of land use changes between forest and pasture for the second group of simulations. In this group of simulations on average about 34.8% of required land for ethanol production comes from forest land. This figure is higher than the corresponding figure of the first group of simulations (i.e. 24.7%).

Table 7. Simulated global land use changes due to the US ethanol production: Off of updated baseline

Changes in US corn ethanol output	Land use changes (hectares)			Distribution of land use changes (%)		
	Forest	Grassland	Crop*	Forest	Grassland	Total*
3.085 BG (2001 to 2006)	-155414	-283921	439349	35.4	64.6	100.0
2.145 BG (2006 to 7 BG)	-107215	-194290	301503	35.6	64.4	100.0

*The difference between the changes in cropland and the sum of forest and grassland is due to rounding

Group 3: Simulations with crop yield and population growth for the time period of 2006-20015

Some advocates of the US corn ethanol program argue that crop yields will increase in the future such that this increase could eliminate the land use implications of ethanol production. This argument neglects the impacts of the future changes in the demand for crops. Demands for crops could increase in the future due to several factors such as changes in population and income, dietary transition as poorer countries consume more meat, or technological progress. In other words, one cannot examine yield (supply) increases alone; we must also include assumptions about increases in crop demand as well. In the third group of simulations we examine impacts of changes in crop yields and demand as important items which could determine demand and supply for crops and food products.

For our model simulations we use population growth as a proxy for food demand increase. We assume that population will continue to grow globally during the time period of 2006-2015 after 2006 at the annual growth rate of 2001-2006. We also assume that crop yield will increase uniformly at 1% annually after 2006 in all regions and across all types of crops. While 1% might seem small, it is actually a large number as it is applied in all regions and for all crops. We also assume that the regional demands for forest products will increase according to their annual rates of 2001-2006. We made the latter assumption to maintain the long run pattern in forest products outputs. These simulations also include all the changes incorporated in the baseline simulation of the second group of simulations.

To find the land use impacts of US ethanol program under these assumptions we did simulations with and without US ethanol production off of the updated data base for 2006 (obtained in the second group of simulations) for the time period of 2006-2015 in the presence of population and yield shocks. The global land use implications of the US ethanol plan under these assumptions are shown in appendix C. To understand the land use implications of the US ethanol program under these assumptions we first analyze the land use implications with no US ethanol production. Table 8 indicates land use changes due to the yield and population growth for US, EU, Brazil, and other regions.

Table 8 indicates that after 2006 the cropland areas of US, EU, Brazil, and other regions would fall due to the simultaneous shocks in yield and population growth. This means that yield growth would dominant the demand growth for crops, and therefore the demand for cropland decreases everywhere. In addition to that, the yield growth contributes to higher levels of food consumption everywhere.

Table 8. Simulated global land use changes due to population and yield growth after 2006 (figures are in 1000 hectares)

Period	Land cover	US	EU	Brazil	Others	World
2006-2007	Forestry	142.8	194.8	430.5	2141.4	2909.5

The simulation results indicate that consumption of crops and food products grow faster than population everywhere across the world. This indicates that the yield effect works through two channels: 1) reduction in crop land area needed to satisfy demand, and 2) higher per capita consumption of food. This means that one percent yield improvement will not end with one percent reduction in cropland, even if there is no population growth.

The released croplands are going to forest to support the long run growth in forest products. Note that as mentioned earlier in this group of simulations we assume the global forest sector will continue to grow according to its 2001-2006 growth rate.

With this discussion we now examine impacts of adding biofuel shocks into this picture. In general, the US ethanol program in this group of simulations generate smaller land use changes compared the results of the second group of simulations. Table 9 shows that under the assumptions of this group of simulations we need 1.5 million hectares of cropland to increase ethanol production from the 2001 level to 15 BGs. This figure is smaller than the corresponding figure obtained from the second group of simulations by 20%. For the earlier time segments after 2006 the size of land requirement is significantly smaller than what we observed in the second group of simulations. For example, in this group of simulations we need only 0.1 hectares of cropland to produce 1000 gallons of ethanol in the time segment of 2006-2007, while the corresponding number obtained from the second group of simulations is about 0.14.

As we move forward towards 2015, the population growth dominants the yield growth in some regions, and the land requirement grows. Table 9 shows that the share of US in land requirement grows at the beginning but it decreases when we move towards 2015.

Table 9. Simulated global land use changes due to the US ethanol production: with yield and population growth after 2006

Changes in US corn ethanol production	Land use changes (hectares)			Distribution of Land Use changes (%)			Hectares per 1000 gallons
	Within US	Other Regions	World	Within US	Other Regions	World	
3.085 BG (2001 to 2006)	119281	320068	439349	27.1	72.9	100.0	0.14
2.145 BG (2006 to 7 BG)	58799	150754	209553	28.1	71.9	100.0	0.10

13.23 BG (2001 to 15 BG)	431544	1109824	1541368	28.0	72.0	100.0	0.12

The distribution of land use changes between forest and pasture land are similar to the second group of simulations. Our assumption on the regional demands for forest products derives this result. It is very important to note that adding income growth or changes in other economic factors into this picture may change the geographical distribution of land use changes or the distribution of the land requirement for ethanol production between forest and grassland. (Table 10)

Table 10. Simulated global land use changes due to the US ethanol production: With yield and population growth after 2006

Changes in US corn ethanol output	Land use changes (hectares)			Distribution of land use changes (%)		
	Forest	Grassland	Crop*	Forest	Grassland	Total*
3.085 BG (2001 to 2006)	-155414	-283921	439349	35.4	64.6	100.0

*The difference between the changes in cropland and the sum of forest and grassland is due to rounding

4. Land use CO_2 emission factors

We use emissions factors to convert land use changes into the land use CO_2 emissions (LUCE). Land conversions of forest and grassland into crop production releases CO_2 emissions from two sources: 1) direct CO_2 emissions from land conversion and 2) foregone CO_2 sequestration by forests. The direct CO_2 emissions consist of carbon stored in the vegetation and in the soil, which are released when forests or grasslands are cleared and converted into croplands. The forgone carbon sequestration accounts for the amount of carbon that could have been stored from annual forest growth, if land had remained forested. This is the opportunity costs of cleared land in terms of its potential to store carbon.

As mentioned earlier in this report we use the Woods Hole data set[9]. This data set divides the world into 10 homogenous regions, determines distributions of forests and grasslands within each region across different types of vegetation cover, and provides detailed information on the carbon stored in the vegetation and in the soil of forests and grasslands within each region.

[9] This data set, which is taken from the supporting documents of SEA

The Woods Hole data set provides two key carbon figures for each type of land according to its natural vegetation. These figures are carbon stored in the soil and carbon stored in the vegetation. We assume that when a natural vegetation area (either forest or grassland) is converted to cropland, about 25% of the carbon stored in its soil will be released into the atmosphere. In addition, we assume 75% of carbon stored in the forest type vegetation and 100% percent of carbon stored in the grassland vegetation will be released into the atmosphere at the time of land conversion[10]. If more than one type of vegetation is available in an area we calculate the weighted average emissions for that area, where weights are shares of vegetation areas. We calculate emissions factors for forest areas and grasslands, separately. Sensitivity analysis can be conducted on any of the data and assumptions used in this analysis.

Regarding the forgone carbon sequestration we assumed when a natural vegetation area is converted to cropland, it loses its carbon sequestration capacity as long as it is under crop production. Again, if more than one type of land is available we use weighted average of forgone carbon sequestration. We simply add the direct and forgone sequestration in each region. Hence, in each area we have two groups of emissions factors: forest and grassland emission factors. The Woods Hole data set along with emissions factors obtained from this data set are presented in Appendix E. Data in this appendix are calculated based on the assumption that the converted land to crop production will remain under crop production for 30 years[11]. We recognize that the 30 year period is somewhat arbitrary, and we have not considered what changes might occur after that period. Thirty years is about the life of a biofuels facility, so it seems as reasonable an assumption as any.

[10] In essence, we are assuming that 25% of the carbon in wood is stored in buildings, furniture, etc.

[11] To test the sensitivity of carbon emissions factors with respect to the time period of ethanol production, we calculated the land use emissions factors for 50, 80, and 100 years from the Woods Hole data in our earlier report (Tyner, Taheripour, and Baldos, 2009).

At this point it is important to note that some research indicates that conservation tillage practices and enhanced rotation programs can increase carbon sequestration ability of croplands. This means that using advanced technologies in corn production can increase carbon stored in soil (West and Post, 2002). In this paper we ignore impacts of advanced tillage methods on the carbon sequestration ability of cropland.

As we mentioned earlier the Woods Hole data set divides the world into 10 regions. On the other hand this version of the GTAP model divides the world into 19 regions. Table 11 relates each region of GTAP to one of the regions of the Woods Hole data set.

Table 11. GTAP and Woods Hole regions

GTAP Regions	Woods Hole Regions
United States	United States
Canada	Canada
Sub Saharan Africa	Africa
European Union 27 East Europe and Rest of Former Soviet Union Rest of European Countries	Europe
Russia	Former Soviet Union
Brazil Central and Caribbean Americas South and Other Americas	Latin America
Middle Eastern and North Africa	North Africa and Middle East
East Asia Oceania Japan	Pacific Developed
China and Hong Kong India	China/India/Pakistan
Rest of South East Asia Rest of South Asia Malaysia and Indonesia	South and Southeast Asia

We now present regional forest[12] and grassland emissions factors derived from the Woods Hole data set in Table 12. Converting forest areas to cropland in South and South East

[12] Searchinger et al. 2008 calculated forest forgone emissions from carbon uptake by growing forest. Indeed they divided growing forest uptake by the area of total area forest in each ecosystem to determine forgone carbon emissions. We followed this approach to make our results comparable with Searchinger et al. 2008 results.

Asia, China, and India generates the highest CO_2 emissions per hectare of land compared to the rest of the world in the Wood's Hole data. For example, the forest emissions factor in these regions is equal to 23 metric tons of CO_2 per hectare of forest per year, when the duration of ethanol production is 30 years. The lowest emissions factor among forest areas is in Sub Saharan Africa. In this region the forest annual emissions factor is equal to 10.4 metric tons of CO_2 per hectare of forest.

Table 12. GTAP regions and their corresponding CO_2 emissions factors for forest and grassland areas (figures are in annual metric ton CO_2 equivalent per hectare for 30 years corn production time horizon)

Regions	Forest emissions factors	Grassland emission factors
United States	19.6	3.7
Canada	15.3	5.7
Sub Saharan Africa	10.4	1.5
European Union 27 East Europe and Rest of Former Soviet Union Rest of European Countries	18.6	6.6
Russia	14.1	7.0
Brazil Central and Caribbean Americas South and Other Americas	16.1	2.5
Middle Eastern and North Africa	12.2	2.2
East Asia Oceania Japan	13.2	3.5
China and Hong Kong India	23.0	6.6
Rest of South East Asia Rest of South Asia Malaysia and Indonesia	23.0	6.6

The third column of Table 12 shows annual emissions factors for grassland areas derived from the Woods Hole. Figures of this table illustrate that converting grasslands to crop

However, this approach underestimates the magnitude of forgone forest emissions. Growing forest update should be divided by the area of growing forest - not the total area in forest. In addition, for many ecosystem types the Woods Hole database shows zeros for growing forest.

production releases smaller CO_2 emissions compared to deforestation. The highest regional grassland annual emissions factor, derived from the Woods Hole data set, is Russia (with 7 metric tons CO_2 per hectare per year), and the lowest is Sub Saharan Africa (with 2.2 metric tons CO_2 per hectare per year).

5. Estimated land use CO_2 emissions due to the US ethanol production

We now combine simulated land use changes due to US ethanol production with the CO_2 release emissions factors. This is a straight forward process. Suppose ΔLF_{rj} (see Tables 2, 6, 9) is the size of change in land type j (for j = forest and grassland) in region r due to X gallons of increase in the US ethanol production. In addition, suppose that the annual CO_2 emissions factor for land type j in region r for a 30 year ethanol production is about Frj (see Table 12). Then the global annual CO_2 emissions due to producing x gallons of ethanol per year in the US will be equal to:

$$(1)\quad LUE_W = \sum_r \sum_j \Delta LF_{rj} \cdot F_{rj} \quad .$$

Using this approach we calculated CO_2 emissions for all land use simulation scenarios (Three groups of simulations and 6 time segments) and for all emissions factors derived from the Woods Hole data sets. Once we have emissions, we can calculate the marginal and average land use emissions due to production of each gallon of pure ethanol (E100) for all groups of simulations examined in this paper. For example, Table 13 shows how we calculated the marginal land use emissions due to producing each gallon of E100 for the 13 to 15 BGs for the first group of our simulations.

Table 13. Estimated marginal land use emissions per gallon of E100 for 13 to 15 billion gallons simulation (30 year pay off method)

Total 30 year emissions from land use changes (million metric tons)	110.77
Change in ethanol production (million gallons) per year	2000
Emissions (metric tons per gallon-year of ethanol)	0.0554
Emissions (grams per gallon-year of ethanol)	55386
One year marginal emissions (grams per gallon of ethanol)	1846

The value of 110.77 million metric tons of emissions presented in this table is obtained by multiplying regional forest and grassland changes due to an increase in ethanol production from 13 to 15 BGs (see appendix C) by their corresponding Woods Hole annual emissions factors presented in the second and third columns of Table 12 and then summed over regions. The result of this calculation is multiplied by 30 to present the magnitude of total emissions over 30 years. One can follow the rest of example through table 13. We now present land use emissions for all groups of simulations discussed earlier in this report.

Land use emissions for the first group of simulations

Table 14 represents marginal and average land use emissions obtained from simulations off of the 2001 database. This table indicates that marginal emissions are increasing in ethanol production. For example, while an increase in ethanol production from 7 BGs to 9 BGs generates 1687 grams CO_2 emissions per gallon of ethanol, moving from 9 BGs to 11BG causes 1745 grams CO_2 per gallon. When ethanol production reaches 15 BGs, then each additional gallon of ethanol generates 1846 grams of CO_2. Table 14 indicates that average emissions are increasing in ethanol production as well. This table shows that during the time period of 2001-6 on average each gallon of US ethanol was generating 1477 grams CO_2. However, if ethanol production reaches 15 BGs, then on average each gallon of ethanol generates 1676 grams of emissions. It is important to note that in this group of simulations about 61% of emissions come from deforestation and 39% come from converting grasslands into crop production.

Table 14. Annual marginal and average estimated land use emissions due to the US ethanol production: Obtained from the simulations off of the 2001 database

Time Segment	Marginal Emissions (grams CO_2 per gallon of ethanol)				Average emissions (grams CO_2 per gallon of ethanol)			
	Changes in ethanol production	**Forest**	**Grasslands**	**TOTAL**	**Total ethanol production**	**Forests**	**Grasslands**	**TOTAL**
2001-6	3.085	886	590	1477	3.085	886	590	1477
2006-7	2.145	990	628	1619	5.23	929	606	1535
2007-9	2.000	1033	654	1687	7.23	958	619	1577
2009-11	2.000	1067	677	1745	9.23	982	632	1613
2011-13	2.000	1097	701	1797	11.23	1002	644	1646
2013-15	2.000	1122	724	1846	13.23	1020	656	1676

Note that in this paper we ignored impacts of the first 1.77 billion gallons of ethanol on the average land use changes per gallon of ethanol production. Incorporating land uses changes due to the first 1.77 billion gallons of ethanol will moderately reduce the average emissions per gallon of ethanol.

Land use emissions obtained from this group of simulations are smaller than our earlier estimates for land use emissions. For example, as shown in table 14, on average each gallon of US generates 1676 grams emissions. The corresponding number in our earlier report was about 2210 grams emissions. This shows about 16.5% reduction emissions per gallon of ethanol. This is due to using the new regional ETAs and incorporating cropland pasture into the picture.

Land use emissions for the second group of simulations

Table 15 presents the marginal and average emissions for the second group of simulations, where we calculate land use changes according to the updated baseline for 2001-6.

Emissions obtained from second group of simulations follow the pattern of the first group. However, their magnitudes are smaller than the first group.

Table 15. Annual marginal and average estimated land use emissions due to the US ethanol production: Obtained from the simulations off of the updated 2006 database

Time Segment	Marginal emissions (grams CO_2 per gallon of ethanol)				Average emissions (grams CO_2 per gallon of ethanol)			
	Changes in ethanol production	Forest	Grasslands	TOTAL	Total ethanol production	Forests	Grasslands	TOTAL
2001-6	3.085	1003	412	1414	3.085	1003	412	1414
2006-7	2.145	1026	349	1376	5.23	1012	386	1399
2007-9	2.000	1002	370	1372	7.23	1009	382	1391
2009-11	2.000	1028	377	1406	9.23	1014	381	1394
2011-13	2.000	1043	385	1429	11.23	1019	382	1400
2013-15	2.000	1052	395	1446	13.23	1024	384	1407

As shown in table 15, when the US ethanol production reaches to 15 BGs of ethanol each additional gallon of ethanol generates about 1446 grams of emissions. At this level of ethanol production, on average each gallon of ethanol causes 1407 grams of CO_2 emissions. These figures are smaller than the corresponding figures of the first group of simulations by 21.7% and 16%. These reductions are due to yield improvement during the time period of 2001-2006. As noted earlier in this time period yield has improved in many regions faster than the demand for crops for food. It is important to note that in this group of simulations more than 70% of emissions come from deforestation and the rest comes from converting grasslands into crop production.

Land use emissions for the third group of simulations

Table 16 shows the marginal and average land use emission for the third group of simulations, where we calculate land use changes according to the simulations with the updated 2001-06 database and population, yield, and forest product growth.

Table 16. Annual marginal and average estimated land use emissions due to the US ethanol production: Obtained from the simulations off of the updated 2006 database and with population and yield growth after 2006

Time Segment	Marginal emissions (grams CO_2 per gallon of ethanol)				Average emissions (grams CO_2 per gallon of ethanol)			
	Changes in ethanol production	Forest	Grasslands	TOTAL	Total ethanol production	Forests	Grasslands	TOTAL
2001-6	3.085	1003	412	1414	3.085	1003	412	1414
2006-7	2.145	674	305	978	5.23	868	368	1236
2007-9	2.000	565	372	937	7.23	784	369	1153
2009-11	2.000	469	477	946	9.23	716	392	1108
2011-13	2.000	433	619	1051	11.23	665	433	1098
2013-15	2.000	480	736	1217	13.23	637	479	1116

As shown in table 16, in this case during the time period of 2006-2015 the marginal emissions grow when the population growth dominates the yield growth. For example, an additional gallon of ethanol produces about 978 grams emissions in the time segment of 2006-7, while each gallon of additional ethanol causes 1217 grams emissions in the time segment of 2013-15. In this group of simulations on average each gallon of ethanol generates about 1116 grams emissions. This figure is smaller than the corresponding figure obtained from the second group of simulations by about 21 percent.

6. Final analysis

We now compare the land use emissions obtained from the three groups of simulations with the results of SEA. Table 17 shows lower emissions due to indirect land use change when we incorporate all economic and demographic and yield growth into account in the third group of simulations. The average value of the third group of simulations is about 13% of the original SEA result. The results of the first and the second groups of simulations are about 21% and 16.4% of SEA.

Table 17. Estimated land use change emissions due to U.S. ethanol production (Comparing GTAP and Searchinger et al. (2008) results)

Searchinger et al. (2008)	Total Emissions for 30 years (million metric tons)	3801
	Change in ethanol production (billion liters of ethanol)	55.92
	Total emissions for 30 years (grams per liter)	67972
	Liters per gallon	3.785
	Total emissions for 30 years (grams per gallon of ethanol)	257302
	One year emissions (grams per gallon of ethanol)	8577
GTAP results off of 2001 database	One year average emissions (gram per gallon of ethanol)	1676
	One year marginal emissions (gram per gallon of ethanol)	1846
GTAP results off of 2006 database	One year average emissions (gram per gallon of ethanol)	1407
	One year marginal emissions (gram per gallon of ethanol)	1446
GTAP results off of 2006 plus population & yield growth	One year average emissions (gram per gallon of ethanol)	1116
	One year marginal emissions (gram per gallon of ethanol)	1217

Total emissions from production and consumption of ethanol

Table 18 contains the estimated well-to-wheel ethanol emissions for the marginal and average land use changes for the three groups of simulations[13]. For the first group of simulations production and consumption of each gallon of ethanol (E100) on average generates about 6800 grams of GHGs emissions. In this case about 24.6% of released emissions are related to land use changes. When we incorporate changes in population and other factors, each gallon of ethanol (E100) on average causes about 6531 grams of GHGs emissions. In this case about 21.5% of released emissions are related to land use changes. Finally, in the third group, when we take into account the population and yield growth after 2006, then production and consumption of each

[13] In this report the direct marginal GHG emissions (i.e. non-land emissions) of ethanol for the post 2006 are taken from 100% dry mill.

gallon of ethanol (E100) generates about 6240 grams of emissions. In the third case, about 17.9% of released emissions are related to land use change.

Table 18 indicates well to wheel ethanol emissions expressed as grams/gal of ethanol and in grams per Megajoule (MJ). For the first, second, and third groups of simulations production and consumption of each gallon of ethanol (E100) on average generates about 84.4 g/MJ, 81.1 g/MJ, 77.5 g/MJ emissions, respectively.

Table 18. Estimated annual well-to wheel ethanol emissions for marginal and average land use changes

Description		Land use emissions (grams/gal)	Land use emissions (grams/MJ)	Well-to-wheel emissions without land use[a] (grams/gal)	Well-to-wheel emissions plus land use (grams/gal)	Well-to-wheel emissions plus land use (grams/MJ)[b]
Simulations Off of 2001	Marginal	1846	22.9	5100	6946	86.3
	Average	1676	20.8	5124	6800	84.4
Simulations Off of 2006	Marginal	1446	18.0	5100	6546	81.3
	Average	1407	17.5	5124	6531	81.1
Simulations Off of 2006 Plus population & yield growth	Marginal	1217	15.1	5100	6317	78.4
	Average	1116	13.9	5124	6240	77.5

[a]From GREET simulations. We used the default values in GREET version 1.3c for 2015 for the simulations. The marginal and average differ for ethanol direct emissions because the fraction that is wet versus dry milling decreases over time yielding slightly lower direct emissions for the marginal case.
[b]Low heating values of gasoline and ethanol are: 116090 BTU/gal and 76330 BTU/gal.

Finally, Table 19 compares total emissions of E100 obtained from the three groups of simulations with the emissions of conventional gasoline. This table indicates that ethanol production induces lower emissions compared to conventional gasoline for all groups of simulations. For example, total GHGs emissions due to production and consumption of E100 (including land use emissions) obtained from the first group of simulations are about 10342 grams per gallon of gasoline equivalent for the average land use changes. This figure is about

90.4% of the emissions due to production and consumption of conventional gasoline. When we use the updated 2006 database, total estimated GHGs emissions due to production and consumption of E100 are about 9933 grams per gallon of gasoline equivalent for the average land use changes. This figure is 86.9% of the emissions due to production and consumption of conventional gasoline. Finally, when we use the updated data base, and we assume population and yield increase after 2006, then total estimated emissions for E100 are 9490 grams per gallon of gasoline equivalent for the average land use changes. In this case the E100 emission estimate is about 83.0% of emissions associated with conventional gasoline. Table 19 presents emissions of ethanol and gasoline in grams per gallon of gasoline equivalent and per MJ.

Table 19. Estimated well-to-wheel ethanol and gasoline emissions for average land use changes

Description		Emissions in grams per gallon of gasoline equivalent			Emissions in grams/MJ		
		Ethanol	Gasoline	Ethanol vs gasoline (percent)	Ethanol	Gasoline	Ethanol vs gasoline (percent)
Simulations Off of 2001	Marginal	10564	11428	92.4	86.3	93.3	92.2
	Average	10342	11428	90.5	84.4	93.3	90.5
Simulations Off of 2006	Marginal	9956	11428	87.1	81.3	93.3	87.1
	Average	9933	11428	86.9	81.1	93.3	86.9
Simulations Off of 2006	Marginal	9608	11428	84.1	78.4	93.3	84.1
	Average	9490	11428	83.0	77.5	93.3	83.0

Since the third group simulations takes into account changes in population, crop yields, economic growth, and growth in primary inputs during the time period of 2001-2006 and after that assumes that population and yield growth will continue, the emissions obtained from this group of simulations are lower than the other cases. However, the results are derived from our assumptions, in particular for the time period of 2006-2015. Any change in these assumptions could alter the results. In other words, we have assumed 1 percent global growth in yields for all crops and 2001-06 population growth through 2015. Changes in these assumptions would alter the numerical results.

7. Conclusions

The overarching objective of this research has been to estimate the global land use changes induced by US corn ethanol programs and in doing so to closely examine some of the critical issues that have been overlooked in some prior studies. It is a very controversial topic. Some argue it is impossible to measure such changes. Others argue that failure to measure the land use changes and the consequent GHG emissions would lead us to incorrect policy conclusions. After working on this topic for over two years, we come out between these extremes. First, with almost a third of the US corn crop today going to ethanol, it is simply not credible to argue that there are no land use change implications of corn ethanol. The valid question to ask is to what extent land use changes would occur. Second, our experience with modeling, data, and parameter estimation and assumptions leads us to conclude that one cannot escape the conclusion that modeling land use change is quite uncertain. Of course, all economic modeling is uncertain, but it is important to point out that we are dealing with a relatively wide range of estimation differences. The estimation range depends on what is being simulated, as will be seen below.

Over the two plus years we have working on this topic, we have made numerous improvements in the models used for the analysis. These improvements are spelled out in the text above and in the appendices. We have better data on land productivity and on cropland pasture and CRP lands, and these data and associated parameters are now in the model. We have improved the treatment of the livestock and livestock feed sectors. Similarly, these changes are reflected in the current version of the model. We have amassed data on crop yields and many other variables for every region of the world and used much of that data in our analysis and model calibration. These data and model improvements have significantly improved the analysis and model results.

Table 20 provides a convenient summary of the evolution of some of our results over the different versions of the model and data. The third column replicates the summary results from our January 2009 draft paper before all the model changes described were implemented. The January 2009 results are provided only for reference, so our comparisons will be based on the three simulations reported in this paper. The fourth column is with all the model improvements and the 2001 data base. The fifth column is with the baseline updated to 2006 as described above. The last column is both with the updated baseline to 2006 and the assumed growth in demand and supply as described above.

Table 20. Summary of the different modeling results

Result	Units	Original Jan. 09 estimates	Model improvements with 2001 data base	Baseline updated to 2006	Updated baseline and growth in demand and yield
Land needed for ethanol	Ha./1000 gal.	0.27	0.22	0.15	0.12
Distribution of land use change between forest and pasture	%forest/%pasture	23/77	25/75	35/65	35/65
Distribution of land use change between U.S. and rest of world	%US/%Others	35/65	34/66	25/75	28/72
Average emissions of 15 bil. gal. program	Grams CO_2/gal. of ethanol	1931	1676	1407	1116
% of Searchinger, et al.	%	22.5	19.5	16.4	13.0
Emissions per gallon gasoline eq.	Grams CO_2/gal.	10564	10342	9933	9490
Emissions per MJ	Grams $C0_2$/MJ	86.3	84.4	81.1	77.5
Total ethanol emissions as % of gasoline	%	92.4	90.5	86.9	83.0

In some cases, the results are fairly stable regardless of the simulation. For example, the percentage of land that comes from forest ranges between 25 and 35 percent depending on the model and assumptions being used. Similarly, the fraction of land use change that occurs in the U.S. ranges between 25 and 34 percent. However, the land needed to meet the ethanol mandate ranges between 0.12 and 0.22 hectares/1000 gallons, which is a fairly wide range. The ethanol CO_2 emissions per gallon range between 1116 and 1676, also a fairly large range. However, the total emissions per MJ range between 77.5 g/MJ and 84.4 g/MJ, a small range. The reason for the small range in this case is that the direct ethanol emissions are assumed to be constant, so the land use emissions are being added to a constant level of direct emissions making the variability in total emissions per mile smaller.

Ethanol emissions as a fraction of gasoline emissions range between 83.0 and 90.5 percent. From these results, we feel confident that corn ethanol would meet a 10 percent savings standard. On the other hand, the results suggest that corn ethanol would not meet a 20 percent emissions reduction standard. However, we cannot conclude that corn ethanol would not meet a 20 percent standard given the inherent uncertainty in the analysis, and potential improvement in direct emissions associated with corn farming and ethanol production. In a recent analysis including uncertainty in GHG estimation using an earlier version of GTAP-BIO, Hertel et al. (2010) concluded that the corn ethanol induced emissions from land use change range between 2 and 51 g/MJ. Our estimate for the last case is 14 g/MJ. This large range taken from another study using similar approaches clearly illustrates the uncertainty inherent in this analysis. It also concludes that zero is not within the error bounds. In other words, we know land use change induced emissions are not zero, but measuring them with high precision is not yet possible.

8. Limitations and future research

As indicated above, analysis such as that undertaken here is very complex and is limited by data availability, validity of parameters, and other modeling constraints. Economic models, like other models, are abstractions from reality. They can never perfectly depict all the forces and drivers of changes in an economy. However, the basic model used for this analysis, GTAP, has withstood the test of time and peer review. Hundreds of peer reviewed articles have been published using the GTAP data base and analytical framework. In this project, we have made many changes in the model and data base to improve its usefulness for evaluating the land use change impacts of large scale biofuels programs. Yet, uncertainties remain. In this paper, we have described the evolution of the modeling and analysis and present openly the evolution of the results. Like other GTAP model versions, once it has been subjected to peer review, this model version will be available to others in the GTAP community to use in their analyses. We believe quite strongly that analysis of this type must be done with models and data bases that are available to others. Replicability and innovation are critical factors for progress in science. They also are important for credibility in policy analysis.

Some of the important topics for future research are as follows:

- More sensitivity on prospective growth in crop demand and supply by region and AEZ. The future growth in demand and supply of agricultural commodities, particularly coarse grains, are critical determinants of the impacts of biofuel programs. If global income and population growth and dietary transition lead to greater growth in demand for coarse grains than in supply, the impacts of biofuels mandates would be greater. On the other hand, if new technologies and broader adoption of these technologies lead to greater growth in supply, then the impacts of biofuels mandates would be reduced.

- Research is needed on the impacts on food and feed systems induced by biofuels under real world conditions of weather variability. Under binding mandates such as the Renewable Fuel Standard, demand is quite inelastic, which would lead to greater commodity price variability in the event of weather shocks such as drought.
- Improved data and information on land use and land cover change could be used in the future to improve model parameters and perhaps the model structure. We are certainly open to considering new information in this domain in the future.
- In this version of the model, substantial improvements in modeling and parameters for livestock production and use of feedstuffs including DDGS have been made. Nonetheless, as the markets evolve we will learn more about the functioning of these markets as feed users adapt to the new animal feeding realities.
- In general, we will need to update the model in many ways as new versions of the GTAP data base are released. This is an on-going process for GTAP. The new version of the GTAP data base is version 7, so constant quality improvement has been part of business as usual since the launch of GTAP in 1994.
- In this research we relied on Woods Hole data set to derive land use carbon emissions. This data set provides limited information on forgone carbon sequestration due to deforestation. This is a major deficiency. We have developed a set of land use emissions using the TEM model at the AEZ for all GTAP regions. However, they have not yet been verified and subjected to peer review, so they are not used in this analysis.

Our primary focus now is to incorporate cellulosic feedstocks into GTAP and to find better ways of getting greater sub-regional specificity in our analysis. We are now working with partners, including Argonne, to accomplish these objectives.

Appendix A

Regional Land Conversion Factors (ETA parameters)
Productivity of new cropland versus productivity of existing cropland

Appendix A: Land Conversion Factors

In the GTAP-BIO-ADV model the parameter ETA, which shows productivity of new cropland versus productivity of exiting cropland, plays an important role in determining the land use impacts of biofuel production. In our past simulations for biofuel analyses we usually assumed that ETA=0.66 for all regions across the world. Indeed, with this setup we assumed that productivity of one unit (let say one acre) of new croplands is equal to 2/3 of the productivity of one acre of existing croplands, all across the world. In this report we leave this assumption and we apply regional ETAs at the AEZ level. The regional ETAs are obtained from a process-based biogeochemistry model (Terrestrial Ecosystem Model (TEM)) along with spatially referenced information on climate, elevation, soils, and vegetation land use data. The new regional ETAs are varying across the world and among AEZs. In this appendix, we first explain the role of ETA in the GTAP-BIO-ADV model. Then we briefly introduce the TEM model and its data sources. Finally we explain derivations of the regional ETA parameters along with the results.

Role of ETA in the land use module

As we mentioned above ETA measures the productivity of the new cropland versus the productivity of existing cropland. To avoid confusion we define these two types of land:

Existing cropland: Is defined as a land which has been cultivated and used for crop production in the past. GTAP classifies these lands under the title of crop cover.

New cropland: Is defined as natural land (could be either forest or pasture land) that will be converted to cropland due to the need for expansion in the demand for crops.

We now use an example to explain the role of ETA in the GTAP-BIO-ADV model. Suppose that we want to expand production of corn in region *A* by 600 bushels and also suppose that this region only produces corn. In addition, suppose that the corn yield of the existing cropland is about 150 bushels/acre. So the question is how much land we need to produce 600 more bushels of corn? The answer is that it depends on the productivity of land that we want to bring into crop production. Suppose that region *A* has a piece of forest which can be converted to crop production and that ETA=2/3=0.66. With these assumptions the GTAP-BIO-ADV model will calculate that in region *A* we need 6 acres of land to meet the target. Because it assumes that the yield of the new cropland is about 100 bushels per acre. Now if we assume that ETA=1, (i.e. the productivity of the new and existing cropland are equal) then we need only 4 acres to satisfy the target for corn production. This example highlights the role of ETA in GATP-BIO-ADV model.

In fact, in GTAP we have a solid and reliable database which provides productivity measures for existing croplands for all regions across the world by AEZ. However, we do not have information on the productivity of new cropland, and there are large uncertainties in predicting future productivity of existing cropland in different parts of the world. So far we used parameter ETA=0.66, based on empirical evidence from US land use and consulting experts on the productivity of the new cropland. In this report we use the TEM model along with spatially referenced information on climate, elevation, soils, and vegetation land use data to determine productivity of new cropland versus the existing cropland at the AEZ level in each region. To accomplish this task using the TEM model we calculate the Net Primary Production, as a proxy for productivity, at 0.5° x 0.5° (latitude by longitude) spatial resolution for all grid cells across the world. In this calculation we assume that all grid cells are producing a generic C4 crop. Then we use this information to derive the land conversion factors at the AEZ level for each region of

GTAP. The next section introduces the TEM model and its calculation steps along with the data used in calculating NPPs. Then we discuss the conversion of NPPs to the land conversion factor.

TEM model

We use a process-based biogeochemistry model, the TEM (Zhuang et al., 2003) to estimate NPP for each 0.5° x 0.5° (longitude and latitude) of the global terrestrial ecosystems. TEM uses spatially referenced information on climate, elevation, soils, and vegetation to make monthly estimates of C and N fluxes and pool sizes of the terrestrial biosphere. In TEM, the net ecosystem exchange of CO_2 between the land ecosystems and atmosphere is calculated as the difference between the uptake of atmospheric CO_2 associated with photosynthesis (i.e., gross primary production or GPP) and the release of CO_2 through autotrophic respiration (R_A), heterotrophic respiration (R_H) associated with decomposition of organic matter. The fluxes GPP, R_A and R_H are influenced by changes in atmospheric CO_2, climate variability and change, and the freeze-thaw status of the soil. The following figure represents this model and its major components.

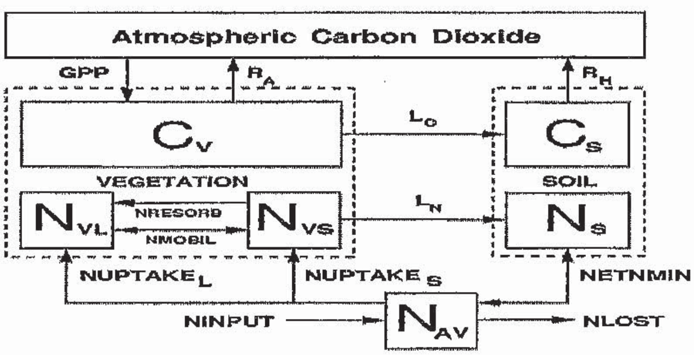

Figure A1. The Terrestrial Ecosystem Model

The model has been extensively used to evaluate C dynamics in northern high latitudes and the globe (e.g., Euskirchen *et al* 2006, Balshi *et al* 2007; Zhuang et al., 2003; Melillo et al., 1993; McGuire et al., 2001). Its structure, algorithm, parameterization, calibration and performance have been well documented.

Parameters in TEM may be specific to different vegetation types, specific to different soil textures, or constant for all vegetation types and soil textures. Most of the parameters in TEM are assigned values derived from the literature, but some parameters are calibrated to the carbon and nitrogen pools and fluxes of intensively studied sites (see Raich et al., 1991 and McGuire et al., 1992 for details). In this paper the model is calibrated for generic C4 crops. The pools and fluxes of ecosystem carbon and nitrogen of these crop ecosystems are shown in table A1.

Table A1. Carbon and nitrogen pools and fluxes used for a generic parameterization

Variable	Values* for C4	Source and Comments
C_v	649	Evrendilek[2004]
N_v	9.9	Evrendilek[2004]
C_s	3071.5	Evrendilek[2004]
N_s	307.1	Evrendilek[2004]
N_{av}	2.64	Based on 0.86%, the mean N_{av}:N_s ratio
GPP	649	Evrendilek[2004]
NPP	296.6	Evrendilek[2004]
NPPSAT	296.6	Evrendilek[2004]
NUPTAKE	3.98	Calculated from NPP_n, 75%NPP_n=NUPTAKE.

*Units for annual gross primary production (GPP), net primary production (NPP), and NPPSAT are g C $m^{-2}yr^{-1}$. Units for vegetation C (C_v) and soil C (C_s) are g C m^{-2}. Units for vegetation N (N_v), soil N (N_s), and inorganic N (N_{av}) are g N m^{-2}. Units for annual N uptake by vegetation (NUPTAKE) are g N m^{-2} yr^{-1}.

Input data sets

To apply TEM to make spatially and temporally explicit estimates of ecosystem carbon storage and net primary production in this study, we use the same input data sets as were used in Zhuang et al., (2003). These input data sets are important for directly affecting processes in the model (e.g., the effects of soil temperature on heterotrophic respiration) and for defining the parameters that are specific to vegetation types and soil textures. We use a potential vegetation data set similar to that described in Melillo et al. (1993) to run the model to equilibrium prior to driving the model with transient changes in atmospheric CO_2 and climate. Soil texture and elevation do not vary in our simulations. The transient historical atmospheric CO_2 concentrations are used. The data sets describing historical changes in monthly air temperature and precipitation are gridded at 0.5° x 0.5° spatial resolution for our simulations (Zhuang et al., 2003).

Global simulations

To run TEM for the globe, we use the data of atmosphere, vegetation, soil texture, and elevation at 0.5° latitude x 0.5° longitude resolution from 1900 to 2000. For the simulations of C4 crops, we assume that each grid cell was replaced with the generic C4 crop and keep the information of soils, elevation and climate as the same as the simulation for natural ecosystems. For each grid cell, we first run TEM to equilibrium for an undisturbed ecosystem using the long-term averaged monthly climate and CO_2 concentrations from 1900 to 2000. We then run the model for 150 years with the climate from 1900 to 1949 to account for the influence of inter-annual climate variability on the initial conditions of the undisturbed ecosystem. We then run the model with transient monthly climate data from 1900 to 2000. The simulated NPP for C4 crop simulations of the year 2000 are used for this analysis.

Using NPP data to obtain ETA

We use the NPP data as a proxy for yield to calculate the regional land conversion factors by AEZ. In this process first we matched the results from TEM with our land database to assign AEZs to all grid cells across the world. Then we imposed several restrictions to drop lands which are not good for crop production. In particular, we dropped the grid cells with the following types of land cover:

- ALPINE_TUNDRA_&_POLAR_DESERT
- FORESTED_BOREAL_WETLANDS
- NON-FORESTED_BOREAL_WETLANDS
- TEMPERATE_FORESTED_WETLANDS
- XERIC_SHRUBLANDS
- TROPICAL_FORESTED_WETLANDS
- DESERTS
- TROPICAL_NON-FORESTED_WETLANDS
- TROPICAL_NON-FORESTED_FLOODPL
- TEMPERATE_NON-FORESTED_WETLAND
- TEMPERATE_FORESTED_FLOODPLAINS
- TEMPERATE_NON-FORESTED_FLOODPL

In addition we dropped all grid cells with cells with median of terrain slopes greater than or equal 5%. We dropped these because they are not appropriate for crop production. Then we used the cleaned database to derive the land conversion factors.

To explain the derivation process first we analyze our data for two sample regions: US AEZ10 and Brazil AEZ4. The following two graphs (figures A2 and A3) represent the shares of available and converted natural grasslands in these two sample areas. In each graph we classified the land into 6 groups of productivities (NPPs). Figure A2 indicates that in this AEZ a big portion of the natural grass land is already converted to crop production. A small amount of grassland is available to be converted to crop production in this AEZ. However, the available land is distributed across all productivity groups. Note that the AEZ10 of the US covers a large area with relatively different land qualities, weather conditions and length of growing periods between 180 to 240 days.

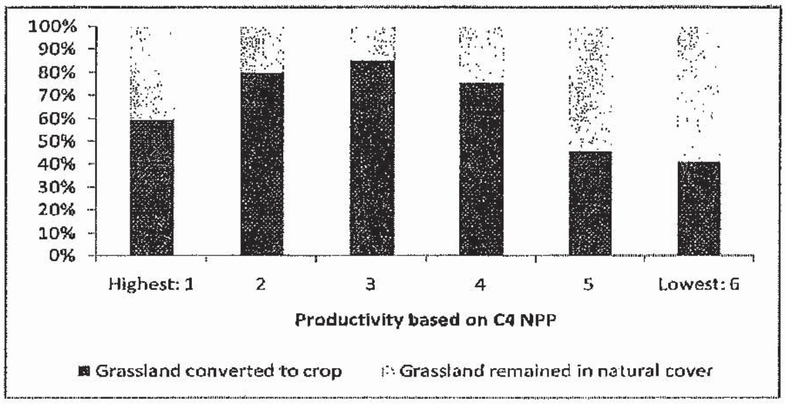

Figure A2. Availability of grassland suitable for crop production in US-AEZ10

Now consider figure A3 which indicates that in the Brazil AEZ4 there are lots of grassland remained in natural cover and only a small portion of grassland in this AEZ has been converted to crop production. In this AEZ available land is distributed across all productivity groups as well.

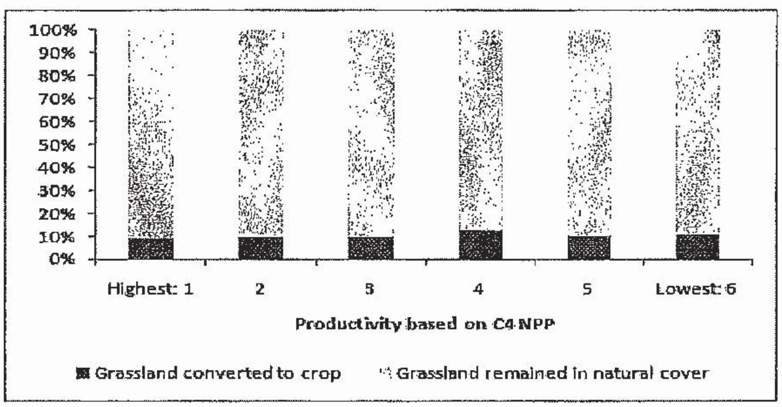

Figure A3. Availability of grassland suitable for crop production in Brazil-AEZ4

Now consider another aspect of the NPP data in these two AEZs. Figure A4 compares the average productivity of grassland converted to crop production in the past with the productivities of all grassland parcels that remained in natural cover in US AEZ10. In this figure grid cells are sorted according to their productivity. So when we move from left side to the right side of the horizontal axis, we move from grid cells with higher productivities to the grid cells with lower productivities.

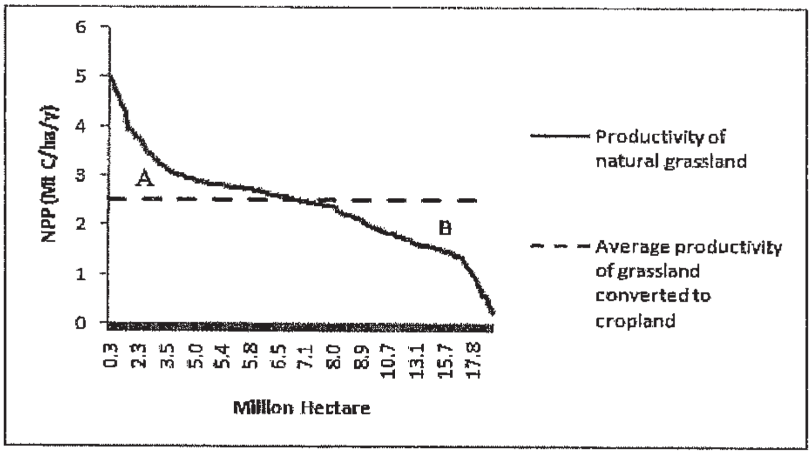

Figure A4. Average and marginal productivities in US AEZ10 for grassland

The ratio of the area A in this graph (area below the productivity of grassland curve and above the average productivity of grassland converted to cropland horizontal line) over the area B (area above the blue curve and below the red line) provides us a land conversion factor for this type of land in this AEZ. All of the land pixels in area A represent pixels with productivity (for C4) higher than the average productivity of existing cropland (the straight line). All of the pixels in B have productivity less than the average cropland. So area A over area B shows average productivity of new land versus average productivity of existing cropland. The assumption then is that the marginal unit of land has this productivity. Figure A5 provides the same information for Brazil AEZ4.

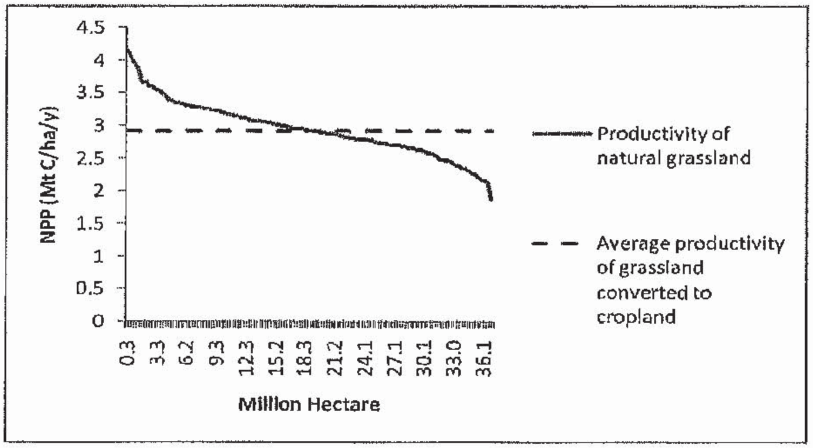

Figure A5. Average and marginal productivities in Brazil AEZ4 for grassland

While we are able to derive the conversion factors for all types of land cover we pooled all land types in each AEZ in each region and we defined the geographical land conversion factors at the AEZ level. It is important to point out that the model does not take into account irrigation. However, in real world in some areas lands are under crop production with irrigation. For this reason we dropped the productivity of all natural land by 10% and we assumed no land conversion factor greater than 1. The results of these calculations are shown in table A2. In this table zero means no land is available and 1 shows that the marginal and average productivities are equal. Table A2 indicates that the US land conversion factors range from 0.51 to 1, depending on the AEZ. Our earlier value for the land conversion factor (i.e. ETA=0.66) falls within this range. However, Table A2 shows that the Brazil land conversion factors range from 0.89 to 1, and most of them are around 0.9. This means that our earlier land conversion factor was underestimating the marginal productivity of land in Brazil. While we apply these land conversion factors in this report we will continue to improve our results in the future.

Table A2. Regional land conversion factors obtained from NPP data for a generic C4 crop[1]

1 In this table zero means no land is available and 1 means that the marginal and average productivities are equal.
2 Rows are AEZs from AEZ1 to AEZ18.
3 Columns are regions and regions are listed in Appendix B.

Appendix B
Lists of Commodities, Industries, and Regions

Table B 1. List of industries and commodities in the new model

Industry	Commodity	Description	Name in the GTAP_BIOB
Paddy_Rice	Paddy_Rice	Paddy rice	Pdr
Wheat	Wheat	Wheat	Wht
CrGrains	CrGrains	Cereal grains	Gro
Oilseeds	Oilseeds	Oil seeds	Osd
OthAgri	OthAgri	Other agriculture goods	ocr, pfb, v_f
Sugarcane	Sugarcane	Sugar cane and sugar beet	c-b
DairyFarms	DairyFarms	Dairy Products	Rmk
Ruminant	Ruminant	Cattle & ruminant meat production and	Ctl, wol
NonRum	Non-Rum	Non-ruminant meat production	oapl
ProcDairy	ProcDairy	Processed dairy products	Mil
ProcRum	ProcRum	Processed ruminant meat production	Cmt
ProcNonRum	ProcNonRum	Processed non-ruminant meat production	Omt
Forestry	Forestry	Forestry	Frs
Cveg_Oil	Cveg_Oil	Crude vegetable oil	A portion of vol
	VOBP	Oil meals	A portion of vol
Rveg_Oil	Rveg_Oil	Refined vegetable oil	A portion of vol
Proc_Rice	Proc_Rice	Processed rice	Pcr
Bev_Sug	Bev_Sug	Beverages, tobacco, and sugar	b_t, sgr
Proc_Food	Proc_Food	Processed food products	A portion of ofd
Proc_Feed	Proc_Feed	Processed animal feed products	A portion of ofd
OthPrimSect	OthPrimSect	Other Primary products	fsh, omn
Coal	Coal	Coal	Coa
Oil	Oil	Crude Oil	Oil
Gas	Gas	Natural gas	gas, gdt
Oil_Pcts	Oil_Pcts	Petroleum and coal products	p-c
Electricity	Electricity	Electricity	Ely
En_Int_Ind	En_Int_Ind	Energy intensive Industries	crpn, i_s, nfm, fmp
Oth_Ind_Se	Oth_Ind_Se	Other industry and services	atp, cmn, cns, ele, isr, lea, lum, mvh, nmm, obs, ofi, ome, omf, otn, otp, ppp, ros, tex, trd, wap, wtp
NTrdServices	BTrdServices	Services generating Non-C02 Emissions	wtr, osg, dwe
EthanolC	Ethanol1	Ethanol produced from grains	
	DDGS	Dried Distillers Grains with Solubles	
Ethanol2	Ethanol2	Ethanol produced from sugarcane	
Biodiesel	Biodiesel	Biodiesel produced from vegetable oil	

Table B 2. Regions and their members

Region	Description	Corresponding Countries in GTAP
USA	United States	Usa
EU27	European Union 27	aut, bel, bgr, cyp, cze, deu, dnk, esp, est, fin, fra, gbr, grc, hun, irl, ita, ltu, lux, lva, mlt, nld, pol, prt, rom, svk, svn, swe
BRAZIL	Brazil	Bra
CAN	Canada	Can
JAPAN	Japan	Jpn
CHIHKG	China and Hong Kong	chn, hkg
INDIA	India	Ind
C_C_Amer	Central and Caribbean Americas	mex, xna, xca, xfa, xcb
S_o_Amer	South and Other Americas	col, per, ven, xap, arg, chl, ury, xsm
E_Asia	East Asia	kor, twn, xea
Mala_Indo	Malaysia and Indonesia	ind, mys
R_SE_Asia	Rest of South East Asia	phl, sgp, tha, vnm, xse
R_S_Asia	Rest of South Asia	bgd, lka, xsa
Russia	Russia	Rus
Oth_CEE_CIS	Other East Europe and Rest of Former Soviet Union	xer, alb, hrv, xsu, tur
R_Europe	Rest of European Countries	che, xef
MEAS_NAfr	Middle Eastern and North Africa	xme,mar, tun, xnf
S_S_AFR	Sub Saharan Africa	Bwa, zaf, xsc, mwi, moz, tza, zmb, zwe, xsd, mdg, uga, xss
Oceania	Oceania countries	aus, nzl, xoc

Appendix D
Experiments Used in Simulations

Introduction

In this appendix first we briefly explain few basic concepts that we use in defining an experiment in GTAP for non professional readers. Then we introduce experiments which we defined for the simulations we introduced in this paper. As we mentioned earlier, GTAP is a computable general equilibrium (CGE) model. This model consists of equations, identities, a database, a set of parameters or elasticities, and several types of variables. Variables in this model are either endogenous (determined within the model) or exogenous (determined outside the model). For example, in GTAP population and tax rates are exogenous variables, but the household demands for goods and services are endogenous variables. The values of the exogenous variables are given to the model but the system determines the values of the endogenous variables using the equations defined in the model.

In GTAP, an experiment consists of a set of commands that guide the system to move the world economy from an existing equilibrium condition to a new equilibrium. The experiment could be simple or complicated. For example, here we introduce two simple experiments.

Suppose that you would like to examine consequences of a 2% increase in the US population for the world economy, assuming no changes in other exogenous variables. For this simple experiment since population is an exogenous variable, we can directly increase (or shock) it by 2% and ask the system to determine consequences of this increase for the world economy. This experiment is simply can be defined by the following command:

Shock pop("US") = 2;

The system starts with the initial equilibrium condition for the world economy (base data), numerically calculates impacts of this shock on the endogenous variables through the equations of the model, and determines a new equilibrium for the world economy.

Now look at another simple experiment. In this experiment we would like to examine impacts of 2% increase in the US demand for meat, while we assume no changes in other exogenous variables. In this case, since the demand for meat is an endogenous variable we cannot directly shock it. Instead, we should shock an exogenous variable which could affect the demand for meat. In this case subsidy is an appropriate exogenous variable. The subsidy on meat consumption could encourage consumers to buy more meat. Now the question is: How much subsidy should be paid to induce the desired increase in the demand for meat? We do not need to answer this question. The system can answer the question through the following swap and shock:

Swap qpd("meat", "US") = tpd("meat", "US");

Shock qpd("meat", "US") = 2;

Here *qpd* and *tpd* represent percentage changes in the demand for meat and its subsidy/tax rate for the US economy. The first command endogenizes the rate of subsidy on meat for the US economy and exogenizes the US demand for this commodity. The second command shocks the US demand for meat, which is now an exogenous variable. The system starts with the initial equilibrium, uses the equations of the system, increases the US subsidy rate on meat to reach 2% increase in the US private demand for meat, and determines a new equilibrium for the world economy through the simulation process. With this introduction we now present the experiments that we used in our simulations. In what follows we present only the main swaps and shocks that derive the results, and we do not present those which we used to fix data problems or avoid minor technical issues.

Experiments of Group 1: Simulations with no economic and yield growth and 2001 base

The experiments used for this group of simulations contain simple shocks and swaps. For the first time period (i.e. 2001-2006) we used the following experiment:

To fix the CRP land of the US

***Swap** tf(AEZ_COMM,"Oth_Ind_Se","USA") =*

p_HARVSTAREA_L(AEZ_COMM,"Oth_Ind_Se","USA");

This swap keeps the area of CRP land unchanged. It swaps changes in CRP land with changes in tax rate on land endowment.

To boost ethanol production

***Swap** qo("Ethanol1","USA") = tpd("Ethanol1","USA");*

***Shock** qo("Ethanol1","USA") = 174.29379;*

Here the swap endogenizes subsidy on ethanol consumption and exogenizes ethanol production and then the shock boosts ethanol production according to its expansion for the time period of 2001-2006 (i.e. 174.3%).

This swap and shock jointly subsidize ethanol production. However, they cause an increase in government subsidies. To offset the impacts of this subsidy we use the following swap to finance the policy through an increase in taxes on biofuel consumption.

To Make the RFS revenue neutral

***Swap** del_taxrpcbio("USA") = tpbio("USA");*

Then we repeated the same experiment for other time slices with appropriate percentage changes in ethanol production.

Experiments of Group 2: Simulations with updated baseline for the time period of 2001-2006

For the first time period of this group of simulations we used more complicated shocks and swaps.

To control CRP land of the USA

Swap tf(AEZ_COMM,"Oth_Ind_Se","USA")=qoes(AEZ_COMM,"Oth_Ind_Se","USA");

This swap controls changes in the US CRP land.

To simulate biofuel economy

swap aosec("oil") = pxwcom("oil");

Shock pxwcom("oil") = 136;

Shock afall("ethanol1","Oil_pcts","USA") = -49;

Shock to("Ethanol1","USA") = -10.93;

Shock to("biodiesel","USA") = -7.00;

Shock to("Ethanol1","EU27") = 50.77;

Shock to("biodiesel","EU27") = 81.18;

Swap qo("ethanol1","USA") = tpd("ethanol1","USA");

Swap tms("ethanol2","Brazil","USA") = qxs("ethanol2","Brazil","USA");

Swap qo("biodiesel","USA") = tpd("biodiesel","USA");

Swap qo("ethanol1","EU27") = tpd("ethanol1","EU27");

Swap qo("biodiesel","EU27") = tpd("biodiesel","EU27");

Swap qo("ethanol2","Brazil") = tpd("ethanol2" ,"Brazil");

Shock qo("ethanol1","USA") = 174.29;

Shock qxs("ethanol2","Brazil","USA") = 591.8636;

Shock qo("biodiesel","USA") = 2823.3992;

Shock qo("ethanol1","EU27") = 3444.0395;

Shock qo("biodiesel","EU27") = 409.5644;

Shock qo("ethanol2","Brazil") = 47.39088;

These swaps and shocks jointly introduce changes in the crude oil price and define the US, EU, and Brazil biofuel performances and their supporting policies in this area for the time period of 2001-2006.

To shock population

Shock POP(REG) = file default.prm header "PO16";

This shock reads the regional population growth rates for the time period of 2001-2006 from the parameter file of the system and introduces them to the model.

To shock GDP

Swap afereg(REG) = qgdp(REG);

Shock qgdp(REG) = file default.prm header "IN16";

This shock and swap read percentage changes in the regional GDPs for the time period of 2001-2006 from the parameter file of the system and introduces them to the model.

To shock skilled and unskilled labor

Shock qo("sklab",REG)= file default.prm header "LS16";

Shock qo("Unsklab",REG)=file default.prm header "LU16";

Supplies of skilled and unskilled labor are two important endowments in GTAP. These shocks read percentage changes in labor force for the time period of 2001-2006 from the parameter file of the system and introduce them to the labor market of each region. The GTAP-BIO does not consider labor movement across regions, meaning that there is no migration.

To shock capital stock

Shock qo("Capital",REG)=file default.prm header "CA16";

Capital stock is a major deriver of economic growth. Unlike the GTAP dynamic, capital stock is an exogenous endowment in the GTAP static model. The above shock introduces changes in the regional capital stocks during the time period of 2001-2006 to the system.

To introduce technological progress

Shock aoall(ALL_INDS,REG) = file default.prm header "PRNE";

Technological progress is another source for economic growth. The above shock introduces technological progress in all industries except for crop industries. Note that the header PRNE contains zero values for crop sectors. The next commands define the technological progress for crop industries. Note that values for technological progress are obtained based on Hertel, Ludena, and Golub (2009) for non-agricultural industries and service.

To shock crop yields

Swap p_YIELD(CROP_INDS,REG) = afall("land",CROP_INDS,REG);

Shock p_YIELD(CROP_INDS,REG) = file default.prm header "YD16";

In GTAP-BIO-ADV crop yields are endogenous variables and they respond to the prices of crops. In this simulation, we use the above swap to make them exogenous. Then we shock them to simulate the historical observation on yield growth for the time period of 2001-2006.

To control forest and pasture land prices

Swap aosec("forestry") = pxwcom("forestry");

Shock pxwcom("forestry") = 21;

Shock aosec("Dairy_Farms")=1;

Shock aosec("Ruminant")=1;

These commands define technological progress for forestry, ruminant, and non ruminant industries according to the observed changes in the world price index of forestry product (21%) during the time period of 2001-2006. It is also necessary to introduce the technology shocks for the dairy and ruminant industries in order to reproduce changes in forest areas.

Finally, for the time slices after 2006 we followed the simple experiments that we introduced for the first group of simulations.

Experiments of Group 3: Simulations with crop yield and population growth for the time period of 2006-20015

The experiment used for the first time slice of this group is similar to the first experiment of the second group of simulations. For the rest of time slices we just shocked population and yield according the assumptions we explained in the text along with shocks for ethanol production.

Appendix E

Woods Hole land use CO_2 emission data set

Definitions:

We used the same Woods Hole emissions data that was used in the Searchinger, et al. paper (2008). The specific source for that data is not given in the paper, but Richard Haughton, one of the authors, is affiliated with Woods Hole.

In this appendix we used the following abbreviations:

FAE_MH: Forest area by ecosystem in million hectares

FAE%: Forest area by ecosystem in percent

CINV_MT/H: Carbon in vegetation in metric ton per hectare

CINS_MT/H: Carbon in soil in metric ton per hectare

DCEFLC_MT/H: Direct carbon emissions from land conversion in metric tons per ha

RGFA_MH: Re-growing forest area in million hectares

GCUBRGF_MMTC/yr: Gross carbon uptake by re-growing forests in million metric tons carbon per year

CUBF_MTC/H/yr: Carbon uptake by forest area in metric ton carbon per hectare per year

FCS30 _MTC/H: Foregone Carbon Sequestration in 30 years in metric ton per hectare

WACE_MT/H: Weighted average carbon emissions in metric ton per hectare

WACO2E_MT/H: Weighted average CO2 emissions in metric ton per hectare

Exhibit 4

RFA RENEWABLE FUELS ASSOCIATION

April 28, 2010

Mary D. Nichols, Chairwoman
California Air Resources Board
Headquarters Building
1001 "I" Street
Sacramento, CA 95812

Dear Chairwoman Nichols,

I am writing to inform you and the Board of an important advancement in the science of indirect land use change (ILUC) that has major implications for California's recently adopted Low Carbon Fuels Standard (LCFS). New research conducted and published by Purdue University using the Global Trade Analysis Project model (GTAP) concludes that land use change emissions potentially associated with corn ethanol expansion are likely *less than half* of the level estimated by the California Air Resources Board (ARB) staff for the LCFS. While we continue to have grave concerns about including highly uncertain and prescriptive indirect emissions penalties in the LCFS (for instance, we do not believe ARB has the authority to account for ILUC consistent with the Commerce Clause of the U.S. Constitution), we write to point out the new Purdue findings because we believe ARB has committed itself to consider and respond to critical developments like these. LCFS B12-16

ARB has repeatedly stated that its ILUC analysis for the LCFS was based on the "best available" science and analytical tools, and that the Board is committed to evaluating and adopting advances in the science that would improve the accuracy of its analysis. Indeed, ARB states, "...the GTAP is the best available tool for estimating the global land use change impacts associated with expanded biofuel production. *When and if the Board is made aware of a better estimation tool, it can direct staff to utilize that tool* (emphasis added)."[1] To be sure, Purdue's recent enhancement of the GTAP model and its new ILUC results represent a "better estimation tool" than was used by ARB for the LCFS. Accordingly, we believe that the Board, given its commitments, must direct the staff to adopt the new Purdue results and use the new, improved GTAP model from this point forward until such time that even better tools are available. Because regulated parties under the LCFS will imminently be making decisions about 2011 fuel purchases and related logistics, the Purdue ILUC value should be adopted in the LCFS look-up table *immediately* so that regulated parties have the certainty they need to make purchasing and logistical decisions for the upcoming 2011 LCFS compliance cycle. LCFS B12-17

The new Purdue University research, which was funded in part by the U.S. Department of Energy (DOE), clearly shows that ARB significantly overestimated corn ethanol indirect land use change emissions under the LCFS. In simulations where the most recent available global economic database (2006) was employed and future crop yield increases and population growth were considered, Purdue economists estimated average corn ethanol land use emissions at 13.9 grams LCFS B12-18

[1] Calif. Air Resources Board, California's Low Carbon Fuels Standard: Final Statement of Reasons (December 2009), 633.

CO2-equivalent per mega joule (g/MJ). These results are less than half of the ILUC value of 30 g/MJ adopted by ARB for the LCFS. Presumably to test the sensitivity of ARB's results to model enhancements excluding the use of the 2006 database, the Purdue researchers also examined a case that mirrored exactly the approach taken by ARB for the LCFS analysis (i.e., the old 2001 GTAP database was used, and crop yield growth and population growth was ignored). Even in this case, Purdue found average corn ethanol land use change emissions to be 20.8 g/MJ, or 31% lower than ARB's estimate of 30 g/MJ. Purdue recently finalized and published these results and shared them with stakeholders, including staff at ARB.[2] LCFS B12-18 cont.

The new results obtained by Purdue can be compared in an apples-to-apples manner to the ARB LCFS results because in both cases: 1.) the exact same economic model (Purdue's GTAP) was used; 2.) the same corn ethanol production scenario (15 billion gallons by 2015) was examined; and 3.) the same department at the same university conducted the simulations and many of the same researchers were involved. To be clear, the differences between the new Purdue results and ARB's LCFS results stem from the many major improvements that Purdue has made to the GTAP model, not from any discrepancies in the analytical objectives or underlying scenarios. Many of these enhancements were made in response to comments and questions submitted to ARB and Purdue in recent years by stakeholders and other users of the GTAP model. The following are among the major improvements that were made to GTAP: LCFS B12-19

- *The model's global economic database was updated from 2001 to 2006.* ARB's analysis for the LCFS used the old (2001) GTAP database, while the new Purdue research draws from a recently integrated 2006 database. The authors of the new Purdue paper state, "The global economy changed significantly over the 2001-2006 period..." and there were changes to "...important factors which could alter the land use implications of biofuels." LCFS B12-20

- *Cropland pasture in the U.S. and Brazil and Conservation Reserve Program (CRP) lands have been added to the model.* These important land types were absent from the model when it was used by ARB and its contractors for the LCFS analysis. Excluding these lands from the model, as ARB did, constrains the amounts and types of land that are available for conversion to crops, which ultimately results in artificially inflated ILUC estimates. LCFS B12-21

- *According to the Purdue authors, the model's treatment of corn ethanol animal feed co-products (called distillers dried grains, or DDG) is "significantly improved" over the version of model used by ARB for the LCFS.* Despite real world data and information to the contrary, ARB simply assumed for the LCFS analysis that DDG replaces only corn in animal feed rations and only on a pound-for-pound basis. LCFS B12-22

---

[2] Purdue economists presented their results at an April 23, 2010, workshop at the University of Chicago. The April 2010 final report was distributed electronically to stakeholders, including ARB staffer John Courtis, on April 15, 2010. The report is available online at http://www.transportation.anl.gov/pdfs/MC/625.PDF.

- *The model's method for estimating crop yields on newly converted(i.e., marginal) lands is much more sophisticated and detailed than previous versions of the model, including the version used by ARB for the LCFS.* The model now estimates crop yields on newly converted lands with regional specificity, rather than applying one generic estimate to all marginal croplands around the world, as ARB did for the LCFS. LCFS B12-23

- *For the new analysis, Purdue took into account crop yield growth and population growth over the period of the simulation.* The new model conservatively assumed growth in crop yields of 1% annually from 2006 to 2015. To account for increased food demand, the Purdue authors also assumed global population will grow at a rate consistent with recent trends. In contrast, ARB ignored both effects for the LCFS analysis and did not assume crop yields would grow at all beyond the period of 2006-2008. LCFS B12-24

- *The new Purdue analysis also assumes that some portion of the carbon stored in trees is not immediately released into the atmosphere when the forest is converted to cropland.* Rather, it is assumed in the new version of the model that a fraction of the carbon in harvested trees will be stored long term in furniture, buildings and other wood products. For the LCFS analysis, ARB assumed 100% of the carbon in trees is immediately released into the atmosphere when the forest is converted (despite the agency's clear statement in the ISOR that it meant to assume that 10% of the carbon would be stored in wood products).[3] LCFS B12-25

In many instances in the LCFS public record, ARB acknowledged that these improvements to the model were necessary. As one example, in regard to the exclusion of cropland pasture and CRP lands, ARB stated that the precision of the GTAP model could be increased by "...expand[ing] the types of land areas available for conversion to agricultural uses. Former Conservation Reserve Program lands could be added in the U.S. Idle croplands that are not currently available could be added worldwide."[4] In regard to this issue, ARB further stated, "There are efforts currently by many institutions and GTAP researchers to include these types of lands in the GTAP database. *Once such a database becomes available, we will evaluate it for possible adoption* (emphasis added)."[5] As another example, ARB also recognized that using the old GTAP database (2001) was a weakness of the analysis. According to ARB, "Staff was aware at the outset of the modeling effort that using 2001 as the baseline year was a limitation. The reason that GTAP employed the 2001 world economic database as the analytical baseline is that this was the most recent year for which a complete global land use database existed as of the time of analysis."[6] Fortunately, a more current world economic database (2006) now exists within GTAP. LCFS B12-26

---

[3] In its Initial Statement of Reasons, ARB stated that it "...assumed that 90 percent of the above-ground...carbon is emitted over the fuel production period," meaning 10 percent is sequestered in building products. However, this assumption was not reflected in ARB's final ILUC results. When ARB was questioned about why this assumption was not reflected in final calculations, it responded in the FSOR that, "A miscommunication between ARB, UC Berkeley, and Purdue resulted in a discrepancy between the emission factors discussed in the Staff Report (and presented on the ARB website) and the emission factors actually used in the land use change modeling for the regulation." ARB suggested that, "Instead of '90 percent,' the actual assumption was '100 percent.'" A correction was made in errata to fix the "mistake." (FSOR, 651-653)
[4] Calif. Air Resources Board, California's Low Carbon Fuels Standard: Final Statement of Reasons (December 2009), 635.
[5] Ibid., 659
[6] Ibid., 693.

Even after these enhancements were made to GTAP, many uncertainties remain. Still, the new Purdue results are being received by the scientific community as the state-of-the-art in terms of land use change modeling. While the Purdue authors acknowledge that "...modeling land use change is quite uncertain..." and that their analysis is "...limited by data availability, validity of parameters, and other modeling constraints...", the new Purdue study undoubtedly represents the cutting edge and best available science on the issue of land use change and biofuels. Without question, the new Purdue results are superior to the results obtained by ARB in terms of robustness, data currency, and detail. Throughout the LCFS process, ARB has repeatedly stated its intent to integrate modeling improvements and new data as they become available. Indeed, in the LCFS Initial Statement of Reasons, the agency writes, "...ARB has committed to determining the total direct and indirect emissions associated with production, distribution, and use of all fuels through conducting complete lifecycle analyses *based on the best available science* (emphasis added)."[7] Further, ARB suggests, "The Board agrees that the issue of land use change impact estimation must be subject to ongoing evaluation and analysis..."[8] and, "The Board has also committed to an ongoing inquiry into the best indirect land use change estimation methodologies."[9]

LCFS B12-26 cont.

In keeping with ARB's stated commitment to using the best available science and data, the Board should move *immediately* to adopt the value of 13.9 g/MJ for the corn ethanol ILUC penalty in lieu of the current 30 g/MJ estimate. ARB has vociferously committed to adopting advancements in the science of the indirect effects as it becomes available. Integrating the new Purdue value would represent a directional shift in the fuels that would be viewed as viable compliance options, i.e. the current carbon intensity scores prevent most corn ethanol from being used beyond 2011, while adjusting the carbon intensity scores to reflect the new Purdue ILUC value would allow many corn ethanol pathways to serve as viable compliance options for several years under the LCFS. As noted above, <u>any delay in considering and adopting the new Purdue results will seriously hamper the ability of regulated parties to comply with 2011 LCFS obligations</u>. Time is of the essence. The California fuels market simply can't afford to wait for possible modifications to the regulation that may result from the expert work group recommendations (which aren't expected until December 2010). Adopting the Purdue ILUC value immediately would greatly enhance the ability of regulated parties to meet their greenhouse gas reduction obligations in the early years of the LCFS, ultimately minimizing fuel cost impacts to the state's consumers.

LCFS B12-27

Further, there is very recent precedent for ARB making material changes to adopted regulations and adjusting implementation deadlines when new information and better data are presented. Just last week at its April Board meeting, ARB staff acknowledged that its previous estimates of off-road diesel emissions related to the off-highway diesel rule were "too high."[10] New analyses from third parties and ARB itself showed the original off-road emissions inventory may have been overestimated by ARB by 140-400%. At last week's meeting, ARB members stated that

LCFS B12-28

[7] California Air Resources Board, Staff Report: Initial Statement of Reasons, Proposed Regulation to Implement the Low Carbon Fuels Standard: Vol. I (March 5, 2009), Page IV-48
[8] Calif. Air Resources Board, California's Low Carbon Fuels Standard: Final Statement of Reasons (December 2009), 638.
[9] Ibid., 642
[10] Calif. Air Resources Board, Staff Presentation at April 2010 Board meeting (April 22, 2010), slide 10.

additional analysis needs to be conducted and affected parties must be given more time to comply with the rules. Similarly, new analyses presented to ARB in December 2009 led the Board to direct staff to re-evaluate the science behind the pending on-road diesel rules for trucks and buses. One Board member stated the staff report upon which the rule is based is "not acceptable" and proposed that ARB "...set aside the rule until this report be redone."[11] In a similar way, we are urging the Board to re-evaluate the science behind ILUC and consider the new evidence presented in the Purdue paper.

LCFS B12-28 cont.

We appreciate your consideration of this new information and your commitment to ensuring the best available science is appropriately integrated into the LCFS regulation. While we view the new Purdue analysis as being the best available to date, we believe much more research and analysis is needed on the issue of land use change. There is still much room for improvement in the GTAP model and the scientific community still has a great deal to learn, in general, on the topic of biofuels and land use change. We would greatly appreciate the opportunity to meet with you and your staff to discuss the new Purdue results in more detail.

Sincerely,

Bob Dinneen

12_B_LCFS_GE Responses (Page 119 – 124)

684. Comment: **LCFS B12-16**

The 2010 letter states that a recent study by Purdue concludes that land use change emissions potentially associated with corn ethanol expansion are likely less than half of the level estimated in the 2009 LCFS proposal.

Agency Response: The document was prepared by the commenter in response to ARB analysis presented in 2009 where the value of 30.0 g/MJ appears, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments in responses to **LCFS 8-1**, **LCFS 8-4**, **LCFS 46-166**, **LCFS 46-216**, **LCFS T25-1**, **LCFS B12-1**, and **LCFS B12-4**.

685. Comment: **LCFS B12-17**

The 2010 letter states that the Purdue iLUC value should be adopted in the LCFS look-up table immediately so that regulated parties have the certainty they need.

Agency Response: The document was prepared by the commenter in response to ARB analysis presented in 2009 where the value of 30.0 g/MJ appears, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments in responses to **LCFS 8-1** and **LCFS 46-216**.

686. Comment: **LCFS B12-18**

The 2010 letter states that the LCFS regulation significantly overestimated corn ethanol indirect land use change emissions.

Agency Response: The document was prepared by the commenter in response to ARB analysis presented in 2009 where the value of 30.0 g/MJ appears, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments in responses to **LCFS 8-1**, **LCFS 8-4**,

LCFS 46-166, **LCFS 46-216**, **LCFS B12-1**, **LCFS B12-2**, and **LCFS B12-13.**

687. Comment: **LCFS B12-19**

The 2010 letter states that the updated GTAP model data is the same, and differences can be accounted for in model enhancements.

Agency Response: The document was prepared by the commenter in response to ARB analysis presented in 2009 and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments in response to **LCFS B12-17**.

688. Comment: **LCFS B12-20**

The 2010 letter alleges that ARB staff's original analysis for the LCFS regulation used outdated data.

Agency Response: This document was prepared by the commenter in response to ARB analysis presented in 2009, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the 2010 letter pertains to the later proposal or the process by which the LCFS was proposed and adopted, ARB addresses the comments as follows:

ARB's version of GTAP uses a 2004 baseline for which data is available for all the elements incorporated into the current version of the model. Consideration of this baseline was related to available data for all elements incorporated into the current version and completing comprehensive testing of all the elements of the GTAP model.

689. Comment: **LCFS B12-21**

The 2010 letter claims that ARB staff did not incorporate the new GTAP model.

Agency Response: This document was prepared by the commenter in response to ARB analysis presented in 2009, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the 2010 letter pertains to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

Cropland Pasture is a new land cover category that was included in the GTAP model in 2010 to enhance the land use analysis. After review of available data, Purdue and ARB updated the GTAP model to include a cropland/pasture land category in the U.S. and Brazil. Inclusion of this land category in the current analysis lowered iLUC emissions for all six biofuels. See response to **LCFS 38-33**.

For a discussion of CRP lands, see also responses to **LCFS 46-15** and **LCFS 46-110**.

690. Comment: **LCFS B12-22**

The 2010 letter states that, according to the Purdue authors, the new GTAP model's treatment of corn ethanol animal feed co-products is significantly improved over the model used in the LCFS regulation.

Agency Response: This document was prepared by the commenter in response to ARB analysis presented in 2009, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. The comment is not relevant since the version of the GTAP model used for the proposed regulation includes updates to the treatment of animal feed co-products.

691. Comment: **LCFS B12-23**

The 2010 letter claims that the Purdue GTAP model crop-yield estimate is preferable to the version used in the LCFS regulation.

Agency Response: This document was prepared by the commenter in response to ARB analysis presented in 2009, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the 2010 letter pertains to the later proposal, or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

The comments are not relevant since ARB staff has included the updates to estimate crop yields on newly-converted land. Data to include updated productivity were derived from published work by

Taheripour et al.[54] The new productivity values by region and AEZ is provided in Appendix I Table I-2 of the ISOR.

692. Comment: **LCFS B12-24**

The 2010 letter states that the ARB staff analysis does not account for growth in crop yields.

Agency Response: The document was prepared by the commenter in response to ARB analysis presented in 2009 and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the 2010 letter pertains to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

The 2010 letter is irrelevant because it refers to updates to the GTAP model implemented by Purdue after the Board Hearing in 2009. The analysis in 2009 and the current analysis (2014) account for the impacts on yields from price changes and technological advances. Changes in population are not relevant to either the 2009 or the current analyses since the modeling exercise estimates impacts from increased biofuel production on various sectors of the global economy. The current version of the Purdue/ARB model is static and is not capable of estimating impacts of population change.

693. Comment: **LCFS B12-25**

The 2010 letter alleges that ARB staff used incorrect values for forest to cropland conversion.

Agency Response: This document was prepared by the commenter in response to ARB analysis presented in 2009, and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the 2010 letter pertains to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

The comments are not relevant to the current analysis. In the current analysis, using published data, ARB staff has updated the analysis and accounts for carbon sequestered in wood products.

[54] F. Taheripour, Q. Zhuang, W. Tyner, and X. Lu, Biofuels, Cropland Expansion, and the Extensive Margin, Energy, Sustainability, and Society, 2:25, 2012, http://www.energsustainsoc.com/content/2/1/25

Details of the analysis are provided in Appendix I, Attachment 2, Section 3.1.4 of the ISOR.

694. Comment: **LCFS B12-26**

The 2010 letter directs ARB staff to incorporate the Purdue analysis using the 2006 database information for GTAP.

Agency Response: The document was prepared by the commenter in response to ARB analysis presented in 2009 and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

After 2009, ARB staff has reviewed not only the research published by Purdue but also other advances in the science of land use change. The current analysis has refined the 2009 iLUC analysis to account for the latest data and updated land use change science. See also responses to **LCFS B12-16**, **LCFS B12-17**, and **LCFS 46-81**.

695. Comment: **LCFS B12-27**

The 2010 letter directs the Board to adopt the commenter's preferred iLUC value for corn ethanol.

Agency Response: The document was prepared by the commenter in response to ARB analysis presented in 2009 and as such does not constitute an objection or recommendation regarding the proposal released in December 2014. To the extent the comments pertain to the later proposal or the process by which the LCFS was proposed and adopted, ARB staff addresses the comments as follows:

In the current proposal, ARB staff has already modified the 30.0 g/MJ value to 19.8 g/MJ for corn ethanol to reflect the latest work. The comments are not relevant since the updates they refer to were implemented by Purdue after the Board Hearing in 2009. It is worth noting that for the period 2011-2014, fuels used under the LCFS have over-complied with the standards and do not support the commenter's view point that delays in modifying iLUC values for corn ethanol could seriously hamper the ability of regulated parties to comply with 2011 obligations.

See also responses to **LCFS B12-8**, **LCFS B12-9**, and **LCFS B12-16**.

696. Comment: **LCFS B12-28**

The 2010 letter requests the Board re-evaluate the science behind the iLUC estimates and consider the Purdue paper.

Agency Response: This document was prepared by the commenter in response to ARB analysis presented in 2009, and as such does not constitute an objection or recommendation regarding the proposal released in December2014. See also response to **LCFS 46-216**.

Air Resources Board

Linda S. Adams
Secretary for Environmental Protection

Arnold Schwarzenegger
Governor

June 9, 2010

Mr. David Bearden
General Counsel
Renewable Fuels Association
One Massachusetts Avenue, N.W., Suite 820
Washington, D.C. 20001

Re: Petition for Rulemaking

Dear Mr. Bearden:

Thank you for your letter to Chairman Mary D. Nichols dated May 10, 2010. Chairman Nichols has asked that I respond on her behalf. In your letter, you petitioned, pursuant to Government Code section 11340.6, on behalf of Growth Energy for the Air Resources Board (ARB or Board) to amend the Low Carbon Fuel Standard (LCFS) regulation, codified in title 17, California Code of Regulations (CCR), sections 95480-95490. Specifically, you petitioned for amendments to section 95486.

After careful consideration of the facts associated with your request, pursuant to Government Code section 11340.7(b), I am denying your petition to amend the LCFS regulation at this time. However, pursuant to Board Resolution 09-31,[1] I will consider recommending possible changes to the regulation in the future based upon the work being done in conjunction with the Expert Workgroup we convened to assist the Board in refining and improving the land use and indirect effect analysis of transportation fuels. Below I provide further details on our denial of your petition.

Your requested "amendment 1" would take effect no later than December 31, 2010, and would eliminate the land use change carbon intensity of corn ethanol for two years, 2011 and 2012. With respect to this requested amendment, the Board has previously found that crop-based biofuel production does entail land use change impacts, and that those impacts do result in significant greenhouse gas emissions. See Board Resolution 09-31. In light of those findings, the Board determined that it would be remiss if it did not account for land-use change effects in the carbon intensities of crop-based biofuels. Moreover, in the April 2010 report released by Purdue for Argonne

[1] Resolution 09-31, April 23, 2009: See: http://www.arb.ca.gov/regact/2009/lcfs09/res0931.pdf

National Laboratories that you cited, the authors also conclude that "it is simply not credible to argue that there are no land use change implications of corn ethanol." Your petition does not refute the Board's finding that the land use change impacts result in significant greenhouse gas emissions, nor does it refute the study authors' conclusion noted above. Thus, your petition presents an insufficient basis for eliminating the land-use change carbon intensity value for corn ethanol.

Alternatively, "amendment 2" of your petition would lower the indirect land-use carbon intensity value for corn ethanol to one of two values. This requested change is based on the Purdue study you cited in your petition, which we are currently reviewing. As discussed below, it is premature to make changes to the LCFS regulation based on this study. Our initial observation is that the Purdue model used for this study is not publicly available; as a result, a more detailed evaluation is not currently feasible at this time.

As part of the Purdue study, the authors varied a number of parameters which resulted in a range of land use carbon intensity values that are 1/3 to 1/2 lower than ARB's published average value. However, the values are generally within the range of results that we found in running various sensitivities. ARB believes that this is important work and is being considered by the Expert Workgroup as part of its comprehensive evaluation.

As noted, the Expert Workgroup was established at the direction of the Board in Resolution 09-31 upon the Board's approval of the LCFS regulation. The Expert Workgroup is charged with refining and improving the land use and indirect effect analysis of transportation fuels. The Expert Workgroup includes individuals from diverse stakeholder groups such as government agencies, academic institutes (including Purdue University), national laboratories, the biofuel and oil industries, and environmental groups. The Expert Workgroup has formed eight (and potentially nine) subgroups that are actively evaluating all facets of the modeling, including comparative models. For more information on the Expert Workgroup, see the following link: http://www.arb.ca.gov/fuels/lcfs/workgroups/ewg/expertworkgroup.htm.

At the next Expert Workgroup meeting on June 17, 2010, Purdue University representatives will make a presentation on their work so that the Expert Workgroup members will have an understanding of the study, including the key assumptions. We have asked Purdue and Argonne National Laboratories to make the updated Global Trade Analysis Project version publically available for inspection and evaluation. When it becomes available, it is likely that ARB will use Purdue's new work as one of the two baselines for evaluating the impact of inputs and assumptions. The assessment of the Expert Workgroup will be reflected in a report, including recommendations, that the Board will consider at the end of the year.

Because the Expert Workgroup will be assisting ARB staff in evaluating the Purdue study and that work has not yet commenced, it is premature to adopt Purdue's recent work. And, as indicated, our understanding is that the model and the underlying details which will need to be considered for a full evaluation are not yet available. However, as mentioned above, we believe that assessing this study is an important part of our effort to evaluate developments regarding the indirect effects issue as directed by the Board.

Finally, you also requested an amendment that would take effect no later than September 30, 2010 and would require the Executive Officer to take final action on a Method 2A or 2B submittal under section 95486 within 90 days of his receipt of a complete submittal pursuant to Method 2A or 2B. In approving the LCFS regulation, the Board considered the need for an expeditious process for reviewing a Method 2A or 2B submittal and weighed that need against the public interest in being able to review the submittal in an open process. While we expect most submittals to be reviewed relatively quickly, in some cases, the complexity of a submittal may warrant a staff review that exceeds 90 days. Therefore, the Board determined that the most appropriate balance of these considerations is reflected in the public review and final action provisions contained in section 95486(f). We believe the existing process in the regulation provides a necessary and appropriate balance between these two considerations and have therefore determined that your requested amendment would be inappropriate.

Based on the reasons discussed above, ARB believes that granting the requested changes specified in your petition would be inappropriate at this time. However, as noted, we are continuing to evaluate the ongoing developments in the field of land use and indirect effect analysis of transportation fuels. ARB will consider revisiting the need for updating the indirect effects carbon intensity value for corn ethanol when the Expert Workgroup completes its analysis.

In accordance with Government Code section 11340.7(d), a copy of this letter is being transmitted to the Office of Administrative Law for publication in the California Regulatory Notice Register. The agency contact person on this matter is Ms. Claudia Nagy, Staff Counsel, Office of Legal Affairs, at (916) 445-5501 or cnagy@arb.ca.gov. Any person who is interested in obtaining a copy of the petition may obtain it from her.

Sincerely,

James N. Goldstene
Executive Officer

697. Comment: **ARB Letter**

Agency Response: This exhibit is a letter from Executive Officer James Goldstene responding to David Beardon's Petition. See responses to **LCFS B12-1** through **LCFS B12-15**.

This page intentionally left blank.

October 14, 2014

Mr. Richard W. Corey, Ph.D.
Executive Officer
California Air Resources Board
1001 I Street
Sacramento, CA 95814

VIA Electronic and Postal Mail

Dear Dr. Corey:

Thank you for the opportunity to participate in the September 29, 2014 workshop on land use change (LUC) emissions. Thank you also for agreeing to provide the updated GTAP model to aid in our evaluation of your latest work in estimating LUC emissions from various feedstocks, and for agreeing to provide the two WRI reports used to evaluate irrigated versus rain-fed cropland.

While some progress in estimating land use emissions has perhaps been made, we have a number of concerns with ARB's presentation and some of the statements made by Staff at the workshop. We summarize each of these concerns below. This letter does not constitute our full comments on the information presented at the workshop, these comments will be submitted by our organizations on or before the due date. However, we thought it was important to highlight these concerns now.

1. AEZ-EF Model

Little has been done to address comments raised on the March 2014 workshop material with respect to the AEZ-EF model. Staff cited contractual reasons for not making progress in this area. However, this now puts ARB in the position of having very little time to address very significant concerns raised by the industry and others. At the same time, while Staff has not made progress in this area, the Staff presentation at page 7 indicates that "minor changes will be made in October 2014", and that the "impacts on ILUC are expected to be negligible." If Staff has not done this work yet, how does Staff know that the impacts on ILUC are expected to be negligible? The comments that were submitted to the Staff following the March workshop, if implemented properly, would not have negligible effects on the emissions. We are therefore disappointed that (1) Staff had not made any progress in this area since March, (2) Staff feel they must now rush to make progress because of deadlines, and (3) Staff are already discounting any impacts these changes may have. This is not a good approach to improving the science of land use change emissions, as it applies to a newly adopted LCFS.

LCFS B12-29

2. Irrigated/Rain-Fed Cropland

Working with Purdue, Staff developed separate rain-fed and irrigated cropland categories in GTAP, so that Staff could evaluate the LUC impact of limiting the growth of irrigated cropland where there appears to be evidence that this growth is limited. Since yields are higher on irrigated farmland, this has the effect of lowering the overall new land converted to crops. Staff indicated that the effect of including these new land categories was "small", however, it appears that this comment was based on what would happen between a scenario where some land has irrigated cropland with limitations to a scenario where all land has irrigated cropland with limitations. This is not the correct comparison. The comparison should have been between some irrigated cropland with limitations and no irrigated cropland with limitations (i.e., the baseline model without this change). Staff indicated this latter effect could be up to 5 g/MJ. Given that the new LUC for corn ethanol is 21.6 g/MJ from ARB's most recent modeling, 5 g/MJ, if it applies to corn ethanol, is hardly "small." We will be evaluating this impact in more detail prior to submitting comments on October 15, including the underlying data and rationale developed by WRI for limiting irrigated land expansion in the various AEZs. LCFS B12-30

3. Effect of Double-Cropping

Double-cropping is not an uncommon practice in many parts of the world when commodity prices are high. Double-cropping directly reduces the pressure to convert pasture, cropland pasture, and forest to crops. There are numerous examples of this. It has been well known that GTAP does not yet account for double-cropping, and since the LCFS was first adopted, comments have been submitted to ARB that ARB should evaluate the LUC impacts of double-cropping. The Expert Work Group elasticities sub-group suggested that if GTAP cannot be modified to directly address double-cropping, the yield-price elasticity could be used to simulate double-cropping effects. And yet, ARB has done nothing in this area. ARB has not even run "what-if" scenarios to determine what kind of impact double cropping would have on the results in countries like the US and Brazil, especially now ARB has apparently modified the model to allow the use of different yield-price elasticities for different crops in different AEZ regions. ARB's lack of progress in this area is unacceptable in improving LUC estimates. LCFS B12-31

4. Yield-Price Elasticity

ARB attempted to show 2 charts (pages 27 and 28 of the presentation) to support its claim that it the price-yield elasticity could be zero or very close to zero. The first chart plotted yield vs price for US corn from FAO data from 1990-2013. The chart appeared to show no relationship. However, one would never really use this kind of approach to develop a relationship between yield and price; there are simply too many factors changing from year-to-year to develop such a relationship. The second chart was a trend plot of corn yield and price from 1990-2013 (using the same data as the first chart). Since the second chart was a different way of presenting the same data as in the first chart, the same comment applies: there are too many things changing to develop any relationship of yield versus price in these data. ARB made no attempt to isolate just the impact of price changes on yields. Therefore, these two charts prove nothing. Purdue's estimated price yield value is 0.25. ARB evaluated a range from 0.05 to 0.35 (minus 0.2 from Purdue's estimate, and plus 0.1 from the Purdue default). The average from ARB's range is 0.19, 24 percent lower than the value recommend by Purdue. We support analyzing a range of price-yield elasticities, but this range should be from LCFS B12-32

0.15 to 0.50 with an average somewhat above 0.25 to simulate some double cropping (as recommended in the RFA comments on the March 11 workshop), not 0.15 to 0.35 (which has an average below the value recommended by Purdue without any double cropping). LCFS B12-32 cont.

5. Cropland Pasture Elasticity

Staff estimated two cropland/pasture elasticitiy scenarios – 0.4/0.2 for US/Brazil, and 0.2/0.1 for US/Brazil. The 0.4/0.2 is the Purdue-estimated set of inputs. Staff has presented no support for its 0.2/0.1 set of inputs, it is simply less than the Purdue-estimated values. Again, if a range is to be used, unless there is specific evidence otherwise to show that the Purdue-estimated values are too high, then the range should be on either side of the Purdue-estimated inputs. LCFS B12-33

6. Comparison of GTAP Outputs With World Data

ARB has received comments from stakeholders that it should compare GTAP's land use changes to real data. ARB rejects this type of comparison as "not productive", because GTAP is evaluating a single factor (increase in biofuel demand) while factors affecting land use changes in the real world are multiple. ARB then showed charts that compared world forest changes from 2000-2012 with GTAP-estimated changes for several feedstocks. The forest changes for the biofuels were very small in comparison with total forest changes from 2000-2012.

We find ARB's excuses on making no attempt to calibrate land use changes to real world data troubling. The expansion of corn ethanol in the US is predicted by GTAP to have converted 75,000 ha of forest in the US. GTAP also knows where in the US that forest is getting converted. If 75,000 ha of managed forestland have been converted to crops in the last 10 years due to biofuel expansion, then it should be apparent from satellite or other data. ARB should have attempted to validate forest conversions, at least in the US, if not in other major countries with predicted forest conversion. LCFS B12-34

We find it troubling that ARB apparently does not believe it is productive to validate model predictions by examining real-world empirical data and trends. The principles of sound, science-based policymaking and regulation dictate that model predictions should be validated when possible. Given that ARB's GTAP shock is meant to simulate impacts from 2001-2015, we now have real-world data for the majority of that period.

7. Effect of Fertilizer, Livestock, and Paddy Rice Emissions

The industry first made comments that ARB should evaluate these 3 effects several years ago. ARB has failed to do anything about these issues. EPA evaluated these in 2010 as a part of the RFS. They had a significant impact on EPA's LUC estimates. ARB cites a concern with double counting emissions between GTAP and GREET. EPA, however, also used GREET for direct emissions, and did not have a concern with double counting. ARB has completely failed to explain why it cannot include factors at this time in this update to LUC emissions that EPA successfully included in its analysis 4 years ago as a part of the RFS. LCFS B12-35

Summary

ARB has perhaps made some progress in updating LUC emissions as part of the LCFS. However, we have serious concerns with the lack of progress in these other areas. There are far too many items that Staff is pushing off to some future update of LUC emissions. LCFS B12-36

12_B_LCFS_GE Responses (Page 128 – 131)

698. Comment: **LCFS B12-29**

The comment alleges that ARB staff did not update the AEZ-EF model.

Agency Response: ARB staff notes that this document was submitted in October 2014, and as such does not constitute an objection or recommendation on the current proposal. The current analysis includes all relevant updates to the Agro-Ecological Zone Emissions Factor (AEZ-EF) model based on available data. The comments submitted were evaluated at first by staff and later by the contractor. Appropriate refinements were made to the model when supported by available data and methodology. For responses to the comments, see responses to **LCFS 46-16**, **LCFS 46-85**, **LCFS 46-92**, and **LCFS 46-93**. At this time, all of the iLUC values being proposed to the Board are a result of ARB staff using the latest science and best available data.

699. Comment: **LCFS B12-30**

The comment argues that ARB staff's conclusion that including the impact of areas with limited growth of irrigated cropland, results in a small effect is not accurate.

Agency Response: The comments related to scenarios where some land has irrigated cropland with limitations to a scenario where all land has irrigated cropland with limitations' are not relevant based on the development of the GTAP model. The GTAP model accounts for all categories of cropland and disaggregates cropland into irrigated and rain-fed types. There is no version of the model which includes all land being irrigated. The "5 g/MJ" difference indicated at the workshop on September 29, 2014, is the difference from an older version of a Purdue model with no separation of irrigated/rain-fed lands and the version which includes the disaggregation. The current ARB analysis uses an updated version of the model. Furthermore, this was an average difference from a few illustrative scenario runs and not the entire 30 runs as is used in the current analysis. The comments related to the 5 g/MJ are therefore not relevant since it does not apply to the current version of the model.

700. Comment: **LCFS B12-31**

The comment directs ARB staff to account for double-cropping in the GTAP model for more accurate results.

Agency Response: See responses to **LCFS 8-4** and **LCFS 8-5**.

701. Comment: **LCFS B12-32**

The comment supports a range of price-yield elasticities but suggests that the range should be changed to the commenter's preferred value.

Agency Response: Please see responses to **LCFS 8-9**, **LCFS 46-79**, **LCFS 46-86**, and **LCFS 46-98**.

702. Comment: **LCFS B12-33**

The comment contends that the Purdue analysis for cropland/pasture elasticity ratio is preferable to the ratio ARB staff used and directs staff to use the preferred value or justify their original value.

Agency Response: See responses to **LCFS 38-33** and **LCFS 46-103**.

703. Comment: **LCFS B12-34**

The comment directs ARB staff to validate the GTAP model predictions with real-world empirical data and trends.

Agency Response: ARB staff disagrees with the commenter that the current analysis should consider real-world data in assessing model outputs. See responses to **LCFS 8-4** and **LCFS 8-5**.

704. Comment: **LCFS B12-35**

The comment argues that ARB staff must explain why the effects of fertilizer, livestock, and paddy rice emissions are not included in the iLUC emissions updates.

Agency Response: See response to **LCFS 42-16** and **LCFS 46-82**.

705. <u>Comment</u>: **LCFS B12-36**

The comment contends that, while some progress has been made in updating iLUC emission estimates, more work is needed.

<u>Agency Response:</u> The current approach used by ARB staff is appropriate since it used the most current data and the latest modeling structure. Any specific issues that were not considered for the current analysis were either due to lack of detailed data or because modeling structure did not allow for the inclusion of a particular effect. See also responses to **LCFS 8-1** and **LCFS T25-1**.

Comments of Growth Energy on the Air Resources Board Staff Presentations at a Public Consultation Meeting on Regulations for Commercialization of Alternative Diesel Fuels

These comments respond to the CARB staff's request for comments on the staff's presentations at the November 21, 2014 public consultation meeting on the proposed adoption of regulations to govern commercialization of alternative diesel fuels, including as part of compliance strategies for the California Low Carbon Fuel Standard ("LCFS") regulation.

1. Methodology for Assessing Impact of Biodiesel Use on NOx Emissions

As Growth Energy has commented previously, CARB staff's approach to assessing the NOx emission impacts of biodiesel and biodiesel blends in heavy-duty diesel engines is flawed.[1] The staff's approach does not adequately protect the environment, in part because it ignores the fact that the existing emissions test data indicate that there are statistically significant increases in emissions of oxides of nitrogen (NOx) at biodiesel blend levels below B5, the lowest level at which CARB staff has chosen to perform testing. As fully explained in an expert report prepared for Growth Energy by Mr. Robert Crawford of Rincon-Ranch Consulting,[2] any sound statistical analysis of the available data indicates that statistically significant increases in NOx emissions occur at biodiesel blend levels below B5. ADF B3-1

In light of the recent release of biodiesel emissions data by CARB staff, Mr. Crawford has updated his work to include all of that data. The results of this updated analysis were summarized by Jim Lyons of Sierra Research during a presentation made at the October 20, 2014 ADF workshop, and detailed documentation regarding the updated analysis was provided to CARB staff ADF B3-2

1 See Attachments A – D.

2 See Crawford, R., "NOx Emission Impact of Soy- and Animal-based Biodiesel Fuels: A Re-Analysis," December 10, 2013.

by Mr. Lyons via email on October 24, 2014,[3] along with a request that it be posted on agency's ADF website.

As CARB staff has been advised, inclusion of the newly released biodiesel emission test data does not alter Mr. Crawford's previous findings. Likewise, the CARB staff's decision to characterize biodiesels as "low saturation" or "high saturation," instead of "soy" or "animal" based," does nothing to alter Mr. Crawford's findings or protect against increases in NOx emissions resulting from biodiesel use in California. CARB staff has not posted Mr. Crawford's updated analysis on the agency's ADF webpage; has never discussed or explained why it has not adopted Mr. Crawford's approach; and did not discuss Mr. Crawford's revised analysis in any way during the November 21, 2014 workshop. CARB staff appears determined to avoid full public review of the available data, in violation of its environmental protection regulations and the statutes that apply to this rulemaking, including the California Environmental Quality Act ("CEQA") and the Global Warming Solutions Act of 2006 ("AB 32").

ADF B3-2 cont.

2. Proposed Biodiesel Control Levels

For what it treats as low saturation biodiesel blends, CARB staff is proposing a control level of B5 from April 1 to October 31 of each year and a control level of B10 throughout California during the rest of the year. What this means, based on the proposed regulatory language[4] released by CARB staff, is that during the summer, mitigation of increased NOx emissions is not required until low saturation biodiesel blend levels exceed B5 (e.g., B6)—despite the fact that ***CARB staff acknowledges that statistically significant impacts occur at the B5***

ADF B3-3

---

3 Although these were already provided to CARB staff, materials related to Mr. Crawford's most recent analysis are attached to these comments.

4 Proposed Section 2293.6(a)(2).

level.[5] Given this, there can be no dispute that the staff proposal will result in increases in NOx emissions in California. Such an outcome, however, is not permitted under CEQA and AB 32. ADF B3-3 cont.

During the winter the control level for low saturation biodiesel blends increases from B5 to B10, meaning that NOx mitigation is not required until the biodiesel blend level reaches B11. As a result, CARB staff is allowing unmitigated increases in NOx emissions in California to as much as double during the winter. Further, Growth Energy is not aware of, nor has CARB staff identified, any other NOx control measure affecting stationary, area, or mobile sources that is allowed to be relaxed during the winter months anywhere in California. Such an inconsistency cannot be squared with CARB's CEQA obligations or the requirements of AB 32, which include the avoidance of controls that would have the effect of increasing regulated emissions (such as NOx) or hampering compliance with state and federal ambient air quality regulations. ADF B3-4

For high saturation biodiesel blends, CARB staff is proposing a year-round control level of B10, meaning that NOx mitigation is not required until the B11 level. Again, this is above the B10 level at which even CARB staff has determined that statistically significant increases in NOx emissions will occur; therefore, it will allow unmitigated increases in NOx emissions to occur throughout California.

Growth Energy again urges CARB staff to revise its proposal to ensure that it is protective of California air quality by requiring mitigation of potential NOx emission increases from all levels of biodiesel blends, the need for which is indicated by Mr. Crawford's work. CARB cannot risk increases in NOx emissions by failing to require year-round NOx mitigation for low saturation

---

[5] This was acknowledged by CARB staff at the October 20th workshop. See *http://www.arb.ca.gov/fuels/diesel/altdiesel/20141017_ADF_statistical_analysis.pdf* and *http://www.arb.ca.gov/fuels/diesel/altdiesel/20141017_ADF_discussion_paper.pdf*

biodiesel blends beginning at the B5 level, and for high saturation biodiesel blends beginning at the B10 level. ADF B3-4 cont.

3. New Technology Diesel Engines and the Sunset and Exemption Provisions

CARB staff claims, currently without empirical support or any other explanation, that the use of biodiesel blends in so-called "new technology diesel engines" (NTDEs) will not result in increased NOx emissions regardless of the type of biodiesel used or the blend level up to at least B20. Based on that claim, CARB staff is proposing to eliminate the requirements for mitigation of biodiesel-related NOx emission increases when the population of vehicles equipped with NTDEs in the California truck fleet reaches a certain level and for biodiesel blends used by centrally fueled truck fleets that are composed of at least 90% of vehicles equipped with NTDEs. The available studies in the peer-reviewed literature, which have been previously identified by Growth Energy for CARB staff,[6] contradict the staff's claim. The proposed exemptions for fleets of vehicles comprised mainly of vehicles equipped with NTDEs and the sunset provisions are therefore not permitted under the governing statutes because they would permit an unmitigated risk of increased NOx emissions, and adverse impacts on air quality. ADF B3-5

4. Definitions of CARB Diesel and Blend Level

At present, CARB staff is proposing to define "CARB diesel" to which biodiesel will be allowed to be blended under the ADF regulation as follows:[7]

> *...a light or middle distillate fuel that may be comingled with up to five (5) volume percent biodiesel and meets the definition and requirements for "diesel fuel" or "California nonvehicular diesel fuel" as specified in 13 CCR 2281, et seq. "CARB diesel" may include: renewable diesel; gas-to-liquid fuels; Fischer-Tropsch diesel; CARB diesel blended with additives specifically formulated to reduce emissions of one or more criteria or toxic air contaminants relative to reference CARB diesel;*

ADF B3-6

[6] See Attachment D

[7] Proposed Section 2293.2(a)(9)

and CARB diesel specifically formulated to reduce emissions of one or more criteria or toxic air contaminants relative to reference CARB diesel.

The "blend level" of a biodiesel blend or blend of another ADF would be defined[8] as follows:

> *...the ratio of an ADF to the CARB diesel it is blended with, expressed as a percent by volume. The blend level may also be expressed as "AXX," where "A" represents the particular ADF and "XX" represents the percent by volume that ADF is present in the blend with CARB diesel (e.g., a 20 percent by volume biodiesel/CARB diesel blend is denoted as "B20").*

Because "CARB diesel" can contain up to 5% biodiesel and the control levels proposed by CARB staff above which NOx mitigation is required are defined in terms of "blend levels," the actual biodiesel content of a biodiesel blend under the staff proposal could be as much as 5% greater than the "blend level" used to determine if NOx mitigation is required. Thus, for example, under the staff proposal NOx mitigation of a summer blend of "low saturation" biodiesel blend would not be required even though it contains 10% biodiesel and the unmitigated NOx emissions would be as much as twice those assumed by CARB staff.

ADF B3-6 cont.

There are at least two ways by which CARB staff could easily address this issue. The first would be to require biodiesel blenders to test the CARB diesel fuels they use in order to determine the biodiesel content and type of biodiesel present in a given CARB diesel before blending occurs. The second would be to require that biodiesel blenders use only CARB diesel fuels that have been certified as containing no biodiesel. In any case, CARB staff must modify its proposal to ensure that the actual biodiesel content of blends is accurately known and that appropriate NOx mitigation requirements are imposed. Failure by CARB staff to require accurate measurement and reporting of the biodiesel content of biodiesel blends will lead to unmitigated increases in NOx emissions

---

[8] Proposed Section 2293.2(a)(4)

along with other potential issues, including violations of pump labeling and vehicle manufacturer warranty requirements.

ADF B3-6 cont.

5. Phase-In Requirements and Program Review

Under the current staff proposal, although the ADF regulation would become effective on January 1, 2016, ***mitigation of increased NOx emissions from the use of biodiesel blends would not be required until 2018.***[9] In addition, CARB staff is proposing to perform a "review" of efficacy of the NOx mitigation requirements of the biodiesel provisions of the ADF regulation by December 31, 2019.[10] As in other respects, the CARB staff proposal fails to adequately protect against adverse air quality impacts and violates the statutes governing this rulemaking. To comply with CEQA and AB 32, the Board must mandate in the ADF rulemaking that mitigation of NOx increases commences as soon as the amended LCFS regulation becomes effective. CARB staff has not explained and cannot explain why California air quality should be exposed for an additional two years to adverse effects from the impacts of increased NOx emissions owing to biodiesel use (which CARB staff itself has estimated to be currently 1.3 tons per day statewide,[11] even after incorrectly assuming that there is no NOx increase from use of biodiesel in NTDEs).

ADF B3-7

Similarly, with respect to the program review, instead of acting to ensure that there are no adverse air quality impacts associated with biodiesel use by proposing mitigation requirements for all biodiesel blends of B1 and above, CARB staff is proposing to wait three years after the implementation of the ADF regulation before making an effort to "determine the efficacy" of the proposed NOx mitigation provisions. As pointed out numerous times in these and previous

ADF B3-8

[9] Proposed Section 2293.6(a)(1)

[10] Proposed Section 2293.6(a)(6)(A)

[11] See *http://www.arb.ca.gov/fuels/diesel/altdiesel/20141017_ADF_discussion_paper.pdf*

Growth Energy comments on the proposed ADF,[12] the currently proposed NOx mitigation provisions are inadequate and will result in increases in NOx emissions and associated adverse impacts on air quality in California. There is no legal basis for waiting until the end of 2019 for CARB staff to make that determination.

ADF B3-8 cont.

6. Authority Granted to the Executive Officer

Under the staff proposal, the Executive Officer, rather than the Board, would be authorized to make findings regarding the potential adverse environmental impacts of potential alternative diesel fuels other than biodiesel.[13] Under CEQA and the Board's implementing regulations, the duty to consider and assess, and to mitigate, potential adverse environmental impacts lies with the Board, not the Executive Officer. In the current rulemaking regarding biodiesel blends, CARB staff is establishing the precedent for the Board, rather than the Executive Officer, to make decisions regarding adverse environment impacts, and the same process must be followed for any future alternative diesel fuel.

ADF B3-9

7. Unfair Competitive Advantages

At present, producers and blenders of biodiesel used in California are allowed to profit from the sale of that fuel under the Low Carbon Fuel Standard (LCFS) regulation through the generation of LCFS credits, despite the fact that use of that fuel results in unmitigated increases in NOx emissions and adverse air quality impacts. Under the proposed ADF regulation, producers and blenders of other alternative diesel fuels would similarly be allowed to profit via the LCFS regulation during Stages 1, 2, and 3a, despite the fact that their products lead to adverse environmental impacts. Such an approach is unexplained and anticompetitive—CARB staff

ADF B3-10

---

[12] See Attachments A – D.

[13] See for example, proposed Sections 2293.5(b)(3), 2293.5(b)(6) 2293.5(c) and 2293.5(d).

should ensure that no ADF for which adverse environmental impacts have been established can generate LCFS credits ***before the producers of that ADF are required to mitigate those impacts***. For example, if CARB adopts the staff proposal that mitigation of biodiesel NOx impacts is not required until January 1, 2018, then no biodiesel sold in California before that time should be allowed to generate LCFS credits. If this issue is not addressed by CARB staff, producers and blenders of low carbon intensity fuels, such as ethanol, for which mitigation measures must be implemented will be disadvantaged, and producers and blenders of fuels such as biodiesel that are not required to mitigate adverse environmental impacts will be undeservedly rewarded.

ADF B3-10 cont.

Respectfully submitted,

GROWTH ENERGY

Re: Proposed Regulation to Govern Commercialization of New Alternative Diesel Fuels (2103 Cal. Reg. Notice Register 1646 (October 25, 2013)

Dear Madam:

Growth Energy, an association of the nation's leading ethanol manufacturers and other companies who serve the nation's need for alternative fuels, is submitting to you the enclosed materials in response to the October 15, 2013, notice of proposed regulatory action to establish rules to govern the commercialization of new alternative diesel fuels.

Growth Energy is a strong supporter of biodiesel fuels, which continue to play an important part in our nation's efforts to achieve energy independence with renewable sources and to address environmental concerns. While we applaud the effort to incentivize greater use of all renewable fuels, including biodiesel, we have several significant concerns about the CARB staff's current regulatory proposal and the regulatory process.

Growth Energy believes that significant but feasible changes must be made to the CARB staff's proposed regulations, because the staff's current proposal does not include all reasonable and feasible methods of mitigating potential increases in emissions of oxides of nitrogen ("NOx"), among other reasons. The required changes to the staff's proposal are explained in the enclosed comment and will facilitate the lawful commercialization and use of biodiesel in California in a manner that fully protects the environment. In addition, the CARB staff has not yet publicly released all the test data and analysis on which it is basing its proposal. The decision to postpone the public hearing until March 2014 affords time for the staff to make full disclosure of all the data and analysis. ADF B3-11

Please contact me or David Bearden, our General Counsel, at 605-965-2375 if you have any questions concerning this submission.

Sincerely,

Tom Buis

Tom Buis
CEO, Growth Energy

STATE OF CALIFORNIA

AIR RESOURCES BOARD

PROPOSED REGULATION TO GOVERN THE COMMERCIALIZATION OF NEW ALTERNATIVE DIESEL FUELS

GROWTH ENERGY'S RESPONSE
TO THE NOTICE OF PUBLIC HEARING DATED OCTOBER 15, 2013
2013 CAL. REG. NOTICE REG. 1646 (OCTOBER 25, 2013)

DECEMBER 12, 2013

Executive Summary

These Comments by Growth Energy on the proposed regulation to govern the commercialization of alternative diesel fuels address two main issues: (1) the duty of the Air Resources Board to mitigate potential increases in exhaust emissions of oxides of nitrogen ("NOx") from engines operated on biodiesel fuels, and (2) the analytical and procedural obligations for this rulemaking under the governing statutes.

Growth Energy strongly supports the use of biodiesel to achieve the Nation's environmental and energy independence objectives. As with other elements of California's effort to participate in those national strategies, however, the proposed alternative diesel fuel regulation must avoid having unintended negative environmental consequences, and must be considered carefully and in a manner that permits full and effective public participation. The flaws in the current regulatory proposal for alternative diesel fuels can be readily addressed through feasible mitigation measures, which would put biodiesel in parity with other alternative fuels for which the Board has for many years required risk mitigation through regulation. ADF B3-12

As explained in these Comments, a detailed review of the Air Resources Board staff's analysis of the impacts of biodiesel use on NOx emissions, and a reanalysis of the data used by the staff made available to the public, shows that statistically significant increases in NOx emissions must be expected from the use of biodiesel blends of less than ten percent including blends of five percent and lower amounts of biodiesel. Applying the Board's normal precautionary principles, and consistent with the obligations of the California Environmental Quality Act and the Global Warming Solutions Act, the staff's proposed "Significance Level" of ten percent for biodiesel blends should instead be reduced to zero, because the use of biodiesel at any level can be expected to result in increased NOx emissions if not mitigated using reasonable and feasible measures. ADF B3-13

These Comments also show that the potential increases in NOx emissions caused by biodiesel use under the proposed regulation are far larger than the NOx levels considered significant enough to require costly mitigation or control measures in the State's two "extreme" areas for ozone nonattainment -- the South Coast Air Basin and the San Joaquin Valley Air Pollution Control District. It would counterproductive, and not consistent with the governing statutes, for the Board to commit itself to measures that will result in NOx emissions increases in order to implement the low-carbon fuel standard under the Global Warming Solutions Act, especially when those increases greatly exceed the levels for which the State's air quality districts currently require mitigation or control of those emissions when they come from other sources. ADF B3-14

These Comments also urge the Board to ensure that all comments and data received by the staff in connection with this rulemaking effort, or relied upon in formulating the proposed regulation, be placed in the public rulemaking file, and that sufficient time be allowed to review those materials before the Board considers regulatory action. If the Board directs the staff to address these important issues of public access and transparency -- which are governed by the Administrative Procedure Act -- this regulatory item can be completed in a timely manner. ADF B3-15

Table of Contents

Page

Comments of Growth Energy on the Proposed Regulation To Govern the Commercialization of New Alternative Diesel Fuels

Growth Energy respectfully submits these comments on the California Air Resources Board's proposed regulation to govern the commercialization of new alternative diesel fuels (the "proposed ADF regulation"). As explained below, Growth Energy believes that the Board should direct the staff to make revisions in the proposed ADF regulation and cannot adopt the proposed ADF regulation in its current form. The proposed ADF regulation does not require the use of feasible measures that are necessary to mitigate adequately the potential adverse environmental impacts of increased use of biodiesel blends in California. ADF B3-16

I. INTRODUCTION AND OVERVIEW

CARB's obligation to examine the impacts of widespread biodiesel usage, and to address potential adverse environmental impacts, have recently been clarified by the California Court of Appeal in *POET LLC, et al. v. California Air Resources Board*, (2013) 218 Cal. App. 4th 681. In that litigation, ARB claimed that it intended to "ensure" that there would be "no" increase in regulated pollutants from Diesel-powered engines in California as a result of the LCFS regulation, and in particular that there would be no increase in exhaust emissions of oxides of nitrogen ("NOx") resulting from the use of biodiesel fuel. 218 Cal. App. 4th at 732. ADF B3-17

The CARB staff's proposed approach to the task of NOx mitigation in the proposed ADF regulation falls far short of the claimed metric: whatever the benefits of the proposed ADF regulation for other purposes, the staff's approach will not ***ensure*** that the implementation of the LCFS regulation can cause ***no*** increase in NOx emissions. These comments briefly outline, and the accompanying materials fully explain, the unnecessary environmental risks to the State's efforts to control NOx emissions that the proposed ADF regulation fails to address.[1] Those risks are not based on unqualified speculation, or merely the opinion of Growth Energy; the risks can be demonstrated from the emissions data that the CARB staff has placed in the docket, when those data are evaluated using simple but appropriate statistical tools and methods.[2] Moreover, the increases in NOx emissions, which the CARB staff's data establish, are significant by any contemporary measure: the increases in NOx emissions that the increased use of biodiesel will cause as a result of the LCFS regulation are many times larger than the NOx increases that CARB and regional air quality authorities require to be mitigated. (*See* pp. 18-19 below.)

ADF B3-17 cont.

Addressing the problem of increased NOx emissions is a feasible task, as the Staff Report that accompanies the proposed ADF regulation concedes. Once the risk is established, and the methods of mitigation are determined to be feasible, CARB's task is clear: under the California Environmental Quality Act ("CEQA"), it must require mitigation before it can proceed with regulation.[3]

In this instance, mitigation may impose direct costs on the firms that choose to use biodiesel to comply with the LCFS regulation, and indirect costs on the operators of Diesel engines, but CARB decided nearly five years ago that the benefits of the LCFS regulation overall were worth the costs. In that respect, biodiesel should be treated no differently than the

[1] In addition to the materials cited below in notes 2 and 4, Growth Energy is also attaching to these comments for inclusion in the rulemaking file -- and for analysis and response by the Board -- its earlier comments on the CARB staff's ADF regulatory proposal, submitted on September 16, 2013. Those comments, and likely many other comments from other parties, were not placed in the rulemaking file when CARB issued its 45-day notice. *See* pp. 13-14 below (requirements of the California Administrative Procedure Act).

[2] *See* R. Crawford, "NOx Emissions Impact of Soy- and Animal-Based Biodiesel Fuels: A Re-Analysis" (Dec. 2013) (hereinafter "Crawford Report"), attached to these Comments as Exhibit A.

[3] *See POET*, 218 Cal. App. 4th at 731-742.

alternative fuels that the LCFS regulation requires for gasoline, which are ethanol, natural gas and electricity. ADF B3-17 cont.

Instead of requiring the Diesel sector to bear its fair share of the costs of the LCFS regulation through proper environmental mitigation, however, the CARB staff's proposed approach deploys what the Staff Report calls an "Effective Blend Level" concept to exempt biodiesel fuel from any meaningful mitigation requirement.[4] Rather than following the precautionary principles that have constantly guided CARB rulemaking -- which in other contexts sometimes have inclined the Board to require extreme regulatory stringency based on scant evidence of actual harm -- in this one instance, the CARB staff appears intent on risking air quality rather than requiring feasible, if costly to some, mitigation measures. The CARB Staff Report suggests in one place that this deviation from the Board's longstanding regulatory strategy may be necessary to protect the growth of the biodiesel "market."[5] But the CARB staff cites no evidence to support its speculation that the biodiesel "market" is at risk, and there is no evidence of such a risk in the public rulemaking file. Even if such a private market risk existed, however, neither the California Global Warming Solutions Act nor the California Government Code allow CARB to consider factors extrinsic to the statutes in meeting the clean-air goals established by law.[6] The California statutes protect California citizens and air quality, not market entrepreneurs and arbitragers. It is not the proper purpose of any California regulation to ADF B3-18

[4] *See* Declaration of James M. Lyons (hereinafter "Lyons Decl."), attached to these Comments as Exhibit B.

[5] *See* Staff Report at 63 (rejecting "immediate" mitigation because "this option has the potential to disrupt or even collapse the burgeoning ADF market by unnecessarily placing overly restrictive requirements that are not warranted by emissions testing"). Tellingly, that portion of the Staff Report has no citations to support the claim.

[6] In its current proposal, the CARB staff is engrafting onto the Global Warming Solutions Act a provision allowing it to avoid mitigation of environmental harm, in order to encourage particular industries or based on general economic preferences. CARB cannot proceed in that fashion. *Cf. Clean Air Constituency v. CARB*, (1974) 11 Cal.3d 801 (CARB lacks authority to establish criteria to govern its actions that are not found in its enabling statutes).

pick "winners" and "losers:" all fuels, including all alternative fuels, must have their environmental risks properly assessed, and when feasible mitigated in full. ADF B3-18 cont.

The balance of these Comments is divided into two parts. The first part, in Section II below, summarizes the technical analyses contained in the accompanying report of Robert Crawford, a statistician with expertise in evaluation of emissions data, and in the Declaration of James M. Lyons, an expert in automotive air pollution who evaluates the "Effective Blend Level" concept as a method of addressing the risks of increased NOx emissions. Section II also summarizes the relevant portions of the Staff Report dealing with the available mitigation methods and their feasibility. The second part, in Section III below, explains the Board's legal obligations to mitigate the risks of increased NOx emissions presented by biodiesel fuel usage.

II. ENVIRONMENTAL ASSESSMENT OF THE PROPOSED REGULATION

Were the matter ever in any doubt, the Court of Appeal's *POET* decision, which the California Supreme Court has recently declined to review, makes it clear that the Board must take seriously the issue of NOx emissions increases from the increased use of biodiesel in order to comply with the LCFS regulation. CARB has recognized, first in the LCFS regulatory process and more recently in court, that the LCFS regulation will increase the use of biodiesel. The CARB staff now claims in the current ADF rulemaking, however, that emissions testing proves that the use of biodiesel blends containing less than 10 percent biodiesel will not increase NOx emissions. That claim is demonstrably wrong, as Mr. Crawford establishes in his analysis of the available emissions data. (*See* Exhibit A and Section A below.) Because the data do not support the CARB staff's claims that operation of engines on blends below 10 percent biodiesel will not increase NOx emissions, and in fact show the opposite, CARB has a duty to mitigate. The CARB staff's environmental analysis is also unsound in other respects as well, as demonstrated in Mr. Lyons' Declaration. (*See* Exhibit B and Section B below.) ADF B3-19

A. Impact of the Proposed Regulation on Exhaust Emissions of Oxides of Nitrogen

Mr. Crawford's report carefully reviews each of the six studies cited in the CARB staff's literature review on biodiesel NOx emissions, as well as CARB's biodiesel characterization study ("Durbin 2011") and the data available from that study. It is important to note at the outset that not all the data from the CARB study has been made available to the public. CARB should publish all of the testing presented in Durbin 2011[7] and any future testing that it sponsors in a complete format that allows for reanalysis, and an opportunity to evaluate those materials prior to the deadline for submission of public comments or CARB's hearing on the approval of the proposed ADF regulation. ADF B3-20

Putting aside the CARB staff's failure to make a complete disclosure of the data reflected in Durbin 2011, it is clear that the data from Durbin and the other six studies do not support the CARB staff's conclusion and, indeed, the data refute the staff's conclusion in some instances. These are the salient points from Mr. Crawford's analysis:

- There is ***no evidence*** supporting the staff conclusion that NOx emissions do not increase until the B10 level is reached. Instead, there is consistent and strong evidence that biodiesel increases NOx emissions in proportion to the biodiesel blending percent. ADF B3-21

- There is ***clear and statistically significant evidence*** that biodiesel increases NOx emissions at the B5 level in at least some engines for both soy- and animal-based biodiesels. ADF B3-22

None of the six studies in the literature measured the NOx emissions impact from biodiesel at blending levels below B10. Only two studies tested a fuel at the B10 level. All

[7] The data should be published in a useable format, and should include (a) the measured emission values for each individual test replication; or (b) averages across all test replications, along with the number of replications and the standard error of the individual tests. The first format (individual test replications) is preferable because that would permit a full examination of the data including effects such as test cell drift over time.

other testing was at the B20 level or higher. Because none tested a B5 (or similar) fuel, the studies do not constitute substantial evidence that NOx emissions are not increased at B5 or other blending levels below B10. Those six studies therefore provide no data or evidence supporting the validity of the staff's claim that biodiesel below B10 does not increase NOx emissions. To the contrary, all of the studies are consistent with the contention that biodiesel increases NOx emissions in proportion to the blending percent. Indeed, two of those six studies present evidence and data that the NOx impact from biodiesel is a continuous effect that is present even at very low blending levels and will increase at higher levels in proportion to the blending percentage. ADF B3-22 cont.

With regard to the CARB biodiesel characterization report, Mr. Crawford has uncovered the fact that for the three engines for which the CARB staff has published the emission values measured in engine dynamometer testing, all of the data demonstrate that biodiesel fuels significantly increase NOx emissions for both soy- and animal-based fuels by amounts that are proportional to the blending percent. That is true for on-road and off-road engines and for a range of test cycles. When B5 fuels were tested for those engines, NOx emissions were observed to increase. NOx emission increases are smaller at B5 than at higher blending levels and the observed increases for two engines were not statistically significant by themselves based on the pair-wise t-test employed in Durbin 2011. However, the testing for one of the engines (the 2007 MBE4000) showed statistically significant NOx emission increases at the B5 level for both soy- and animal-based blends. The data are sufficient to disprove the staff's contention that biodiesel blends at the B5 level will not increase NOx emissions. ADF B3-23

In sum, based on examination of all of the studies cited by CARB as the basis for its proposal to exempt biodiesels below B10 from mitigation, it is clear that the available research ADF B3-24 points to a very substantial risk, if not a certainty, that both soy- and animal-based biodiesel blends will increase NOx emissions in proportion to their biodiesel content, including at the B5 level. Based on data in the CARB Biodiesel Characterization Report, soy-based biodiesels will increase NOx emissions by about 1% at B5 and 2% at B10, while animal-based biodiesels will increase NOx emissions by about one-half as much: 0.45% at B5 and 0.9% at B10. All of the available research shows that the NOx increases are real and implementation of mitigation measures will be required to prevent increases in NOx emissions due to biodiesel use at blending levels below B10. The available research likewise demonstrates that, to the extent CARB is identifying B10 as a "threshold of significance" under CEQA, (1) the utilization of this threshold is unsupported by the evidence in the record. For the same reasons, and for the reasons discussed in Section III.B below, the utilization of B10 as a "threshold" is contrary to the Legislature's mandate that the regulations should "not interfere with ... efforts to achieve and maintain federal and state ambient air quality standards." Cal Health & Safety Code § 38562(b)(4).

ADF B3-24 cont.

ADF B3-25

B. The "Effective Blend Level" Concept

Mr. Lyons' Declaration builds on the analysis performed by Mr. Crawford and demonstrates that the CARB staff's "effective blend level" concept will operate to exempt biodiesel from any meaningful mitigation, even if biodiesel is causing real-world increases in NOx exhaust emissions from Diesel engines operated in California. Mr. Lyons demonstrates, in particular, that "despite the forecast nine-fold increase in biodiesel use in California from 50 million to 450 million gallons from 2013 to 2023 ... the forecast Effective Blend Level of biodiesel decreases to less than zero over virtually all of the period in question." (Lyons Decl. ¶ 14.)

ADF B3-26

If the fractional coefficients being applied in the "effective blend level" equation (*see* Lyons Decl. ¶¶ 11-12) are incorrect to any significant extent, the environment will not be protected. The CARB staff has apparently selected those coefficients without allowing for the possibility of errors that could understate NOx impacts -- a clear violation of CARB's precautionary norms. The adverse effects will be severe if there is error in the coefficients, because the CARB staff itself recites evidence that the biodiesel market will be concentrated in low-blend biodiesel. (*See* Lyons Decl. ¶¶ 15, 17.) Growth Energy is aware of no other regulatory concept in any CARB program in which mitigation measures required by CEQA depend on a formula that could err as easily as the "effective blend level" equation could. ADF B3-27

The mischief in the "effective blend level" coefficients lies in their complexity and the risk of quantitative error. A much simpler but equally fatal analytical flaw, which also violates both sound regulatory policy and the requirements of CEQA, is the failure of the effective blend level calculation to ensure that any NOx increases that require mitigation will be addressed by the use of a mitigation measure in the ***same*** relevant location, and at the ***same*** time, as the NOx increases are occurring. If NOx mitigation does not occur in the same area and at the same time as biodiesel use that increases NOx emissions, the environmental harm presented by those increased NOx emissions will go unmitigated; the adverse impacts of NOx increases are defined by their location, and their severity is greatest at the time when the emissions occur. ADF B3-28

As Mr. Lyons points out, the "effective blend level" concept does not fully protect, for example, Los Angeles residents, if NOx increases experienced in the summertime in Los Angeles can be offset by the biodiesel "market" in whole or part by practices that mitigate those emissions in a different season and in another place. (*See* Lyons Decl. ¶¶ 19-20.) The regulation, as proposed by the CARB staff, does nothing even to incentivize, much less require, ADF B3-29 the biodiesel "market" to deliver mitigation at the time and place it is needed. That may be a result of the CARB staff's conclusion that, as they have written the mitigation rule, it is unlikely that mitigation will ever be required; if so, that simply underscores the weakness of the mitigation rule itself (*see*, *e.g.*, Lyons Decl. ¶¶ 8-10, 15-18). CEQA and its implementing guidelines must be read to require mitigation where and when the adverse effect would otherwise occur. By not accounting for that requirement, the "effective blend level" concept violates CEQA. ADF B3-29 cont.

Mr. Lyons' Declaration identifies other flaws in the staff proposal that must be addressed. As his Declaration establishes, the data on which CARB relies for its assumption that "new-technology" diesel engines will have lower NOx emissions when operated on biodiesel is inadequate to support the weight it is given by the CARB staff (*see* Lyons Decl. ¶¶ 21-23); that data cannot be treated as substantial evidence to support a regulation that posits lower emissions from such engines. Each of the issues raised in Mr. Lyons' Declaration must be addressed by the Board. ADF B3-30

C. Available Mitigation Measures

Mitigation of the risks of NOx increases from biodiesel usage is entirely feasible. The proposed ADF regulation can easily be modified to ensure that the use of biodiesel will not result in increased NOx emissions by setting the "Significance Level" for biodiesel blends at zero -- which is the level that the available data require -- so that mitigation would occur whenever and wherever it should. In addition, CARB must eliminate the use of annual statewide averages for determining the "effective blend levels" and instead use actual blend levels at the batch level. These two changes would require that mitigation be applied to all biodiesel blends in light of the actual amount of biodiesel present in each specific blend. ADF B3-31

Appendix 1 to proposed Section 2293.5(c) specifies the three mitigation measures that CARB staff has identified for mitigation of increases in NOx emissions due to biodiesel use. They include (i) addition of di-tert-butyl peroxide to biodiesel blends at a level that varies with the amount of biodiesel in the blend and (ii) blending of low-NOx diesel fuel along with biodiesel into biodiesel blends. Under the staff's proposal, parties responsible for mitigation of increased NOx emissions from biodiesel can choose either of those approaches. They all could be easily applied to any blend containing ten percent or less biodiesel, as well as blends of more than ten percent, if appropriately modified to ensure that there would be no increase in NOx emissions associated with the use of biodiesel. The Staff Report and the rulemaking file contain no significant evidence that such approaches could not be applied at the batch level. ADF B3-32

In addition to conceding the feasibility of the three identified mitigation measures by including them in the proposed ADF regulation, the Staff Report also provides cost estimates for the application of each measure.[8] Absorption of those estimated costs by entities or individuals choosing to use biodiesel is in no way inconsistent with the types of costs that have been imposed by CARB on other California businesses and residents in other regulatory programs. Indeed, the Global Warming Solutions Act gives CARB no choice but to require the regulated parties and their downstream customers to absorb those costs: the Legislature has specifically directed that CARB is to "ensure" that "activities undertaken pursuant to the regulations" adopted to implement the Act -- including the use of biodiesel to comply with the LCFS regulation -- "do not interfere with … efforts to achieve and maintain federal and state ambient air quality standards." Cal. Health & Safety Code § 38562(b)(4). ADF B3-33

[8] Those costs are $0.25 per gallon of biodiesel blended for di-tert-butyl peroxide, $1.20 per gallon of biodiesel blended for low-NOx diesel and a one-time expense of between $100,000 and $200,000 for the certification of a biodiesel blend that could then be sold in California in any volume. *See* Staff Report at 59 and *id.* App. C.

In addition to being technically feasible, consistent with costs required by other CARB regulations, the mitigation measures outlined in the Staff Report can be implemented. In some instances, regulated parties would simply have to ensure that steps have been taken to ensure their final blends meet the fuel property specifications associated with the certified blend. Mitigation using di-tert-butyl peroxide or low NOx diesel requires only knowing the amount of biodiesel in the blend and ensuring that the entity performing the blending also be responsible for adding di-tert-butyl peroxide or low NOx diesel to the blend. ADF B3-34

The Staff Report claims that "[i]t would be impractical to determine the individual blend level for each gallon of biodiesel blend being sold across the State." The Staff Report continues: "To do so would require the retailers and marketers of biodiesel blends (i.e., the diesel dispensing facilities) to continuously test and determine the biodiesel blend level for each of the approximately 3 billion gallons of on-road diesel fuel sold in California each year."[9] The Staff Report offers no support for that claim, however, and it is contradicted by the overall regulatory experience under the LCFS regulation as well as the data necessary to actually to employ the Effective Blend concept. The LCFS regulation already requires producers of biodiesel sold in California or other entities to which the fuel is transferred to report the volumes of biodiesel to CARB via the Low Carbon Fuel Standard Reporting Tool ("LRT") in order to receive greenhouse gas emission reduction credits. (*See* 17 C.C.R. § 95484(b)(B)(2).) Moreover, in order to employ the Effective Blend concept, data regarding the amount of biodiesel used in blends of five percent or less, as well as the type and volumes of biodiesel used in blends of more than five percent, would be required. Presumably, this data will also be derived from the LRT. The LRT is currently treated by CARB as an accurate source of data regarding biodiesel use in ADF B3-35

[9] Staff Report at 23.

California.[10] The CARB staff regularly publishes quarterly summaries of greenhouse gas credits generated from biodiesel and other fuels under the LCFS.[11]

ADF B3-35 cont.

Given that biodiesel producers must report both their production volumes and production pathways (*e.g.*, soy-based, animal-based, or other) to CARB via the LRT in order to generate greenhouse gas credits under the LCFS regulation, the implementation of NOx mitigation measures involving use of di-tert-butyl peroxide or low NOx diesel under the ADF regulation would be simple and straightforward. All that CARB would have to do is to require entities earning greenhouse gas credits under the LCFS for non-certified biodiesel blends to also report to CARB via the LRT how, when, and where mitigation of the NOx emissions associated with the use of that biodiesel via di-tert-butyl peroxide or low NOx diesel was achieved. Recordkeeping requirements analogous to those that already apply to data reported via the LRT would also apply to mitigation of biodiesel NOx impacts.

ADF B3-36

By following that approach, CARB staff can both ensure that there are no NOx increases associated with the use of biodiesel in California while simultaneously avoiding any need to involve retailers and marketers of biodiesel in the "impractical" activity described in the Staff Report unless those same retailers and marketers of biodiesel were earning greenhouse gas reduction credits from biodiesel under the LCFS. If the CARB Executive Officer or the staff disagrees with Growth Energy on this point, it is incumbent upon them to explain why and for the Board to give the public an opportunity to respond before CARB weighs the evidence and arguments, because this is an issue involving available and practical mitigation measures under CEQA.

ADF B3-37

---

[10] *See, e.g.*, Staff Report at 30.

[11] The most recent summary for the second quarter of 2013 is available at http://www.arb.ca.gov/fuels/lcfs/20130930_q2datasummary.pdf.

III. THE BOARD'S LEGAL OBLIGATIONS

The Court of Appeal clarified in *POET* that CARB is subject, among other provisions, to sections 15004 and 15352 of the CEQA Guidelines. The Court of Appeal also gave clear instructions about the need to comply with the rulemaking-file requirements of the Administrative Procedure Act. Perhaps most importantly, the Court of Appeal made plain the Board's duty to mitigate, in particular with respect to the subject of NOx exhaust emissions from engines operated on biodiesel. This final section of Growth Energy's comments summarizes the steps that CARB must take to meet its obligations under the governing statutes as clarified by the Court in *POET*, with primary emphasis on the duty to mitigate under CEQA.

A. Procedural and Structural Rulemaking Requirements

CARB must recognize that *any* communications it has received of a factual nature, or data that it has acquired in connection with regulatory action, are not exempt from the requirement to disclose those communications in the public rulemaking file under Gov't Code § 11347.3 (absent a valid and complete demonstration of privilege). *See POET*, 218 Cal. App. 4th at 741-754. At present, the rulemaking file for the ADF proposal cannot possibly be claimed to include all material required for the rulemaking file: Growth Energy knows this, because its own comments of September 16, 2013 (*see* Exhibit C) have not been placed in that file. As noted above, CARB has apparently not made full disclosure of all data relevant to the Durbin emissions study. (*See* p. 5 above.) Likewise, the Staff Report claims that the proposed ADF regulation "is based upon feedback from nearly every corner of the regulated industry as well as other impacted organizations and individuals that are impacted by actions concerning or that regulate the fuels industry."[12] The rulemaking file, when last checked in the week of

ADF B3-38

ADF B3-39

[12] Staff Report at 3-4.

December 2, 2013, did not contain any written comments reflecting that "feedback;" those materials should have been in the rulemaking file no later than October 15, 2013, when the public hearing on the proposed ADF regulation was announced. *See* Cal. Gov't Code § 11347.3(a), (b)(6), (7). ADF B3-39 cont.

Accordingly, one of the first steps that CARB must take in the current proceeding is to ensure compliance with section 11347.3 of the Government Code, and re-issue a notice of proposed rulemaking to allow 45 days of comment prior to a public hearing at which it would take action on a proposed ADF regulation. If CARB takes this action quickly, there will be no delay in program objections, including reconsideration of the LCFS standards during 2014. ADF B3-40

It is also clear from *POET* that, as CEQA and the guidelines direct, there are other reasons why CARB cannot take action with respect to the proposed ADF regulation. *See POET*, 218 Cal. App. 4th at 717-731. If CARB is the decision-maker with respect to the proposed ADF regulation, it must evaluate the environmental issues presented by the staff proposal for itself, and complete the environmental review process required under CEQA and CARB regulations, *before* the Board commits CARB to the proposed ADF regulation. Likewise, the opportunity to participate in the environmental analysis must be adequate -- which in this instance, it is not, in part because not all the relevant data has been publicly released. A comment deadline scarcely 45 days after the staff analysis has been released, when all relevant data have not been provided, will not permit an adequate environmental assessment. ADF B3-41

To comply with the procedural requirements of CEQA as confirmed in *POET*, CARB should direct the staff to complete the environmental review process (including full disclosure of the basis for its proposal); prepare a complete rulemaking file; respond to public comment; and publish a Final Statement of Reasons, before considering the proposed ADF regulation on its ADF B3-42 merits at a subsequent hearing. At that hearing, interested parties should be allowed all the time required to present and to respond to legitimate technical, empirically-based analysis of the environmental issues presented by the proposed ADF regulation. CARB can neither approve the proposed ADF regulation with the record in its current status and at the type of hearing planned for this week, nor defer the environmental assessment to a point after it has committed itself to the proposed regulation, nor delegate any of its CEQA responsibilities identified by the Court of Appeal in *POET*.

ADF B3-42 cont.

B. The Duty to Analyze Potential Impacts and Mitigate Significant Impacts

The importance of NOx emissions control for California air quality is well known and is illustrated, for example, by a June 2012 CARB Report entitled "Vision for Clean Air: A Framework for Air Quality and Climate Planning," prepared in conjunction with the South Coast Air Quality Management District and the San Joaquin Valley Unified Air Pollution Control District.[13] That report addressed potential control strategies that will be required to bring the only two areas of the country designated as being in extreme nonattainment of the National Ambient Air Quality Standard ("NAAQS") for ozone[14] into attainment. In working to identify potential control strategies, these three agencies chose to focus on ways to reduce NOx emissions (and not hydrocarbon emissions) because "NOx is the most critical pollutant for reducing regional ozone and fine particulate matter."[15] The report also identifies diesel-powered heavy-duty vehicles as the largest source of NOx emissions in California, and classifies diesel-powered

ADF B3-43

---

[13] *See* CARB, Vision for Clean Air: A Framework for Air Quality and Climate Planning (June 27, 2012) (available at http://www.arb.ca.gov/planning/vision/docs/vision_for_clean_air_public_review_draft.pdf).

[14] *See* http://www.epa.gov/airquality/ozonepollution/designations/2008standards/final/region9f.htm.

[15] *See* Vision for Clean Air at 10.

construction, mining and agricultural equipment as other significant sources of NOx emissions in California. ADF B3-43 cont.

As indicated above, CEQA requires that mitigation measures must be implemented locally and must be contemporaneous with the emissions events of concern; the type of statewide mitigation concept contained in the Staff Report, unbounded to relevant time intervals, does not comply with CEQA. It is therefore relevant to consider, by way of example, the heavy-duty diesel vehicle NOx emissions inventory for the South Coast and San Joaquin Valley areas during calendar years 2015 and 2020. On-road heavy-duty diesel emission estimates were developed using CARB's latest emission factor modeling software EMFAC2011.[16] The model estimates regional emissions, in tons/day, by vehicle class and model year. Emission estimates were computed for both older vehicles as well as vehicles using what CARB would consider to be NTDEs -- which in this case were assumed to be 2010 and later model-year vehicles. Emissions from off-road construction equipment were estimated using CARB's 2011 In-Use Inventory model.[17] Emissions from agricultural equipment were developed using CARB's OFFROAD2007 model because CARB's regulatory in-use inventory model is still under development for this sector.[18] For construction and agricultural equipment, NTDE vehicles were assumed to be those with engines certified to Tier 4 emission standards. It was assumed Tier 4 engines are used in 2013-and-later model year engines rated at or below 50 HP, 2014-and-later model year engines between 51 and 750 HP, and to 2015-and-later model years for engines ADF B3-44 cont.

[16] For more information on EMFAC2011 and to download modeling materials, *see* http://www.arb.ca.gov/msei/modeling.htm.

[17] For more information on CARB's off-road model, *see* http://www.arb.ca.gov/msei/categories.htm#offroad_motor_vehicles.

[18] Information about OFFROAD2007 and the pending in-use agricultural sector model can also be found at http://www.arb.ca.gov/msei/categories.htm#offroad_motor_vehicles.

above 750 HP. The resulting inventories are presented in Tables 1 and 2 for calendar years 2015 and 2020, respectively.

Table 1

2015 Heavy-Duty NOx Emission Inventories for the South Coast and San Joaquin Valley Air Basins (tons per day)

Air Basin	On-Road		Construction		Agricultural		Total
	Older	NTDE	Older	NTDE	Older	NTDE	
South Coast	117.27	14.91	24.04	0.42	3.92	0.26	160.82
San Joaquin	83.07	15.44	11.85	0.21	26.73	1.86	139.16

Table 2

2020 Heavy-Duty NOx Emission Inventories for the South Coast and San Joaquin Valley Air Basins (tons per day)

Air Basin	On-Road		Construction		Agricultural		Total
	Older	NTDE	Older	NTDE	Older	NTDE	
South Coast	66.53	28.44	20.0	1.8	2.2	0.5	119.47
San Joaquin	32.13	30.33	11.5	1.0	15.0	3.8	93.76

Tables 1 and 2 show that vehicles with NTDEs account for only about 10% of NOx emissions in 2015 and between 25% and 40% of NOx emissions in 2020. Therefore, even if the CARB staff's assertion that biodiesel does not increase emissions from NTDEs were correct, the majority of NOx emissions would still be coming from older engines where, it has been clearly demonstrated, NOx emissions increase with the use of higher biodiesel blends. Applying the estimated NOx increases developed from the available emissions data analyzed by CARB staff (*see* Lyons Decl. ¶ 9, Table 1), and assuming more realistically and conservatively (as CEQA requires) that NTDEs will be affected by biodiesel in the same way as other engines, the overall increases in NOx emissions caused by biodiesel use will be (i) between 0.7 and 1.6 tons per day

ADF B3-44 cont.

in 2015 and between 0.5 and 1.2 tons per day in 2020 in the South Coast, and (ii) between 0.6 and 1.4 tons per day in 2015 and between 0.4 and 0.9 tons per day in 2020 in the San Joaquin Valley. ADF B3-44 cont.

One way to put the magnitude of these potential increases in NOx emissions into context is to compare them with the air quality significance thresholds applied by the South Coast Air Quality Management District[19] and the San Joaquin Valley Air Pollution Control District[20] when evaluating the potential emission impacts of proposed projects in their jurisdictions. In the San Joaquin Valley Air Pollution Control District, the threshold is 10 tons per year while in the South Coast basin, the threshold is 0.0275 tons per day which equals 10 tons per year if daily emissions occurring over the course of the year are equal. The potential 2015 emission increases from the use of five percent biodiesel blends in the South Coast and the San Joaquin Valley are ***25 to 60 times higher*** than the 10-ton-per-year threshold. Even with reductions in diesel NOx emissions by 2020, the potential NOx increases due to biodiesel remains ***15 to 40 times higher*** than the 10-ton-per-year threshold. Potential increases of NOx emissions on such a scale require mitigation at the time and in the place where they will occur. *See POET*, 218 Cal. App. 4th at 740 (under CEQA, "ARB must adopt mitigation measures that minimize the adverse impact" of a potential increase in NOx emissions). Moreover, despite the fact that increases of NOx emissions resulting from the proposed ADF regulation would significantly exceed thresholds adopted by the South Coast Air Quality Management District and the San Joaquin Valley Air Pollution Control District, the ISOR fails to analyze whether the proposed ADF regulation has the potential to conflict with, or obstruct, applicable air quality plans. ADF B3-45

---

[20] *See* http://www.valleyair.org/transportation/CEQA%20Rules/GAMAQI%20Jan%202002%20Rev.pdf.

There is no question that an increase in biodiesel usage will occur as a result of the LCFS regulation, a measure adopted under the Global Warming Solutions Act. *See POET*, 218 Cal. App. 4th at 700-01. Consequently, under not only CEQA, but also the Global Warming Solutions Act, CARB cannot permit emissions increases from biodiesel of such a magnitude when both the South Coast Air Quality Management District's 2012 Air Quality Management Plan[21] and the San Joaquin Valley's 2013 One Hour Ozone Plan[22] contain control measures intended to reduce NOx emissions by amounts of about the same magnitude as the potential emission increases resulting from biodiesel use at the five percent level. *See* Cal Health & Safety Code § 38562(b)(4) (greenhouse gas control measures such as the LCFS regulation are not to "interfere with ... efforts to achieve and maintain federal and state ambient air quality standards."). ADF B3-45

IV. CONCLUSION

For the reasons explained above and in the reports and analyses accompanying these Comments, CARB cannot lawfully approve the proposed ADF regulation at this week's public hearing. CARB cannot commit itself now to the proposed ADF regulation and adjourn the important task of environmental assessment to a post hoc process. The available emissions data do not support, and indeed refute, the CARB staff's claim that low-level biodiesel blends are benign. Mitigation is required, and is required at the time and in the places where the NOx emissions increases can be expected to occur. If CARB directs the staff to make straightforward changes in the proposed ADF regulation in a timely manner that will require feasible mitigation ADF B3-46

[21] *See* South Coast Air Quality Management District, 2012 Air Quality Management Plan, 2012 AQMP CARB/EPA/SIP Submittal (Dec. 2012) (available at http://www.aqmd.gov/aqmp/2012aqmp/Final/index.html).

List of Figures

1. EXECUTIVE SUMMARY

1.1 Background on the Proposed Rule

The California Air Resources Board (CARB) has proposed regulations on the commercialization of alternative diesel fuel (ADF) that were to be heard at the December 2013 meeting of the Board. The proposed regulations seek to "... create a streamlined legal framework that protects California's residents and environment while allowing innovative ADFs to enter the commercial market as efficiently is possible."[1] In this context ADF refers to biodiesel fuel blends. Biodiesel fuels are generally recognized to have the potential to decrease emissions of several pollutants, including hydrocarbons (HC), carbon monoxide (CO), and particulate matter (PM), but are also recognized to have the potential to increase oxides of nitrogen (NOx) unless mitigated in some way. NOx emissions are an important precursor to smog and have historically been subject to stringent emission standards and mitigation programs to prevent growth in emissions over time. A crucial issue with respect to biodiesel is how to "... safeguard against potential increases in oxides of nitrogen (NOx) emissions."[2]

The proposed regulations are presented in the Staff Report: Initial Statement of Reasons (ISOR) for the Proposed Regulation on the Commercialization of New Alternative Diesel Fuels[3] (referenced as ISOR). Chapter 5 of the document describes the proposed regulations, which exempt diesel blends with less than 10 percent biodiesel (B10) from requirements to mitigate NOx emissions:

> There are two distinct blend levels relative to biodiesel that have been identified as important for this analysis. Based on our analysis to date, we have found that diesel blends with less than 10 percent biodiesel by volume (<B10) have no significant increase in any of the pollutants of concern and therefore will be regulated at Stage 3B (Commercial Sales not Subject to Mitigation). However, we have found that biodiesel blends of 10 percent and above (≥B10) have potentially significant increases in NOx emissions, in the absence of any mitigating factors, and therefore those higher blend levels will be regulated under Stage 3A (Commercial Sales Subject to Mitigation).[4]

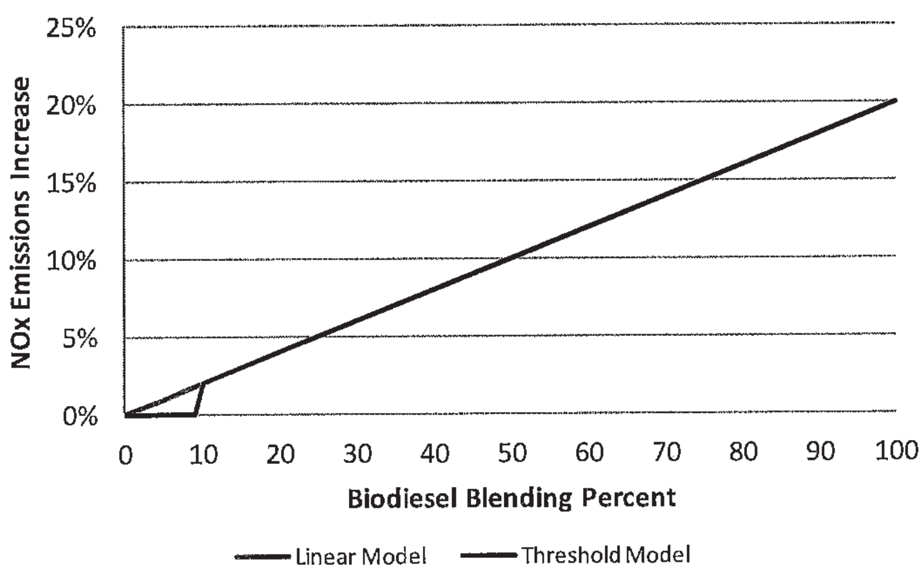
[4] Ibid, p. 22.

Existing research on the NOx emission effects of biodiesel has consistently been conducted under the hypothesis that the emission effect will be linearly proportional to the blending percent of neat biodiesel (B100) with the base diesel fuel. The Linear Model that has been accepted by researchers is shown as the blue line in Figure 1-1. The Staff position cited above is that biodiesel fuels do not increase NOx emissions until the fuel blend reaches 10% biodiesel. This so-called Staff Threshold Model departs from the Linear Model that underlies past and current biodiesel research by claiming that NOx emissions do not increase until the biodiesel content reaches 10 percent. ADF B3-46 cont.

Figure 1-1
Linear and Staff Threshold Models for Biodiesel NOx Impacts



The Staff Threshold model is justified by the statement: "Based on our analysis to date, we have found that diesel blends with less than 10 percent biodiesel by volume (<B10) have no significant increase in any of the pollutants of concern." Other portions of the ISOR state that Staff will track "... the effective blend level on an annual statewide average basis until the effective blend level reaches 9.5 percent. At that point, the biodiesel producers, importers, blenders, and other suppliers are put on notice that the effective blend-level trigger of 9.5 percent is approaching and mitigation measures will be required once the trigger is reached."[5] Until such time, NOx emission increases from biodiesel blends below B10 will not require mitigation.

Section 6 of the ISOR presents a Technology Assessment that includes a literature search the Staff conducted to obtain past studies on the NOx impact of biodiesel in heavy-duty ADF B3-47

[5] Ibid, p. 24.

engines using California diesel (or other high-cetane diesel) as a base fuel. Section 6.d presents the results of the literature search with additional technical information provided in Appendix B. The past studies include the Biodiesel Characterization and NOx Mitigation Study[6] sponsored by CARB (referenced as Durbin 2011).

The results of the Staff literature search are summarized in Table 1-1, which has been reproduced from Table 6.1 of the ISOR. For B5 and B20, the data represent averages for a mix of soy- and animal-based biodiesels, which tend to have different impacts on NOx emissions (animal-based biodiesels increase NOx to a lesser extent). For B10, the data represent an average for soy-based biodiesels only. Staff uses the +0.3% average NOx increase at B5 in comparison to the 1.3% standard deviation to conclude:

> Overall, the testing indicates different NOx impacts at different biodiesel percentages. Staff analysis shows there is a wide statistical variance in NOx emissions at biodiesel levels of B5, providing no demonstrable NOxemissions impact at this level and below. Atbiodiesel levels of B10 and above, multiple studies demonstrate statistically significant NOx increases, without additional mitigation.[7]

Table 1-1
Results of Literature Search Analysis

Biodiesel Blend Level	NOx Difference	Standard Deviation
B5	0.3%	1.3%
B10[a]	2.7%	0.2%
B20	3.2%	2.3%

Source: Table 6.1 of Durbin 2011
Notes:
[a] Represents data using biodiesel from soy feedstocks.

ADF B3-47 cont.

The Staff conclusion is erroneous because it relies upon an apples-to-oranges comparison among the blending levels. Each of the B5, B10, and B20 levels include data from a different mix of studies, involving different fuels (soy- and/or animal-based), different test engines, and different test cycles. The B5 values come solely from the CARB Biodiesel Characterization study, while the B10 values come solely from other studies. The B20 values are a mix of data from the CARB and other studies. The results seen in the table above are the product of the uncontrolled aggregation of different studies that produces incomparable estimates of the NOx emission impact at the three blending levels.

[6] "CARB Assessment of the Emissions from the Use of Biodiesel as a Motor Vehicle Fuel in California: Biodiesel Characterization and NOx Mitigation Study." Prepared by Thomas D. Durbin, J. Wayne Miller and others. Prepared for Robert Okamoto and Alexander Mitchell, California Air Resources Board. October 2011.
[7] ISOR, p. 32.

As will be demonstrated in this report, the Staff conclusion drawn from the data in Table 1-1 is not supported by past or current biodiesel research, including the recent testing program sponsored by CARB. In fact, past and current studies indicate that biodiesel blends at any level will increase NOx emissions in proportion to the blending percent unless specifically mitigated by additives or other measures. ADF B3-47 cont.

1.2 Summary and Conclusions

The following sections of this report examine the studies cited by CARB one-by-one. As evidenced from this review, it is clear that the data do not support the Staff conclusion and, indeed, the data refute the Staff conclusion in some instances. Specifically:

- There is no evidence supporting the Staff conclusion that NOx emissions do not increase until the B10 level is reached. Instead, there is consistent and strong evidence that biodiesel increases NOx emissions in proportion to the biodiesel blending percent. ADF B3-48

- There is clear and statistically significant evidence that biodiesel increases NOx emissions at the B5 level in at least some engines for both soy- and animal-based biodiesels. ADF B3-49

Considering each of the six past studies obtained from the technical literature and their data on high-cetane biodiesels comparable to California fuels, we find the following:

1. None of the six studies measured the NOx emissions impact from biodiesel at blending levels below B10. Only two studies tested a fuel at the B10 level. All other testing was at the B20 level or higher. Because none tested a B5 (or similar) fuel, none of them can provide direct evidence that NOx emissions are not increased at B5 or other blending levels below B10. ADF B3-50

2. These studies provide no data or evidence supporting the validity of the Staff's Threshold Model that biodiesel below B10 does not increase NOx emissions. In fact, all of the studies are consistent with the contention that biodiesel increases NOx emissions in proportion to the blending percent. ADF B3-51

3. Two of the studies present evidence and arguments that the NOx impact from biodiesel is a continuous effect that is present even at very low blending levels and will increase at higher levels in proportion to the blending percentage. ADF B3-52

Considering the CARB Biodiesel Characterization report, we find that:

4. For the three engines where CARB has published the emission values measured in engine dynamometer testing, all of the data demonstrate that biodiesel fuels significantly increase NOx emissions for both soy- and animal-based fuels by amounts that are proportional to the blending percent. This is true for on-road and off-road engines and for a range of test cycles. ADF B3-53

5. Where B5 fuels were tested for these engines, NOx emissions were observed to increase. NOx emission increases are smaller at B5 than at higher blending levels and the observed increases for two engines were not statistically significant by themselves based on the pair-wise t-test employed in Durbin 2011.[8] However, the testing for one of the engines (the 2007 MBE4000) showed statistically significant NOx emission increases at the B5 level for <u>both</u> soy- and animal-based blends. ADF B3-54

By itself, <u>the latter result is sufficient to disprove the Staff's contention that biodiesel blends at the B5 level will not increase NOx emissions</u>.

Based on examination of all of the studies cited by CARB as the basis for its proposal to exempt biodiesels below B10 from mitigation, it is clear that the available research points to the expectation that both soy- and animal-based biodiesel blends will increase NOx emissions in proportion to their biodiesel content, including at the B5 level. <u>CARB's own test data demonstrate that B5 will significantly increase NOx emissions in at least some engines</u>. ADF B3-55

Based on data in the CARB Biodiesel Characterization report, soy-based biodiesels will increase NOx emissions by about 1% at B5 (and 2% at B10), while animal-based biodiesels will increase NOx emissions by about one-half as much: 0.45% at B5 (and 0.9% at B10). <u>All of the available research says that the NOx increases are real and implementation of mitigation measures will be required to prevent increases in NOx emissions due to biodiesel use at blending levels below B10</u>. ADF B3-56

Finally, we note that CARB has not published fully the biodiesel testing data that it relied on in support of the Proposed Rule and thereby has failed to adequately serve the interest of full public disclosure in this matter. The CARB-sponsored testing reported in Durbin 2011 is the sole source of B5 testing cited by CARB as support for the Proposed Rule. Durbin 2011 publishes only portions of the measured emissions data in a form that permits re-analysis; it does not publish any of the B5 data in such a form. It has not been possible to obtain the remaining data through a personal request to Durbin or an official public records request to CARB and, to the best of our knowledge, the data are not otherwise available online or through another source. ADF B3-57

CARB should publish all of the testing presented in Durbin 2011 and any future testing that it sponsors in a complete format that allows for re-analysis. Such a format would be (a) the measured emission values for each individual test replication; or (b) averages across all test replications, along with the number of replications and the standard error of the individual tests. The first format (individual test replications) is preferable because that would permit a full examination of the data including effects such as test cell drift over time. Such publication is necessary to assure that full public disclosure is achieved and that future proposed rules are fully and adequately informed by the data. ADF B3-58

---

[8]As discussed in Section 3.3, the pair-wise t-test is not the preferred method for demonstrating statistical significance.

1.3 Review of 2013 CARB B5 Emission Testing

In December 2013, after the release of the ISOR and in response to an earlier Public Records Act request, CARB released a copy of new CARB-sponsored emission testing conducted by Durbin and others at the University of California CE-CERT[9]. The purpose of the study was "... to evaluate different B5 blends as potential emissions equivalent biodiesel fuel formulations for California."[10] Three B5 blends derived from soy, waste vegetable oil (WVO), and animal biodiesel stocks were tested on one 2006 Cummins ISM 370 engine using the hot-start EPA heavy-duty engine dynamometer cycle. A preliminary round of testing was conducted for all three fuels followed by emissions-equivalent certification testing per 13 CCR 2282(g) for two of the fuels. As noted by Durbin: "[t]he emissions equivalent diesel certification procedure is robust in that it requires at least twenty replicate tests on the reference and candidate fuels, providing the ability to differentiate small differences in emissions."[11]

Soy and WVO B5 Biodiesel

The B5-soy and B5-WVO fuels were blended from biodiesel stocks that were generally similar to the soy-based stock used in the earlier CARB Biodiesel Characterization Study (Durbin 2011) with respect to API gravity and cetane number. In the preliminary testing, the two fuels "...showed 1.2-1.3% statistically significant [NOx emissions] increases with the B5-soy and B5-WVO biodiesel blends compared to the CARB reference fuel."[12] The B5-WVO fuel caused the smaller NOx increase (1.2%) and was selected for the certification phase of the testing. There, it "... showed a statistically significant 1.0% increase in NOx compared to the CARB reference fuel"[13] and failed the emissions-equivalent certification due to NOx emissions. ADF B3-59

Animal B5 Biodiesel

The B5-animal derived fuel was blended from an animal tallow derived biodiesel that was substantially different from the animal based biodiesel used in the earlier Durbin study, and was higher in both API gravity and cetane number. The blending response for cetane number was also surprising, in that blending 5 percent by volume of a B100 stock (cetane number 61.1) with 95% of CARB ULSD (cetane number 53.1) produced a B5 fuel blend with cetane number 61. ADF B3-60

In preliminary testing, the B5-animal fuel showed a small NOx increase which was not statistically significant, causing it to be judged the best candidate for emissions-equivalent certification. In the certification testing, it "...showed a statistically ADF B3-61

[9] "CARBB5 Biodiesel Preliminary and Certification Testing." Prepared by Thomas D. Durbin, G. Karavalakis and others. Prepared for Alexander Mitchell, California Air Resources Board. July 2013. This study is not referenced in the ISOR, nor was it included in the rule making file when the hearing notice for the ADF regulation was published in October 2013.
[10] Ibid, p. vi.
[11] Ibid, p. viii.
[12] Ibid, p. 8.
[13] Ibid, p. 9.

significant 0.5% reduction in NOx compared to the CARB reference fuel"[13] and passed the emissions-equivalent certification. The NOx emission reduction for this fuel blend appears to be real for this engine, but given the differences between the blendstock and the animal based biodiesel blendstock used in the earlier Durbin study it is unclear that it is representative for animal-based biodiesels in general.. ADF B3-61 cont.

Summary

The conclusions drawn in the preceding section are not changed by the consideration of these new emission testing results. For plant-based biodiesels (soy- and WVO-based), the new testing provides additional and statistically significant evidence that B5 blends will increase NOx emissions at the B5 level. The result of decreased NOx for the B5 animal-based blend stands out from the general trend of research results reviewed in this report. However:

- The same result – reduced NOx emissions for some fuels and engines – has sometimes been observed in past research, as evidenced by the emissions data considered by CARB staff in ISOR Figure B.3 (reproduced in Figure 2.1 below). As shown, some animal-based B5 and B20 fuels reduced NOx emissions while others increased NOx emissions with the overall conclusion being that NOx emissions increase in direct proportion to biodiesel content of the blends and that there is no emissions threshold. ADF B3-62 cont.

- Increasing cetane is known to generally reduce NOx emissions and has already been proposed by CARB as a mitigation strategy for increased NOx emissions from biodiesel[14]. The unusual cetane number response in the blending and the high cetane number of the B5-animal fuel may account for the results presented in the recently released study.

Considering the broad range of plant- and animal-based biodiesel stocks that will be used in biodiesel fuels, we conclude that the available research (including the recently released CARB test results) indicates that unrestricted biodiesel use at the B5 level will cause real increases in NOx emissions and that countermeasures may be required to prevent increases in NOx emissions due to biodiesel use at blending levels below B10.

###

[14] For example, see Durbin 2011 Section 7.0 for a discussion of NOx mitigation results through blending of cetane improvers and other measures.

2. CARB LITERA TURE REVIEW

The Staff ISOR explains that the Appendix B Technology Assessment is the basis for CARB's conclusion that biodiesels below B10 have no significant impact on NOx emissions. The assessment is based on data from seven studies (identified in Table 2-1) that tested high-cetane diesel fuels. The first study (Durbin 2011) is the Biodiesel Characterization Study that was conducted for CARB, while the others were obtained through a literature search.

Table 2-1

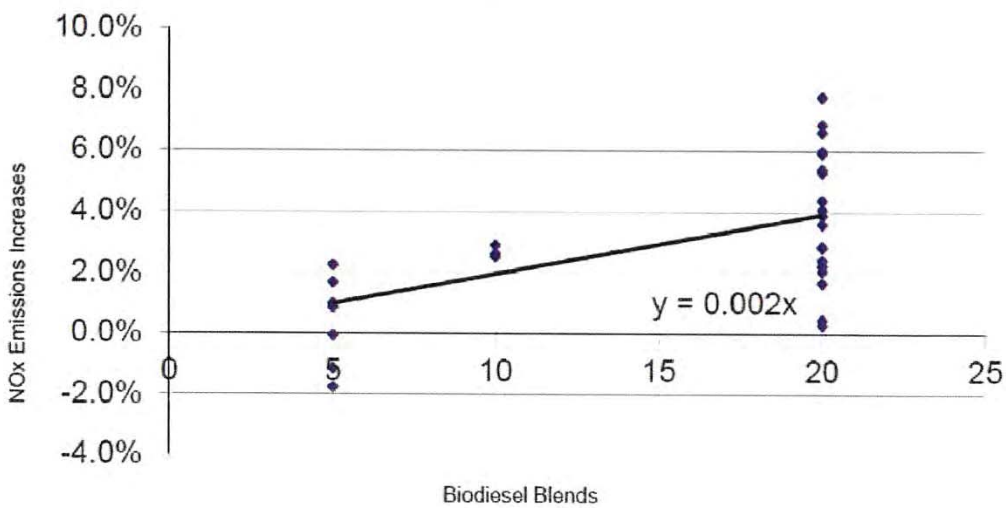
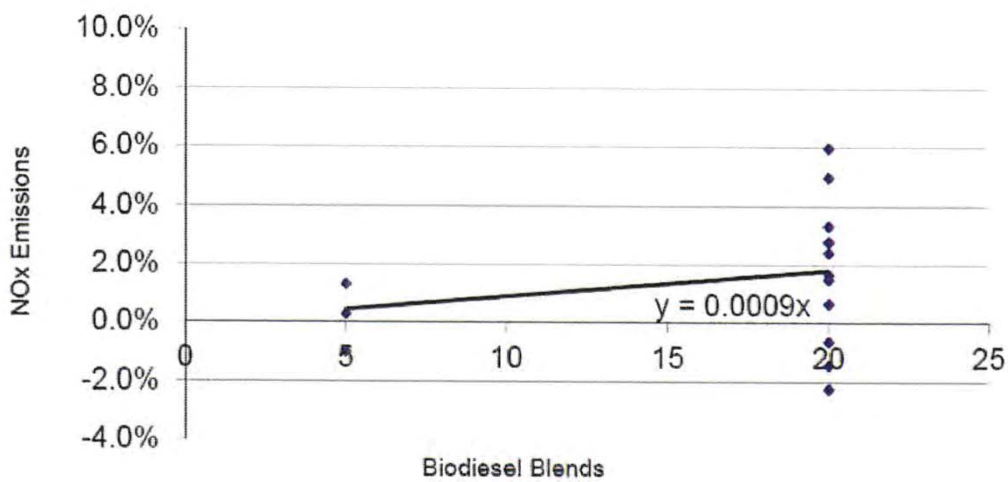
Figure B.2: NOx Impact of Soy Biodiesel Blended in High Cetane Base Fuel



ADF B3-63

Figure B.3: NOx Impact of Animal Biodiesel Blended in High Cetane Base Fuel



Source: Figures B.2 and B.3 of Appendix B: Technology Assessment soy-based biodiesels are shown to increase NOx emissions by approximately 1% at B5, 2% at B10, and 4% at B20. Animal-based biodiesels are shown to increase NOx emissions by about one-half as much: 0.45% at B5, 0.9% at B10, and 1.8% at B20. Although there is substantial scatter in the results, these data do not appear to support the Staff Threshold Model that biodiesel does not increase NOx emissions at B5 but does so at B10. ADF B3-63 cont.

We will examine the Durbin 2011 study at some length in Section 3. In this section, we look at each of the other studies cited by the Staff to find out what the studies say about NOx emissions impacts at and below B10.

2.1 Review of Literature Cited in the ISOR

The Staff literature search sought and selected testing that used fuels with cetane levels comparable to California diesel fuels; the Staff does not, however, list those fuels or provide the data that support the tables and figures in Appendix B of the ISOR. Therefore, we have necessarily made our own selection of high-cetane fuels in the course of reviewing the studies. The key testing and findings of each study are summarized below, with a specific focus on what they tell us about NOx emission impacts at B10 and below.

2.1.1 Clark 1999

This study tested a variety of fuels on a 1994 7.3L Navistar T444E engine. Of the high-cetane base fuels, one base fuel (Diesel A, off-road LSD) was blended and tested at levels of B20, B50, and B100. NOx emissions were significantly increased for all of the blends. The other base fuel (CA Diesel) was tested only as a base fuel. Its NOx emissions were 12% below that of Diesel A, making it is unclear whether Diesel A is representative of fuels in CA. This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below.

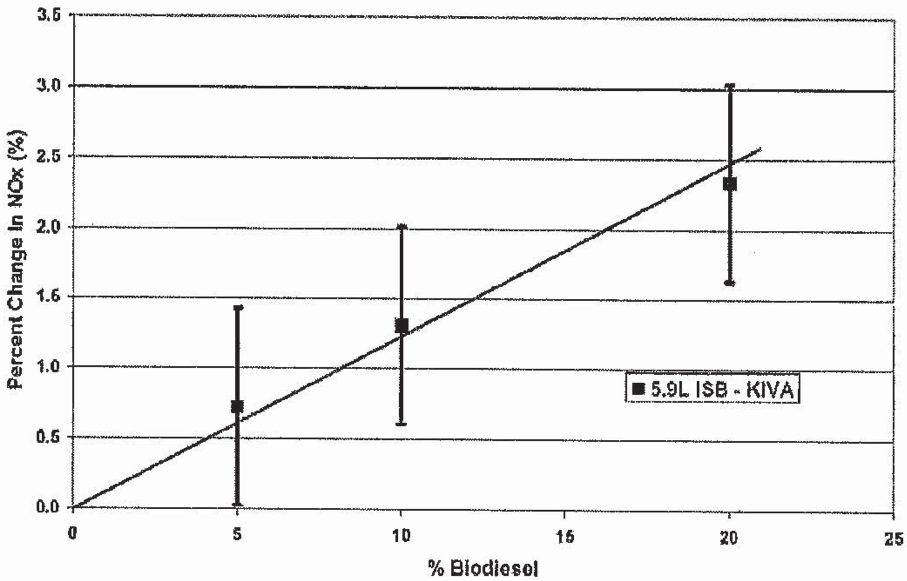
2.1.2 Eckerle 2008

This study tested low and mid/high-cetane base fuels alone and blended with soy-based biodiesel at the B20 level. The Cummins single-cylinder test engine facility was used in a configuration representative of modern diesel technology, including cooled EGR. Testing was conducted under a variety of engine speed and load conditions. FTP cycle emissions were then calculated from the speed/load data points. The test results show that B20 blends increase NOx emissions compared to both low- and high-cetane base fuels. This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below. ADF B3-64

The study notes that two other studies "show that NOx emissions increase nearly linearly with the increase in the percentage of biodiesel added to diesel fuel." Eckerle's Figure 21 (reproduced below as Figure 2-2) indicates a NOx emissions increase at B5, which is the basis for the statement in the abstract that "Results also show that for biodiesel blends containing less than 20% biodiesel, the NOx impact over the FTP cycle is proportional to

the blend percentage of biodiesel." The authors clearly believe that biodiesel fuels have NOx emission impacts proportional to the blending percent at all levels including B5.

Figure 2-2
Impact of Biodiesel Blends on Percent NOx Change for the 5.9L ISB Engine Operation Over the FTP Cycle



Source: Figure 21 of Eckerle 2008

ADF B3-64 cont.

2.1.3 <u>McCormick 2002</u>

This study tested low- and mid-cetane base fuels alone and blended with soy- and animal-based biodiesel at the B20 level. The testing was conducted on a 1991 DDC Series 60 engine using the hot-start U.S. heavy-duty FTP. NOx emission increases were observed for both fuels at the B20 level. Mitigation of NOx impacts was investigated by blending a Fisher-Tropsch fuel, a 10% aromatics fuel and fuel additives. <u>This study conducted no testing of the NOx emissions impact from commercial biodiesels at the B10 level or below.</u>

ADF B3-65

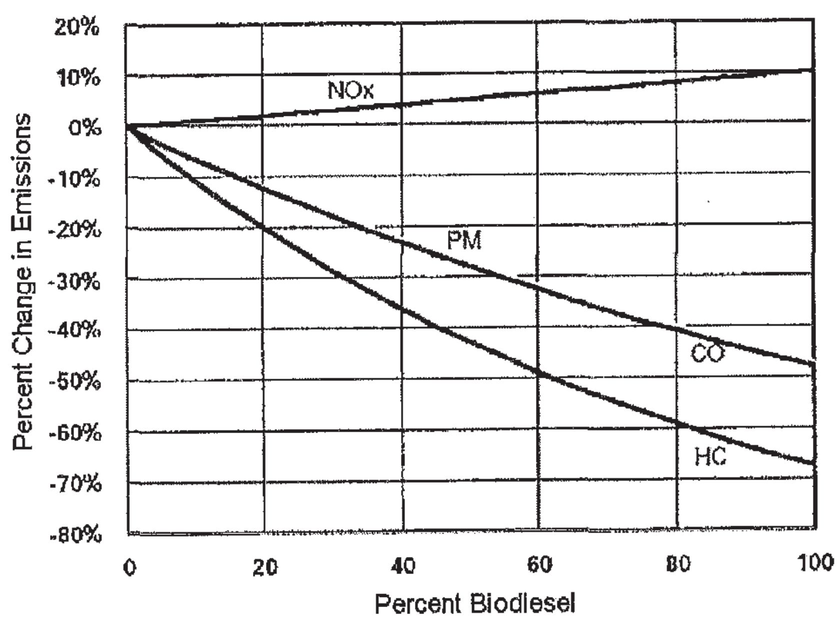
This study also tested a Fisher-Tropsch (FT) base fuel blended at the B1, B20, and B80 levels. Although the very high cetane number ($\geq$75) takes it out of the range of commercial diesel fuels, it is interesting to note that the study measured higher NOx emissions at the B1 level than it did on the FT base fuel and substantially higher NOx emissions at the B20 and B80 levels. While the B1 increase was not statistically significant given the uncertainties in the emission measurements (averages of three test runs), <u>it is clear that increased NOx emissions have been observed at very low blending levels.</u>

2.1.4 McCormick 2005

This study tested blends of soy- and animal-based biodiesels with a high-cetane ULSD base fuel at B10 levels and higher. Two engines were tested -- a 2002 Cummins ISB and a 2003 DDC Series 60, both with cooled EGR. The hot-start U.S. heavy-duty FTP test cycle was used. The majority of testing was at the B20 level with additional testing at the B50 and B100 levels. One soy-based fuel was tested at B10. The study showed NOx emission increases at B10, B20, and higher levels. The study also investigated mitigation of NOx increases. This study conducted no testing of the NOx emissions impact from biodiesels below the B10 level.

The authors present a figure (reproduced as Figure 2-3) in their introduction that shows their summary of biodiesel emission impacts based on an EPA review of heavy-duty engine testing. It shows NOx emissions increasing linearly with the biodiesel blend percentage.

Figure 2-3
Trend in HC, CO, NOx and PM Emissions with Biodiesel Percent



Source: McCormick 2005

ADF B3-66

2.1.5 Nuszkowski 2009

This study tested five different diesel engines: one 1991 DDC Series 60, two 1992 DDC Series 60, one 1999 Cummins ISM, and one 2004 Cummins ISM. Only the 2004 Cummins ISM was equipped with EGR. All testing was done using the hot-start U.S. heavy-duty FTP test cycle. The testing was designed to test emissions from fuels with and without cetane-improving additives. Although a total of five engines were tested, the base diesel and B20 fuels were tested on only two engines (one Cummins and one DDC Series 60) because there was a limited supply of fuel available. NOx emissions increased on the B20 fuel for both engines. A third engine (Cummins) was tested on B20 and B20 blended with cetane improvers to examine mitigation of NOx emissions. This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below. ADF B3-67

2.1.6 Thompson 2010

This study examined the emissions impacts of soy-based biodiesel at the B10 and B20 levels relative to low-cetane (42), mid-cetane (49), and high-cetane (63) base fuels using one 1992 DDC Series 60 engine. The emissions results were measured on the hot-start U.S. heavy-duty FTP cycle. The study found that NOx emissions were unchanged (observed differences were not statistically significant) at B10 and B20 levels for the low- and mid-cetane fuels. NOx emissions increased significantly at B10 and B20 levels for the high-cetane fuels. This study conducted no testing of the NOx emissions impact from biodiesels at levels below B10. ADF B3-68

2.2 Conclusions Based on Studies Obtained in Literature Search

From the foregoing summary of the studies cited by Staff, we reach the conclusions given below.

1. None of the six studies measured the NOx emissions impact from commercial-grade biodiesel at blending levels below B10, and only two studies tested a fuel at the B10 level. All other testing was at the B20 level or higher. Because none tested a B5 (or similar) fuel, none is capable of providing direct evidence regarding NOx emissions at B5 or other blending levels below B10. ADF B3-69

2. These studies provide no data or evidence supporting the validity of Staff's Threshold Model that biodiesel below B10 does not increase NOx emissions. In fact, all of the studies are consistent with the contention that biodiesel increases NOx emissions in proportion to the blending percent. ADF B3-70

3. Two of the studies present evidence and arguments that the NOx impact from biodiesel is a continuous effect that is present even at very low blending levels and will increase at higher levels in proportion to the blending percentage. One study tested a Fischer-Tropsch biodiesel blend at B1 and observed NOx emissions to increase (but not by a statistically significant amount). ADF B3-71

###

3. CARB BIODIESEL CHARACTERIZATION STUDY

3.1 Background

CARB sponsored a comprehensive study of biodiesel and other alternative diesel blends in order "... to better characterize the emissions impacts of renewable fuels under a variety of conditions."[15] The study was designed to test eight different heavy- duty engines or vehicles, including both highway and off-road engines using engine or chassis dynamometer testing. Five different test cycles were used: the Urban Dynamometer Driving Schedule (UDDS), the Federal Test Procedure (FTP), and 40 mph and 50 mph CARB heavy-heavy-duty diesel truck (HHDDT) cruise cycles, and the ISO 8178 (8 mode) cycle. Table 3-1 (reproduced from Table ES-1 of Durbin 2011) documents the scope of the test program. Because the Staff relied only on engine dynamometer testing in its Technology Assessment, only the data for the first four engines (shaded) are considered here.

Table 3-1
A Breakdown of the Test Engines for the Different Categories of Testing

2006 Cummins ISM[a]	Heavy-duty on-highway	Engine dynamometer	
2007 MBE4000	Heavy-duty on-highway	Engine dynamometer

2007 BME4000	Heavy-duty on-highway	Chassis dynamometer	Freightliner chassis
2010 Cummins ISX15	Heavy-duty on-highway	Chassis dynamometer	Kenworth chassis

Source: Table ES-1 of Durbin 2011, page xxvi
Notes:
[a] Data for the first four engines (shaded) are considered in this report.

[15] Durbin 2011, p. xxiv.

The original goal of this report was to subject all of the NOx emission testing in Durbin 2011 to a fresh re-analysis. However, it was discovered that Durbin 2011 did not report all of the data that were obtained during the program and are discussed in the report. The chassis dynamometer testing was conducted at the CARB Los Angeles facility. Emission results for the chassis dynamometer testing are presented in tabular and graphical form, but the report does not contain the actual emissions test data. For the engine dynamometer testing, some of the measured emission values are not reported even though the emission results are reported in tabulated or graphical form. Requests for the missing data were directed to Durbin in a personal request and to CARB through an official records request. No information has been provided in response and we have not been able to obtain the missing data from online or other sources. ADF B3-72

For this report, we have worked with the data in the forms that are provided in Durbin 2011 as being the best-available record of the results of the CARB study. Because Staff used only data obtained in engine dynamometer testing, the analysis presented in this report has done the same. Nevertheless, the results of the chassis dynamometer testing are generally supportive of the results and conclusions presented here. Durbin 2011 notes:

> "... The NOx emissions showed a consistent trend of increasing emissions with increasing biodiesel blend level. These differences were statistically significant or marginall y significant for nearly all of the test sequences for the B50 and B100 fuels, and for a subset of the tests on the B20 blends."[16]

Durbin notes that emissions variability was greater in the chassis dynamometer testing, which leads to the sometimes lower levels of statistical significance. There was also a noticeable drift over time in NOx emissions that complicated the results for one engine.

3.2 Data and Methodology

Table 3-2 compiles descriptive information on the engine dynamometer testing performed in Durbin 2011. The experimental matrix involves four engines, two types of biodiesel fuels (soy- and animal-based), and up to four test cycles per engine. However, the matrix is not completely filled with all fuels tested on all engines on all applicable test cycles. The most complete testing is for the ULSD base fuel and B20, B50, and B100 blends. There is less testing for the B5 blend, and B5 is tested using only a subset of cycles. For this reason, we first examine the testing for ULSD, B20, B50, and B100 fuels to determine the overall impact of biodiesels on NOx emissions. We then examine the more limited testing for B5 to determine the extent to which it impacts NOx emissions.

This examination is limited by the form in which emissions test information is reported in Durbin 2011. A complete statistical analysis can be conducted only for the two on-road engines for which Appendices G and H of Durbin 2011 provide measured emissions, and for a portion of the testing of the Kubota off-road engine for which Appendix I provides

[16] Durbin 2011, p. 126.

Table 3-2 Experimental Matrix for Heavy-Duty Engine Dynamometer Testing Reported in Durbin 2011				
Engine	Biodiesel Type	Fuels Tested	Test Cycles	Notes
On-Road Engines				
2006 Cummins ISM	Soy	ULSD, B20, B50, B100, B5	UDDS, FTP, 40 mph, 50 mph	B5 tested on 40 mph and 50 mph cruise cycles
	Animal	ULSD, B20, B50, B100, B5	UDDS, FTP, 50 mph	B5 tested only on FTP.
2007 MBE4000	Soy	ULSD, B20, B50, B100, B5	UDDS, FTP, 50 mph	B5 tested only on FTP.
	Animal	ULSD, B20, B50, B100, B5		B5 tested only on FTP.
Off-Road Engines				
1998 Kubota V2203-DIB	Soy	ULSD, B20, B50, B100, B5	ISO 8178 (8 Mode)	none
	Animal	Not tested		
2009 John Deere	Soy	ULSD, B20, B50, B100	ISO 8178 (8 Mode)	B5 not tested
	Animal	ULSD, B20, B5		none

measured emissions. The data needed to support a full re-analysis consist of measured emissions on each fuel in gm/hp-hr terms, which are stated in Durbin 2011 as averages across all test replications along with the number of replications and the standard error of the individual tests. With this information, the dependence of NOx emissions on biodiesel blending percent can be determined as accurately as if the individual test values had been reported and the appropriate statistical tests for the significance of results can be performed.

Regression analysis is used as the primary method of analysis. For each engine and test cycle, the emission averages for each fuel are regressed against the biodiesel blending percent to determine a straight line. The regression weights each data point in inverse proportion to the square of its standard error to account for differences in the number and reliability of emission measurements that make up each average. The resulting regression line will pass through the mean value estimated from the data (i.e., the average NOx emission level at the average blending percent), while the emission averages for each fuel may scatter above and below the regression line due to uncertainties in their measurement. The slope of the line estimates the dependence of NOx emissions on the blending percentage.

Where the data points closely follow a straight line and the slope is determined to be statistically significant, one can conclude that blending biodiesel with a base fuel will increase NOx emissions in proportion to the blending percent. The regression line can then be used to estimate the predicted emissions increase for a given blending percent. The predicted emissions increase is the value one would expect on average over many measurements and is comparable to the average emissions increase one would expect in a fleet of vehicles.

The same level of analysis is not possible for the testing on B5 fuel, which is reported as a simple average for the on-road engines and is not reported at all for the off-road engines. For the B5 fuel, Durbin 2011 presents emission test results in a tabulated form where the percentage change in NOx emissions has been computed compared to ULSD base fuel. This form supports the presentation of results graphically, but it does not permit a proper statistical analysis to be performed. Specifically, the computation of percentage emission changes will perturb the error distribution of the data, by mixing the uncertainty in measured emissions on the base fuel with the uncertainties in measured emissions on each biodiesel blend, and it can introduce bias as a result of the mixing. Further statistical analysis of the computed percent values should be avoided because of these problems. Therefore, a more limited trend analysis of the NOx emissions data for B5 and the John Deere engine is conducted.

3.3 2006 Cummins Engine (Engine Dynamometer Testing)

Table 3-3 shows the NOx emission results for the 2006 model-year Cummins heavy-duty diesel engine based on a re-analysis of the data for this report. As indicated by highlighting in the table, the relationship between increasing biodiesel content and increased NOx emissions for soy-based biodiesel is statistically significant at >95% confidence level[17] in all cases. For the animal-based biodiesel, the relationship is statistically significant at the 92% confidence level for the UDDS cycle, the 94% confidence level for the 50 mph cruise, and the >99% confidence level for the FTP cycle.

For the soy-based fuels, the R^2 statistics show that the emissions effect of biodiesel is almost perfectly linear with increasing biodiesel content over the range B20, B50, and B100. Although not as high for the animal-based fuels (because the emissions effect is smaller and measurement errors are relatively larger in comparison to the trend), the R^2 statistics nevertheless establish a linear increase in NOx emissions with increasing biodiesel content over the same range. The linearity of the response with blending percent is well supported by the many NOx emissions graphs contained in Durbin 2011.

The table also gives the estimated NOx emission increases for B5 and B10 as predicted by the regression lines. For soy-based fuels, the values are 1% for B5 (range 0.8% to 1.3% depending on the cycle) and 2% for B10 (range 1.6% to 2.6% depending on cycle).

[17] A result is said to be statistically significant at the 95% confidence level when the p value is reported as $p \leq 0.05$. At the $p \leq 0.01$ level, a result is said to be statistically significant at the 99% confidence level, and so forth.

Table 3-3 Re-Analysis for 2006 Cummins Engine (Engine Dynamometer Testing) Model: NOx = A + B · BioPct Using ULSD, B20, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A	BioPct Slope B		Predicted NOx Increase for B5	Predicted NOx Increase for B10
			Value	Value	p value	Pct Change	Pct Change
Soy-based							
	UDDS	0.997	5.896	0.0100 [a]	0.001	0.8%	1.7%
	FTP	0.995	2.024	0.0052	0.003	1.3%	2.6%
	40 mph	1.000	2.030	0.0037	<0.0001	0.9%	1.8%
	50 mph	0.969	1.733	0.0028	0.016	0.8%	1.6%
Animal-based							
	UDDS	0.847	5.911	0.0021 [b]	0.080	0.2%	0.4%
	FTP	0.981	2.067	0.0031	0.001	0.7%	1.4%
	50 mph	0.887	1.768	0.0011	0.058	0.3%	0.6%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.
[b] Orange highlight indicates result is statistically significant at the 90% confidence level or better.

For animal-based fuels, the values are approximately one-half as large: 0.4% for B5 (range 0.2% to 0.7%) and 0.8% for B10 (range 0.4% to 1.4%). These predicted increases are statistically significant to the same degree as the slope of the regression line from which they are estimated. That is, the NOx increases predicted by the regression line for soy-based fuels are statistically significant at the 95% confidence level (or better) on all cycles and the predicted NOx increases for animal-based fuels are statistically significant at the 90% confidence level (or better) on all cycles and at the >99% confidence level for the FTP.

Because the limited data on B5 were not used to develop the regression lines for each cycle, and no test data on B10 are available, use of the lines to make predictions for B5 and B10 depends on their linearity over the range between ULSD and B20. Based on the R^2 statistics and the graphs in Durbin 2011, the slopes observed between ULSD and B20 are the same as the slopes observed between B20 and B100 for each of the test cycles. We believe that the linearity of the response with blending percent for values over the range ULSD to B100 would be accepted by the large majority of researchers in the field, as would the use of regression analysis to make predictions for B5 and B10. ADF B3-73

The Durbin 2011 report takes a different approach for determining the statistical significance of NOx emission increases for each fuel. For each fuel tested, it computes a percentage change in emissions for NOx (and other pollutants) relative to the ULSD base fuel. It then determines the statistical significance of each observed change using a conventional t-test for the difference of two mean values (2-tailed, 2 sample equal

variance t-test). The t-test is conducted on the measured emission values before the percentage emission change is computed.

The t-test would be the appropriate approach for determining statistical significance if only two fuels were tested. However, it is a simplistic approach when three or more fuels are tested because it is applied on a pair-wise basis (B5 vs. ULSD, B20 vs. ULSD, etc.) and does not make use of all of the data that is available. It will have less power than the regression approach to detect emission changes that are real. This limitation is in one direction, however, in that the test is too weak when 3 or more data points are available, but a finding of statistical significance is valid when it occurs. As long as the linear hypothesis is valid, the regression approach should be the preferred method for analysis and for the determination of whether biodiesel blending significantly increases NOx emissions. ADF B3-74

Because emission changes will be smallest for B5 (because of the low blending volume), the pair-wise t-test is most likely to fail to find statistical significance at the B5 level. In cases where the pair-wise t-test for B5 says that the emission change vs. ULSD is not statistically significant – but slope of the regression line <u>is</u> statistically significant – the proper conclusion is that additional B5 testing (to improve the precision of the emission averages) would likely lead to the detection of a statistically significant B5 emissions change using the t-test. In this case, <u>the failure to find statistical significance using the t-test is not evidence that B5 does not increase NOx emissions</u>.

For this engine, soy-based B5 was tested on the 40 mph and 50 mph cruise cycles and animal-based B5 was tested on the FTP. To examine this matter further, Table 3-4 reproduces NOx emission results reported in Tables ES-2 and ES-3 of Durbin 2011. Soy-based B5 was shown to increase NOx emissions on the 40 mph cruise cycle, but not on the 50 mph cruise cycle. Animal-based B5 was shown to increase NOx emissions on the FTP. Durbin 2011 noted (p. xxxii) that "[t]he 50 mph cruise results were obscured, however, by changes in the engine operation and control strategy that occurred over a segment of this cycle." Therefore, we discount the 50 mph cruise results and do not consider them further. Neither of the remaining B5 NOx emission increases (for the 40 mph Cruise and FTP cycles) were found to be statistically significant using the t-test, although the 40 mph cruise result for soy-based fuels comes close to being marginally significant (it would be statistically significant at an 86.5% level). The NOx emission increases at higher blending levels were found have high statistical significance (>99% confidence level). ADF B3-75

This format, used throughout Durbin 2011 to report emission test data and to show the effect of biodiesel on emissions, is subject to an important statistical caveat. The percent changes are computed by dividing the biodiesel emission values by the emissions measured for the ULSD base fuel. Therefore, measurement errors in the ULSD measurement are blended with the measurement errors for each of the biodiesel fuels. The blending of errors in each computed percent change can bias the apparent trend of emissions with increasing biodiesel content. As will be shown in Section 3.3.2, we can see this problem in the animal-based B5 test data for this engine.

Table 3-4 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 2006 Cummins Engine (Engine Dynamometer Testing)						
	Soy-based Biodiesel				Animal-based Biodiesel	
	40 mph Cruise		50 mph Cruise		FTP	
	NOx % Diff	p value	NOx % Diff	p value	NOx % Diff	p value
B5	1.7%	0.135	-1.1%	0.588	0.3%	0.298
B20	3.9% [a]	0.000	0.5%	0.800	1.5%	0.000
B50	9.1%	0.000	6.3%	0.001	6.4%	0.000
B100	20.9%	0.000	18.3%	0.000	14.1%	0.000

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on the pair-wise t-test.

3.3.1 NOx Impact of Soy-based Biodiesel at the B5 Level

Figures 3-1a and 3-1b display the trend of NOx emissions with blending percent for the soy-based biodiesel on the 40 mph cruise cycle. Figure 3-1a plots the percentage increases as reported by Durbin 2011 in contrast to two different analytical models for the relationship:

- The Linear Model shown by the blue line; and
- The Staff Threshold model (black line), in which the NOx emission change is zero through B9 and then increases abruptly to join the linear model.

In Figure 3-1a, the linear model is an Excel trendline for the computed percent changes. While the data violate a key assumption for the proper use of regression analysis, this approach is the only way to establish a trendline given the form in which Durbin 2011 tabulates the data and presents the results of its testing.

Figure 3-1b plots the actual measured emission values in g/bhp-hr terms in contrast to the same two analytical models. Here, the linear model line is determined through a proper use of regression analysis, in which each emission average in g/bhp-hr terms is weighted inversely by the square of its standard error, using the data for ULSD, B20, B50 and B100 (i.e., excluding the B5 data point). In the case of this engine and biodiesel fuel, both forms of assessment show generally the same trend for NOx emissions as a function of blending percent. Although the NOx emission increases for B5 may fail the t-test for significance, emissions are increased at B5 and the B5 data point is fully consistent with the Linear Model. The Threshold model is clearly a less-satisfactory representation of the test data. ADF B3-76

Figure 3-1a
Durbin 2011 Assessment: 40 mph Cruise Cycle NOx Emissions Increases for Soy-Biodiesel Blends (2006 Cummins Engine)

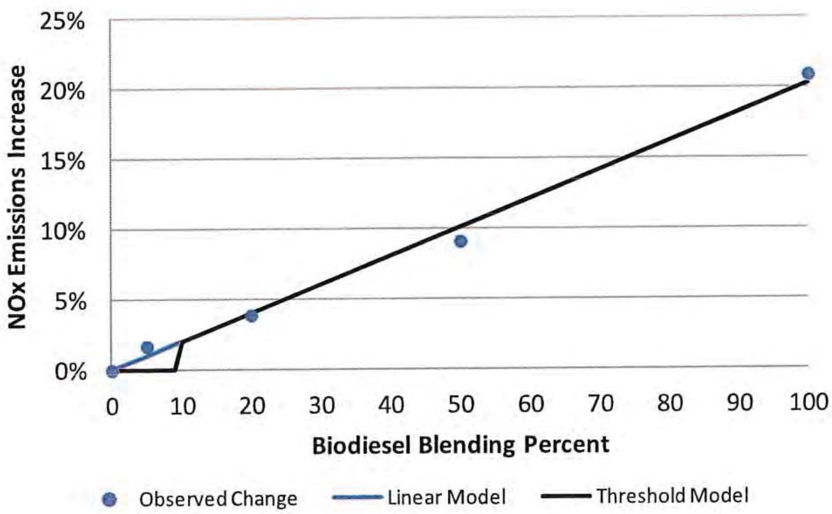

Figure 3-1b
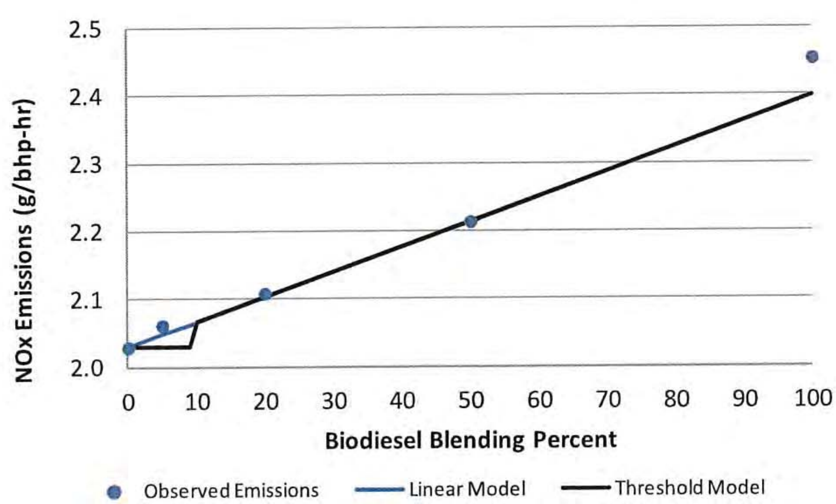
Re-assessment of 40 mph Cruise Cycle NOx Emissions Increases for Soy-Biodiesel Blends (2006 Cummins Engine)



Note that the slope of the trendline (Figure 3-1a) is greater than the slope of the regression line (Figure 3-1b). In the latter figure, the B100 data point stands above the regression line, which passes below it. The regression line (but not the trendline) is fit in

a manner that accounts for the uncertainties in each data point, so that the line will pass closer to points that have smaller uncertainties and farther from points that have greater uncertainties. For these data, the B100 data point has the largest uncertainty (±0.026 g/bhp-hr) followed by the B20 data point (±0.025 g/bhp-hr). The other three data points (ULSD, B5, and B50) have uncertainties less than ±0.001 g/bhp-hr. The B20 data point happens to fall on the line, but the B100 data point is found to diverge above. Because the regression analysis can account for the relative uncertainties of the data points, it provides a more accurate and reliable assessment of the impact on NOx emissions. ADF B3-77

3.3.2 NOx Impact of Animal-based Biodiesel at the B5 level

Figures 3-2a and 3-2b display the trend of NOx emissions with blending percent for the animal-based biodiesel on the FTP test cycle as reported by Durbin 2011 and as re-assessed in this report using regression analysis, respectively. As Figure 3-2a shows, the NOx percent change values reported by Durbin 2011 appear to follow the Staff Threshold model in that NOx emissions are not materially increased at B5, but are increased significantly at B20 and above. As a result, the blue trendline in the figure (fit from the B20, B50 and B100 data points) has a negative intercept.

Figure 3-2b paints a very different picture from the data. Here, the ULSD and B5 data points stand above the weighted regression line (blue) developed from the data for ULSD, B20, B50 and B100. In the data used to fit the regression line, the ULSD data point has the largest uncertainty (±0.013 g/bhp-hr) while the other three data points (B20, B50, and B100) have uncertainties of ±0.002 g/bhp-hr (one case) and ±0.001 g/bhp-hr (two cases). Considering all of the data, the B5 data point has the second highest uncertainty (±0.007 g/bhp-hr). The regression line closely follows a linear model with a high R^2 (0.981) considering the weighted errors, while the ULSD and B5 points lie above it. ADF B3-78

Because the ULSD data point is subject to more uncertainty and appears to be biased high compared to the regression line, the NOx percent changes computed by Durbin 2011 are themselves biased. The trendline result in Figure 3-2a that appeared to be supportive of the Staff Threshold model now appears to be the result of biases in the ULSD and B5 emission averages.

Two important conclusions can be drawn from the foregoing:

1. Accurate and reliable conclusions regarding the impact of B5 on NOx emissions cannot be drawn from the computed percent changes that are reported in Durbin 2011. Nor can accurate and reliable conclusions be drawn from visual inspection of graphs that present such data. Weighted regression analysis of the measured emission values (g/bhp-hr terms) must be performed so that the uncertainties in emissions measurements can be fully accounted for. ADF B3-79

2. When a weighted regression analysis is performed using the testing for this engine, there is no evidence that supports the conclusion that B5 blends will not increase NOx emissions. In fact, the data are consistent with the conclusion that biodiesel increases NOx emissions in proportion to the blending percent. ADF B3-80

Figure 3-2a
Durbin 2011 Assessment: FTP NOx Emissions Increases for Animal-based Biodiesel Blends (2006 Cummins Engine)

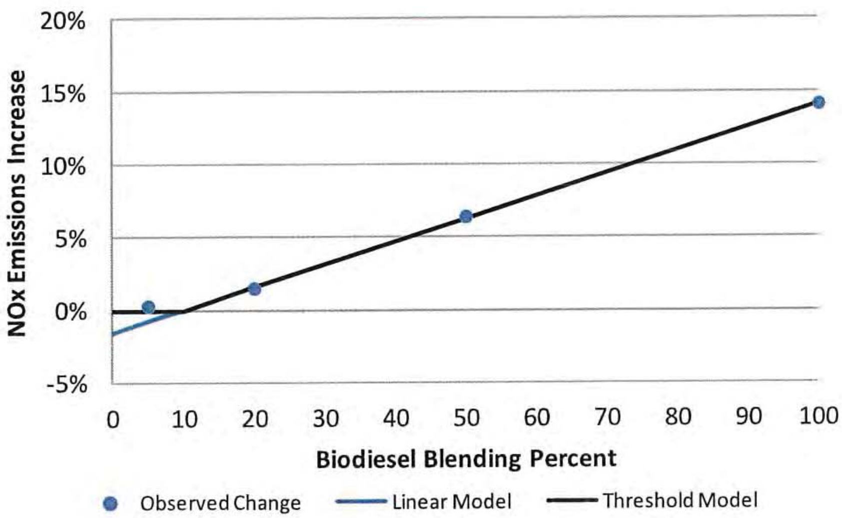


Figure 3-2b
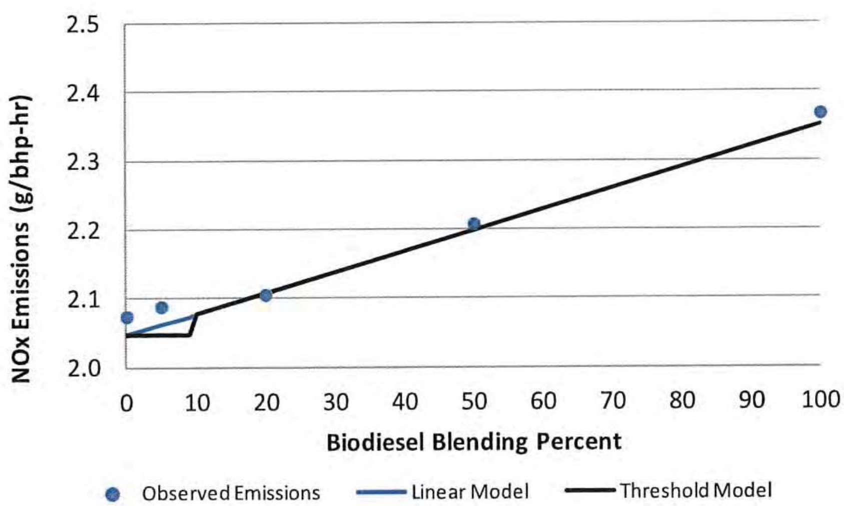
Re-assessment of FTP NOx Emissions Increases for Animal-based Biodiesel Blends (2006 Cummins Engine)



3.4 2007 MBE4000 Engine (Engine Dynamometer Testing)

To analyze the data for the 2007 MBE4000 engine, it has proved necessary to remove two data points, one for the soy-based B20 fuel on the 50 mpg cruise cycle and one for the animal-based B50 fuel on the FTP test cycle:

- Appendix H reports the 50 mph cruise emission average for soy-based B20 to be 0.014 ± 0.020 g/bhp-hr. This value is implausible and wholly inconsistent with the NOx emission change of +6.9% reported in Table ES-4 of Durbin 2011, which would imply a NOx emission average of 1.21*1.069 = 1.30 g/bhp-hr.

- Appendix H reports the FTP emission average for the animal-based B50 fuel to be 2.592 ± 0.028 g/bhp-hr, which stands well above the other test data on animal-based biodiesel. This value is also inconsistent with the NOx emission change of +12.1% reported in Table ES-4 of Durbin 2011, which would imply a NOx emission average of 1.29*1.121 = 1.45 g/bhp-hr.

We believe these reported values are affected by typographical errors and have deleted them from the dataset used here.

With these corrections, Table 3-5 shows the results of the NOx emissions analysis for the 2007 model-year MBE4000 heavy-duty diesel engine. As indicated by highlighting in the table, the relationship between increasing biodiesel content and increased NOx emissions is statistically significant at >99% confidence level in two cases for soy-based biodiesel (the UDDS and FTP cycles) and at the 90% confidence level in one case (the 50 mph cycle). For the animal-based biodiesel, the relationship is statistically significant at the 96% confidence level for the UDDS cycle, the 98% confidence level for the FTP cycle, and >99% confidence level for the 50 mph cycle. ADF B3-81

Durbin 2011 again notes a problem with the 50 mph cruise test results, saying (p. xxxii) that "[the NOx] trend was obscured, however, by the differences in engine operation that were observed for the 50 mph cruise cycle." Therefore, we will focus the discussion on the UDDS and FTP results.

For the soy-based fuels, the R^2 statistics show that the emissions effect of biodiesel is almost perfectly linear with increasing biodiesel content over the range from ULSD to B20, B50, and B100 for all cycles (including the 50 mph cruise). That is, the NOx emissions increase between ULSD and B20 shares the same slope as the NOx emissions increase between B20 and B100. For the animal-based biodiesel, the R^2 statistics also establish a linear increase in NOx emissions with increasing biodiesel content over the same range. The linearity of the response with blending percent is also well supported by the many NOx emissions graphs contained in Durbin 2011.

Table 3-5 Re-Analysis for 2007 MBE4000 Engine (Engine Dynamometer Testing) Model: NOx = A + B · BioPct Using ULSD, B20, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A	BioPct Slope B		Predicted NOx Increase for B5	Predicted NOx Increase for B10
			Value	Value	p value	Pct Change	Pct Change
Soy-based							
	UDDS	0.989	2.319	0.0090 [a]	0.005	4.6%	9.1%
	FTP	0.998	1.268	0.0049	0.006	2.5%	5.0%
	50 mph	0.979	1.198	0.0054 [b]	0.092	2.7%	5.5%
Animal-based							
	UDDS	0.913	2.441	0.0036	0.044	2.0%	4.0%
	FTP	0.999	1.288	0.0038	0.020	2.5%	5.0%
	50 mph	0.994	1.205	0.0049	0.003	2.5%	5.0%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.
[b] Orange highlight indicates result is statistically significant at the 90% confidence level or better.

The table also gives the estimated NOx emission increases for B5 and B10 as predicted by the regression lines. For soy-based fuels, the values are ~3.5% for B5 (range 2.5% to 4.6% depending on the cycle) and ~7.5% for B10 (range 5.0% to 9.1% depending on cycle). For animal-based fuels, the values are approximately two-thirds as large: ~2.3% for B5 (range 2.0% to 2.5%) and ~4.5% for B10 (range 4.0% to 5.0%). The predicted increases are statistically significant to the same degree as the slope of the regression line from which they are estimated. That is, the predicted NOx increases are statistically significant at the >99% confidence level for soy-based fuels on the UDDS and FTP cycles and at the >95% confidence level for animal-based fuels on all cycles. The predicted NOx increase is statistically significant at the 90% confidence level for soy-based fuels on the 50 mph cruise cycle.

ADF B3-82

For this engine, soy- and animal-based B5 were tested on the FTP. Table 3-6 reproduces the NOx emission results reported in Tables ES-4 and ES-5 of Durbin 2011. While there are caveats on use of the pair-wise t-test, the FTP test data for this engine show NOx emissions at the B5 level for both soy- and animal-based fuels that are statistically significant at the 99% confidence level (or better) in this case. That is, the test data for this engine as reported by Durbin 2011 refute the Staff Threshold Model that biodiesel blends below B10 do not increase NOx emissions.

Table 3-6 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 2007 MBE4000 Engine (Engine Dynamometer Testing)				
	Soy-Based Biodiesel FTP		Animal-Based Biodiesel FTP	
	NOx % Diff	p value	NOx % Diff	p value
B5	0.9% [a]	0.007	1.3%	0.000
B20	5.9%	0.000	5%	0.000
B50	15.3%	0.000	12.1	0.000
B100	38.1%	0.000	29%	0.000

Source: Table ES-4/5 of Durbin 2011, p. xxix
Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on pair-wise t-test.

Figures 3-3a and 3-3b below compare the FTP data for this engine to the regression line representing the linear model (blue) and the Staff Threshold model (black) for both soy- and animal-based biodiesel. In both cases, the regression line was developed using the data for ULSD, B20, B50, and B100 (i.e., excluding the B5 data point). For both soy- and animal-based biodiesels, the data point for B5 falls on the established line, while the Staff Threshold model is inconsistent with the data. For this engine, it is clear that soy- and animal-based biodiesels increase NOx emissions at all blending levels. ADF B3-83

Figure 3-3a
Re-assessment of FTP Cycle NOx Emissions Increases for Soy-based Biodiesel Blends (2007 MBE4000 Engine)

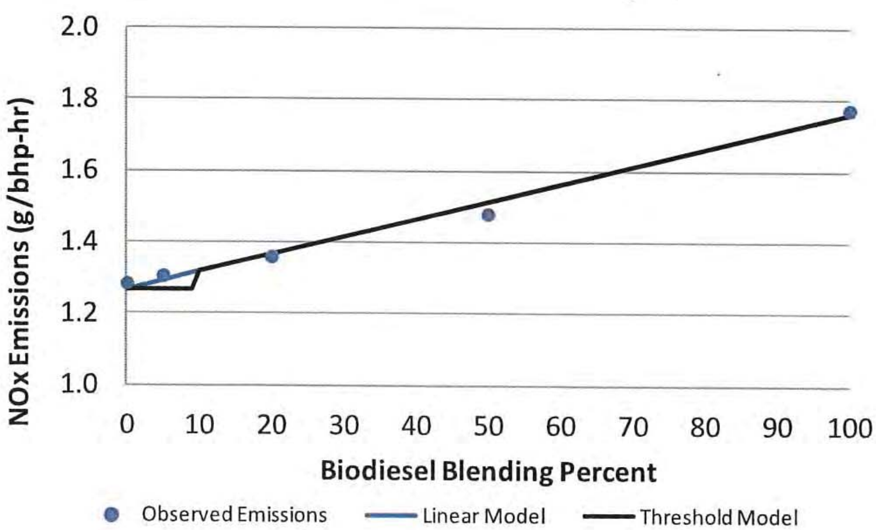


Figure 3-3b
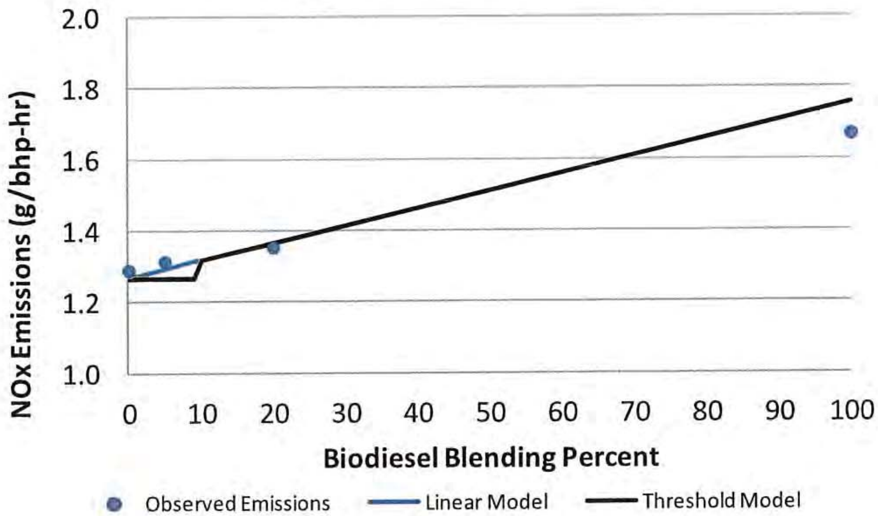
Re-assessment of FTP Cycle NOx Emissions Increases for Animal-based Biodiesel Blends (2007 MBE4000 Engine)



3.5 1998 Kubota TRU Engine (Engine Dynamometer Testing)

The 1998 Kubota V2203-DIB off-road engine was tested on the base fuel (ULSD) and soy-based biodiesel at four blending levels (B5, B20, B50, B100) in two different series using the ISO 8178 (8-mode) test cycle. Appendix I reports the measured emissions data only for the first series (ULSD, B50, B100). Using this subset of data, Table 3-7 summarizes the results of the re-analysis for this engine.

As for the other engines, the results of the analysis demonstrate the following:

- The high R^2 statistic shows that the emissions effect of biodiesel is almost perfectly linear over the range B50 and B100. That is, the slope from ULSD to B50 is the same as the slope from B50 to B100. The slope of the regression line is statistically significant at the 99% confidence level.

- NOx emissions are estimated to increase by 1.0% at the B5 level and by 2.1% at the B10 level. These estimated NOx emission increases are statistically significant to the same high degree as the regression slope on which they are based.

ADF B3-84

Table 3-7 Re-Analysis for 1998 Kubota V2203-DIB Engine (Engine Dynamometer Testing) Model: NOx = A + B · BioPct Using ULSD, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A	BioPct Slope B		Predicted NOx Increase for B5	Predicted NOx Increase for B10
			Value	Value	p value	Pct Change	Pct Change
Soy-based	ISO 8178	0.999	12.19	0.0256 [a]	0.01	1.0%	2.1%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.

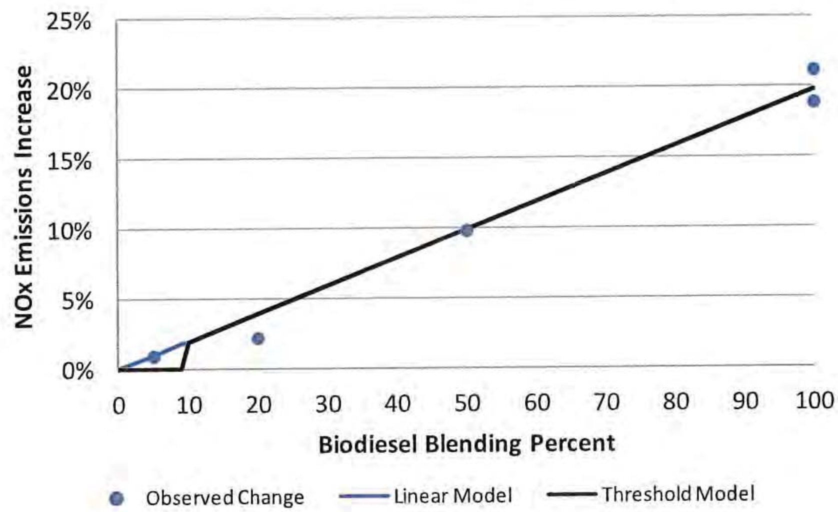
The second test series involved ULSD, B5, B20, and B100 fuels. Measured emissions data are not given in Appendix I, so we must work with the calculated percent changes in NOx emissions tabulated in Durbin 2011. Table 3-8 reproduces the NOx emission results reported in Table ES-8 of Durbin 2011 for the two test series. For the second test series, biodiesel at the B5 level increased NOx emissions, but the result fails the pair-wise t-test for statistical significance. The NOx emission increase at the B20 level was statistically significant at the 90% confidence level, and the increase at the B100 level was statistically significant at the >99% confidence level. The significance determinations use the pair-wise t-test, which is subject to caveats, but this is the only method available to gauge significance because re-analysis of the computed percentage changes is not possible. ADF B3-85

Table 3-8 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 1998 Kubota TRU Engine (Engine Dynamometer Testing)				
	Soy-Based Biodiesel Series 1 ISO 8178		Soy-Based Biodiesel Series 2 ISO 8178	
	NOx % Diff	p value	NOx % Diff	p value
B5	Not tested		0.97%	0.412
B20	Not tested		2.25% [a]	0.086
B50	7.63% [b]	0.000	Not tested	
B100	13.76%	0.000	18.89%	0.000

Source: Table ES-8 of Durbin 2011, p. xxxviii
Notes:
[a] Orange highlight indicates result is statistically significant at the 90% confidence level or better based on pair-wise t-test.
[b] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on pair-wise t-test

Figure 3-4 displays the trend of NOx emissions with blending percent for the first and second test series combined. As the figure shows, the available data points scatter around the trendline determined from the emission change percentages (not from regression analysis). The B20 data point falls below the trend line while the two B100 data points bracket the trend line. It is not possible to explain the divergence of the B20 data point

Figure 3-4
Durbin 2011 Assessment: ISO 8178 Cycle NOx Emissions Increases for Soy-based Biodiesel Blends (1998 Kubota Engine, Test Series 1 and 2 Combined)



because the emissions data for the second test series are not published in Durbin 2011. The B5 data point clearly supports the Linear Model and is inconsistent with the Staff Threshold Model. ADF B3-86

3.6 2009 John Deere Off-Road Engine (Engine Dynamometer Testing)

The only information on the 2009 John Deere off-road engine comes from the tabulation of calculated percentage emission changes. Table 3-9 reproduces these data from Table ES-7 of Durbin 2011. For the soy-based biodiesel, NOx emissions are significantly increased at the B20 and higher blend levels. The increase for B20 is statistically significant at the 90% confidence level and the increases for B50 and B100 are statistically significant at the >99% confidence level based on the pair-wise t-test. A soy-based B5 fuel was not tested. ADF B3-87

Table 3-9 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 2009 John Deere Engine (Engine Dynamometer Testing)				
	Soy-Based Biodiesel ISO 8178		Animal-Based Biodiesel ISO 8178	
	NOx % Diff	p value	NOx % Diff	p value
B5	Not tested		-3.82	0.318
B20	2.82%[a]	0.021	-2.20	0.528
B50	7.63%	0.000	Not tested	
B100	13.76%	0.000	4.57	0.000

Source: Table ES-7 of Durbin 2011, p. xxxviii
Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on pair-wise t-test.

For animal-based biodiesel, the testing shows the unusual result that B5 and B20 appear to decrease NOx emissions, while B100 increases NOx. The B5 and B20 decreases are not statistically significant, while the B100 increase is statistically significant at the >99% confidence level. Durbin 2011 concludes:

> The animal-based biodiesel also did not show as great a tendency to increase NOx emissions compared to the soy-based biodiesel for the John Deere engine, with only the B100 animal-based biodiesel showing statistically significant increases in NOx emissions.[18]

Durbin 2011 does not discuss these results further and does not note any problems in the testing, making further interpretation of the results difficult. Figure 8-1 of Durbin 2011 presents the NOx results for this engine with error bars. First, we note that the figure appears to suggest that NOx emissions were increased on the B20 fuel in contradiction to the table above. Second, it is clear that the error bars are large enough that no difference in NOx emissions can be detected among ULSD, B5, and B20 fuels. Overall, this result could be consistent with the Staff Threshold Model through B5, but the failure to detect a NOx emission increase at B20 is not. Without further information, it is not possible to determine whether the result seen here is a unique response of the John Deere engine to animal-based biodiesel or is the result of a statistical fluctuation or an artifact in the emissions data.

ADF B3-87 cont.

3.7 Conclusions

The Biodiesel Characterization report prepared by Durbin et al. for CARB is an important source of information on the NOx emissions impact of biodiesel fuels in heavy-duty engines. It is the sole source of information on the NOx impact of B5 blends cited in the ISOR. When the engine dynamometer test data are examined for

ADF B3-88 cont.

[18] Durbin 2011, p. xx.

the three engines for which emissions test data have been published, we find clear evidence that biodiesel increases NOx emissions in proportion to the blending percent. Where B5 fuels were tested for these engines, NOx emissions are found to increase above ULSD for both soy- and animal-based blends in all three engines and by statistically significant amounts in one engine.

ADF B3-88 cont.

Specifically, a re-analysis of the NOx emissions test data demonstrates the following:

1. For the 2006 Cummins engine, biodiesel fuels are found to significantly increase NOx emissions for both soy- and animal-based blends by amounts that are proportional to the blending percent. This result indicates that biodiesels will increase NOx emissions at blending levels below B10. When B5 fuels were tested, NOx emissions were observed to increase but by amounts that fail to reach statistical significance according to the pair-wise test.[19] Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

ADF B3-89

2. For the 2007 MBD4000 engine, biodiesel fuels are found to significantly increase NOx emissions for both soy- and animal-based blends by amounts that are proportional to the blending percent. This result indicates that biodiesels will increase NOx emissions at blending levels below B10. When B5 fuels were tested, NOx emissions were observed to increase and by amounts that are found to be statistically significant using the pair-wise t-test.[13] This result alone is sufficient to disprove the Staff Threshold Model. Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

ADF B3-90

3. For the 1998 Kubota TRU (off-road) engine, soy-based biodiesel fuels are found to significantly increase NOx missions. Animal-based biodiesel was not tested. When a soy-based B5 fuel was tested, NOx emissions were observed to increase but by amounts that fail to reach statistical significance according to the pair-wise test.[13] Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

ADF B3-91

The measured emissions test data for the other off-road engine (2009 John Deere) are not contained in the Durbin 2011 report and CARB has not made them publicly available. Thus, a re-analysis was not possible. Based on the tables and figures in Durbin 2011, soy-based biodiesel fuels were shown to significantly increase NOx emissions at B20 levels and higher, but B5 was not tested. Testing of animal-based blends shows no change in NOx emissions at B5 and B20 levels, but B100 is shown to significantly increase NOx emissions. Durbin 2011 discusses this result only briefly, and it is unclear what conclusions can be drawn from it.

ADF B3-92

###

[19] As discussed in Section 3.3, the pair-wise t-test is not the preferred method for demonstrating statistical significance.

APPENDIX A

RESUME OF ROBERT W. CRAWFORD

Education

1978 Doctoral Candidate, ScM. Physics, Brown University, Providence, Rhode Island
1976 B.A. Physics, Pomona College, Claremont, California

Professional Experience

1998-Present Independent Consultant

Individual consulting practice emphasizing the statistical analysis of environment and energy data with an emphasis on how data and statistics are properly used to make scientific inferences. Mr. Crawford provides support on statistical, data analysis, and modeling problems related to ambient air quality data and emissions from mobile and stationary sources.

Ambient Air Quality and Mobile Source Emissions – Mr. Crawford has worked with Sierra Research on elevated ambient CO and PM concentrations in Fairbanks AK and Phoenix AZ, including the effect of meteorological conditions on ambient concentrations, the relationship of concentrations to source inventories, and the use of non-parametric techniques to infer source location from wind speed and direction data. Ongoing work is employing Principal Components Analysis to elucidate the relationship between meteorology and $PM_{2.5}$ concentrations in Fairbanks. In the past year, this work led to creation of the AQ Alert System, a tool used by air quality staff to track $PM_{2.5}$ monitor concentrations during the day and to prepare AQ alerts over the next 3 days based on the meteorological forecast.

In past work for Sierra, he has also conducted studies of fuel effects on motor vehicle emissions for Sierra. For CRC, he determined the relationship between gasoline volatility and oxygen content on tailpipe emissions of late model vehicles at FTP and cold-ambient temperatures. For SEMPRA, he determined the relationship between CNG formulation and tailpipe emissions of criteria pollutants and a range of air toxics. Other work has included the design of vehicle surveillance surveys and determination of sample sizes, development of screening techniques similar to discriminant functions to improve the efficiency of vehicle recruitment, the analysis of vehicle failure rates measured in inspection & maintenance programs, and the statistical evaluation of data collected on freeway speeds using automated sensors.

Stationary Source Emissions – Over the past 5 years, Mr. Crawford has worked with AEMS, LLC on EPA's MACT and CISWI rulemakings for Portland Cement plants, in which significant issues related to data quality, data reliability, and emissions variability are evident. Key issues include the need to properly account for uncertainty and emissions variability in setting emission standards. He also supported AEMS in the

current EPA rulemaking on reporting of greenhouse gas emissions from semiconductor facilities, where the proper characterization of emission control device performance was a key issue. He is currently supporting AEMS in a regulatory process to re-determine emission standards for an industrial facility where the new standard will be enforced by continuous emissions monitoring (CEMS). At issue is how to set the standard in such a way that there will be no more than a small, defined risk that 30-day emission averages will exceed the limitations while emissions remain well-controlled .

Advanced Combustion Research – In recent work for Oak Ridge National Laboratory, Mr. Crawford conducted a series of statistical studies on the fuel consumption and emissions performance of Homogenous Charge Compression Ignition (HCCI) engines. One of these studies was for CRC, in which fuel chemistry impacts were examined in gasoline HCCI. In HCCI, the fuel is atomized and fully-mixed with the intake air charge outside the cylinder, inducted during the intake stroke, and then compressed to the point of spontaneous combustion. The timing of combustion is controlled by heating of the intake air. If R&D work can demonstrate a sufficient understanding of how fuel properties influence engine performance, the HCCI combustion strategy potentially offers the fuel economy benefit of a diesel engine with inherently lower emissions.

1979-1997 Energy and Environmental Analysis, Inc., Arlington, VA. Director & Partner (from 1989).

Primary work areas: Studies of U.S. energy industries for private and institutional clients emphasizing statistical analysis, business planning and computer modeling/forecasting. Responsible for the EEA practice area that provided strategic planning and forecasting services to major energy companies. Primary topical areas included: U.S. energy market analysis and strategic planning; gas utility operations; and natural gas supply planning.

U.S. Energy Market Analysis

During 1995-1997, Mr. Crawford directed EEA's program to provide comprehensive energy supply and demand forecasting for the Gas Research Institute (GRI) in its annual Baseline Projection of U.S. Energy Supply and Demand. Services included: development of U.S. energy supply, demand, and price forecasts; sector-specific analyses covering energy end-use (residential, commercial, industrial, transportation), electricity supply, and natural gas supply and transportation; and the preparation of a range of publications on the forecasts and energy sector trends.

From 1989 through 1997, he directed the use of EEA's Energy Overview Model in strategic planning and long-term market analysis for a client base of major energy producers, pipelines, and distributors in both the United States and Canada. The Energy Overview Model was used under his direction as the primary analytical basis for the 1992 National Petroleum Council study The Potential for Natural Gas in the United States. Mr. Crawford also provided analysis for clients on a wide range of other energy market issues, including negotiations related to an LNG import project intended to serve U.S. East Coast markets. This work assessed the utilization and economic value of seasonal

gas deliverability in order to develop LNG pricing formulas and evaluate the project's viability.

Other topical areas of work during his period of employment with EEA include:

Gas Load Analysis and Utility Operations – Principal investigator in a multi-year research program for the Gas Research Institute (GRI) that examined seasonal gas loads, utility operations, and the implications for transmission and storage system reliability and capacity planning.

Gas Transmission and Storage – Principal investigator for a study of industry plans for expansion of underground gas storage capacity in the post-Order 636 environment, including additions of depleted-reservoir and salt-formation storage, an engineering analysis of capital and operating costs for the projects, and unbundled rates for new storage services.

Natural Gas Supply Planning – Mr. Crawford was EEA's senior manager and lead analyst on gas supply planning issues for both pipeline and distribution companies, which included technical and analytic support in development and justification of gas supply strategies; and identification of optimal seasonal supply portfolios for Integrated Resource Planning proceedings.

Transportation Systems Research

Mr. Crawford also had extensive experience in motor vehicle fuel economy and emissions while at EEA. He participated for five years in a DOE research program on fuel economy, with emphasis on the evaluation of differences between laboratory and on-road fuel economy. His work included analysis of vehicle use databases to understand how driving patterns and ambient (environmental) conditions influence actual on-road fuel economy. He also developed a software system to link vehicle certification data systems to vehicle inspection and testing programs and participated in a range of studies on vehicle technology, fuel economy, and emissions for DOE, EPA, and other governmental agencies.

EXHIBIT B

BEFORE THE
CALIFORNIA AIR RESOURCES BOARD

In re:	)
	)
Proposed Regulation on the Commercialization of Alternative Diesel Fuels (Public Hearing Scheduled for March 20, 2014)	)
	)

Declaration of James M. Lyons

I, James M. Lyons, declare and state as follows:

1. I am an engineer with training and expertise in motor vehicle fuels, automotive emissions control, and automotive air pollution. I am a Senior Partner of Sierra Research, Inc. ("Sierra"), an environmental consulting firm located at 1801 J Street, Sacramento, California. Sierra specializes in research and regulatory matters pertaining to air pollution control, and does work for both governmental and private sector clients. I have been employed at Sierra Research since 1991. I received a B.S. degree in Chemistry from the University of California, Irvine, and a M.S. Degree in Chemical Engineering from the University of California, Los Angeles. Before joining Sierra in 1991, I was employed by the State of California in the Mobile Source Division of the California Air Resources Board ("CARB").

I. Introduction, Qualifications, and Materials Considered

2. I have prepared this Declaration and the analysis it contains for Growth Energy. I hold the opinions expressed in this Declaration with a reasonable degree of engineering and scientific certainty. I plan to request an opportunity to testify before CARB at the public hearing scheduled for this matter, so that I may answer any questions concerning my opinions and the analysis and sources on which I have based those opinions. I also request that CARB review and

respond to each part of the analysis and opinions presented in this Declaration before deciding what action to take on the CARB staff's proposed alternative diesel fuel ("ADF") regulation.

3. During my career, I have worked on many projects related to the following areas: (1) the assessment of emissions from on- and non-road mobile sources, including ships and locomotives; (2) analyses of the unintended consequences of regulatory actions; and (3) the feasibility of compliance with air quality regulations. I have also studied how the use of biodiesel fuels can influence exhaust emissions of oxides of nitrogen ("NOx") when used in vehicles and engines operated in California, and I have prepared and filed declarations regarding that issue in *POET LLC et al. v. California Air Resources Board*, an action in which I was a co-petitioner.

4. I have testified as an expert under state and federal court rules in cases involving CARB regulations for gasoline, Stage II vapor recovery systems and their design, combustion chamber system design, and issues related to emissions from heavy-duty vehicles and engines. While at Sierra I have acted as a consultant on automobile air pollution control matters for CARB and other governmental organizations. I am a member of the American Chemical Society and the Society of Automotive Engineers and have co-authored nine peer-reviewed monographs concerned with automotive emissions, including greenhouse gases and their control. In addition, over the course of my career, I have conducted peer-reviews of numerous papers related to a wide variety of issues associated with pollutant emissions and air quality. My résumé is attached as Attachment A.

5. I have reviewed a report being filed along with this Declaration by Growth Energy that has been prepared by Mr. Robert Crawford of Rincon Ranch Consulting, entitled *NOx Emissions Impact of Soy- and Animal-based Biodiesel Fuels: A Re-Analysis* (December

2013). I have also studied the CARB Initial Statement of Reasons ("ISOR" or "Staff Report") released to support the proposed ADF regulation, and the studies cited in the ISOR that are pertinent to Mr. Crawford's analysis. The additional materials I have considered to prepare this Declaration are identified as references.

6. Mr. Crawford's report examines the empirical basis for the CARB staff's claims that the use of biodiesel in California is unlikely to warrant environmental mitigation, and that the use of biodiesel blends below the ten percent blend level (B10) in California pursuant to the proposed ADF regulation will not result in increases in NOx emissions.

7. Mr. Crawford's report applies generally accepted methods of data analysis and demonstrates expertise in the subject-matter of the report; Mr. Crawford is an expert in the field in which he opines in his report; and his report is the type of analysis on which experts in the field of automotive emissions control rely.

II. Analysis and Opinions

A. Increases in NOx Emissions from Biodiesel Blends Below B10

8. As explained in detail in Mr. Crawford's report, a proper statistical analysis of the available emissions data relied upon by CARB staff in developing the proposed ADF regulation demonstrates that statistically significant increases in NOx emissions will result from biodiesel blends that contain less than ten percent biodiesel, including at the five percent level (B5) and below. In addition, Mr. Crawford's report demonstrates that NOx emissions increase in direct proportion of the amount of biodiesel in a blend and there is not, as CARB staff claims, a "threshold" below which biodiesel use in a blend will not increase NOx emissions. Given this, as I explain below in more detail, CARB staff should be proposing a Significance Level of zero, rather than ten percent, for biodiesel. Given the issues identified with the CARB staff analysis of

ADF B3-93

biodiesel impacts on NOx emissions by Mr. Crawford, CARB has no credible scientific basis upon which to adopt the ADF regulation as proposed with the biodiesel Significance Level set at ten percent.

ADF B3-93 cont.

9. CARB staff presents, in Figures B.2 and B.3 of the ISOR, regressions of all the available emissions data considered by CARB staff in developing the proposed ADF regulation. Based on Mr. Crawford's findings, the slopes of these regression lines can be used to calculate the increases in NOx emissions expected from the use of soy- and animal-based biodiesel as a function of biodiesel content in the blend. The values calculated for soy- and animal-based biodiesel at selected blends levels over the range from one percent to twenty percent are shown in Table 1.

Table 1
Expected Increases In NOx Emissions from Biodiesel Use Based on Available Emissions Data Considered by CARB Staff

Biodiesel Blend Level %	Percentage Increase in NOx Emissions	
	Soy-Based	Animal-Based
1	0.2	0.09
2	0.4	0.18
3	0.6	0.27
4	0.8	0.36
5	1	0.45
10	2	0.90
20	4	1.80

ADF B3-94

10. As shown in Table 1, the magnitude of the NOx increase for animal-based biodiesel is approximately half that observed for soy-based biodiesel. As also shown in Table 1, the emissions data considered by CARB show that increases in NOx emissions between about one and two percent occur at the proposed B10 significance threshold.

ADF B3-95

B. The "Effective Blend Level" Concept Provides No Assurance Against Increases in NOx Emissions Due to Biodiesel Use

11. The proposed ADF regulation relies on a concept called the "Effective Blend Level" (EB) for biodiesel to determine when mitigation would be required. The formula proposed by CARB staff for calculating the Effective Blend Level for biodiesel is found in proposed Section 2293.6(a) and is reproduced below.

$$EB = 100 \times \left[\frac{NBV - 0.5LN - 0.73RD - VM - 0.55AB}{TCV}\right]$$

As specified in Section 2293.6(a), the above formula is to be used to compute an annual average statewide value for the Effective Blend Level relative to the total volume of fuel used in compression ignition engines excluding alternative fuels such as natural gas and liquefied petroleum gas ("TCV") in the state during that year.

12. The calculation begins with establishing the net volume of biodiesel of all types used in California *excluding biodiesel used in blends of five percent or less* (NBV) — a step that has no scientific basis, as demonstrated by Mr. Crawford's analysis, and that, on its own, completely invalidates the use of the EB metric for the intended purpose. The NBV value is then further reduced by subtracting 50% of the volume of low NOx Diesel (LN) used statewide and 73% of the volume of renewable Diesel used statewide. The remainder is then further reduced by subtracting the volume of biodiesel of all types used in blends where steps have been taken to voluntarily mitigate NOx increases (VM) and then again by subtracting 55% of the volume of animal-based biodiesel (AB) to account for the smaller magnitude of the NOx emission increases observed with that fuel.[1] The final value is then divided by TCV (i.e., the total volume of fuel

1 Those voluntary mitigation measures are assumed to have been taken before the so-called "Significance Level" is reached and mitigation would be required under the staff's proposal. *See* ¶ 13.

used in compression ignition engines excluding alternative fuels such as natural gas and liquefied petroleum gas in the state during that year) and multiplied by 100 to yield the Effective Blend Level on a percentage basis.

13. As specified in proposed Section 2293.5(c)(4), mitigation of NOx increases associated with biodiesel would be required only when the value of EB reaches 9.5 percent, which is 95% of the 10% Significance Level proposed for biodiesel.

14. There are a number of specific problems with the concept and calculation of the predicted Effective Blend Level that create the potential for significant increases in NOx emissions to result from the use of biodiesel in California; these are explained in detail below and should be addressed by CARB. As an initial matter, however, the overall problem with the EB concept will allow massive increases in the amount of biodiesel used in California without requiring any mitigation of the associated increase in NOx emissions. This can be seen readily by comparing CARB staff's projections of biodiesel use in California (Figure 6.2 of the ISOR) with CARB staff's projections regarding the Effective Blend Level for biodiesel (Figure 6.5 of the ISOR). Those two figures are reproduced below in Figure 1. As can been seen, despite the forecast nine-fold increase in annual biodiesel use in California from 50 million to 450 million gallons from 2013 to 2023 shown in Figure 6.2 of the ISOR, the forecast Effective Blend Level of biodiesel **decreases** to less than zero over virtually all of the period in question — meaning that, under the CARB staff's proposal, no mitigation of the increase in NOx emissions in California from biodiesel use will ever occur. CARB needs to confront and eliminate the EB concept from the staff's proposal, in light of this very simple demonstration of why the EB concept will not protect the environment against increases in NOx emissions. ADF B3-96

Figure 1. CARB Biodiesel Forecasts

Figure 6.2: Statewide Biodiesel Volume

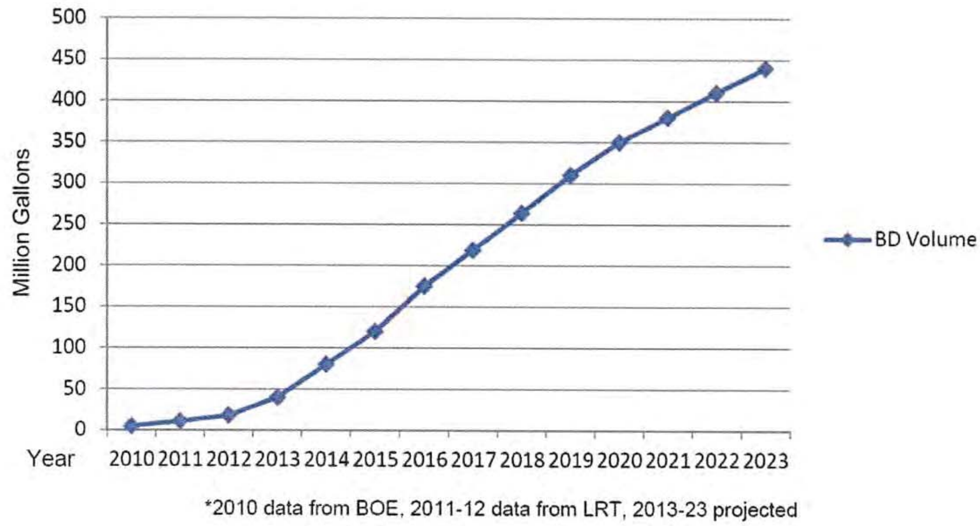

Figure 6.5: Effective Biodiesel Blend Level Forecast

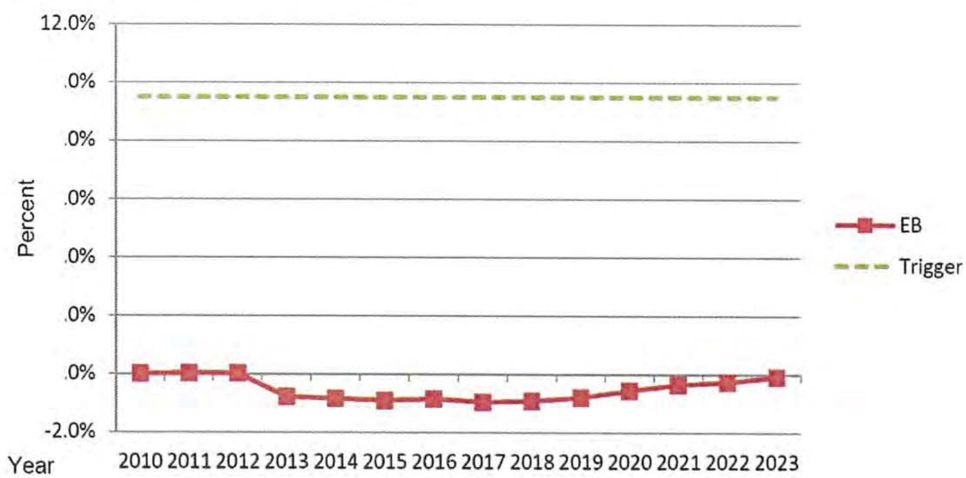

Source: CARB Initial Statement of Reasons. Note that Figure 6.5 is reproduced directly from the ISOR, which is missing some increments on the y-axis.

15. Next, CARB needs to modify the proposed ADF regulation in order to address CARB staff's faulty assumption that biodiesel blends of up to five percent will have no impact on NOx emissions. With respect to five percent blends, CARB staff states on page ES-3 of the Staff ADF B3-97

Report that "biodiesel used in blends at B9 or below, including the B5 (B0 to B5) in predominant use today, does not increase NOx." The Staff Report also attempts to justify the exclusion of five percent blends from the EB calculation by arbitrarily excluding these blends from the ADF regulation. That assertion is undercut by the Staff Report's frank and correct admission on page 51 that "[g]iven the significant price premium for higher biodiesel blends such as B20 or B100, it is highly unlikely that operators of heavy-duty, legacy diesel fleets would opt to use the more expensive, higher biodiesel blends when comparable, lower cost conventional CARB diesel or B5 blends are readily available." ADF B3-97 cont.

16. As noted above, Mr. Crawford's analysis demonstrates that statistically significant increases in NOx emissions will occur from the use of five percent biodiesel blends and, as Table 1 shows, the available emissions data relied upon by CARB staff indicate that at the five percent blend level, biodiesel use is expected to increase NOx emission by between about 0.5 and one percent. There is no doubt that unmitigated NOx emission increases of this magnitude have the potential to create significant adverse environmental impacts in areas of California with severe air quality problems. ADF B3-98

17. It is also important for CARB to understand the import of the staff's prediction that biodiesel blends of five percent or less will be the primary means by which biodiesel will be used in California. As the Staff Report states on page 30:

> Staff has communicated with many of the stations that sell biodiesel as well as the major terminal operators in the state, and has found that the vast majority of the biodiesel currently being sold in California and expected to be sold in the future is sold as blends of B5 or less. ADF B3-99

The fact that most biodiesel used in California will be sold as blends of five percent biodiesel or less, coupled with the fact that – as Mr. Crawford has explained – the available data show statistically significant increases in NOx emissions from such blends, means that biodiesel use in

California under the proposed ADF regulation will result in unmitigated increases in NOx emissions. Again, the critical nature of the CARB staff's invalid assumption about the NOx impacts of blends at or below five percent simply cannot be ignored by CARB. ADF B3-99 cont.

18. Even if it were correct that blends of B5 and less have no impact on NOx emissions, the EB calculation double-counts for the supposedly benign effect of those blends, and therefore makes mitigation even more unlikely. This can be illustrated by noting that CARB staff estimates that 450 million gallons per year of biodiesel will be used in California in 2023. (See Figure 6.2 of the Staff Report.) A recent California Energy Commission forecast[2] for total Diesel use in California in 2023 is about 4 billion gallons. On that basis, and without discounting for low NOx, renewable Diesel, or voluntary mitigation, the actual Effective Blend Level would be 11.25 percent and mitigation would be required for at least some biodiesel blends under the proposed ADF. Under CARB staff's approach, however, if a substantial portion of that biodiesel — for example, 50 percent — is five percent or lower blends, the Effective Blend Level drops to 5.6 percent and no mitigation of any kind is required for any biodiesel blends. That result is clearly incorrect, and the EB calculation must be modified to include, rather than exclude, B5 blends. ADF B3-100

19. Another fundamental problem with the proposed EB calculation is that it is based on annual statewide average fuel use. NOx emissions have local and immediate impacts on air quality, with the questions of when and where they occur in the state being of critical importance with respect to the significance of those impacts. It follows directly that mitigation of NOx increases associated with biodiesel use must occur in the same area at the same time if air quality ADF B3-101

---

[2] See *http://www.energy.ca.gov/2011publications/CEC-600-2011-007/CEC-600-2011-007-SD.pdf*.

impacts are to be avoided. However, the EB completely fails to provide this assurance because CARB staff has either (1) ignored that reductions in NOx emissions from mitigation must take place at the same time and in the same area as NOx increases from biodiesel use, or (2) without support from anything in the rulemaking file, assumed that mitigation will occur in the same area and at the same time as the increases in NOx emissions.

ADF B3-101 cont.

20. To illustrate the problems the EB creates for mitigation, consider, for example, that under the proposed ADF regulation, increases in NOx emissions could occur from trucks operating on biodiesel in Los Angeles during August and exacerbate already high ambient ozone levels in that area. In turn, this increase in NOx emissions could be "mitigated" by reductions in NOx emissions from trucks operating on renewable diesel in the San Francisco area during December, when high ozone levels are not a problem. In this example, the EB concept would allow residents of Los Angeles to suffer adverse environmental impacts while the residents of San Francisco would realize no environmental benefit. Clearly the approach to mitigation designed into the EB concept by CARB staff makes no sense.

ADF B3-102

C. CARB Staff's Assumption that Biodiesel Use Will not Increase Emissions from New Technology Diesel Engines Is Not Adequately Supported

21. In the Staff Report, CARB staff makes frequent statements regarding the impact of biodiesel on NOx emissions from "new technology diesel engines" (or "NTDEs"). For example, on page ES-3 of the ISOR, the staff states categorically that "use of biodiesel in 2010-compliant engines and other so-called 'New Technology Diesel Engines' does not increase NOx, regardless of the biodiesel blend level." Only one reference, Lammert et al.,[3] is provided in the staff report

ADF B3-103

[3] Lammert, M., McCormick, R., Sindler, P. and Williams, A., "Effect of B20 and Low Aromatic Diesel on Transit Bus NOx Emissions Over Driving Cycles with a Range of Kinetic Intensity," *SAE Int. J. Fuels Lubr.* 5(3):2012,

(Continued...)

to support this and other, analogous, statements by CARB staff. As CARB staff acknowledges, this single study involved chassis dynamometer testing of only two urban buses with NTDEs, with both engines being the same model produced by the same manufacturer. The extrapolation of that limited testing to the entire population of heavy-duty Diesel vehicles with NTDEs used in different applications and with different engine designs produced by a number of different manufacturers is simply not credible or reliable.

ADF B3-103 cont.

22. In addition, the CARB staff fails to acknowledge the following statement made by the authors of the Lammert study about the measurement of NOx emissions: "For much of the cycle[,] NOx would be at or near the detection limit of the laboratory equipment which resulted in a 95 percent confidence interval that was high relative to the value of the cycle emissions." That effect, which can be clearly seen in Figures 10 and 11 of the Lammert study, renders the claim that there was no statistically significant increase in NOx emissions observed from the use of biodiesel in NTDEs an artifact attributable to the lack of sensitivity of the NOx measurement instrumentation used in the study.

ADF B3-104

23. In sum, the CARB staff's unequivocal statements regarding the impact of biodiesel on NOx emissions from all vehicles with NTDEs is simply not reasonable based on data from (1) a single study that (2) that tested only two urban buses equipped with the same engine and (3) used instrumentation that was, at best, barely able to measure NOx emissions from the test vehicles in general, and clearly was not sensitive enough to reliably detect changes in NOx emissions due to use of different fuels. Nothing else in the rulemaking file supports the CARB staff's claim that there will not be increased NOx emissions from the use of biodiesel in NTDEs.

ADF B3-105

I declare under penalty of perjury under the laws of California that the foregoing is true and correct to the best of my knowledge and belief.

Executed this __12th__ day of December 2013 at Sacramento, California.

Résumé

James Michael Lyons

Education

1985, M.S., Chemical Engineering, University of California, Los Angeles

1983, B.S., Cum Laude, Chemistry, University of California, Irvine

Professional Experience

4/91 to present — Senior Engineer/Partner/Senior Partner
Sierra Research

Primary responsibilities include oversight and execution of complex analyses of the emission benefits, costs, and cost-effectiveness of mobile source air pollution control measures. Mr. Lyons has developed particular expertise with respect to the assessment of control measures involving fuel reformulation, fuel additives, and alternative fuels, as well as accelerated vehicle/engine retirement programs, the deployment of advanced emission control systems for on- and non-road gasoline- and Diesel-powered engines, on-vehicle evaporative and refueling emission control systems, and Stage I and Stage II service station vapor recovery systems. Additional duties include assessments of the activities of federal, state, and local regulatory agencies with respect to motor vehicle emissions and reports to clients regarding those activities. Mr. Lyons has extensive litigation experience related to air quality regulations, product liability, and intellectual property issues.

7/89 to 4/91 — Senior Air Pollution Specialist
California Air Resources Board

Supervised a staff of four professionals responsible for identifying and controlling emissions of toxic air contaminants from mobile sources and determining the effects of compositional changes to gasoline and diesel fuel on emissions of regulated and unregulated pollutants. Other responsibilities included development of new test procedures and emission standards for evaporative and running loss emissions of hydrocarbons from vehicles; overseeing the development of the state plan to control toxic emissions from motor vehicles; and reducing emissions of CFCs from motor vehicles.

4/89 to 7/89 Air Pollution Research Specialist
California Air Resources Board

Responsibilities included identification of motor vehicle research needs; writing requests for proposals; preparation of technical papers and reports; as well as monitoring and overseeing research programs.

9/85 to 4/89 Associate Engineer/Engineer
California Air Resources Board

Duties included analysis of vehicle emissions data for trends and determining the effectiveness of various types of emissions control systems for both regulated and toxic emissions; determining the impact of gasoline and diesel powered vehicles on ambient levels of toxic air contaminants; participation in the development of regulations for "gray market" vehicles; and preparation of technical papers and reports.

Re: Comments Regarding CARB's Alternative Diesel Fuels Rulemaking

Dear Sirs:

Growth Energy, an organization of ethanol producers and supporters, has a number of concerns with the Alternative Diesel Fuels (ADF) Regulations currently under development by the staff of the California Air Resources Board (CARB) which were the subject of a September 5th workshop held in Sacramento. These concerns, which are described in detail below, focus on the treatment of biodiesel and biodiesel blends currently being proposed by CARB staff. Overall, the provisions of the proposed ADF regulations would allow for the widespread use of biodiesel and biodiesel blends in California without adequately mitigating the resulting increases in emissions of oxides of nitrogen (NOx). The treatment being proposed by CARB staff for biodiesel and biodiesel blends is unacceptable in that it will result in adverse air quality impacts and violates several of the "underlying principles" in the February 15, 2013, CARB White Paper concerning its conceptual approach to the regulation of alternative diesel fuels, including:[1]

1. Protection of public health;
2. Preservation or improvement of air quality; and
3. Reliance on the best scientific knowledge available.

Given the above, Growth Energy urges CARB staff to revise the proposed ADF regulations to eliminate the potential for biodiesel use in California to result in increased emissions, degraded air quality and adverse impacts on public health.

[1] See page 3 of CARB's White Paper "Discussion of Conceptual Approach to Regulation of Alternative Diesel Fuels", February 15, 2013 which is available at http://www.arb.ca.gov/fuels/diesel/altdiesel/20130212ADFRegConcept.pdf

1. The Proposed ADF Regulation Incorrectly Ignores Increases in NOx Emissions Associated with Use of Biodiesel Blends

As currently drafted, the proposed ADF regulation fails to require any mitigation for increases in NOx emissions associated with the use of biodiesel until total biodiesel usage in the state amounts to at least 10% of all fuel used in diesel engines in California on an annual basis.[2] While the potential for increased NOx emissions due to this arbitrarily established "significance level" for biodiesel use is discussed in Section 2 below, its basic premise appears to be an assumption that there are no NOx emissions associated with the use of biodiesel blends at or below the B10 level. In support of the inaccurate assumption that there is some threshold level below which biodiesel use will not increase emissions, CARB cites its White Paper, which states:[1]

> *Furthermore, for purposes of this rulemaking B5 blends will be considered a legal California diesel fuel with no emissions mitigation required.*

This arbitrary threshold is not supported by any data or analysis, and we are unaware of any published analysis of emissions test data that supports the assumptions that there are no increases in NOx emissions at either the B5 or up to the B10 levels. ADF B3-106

In contrast, a preliminary analysis of data from CARB's most recently funded biodiesel testing program[3] demonstrates that NOx emissions would increase significantly at the B5 and B10 levels in at least some engines and for some biodiesel types. Here, the term "significant" means both that the NOx increase is statistically significant and that it is large enough to be of concern. Although the fact that CARB has not made all of the emissions data from this testing program publically available makes analysis difficult, results of a preliminary analysis are shown in Table 1 below for a 2006 model-year Cummins heavy-duty diesel engine. As shown, the relationship between increasing biodiesel content and increased NOx emissions is statistically significant at the 95% confidence level in all cases for soy-based biodiesel and at the 90% confidence level or better for animal-based biodiesel. ADF B3-107

Further, the R^2 statistics for soy-based fuels show that the emissions effect of biodiesel is almost perfectly linear with increasing biodiesel content. Although not as high because the emissions effect is smaller and measurement errors are relatively larger in comparison to the trend, the R^2 statistics for the animal-based fuels also clearly establish a linear increase in NOx emissions with increasing biodiesel content. Because the slope or the regression equations are statistically significant in all cases and the R^2 statistics are high, there is no evidence in the data for the Cummins engine of the "threshold effect" that CARB staff claims which purports that biodiesel content has to reach the B5 or B10 level before NOx emissions begin to increase.

[2] See slide 18 of the staff presentation for the September 5th workshop which is available at http://www.arb.ca.gov/fuels/diesel/altdiesel/20130905ADFWorkshopPresentation.pdf

PRELIMINARY ANALYSIS SUBJECT TO REVISON

Table 1. 2006 Cummins Engine (Dynamometer Testing)

Model: NOx = A + B · BioPct

(Note: Dataset does not yet include the data on B5.)

Bright yellow highlight indicates result is statistically significant at 95% confidence level or better.
Light yellow highlight indicates result is statistically significant at the 90% confidence level or better.

Biodiesel Type	Test Cycle	R^2	Intercept A	BioPct Slope B		Predicted NOx Increase for B5	Predicted NOx Increase for B10
			Value	Value	p value	% Change	Pct Change
Soy-based							
	UDDS	0.997	5.896	0.0100	0.001	0.8%	1.7%
	FTP	0.995	2.024	0.0052	0.003	1.3%	2.6%
	40 mph	1.000	2.030	0.0037	<0.0001	0.9%	1.8%
	50 mph	0.969	1.733	0.0028	0.016	0.8%	1.6%
Animal-based							
	UDDS	0.847	5.911	0.0021	0.080	0.2%	0.4%
	FTP	0.981	2.067	0.0031	0.001	0.7%	1.4%
	50 mph	0.887	1.768	0.0011	0.058	0.3%	0.6%

Turning to the importance of the magnitude of the NOx increases, the South Coast Air Quality Management District (SCAQMD) Final 2012 Air Quality Management Plan estimates 2014 NOx emissions from on-road and non-road diesel vehicles to be approximately 190 tons per day.[4] This means that the approximately 1% increase in NOx emissions due to B5 blends translates to an increase of about 2 tons per day in NOx emissions in the South Coast Air Basin alone, while an approximately 2% increase at B10 equals 4 tons per day within that basin. Continuing to B20 the impact would be 8 tons per day. That these are significant increases is clearly evidenced by the fact that both CARB and SCAQMD have adopted numerous emission control measures targeting NOx that have achieved reductions that are similar to or smaller than these values.

ADF B3-108

Instead of acknowledging emissions testing data CARB itself generated that show increases in NOx emissions associated with B5 and B10 blends, CARB staff instead claims that more research is necessary before it can consider mitigation of B5 impacts: [5]

> *Staff is currently contracting with the University of California at Riverside to develop data to determine whether there are significant adverse air-related impacts from the use of B5 blends sufficient to warrant mitigation in the future.*

[4] See Figure 3-9 available at http://www.aqmd.gov/aqmp/2012aqmp/Final-February2013/MainDoc.pdf

[5] See page 4 of CARB's White Paper "Discussion of Conceptual Approach to Regulation of Alternative Diesel Fuels", February 15, 2013 which is available at http://www.arb.ca.gov/fuels/diesel/altdiesel/20130212ADFRegConcept.pdf

This represents an impermissible deferral of analysis and mitigation of significant impacts under CEQA. Moreover, as participants in the process that lead to the adoption of CARB's Low Carbon Fuel Standard (LCFS) regulation in 2009 where CARB adopted indirect land use change (ILUC) values based on preliminary and unsubstantiated modeling results claiming a need to rely on the best available science, Growth Energy finds CARB staff's current position that ignores actual data showing NOx increases from low level biodiesel blends to be unsupported.

ADF B3-108 cont.

2. The Proposed "Significance Threshold" for Biodiesel would Allow Significant Increases in NOx Emissions to Occur in the South Coast and San Joaquin Valley Air Basins Exacerbating Existing Air Quality Problems

In addition to CARB staff's failure to analyze low-level biodiesel blends, the "significance threshold" proposed by CARB staff for biodiesel use in California would allow significant increases in NOx emissions due to biodiesel use to occur in the South Coast and San Joaquin Valley air basins that experience the worst air quality problems in the state.

According to CARB staff's presentation for the September workshop,[6] staff is proposing to evaluate the significance of NOx increases due to biodiesel use on a statewide rather than a regional basis. Given the proposed use of a statewide average biodiesel level and the B10 significance threshold, the potential exists for significant quantities of B20 or even higher levels of biodiesel blends to be used without mitigation in areas of the state with significant air quality problems, such as the South Coast and/or San Joaquin Valley air basins. At this point, even CARB staff acknowledges that use of B20 blends results in significant NOx increases and as noted above based on CARB's own test data B20 use in the South Coast Air Basin could increase NOx emissions by as much as 8 tons per day in 2014.

ADF B3-109

Given the severe air quality problems that exist in the South Coast and San Joaquin Valley air basins, CARB must modify the proposed ADF regulation so that it guarantees that increased NOx emissions related to biodiesel use would not occur in these areas. The reduction of NOx emissions is important, particularly in light of CARB's "Vision for Clean Air,"[7] which demands the elimination of NOx emissions from diesel engines in both air basins as a perquisite for achieving the state's air quality goals.

3. The Proposed Transfer of Credit for Reductions in NOx Emissions Generated by Low NOx Diesel Producers to Offset Increases in NOx Emissions Generated by Biodiesel Producers is Not Equitable

[6] See slide 18 of the staff presentation for the September 5th workshop which is available at http://www.arb.ca.gov/fuels/diesel/altdiesel/20130905ADFWorkshopPresentation.pdf
[7] See http://www.arb.ca.gov/planning/vision/docs/vision_for_clean_air_public_review_draft.pdf

According to CARB staff's presentation at the September workshop,[8] staff is proposing to directly offset increases in NOx emissions resulting from the use of biodiesel with reductions in emissions due to the use of "low NOx" diesel fuels, which are defined by specific properties as shown in the staff presentation for the September 5th workshop.[9] To date, however, we are unaware of any information or explanation from CARB staff as to why producers of low NOx diesel fuels should be forced by CARB regulations to surrender credit for the NOx emission reductions their fuels achieve in order to benefit the producers of biodiesel fuels which increase NOx emissions.

Given that the production of low NOx diesel fuel is not currently mandated by any existing CARB regulation, the resulting emission benefits should be considered "surplus," and could presumably be used to generate Mobile Source Emission Reduction Credits under CARB regulations.[10] Further, the use of such fuels by fleets or distribution of such fuels by fuel providers could potentially be considered to be projects that qualify for incentive funding under the Carl Moyer Program.[11] ADF B3-110

Instead of forcing producers of low NOx diesel fuels to transfer the credit for the NOx reductions attributable to their products without compensation to producers of biodiesel fuels that increase NOx emissions, CARB should establish a market mechanism to incentivize the production of low NOx fuels and to disincentivize the production of NOx-increasing biodiesel fuels. The most logical approach to accomplish this would seem to be providing NOx reduction credits to producers of low NOx fuels under the LCFS regulation while assigning NOx emission debits to producers of biodiesel and then requiring the latter to purchase and surrender credits sufficient to offset the increases in NOx emissions associated with their products.

4. The Proposed Treatment of Biodiesel and Biodiesel Blends Used in "New Technology Diesel Engines" (NTDEs) is Not Equitable With CARB's Treatment of Other Fuels

In addition to defects with the proposed ADF regulations described above, we are unaware of any published analysis or supporting data that the use of biodiesel at any concentration in NTDE's would not result in increased NOx emissions. The rationale for this treatment appears to be an assumption that the advanced emission control systems found on NTDEs eliminate any impact of fuel composition on emissions of NOx and potentially other pollutants.

ADF B3-111

Our primary concern with this proposal is that CARB staff has not provided any supporting data or analysis. In addition, if NTDEs are truly insensitive to fuel composition impacts, CARB should make changes similar to those proposed by biodiesel for other fuels. More specifically, if CARB staff's assumption that NTDE emissions are not sensitive to fuel composition is in fact correct, it follows that there is no longer any need to use CARB diesel fuel in NTDEs instead of less expensive federal diesel fuels which could be substituted without any adverse emission impacts.

---

[8] See slide 19 of the staff presentation for the September 5th workshop which is available at http://www.arb.ca.gov/fuels/diesel/altdiesel/20130905ADFWorkshopPresentation.pdf

[9] See slide 24 of the staff presentation for the September 5th workshop which is available at http://www.arb.ca.gov/fuels/diesel/altdiesel/20130905ADFWorkshopPresentation.pdf

[10] See http://www.arb.ca.gov/msprog/mserc/mserc.htm

[11] See http://www.arb.ca.gov/msprog/moyer/moyer.htm

Clearly, CARB could develop a "significance threshold" for the sale of federal diesel fuel in California similar to that proposed for biodiesel which would achieve this objective while providing the benefit of reduced diesel costs without adverse air quality impacts. Growth Energy therefore encourages CARB staff to revise the ADF to avoid these impacts.

Vision for Clean Air: A Framework for Air Quality and Climate Planning

This document has been prepared by the staffs of the California Air Resources Board, the South Coast Air Quality Management District and the San Joaquin Valley Unified Air Pollution Control District. Publication does not signify that the contents reflect the views and policies of the Air Resources Board, the South Coast Air Quality Management District or the San Joaquin Valley Unified Air Pollution Control District. This document will be presented as an informational item at a noticed public meeting scheduled for June 28, 2012.

Table of Contents

Executive Summary

As California plans for the future, transformational technologies, cleaner energy, and greater efficiency are expected to provide the foundation for meeting air quality standards and climate goals. California's success in reducing smog has largely relied on technology and fuel advances, and as health-based air quality standards are tightened, the introduction of cleaner technologies must keep pace. More broadly, a transition to zero- and near-zero emission technologies is necessary to meet 2023 and 2032 air quality standards and 2050 climate goals. Many of the same technologies will address both air quality and climate needs. As such, strategies developed for air quality and climate change planning should be coordinated to make the most efficient use of limited resources and the time needed to develop cleaner technologies.

Vision for Clean Air: A Framework for Air Quality and Climate Planning takes a coordinated look at strategies to meet California's multiple air quality and climate goals well into the future. Its quantitative demonstration of the needed technology and energy transformation provides a foundation for future integrated air quality and climate program development. *Vision for Clean Air* focuses on mobile sources and associated energy production. Similar analyses will be necessary for industrial and other emission sources to develop a complete foundation for integrated planning.

Recognizing that the severity of California's air quality problems varies by region, *Vision for Clean Air* examines what is needed to attain air quality standards by the federal deadlines in the areas with the worst air quality -- the South Coast Air Basin and the San Joaquin Valley Air Basin. However, the technologies and strategies identified will pay clean air dividends for all air districts, helping them achieve or maintain federal air quality standards and reduce local air toxics exposure.

Ozone and Climate Planning Horizons

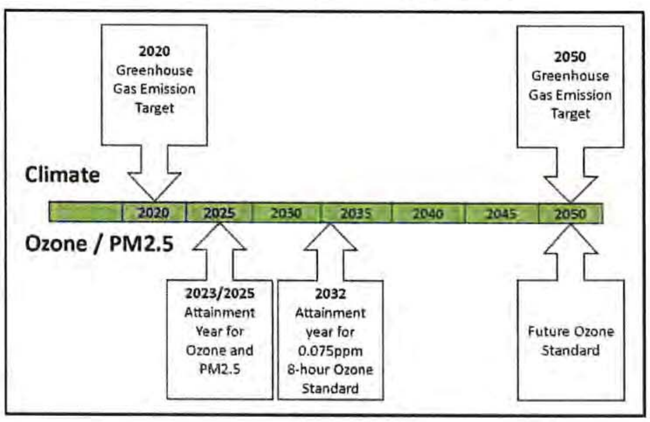

Figure 1

Achieving the 2020 greenhouse gas emission target established by the Global Warming Solutions Act of 2006 (AB 32) is a statewide goal. For the long term, California has set for itself the 2050 goal of greenhouse gas emissions of 80 percent less than 1990 levels overall, and specifically 80 percent less than 1990 levels for the transportation sector.[1] In 2013, the

[1] Governor Brown Executive Order B-16-2012

AB 32 Scoping Plan will be updated to address post-2020 greenhouse gas emissions.

In 2009, the Air Resources Board (ARB), the South Coast Air Quality Management District (SCAQMD) and the San Joaquin Valley Air Pollution Control District (SJVAPCD) developed a partnership with the U.S. Environmental Protection Agency (U.S. EPA) to promote technology advancements needed to meet air quality standards by federal deadlines. In *Vision for Clean Air,* ARB and the South Coast and San Joaquin Valley air districts examine how those technologies can meet both air quality and climate goals over time.

California's deadlines for meeting federal air quality standards extend past 2020, and U.S. EPA recently announced that the deadline for the updated ozone standard will be 2032.[2] Since scientific studies continue to document health impacts of air pollution at progressively lower levels, air quality standards are periodically revised, becoming more stringent over time. Broad deployment of zero- and near-zero emission technologies in the South Coast and San Joaquin Valley air basins will be needed in the 2023 to 2032 timeframe to attain current national health-based air quality standards as required by federal law.

For greenhouse gases, California's 2050 climate goal provides an ambitious long-term target. Many strategies developed to meet the shorter-term air quality standards — notably use of cleaner energy sources — will have benefits toward the longer-term climate goal. Pursuing cleaner energy sources is also the focus of the State's energy policies, providing the opportunity for economic, as well as environmental benefits. Coordinated planning with identified milestones will support the transition to zero-and near-zero emission technologies needed to meet these goals.

To explore the scope of technology advancements needed to meet air quality and climate goals, several key questions are posed:

- What technologies, fuels, and other strategies are needed to meet local air quality and greenhouse gas goals? Are they the same?
- What are the implications of federal air quality deadlines coming 20 to 30 years before the 2050 greenhouse gas goal?
- How can the strategies to meet local air quality targets and greenhouse gas goals best complement each other?
- What are the energy infrastructure demands of coordinated air quality and greenhouse gas strategies?

[2] *Vision for Clean Air* uses 2035 as the target date for the updated ozone standard. After the analytical effort for *Vision for Clean Air* began, U.S. EPA formally set the attainment deadline at 2032.

- How do California's air quality and climate policies need to adapt as emissions move from the vehicle itself to predominantly upstream sources such as electricity and hydrogen or equivalent generation facilities?

Quantitative scenarios were developed for key transportation-related sectors to gain insight into the key questions above. The sectors that are the focus of this report are by far the largest contributors to greenhouse gas emissions and regional air pollution in California. Greenhouse gas emission reduction goals are statewide and the scenarios use a lifecycle emissions analysis approach. The analysis of smog-forming pollutants is regional, reflecting the need to meet air quality standards on that basis. The localized impacts of toxic diesel particulate matter are recognized, and play an important role when evaluating the passenger and freight transport systems. Reducing emissions in these mobile source sectors is key to attaining air quality and climate goals, but does not represent all of the emission reductions needed for individual regions to demonstrate attainment of federal air quality standards. Comprehensive attainment strategies containing both mobile and stationary source measures will be developed as individual regions develop new air quality plans.

The scenarios illustrate the nature of the technology transformation needed to meet the multiple program milestones through 2050. The scenarios highlight the interplay between reducing smog-forming pollutants and greenhouse gases. The scenario results demonstrate the importance of considering the multi-pollutant impacts of policy choices. Planning efforts, public investment, and rulemaking decisions by State, federal, and local agencies will play an important role in the outcome. In making these decisions, agencies will need to consider factors including technical feasibility and cost, downstream and upstream emission reduction potential, energy production capacity and infrastructure, and the necessary pace of transformation needed to meet air quality and climate goals.

In designing the scenarios, it was necessary to make general assumptions about future growth, the pace of introduction of various technologies, and other factors. It is recognized that the scenarios contained herein are not the only pathways to meet air quality and climate goals. Thus, the scenarios are not refined analyses that would be directly used for program development, but will provide input into future planning efforts by air quality agencies. Similarly, economic and environmental analyses are steps that need to be done in future plans.

An update to the AB 32 Scoping Plan is due in 2013. State Implementation Plans (SIPs) to meet the federal particulate matter air quality standards in the South Coast and the San Joaquin Valley are due later this year and major ozone SIPs for the recently updated federal ozone standard will be due in 2015. More detailed analyses will begin to emerge as part of these efforts.

Achieving California's Air Quality and Climate Goals

The federal Clean Air Act requires states to identify the reductions of smog-forming emissions necessary to meet each federal air quality standard. Also under the federal planning process, states must identify the actions needed to bring emissions down to the attainment levels by the required deadlines. These two parts of a state's SIP comprise the attainment demonstration. Federal rules set out detailed procedures, technical requirements, and public processes for the development of attainment demonstrations. As mentioned earlier, the scenarios in *Vision for Clean Air* are not intended to be attainment demonstrations within the meaning of the Clean Air Act, but they do serve to illustrate the scale of technology change needed to meet the federal standards in 2023 and beyond. The federal Clean Air Act specifically recognizes the need for advanced technologies in attainment demonstrations for extreme ozone nonattainment areas. The South Coast and San Joaquin Valley air basins are the only two extreme ozone areas in the nation.

> ***Meeting Federal Ozone Standards***
>
> **For the South Coast Air Basin, it is estimated that oxides of nitrogen, one of the key ingredients in ozone and fine particulate formation, must be reduced by around 80 percent from 2010 levels by 2023, and almost 90 percent by 2032. Similar levels of emissions reductions are likely needed in the San Joaquin Valley by 2032.**

The federally approved SIPs for these two regions rely on a mix of currently available technologies and the development of advanced technologies in order to attain the ozone air quality standard by 2023. Reaching the longer-term 2032 ozone air quality standard and the 2050 climate goal requires even greater transformation. This includes, for example, nearly complete transformation of passenger vehicles to zero-emission technologies, approximately 80 percent of the truck fleet to zero-or near-zero technology, and nearly all locomotives operating in the South Coast air basin to be using some form of zero-emission technology.

> ***Meeting Climate Change Goals***
>
> **To meet the goal of reducing California's greenhouse gas emissions to 1990 levels by 2050, emissions must be reduced by 85 percent from today's levels.**

The Global Warming Solutions Act of 2006 set the 2020 greenhouse gas emissions reduction goal into law. It directed ARB to develop early actions to reduce greenhouse gases while also preparing a Scoping Plan to identify how best to reach the 2020 limit. The State's goal to further reduce greenhouse gases by 2050 was first established when Governor Schwarzenegger signed Executive Order S-3-05 in 2005. In March 2012, Governor Brown issued Executive Order B-16-2012 setting a California target for reductions of greenhouse gas emissions from the transportation sector of 80 percent less than 1990 levels by 2050 and calling for the establishment of benchmarks for the penetration of zero-emission vehicles and infrastructure for 2015, 2020, and 2025.

Coordinated Air Quality and Climate Planning

The *Vision for Clean Air* scenarios illustrate seven key concepts that together provide a foundation for coordinated solutions to California's air quality and climate goals.

- **Technology Transformation:** Transformation to advanced, zero-and near-zero emission technologies, renewable clean fuels, and greater efficiency that can achieve both federal air quality standards and climate goals.
- **Early Action:** Acceleration of the pace of transformation to meet federal air quality standard deadlines, with early actions to develop and deploy zero- and near-zero technologies also needed to meet climate goals.
- **Cleaner Combustion:** Advanced technology NOx emissions standards for on- and off-road heavy-duty engines beyond the cleanest available today to meet federal air quality standards in a timely manner.
- **Multiple Strategies:** A combination of strategies — technology, energy, and efficiency — applied to each sector.
- **Federal Action:** Federal actions, in addition to actions by state and local agencies and governments, to help clean-up sources that travel nationally and internationally such as trucks, ships, locomotives and aircraft.
- **Efficiency Gains:** Greater system and operational efficiencies to mitigate the impacts of growth, especially in high-growth freight transport sectors and vehicle efficiency gains to reduce fuel usage and mitigate the cost of new technologies.
- **Energy Transformation:** Transformation of the upstream energy sector and its greenhouse gas and smog forming emissions concurrent with the transformation to advanced technologies downstream.

Development of coordinated solutions to California's air quality and climate goals will require the efforts of multiple agencies at all levels of government. The solutions span all sectors, rely on the development of multiple technologies, and require the coordinated deployment of technologies and energy infrastructure. ARB has the role of setting technology-forcing standards for mobile sources that have been the distinguishing feature of the State's air quality progress and climate leadership. Action by the federal government, for trucks, locomotives, aircraft, and ships, is also critical. Finally, transformation of the energy sector will require multiple agencies, including the California Energy Commission, the Public Utilities Commission, ARB, and local air districts, to share a common vision.

The SCAQMD, SJVAPCD, and other local air districts play a key role through actions to accelerate the use of new, cleaner mobile technologies at the regional level to improve air quality and meet federal air quality standards. While *Vision for Clean Air* focuses on the mobile sectors and the energy system to power them, attainment of the federal air quality standards will also require similar transformation of traditional stationary sources covered through SIP planning. Air districts will need to continue their actions to reduce emissions from these sources in order to meet federal requirements. Metropolitan planning organizations, port authorities, and local governments will also play important roles in the overall pollution control strategies.

Private sector activities will be key to developing the technology, building the engines, and implementing the necessary transformation. Engine and vehicle manufacturers will need to continue the development and marketing of advanced technologies. Energy industries will need to supply the renewable fuels and energy, including the necessary infrastructure. In the freight transport industries, increased efficiencies that support growth while mitigating environmental impacts will be essential. Both public and private investment will be needed to enable the technology transformation necessary to achieve California's air quality and climate goals.

Vision for Clean Air lays the foundation for an integrated approach to develop and deploy the cleanest emissions control technologies. For many of the sectors discussed, zero- and near-zero emission technologies have been developed or anticipated to be developed over the next few years. *Vision for Clean Air* provides a timeline for coordinated development and accelerated deployment of the types of technologies expected to be needed in each of the sectors.

Vision for Clean Air is being released as a draft document for discussion at a public meeting in June 2012 and at public workshops in August. The document sets the stage for subsequent planning efforts through scenarios designed to illustrate the scope of change needed to meet federal air quality standards and California's climate goals. The scenarios presented are not intended to identify a specific course of action to meet each air quality and climate goal. Nor are the scenarios a prediction of the actual mix of vehicle technologies, fuels, and clean energy sources expected to emerge in the long term. Public and private investment, regulatory decisions, and consumer preferences will all affect the success of specific strategies and options to meet these ambitious goals.

An Approach for Integrating Air Quality and Climate Planning

The federally approved 2007 State Implementation Plans for the South Coast Air Basin and the San Joaquin Valley Air Basin call for broad use of advanced technologies, clean energy, and greater efficiencies to provide the foundation for meeting federal air quality standards. The 2008 Scoping Plan, required by California's Global Warming Solutions Act of 2006, similarly called for a statewide transition to clean energy and advanced technologies and outlined actions toward that end. To understand the interplay among strategies to meet air quality and climate goals, and to develop common and effective solutions to both, basic questions need to be answered. These include:

Crosscutting Issues

Figure 2

- What technologies, fuels, and other strategies are needed to meet local air quality and greenhouse gas goals? Are they the same?
- What are the implications of federal air quality deadlines coming 20 to 30 years before the 2050 greenhouse gas goal?
- Is the pace of needed transformation the same? How can the strategies to meet air quality targets and greenhouse gas goals best complement each other?
- What are the energy infrastructure demands of coordinated air quality and greenhouse gas strategies?
- How do California's air quality and climate policies need to adapt as emissions move from the vehicle itself to predominantly upstream sources such as electricity and hydrogen generation facilities?

To begin to answer these questions and lay a foundation for future coordinated planning for criteria pollutants regulated through air quality standards (i.e., criteria pollutants), toxic pollutants such as diesel particulate matter, and greenhouse gases, *Vision for Clean Air* uses quantitative scenarios. These scenarios examine the nature of the technology and fuel transformation needed to meet the multiple air quality and greenhouse gas milestones between now and 2050.

Vision Scenarios

Under the Clean Air Act, traditional air quality planning typically focuses on the emissions reductions expected in a single future year from regulations adopted in the immediate three to five years. *Vision for Clean Air* takes a broader approach and uses scenarios to illustrate the change needed in multiple milestone years to meet future emissions targets. This effort is not a plan, but rather, it provides valuable insight for future planning efforts that will include a stakeholder input process. This long-term approach is more common in greenhouse gas analyses. The advantage of long-term planning is that it reveals the scope of advanced technologies needed, how quickly the technologies need to come on line, and the key decision points for technology development and deployment along the way.

A scenario is a combination of technology, energy, and efficiency assumptions that change over time. Scenarios represent a projection of what could be possible — a ~~-~~what if" story that provides context for decision-making. Scenarios are intended to inform decision-making but are not predictions of what the future will be. So rather than being a list of State Implementation Plan or SIP-ready control measures, the scenarios provide a view of a mix of technologies that could be successful in helping California meet its multi-pollutant goals. Further, the scenarios do not represent a policy choice that favors certain technologies and fuels over others. This scenario planning effort does not identify winners or losers on a specific path to meet air quality and climate goals. Rather, it demonstrates a combination of technologies and fuels that yield the scale of needed transformation. Any other mix of technologies and fuels achieving equivalent or better regional criteria pollutant and life cycle greenhouse gas reductions can be considered part of the scenario.

A Scenario is a "What If" Set of Assumptions about Technologies, Fuels and Efficiencies

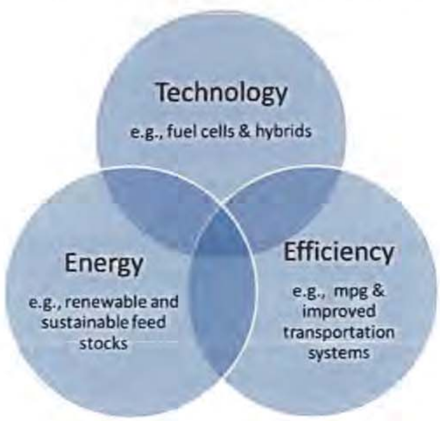

Figure 3

Scenarios were developed through an iterative process of assuming varying levels of technology sales penetration, fuel supply, and efficiency changes. These are ambitious assumptions going beyond the existing programs, and could be expected to require further actions, such as innovation, investment, incentives, and regulations to achieve. However, the scenarios do not include actions such as further incentive funding to accelerate penetration of advanced technologies and clean fuels to meet federal

Scenarios for Mobile Sectors

Scenarios have been developed for passenger cars; freight transport, including trucks, ships, locomotives, cargo handling equipment, and harbor craft; planes, and off-road equipment. The scenarios also include the refineries and power plants needed to produce the fuels and electricity to power the engines in these devices. Together, this covers approximately 45 percent of the State's greenhouse gas emissions and approximately 85 percent of its NOx emissions. The remainder of the greenhouse gas emissions are from non-transportation related sources such as industrial, power generation, commercial, residential and agricultural uses.

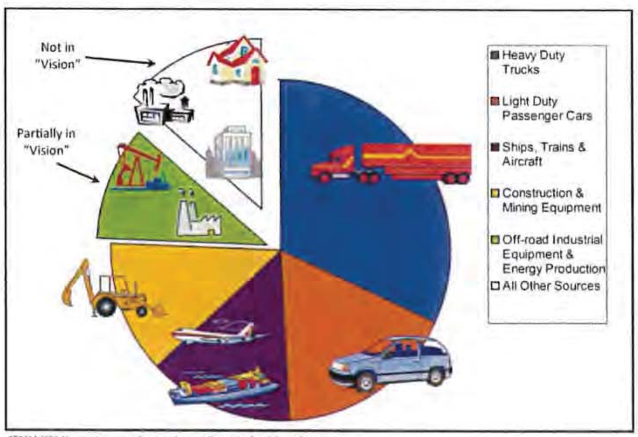
air quality deadlines. For example, expedited turnover of vehicles, as has been achieved with incentives programs implemented by State and local jurisdictions, is not assumed in the scenarios. All of the scenarios include as the starting point all technology and fuel regulations in place today, including passenger vehicle standards, truck and engine standards, the low carbon fuel standard, and the 33 percent renewable electricity requirement.

Most of the technologies and energy sources relied on in the scenarios exist in some form today; some technologies are already on the market, while others are still maturing through demonstration programs and limited test markets.[3] As a result, *Vision for Clean Air* focuses on the development and deployment of emerging technologies not the invention of undefined future technologies. The available technologies that provide fewer smog-forming and greenhouse gas emissions are fuel cells, electric hybrids with a large portion operating in an —all lectric range", and electric vehicles, a combination of which is assumed to be the future norm over time. Similarly, alternative fuels such as hydrogen and clean biofuels such as cellulosic ethanol and biomethane and other renewable energy sources are assumed to play an important role in the energy sectors. Additional operational efficiencies to reduce vehicle miles traveled and overall energy demand are also assumed to occur.

Vision Targets

Targets are characterized as the percent reduction needed from today's emission levels in order to meet the federal air quality standards for ozone and the State's long-term goal to reduce greenhouse gas emissions to 80 percent below 1990 levels by 2050. New federal air quality standards for particulate matter are also expected in the near future. Legally-binding emission targets to attain federal air quality standards are established through the air quality planning process set out in State and federal law. The attainment targets for the 0.080 ppm ozone standard, with a 2023 attainment date, are set in the State's federally approved ozone plans. Planning for the 0.075 ppm federal standard is just beginning, but the attainment target is 2032 for the

Relationship of Vision Inventory to SIP Inventory
2010 NOx SIP Sources as Portion of Total Inventory



CEPAM 2009 Almanac Inventory, Summer Average Emissions, South Coast Emissions

Figure 4

[3] The single exception is the carbon capture sequestration process that will be necessary if fossil fuels are to remain in the energy mix of the future. This process has been demonstrated in limited cases, but long-term data has yet to be developed.

extreme ozone areas of the South Coast Air Basin and San Joaquin Valley. The targets used here are estimates of what the attainment targets could be past 2023 based on current air quality information. *Vision for Clean Air* focuses on oxides of nitrogen (NOx) emissions as NOx is the most critical pollutant for reducing regional ozone and fine particulate matter.

The SIP air quality targets and the 2050 greenhouse gas goal apply to the total emissions from all sources. In developing future SIPs and climate plans, the full spectrum of emissions sources must be considered. *Vision for Clean Air* focuses on mobile sectors and assumes the same percent reduction must be achieved by each. Future planning efforts will need to look at the tradeoffs among strategies for specific source categories that achieve relatively more or fewer reductions in light of technological, economic, and other factors. The following are the air quality goals used in the scenario development process:

- Achieve the 0.08 ppm 8-hour federal ozone standard by 2023 by reducing NOx emissions by 80 percent from 2010 levels.

- Achieve the 0.075 ppm 8-hour federal ozone standard by 2032 by reducing NOx emissions by 90 percent from 2010 levels.

- Reduce greenhouse gas emissions by 80 percent below 1990 levels by 2050. This is equivalent to 85 percent from today's levels.

This document does not evaluate emission reductions needed to attain a potential new ozone standard (i.e., 0.06 - 0.07 ppm 8-hr standard). As scientific studies are documenting health impacts of air pollution at very low levels, it is expected that further NOx reductions will be needed in the long-term. U.S. EPA is expected to consider adopting an ozone standard lower than 0.075 ppm in 2013. Achieving a future ozone standard in the range EPA is expected to consider could require additional NOx emissions reductions, totaling 95 percent from 2010 levels.

Air Quality Challenges in the South Coast and San Joaquin Valley

California is home to two of the nation's most pressing air quality challenges. The South Coast and the San Joaquin Valley are the only two areas in the country designated as extreme nonattainment for the federal ozone standard. These same two areas also experience high levels of fine particulate matter. Because of the severity of the air quality changes in these two areas, they determine the transformational change needed to meet federal air quality standards throughout the State. Still, while they face a similar air quality challenge, they are different in terms of the nature of their emission sources.

South Coast Air Basin

The 2007 SIP for the federal ozone standard contains commitments for emission reductions from mobile sources that rely on advancement of technologies, as authorized under Section 182(e)(5) of the federal Clean Air Act. These measures, which have come to be known as the —Black Box," account for a substantial portion of the NOx emission reductions needed to attain the federal ozone standards — over 200 tons/day. Attaining these standards will require reductions in emissions of nitrogen oxides (NOx) well beyond reductions resulting from current rules, programs, and commercially-available technologies.

Mobile sources emit over 80 percent of regional NOx and therefore must be the largest part of the solution. For the South Coast, the top NOx emission sources projected in 2023 are shown in Figure 5. On-road truck categories are projected to comprise the single largest contributor to regional NOx in 2023. Other equipment involved in goods movement, such as marine vessels, locomotives and aircraft, are also substantial NOx sources.

Largest South Coast NOx Emission Sources
2023 in tons per day

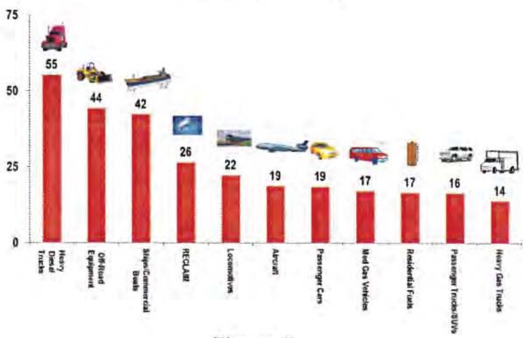


Figure 5

Preliminary projections indicate that the region must reduce regional NOx emissions by about two-thirds by 2023 beyond the benefits of adopted rules and programs, and three quarters by 2032, to attain the national ozone standards as required by federal law.

Since most of the significant sources are already controlled by over 90 percent, attainment of the ozone standards in the South Coast Air Basin will require broad deployment of zero- and near-zero emission technologies in the 2023 to 2032 timeframe. On-land transportation sources such as trucks, locomotives, and cargo handling equipment have technological potential to achieve zero- and near-zero emission levels. Current and potential technologies include hybrid-electric, battery-electric, and hydrogen fuel cell on-road vehicle technologies. Other technologies and fuels may also serve regional

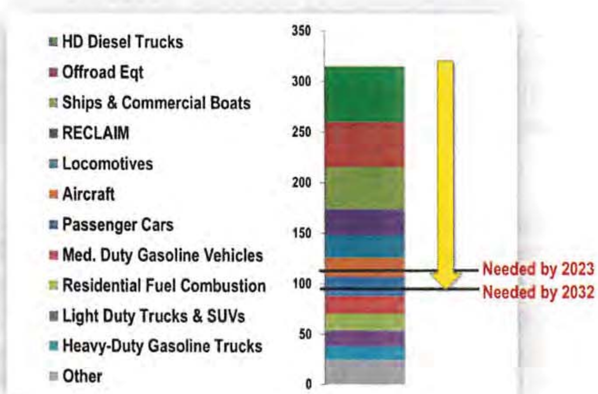

Figure 6

needs, e.g. natural gas-electric hybrids or alternative fuels coupled with advanced aftertreatment technologies. Air quality regulatory agencies have historically set policies and requirements that are performance based and allow any technologies that will achieve needed emission reductions on time.

While there has been much progress in developing and deploying transportation technologies with zero- and near-zero emissions (particularly for light-duty vehicles and passenger transit), additional technology development, demonstration, and commercialization will be required prior to broad deployment in freight and other applications.

San Joaquin Valley Air Basin

Diesel trucks are also the single largest source of NOx emissions in the San Joaquin Valley. However, truck traffic in the Valley is dominated by interstate trucks and other through traffic traveling on the major north-south corridors of Interstate 5 and State Route 99. In contrast, a significant amount of South Coast truck traffic is associated with freight transport from the ports and inland. As a result, the age and activity of the trucks in the two regions differ, suggesting that there may be different options and constraints in terms of technology transformation for trucks that operate in the Valley.

Passenger vehicles are the second largest source of NOx emissions in the San Joaquin Valley. The Valley may present different challenges in terms of infrastructure to support advanced technology passenger vehicles given the nature of urban development in the region.

With the most productive agricultural region in the nation, the San Joaquin Valley is also home to the unique emissions sources of the agricultural industry. While mobile agricultural equipment emissions are significant, a separate scenario was not developed for these sources. Efforts are underway now to clean up mobile agricultural equipment to the cleanest currently available conventional technology. Emission reductions from those efforts are important for reducing ozone levels and measures to achieve these reductions are part of the region's ozone SIP. Given the challenges posed by the operational requirements of this type of equipment and the importance of continuing the current cleanup efforts, consideration of potential future technologies is not included here.

The current NOx targets are set in the approved ozone SIP for the San Joaquin Valley. Like the South Coast, the San Joaquin Valley SIP includes longer-term (—BlackBox") emission reductions due by 2023. Because emissions in the South Coast are so large compared to the Valley, the absolute magnitude of the reductions needed is less than in the South Coast. Nevertheless, the scale of needed transformation is similar. Air quality modeling for the San Joaquin Valley to determine what emission reductions are needed to attain the 0.075 ppm ozone standard in 2032 will be done for the SIP due in 2015. Given the stringent level of the standard, it is expected that on a percentage basis the San Joaquin Valley and South Coast will need a similar magnitude of new reductions.

Vision Tool

A spreadsheet-based tool developed from the Argonne National Laboratory Vision 2011 Model was used to evaluate the scenarios. The Argonne model was intended to be used to evaluate transportation energy policy questions in the context of greenhouse gas emissions. The *Vision for Clean Air* effort started with the Argonne model and was heavily modified and expanded, such that the tool used for *Vision for Clean Air* is fundamentally a different model.

The basic steps outlined in Figure 7 forecast penetration of vehicle technology and fuels into passenger car and truck fleets based on vehicle stock turnover rates, the rates at which new vehicles and technologies enter the fleet and old vehicles leave. The Argonne model is limited in that it only models greenhouse gases and only for passenger vehicles and trucks based on national fleet characteristics. The tool used for *Vision for Clean Air* adds forecasting capability for smog-forming pollutants (NOx and reactive organic gases) and diesel particles. It is also a California-specific model using new vehicle sales, vehicle miles traveled, vehicle survival rates, and emission rates from ARB's mobile source emissions model, EMFAC. Finally, non-road mobile sources, off-road equipment, locomotives, ships, harbor craft, and cargo handling equipment are included based on ARB's existing emissions inventory models for these sources.

Vision for Clean Air Modeling Structure

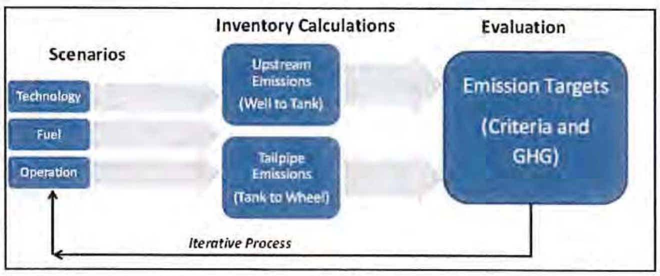

Figure 7

Fuel and electricity demand are estimated by type based on the fleet technology mix, vehicle miles traveled, and engine efficiencies. Emissions from energy production activities are then calculated using assumptions about fuel feedstock, carbon intensity, and NOx emission rates. Carbon emissions are calculated with a global lifecycle from energy production to end use. Smog-forming emissions use a modified life-cycle approach where upstream, fuel pathway emissions are included only if they are within the region studied in the scenario. For simplicity, it was assumed that one half of the NOx emissions from mobile source-related energy production occur within the region in which the energy is used.

This modified lifecycle approach for analyzing smog-forming emissions associated with mobile-source energy production differs from typical air quality planning. In SIPs, mobile and stationary source emissions (including refineries and power plants) are calculated and reported separately. The advantage to linking upstream and

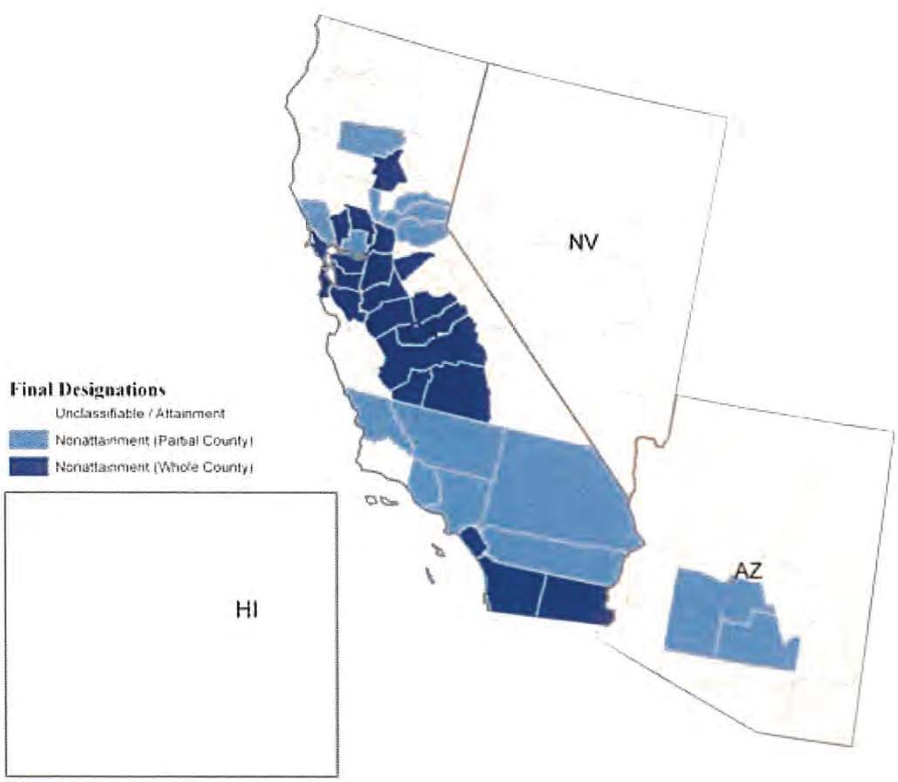
Area Designations for 2008 Ground-level Ozone Standards

2008 Ground-level Ozone Standards — Region 9 Final Designations, April 2012

EPA is implementing the 2008 ozone standards as required by the Clean Air Act. Meeting these standards will provide important public and environmental health benefits. EPA has worked closely with states and tribes to identify areas in the country that meet the standards and those that need to take steps to reduce ozone pollution.

EPAs final designations are based on air quality monitoring data, recommendations submitted by the states and tribes, and other technical information. EPA will work closely with states and tribes to implement the standards using a common sense approach that improves air quality, maximizes flexibilities and minimizes burden on state and local governments.

Map of Final Designations - EPA Region 9



This table identifies area designations for EPAs region 9 states. In some cases EPA designated partial counties. These are identified by a (P). If a county is not listed below, EPA has designated it as unclassifiable/attainment.

EPA Areas for Designations for the 2008 Ozone Standards

State	Area Name	Counties	Area Classification
American Samoa	Entire territory is unclassifiable/attainment		
Arizona	Phoenix-Mesa, AZ	Maricopa (p)	Marginal
		Pinal (p)	
	Rest of state is unclassifiable/attainment		
California	Calaveras County, CA	Calaveras	Marginal
	Chico (Butte County), CA	Butte	Marginal
	Imperial County, CA	Imperial	Marginal
	Kern County (Eastern Kern), CA	Kern (p)	Marginal
	Los Angeles-San Bernardino Counties (West Mojave Desert), CA	Los Angeles (p)	Severe
		San Bernardino (p)	
	Los Angeles-South Coast Air Basin, CA	Los Angeles (p)	Extreme
		Orange	
		Riverside (p)	
		San Bernardino (p)	
	Mariposa County, CA	Mariposa	Marginal
	Nevada County (Western part), CA	Nevada (p)	Marginal
	Riverside County (Coachella Valley), CA	Riverside (p)	Severe
	Sacramento Metro, CA	El Dorado (p)	Severe
		Placer (p)	
		Sacramento	
		Solano (p)	
		Sutter (p)	
		Yolo	
	San Diego County, CA	San Diego	Marginal
	San Francisco Bay Area, CA	Alameda	Marginal
		Contra Costa	
		Marin	
		Napa	
		San Francisco	
		San Mateo	

State	Area Name	Counties	Area Classification
		Santa Clara	
		Solano (p)	
		Sonoma (p)	
	San Joaquin Valley, CA	Fresno	Extreme
		Kern (p)	
		Kings	
		Madera	
		Merced	
		San Joaquin	
		Stanislaus	
		Tulare	
	San Luis Obispo (Eastern San Luis Obispo), CA	San Luis Obispo (p)	Marginal
	Tuscan Buttes, CA	Tehama (p)	Marginal
	Ventura County, CA	Ventura (p)	Serious
	Morongo Areas of Indian Country (Morongo Band of Mission Indians)	Areas of Indian Country	Serious
	Pechanga Areas of Indian Country (Pechanga Band of Luiseno Mission Indians of the Pechanga Reservation)	Areas of Indian Country	Moderate
	Rest of state is unclassifiable/attainment		
Guam	Entire territory is unclassifiable/attainment		
Hawaii	Entire state is unclassifiable/attainment		
Nevada	Entire state is unclassifiable/attainment		
Northern Mariana Islands	Entire territory is unclassifiable/attainment

GUIDE FOR ASSESSING AND MITIGATING AIR QUALITY IMPACTS

Prepared by
the Mobile Source/CEQA Section
of the Planning Division
of the San Joaquin Valley Air Pollution Control District
1990 E. Gettysburg Avenue
Fresno, CA 93726

January 10, 2002 revision
Adopted August 20, 1998

This document is an advisory document, that provides Lead Agencies, consultants, and project applicants with uniform procedures for addressing air quality in environmental documents. Copies and updates are available from the SJVAPCD Planning Division at (559) 230-5800. Questions on content should be addressed to either the Mobile Source/ CEQA Section at (559) 230-5800 or the SJVAPCD CEQA representative at the regional office that covers the county in which the project is located.

David L. Crow – Executive Director/Air Pollution Control Officer
Mark Boese – Deputy Air Pollution Control Officer
Robert Dowell – Director of Planning
Richard Milhorn – Planning Manager

ACKNOWLEDGEMENTS

The principal authors of this document were:

- Dave Mitchell – Supervisor, Mobile Source / CEQA Section
- Joe O'Bannon – (former) Air Quality Planner, Southern Region
- Joan Merchen – Senior Air Quality Planner, Central Region

Significant contributions were also made by:

- Phil Jay – District Counsel

- Cheryl Lesinski – (former) Environmental Planner, Central Region
- Dave Stagnaro – (former) Environmental Planner, Northern Region

GUIDE FOR ASSESSING AND MITIGATING AIR QUALITY IMPACTS

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

Demolition Asbestos Impacts. Project construction sometimes requires the demolition of existing buildings at the project site. Buildings often include materials containing asbestos. Airborne asbestos fibers pose a serious health threat if adequate control techniques are not carried out when the material is disturbed. The demolition, renovation, or removal of asbestos-containing materials is subject to the limitations of the National Emissions Standards for Hazardous Air Pollutants (NESHAP) regulations as listed in the Code of Federal Regulations[34] requiring notification and inspection. Most demolitions and many renovations are subject to an asbestos inspection prior to start of activity. The SJVAPCD's Compliance Division in the appropriate region should be consulted prior to commencing any demolition or renovation of any building to determine inspection and compliance requirements. Strict compliance with existing asbestos regulations will normally prevent asbestos from being considered a significant adverse impact.

4.3.2 Thresholds of Significance for Impacts from Project Operations

The term "project operations" refers to the full range of activities that can or may generate pollutant emissions when the development is functioning in its intended use. For projects such as office parks, shopping centers, residential subdivisions, and other indirect sources, motor vehicles traveling to and from the projects represent the primary source of air pollutant emissions. For industrial projects and some commercial projects, equipment operation and manufacturing processes can be of greatest concern from an emissions standpoint. Significance thresholds discussed below address the impacts of these emission sources on local and regional air quality. Thresholds are also provided for other potential impacts related to project operations, such as odors and toxic air contaminants.

(Lead Agencies may refer to Section 5, for guidance on calculating emissions and determining whether significance thresholds for project operations may be exceeded, and thus whether more detailed air quality analysis may be needed.)

Ozone Precursor Emissions Threshold. Ozone precursor emissions from project operations should be compared to the thresholds provided in Table 4-1. Projects that emit ozone precursor air pollutants in excess of the levels in Table 4-1 will be considered to have a significant air quality impact.

Both direct and indirect emissions should be included when determining whether the project exceeds these thresholds. The following total emissions thresholds for air quality have been established by the SJVAPCD for project operations. Projects in the SJVAB with operation-related emissions that exceed these emission thresholds will be considered to have significant air quality impacts.

[34] 40CFR Part 61, Subpart M

Table 4-1
Ozone Precursor Emissions Thresholds
For Project Operations

Pollutant	Tons/yr.
ROG	10
NOx	10

Local Carbon Monoxide Concentrations Threshold. Estimated CO concentrations, as determined by an appropriate model, exceeding the California Ambient Air Quality Standard (CAAQS) of 9 parts per million (ppm) averaged over 8 hours and 20 ppm for 1 hour will be considered a significant impact.

Odor Impacts Threshold. While offensive odors rarely cause any physical harm, they can be very unpleasant, leading to considerable distress among the public and often generating citizen complaints to local governments and the SJVAPCD. Any project with the potential to frequently expose members of the public to objectionable odors will be deemed to have a significant impact. Odor impacts on residential areas and other sensitive receptors, such as hospitals, day-care centers, schools, etc., warrant the closest scrutiny, but consideration should also be given to other land uses where people may congregate, such as recreational facilities, worksites, and commercial areas. Analysis of potential odor impacts should be conducted for the following two situations:

- **Generators** – projects that would potentially generate odorous emissions proposed to locate near existing sensitive receptors or other land uses where people may congregate, *and*

- **Receivers** – residential or other sensitive receptor projects or other projects built for the intent of attracting people locating near existing odor sources.

The SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJV. These are presented in Table 4-2 along with a reasonable distance from the source where the degree of odors could possibly be significant.

A Lead Agency should use Table 4-2 to determine whether the proposed project, either as a generator or a receiver, would result in sensitive receptors being within the distances indicated in Table 4-2. In addition, recognizing that this list of facilities is not meant to be all-inclusive, the Lead Agency should evaluate facilities not included in the table or projects separated by greater distances than indicated in Table 4-2 if warranted by local conditions or special circumstances. If the proposed project would result in sensitive receptors being located closer than the screening level distances indicated in Table 4-2, a more detailed analysis, as described in Section 5, should be conducted.

VIA EMAIL

February 18, 2014

Jim Aguila, Manager
Substance Evaluation Section
Stationary Source Division
California Air Resources Board
1001 I Street
Sacramento, CA 95812

Dear Mr. Aguila:

This letter transmits comments regarding the workshop held on February 13, 2014, concerning the Alternative Diesel Fuels (ADF) regulations proposed by the staff on October 15, 2013. The scope of the comments presented here was constrained by the fact that there were only five calendar days and only two business days provided between the date of the workshop and the February 18th deadline for comments announced by CARB staff at the workshop.

ADF B3-112

As explained below, the modified ADF regulations discussed at the workshop would allow for the widespread use of biodiesel and biodiesel blends in California without adequately mitigating the resulting increases in emissions of oxides of nitrogen (NOx). The workshop proceedings also confirm concerns expressed during the 45-day comment period for the ADF regulations last year that CARB is not providing adequate and prompt public access to relevant documents and information that are in the agency's possession.

Sincerely,

Jim Lyons
Senior Partner

ADF Regulation Comments
Submitted by James M. Lyons, Sierra Research
February 18, 2014

1. **CARB Has Not Published the Comments from the South Coast Air Quality Management District That Underlie Staff's Proposed Modifications for Extreme Ozone Non-Attainment Areas.**

In the January 31, 2014 workshop notice,[1] CARB states:

> *During the 45-day public review process, staff received comments and proposed alternatives to the noticed regulation that staff would like to more fully consider and evaluate. Staff will be preparing modifications to the original proposal and make the modifications available for public review during a supplemental 15-day public comment period.*

Furthermore, CARB staff notes on slide 8 of the workshop presentation[2] with respect to "45-day rulemaking comments" that:

> *SCAQMD comment requested additional protections for extreme ozone non-attainment areas (South Coast Air Basin, Jan Joaquin Valley).*

ADF B3-113

However, the relevant comment document from the South Coast Air Quality Management District ("SCAQMD") does not appear as part of the comments submitted during the 45-day comment period posted on the CARB website as shown in the screen shot taken on February 17, 2014, and presented as Figure 1 below. In addition, since there was no public hearing on the proposed regulations held on December 12 or 13, 2013, no comment document could have been provided in that venue.

Because the SCAQMD comments have not been made available to the public, it is impossible for any stakeholder to understand or comment on either the scope of the SCAQMD request or the responsiveness of the modifications proposed by CARB staff at the workshop. CARB staff should make all documents and correspondence related to the SCAQMD comments publicly available and include them in the rulemaking file.

Comments posted to adf2013 that were presented during the Hearing:

There are no comments posted to adf2013 that were presented during the Board Hearing.

We expect that any written comments received during the Board Hearing will be posted within one week of the Board Hearing

2. CARB Staff Has Failed to Include Results from On-Going CARB-Sponsored Research Regarding the Impacts of Biodiesel on NOx Emissions in the Rulemaking Process.

During last week's workshop, a representative of the SCAQMD commented that increases in NOx emissions due to biodiesel use at levels as low as five percent biodiesel ("B5") remained a concern to his agency based on emission test results from an ongoing CARB-sponsored study being conducted by the University of California, Riverside ("UCR"). The SCAQMD representative stated that the UCR data showed statistically significant increases in NOx emissions for some types of B5 blends compared to conventional diesel fuel. CARB staff's response to this comment was that the study was still "on-going" and that no conclusions can be drawn from the emission testing until the study is completed. In response to questioning, CARB staff indicated that the contract for the project expires in July 2014 and suggested that all work related to the study would be complete by that date. As stakeholders have previously commented, CARB staff must include all available emission data regarding biodiesel impacts on emissions of NOx and other pollutants in the file for this rulemaking. ADF B3-114

It should be noted that, even if some members of the CARB staff consider the UCR work to be incomplete, other members of the CARB staff evidently consider the UCR data to be complete enough to warrant use in public meetings. Direct evidence supporting the assertion made by the SCAQMD representative at the workshop is provided by a presentation made by Georgios Karavalakis of UCR on April 10, 2013, at the 23rd Coordinating Research Council (CRC) Real World Emission Workshop, which lists among the coauthors two CARB staff members and acknowledges funding from CARB contract No. 10-417. A copy of this presentation and documentation demonstrating that it was presented at the April 2013 workshop is attached to these comments. ADF B3-115

In the section of the presentation labelled "CARB HD Engine Study Results," data are presented from preliminary emissions testing of B5 blends of both soy and waste vegetable oil ("WVO") based biodiesels using procedures similar to those set forth in Appendix A of the Initial Statement of Reasons ("ISOR") for the proposed ADF regulations. Based on these data, the authors conclude in the presentation that "NOx emissions showed slight but statistically significant, increase for B5-WVO and B5-soy blends." The authors conclude with respect to "certification testing" that "NOx emissions showed a statistically significant increase for B5-WVO" and that "The B5-WVO failed the statistical certification test, based on NOx emissions." ADF B3-116

This presentation raises a number of issues that CARB staff must address. First, the presentation provides evidence that directly contradicts the assertion made by CARB staff in the ISOR that there is no evidence of increased NOx emissions at biodiesel levels below B10—an assertion that is the foundation for the CARB environmental impact analysis presented in the ISOR. Second, these data directly support Robert Crawford's conclusions[3] that biodiesel use at levels below B10 will result in increased NOx emissions. Mr. Crawford's work was included by Growth Energy in its comments submitted to CARB staff during the 45-day comment period. Third, given that these data were available at least as early as April 2013, CARB staff should explain why they were not included in the staff's analysis of NOx impacts published in the ISOR nor in the rulemaking file for the ADF regulation. ADF B3-117

Again, CARB staff must include in the rulemaking file for this proceeding all emission test data currently available from this B5 testing program and any other biodiesel testing programs that the agency is sponsoring or otherwise participating in. This is particularly important here as the test data being excluded do not support the staff's assumption in the ISOR that there is no increase in NOx emissions until biodiesel blends reach the B10 level. ADF B3-118

3. **The Proposed Modifications to the ADF Regulation Affecting Extreme Ozone Non-Attainment Areas Will Not Prevent Significant Increases in NOx Emissions from Biodiesel Use.**

As presented by CARB staff at last week's workshop, the modifications to the proposed ADF regulation that would impose different requirements for extreme ozone non-attainment areas would be limited to the following: ADF B3-119

[3] Crawford, R., "NOx emission Impact of Soy- and Animal-based Biodiesel fuels: A Re-Analysis", December 10, 2013.

1. Establishment of "effective blend" (EB) requirements for biodiesel producers and importers;

2. Requirements for biodiesel producers and importers to submit compliance plans demonstrating how NOx emission increases will be mitigated once their EB level reaches five percent; and

3. Implementation of NOx mitigation measures once their EB level reaches seven and a half percent.

Presumably CARB staff has proposed these changes because they recognize that the originally proposed ADF regulation could lead to unacceptable increases in NOx emissions in the South Coast and San Joaquin Valley Air Basins. Nevertheless, the changes do nothing to ensure that increased NOx emissions due to biodiesel use will not actually occur.

ADF B3-119 cont.

The basic problem with the staff's proposed modifications is their continued reliance on the flawed effective blend (or EB) concept which, as pointed out in comments provided during the 45-day comment period, virtually ensures that the use of biodiesel in California will result in unmitigated increases in NOx emissions. As stakeholders indicated during the 45-day comment period, the only way to ensure that there are no increases in NOx emissions is for CARB staff to abandon the EB concept and to impose appropriate mitigation requirements based on the **actual** biodiesel content of all biodiesel blends. Furthermore, by appropriately mitigating the increases in the NOx emissions associated with biodiesel use, areas like the South Coast and San Joaquin Valley Air Basins will also realize the benefits of any NOx reductions associated with the use of "Low NOx diesel."

4. **The Proposed ADF Regulation Should Be Modified to Require Determination and Reporting of the Biodiesel Content of All Biodiesel Blends Prior to Their Sale to Ultimate Consumers.**

During last week's workshop, it became clear that the proposed ADF regulation will not ensure that the biodiesel content of blends sold in California will be accurately known or reported to CARB. As indicated by workshop participants, at present CARB has no requirement for determining the biodiesel content of diesel fuels being imported or distributed in the state that contain biodiesel up to the B5 level. Given this, a party interested in blending 5% biodiesel into a "diesel" fuel may be unaware of the fact that the "diesel" fuel could already contain up to 5% biodiesel and that the resulting blend would therefore be B10, not B5. Similarly, a party interested in blending 20% biodiesel into a "diesel" could in fact produce a B25 blend, instead of the intended B20 blend. Obviously, both circumstances have substantial ramifications with respect to potential NOx increases associated with the use of biodiesel in California.

ADF B3-120

Given the above, CARB must modify as necessary its existing diesel fuel regulations as well as the proposed ADF regulations to ensure that the biodiesel content of all blends of biodiesel and diesel sold in California is accurately known and reported to both CARB as well as the Division of Measurement Standards. This could easily be accomplished by requiring that all "diesel" fuels used in biodiesel blends be tested before blending for Fatty Acid Methyl Ester (FAME) content using appropriate test procedures such as the EN14103:2011 procedure already referenced in the proposed ADF Regulations or the ASTM D7371 procedure. Alternatively, CARB could require testing of final blends for FAME content. Again, failure by CARB to require accurate measurement and reporting of the biodiesel content of biodiesel-diesel blends will lead to unmitigated increases in NOx emissions along with other potential issues, including violations of pump labeling and vehicle manufacturer warranty requirements.

ADF B3-120 cont.

5. CARB Staff Must Publish an Analysis of All Alternatives to the Proposed ADF Regulation Raised During the 45-Day Comment Period.

The "Analysis of Alternatives" presented on pages 62 and 63 of the ISOR states:

> *Specifically for biodiesel, we considered two alternatives to the proposal: business as usual (i.e., no proposed regulation), and requiring implementation of the mitigation measures for all biodiesel blends above B10 immediately without the proposed phase in process.*

ADF B3-121

CARB staff must perform an expanded analysis of alternatives that includes not only the modifications to the original proposal discussed at the workshop but also all alternatives recommended during the 45-day comment period. No such analysis was presented at last week's workshop. Clearly CARB staff should perform this analysis and consider the results, including public comment, before formally proposing modifications to the ADF regulation.

12_B_LCFS_GE Responses (Page 271 – 277)

722. Comment: **ADF B3-113 through ADF B3-115, ADF B3-117 through ADF B3-121**

Agency Response: These comments are responded to in the Alternative Diesel Regulation Final Statement of Reasons under comment letter **3_B_ADF_GE**.

723. Comment: **ADF B3-112 and ADF B3-116**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

Introduction

- **Potential Sources of Biodiesel**
  - Vegetable oils
    - Edible oils: Soybean oil, rapeseed oil, palm oil, etc.
    - Inedible oils: Jatropha, Camelina, Karanja, etc.
  - Animal Fats
  - Waste Cooking Oils
  - 'Alternative' Oils
    - Algae
- **Benefits**
  - Reduce petroleum dependence
  - Reduce overall life cycle CO_2 emissions
  - Potential improvements in "smog" emissions

Alternative Fuels Legislation

Federal

- Energy Policy Act
  - Renewable Fuels Standard
  - Biofuels Research and Development

California

- Low Carbon Fuel Standard (LCFS)
  - Reduce 10% carbon intensity of California's transport fuels by 2020.
- AB 32 – Global Warming Solutions Act
- Bioenergy Action Plan
- AB 1007 – Alternative Fuels Plan
- AB 118 – Alternative and Renewable Fuel and Vehicle Technology Program

UCR | College of Engineering- Center for Environmental Research & Technology

Concerns about using Biodiesel from Emissions Perspective

- Concern about NOx emissions increases with biodiesel
  - Lack of information with vehicles/engines fitted with DPF, SCR, and LNT controls
- A general trend towards higher aldehyde emissions (i.e., formaldehyde, acetaldehyde, acrolein, etc.)
- Biodiesel origin and quality may adversely affect the formation of light molecular-weight PAH emissions
- Characterization of biodiesel exhaust from SCR-fitted vehicles is still incomplete; potential formation of nitrogen-containing compounds (nitro-PAHs)
- Concern about nanoparticle number emission increases with biodiesel

www.cert.ucr.edu

Objectives of the AVFL – 17b Study

- Evaluation of fuel type and quality on exhaust emissions of modern technology light-duty diesel vehicles.
- Assessment of the impact of modern technology aftertreatment control devices on the emissions formation from biodiesel and renewable diesel fueled vehicles.
- Emphasis on gaseous toxic emissions, ammonia, and ultrafine particles.
- Chemical characterization of PM emissions; Concern about EC/OC fractions, PAH, and nitro-PAH compounds some of which are carcinogenic and mutagenic to humans.
- Evaluation of emissions during DPF regeneration events on different fuels; physicochemical characterization of PM.

Test Fuels and Vehicles for the AVFL – 17b Study

- A total of seven fuels will be used in the study
  - A Federal ULSD and a CARB ULSD, which will serve as baseline fuels
  - Three biodiesels obtained from soy, waste cooking oil, and animal fat
  - A renewable diesel (Hydrogenated Vegetable Oil - HVO)
  - All biodiesels and HVO will be blended with Federal diesel at 20% by volume. CARB diesel will be blended with WCO.
- Currently, we tested a total of 3 vehicles with plans to test 5 additional vehicles.

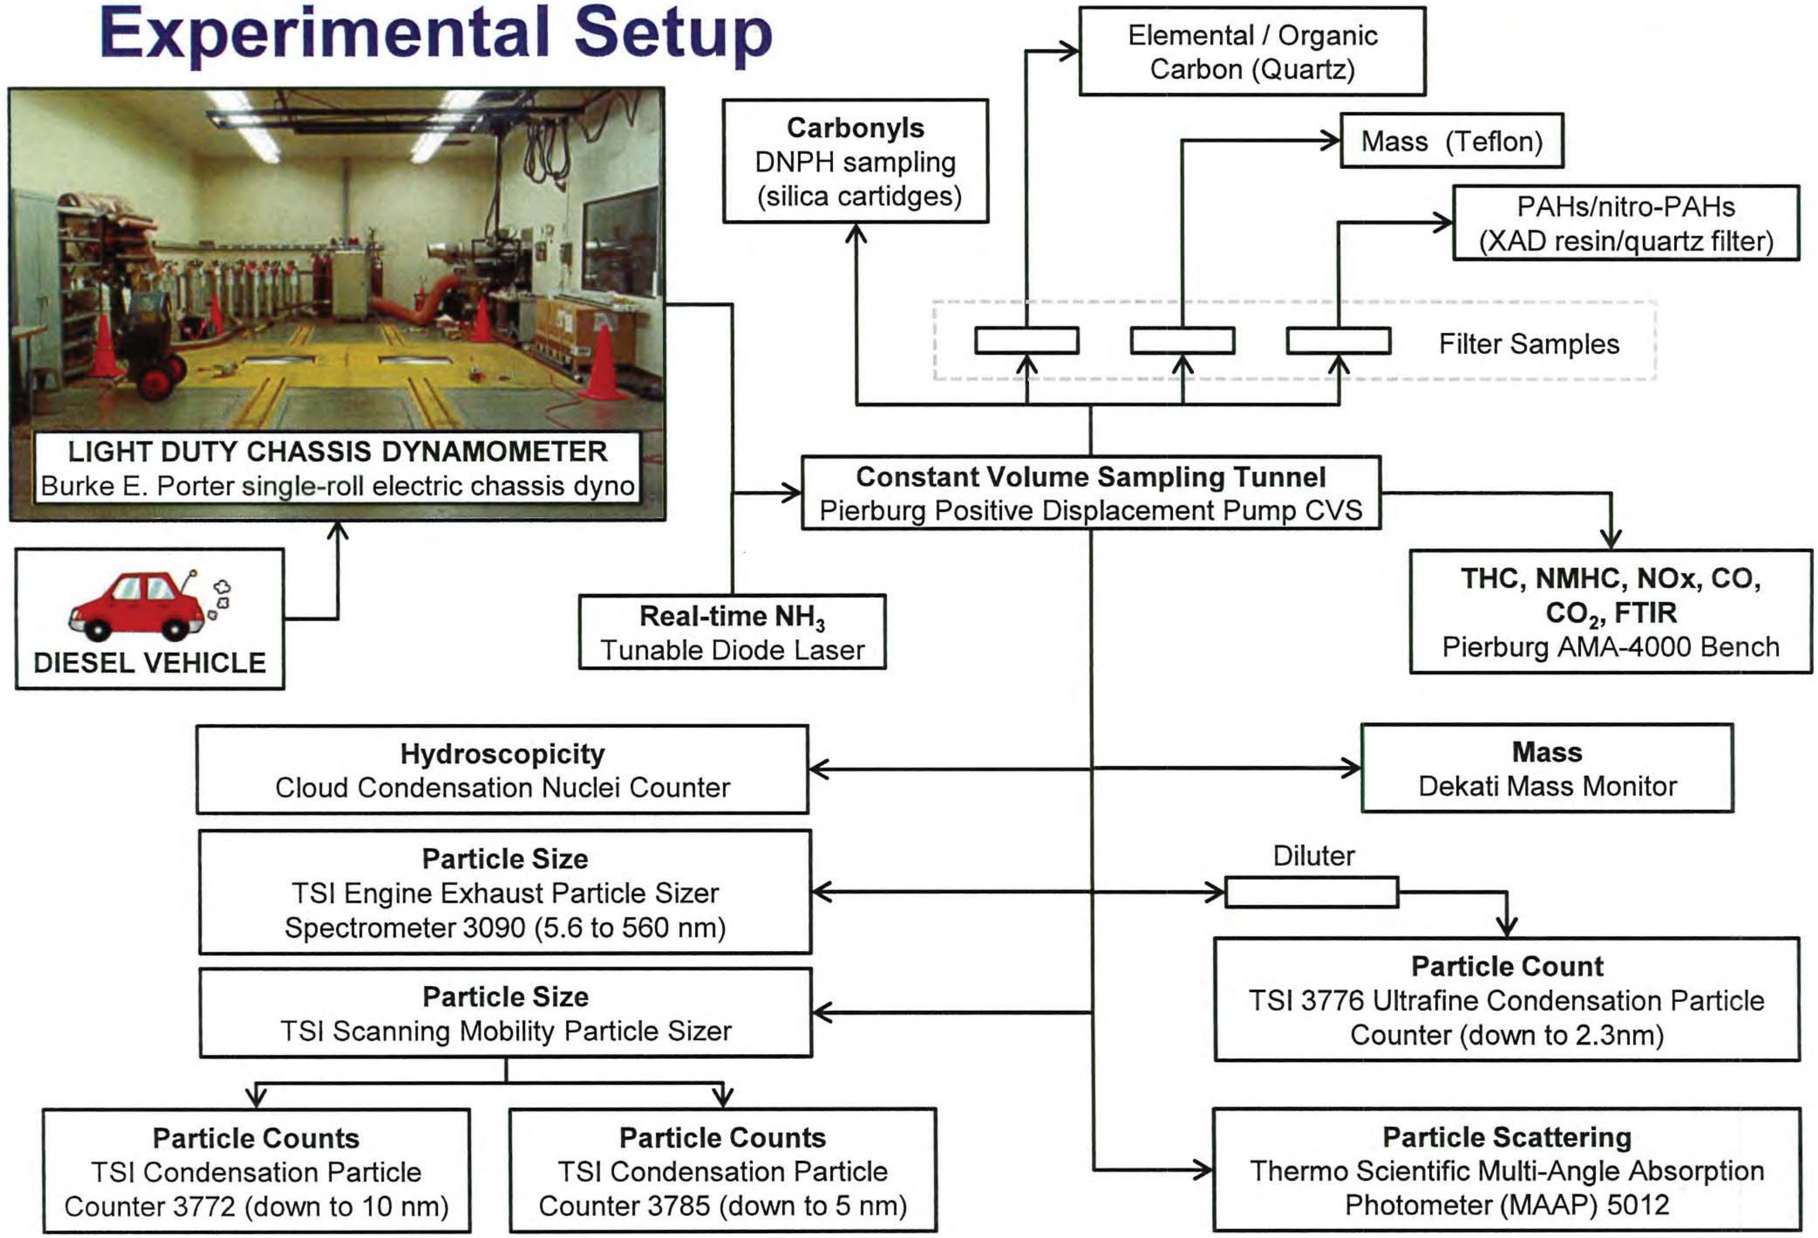
#	Aftertreatment	MY	Displacement	Configuration
Veh #1	DOC+DPF+SCR	2012	3.0L	V6
Veh #2	DOC+DPF+SCR	2012	6.6L	V8
Veh #3	DOC+DPF+SCR	2012	2.0L	4 cylinders
Veh #4	DOC+DPF+LNT	2012 or 2013	6.7L	6 cylinders
Veh #5	DOC+DPF+SCR	2012/13	6.7L	V8
Veh #6	DOC+DPF+SCR	2012/13	3.0L	V6
Veh #7	DOC+DPF+LNT	2012/13	2.0L	4 cylinders
Veh #8	TBD	2012 or 2013	TBD	TBD

Testing Protocol

- Emissions and fuel economy tests will be performed on the Federal Test Procedure (FTP) driving cycle.
  - Each vehicle/fuel combination will be tested at least twice.
  - A third test will be performed if the differences in FTP regulated emissions exceed a predefined limit: THC 33%, NO_x 29%, CO 70%, provided the absolute difference in the measurements is greater than 5 mg/mi.
- For the oil conditioning protocol, the vehicle will be conditioned on the oil for a period approximately equivalent to two US06 cycles, followed by an LA4 and a US06 cycle sequence repeated twice. This protocol provides more robust preconditioning, especially for improving the repeatability of the nucleation mode particles under hot start/running conditions.

UCR | College of Engineering- Center for Environmental Research & Technology

Experimental Setup



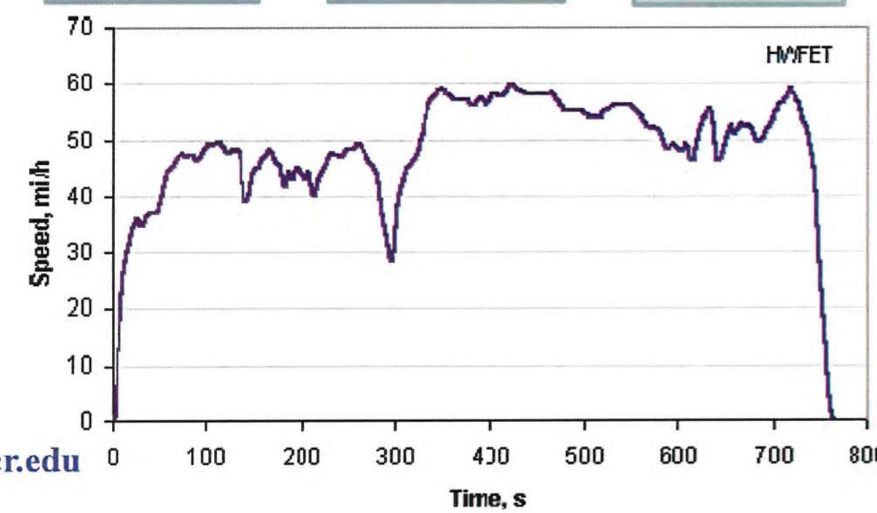
UCR | College of Engineering- Center for Environmental Research & Technology

Regeneration Testing Protocol

- A total of two fuels were tested during regeneration testing: Federal ULSD and Fed/SME-20.
- The regeneration testing protocol included driving the vehicle on-road on a route designed to simulate the LA4 portion of the FTP cycle in terms of typical speeds as well as number of stops, for approximately 170 miles (20 LA4s) to build up soot in the DPF.
- Testing was conducted over a double EPA Highway Fuel Economy Cycle (HWFET).

Baseline HWFET (emissions collection) → Baseline Regen → 20 LA4s (on-road) → Regen #1 → 20 LA4s (on-road) → Regen #2

- Regulated emissions, PM mass, particle number emissions and particle size distributions, carbonyls, PAHs/nitro-PAHs, EC/OC, and NH_3 emissions will be measured during a regeneration event for each vehicle/fuel combination.



www.cert.ucr.edu

Current Status

- Measurements are being made for:
  - Regulated emissions (NOx, PM, THC, CO, CH_4, NMHC, and CO_2) and fuel economy
  - Aldehydes and ketones
  - Real-time ammonia
  - EC/OC fractions
  - Particle number emissions
  - PAHs and nitro-PAHs
- Additional measurements are being made for:
  - Particle size distributions
  - Black carbon
  - Particles solubility
  - Hydroscopicity

Additional Work

- Comprehensive statistical analysis based on a complete data set
- QA/QC

- Future Work:
  - Further study on the emissions from low-environmental impact feedstock biodiesels, such as algae-based fuels
  - A more complete assessment on the emissions performance of high concentration renewable diesel (HVO) blends in modern technology diesel vehicles.
  - More information is needed on the physical, chemical, and biological characterization of particulate emissions during regeneration events from light- and heavy-duty vehicles operated on alternative fuels.

Acknowledgements

- This project is totally funded by the Coordinating Research Council (CRC) under contract No. CRC AVFL – 17b.
- Mr. Kurt Bumiller and Mr. Mark Villela of the University of California, Riverside for their contributions in conducting the emissions testing for this program.
- Thanks for the technical guidance from the CRC AVFL- committee and the AVFL-17b technical panel led by Dr. Mani Natarajan of Marathon Petroleum Company.
- Thanks to Mercedes Benz and Volkswagen for providing the vehicles.
- The Panel Members are: Brent Bailey (CRC), Mani Natarajan (Marathon Petroleum Company), Bill Cannella (Chevron), Dominic DiCicco (Ford), King Eng (Shell), Garry Gunter (Phillips 66), Scott Jorgensen (GM), David Lax (API), Shailesh Lopes (GM), Jenny Sigelko (Volkswagen), Marie Valentine (Toyota), William Woebkenberg (Daimler), Krystal Wrigley (Exxon Mobil)

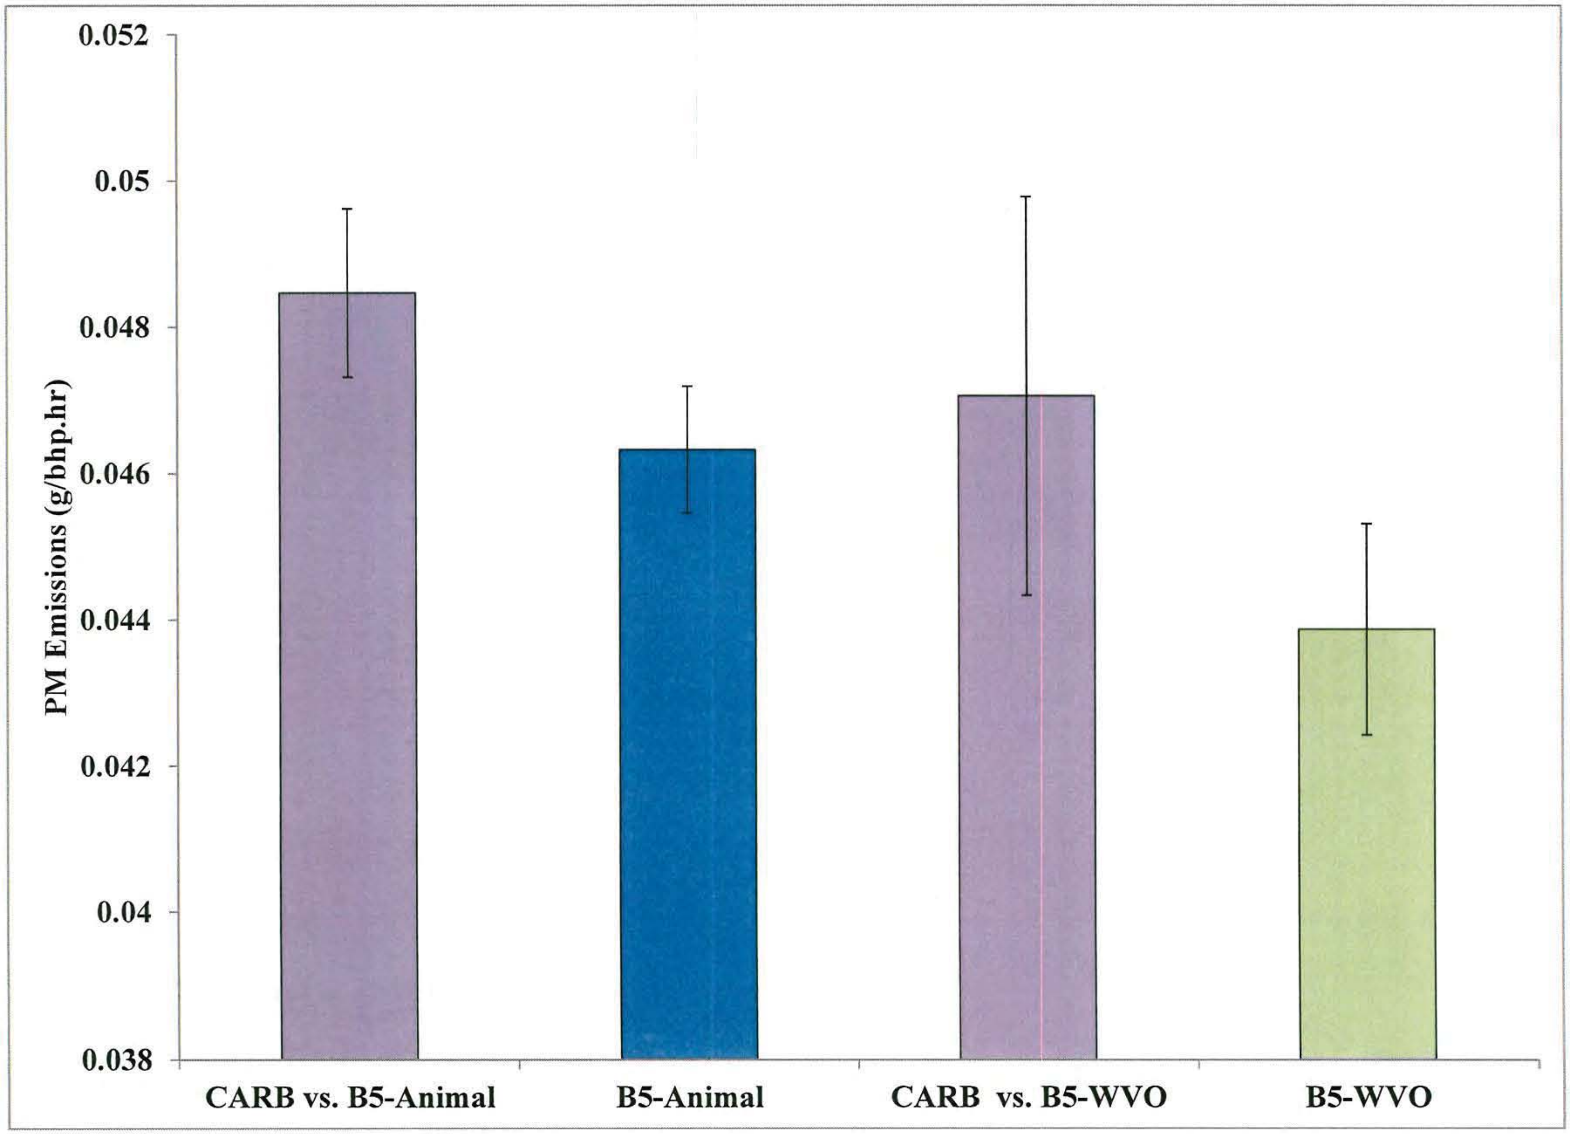
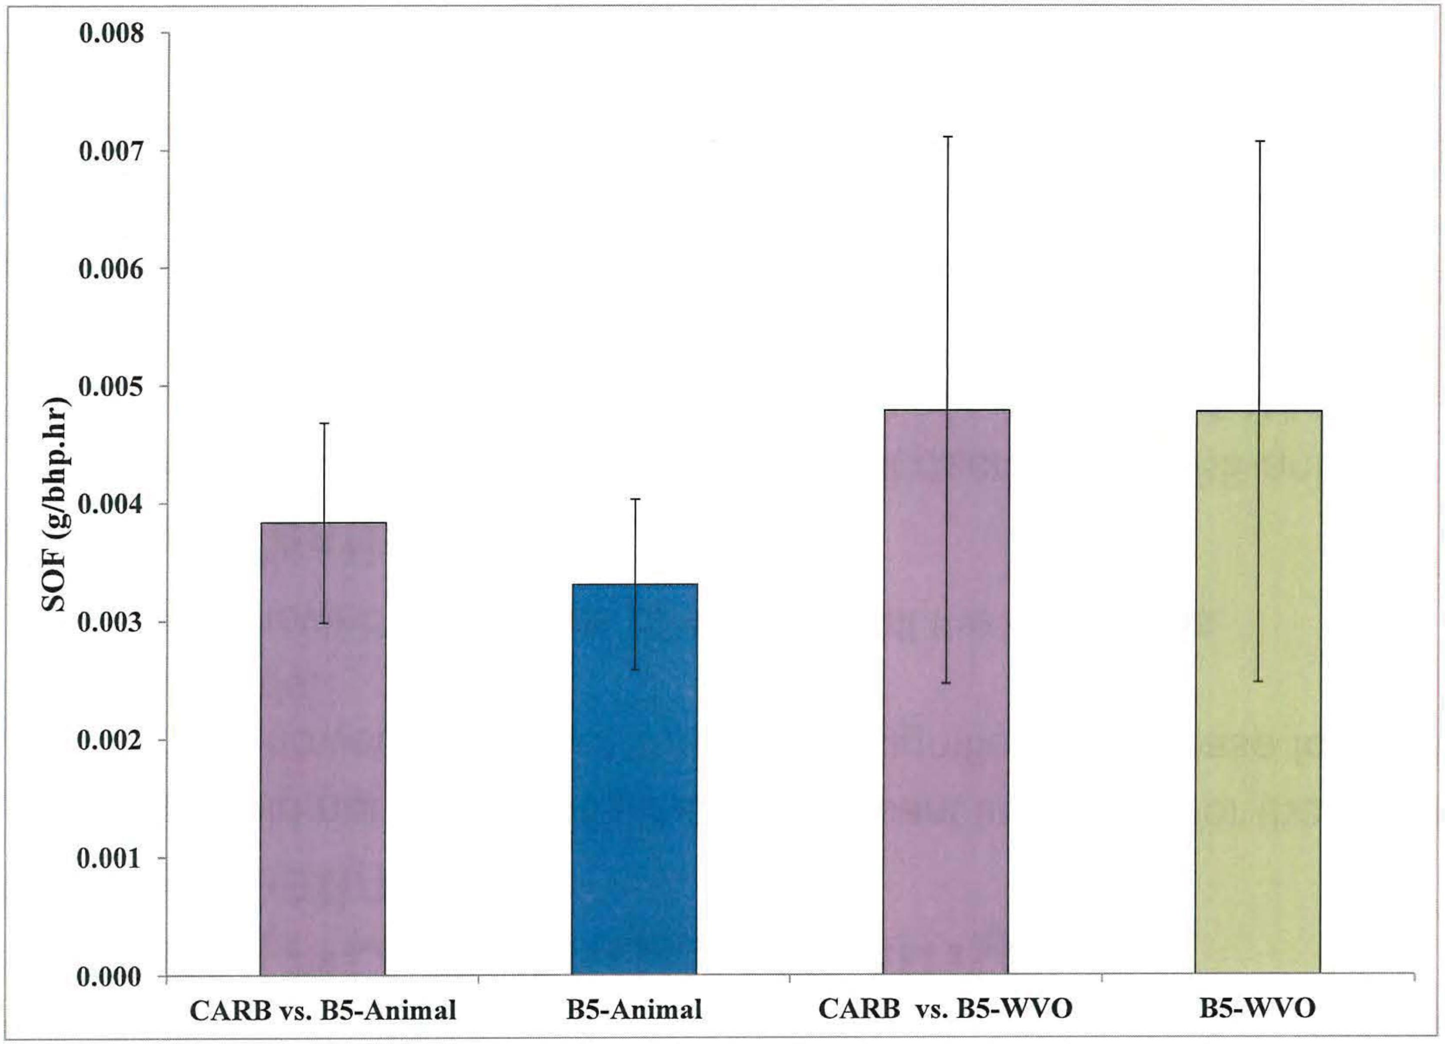
PM Emissions - Certification Testing



UCR | College of Engineering- Center for Environmental Research & Technology

SOF Analysis- Certification Testing



Summary (HD Engine Testing)

Preliminary Testing

- NO_x emissions did not show statistically significant increases for the B5-animal.
- NO_x emissions showed slight, but statistically significant, increase for B5-WVO and B5-soy blends.
- PM emissions showed reductions of 4-6% for all the B5 blends.

Certification Testing

- NO_x emissions showed a statistically significant decrease for B5-animal.
- NO_x emissions showed a statistically significant increase for B5-WVO.
- PM showed reductions for both tested B5 blends.
- B5-animal showed a reduction in SOF compared to CARB reference fuel.
- The B5-animal successfully passed the certification statistical test.
- The B5-WVO failed the statistical certification test, based on NO_x emissions.

Additional work

- Further testing on B20 blends with additives has been conducted and is being analyzed.
- A more comprehensive study of the impacts of B5 on NO_x emissions in CARB diesel is planned in the near future.

Acknowledgements

AGENDA

23rd CRC REAL WORLD EMISSIONS WORKSHOP

Workshop Organizers

Mani Natarajan, Co-Chairman, Marathon Petroleum Company
Dominic DiCicco, Co-Chairman, Ford Motor Company
Alberto Ayala, California Air Resources Board
Brent Bailey, Coordinating Research Council
Megan Beardsley, U.S. Environmental Protection Agency OTAQ
Kevin Black, Federal Highway Administration
Rob R. Graze, Jr., Caterpillar, Inc. Technical Center
Philip Heirigs, Chevron Global Downstream
Jorn Dinh Herner, California Air Resources Board
Henry Hogo, South Coast Air Quality Management District
John Koupal, Eastern Research Group
Tom Long, U.S. Environmental Protection Agency NRMRL
Chris Tennant, Coordinating Research Council
Matthew Thornton, National Renewable Energy Laboratory

Hyatt Regency Mission Bay, San Diego, California
April 7-10, 2013

23rd CRC Real World Emissions Workshop

Schedule of Events

Sunday, April 7, 2013		
4:30 PM	- 6:00 PM	Registration and Poster Setup
6:00 PM	- 7:00 PM	Welcome Reception
Monday, April 8, 2013		
7:30 AM	- 8:30 AM	Registration and Continental Breakfast
8:30 AM	- 8:40 AM	Welcome from the Chairs
8:40 AM	**- 10:15 AM**	**Session 1: Emission Rates and Inventory**
10:15 AM	- 10:55 AM	Poster Session and Demonstrations
10:55 AM	**- 12:00 PM**	**Session 2: Emissions Control Measures and Emerging Technologies**
12:00 PM	- 1:30 PM	Lunch
1:30 PM	**- 2:15 PM**	**Session 2 continued**
2:15 PM	**- 2:50 PM**	**Session 3: I/M and In-Field Measurement Method Development**
2:50 PM	- 3:20 PM	Poster and Demonstration Viewing
3:20 PM	**- 4:35 PM**	**Session 3 continued**
4:35 PM		End of Day
6:00 PM	- 9:30 PM	Evening Cruise of San Diego Harbor
Tuesday, April 9, 2013		
7:30 AM	- 8:00 AM	Registration and Continental Breakfast
8:00 AM	- 8:50 AM	Keynote Speaker
8:50 AM	**- 9:40 AM**	**Session 4: Emission Trends and Modeling**
9:40 AM	- 10:20 AM	Poster and Demonstration Viewing
10:20 AM	**- 11:05 AM**	**Session 4 continued**
11:05 AM	**- 12:10 PM**	**Session 5: Laboratory Measurement Method Development**
12:10 PM	- 1:40 PM	Lunch
1:40 PM	**- 2:55 PM**	**Session 5 continued**
2:55 PM	- 3:25 PM	Poster and Demonstration Viewing
3:25 PM	**- 5:15 PM**	**Session 6: Particulate Matter Characterization**
5:15 PM		End of Day
5:30 PM	- 6:30 PM	Poster Exhibition and Reception
Wednesday, April 10, 2013		
7:30 AM	- 8:00 AM	Registration and Continental Breakfast
8:00 AM	**- 10:05 AM**	**Session 7: Off-Road**
10:05 AM	- 10:35 AM	Poster and Demonstration Viewing
10:35 AM	**- 12:10 PM**	**Session 8: Fuel Effects: Spark Ignition**
12:10 PM	- 1:40 PM	Lunch
1:40 PM	**- 3:05 PM**	**Session 9: Fuel Effects: Compression Ignition**
3:05 PM	- 3:25 PM	Open Discussion
3:25 PM		End of Workshop

Welcome Sunday, April 07, 2013

4:30-6:00 pm	**Registration in Bayview Ballroom Foyer and Poster Setup in Mission Ballroom**
6:00-7:00 pm	**Welcome Reception in the Cabanas**

DAY ONE Monday, April 08, 2013

All sessions take place in Bayview Ballroom unless otherwise noted.

7:30 AM	**Registration in Bayview Ballroom Foyer** Continental Breakfast in Mission Ballroom		
8:30 AM	Welcome from the Chairs: Mani Natarajan, Marathon Petroleum Co., and Dominic DiCicco, Ford Motor Co.		

SESSION 1: Emission Rates and Inventory

8:40 AM	*Introduction by Session Leaders Henry Hogo, South Coast Air Quality Management District, and John Koupal, Eastern Research Group*		
■ 8:45 AM	Black Carbon and Primary Organic Aerosol Emissions From On-Road Gasoline and Diesel Vehicles	Robert Harley	University of California Berkeley
■ 9:00 AM	Trends in Heavy-Duty Truck Emissions in the South Coast Air Basin	Gary Bishop	University of Denver
■ 9:15 AM	Cold Temperature Measurement of Particulate and Gaseous Emissions from Tier 2 MSAT Vehicles	David Hawkins	U.S. Environmental Protection Agency
■ 9:30 AM	Characterization of Drayage Activities at the Port of Houston	Carl Fulper	U.S. Environmental Protection Agency
■ 9:45 AM	Integrated Emissions from 938 Heavy-Duty Vehicles under Realistic Driving Conditions in Vancouver Canada	Don Stedman	University of Denver
10:00 AM	General Discussion of Session 1		

10:15 AM Poster Session and Demonstrations in Mission Ballroom *(see Pages 10-12 for Listings)*

SESSION 2: Emissions Control Measures and Emerging Technologies

10:55 AM	*Introduction by Session Leader Jorn Herner, California Air Resources Board*		
■ 11:00 AM	Phase 2 of the Advanced Collaborative Emissions Study (ACES): Highlights of Project Finding	Imad Khalek	Southwest Research Institute
■ 11:15 AM	Summary of Heavy-Duty Diesel Vehicle Selective Catalytic Reduction (SCR) Performance: Lessons to Date	John Collins	California Air Resources Board
■ 11:30 AM	The Air Quality Impacts of Trains in London Paddington Station	Uven Chong	University of Cambridge
■ 11:45 AM	Investigation on the Effect of Injection System Parameters on Emission Characteristics During Low Temperature Combustion Using Response Surface Methodology	Mario Velardi	West Virginia University

12:00 PM Lunch in Red Marlin Restaurant

■	1:30 PM	Quantification of Perturbation Effects on an Alternative Ignition System	Greg Yoder	West Virginia University
■	1:45 PM	Bivento.org - An Online Platform to Manage Real Traffic Emissions	Francisco Gala	Bivento-Technet
	2:00 PM	General Discussion of Session 2		

SESSION 3: I/M and In-Field Measurement Method Development

	2:15 PM	*Introduction by Session Leader Phil Heirigs, Chevron Global Downstream*		
■	2:20 PM	Assessing the Prevalence and Emissions Impact of High Emitters in California	Sherrie Sala-Moore	California Air Resources Board
■	2:35 PM	Results of Field Study of On-Board Diagnostic (OBD) Evaporative Codes	Carl Fulper	U.S. Environmental Protection Agency
	2:50 PM	**Poster and Demonstration Viewing in Mission Ballroom** *(see Pages 10-12 for Listings)*		
■	3:20 PM	Characterizing Emissions Reduction Performance and Test Methods of In-Use Diesel Retrofit Technologies from the National Clean Diesel Campaign	Britney McCoy	U.S. Environmental Protection Agency
■	3:35 PM	Synchronization of Portable Emissions Measurements Systems Data	Chris Frey	North Carolina State University
■	3:50 PM	Establishment of the PEMS-M Instrumentation Specifications for the In-Service Conformity of HDE in Europe	Athanasios Mamakos	Southwest Research Institute
■	4:05 PM	Evaluation, Quantification, and Performance of Accurate In-Use Fuel Economy Measurements	Kent Johnson	University of California, Riverside (CE-CERT)
	4:20 PM	General Discussion of Session 3		
	4:35 PM	**END OF DAY**		
	6:00 PM	Evening cruise of San Diego Harbor - meet in front of hotel lobby to board coaches. LAST BUS LEAVES AT 6:10 PM		

DAY TWO Tuesday, April 09, 2013

	7:30 AM	**Registration in Bayview Ballroom Foyer**		
		Continental Breakfast in Mission Ballroom		
	8:00 AM	KEYNOTE SPEAKER		

SESSION 4: Emission Trends and Modeling

	8:50 AM	*Introduction by Session Leader Megan Beardsley, U.S. Environmental Protection Agency*		
■	8:55 AM	Improving the Accuracy of Modeling Compressed Natural Gas Transit Buses in MOVES	Andrew Eilbert	U.S. Environmental Protection Agency
■	9:10 AM	Projecting 2025 California Light-Duty Vehicle Fleet Emissions -- MOVES, EMFAC, and Suggested Updates	Robert Sawyer	University of California, Berkeley
■	9:25 AM	Current Analysis and Potential Updates to the EMFAC Model in California	Sam Pournazeri	California Air Resources Board
	9:40 AM	Poster and Demonstration Viewing in Mission Ballroom *(see Pages 10-12 for Listings)*		
■	10:20 AM	Updated Emissions Estimates for Pleasure Craft and Recreational Vehicles in California	David Chou	California Air Resources Board
■	10:35 AM	Development of a Simplified Version of MOVES and Incorporation into a Traffic Simulation Model	Chris Frey	North Carolina State University
■	10:50 AM	General Discussion of Session 4		

SESSION 5: Laboratory Measurement Method Development

	11:05 AM	*Introduction by Session Leaders Kevin Black, Federal Highway Administration, and Matt Thornton, NREL*		
■	11:10 AM	Low PM Mass Assessment and Analysis E-99	Kent Johnson	University of California, Riverside (CE-CERT)
■	11:25 AM	An Analysis of Sub 1 mg/mi PM Mass from Light-Duty Vehicles	Jim Watson	California Air Resources Board
■	11:40 AM	A New Laboratory Method for Very Low Particular Mass Emissions Measurement	Jonathan Bushkuhl	AVL North America
■	11:55 AM	Particle Generator for Engine Exhaust Simulation	Imad Khalek	Southwest Research Institute
	12:10 PM	Lunch in Red Marlin Restaurant		
■	1:40 PM	Optimization of the Pegasor Particle Sensor for Automotive Exhaust Measurements	Leonidas Ntziachristos	Aristotle University
■	1:55 PM	Toward the Inclusion of FT-IR in the Certification of Engine Emissions for Both Standard and Alcohol-Based Fuel Blends	Richard Frazee	AVL North America
■	2:10 PM	Real-time Measurements of Metallic Ash Emissions from Engines	David Kittelson	University of Minnesota
■	2:25 PM	Impact of Modern Diesel Engine and Aftertreatment Technology on Test Repeatability and Emissions Prediction	Nigel Clark	West Virginia University CAFEE
	2:40 PM	General Discussion of Session 5		

2:55 PM Poster and Demonstration Viewing in Mission Ballroom *(see Pages 10-12 for Listings)*

SESSION 6: Particulate Matter Characterization

	3:25 PM	*Introduction by Session Leader Rob Graze, Caterpillar, Inc.*		
■	3:30 PM	Real-time DPF Filtration Efficiencies and Particle Number Emissions from Modern Diesel and Dual-Fueled HD Engines	Marc Besch	West Virginia University
■	3:45 PM	Morphology and Nanostructures of Particulates from an Engine-Simulating Particle Generator	Heeje Seong	Argonne National Laboratory
■	4:00 PM	Study of Variability in Particulate Mass Measurement and Comparison with Particle Number Count Measurement Method	Pragalath Thiruvengadam	West Virginia University
■	4:15 PM	Quantifying Particulate Matter Emissions from Gasoline and Diesel Vehicles: Gas Particle Portioning and Sampling Artifacts	Albert Presto	Carnegie Mellon University
■	4:30 PM	Physiochemical and Toxicological Properties of Size Segregated PM Emissions from a 2010 Compliant Heavy-Duty Diesel Truck - Is Diesel PM Still Diesel PM?	Jorn Herner	California Air Resources Board
■	4:45 PM	Investigation of Particle Size Distributions in a Exhaust Plume Emitted by Heavy-Duty Diesel Trucks at Cruise and Idling Operations	Presented by Mario Velardi for Daniele Littera	West Virginia University
	5:00 PM	General Discussion of Session 6		

5:15 PM **END OF DAY**

5:30 PM Poster Exhibition and Reception in the Mission Ballroom (5:30-6:30 pm)

DAY THREE Wednesday, April 10, 2013

7:30 AM	**Registration in Bayview Ballroom Foyer** Continental Breakfast in Mission Ballroom		

SESSION 7: Off-Road

8:00 AM	*Introduction by Session Leader Alberto Ayala, California Air Resources Board*		
■ 8:05 AM	Load Factors, Emission Factors, Duty Cycles, and Activity of Diesel Nonroad Vehicles	Tim DeFries	Eastern Research Group
■ 8:20 AM	Emission Factors from In-Use Non-Road Construction Equipment Using 1065 Compliant PEMS	Tanfeng (Sam) Cao	University of California, Riverside (CE-CERT)
■ 8:35 AM	Remote Sensing Measurements of In-Use Locomotive NOx Emissions	Matthew Breuer	University of Puget Sound
■ 8:50 AM	Projected Growth for Ocean-Going Vessels	Louis Browning	ICF International
■ 9:05 AM	Evaluation of Hybrid Retrofit System for a Tugboat	Nicholas Gysel	University of California, Riverside (CE-CERT)
■ 9:20 AM	In-Use Measurement of Passenger Diesel Locomotive Emissions for Biodiesel and Petroleum Diesel Fuels	Christopher Frey	North Carolina State University
■ 9:35 AM	Particulate Matter and Other Criteria Pollutants Reduced by Algae Fuels in Marine Vessels	Yusuf Khan	University of California, Riverside (CE-CERT)
9:50 AM	General Discussion of Session 7		

10:05 AM **Poster and Demonstration Viewing in Mission Ballroom** *(see Pages 10-12 for Listings)*

SESSION 8: Fuel Effects: Spark Ignition

10:35 AM	*Introduction by Session Leader Tom Long, U.S. Environmental Protection Agency*		
■ 10:40 AM	Characterization of Particular Matter Emissions from Light-Duty Vehicles Technologies Using Physical, Chemical and Cellular Assays	Satya Sardar	California Air Resources Board
■ 10:55 AM	Effects of Five Gasoline Properties on Exhaust Emissions from Light-Duty Tier 2 Vehicles	Aron Butler	U.S. Environmental Protection Agency
■ 11:10 AM	Effects of Fuel Sulfur Level on Emissions from Tier 2 Vehicles in the In-Use Fleet	Aron Butler	U.S. Environmental Protection Agency
■ 11:25 AM	Criteria Emissions, Toxic Pollutants, and Particle Number Emissions from Gasoline PFI and GDI Vehicles Operated on Ethanol and Isobutanol Blends	Daniel Short	University of California, Riverside (CE-CERT)
■ 11:40 AM	A Comprehensive Evaluation of PM, NOx, Ammonia, and Greenhouse Gas Emissions from Current Model Year Heavy-Duty Vehicles	Arvind Thiruvengadam	West Virginia University
11:55 AM	General Discussion of Session 8		

12:10 PM Lunch in Red Marlin Restaurant

SESSION 9: Fuel Effects: Compression Ignition

1:40 PM	*Introduction by Session Leader Mani Natarajan, Marathon Petroleum Company*		
■ 1:45 PM	Biodiesel and Renewable Diesel Characterization and Testing in Modern LD Diesel Passenger Cars and Trucks and HD Engines	Georgios Karavalakis	University of California, Riverside (CE-CERT)
■ 2:05 PM	Emissions, Fuel Economy and Duty Cycle Testing and Analysis of Hybrid Electric Trucks Operating in the California Fleet	Matthew Thornton	National Renewable Energy Laboratory
■ 2:20 PM	Hybrid and Electric Bus Emissions and Energy Test Program in South America	Sebastian Tolvett	Sistemas Sustentables
2:35 PM	General Discussion of Session 9		
2:50 PM	Open discussion - Mani Natarajan and Dominic DiCicco, Chairmen		

3:25 PM **END OF Workshop**

Poster Exhibits

Emission Rates and Inventory

Measurement of Regulated and Greenhouse Gas Emissions from In-Use Vehicle Activity during a Cross-Continental Trip	Hemanth Kappanna [presented by Pragalath Thirvengadam]	West Virginia University
On-Board Measurement of Reduced-Nitrogen Emissions from Vehicles during Real-World Driving	John Moss	Oak Crest Institute of Science
Technology Significantly Lowers Emissions from Yard Tractors over Past 10 Years	Poornima Dixit	University of California, Riverside (CE-CERT)
Benchmarking Vehicle Fleet Performance: Real World Monitoring as an Everyday Activity	Stephen Hanley	University of Leeds Institute for Transport Studies
Emissions of Air Toxic Species from Light-Duty Vehicles with Gasoline Direct Injection (GDI) and Port Fuel Injection (PFI) Engines	Oliver Chang	California Air Resources Board
Idling Emissions from Recent Model Year Heavy-Duty Diesel Vehicles	Doh-Won Lee (presented by Josias Zietsman)	Texas A&M Transportation Institute
Contribution of Cold Starts to Real-World Total Trip Emissions for Light-Duty Gasoline Vehicles	Chris Frey	North Carolina State University

Emission Control Measures and Emerging Technologies

Exhaust Emissions Reductions Using a Seawater Scrubber on a Container Ship	Andrew Burnette	Infowedge
In-Use NOx Emissions from 2010 or Newer Heavy-Duty Diesel Engines Equipped with OEM Aftertreatment Devices	Chandan Misra [presented by John Collins]	California Air Resources Board
Update on Pase 2 of the Advanced Collaborative Emissions Study (ACES Phase 2)	Chris Tennant	Coordinating Research Council

I/M and In-Field Measurement Methods

Results of the TEDDIE Project and Future Developments Concerning Emissions Testing in Europe EmissionCheck 2020	Hans Juergen Maeurer	DEKRA Automobil GmBH Germany
Operational Challenges Faced During Vehicle Emissions Testing in Hong Kong	Kwok-Lam Ng	Hong Kong Environmental Protection Department
Evidence of Flipper Vehicles in Arizona Random Sample Triplicate IM147 Data	Tom Wenzel	Lawrence Berkeley National Laboratory
Ultrafine Particle Measurements and Evaluation of the Mobile Source Contribution in New York City	Robert Anderson	TSI, Inc.

■	Comparison of a Portable FTIR with SEMTECH-DS under Real-World Urban Driving Conditions	Eddie Lo	Hong Kong Environmental Protection Department
■	Relative Amounts of Gases in Exhaust Plumes by Laser Remote Sensing	Stewart Hager	HEAT, LLC
■	Off-Cycle Light-Duty Diesel Vehicle Emissions Measurement with PEMS: Project Description and Preliminary Data	Marc Besch	West Virginia University

Emission Trends and Modeling

■	Methodology to Predict Real World Aerodynamic Drag Losses Due to On-Road Cross-Wind Effects	Nigel Clark	West Virginia University

Laboratory Measurement Methods Development

■	An Analysis of Light-Duty Vehicle PM Data Generated in CARB HSL Cell 2 and Cell 3	Mang Zhang	California Air Resources Board
■	Time-Resolved FTIR Measurements of Non-Methane Organic Gases (NMOG) in Vehicle Exhaust Gas	Christine Gierczak	Ford Motor Company
■	Pulse Height Monitor to Improve Data Reliability of Condensation Particle Counter for Engine Emission Applications	Tim Johnson	TSI, Inc.
■	Measurement of Dioxin Formation in Heavy-Duty Diesel Engines	Robert Fanick	Southwest Research Institute
■	~~Variability of PM Mass Measurement for Two Sub 1 Mg/Mi Vehicles~~ (withdrawn)	~~Satya Sardar~~	~~California Air Resources Board~~
■	Onsite Checks on Particle Number Equipment	Manfred Linke	AVL List GmbH

Particulate Matter Characterization

■	Determination of Suspended Exhaust PM Mass for Light-Duty Vehicles	Heejung Jung	University of California Riverside (CE-CERT)
■	Insight Into Detailed Properties of Nano-Particles from Various Engine Combustion Sources	Kyeong Lee	Argonne National Laboratory

Off-Road

■	Real-World In-Use Tailpipe Emissions Measurements of Over the Snow Vehicles at Yellowstone National Park	Christopher Frey	North Carolina State University
■	Hybrid Off-Road Equipment Evaluation: Part 1 - Duty Cycle Development	Tangfeng (Sam) Cao	University of California Riverside (CE-CERT)

■ Techniques for the Convenient Off-Road Monitoring an dEnforcement of Heavy-Duty Vehicle Exhaust Emissions	Peter McClintock	Applied Analysis
■ Characterization of Real-World Emissions from Heavy Haulers in Canadian Oil Sands Mining	Xiaoliang Wang	Desert Research Institute

Fuel Effects: Compression Ignition

■ Effect of Biodiesel Feedstock on Regulated Emissions, Gaseous Toxics, and Ultrafine Particles from Two Trucks Fitted With and Without Aftertreatment Controls	Nicholas Gysel	University of California Riverside (CE-CERT)

Fuel Effects: Spark Ignition

■ Impact of Natural Gas Fuel Composition on Criteria and Toxic Emissions from Transit Buses	Maryam Hajbabaei	University of California Riverside (CE-CERT)

Demonstrations

■ TSI Engine Emissions Solutions	Tim Johnson Bob Anderson	TSI, Inc.
■ Photoacoustic Measurement of Black Carbon Emissions	Gavin McMeeking	Droplet Measurement Technologies
■ Particle Mass and Particle Number Measurement for Automotive Engine and Aircraft Turbine Applications	Siegfried Roeck	AVL
■ RDE Real Driving Emissions Measurement with AVL PEMS Equipment*	Siegfried Roeck	AVL
■ Sensors, Inc.	Robert Wilson	Sensors, Inc.
■ Dekati and Pegasor Instruments for PM Sampling, Conditioning, and Analysis	Tyler Beck	Particle Instruments
■ Real-World Emissions Testing Based on FTIR Technology	Ron Tandy	A&D Technology

*This demonstration is located in the parking lot outside the ballroom.

Chairmen

■ Mani Natarajan, Co-Chairman, Marathon Petroleum Company

Mani Natarajan is currently working at Marathon Petroleum Company as a Fuels Technology Advisor. He is leading a CRC project on biodiesel and renewable diesel characterization in modern LD diesel passenger cars and trucks. He is currently the co-chairman of the CRC Real World Emissions and Emissions Modeling Group. He is a member of the CRC Emissions Committee, CRC AVFL Committee, CRC Atmospheric Impacts Committee and API Vehicle Emissions Group. Over the past 23 years, he has been very active in CRC and API projects, conducting fuels/emissions-related research. He has a B.S and M.S. in Chemistry and a M.S. and Ph.D. in Chemical Engineering. He was an Associate Professor at the College of Engineering, The University of Toledo. Previously, as Manager of Research at Surface Combustion, he led projects in advanced combustion, renewable energy and heat treatment. He was a consultant for Pratt & Whitney in the super alloy manufacturing development of the Integrally Bladed Rotors (IBR) for jet engines. He is a member of SAE, AIChE and ACS.

■ Dominic DiCicco, Co-Chairman, Ford Motor Company

Dominic DiCicco was recently appointed to the position of Environmental Policy Manager in the Sustainability and Vehicle Environmental Matters Division at Ford Motor Company. His new role involves supporting the execution of Ford Motor Company's strategic product plans as well as topics of mutual interest on improving fuel quality and regulations, requiring interaction with the US Environmental Protection Agency (US EPA), California Air Resources Board (CARB) and other government entities around the world. Mr. DiCicco is the co-chairman of the CRC Real World Emissions and Emissions Modeling Group and serves as a member on both the CRC Emissions Committee and CRC AVFL Committee. He is a Ford representative on the Fuels Working Group of United States Council for Automotive Research (USCAR), the Alliance of Automobiles and other industry-related efforts. Recent and past major projects have included key roles in working towards the successful reduction in sulfur content in fuels, elimination of manganese across the Canadian marketplace and more recently in the evaluation of mid-level ethanol blends (such as E15 and E20). His career with Ford Motor Company is nearly 20 years young, more than half this time supporting fuels after starting at the Ford Research Laboratory in the Chemical Engineering Department researching exhaust emission catalytic systems. Mr. DiCicco holds a M.S. and B.S. in Chemical Engineering and a B.A. in Chemistry, all from Wayne State University.

Session Leaders

■ Alberto Ayala, California Air Resources Board

Alberto Ayala was appointed as Deputy Executive Officer of the California Air Resources Board at the end of 2012. In this capacity, Alberto is responsible for the Board's ambient monitoring and laboratories and mobile source control and operations programs. Alberto became a member of CARB's research staff in 2000 and has since held various management assignments in programs such as Carl Moyer Incentives, AB 32 early actions, mobile refrigerant rules, diesel retrofits, and car, truck, and bus emissions research. Most recently he served as Chief of the Monitoring and Laboratory Division. Alberto oversees the full range of policy, regulatory, and research efforts of over 400 professionals focused on achieving CARB's goals for clean, zero-emission, and low-carbon transportation; state-of-the-art monitoring for air and climate pollution; and a widely recognized motor vehicle emissions and fuels testing program. He contributed to the first car GHG emissions regulation in 2004 and is now directing one of CARB's most important efforts, the advanced clean cars program.

Prior to CARB, Alberto was a member of the engineering faculty at West Virginia University, where he now holds an adjunct appointment, and was an ordnance system design engineer for Teledyne Ryan Aeronautical. He holds B.S., M.S., and Ph.D. degrees in Mechanical Engineering from the University of California, Davis. His internships were with GE, the California Energy Commission, and the Atmospheric Boundary Layer Wind Tunnel Laboratory at UC Davis. He has published extensively, been a speaker nationally and internationally, and lectured as a Visiting Professor in California and abroad.

■ Megan Beardsley, US Environmental Protection Agency OTAQ

Megan Beardsley is an environmental scientist in the Air Quality & Modeling Center within the Assessment and Standards Division of EPA's Office of Transportation and Air Quality. Her group is responsible for the development of mobile source models, including MOVES and NONROAD, and supporting EPA programs and policies through emissions and activity research, policy analysis, emissions inventory development and air quality modeling support. Megan has worked for EPA since 1992. She has an interdisciplinary B.S. from Stanford University and an M.S. in Resource Policy from the University of Michigan.

■ Kevin Black, Federal Highway Administration

Kevin Black is a Highway Engineer working as an Air Quality Analyst on air quality issues for the Federal Highway Administration's Resource Center in Baltimore. He has a B.A. in Geography from George Mason University, a B.S. in Civil Engineering from Virginia Tech and an M.S. in Civil Engineering from George Mason University. He has worked in several offices within FHWA, including the Office of Research, the Office of Engineering, the Office of Natural and Human Environment, and currently the Resource Center. His present position is responsible for analyzing the environmental impacts of air pollutants in support of FHWA air quality policy.

■ R. Rob Graze, Jr., Caterpillar, Inc. Technical Center

Rob Graze is degreed in Physics with additional study in Mechanical Engineering. His Research Background includes work in the areas of tribology, lube system and bearing design, diesel and large SI engine combustion development, particulate and gaseous emissions measurement, and partial flow dilution system design and refinement.

■ Philip Heirigs, Chevron Global Downstream

Phil Heirigs, a native of California, holds a B.S. in Engineering and a M.S. in Chemical Engineering from the University of California, Los Angeles, and is a licensed Professional Engineer in the state. His professional career began with a short stint in the nuclear power industry, which was followed by nearly seven years with the California Air Resources Board. Mr. Heirigs then spent 15 years at Sierra Research, a Sacramento-based consulting firm. In June 2007, Mr. Heirigs joined Chevron, where his key responsibilities have included the analysis of issues related to the life cycle assessment of transportation fuels, vehicle fuel economy, advanced vehicle technologies and costs, transportation fuel demand, the impact of fuel specification changes on vehicle emissions, and vehicle emissions modeling.

■ Jorn Dinh Herner, California Air Resources Board

Jorn Herner has worked for the last eight years at the California Air Resources Board. In his current position as Chief of the Research Planning and Emission Mitigation Branch in the Research Division, he oversees the division's extramural research program, the implementation of measures to reduce greenhouse gases, and the vehicle emissions research program. His main research interests are the effect of new emission control technologies and fuels and the relative toxicity of emissions from various combustion sources. Jorn has a B.A. and M.S. from the University of California, Berkeley, and earned his Ph.D. in Civil and Environmental Engineering from the University of California, Davis.

■ Henry Hogo, South Coast Air Quality Management District

Henry Hogo is the Assistant Deputy Executive Officer for the Mobile Source Division in the Office of Science and Technology Advancement at the South Coast Air Quality Management District (SCAQMD). Mr. Hogo received a Bachelor of Science degree in chemistry from the University of California, Berkeley, and has been working in the air pollution field for over 35 years. As Assistant Deputy Executive Officer in the Mobile Source Division, Mr. Hogo is responsible for the implementation of the District's Clean Fleet Vehicle Rules, development of mobile source strategies for the SCAQMD's air quality management plans, analysis of mobile source emissions impacts on air quality, and providing input on state and federal mobile source regulations.

■ John Koupal, Eastern Research Group

John Koupal is a Principal Engineer with Eastern Research Group, Inc. (ERG) with over twenty years of experience in mobile source emission research, policy, modeling and inventory development in the U.S. and abroad. Prior to joining ERG, Mr. Koupal served many roles within the U.S. EPA's Office of Transportation and Air Quality, including directing the group responsible for mobile source modeling and emission inventory development, providing technical and analytical support for several EPA rules, and leading the development of the MOVES model. Mr. Koupal worked for Nissan from 1995-1997 on emissions certification and regulatory issues. Mr. Koupal was named to the Advisory Committee on the National Mobile Source Emission Inventory of China in 2010, and the Board of Advisors for UC Riverside?s Center for Environmental Research and Technology (CE-CERT) in 2012. Mr. Koupal graduated from the University of Michigan with a Bachelor's Degree in Industrial and Operations Engineering in 1989.

■ Tom Long, US Environmental Protection Agency NRMRL

Tom Long received his M.S. in Engineering from West Virginia University, where he worked with Nigel Clark on the design of the first heavy-duty mobile dynamometer. Later, he served as the West Coast Coordinator for West Virginia's Center for Alternative Fuels, Engines, and Emissions (CAFEE). After working as a contractor to the U.S. EPA in RTP, North Carolina, Tom was hired by the government to coordinate the dynamometer facility operated by the EPA's Office of Research and Development. His area of research includes the measurement of mobile source emissions using both stationary and chassis dynamometer, PEMS, and near road stationary sites. He is particularly interested in fuel and temperature effects on the quantity and characteristics of mobile source emissions.

■ Matthew Thornton, National Renewable Energy Laboratory

Matt Thornton is a principal research engineer at the National Renewable Energy Laboratory. He received his Ph.D. from Georgia Institute of Technology. He is involved in testing and analysis research programs that assess the fuel economy and performance impacts of advanced fuels and powertrains for light- and heavy-duty vehicles, and is currently the acting director for NREL's Center for Transportation Technologies and Systems.

12_B_LCFS_GE Responses (Page 301 – 316)

725. Comment: **CRC Emissions Workshop Agenda**

Agency Response: This document is an agenda from the April 2013 CRC Emissions Workshop. It does not constitute an objection or suggestion on the proposal; however the document was referenced in comment **ADF B3-115**. The comment is responded to in the Alternative Diesel Regulation Final Statement of Reasons under comment letter **3_B_ADF_GE**.

ATTACHMENT C

Comments of Growth Energy on the Air Resources Board Staff Presentations at a Public Consultation Meeting on Regulations for Commercialization of Alternative Diesel Fuels

These comments respond to the CARB staff's request for comments on the staff's presentations at the April 17, 2014 public consultation meeting on the proposed adoption of regulations to govern commercialization of alternative diesel fuels, including as part of compliance strategies for the California low-carbon fuel standard ("LCFS") regulation.

1. CARB-Sponsored and Related Emissions Testing and Research

During the April 17th meeting, CARB staff indicated that the agency had an "ongoing" study of the emission impacts of B5 and B10 blends underway and that data from that study would be released to the public and incorporated into the rulemaking process. Incorporation of this data into the rulemaking process is essential in order to comply with the Global Warming Solutions Act of 2006 and other statutes that apply to CARB's implementation of the 2006 Act.[1] CARB must provide not only a full report on that study, but also all data that it has obtained in connection with the study and related materials. Nearly four weeks have passed since the April 17th public meeting and, to Growth Energy's knowledge, the CARB staff has not met its commitments.[2] Growth Energy and other stakeholders will need sufficient time to review the data and related materials in order to participate effectively in the ADF and LCFS rulemakings. Also during the course of the workshop, CARB staff indicated that two other agency-sponsored studies of biodiesel blends had been conducted but not yet released to the public. Again, all

ADF B3-122

1 *See, e.g.*, Cal. Health & Safety Code § 38562(e) ("The state board shall rely upon the best available ... scientific information ... when adopting regulations required by this section."); *see also id.* § 38563(b)(4) (regulations to implement the 2006 Act must not "interfere with[] efforts to achieve and maintain federal and state ambient air quality standards."). The California Environmental Quality Act's requirements likewise cannot be met unless CARB considers all relevant data on the potential of biodiesel usage to increase NOx emissions.

2 Much of the data from this study and related materials may also be responsive to a Public Records Act request that Growth Energy has filed with CARB, but no data and very few related materials have been released to date.

reports as well as underlying data and other relevant materials must be made publicly available. All these materials, from each study, must be placed in a public rulemaking file without further delay, pursuant to subsections 6 and 7 of section 11347.3(a) of the Government Code. ADF B3-122 cont.

2. Methodology to Establish a Significance Threshold and Related Issues

To date, CARB staff has indicated that it has attempted to identify a significance threshold for biodiesel blends by comparing emissions results when engines are tested on nominally specific biodiesel blends, and when the same engines are tested in similar ways on fuel containing no diesel. The defect in such a method is that it does not permit assessment of emissions when engines are operated on biodiesel blends other than those tested, including, for example, biodiesel blends below B5. The appropriate method to determine the significance threshold is contained in an analysis prepared for Growth Energy by Mr. Robert Crawford and placed in the rulemaking file last year.[3] After evaluating the linearity and statistical significance of the relationship between NOx emissions and biodiesel content, Mr. Crawford demonstrates that use of biodiesel even at levels below B5 will result in increased NOx emissions. CARB should adopt Mr. Crawford's approach to establishing the significance threshold for biodiesel, or explain in full any reasons for not doing so. ADF B3-123

Despite the fact that CARB staff has correctly chosen to propose mitigation of biodiesel NOx impacts on a per-gallon basis in extreme ozone non-attainment areas, this issue is important because the use of the current methodology for establishing the significance level will not prevent significant increases in NOx emissions in these areas. ADF B3-124

---

3 Crawford, R., "NOx Emission Impact of Soy- and Animal-based Biodiesel Fuels: A Re-Analysis," December 10, 2013.

3. Protection of the Environment on a Statewide Basis

Based on the presentation at the recent public consultation meeting, CARB staff continues to propose the highly flawed "effective blend" approach for determining the point at which mitigation of biodiesel NOx impacts would be required under the proposed ADF regulation. Instead, CARB staff should also require the per-gallon mitigation concept proposed for extreme ozone nonattainment areas and the appropriate significance threshold to be used in all other areas of the state. ADF B3-125

4. Minimum Requirements to Determine and Report Blend Levels

The CARB staff's presentation at the recent meeting did not clarify how the proposed ADF regulation will ensure that the biodiesel content of blends sold in California will be accurately known to fuel purchasers or reported to CARB. At present, CARB appears to have no requirement for determining the biodiesel content of diesel fuels being imported or distributed in the state that contain biodiesel up to the B5 level. Given this, a party interested in blending 5% biodiesel into a "diesel" fuel may be unaware of the fact that the "diesel" fuel could already contain up to 5% biodiesel and that the resulting blend would therefore be B10, not B5. Similarly, a party interested in blending 20% biodiesel into a "diesel" could in fact produce a B25 blend, instead of the intended B20 blend. Obviously, both circumstances have substantial ramifications with respect to potential NOx increases associated with the use of biodiesel in California. ADF B3-126

Given the above, CARB must modify as necessary its existing diesel fuel regulations as well as the proposed ADF regulations to ensure that the biodiesel content of all blends of biodiesel and diesel sold in California is accurately known and reported to both CARB as well as the Division of Measurement Standards. This could easily be accomplished by requiring that all ADF B3-127 "diesel" fuels used in biodiesel blends be tested before blending for Fatty Acid Methyl Ester ("FAME") content using appropriate test procedures such as the EN14103:2011 procedure already referenced in the proposed ADF regulations or the ASTM D7371 procedure. Alternatively, CARB could require testing of final blends for FAME content. Again, failure by CARB to require accurate measurement and reporting of the biodiesel content of biodiesel-diesel blends will lead to unmitigated increases in NOx emissions along with other potential issues, including violations of pump labeling and vehicle manufacturer warranty requirements.

ADF B3-127 cont.

Respectfully submitted,

GROWTH ENERGY

1. EXECUTIVE SUMMARY

1.1 Background on the Proposed Rule

The California Air Resources Board (CARB) has proposed regulations on the commercialization of alternative diesel fuel (ADF) that were to be heard at the December 2013 meeting of the Board. The proposed regulations seek to "... create a streamlined legal framework that protects California's residents and environment while allowing innovative ADFs to enter the commercial market as efficiently is possible."[1] In this context ADF refers to biodiesel fuel blends. Biodiesel fuels are generally recognized to have the potential to decrease emissions of several pollutants, including hydrocarbons (HC), carbon monoxide (CO), and particulate matter (PM), but are also recognized to have the potential to increase oxides of nitrogen (NOx) unless mitigated in some way. NOx emissions are an important precursor to smog and have historically been subject to stringent emission standards and mitigation programs to prevent growth in emissions over time. A crucial issue with respect to biodiesel is how to "... safeguard against potential increases in oxides of nitrogen (NOx) emissions."[2]

The proposed regulations are presented in the Staff Report: Initial Statement of Reasons (ISOR) for the Proposed Regulation on the Commercialization of New Alternative Diesel Fuels[3] (referenced as ISOR). Chapter 5 of the document describes the proposed regulations, which exempt diesel blends with less than 10 percent biodiesel (B10) from requirements to mitigate NOx emissions:

> There are two distinct blend levels relative to biodiesel that have been identified as important for this analysis. Based on our analysis to date, we have found that diesel blends with less than 10 percent biodiesel by volume (<B10) have no significant increase in any of the pollutants of concern and therefore will be regulated at Stage 3B (Commercial Sales not Subject to Mitigation). However, we have found that biodiesel blends of 10 percent and above (≥B10) have potentially significant increases in NOx emissions, in the absence of any mitigating factors, and therefore those higher blend levels will be regulated under Stage 3A (Commercial Sales Subject to Mitigation).[4]

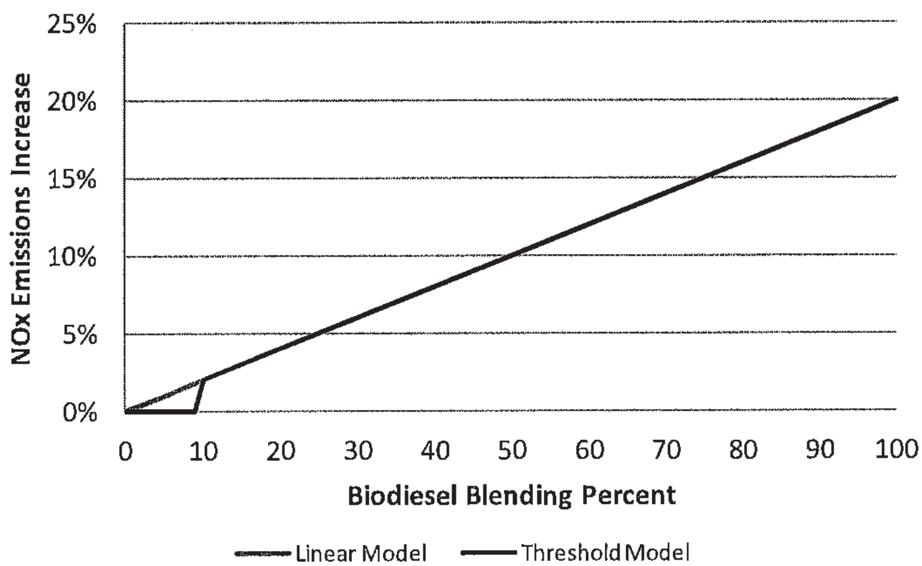
[4] Ibid, p. 22.

Existing research on the NOx emission effects of biodiesel has consistently been conducted under the hypothesis that the emission effect will be linearly proportional to the blending percent of neat biodiesel (B100) with the base diesel fuel. The Linear Model that has been accepted by researchers is shown as the blue line in Figure 1-1. The Staff position cited above is that biodiesel fuels do not increase NOx emissions until the fuel blend reaches 10% biodiesel. This so-called Staff Threshold Model departs from the Linear Model that underlies past and current biodiesel research by claiming that NOx emissions do not increase until the biodiesel content reaches 10 percent.

Figure 1-1
Linear and Staff Threshold Models for Biodiesel NOx Impacts



The Staff Threshold model is justified by the statement: "Based on our analysis to date, we have found that diesel blends with less than 10 percent biodiesel by volume (<B10) have no significant increase in any of the pollutants of concern." Other portions of the ISOR state that Staff will track "... the effective blend level on an annual statewide average basis until the effective blend level reaches 9.5 percent. At that point, the biodiesel producers, importers, blenders, and other suppliers are put on notice that the effective blend-level trigger of 9.5 percent is approaching and mitigation measures will be required once the trigger is reached."[5] Until such time, NOx emission increases from biodiesel blends below B10 will not require mitigation.

Section 6 of the ISOR presents a Technology Assessment that includes a literature search the Staff conducted to obtain past studies on the NOx impact of biodiesel in heavy-duty

[5] Ibid, p. 24.

engines using California diesel (or other high-cetane diesel) as a base fuel. Section 6.d presents the results of the literature search with additional technical information provided in Appendix B. The past studies include the Biodiesel Characterization and NOx Mitigation Study[6] sponsored by CARB (referenced as Durbin 2011).

The results of the Staff literature search are summarized in Table 1-1, which has been reproduced from Table 6.1 of the ISOR. For B5 and B20, the data represent averages for a mix of soy- and animal-based biodiesels, which tend to have different impacts on NOx emissions (animal-based biodiesels increase NOx to a lesser extent). For B10, the data represent an average for soy-based biodiesels only. Staff uses the +0.3% average NOx increase at B5 in comparison to the 1.3% standard deviation to conclude:

> Overall, the testing indicates different NOx impacts at different biodiesel percentages. Staff analysis shows there is a wide statistical variance in NOx emissions at biodiesel levels of B5, providing no demonstrable NOx emissions impact at this level and below. At biodiesel levels of B10 and above, multiple studies demonstrate statistically significant NOx increases, without additional mitigation.[7]

Table 1-1
Results of Literature Search Analysis

Biodiesel Blend Level	NOx Difference	Standard Deviation
B5	0.3%	1.3%
B10[a]	2.7%	0.2%
B20	3.2%	2.3%

Source: Table 6.1 of Durbin 2011
Notes:
[a] Represents data using biodiesel from soy feedstocks.

The Staff conclusion is erroneous because it relies upon an apples-to-oranges comparison among the blending levels. Each of the B5, B10, and B20 levels include data from a different mix of studies, involving different fuels (soy- and/or animal-based), different test engines, and different test cycles. The B5 values come solely from the CARB Biodiesel Characterization study, while the B10 values come solely from other studies. The B20 values are a mix of data from the CARB and other studies. The results seen in the table above are the product of the uncontrolled aggregation of different studies that produces incomparable estimates of the NOx emission impact at the three blending levels.

[6] "CARB Assessment of the Emissions from the Use of Biodiesel as a Motor Vehicle Fuel in California: Biodiesel Characterization and NOx Mitigation Study." Prepared by Thomas D. Durbin, J. Wayne Miller and others. Prepared for Robert Okamoto and Alexander Mitchell, California Air Resources Board. October 2011.

[7] ISOR, p. 32.

As will be demonstrated in this report, the Staff conclusion drawn from the data in Table 1-1 is not supported by past or current biodiesel research, including the recent testing program sponsored by CARB. In fact, past and current studies indicate that biodiesel blends at any level will increase NOx emissions in proportion to the blending percent unless specifically mitigated by additives or other measures.

1.2 Summary and Conclusions

The following sections of this report examine the studies cited by CARB one-by-one. As evidenced from this review, it is clear that the data do not support the Staff conclusion and, indeed, the data refute the Staff conclusion in some instances. Specifically:

- There is no evidence supporting the Staff conclusion that NOx emissions do not increase until the B10 level is reached. Instead, there is consistent and strong evidence that biodiesel increases NOx emissions in proportion to the biodiesel blending percent.

- There is clear and statistically significant evidence that biodiesel increases NOx emissions at the B5 level in at least some engines for both soy- and animal-based biodiesels.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

Considering each of the six past studies obtained from the technical literature and their data on high-cetane biodiesels comparable to California fuels, we find the following:

1. None of the six studies measured the NOx emissions impact from biodiesel at blending levels below B10. Only two studies tested a fuel at the B10 level. All other testing was at the B20 level or higher. Because none tested a B5 (or similar) fuel, none of them can provide direct evidence that NOx emissions are not increased at B5 or other blending levels below B10.

2. These studies provide no data or evidence supporting the validity of the Staff's Threshold Model that biodiesel below B10 does not increase NOx emissions. In fact, all of the studies are consistent with the contention that biodiesel increases NOx emissions in proportion to the blending percent.

3. Two of the studies present evidence and arguments that the NOx impact from biodiesel is a continuous effect that is present even at very low blending levels and will increase at higher levels in proportion to the blending percentage.

Considering the CARB Biodiesel Characterization report, we find that:

4. For the three engines where CARB has published the emission values measured in engine dynamometer testing, all of the data demonstrate that biodiesel fuels significantly increase NOx emissions for both soy- and animal-based fuels by amounts that are proportional to the blending percent. This is true for on-road and off-road engines and for a range of test cycles.

5. Where B5 fuels were tested for these engines, NOx emissions were observed to increase. NOx emission increases are smaller at B5 than at higher blending levels and the observed increases for two engines were not statistically significant by themselves based on the pair-wise t-test employed in Durbin 2011.[8] However, the testing for one of the engines (the 2007 MBE4000) showed statistically significant NOx emission increases at the B5 level for both soy- and animal-based blends.

By itself, the latter result is sufficient to disprove the Staff's contention that biodiesel blends at the B5 level will not increase NOx emissions.

Based on examination of all of the studies cited by CARB as the basis for its proposal to exempt biodiesels below B10 from mitigation, it is clear that the available research points to the expectation that both soy- and animal-based biodiesel blends will increase NOx emissions in proportion to their biodiesel content, including at the B5 level. CARB's own test data demonstrate that B5 will significantly increase NOx emissions in at least some engines.

Based on data in the CARB Biodiesel Characterization report, soy-based biodiesels will increase NOx emissions by about 1% at B5 (and 2% at B10), while animal-based biodiesels will increase NOx emissions by about one-half as much: 0.45% at B5 (and 0.9% at B10). All of the available research says that the NOx increases are real and implementation of mitigation measures will be required to prevent increases in NOx emissions due to biodiesel use at blending levels below B10.

Finally, we note that CARB has not published fully the biodiesel testing data that it relied on in support of the Proposed Rule and thereby has failed to adequately serve the interest of full public disclosure in this matter. The CARB-sponsored testing reported in Durbin 2011 is the sole source of B5 testing cited by CARB as support for the Proposed Rule. Durbin 2011 publishes only portions of the measured emissions data in a form that permits re-analysis; it does not publish any of the B5 data in such a form. It has not been possible to obtain the remaining data through a personal request to Durbin or an official public records request to CARB and, to the best of our knowledge, the data are not otherwise available online or through another source.

CARB should publish all of the testing presented in Durbin 2011 and any future testing that it sponsors in a complete format that allows for re-analysis. Such a format would be (a) the measured emission values for each individual test replication; or (b) averages across all test replications, along with the number of replications and the standard error of the individual tests. The first format (individual test replications) is preferable because that would permit a full examination of the data including effects such as test cell drift over time. Such publication is necessary to assure that full public disclosure is achieved and that future proposed rules are fully and adequately informed by the data.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

[8]As discussed in Section 3.3, the pair-wise t-test is not the preferred method for demonstrating statistical significance.

1.3 Review of 2013 CARB B5 Emission Testing

In December 2013, after the release of the ISOR and in response to an earlier Public Records Act request, CARB released a copy of new CARB-sponsored emission testing conducted by Durbin and others at the University of California CE-CERT[9]. The purpose of the study was "... to evaluate different B5 blends as potential emissions equivalent biodiesel fuel formulations for California."[10] Three B5 blends derived from soy, waste vegetable oil (WVO), and animal biodiesel stocks were tested on one 2006 Cummins ISM 370 engine using the hot-start EPA heavy-duty engine dynamometer cycle. A preliminary round of testing was conducted for all three fuels followed by emissions-equivalent certification testing per 13 CCR 2282(g) for two of the fuels. As noted by Durbin: "[t]he emissions equivalent diesel certification procedure is robust in that it requires at least twenty replicate tests on the reference and candidate fuels, providing the ability to differentiate small differences in emissions."[11]

Soy and WVO B5 Biodiesel

The B5-soy and B5-WVO fuels were blended from biodiesel stocks that were generally similar to the soy-based stock used in the earlier CARB Biodiesel Characterization Study (Durbin 2011) with respect to API gravity and cetane number. In the preliminary testing, the two fuels "...showed 1.2-1.3% statistically significant [NOx emissions] increases with the B5-soy and B5-WVO biodiesel blends compared to the CARB reference fuel."[12] The B5-WVO fuel caused the smaller NOx increase (1.2%) and was selected for the certification phase of the testing. There, it "... showed a statistically significant 1.0% increase in NOx compared to the CARB reference fuel"[13] and failed the emissions-equivalent certification due to NOx emissions.

Reproduction of
Pages 167 - 204
Consisting of
Comments ADF B3-146
through ADF B3-92

Animal B5 Biodiesel

The B5-animal derived fuel was blended from an animal tallow derived biodiesel that was substantially different from the animal based biodiesel used in the earlier Durbin study, and was higher in both API gravity and cetane number. The blending response for cetane number was also surprising, in that blending 5 percent by volume of a B100 stock (cetane number 61.1) with 95% of CARB ULSD (cetane number 53.1) produced a B5 fuel blend with cetane number 61.

In preliminary testing, the B5-animal fuel showed a small NOx increase which was not statistically significant, causing it to be judged the best candidate for emissions-equivalent certification. In the certification testing, it "...showed a statistically

[9] "CARB B5 Biodiesel Preliminary and Certification Testing." Prepared by Thomas D. Durbin, G. Karavalakis and others. Prepared for Alexander Mitchell, California Air Resources Board. July 2013. This study is not referenced in the ISOR, nor was it included in the rule making file when the hearing notice for the ADF regulation was published in October 2013.

[12] Ibid, p. 8.
[13] Ibid, p. 9.

significant 0.5% reduction in NOx compared to the CARB reference fuel"[13] and passed the emissions-equivalent certification. The NOx emission reduction for this fuel blend appears to be real for this engine, but given the differences between the blendstock and the animal based biodiesel blendstock used in the earlier Durbin study it is unclear that it is representative for animal-based biodiesels in general..

Summary

The conclusions drawn in the preceding section are not changed by the consideration of these new emission testing results. For plant-based biodiesels (soy- and WVO-based), the new testing provides additional and statistically significant evidence that B5 blends will increase NOx emissions at the B5 level. The result of decreased NOx for the B5 animal-based blend stands out from the general trend of research results reviewed in this report. However:

- The same result – reduced NOx emissions for some fuels and engines – has sometimes been observed in past research, as evidenced by the emissions data considered by CARB staff in ISOR Figure B.3 (reproduced in Figure 2.1 below). As shown, some animal-based B5 and B20 fuels reduced NOx emissions while others increased NOx emissions with the overall conclusion being that NOx emissions increase in direct proportion to biodiesel content of the blends and that there is no emissions threshold.

- Increasing cetane is known to generally reduce NOx emissions and has already been proposed by CARB as a mitigation strategy for increased NOx emissions from biodiesel[14]. The unusual cetane number response in the blending and the high cetane number of the B5-animal fuel may account for the results presented in the recently released study.

Considering the broad range of plant- and animal-based biodiesel stocks that will be used in biodiesel fuels, we conclude that the available research (including the recently released CARB test results) indicates that unrestricted biodiesel use at the B5 level will cause real increases in NOx emissions and that countermeasures may be required to prevent increases in NOx emissions due to biodiesel use at blending levels below B10.

2. CARB LITERA TURE REVIEW

The Staff ISOR explains that the Appendix B Technology Assessment is the basis for CARB's conclusion that biodiesels below B10 have no significant impact on NOx emissions. The assessment is based on data from seven studies (identified in Table 2-1) that tested high-cetane diesel fuels. The first study (Durbin 2011) is the Biodiesel Characterization Study that was conducted for CARB, while the others were obtained through a literature search.

Tab le 2-1

soy-based biodiesels are shown to increase NOx emissions by approximately 1% at B5, 2% at B10, and 4% at B20. Animal-based biodiesels are shown to increase NOx emissions by about one-half as much: 0.45% at B5, 0.9% at B10, and 1.8% at B20. Although there is substantial scatter in the results, these data do not appear to support the Staff Threshold Model that biodiesel does not increase NOx emissions at B5 but does so at B10.

We will examine the Durbin 2011 study at some length in Section 3. In this section, we look at each of the other studies cited by the Staff to find out what the studies say about NOx emissions impacts at and below B10.

2.1 Review of Literature Cited in the ISOR

The Staff literature search sought and selected testing that used fuels with cetane levels comparable to California diesel fuels; the Staff does not, however, list those fuels or provide the data that support the tables and figures in Appendix B of the ISOR. Therefore, we have necessarily made our own selection of high-cetane fuels in the course of reviewing the studies. The key testing and findings of each study are summarized below, with a specific focus on what they tell us about NOx emission impacts at B10 and below.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

2.1.1 Clark 1999

This study tested a variety of fuels on a 1994 7.3L Navistar T444E engine. Of the high-cetane base fuels, one base fuel (Diesel A, off-road LSD) was blended and tested at levels of B20, B50, and B100. NOx emissions were significantly increased for all of the blends. The other base fuel (CA Diesel) was tested only as a base fuel. Its NOx emissions were 12% below that of Diesel A, making it is unclear whether Diesel A is representative of fuels in CA. This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below.

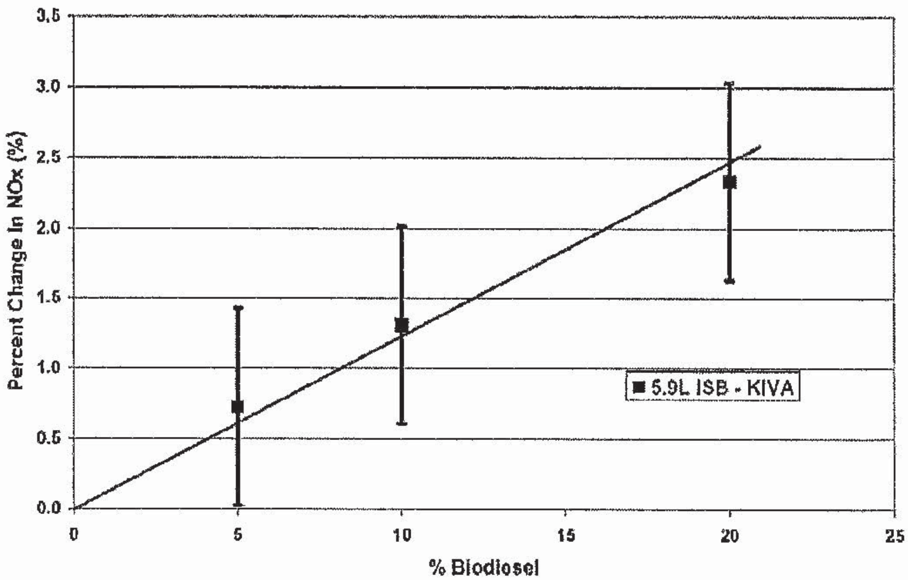
2.1.2 Eckerle 2008

This study tested low and mid/high-cetane base fuels alone and blended with soy-based biodiesel at the B20 level. The Cummins single-cylinder test engine facility was used in a configuration representative of modern diesel technology, including cooled EGR. Testing was conducted under a variety of engine speed and load conditions. FTP cycle emissions were then calculated from the speed/load data points. The test results show that B20 blends increase NOx emissions compared to both low- and high-cetane base fuels. This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below.

The study notes that two other studies "show that NOx emissions increase nearly linearly with the increase in the percentage of biodiesel added to diesel fuel." Eckerle's Figure 21 (reproduced below as Figure 2-2) indicates a NOx emissions increase at B5, which is the basis for the statement in the abstract that "Results also show that for biodiesel blends containing less than 20% biodiesel, the NOx impact over the FTP cycle is proportional to

the blend percentage of biodiesel." The authors clearly believe that biodiesel fuels have NOx emission impacts proportional to the blending percent at all levels including B5.

Figure 2-2
Impact of Biodiesel Blends on Percent NOx Change for the 5.9L ISB Engine Operation Over the FTP Cycle



Source: Figure 21 of Eckerle 2008

2.1.3 McCormick 2002

This study tested low- and mid-cetane base fuels alone and blended with soy- and animal-based biodiesel at the B20 level. The testing was conducted on a 1991 DDC Series 60 engine using the hot-start U.S. heavy-duty FTP. NOx emission increases were observed for both fuels at the B20 level. Mitigation of NOx impacts was investigated by blending a Fisher-Tropsch fuel, a 10% aromatics fuel and fuel additives. This study conducted no testing of the NOx emissions impact from commercial biodiesels at the B10 level or below.

This study also tested a Fisher-Tropsch (FT) base fuel blended at the B1, B20, and B80 levels. Although the very high cetane number (≥75) takes it out of the range of commercial diesel fuels, it is interesting to note that the study measured higher NOx emissions at the B1 level than it did on the FT base fuel and substantially higher NOx emissions at the B20 and B80 levels. While the B1 increase was not statistically significant given the uncertainties in the emission measurements (averages of three test runs), it is clear that increased NOx emissions have been observed at very low blending levels.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

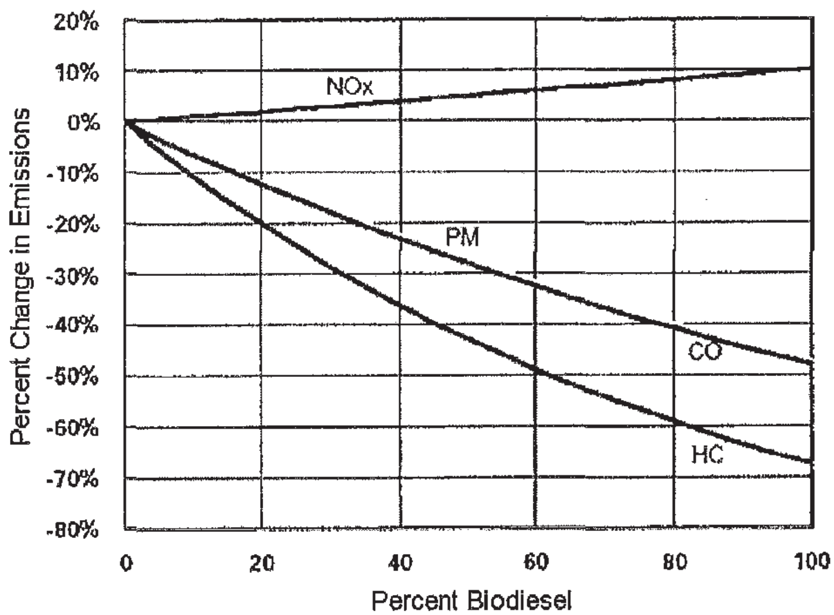
2.1.4 McCormick 2005

This study tested blends of soy- and animal-based biodiesels with a high-cetane ULSD base fuel at B10 levels and higher. Two engines were tested – a 2002 Cummins ISB and a 2003 DDC Series 60, both with cooled EGR. The hot-start U.S. heavy-duty FTP test cycle was used. The majority of testing was at the B20 level with additional testing at the B50 and B100 levels. One soy-based fuel was tested at B10. The study showed NOx emission increases at B10, B20, and higher levels. The study also investigated mitigation of NOx increases. This study conducted no testing of the NOx emissions impact from biodiesels below the B10 level.

The authors present a figure (reproduced as Figure 2-3) in their introduction that shows their summary of biodiesel emission impacts based on an EPA review of heavy-duty engine testing. It shows NOx emissions increasing linearly with the biodiesel blend percentage.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

Figure 2-3
Trend in HC, CO, NOx and PM Emissions with Biodiesel Percent



Source: McCormick 2005

2.1.5 Nuszkowski 2009

This study tested five different diesel engines: one 1991 DDC Series 60, two 1992 DDC Series 60, one 1999 Cummins ISM, and one 2004 Cummins ISM. Only the 2004 Cummins ISM was equipped with EGR. All testing was done using the hot-start U.S. heavy-duty FTP test cycle. The testing was designed to test emissions from fuels with and without cetane-improving additives. Although a total of five engines were tested, the base diesel and B20 fuels were tested on only two engines (one Cummins and one DDC Series 60) because there was a limited supply of fuel available. NOx emissions increased on the B20 fuel for both engines. A third engine (Cummins) was tested on B20 and B20 blended with cetane improvers to examine mitigation of NOx emissions. This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below.

2.1.6 Thompson 2010

This study examined the emissions impacts of soy-based biodiesel at the B10 and B20 levels relative to low-cetane (42), mid-cetane (49), and high-cetane (63) base fuels using one 1992 DDC Series 60 engine. The emissions results were measured on the hot-start U.S. heavy-duty FTP cycle. The study found that NOx emissions were unchanged (observed differences were not statistically significant) at B10 and B20 levels for the low- and mid-cetane fuels. NOx emissions increased significantly at B10 and B20 levels for the high-cetane fuels. This study conducted no testing of the NOx emissions impact from biodiesels at levels below B10.

2.2 Conclusions Based on Studies Obtained in Literature Search

From the foregoing summary of the studies cited by Staff, we reach the conclusions given below.

1. None of the six studies measured the NOx emissions impact from commercial-grade biodiesel at blending levels below B10, and only two studies tested a fuel at the B10 level. All other testing was at the B20 level or higher. Because none tested a B5 (or similar) fuel, none is capable of providing direct evidence regarding NOx emissions at B5 or other blending levels below B10.

2. These studies provide no data or evidence supporting the validity of Staff's Threshold Model that biodiesel below B10 does not increase NOx emissions. In fact, all of the studies are consistent with the contention that biodiesel increases NOx emissions in proportion to the blending percent.

3. Two of the studies present evidence and arguments that the NOx impact from biodiesel is a continuous effect that is present even at very low blending levels and will increase at higher levels in proportion to the blending percentage. One study tested a Fischer-Tropsch biodiesel blend at B1 and observed NOx emissions to increase (but not by a statistically significant amount).

3. CARB BIODIESEL CHARACTERIZATION STUDY

3.1 Background

CARB sponsored a comprehensive study of biodiesel and other alternative diesel blends in order "... to better characterize the emissions impacts of renewable fuels under a variety of conditions."[15] The study was designed to test eight different heavy- duty engines or vehicles, including both highway and off-road engines using engine or chassis dynamometer testing. Five different test cycles were used: the Urban Dynamometer Driving Schedule (UDDS), the Federal Test Procedure (FTP), and 40 mph and 50 mph CARB heavy-heavy-duty diesel truck (HHDDT) cruise cycles, and the ISO 8178 (8 mode) cycle. Table 3-1 (reproduced from Table ES-1 of Durbin 2011) documents the scope of the test program. Because the Staff relied only on engine dynamometer testing in its Technology Assessment, only the data for the first four engines (shaded) are considered here.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

Source: Table ES-1 of Durbin 2011, page xxvi
Notes:
[a] Data for the first four engines (shaded) are considered in this report.

[15] Durbin 2011, p. xxiv.

The original goal of this report was to subject all of the NOx emission testing in Durbin 2011 to a fresh re-analysis. However, it was discovered that Durbin 2011 did not report all of the data that were obtained during the program and are discussed in the report. The chassis dynamometer testing was conducted at the CARB Los Angeles facility. Emission results for the chassis dynamometer testing are presented in tabular and graphical form, but the report does not contain the actual emissions test data. For the engine dynamometer testing, some of the measured emission values are not reported even though the emission results are reported in tabulated or graphical form. Requests for the missing data were directed to Durbin in a personal request and to CARB through an official records request. No information has been provided in response and we have not been able to obtain the missing data from online or other sources.

For this report, we have worked with the data in the forms that are provided in Durbin 2011 as being the best-available record of the results of the CARB study. Because Staff used only data obtained in engine dynamometer testing, the analysis presented in this report has done the same. Nevertheless, the results of the chassis dynamometer testing are generally supportive of the results and conclusions presented here. Durbin 2011 notes:

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

> "... The NOx emissions showed a consistent trend of increasing emissions with increasing biodiesel blend level. These differences were statistically significant or marginally significant for nearly all of the test sequences for the B50 and B100 fuels, and for a subset of the tests on the B20 blends."[16]

Durbin notes that emissions variability was greater in the chassis dynamometer testing, which leads to the sometimes lower levels of statistical significance. There was also a noticeable drift over time in NOx emissions that complicated the results for one engine.

3.2 Data and Methodology

Table 3-2 compiles descriptive information on the engine dynamometer testing performed in Durbin 2011. The experimental matrix involves four engines, two types of biodiesel fuels (soy- and animal-based), and up to four test cycles per engine. However, the matrix is not completely filled with all fuels tested on all engines on all applicable test cycles. The most complete testing is for the ULSD base fuel and B20, B50, and B100 blends. There is less testing for the B5 blend, and B5 is tested using only a subset of cycles. For this reason, we first examine the testing for ULSD, B20, B50, and B100 fuels to determine the overall impact of biodiesels on NOx emissions. We then examine the more limited testing for B5 to determine the extent to which it impacts NOx emissions.

This examination is limited by the form in which emissions test information is reported in Durbin 2011. A complete statistical analysis can be conducted only for the two on-road engines for which Appendices G and H of Durbin 2011 provide measured emissions, and for a portion of the testing of the Kubota off-road engine for which Appendix I provides

[16] Durbin 2011, p. 126.

Table 3-2
Experimental Matrix for Heavy-Duty Engine Dynamometer Testing Reported in Durbin 2011

Engine	Biodiesel Type	Fuels Tested	Test Cycles	Notes
On-Road Engines				
2006 Cummins ISM	Soy	ULSD, B20, B50, B100, B5	UDDS, FTP, 40 mph, 50 mph	B5 tested on 40 mph and 50 mph cruise cycles
	Animal	ULSD, B20, B50, B100, B5	UDDS, FTP, 50 mph	B5 tested only on FTP.
2007 MBE4000	Soy	ULSD, B20, B50, B100, B5	UDDS, FTP, 50 mph	B5 tested only on FTP.

measured emissions. The data needed to support a full re-analysis consist of measured emissions on each fuel in gm/hp-hr terms, which are stated in Durbin 2011 as averages across all test replications along with the number of replications and the standard error of the individual tests. With this information, the dependence of NOx emissions on biodiesel blending percent can be determined as accurately as if the individual test values had been reported and the appropriate statistical tests for the significance of results can be performed.

Regression analysis is used as the primary method of analysis. For each engine and test cycle, the emission averages for each fuel are regressed against the biodiesel blending percent to determine a straight line. The regression weights each data point in inverse proportion to the square of its standard error to account for differences in the number and reliability of emission measurements that make up each average. The resulting regression line will pass through the mean value estimated from the data (i.e., the average NOx emission level at the average blending percent), while the emission averages for each fuel may scatter above and below the regression line due to uncertainties in their measurement. The slope of the line estimates the dependence of NOx emissions on the blending percentage.

Where the data points closely follow a straight line and the slope is determined to be statistically significant, one can conclude that blending biodiesel with a base fuel will increase NOx emissions in proportion to the blending percent. The regression line can then be used to estimate the predicted emissions increase for a given blending percent. The predicted emissions increase is the value one would expect on average over many measurements and is comparable to the average emissions increase one would expect in a fleet of vehicles.

The same level of analysis is not possible for the testing on B5 fuel, which is reported as a simple average for the on-road engines and is not reported at all for the off-road engines. For the B5 fuel, Durbin 2011 presents emission test results in a tabulated form where the percentage change in NOx emissions has been computed compared to ULSD base fuel. This form supports the presentation of results graphically, but it does not permit a proper statistical analysis to be performed. Specifically, the computation of percentage emission changes will perturb the error distribution of the data, by mixing the uncertainty in measured emissions on the base fuel with the uncertainties in measured emissions on each biodiesel blend, and it can introduce bias as a result of the mixing. Further statistical analysis of the computed percent values should be avoided because of these problems. Therefore, a more limited trend analysis of the NOx emissions data for B5 and the John Deere engine is conducted.

3.3 2006 Cummins Engine (Engine Dynamometer Testing)

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

Table 3-3 shows the NOx emission results for the 2006 model-year Cummins heavy-duty diesel engine based on a re-analysis of the data for this report. As indicated by highlighting in the table, the relationship between increasing biodiesel content and increased NOx emissions for soy-based biodiesel is statistically significant at >95% confidence level[17] in all cases. For the animal-based biodiesel, the relationship is statistically significant at the 92% confidence level for the UDDS cycle, the 94% confidence level for the 50 mph cruise, and the >99% confidence level for the FTP cycle.

For the soy-based fuels, the R^2 statistics show that the emissions effect of biodiesel is almost perfectly linear with increasing biodiesel content over the range B20, B50, and B100. Although not as high for the animal-based fuels (because the emissions effect is smaller and measurement errors are relatively larger in comparison to the trend), the R^2 statistics nevertheless establish a linear increase in NOx emissions with increasing biodiesel content over the same range. The linearity of the response with blending percent is well supported by the many NOx emissions graphs contained in Durbin 2011.

The table also gives the estimated NOx emission increases for B5 and B10 as predicted by the regression lines. For soy-based fuels, the values are 1% for B5 (range 0.8% to 1.3% depending on the cycle) and 2% for B10 (range 1.6% to 2.6% depending on cycle).

[17] A result is said to be statistically significant at the 95% confidence level when the p value is reported as $p \leq 0.05$. At the $p \leq 0.01$ level, a result is said to be statistically significant at the 99% confidence level, and so forth.

Table 3-3 Re-Analysis for 2006 Cummins Engine (Engine Dynamometer Testing) Model: NOx = A + B · BioPct Using ULSD, B20, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A Value	BioPct Slope B Value	p value	Predicted NOx Increase for B5 Pct Change	Predicted NOx Increase for B10 Pct Change
Soy-based							
	UDDS	0.997	5.896	0.0100 [a]	0.001	0.8%	1.7%
	FTP	0.995	2.024	0.0052	0.003	1.3%	2.6%
	40 mph	1.000	2.030	0.0037	<0.0001	0.9%	1.8%
	50 mph	0.969	1.733	0.0028	0.016	0.8%	1.6%
Animal-based							
	UDDS	0.847	5.911	0.0021 [b]	0.080	0.2%	0.4%
	FTP	0.981	2.067	0.0031	0.001	0.7%	1.4%
	50 mph	0.887	1.768	0.0011	0.058	0.3%	0.6%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.
[b] Orange highlight indicates result is statistically significant at the 90% confidence level or better.

For animal-based fuels, the values are approximately one-half as large: 0.4% for B5 (range 0.2% to 0.7%) and 0.8% for B10 (range 0.4% to 1.4%). These predicted increases are statistically significant to the same degree as the slope of the regression line from which they are estimated. That is, the NOx increases predicted by the regression line for soy-based fuels are statistically significant at the 95% confidence level (or better) on all cycles and the predicted NOx increases for animal-based fuels are statistically significant at the 90% confidence level (or better) on all cycles and at the >99% confidence level for the FTP.

Because the limited data on B5 were not used to develop the regression lines for each cycle, and no test data on B10 are available, use of the lines to make predictions for B5 and B10 depends on their linearity over the range between ULSD and B20. Based on the R^2 statistics and the graphs in Durbin 2011, the slopes observed between ULSD and B20 are the same as the slopes observed between B20 and B100 for each of the test cycles. We believe that the linearity of the response with blending percent for values over the range ULSD to B100 would be accepted by the large majority of researchers in the field, as would the use of regression analysis to make predictions for B5 and B10.

The Durbin 2011 report takes a different approach for determining the statistical significance of NOx emission increases for each fuel. For each fuel tested, it computes a percentage change in emissions for NOx (and other pollutants) relative to the ULSD base fuel. It then determines the statistical significance of each observed change using a conventional t-test for the difference of two mean values (2-tailed, 2 sample equal

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

variance t-test). The t-test is conducted on the measured emission values before the percentage emission change is computed.

The t-test would be the appropriate approach for determining statistical significance if only two fuels were tested. However, it is a simplistic approach when three or more fuels are tested because it is applied on a pair-wise basis (B5 vs. ULSD, B20 vs. ULSD, etc.) and does not make use of all of the data that is available. It will have less power than the regression approach to detect emission changes that are real. This limitation is in one direction, however, in that the test is too weak when 3 or more data points are available, but a finding of statistical significance is valid when it occurs. As long as the linear hypothesis is valid, the regression approach should be the preferred method for analysis and for the determination of whether biodiesel blending significantly increases NOx emissions.

Because emission changes will be smallest for B5 (because of the low blending volume), the pair-wise t-test is most likely to fail to find statistical significance at the B5 level. In cases where the pair-wise t-test for B5 says that the emission change vs. ULSD is not statistically significant – but slope of the regression line <u>is</u> statistically significant – the proper conclusion is that additional B5 testing (to improve the precision of the emission averages) would likely lead to the detection of a statistically significant B5 emissions change using the t-test. In this case, <u>the failure to find statistical significance using the t-test is not evidence that B5 does not increase NOx emissions</u>.

For this engine, soy-based B5 was tested on the 40 mph and 50 mph cruise cycles and animal-based B5 was tested on the FTP. To examine this matter further, Table 3-4 reproduces NOx emission results reported in Tables ES-2 and ES-3 of Durbin 2011. Soy-based B5 was shown to increase NOx emissions on the 40 mph cruise cycle, but not on the 50 mph cruise cycle. Animal-based B5 was shown to increase NOx emissions on the FTP. Durbin 2011 noted (p. xxxii) that "[t]he 50 mph cruise results were obscured, however, by changes in the engine operation and control strategy that occurred over a segment of this cycle." Therefore, we discount the 50 mph cruise results and do not consider them further. Neither of the remaining B5 NOx emission increases (for the 40 mph Cruise and FTP cycles) were found to be statistically significant using the t-test, although the 40 mph cruise result for soy-based fuels comes close to being marginally significant (it would be statistically significant at an 86.5% level). The NOx emission increases at higher blending levels were found have high statistical significance (>99% confidence level).

This format, used throughout Durbin 2011 to report emission test data and to show the effect of biodiesel on emissions, is subject to an important statistical caveat. The percent changes are computed by dividing the biodiesel emission values by the emissions measured for the ULSD base fuel. Therefore, measurement errors in the ULSD measurement are blended with the measurement errors for each of the biodiesel fuels. The blending of errors in each computed percent change can bias the apparent trend of emissions with increasing biodiesel content. As will be shown in Section 3.3.2, we can see this problem in the animal-based B5 test data for this engine.

3.3.1 NOx Impact of Soy-based Biodiesel at the B5 Level

Figures 3-1a and 3-1b display the trend of NOx emissions with blending percent for the soy-based biodiesel on the 40 mph cruise cycle. Figure 3-1a plots the percentage increases as reported by Durbin 2011 in contrast to two different analytical models for the relationship:

- The Linear Model shown by the blue line; and
- The Staff Threshold model (black line), in which the NOx emission change is zero through B9 and then increases abruptly to join the linear model.

In Figure 3-1a, the linear model is an Excel trendline for the computed percent changes. While the data violate a key assumption for the proper use of regression analysis, this approach is the only way to establish a trendline given the form in which Durbin 2011 tabulates the data and presents the results of its testing.

Figure 3-1b plots the actual measured emission values in g/bhp-hr terms in contrast to the same two analytical models. Here, the linear model line is determined through a proper use of regression analysis, in which each emission average in g/bhp-hr terms is weighted inversely by the square of its standard error, using the data for ULSD, B20, B50 and B100 (i.e., excluding the B5 data point). In the case of this engine and biodiesel fuel, both forms of assessment show generally the same trend for NOx emissions as a function of blending percent. Although the NOx emission increases for B5 may fail the t-test for significance, emissions are increased at B5 and the B5 data point is fully consistent with the Linear Model. The Threshold model is clearly a less-satisfactory representation of the test data.

Note that the slope of the trendline (Figure 3-1a) is greater than the slope of the regression line (Figure 3-1b). In the latter figure, the B100 data point stands above the regression line, which passes below it. The regression line (but not the trendline) is fit in

a manner that accounts for the uncertainties in each data point, so that the line will pass closer to points that have smaller uncertainties and farther from points that have greater uncertainties. For these data, the B100 data point has the largest uncertainty (±0.026 g/bhp-hr) followed by the B20 data point (±0.025 g/bhp-hr). The other three data points (ULSD, B5, and B50) have uncertainties less than ±0.001 g/bhp-hr. The B20 data point happens to fall on the line, but the B100 data point is found to diverge above. Because the regression analysis can account for the relative uncertainties of the data points, it provides a more accurate and reliable assessment of the impact on NOx emissions.

3.3.2 NOx Impact of Animal-based Biodiesel at the B5 level

Figures 3-2a and 3-2b display the trend of NOx emissions with blending percent for the animal-based biodiesel on the FTP test cycle as reported by Durbin 2011 and as re-assessed in this report using regression analysis, respectively. As Figure 3-2a shows, the NOx percent change values reported by Durbin 2011 appear to follow the Staff Threshold model in that NOx emissions are not materially increased at B5, but are increased significantly at B20 and above. As a result, the blue trendline in the figure (fit from the B20, B50 and B100 data points) has a negative intercept.

Figure 3-2b paints a very different picture from the data. Here, the ULSD and B5 data points stand above the weighted regression line (blue) developed from the data for ULSD, B20, B50 and B100. In the data used to fit the regression line, the ULSD data point has the largest uncertainty (±0.013 g/bhp-hr) while the other three data points (B20, B50, and B100) have uncertainties of ±0.002 g/bhp-hr (one case) and ±0.001 g/bhp-hr (two cases). Considering all of the data, the B5 data point has the second highest uncertainty (±0.007 g/bhp-hr). The regression line closely follows a linear model with a high R^2 (0.981) considering the weighted errors, while the ULSD and B5 points lie above it.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

Because the ULSD data point is subject to more uncertainty and appears to be biased high compared to the regression line, the NOx percent changes computed by Durbin 2011 are themselves biased. The trendline result in Figure 3-2a that appeared to be supportive of the Staff Threshold model now appears to be the result of biases in the ULSD and B5 emission averages.

Two important conclusions can be drawn from the foregoing:

1. Accurate and reliable conclusions regarding the impact of B5 on NOx emissions cannot be drawn from the computed percent changes that are reported in Durbin 2011. Nor can accurate and reliable conclusions be drawn from visual inspection of graphs that present such data. Weighted regression analysis of the measured emission values (g/bhp-hr terms) must be performed so that the uncertainties in emissions measurements can be fully accounted for.

2. When a weighted regression analysis is performed using the testing for this engine, there is no evidence that supports the conclusion that B5 blends will not increase NOx emissions. In fact, the data are consistent with the conclusion that biodiesel increases NOx emissions in proportion to the blending percent.

3.4 2007 MBE4000 Engine (Engine Dynamometer Testing)

To analyze the data for the 2007 MBE4000 engine, it has proved necessary to remove two data points, one for the soy-based B20 fuel on the 50 mpg cruise cycle and one for the animal-based B50 fuel on the FTP test cycle:

- Appendix H reports the 50 mph cruise emission average for soy-based B20 to be 0.014 ± 0.020 g/bhp-hr. This value is implausible and wholly inconsistent with the NOx emission change of +6.9% reported in Table ES-4 of Durbin 2011, which would imply a NOx emission average of 1.21*1.069 = 1.30 g/bhp-hr.

- Appendix H reports the FTP emission average for the animal-based B50 fuel to be 2.592 ± 0.028 g/bhp-hr, which stands well above the other test data on animal-based biodiesel. This value is also inconsistent with the NOx emission change of +12.1% reported in Table ES-4 of Durbin 2011, which would imply a NOx emission average of 1.29*1.121 = 1.45 g/bhp-hr.

We believe these reported values are affected by typographical errors and have deleted them from the dataset used here.

With these corrections, Table 3-5 shows the results of the NOx emissions analysis for the 2007 model-year MBE4000 heavy-duty diesel engine. As indicated by highlighting in the table, the relationship between increasing biodiesel content and increased NOx emissions is statistically significant at >99% confidence level in two cases for soy-based biodiesel (the UDDS and FTP cycles) and at the 90% confidence level in one case (the 50 mph cycle). For the animal-based biodiesel, the relationship is statistically significant at the 96% confidence level for the UDDS cycle, the 98% confidence level for the FTP cycle, and >99% confidence level for the 50 mph cycle.

Durbin 2011 again notes a problem with the 50 mph cruise test results, saying (p. xxxii) that "[the NOx] trend was obscured, however, by the differences in engine operation that were observed for the 50 mph cruise cycle." Therefore, we will focus the discussion on the UDDS and FTP results.

For the soy-based fuels, the R^2 statistics show that the emissions effect of biodiesel is almost perfectly linear with increasing biodiesel content over the range from ULSD to B20, B50, and B100 for all cycles (including the 50 mph cruise). That is, the NOx emissions increase between ULSD and B20 shares the same slope as the NOx emissions increase between B20 and B100. For the animal-based biodiesel, the R^2 statistics also establish a linear increase in NOx emissions with increasing biodiesel content over the same range. The linearity of the response with blending percent is also well supported by the many NOx emissions graphs contained in Durbin 2011.

Table 3-5 Re-Analysis for 2007 MBE4000 Engine (Engine Dynamometer Testing) Model: NOx = A + B · BioPct Using ULSD, B20, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A	BioPct Slope B		Predicted NOx Increase for B5	Predicted NOx Increase for B10
			Value	Value	p value	Pct Change	Pct Change
Soy-based							
	UDDS	0.989	2.319	0.0090 [a]	0.005	4.6%	9.1%
	FTP	0.998	1.268	0.0049	0.006	2.5%	5.0%
	50 mph	0.979	1.198	0.0054 [b]	0.092	2.7%	5.5%
Animal-based							
	UDDS	0.913	2.441	0.0036	0.044	2.0%	4.0%
	FTP	0.999	1.288	0.0038	0.020	2.5%	5.0%
	50 mph	0.994	1.205	0.0049	0.003	2.5%	5.0%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.
[b] Orange highlight indicates result is statistically significant at the 90% confidence level or better.

The table also gives the estimated NOx emission increases for B5 and B10 as predicted by the regression lines. For soy-based fuels, the values are ~3.5% for B5 (range 2.5% to 4.6% depending on the cycle) and ~7.5% for B10 (range 5.0% to 9.1% depending on cycle). For animal-based fuels, the values are approximately two-thirds as large: ~2.3% for B5 (range 2.0% to 2.5%) and ~4.5% for B10 (range 4.0% to 5.0%). The predicted increases are statistically significant to the same degree as the slope of the regression line from which they are estimated. That is, the predicted NOx increases are statistically significant at the >99% confidence level for soy-based fuels on the UDDS and FTP cycles and at the >95% confidence level for animal-based fuels on all cycles. The predicted NOx increase is statistically significant at the 90% confidence level for soy-based fuels on the 50 mph cruise cycle.

For this engine, soy- and animal-based B5 were tested on the FTP. Table 3-6 reproduces the NOx emission results reported in Tables ES-4 and ES-5 of Durbin 2011. While there are caveats on use of the pair-wise t-test, the FTP test data for this engine show NOx emissions at the B5 level for both soy- and animal-based fuels that are statistically significant at the 99% confidence level (or better) in this case. That is, the test data for this engine as reported by Durbin 2011 refute the Staff Threshold Model that biodiesel blends below B10 do not increase NOx emissions.

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on pair-wise t-test.

Figures 3-3a and 3-3b below compare the FTP data for this engine to the regression line representing the linear model (blue) and the Staff Threshold model (black) for both soy- and animal-based biodiesel. In both cases, the regression line was developed using the data for ULSD, B20, B50, and B100 (i.e., excluding the B5 data point). For both soy- and animal-based biodiesels, the data point for B5 falls on the established line, while the Staff Threshold model is inconsistent with the data. For this engine, it is clear that soy- and animal-based biodiesels increase NOx emissions at all blending levels.

3.5 1998 Kubota TRU Engine (Engine Dynamometer Testing)

The 1998 Kubota V2203-DIB off-road engine was tested on the base fuel (ULSD) and soy-based biodiesel at four blending levels (B5, B20, B50, B100) in two different series using the ISO 8178 (8-mode) test cycle. Appendix I reports the measured emissions data only for the first series (ULSD, B50, B100). Using this subset of data, Table 3-7 summarizes the results of the re-analysis for this engine.

As for the other engines, the results of the analysis demonstrate the following:

- The high R^2 statistic shows that the emissions effect of biodiesel is almost perfectly linear over the range B50 and B100. That is, the slope from ULSD to B50 is the same as the slope from B50 to B100. The slope of the regression line is statistically significant at the 99% confidence level.

- NOx emissions are estimated to increase by 1.0% at the B5 level and by 2.1% at the B10 level. These estimated NOx emission increases are statistically significant to the same high degree as the regression slope on which they are based.

Table 3-7 Re-Analysis for 1998 Kubota V2203-DIB Engine (Engine Dynamometer Testing) Model: NOx = A + B · BioPct Using ULSD, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A Value	BioPct Slope B Value	BioPct Slope B p value	Predicted NOx Increase for B5 Pct Change	Predicted NOx Increase for B10 Pct Change
Soy-based	ISO 8178	0.999	12.19	0.0256 [a]	0.01	1.0%	2.1%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.

The second test series involved ULSD, B5, B20, and B100 fuels. Measured emissions data are not given in Appendix I, so we must work with the calculated percent changes in NOx emissions tabulated in Durbin 2011. Table 3-8 reproduces the NOx emission results reported in Table ES-8 of Durbin 2011 for the two test series. For the second test series, biodiesel at the B5 level increased NOx emissions, but the result fails the pair-wise t-test for statistical significance. The NOx emission increase at the B20 level was statistically significant at the 90% confidence level, and the increase at the B100 level was statistically significant at the >99% confidence level. The significance determinations use the pair-wise t-test, which is subject to caveats, but this is the only method available to gauge significance because re-analysis of the computed percentage changes is not possible.

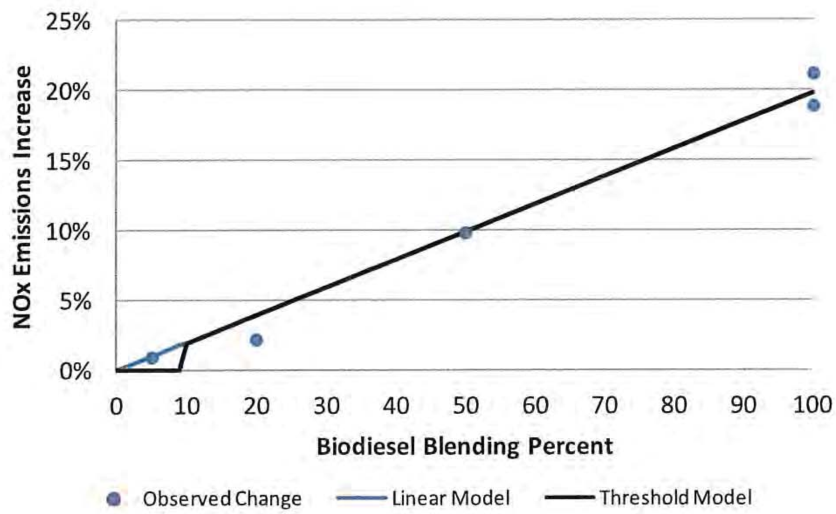
Figure 3-4 displays the trend of NOx emissions with blending percent for the first and second test series combined. As the figure shows, the available data points scatter around the trendline determined from the emission change percentages (not from regression analysis). The B20 data point falls below the trend line while the two B100 data points bracket the trend line. It is not possible to explain the divergence of the B20 data point

Figure 3-4
Durbin 2011 Assessment: ISO 8178 Cycle NOx Emissions Increases for Soy-based Biodiesel Blends (1998 Kubota Engine, Test Series 1 and 2 Combined)



because the emissions data for the second test series are not published in Durbin 2011. The B5 data point clearly supports the Linear Model and is inconsistent with the Staff Threshold Model.

3.6 2009 John Deere Off-Road Engine (Engine Dynamometer Testing)

The only information on the 2009 John Deere off-road engine comes from the tabulation of calculated percentage emission changes. Table 3-9 reproduces these data from Table ES-7 of Durbin 2011. For the soy-based biodiesel, NOx emissions are significantly increased at the B20 and higher blend levels. The increase for B20 is statistically significant at the 90% confidence level and the increases for B50 and B100 are statistically significant at the >99% confidence level based on the pair-wise t-test. A soy-based B5 fuel was not tested.

B100	13.76%	0.000	4.57	0.000

Source: Table ES-7 of Durbin 2011, p. xxxviii
Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on pair-wise t-test.

For animal-based biodiesel, the testing shows the unusual result that B5 and B20 appear to decrease NOx emissions, while B100 increases NOx. The B5 and B20 decreases are not statistically significant, while the B100 increase is statistically significant at the >99% confidence level. Durbin 2011 concludes:

> The animal-based biodiesel also did not show as great a tendency to increase NOx emissions compared to the soy-based biodiesel for the John Deere engine, with only the B100 animal-based biodiesel showing statistically significant increases in NOx emissions.[18]

Durbin 2011 does not discuss these results further and does not note any problems in the testing, making further interpretation of the results difficult. Figure 8-1 of Durbin 2011 presents the NOx results for this engine with error bars. First, we note that the figure appears to suggest that NOx emissions were increased on the B20 fuel in contradiction to the table above. Second, it is clear that the error bars are large enough that no difference in NOx emissions can be detected among ULSD, B5, and B20 fuels. Overall, this result could be consistent with the Staff Threshold Model through B5, but the failure to detect a NOx emission increase at B20 is not. Without further information, it is not possible to determine whether the result seen here is a unique response of the John Deere engine to animal-based biodiesel or is the result of a statistical fluctuation or an artifact in the emissions data.

3.7 Conclusions

The Biodiesel Characterization report prepared by Durbin et al. for CARB is an important source of information on the NOx emissions impact of biodiesel fuels in heavy-duty engines. It is the sole source of information on the NOx impact of B5 blends cited in the ISOR. When the engine dynamometer test data are examined for

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

[18] Durbin 2011, p. xx.

the three engines for which emissions test data have been published, we find clear evidence that biodiesel increases NOx emissions in proportion to the blending percent. Where B5 fuels were tested for these engines, NOx emissions are found to increase above ULSD for both soy- and animal-based blends in all three engines and by statistically significant amounts in one engine.

Specifically, a re-analysis of the NOx emissions test data demonstrates the following:

1. For the 2006 Cummins engine, biodiesel fuels are found to significantly increase NOx emissions for both soy- and animal-based blends by amounts that are proportional to the blending percent. This result indicates that biodiesels will increase NOx emissions at blending levels below B10. When B5 fuels were tested, NOx emissions were observed to increase but by amounts that fail to reach statistical significance according to the pair-wise test.[19] Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

2. For the 2007 MBD4000 engine, biodiesel fuels are found to significantly increase NOx emissions for both soy- and animal-based blends by amounts that are proportional to the blending percent. This result indicates that biodiesels will increase NOx emissions at blending levels below B10. When B5 fuels were tested, NOx emissions were observed to increase and by amounts that are found to be statistically significant using the pair-wise t-test.[13] This result alone is sufficient to disprove the Staff Threshold Model. Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

3. For the 1998 Kubota TRU (off-road) engine, soy-based biodiesel fuels are found to significantly increase NOx missions. Animal-based biodiesel was not tested. When a soy-based B5 fuel was tested, NOx emissions were observed to increase but by amounts that fail to reach statistical significance according to the pair-wise test.[13] Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

The measured emissions test data for the other off-road engine (2009 John Deere) are not contained in the Durbin 2011 report and CARB has not made them publicly available. Thus, a re-analysis was not possible. Based on the tables and figures in Durbin 2011, soy-based biodiesel fuels were shown to significantly increase NOx emissions at B20 levels and higher, but B5 was not tested. Testing of animal-based blends shows no change in NOx emissions at B5 and B20 levels, but B100 is shown to significantly increase NOx emissions. Durbin 2011 discusses this result only briefly, and it is unclear what conclusions can be drawn from it.

APPENDIX A

RESUME OF ROBERT W. CRAWFORD

Education

1978 Doctoral Candidate, ScM. Physics, Brown University, Providence, Rhode Island
1976 B.A. Physics, Pomona College, Claremont, California

Professional Experience

1998-Present Independent Consultant

Individual consulting practice emphasizing the statistical analysis of environment and energy data with an emphasis on how data and statistics are properly used to make scientific inferences. Mr. Crawford provides support on statistical, data analysis, and modeling problems related to ambient air quality data and emissions from mobile and stationary sources.

Ambient Air Quality and Mobile Source Emissions – Mr. Crawford has worked with Sierra Research on elevated ambient CO and PM concentrations in Fairbanks AK and Phoenix AZ, including the effect of meteorological conditions on ambient concentrations, the relationship of concentrations to source inventories, and the use of non-parametric techniques to infer source location from wind speed and direction data. Ongoing work is employing Principal Components Analysis to elucidate the relationship between meteorology and $PM_{2.5}$ concentrations in Fairbanks. In the past year, this work led to creation of the AQ Alert System, a tool used by air quality staff to track $PM_{2.5}$ monitor concentrations during the day and to prepare AQ alerts over the next 3 days based on the meteorological forecast.

In past work for Sierra, he has also conducted studies of fuel effects on motor vehicle emissions for Sierra. For CRC, he determined the relationship between gasoline volatility and oxygen content on tailpipe emissions of late model vehicles at FTP and cold-ambient temperatures. For SEMPRA, he determined the relationship between CNG formulation and tailpipe emissions of criteria pollutants and a range of air toxics. Other work has included the design of vehicle surveillance surveys and determination of sample sizes, development of screening techniques similar to discriminant functions to improve the efficiency of vehicle recruitment, the analysis of vehicle failure rates measured in inspection & maintenance programs, and the statistical evaluation of data collected on freeway speeds using automated sensors.

Stationary Source Emissions – Over the past 5 years, Mr. Crawford has worked with AEMS, LLC on EPA's MACT and CISWI rulemakings for Portland Cement plants, in which significant issues related to data quality, data reliability, and emissions variability are evident. Key issues include the need to properly account for uncertainty and emissions variability in setting emission standards. He also supported AEMS in the

current EPA rulemaking on reporting of greenhouse gas emissions from semiconductor facilities, where the proper characterization of emission control device performance was a key issue. He is currently supporting AEMS in a regulatory process to re-determine emission standards for an industrial facility where the new standard will be enforced by continuous emissions monitoring (CEMS). At issue is how to set the standard in such a way that there will be no more than a small, defined risk that 30-day emission averages will exceed the limitations while emissions remain well-controlled .

Advanced Combustion Research – In recent work for Oak Ridge National Laboratory, Mr. Crawford conducted a series of statistical studies on the fuel consumption and emissions performance of Homogenous Charge Compression Ignition (HCCI) engines. One of these studies was for CRC, in which fuel chemistry impacts were examined in gasoline HCCI. In HCCI, the fuel is atomized and fully-mixed with the intake air charge outside the cylinder, inducted during the intake stroke, and then compressed to the point of spontaneous combustion. The timing of combustion is controlled by heating of the intake air. If R&D work can demonstrate a sufficient understanding of how fuel properties influence engine performance, the HCCI combustion strategy potentially offers the fuel economy benefit of a diesel engine with inherently lower emissions.

1979-1997 Energy and Environmental Analysis, Inc., Arlington, VA. Director & Partner (from 1989).

Primary work areas: Studies of U.S. energy industries for private and institutional clients emphasizing statistical analysis, business planning and computer modeling/forecasting. Responsible for the EEA practice area that provided strategic planning and forecasting services to major energy companies. Primary topical areas included: U.S. energy market analysis and strategic planning; gas utility operations; and natural gas supply planning.

U.S. Energy Market Analysis

During 1995-1997, Mr. Crawford directed EEA's program to provide comprehensive energy supply and demand forecasting for the Gas Research Institute (GRI) in its annual Baseline Projection of U.S. Energy Supply and Demand. Services included: development of U.S. energy supply, demand, and price forecasts; sector-specific analyses covering energy end-use (residential, commercial, industrial, transportation), electricity supply, and natural gas supply and transportation; and the preparation of a range of publications on the forecasts and energy sector trends.

From 1989 through 1997, he directed the use of EEA's Energy Overview Model in strategic planning and long-term market analysis for a client base of major energy producers, pipelines, and distributors in both the United States and Canada. The Energy Overview Model was used under his direction as the primary analytical basis for the 1992 National Petroleum Council study The Potential for Natural Gas in the United States. Mr. Crawford also provided analysis for clients on a wide range of other energy market issues, including negotiations related to an LNG import project intended to serve U.S. East Coast markets. This work assessed the utilization and economic value of seasonal

gas deliverability in order to develop LNG pricing formulas and evaluate the project's viability.

Other topical areas of work during his period of employment with EEA include:

Gas Load Analysis and Utility Operations – Principal investigator in a multi-year research program for the Gas Research Institute (GRI) that examined seasonal gas loads, utility operations, and the implications for transmission and storage system reliability and capacity planning.

Gas Transmission and Storage – Principal investigator for a study of industry plans for expansion of underground gas storage capacity in the post-Order 636 environment, including additions of depleted-reservoir and salt-formation storage, an engineering analysis of capital and operating costs for the projects, and unbundled rates for new storage services.

Natural Gas Supply Planning – Mr. Crawford was EEA's senior manager and lead analyst on gas supply planning issues for both pipeline and distribution companies, which included technical and analytic support in development and justification of gas supply strategies; and identification of optimal seasonal supply portfolios for Integrated Resource Planning proceedings.

Transportation Systems Research

Mr. Crawford also had extensive experience in motor vehicle fuel economy and emissions while at EEA. He participated for five years in a DOE research program on fuel economy, with emphasis on the evaluation of differences between laboratory and on-road fuel economy. His work included analysis of vehicle use databases to understand how driving patterns and ambient (environmental) conditions influence actual on-road fuel economy. He also developed a software system to link vehicle certification data systems to vehicle inspection and testing programs and participated in a range of studies on vehicle technology, fuel economy, and emissions for DOE, EPA, and other governmental agencies.

Re: Alternative Diesel Fuel Rulemaking

Dear Mr. Mitchell:

Please find attached the comments of Growth Energy in response to the staff's request for public input on alternatives to the 2013 regulatory proposal for the Alternative Diesel Fuel regulation. Growth Energy hopes to make a further submission regarding regulatory alternatives following the public consultation meeting to discuss biodiesel emissions testing sponsored by the Board.

ADF B3-128

Please place this letter and its attachments in the public docket that I understand the staff is establishing for materials it receives in connection with this rulemaking effort.

STATE OF CALIFORNIA

AIR RESOURCES BOARD

RESPONSE TO REQUEST FOR PUBLIC INPUT ON REGULATION OF ALTERNATIVE DIESEL FUEL

GROWTH ENERGY

AUGUST 15, 2014

Growth Energy's Response to Request for Public Input
On Regulation of Alternative Diesel Fuel

Growth Energy respectfully submits this response to the request by the staff of the California Air Resources Board ("CARB") for public input on alternatives to the staff's currently proposed method for regulating the use of alternative diesel fuel ("ADF") as part of compliance with the low-carbon fuel standard ("LCFS") regulation. The CARB staff presented its request for public comment in a notice dated July 29, 2014, and has established today as the deadline for that input. In these brief comments, Growth Energy assumes CARB's familiarity with and incorporates by reference its June 23, 2014 submission in response to a similar staff request concerning the LCFS regulation itself, as well as Growth Energy's submissions in an earlier phase of the ADF rulemaking in 2013.

I. Introduction and Background

The stated purpose of the July 29 notice is to seek input on regulatory alternatives pursuant to the 2011 amendments to the Government Code contained in SB 617. The proposed ADF regulation is intended to provide a legal pathway for new emerging diesel fuel substitutes to enter the commercial market in California, while managing and minimizing environmental and public health impacts, and to preserve the emission benefits derived from the CARB motor vehicle diesel regulations.[1] In light of that goal, the current ADF rulemaking as most recently described by CARB staff would establish: ADF B3-129

- A general process governing the commercialization of new ADF formulations in California, and
- Specific requirements for biodiesel and biodiesel blends that are consistent with the general ADF process and that would mitigate increases in emissions of oxides

[1] *See* "Initial Statement of Reasons, Proposed Regulation on the Commercialization of New Alternative Diesel Fuel," October 23, 2013 available at http://www.arb.ca.gov/regact/2013/adf2013/adf2013isor.pdf.

of nitrogen (NOx) from diesel engines and vehicles that have been identified to occur relative to conventional California diesel fuel from the use of biodiesel and biodiesel blends.[2]

There are no specific compositional requirements proposed for ADFs other than "biodiesel," inasmuch as none have yet sought to be commercialized in California.

CARB has a duty to mitigate any potential significant environmental impacts that could result from commercialization of biodiesel. Mitigation strategies will drive the costs and affect the benefits of the ADF regulation, and so the first step in the SB 617 process for the ADF regulation should be to develop a range of potential mitigation strategies. CARB has sponsored, but has not yet fully digested, a body of tests using biodiesel fuels. The CARB staff, for its part, has recently asserted that those tests have informed several major findings about mitigation strategies; nevertheless, the staff also acknowledges that some of its major findings are preliminary and subject to change because the data upon which they are based has only recently made available to the public. Nor has the CARB staff fully developed and explained its findings. Once the staff does so, it should then seek better-informed public input under SB 617.

ADF B3-129 cont.

Based on its current analysis, the CARB staff has indicated that it expects that the yet unpublished proposed ADF regulation will require NOx mitigation for biodiesel blends containing more than five percent of an animal-based biodiesel or more than one percent of soy-based or other types of biodiesel blends. Staff also indicates that it expects to propose an exemption for all biodiesel blends when used in vehicle fleets containing more than 95% "new technology diesel engines (NTDEs)"[3] from NOx mitigation requirements and a sunset clause

ADF B3-130

---

2 *See* "Preliminary Rulemaking Proposal for Biodiesel Use as an Alternative Diesel Fuel," July 29, 2014 available at http://www.arb.ca.gov/fuels/diesel/altdiesel/20140729ADF_SRIA_Proposal.pdf.

3 In the October 23, 2013 Initial Statement Reasons, CARB staff defined NTDEs as meaning:

eliminating all NOx mitigation requirements "once NTDEs represent 95 percent of the heavy duty diesel engines in California."

The CARB staff's approach appears to rest on two beliefs: (i) no NOx increases occur in blends containing five percent or less of animal-based biodiesel or one percent or less of soy-based or other biodiesel; and (ii) there are no NOx increases from biodiesel use in NTDEs.

Turning first to the need to mitigate NOx emissions for animal-based biodiesel blends below five percent and below one percent for soy-based and other biodiesel blends, the flaws here are due to the fact that the CARB staff continues to cling to the concept of there being a "threshold" biodiesel blend level below which there are no increases in NOx emissions, rather than accepting that there is a linear relationship between NOx emissions and increases in biodiesel content. That the staff's "threshold" model is flawed with respect to both soy- and animal-based biodiesel blends and should be replaced by the linear model was made clear in a technical report prepared by Robert Crawford[4] that was submitted to CARB as part of Growth Energy's formal comments on the abandoned 2013 ADF rulemaking.

ADF B3-130 cont.

With respect to the impact of biodiesel on NOx emissions from NTDEs, CARB staff's major finding in this area — that biodiesel does not increase NOx emissions from NTDEs — continues to rely, as it did in the October 2013 rulemaking, on only one reference, a paper by

ADF B3-131

a diesel engine that meets at least one of the following criteria:

(1) 2010 ARB emission standards for on-road heavy duty diesel engines under 13 CCR 1956.8,
(2) Tier 4 emission standards for non-road compression ignition engines under 13 CCR 2421, 2423, 2424, 2425, 2425.1, 2426, and 2427, or
(3) equipped with or employs a Diesel Emissions Control Strategy (DECS), verified by ARB pursuant to 13 CCR 2700 et seq., which uses selective catalytic reduction to control NOx.

ADF B3-130 cont.

4 Crawford, R., "NOx Emission Impact of Soy- and Animal-based Biodiesel Fuels: A Reanalysis," December 10, 2013.

Lammert *et al.*[5] The flaws in the basis for this major finding were explained in Growth Energy's submission in the 2013 ADF rulemaking.[6] A 2014 peer-reviewed publication authored by researchers from the University of California at Riverside[7] (Gysel, *et al.*) who report results from a study funded by the South Coast Air Quality Management District confirms that CARB staff's major finding in this area is flawed. With respect to biodiesel impacts on NOx emissions from NTDEs, Gysel *et al.* report large percentage increases in NOx emissions with biodiesel use in NTDEs and state:

> Lammert *et al.* showed that the effect of SCR aftertreatment negates the effect of fuels on NOx emissions when they tested a 2011 Cummins ISL engine on B20 and B100. This is in strong contrast to the current study vehicle shows that there is rather strong fuel effect with the B50 blends compared to CARB ULSD from the Cummins ISX-15 engine with SCR.

In addition, Gysel *et al.*, provides a discussion referencing at least four other peer-reviewed technical papers[8] which further confirm this flaw in the staff's finding, showing increases in

ADF B3-131 cont.

5 Lammert, M., McCormick, R., Sindler, P. and Williams, A., "Effect of B20 and Low Aromatic Diesel on Transit Bus NOx Emissions Over Driving Cycles with a Range of Kinetic Intensity," *SAE Int. J. Fuels Lubr.* 5(3):2012, doi:10.4271/2012-01-1984.

6 As an expert stated in Growth Energy's submission:

> ... [T]he CARB staff's unequivocal statements regarding the impact of biodiesel on NOx emissions from all vehicles with NTDEs is simply not reasonable based on data from (1) a single study that (2) tested only two urban buses equipped with the same engine and (3) used instrumentation that was, at best, barely able to measure NOx emissions from the test vehicles in general, and clearly was not sensitive enough to reliably detect changes in NOx emissions due to use of different fuels. Nothing else in the rulemaking file supports the CARB staff's claim that there will not be increased NOx emissions from the use of biodiesel in NTDEs.

Declaration of James M. Lyons, ¶ 23 (Dec. 12, 2013).

8 Walkowicz, K., Na, K., Robertson, W., Sahay, K., Bogdanoff, M., Weaver C., and Carlson, R., "On-road and In-Laboratory Testing to Demonstrate Effects of ULSD, B20 and B99 on a Retrofit Urea-SCR Aftertreatment System," SAE Technical Paper 2009-01-2733, November 2, 2009; McWilliam, L. and Zimmermann, A., "Emissions and Performance Implications of Biodiesel Use in an SCR-equipped Caterpillar C6.6," SAE Technical Paper 2010-01-2157, October 25, 2010; Mizushima, N., Murata, Y., Suzuki, H., Ishii, H., Goto, Y.,

NOx emissions from biodiesel use with NTDEs. It should also be noted that the observed NOx increases from biodiesel use in NTDEs are consistent with the widely accepted linear model form which Crawford's report demonstrates is technical superior to CARB's flawed threshold model. ADF B3-131 cont.

II. Necessary Changes in the CARB Staff's Approach

In light of the currently available data and the relevant literature, the CARB staff's current approach is insufficient to mitigate the impacts of biodiesel usage. On that basis, Growth Energy asks the staff to consider a regulatory alternative having the following three key elements: ADF B3-132

1. Require that the mitigation strategies for increased NOx emissions be applied to all biodiesel and blends of biodiesel and diesel fuel where biodiesel was intentionally blended.[9] ADF B3-133

2. Eliminate exemptions from NOx mitigation requirements for biodiesel used in vehicle fleets comprised of at least 95% NTDEs. ADF B3-134

3. Eliminate the sunset provision for NOx mitigation requirements. ADF B3-135

It is critical for the staff to evaluate the need for those three changes in light of other measures that CARB has adopted or is considering adopting to reduce NOx emissions, including the Advanced Clean Cars program and CARB's Sustainable Freight Transport Initiative which involve requirements for "zero-emission" heavy-duty vehicles. ADF B3-136

---

and Kawano, D., "Effect of Biodiesel on NOx Reduction Performance of Urea-SCR System," SAE Technical Paper 2010-01-2278, October 25, 2010.

9 The reference to intentional blending has been included to ensure that mitigation is not required for inadvertent blends of biodiesel and diesel that could result from mixing of diesel with biodiesel remaining in storage tanks or in fuel transfer lines.

Growth Energy appreciates the opportunity to provide this input on alternatives to the current approach to developing an ADF regulation, and as noted above, plans to provide additional input once the CARB staff has reviewed the available data in one or more workshops.

Respectfully submitted,

GROWTH ENERGY

STATE OF CALIFORNIA

AIR RESOURCES BOARD

RESPONSE TO REQUEST FOR PUBLIC INPUT ON ALTERNATIVES TO THE LOW- CARBON FUEL STANDARD REGULATION

GROWTH ENERGY

JUNE 23, 2014

Executive Summary

The staff of the California Air Resources Board ("CARB") has identified the Low-Carbon Fuel Standard ("LCFS") as a "major regulation" that requires enhanced review for compliance with SB 617 (Calderon and Pavley), a 2011 amendment to the California Administrative Procedure Act (the "APA"). The California Department of Finance ("the Department") has published regulations that implement SB 617. Those regulations require rulemaking agencies like CARB to seek early public input on possible alternatives to the rules being developed by the rulemaking agencies.

Growth Energy, an association of the Nation's leading ethanol producers and other companies that serve America's need for renewable fuels, is submitting to the CARB staff a proposed alternative to the LCFS regulation that would allow the State to eliminate the LCFS program without loss of environmental benefits. Growth Energy's proposal recognizes important changes in the regulatory baseline for the control of greenhouse gas ("GHG") emissions that have occurred since 2009. In particular, the federal renewable fuels standard ("RFS") program, combined with the California cap-and-trade program and a number of California-specific vehicle- and engine-based regulations, now assure that California will receive most if not all of the direct GHG emissions reductions that can be attributed to the LCFS regulation. To the extent that CARB believes that there is still an emissions shortfall from elimination of the LCFS or that it has authority to address lifecycle GHG emissions occurring outside of California under state and federal law (which are issues not addressed in this submittal), Growth Energy proposes that CARB address those remaining issues by modifying the California GHG cap-and-trade regulations, which are now in effect in California and which apply to transportation fuels providers beginning in 2015.

Growth Energy's description of its proposed alternative to the LCFS regulation is as detailed as possible, given currently available information. In this submittal, Growth Energy urges the CARB staff to provide the additional information needed to provide further analysis of alternatives to the LCFS regulation.

Growth Energy's Response to Request for Public Input
On Alternatives to the Low-Carbon Fuel Standard Regulation

Growth Energy respectfully submits this response to the request by the staff of the California Air Resources Board ("CARB") for public input on alternatives to the low-carbon fuel standard ("LCFS") regulation. The CARB staff presented its request for public comment in a notice dated May 23, 2014, and has established today as the deadline for that input.

The CARB staff is seeking public input in connection with its proposal that CARB revise and readopt the LCFS regulation at a public hearing later this year. The purpose of the LCFS regulation, which the Board first adopted in 2009, is to achieve reductions in greenhouse gas ("GHG") emissions from the California transportation sector pursuant to the Global Warming Solutions Act of 2006, commonly called AB 32. Other regulations adopted since 2008 under AB 32 to achieve the same objectives as the LCFS regulation include the "cap and trade" regulation (17 C.C.R. §§ 95801-96022), the GHG emissions standards contained in the Advanced Clean Cars (or "ACC") program (13 C.C.R. §§ 1960.1-1962.2), and a set of regulations to control GHG emissions from heavy-duty vehicles and engines.[1]

Overview

Growth Energy has organized its analysis of alternatives to the LCFS regulation in this submission into four parts.

Part I of this submission briefly outlines the statutory and regulatory framework for the CARB staff's request for input on alternatives to the LCFS regulation. As explained in Part I, regulations adopted by the California Department of Finance pursuant to a recent amendment to the APA require CARB to seek and permit effective early public input on rulemaking concerning

[1] These include California's Heavy-Duty GHG regulations now completing the rulemaking process, a second phase of regulations that are under development, and the so-called "Tractor-Trailer" GHG regulation adopted in 2008. *See* http://www.arb.ca.gov/regact/2013/hdghg2013; http://www.arb.ca.gov/cc/hdghg/hdghg.htm.

"major" regulations, including the LCFS. That amendment was contained in SB 617 (Calderon and Pavley). The LCFS rulemaking, and this stage of the LCFS rulemaking, are particularly important, because this rulemaking is one of the first CARB rulemakings governed by SB 617. *See* pp. 4-7 below.

Part II of Growth Energy's submittal addresses some of the important factors that affect a regulatory alternatives analysis undertaken under SB 617. Since 2009, there have been significant changes in the "baseline" conditions for GHG regulation relevant to the LCFS program. As explained in Part II, most of the GHG emissions reductions sought by CARB when it adopted the LCFS regulation in 2009 will be provided by a combination of the federal renewable fuels standard ("RFS") program, along with California's cap-and-trade regulation, ACC program, and regulations limiting GHG emissions from heavy-duty vehicles and engines. Given that most, if not all, of the GHG emissions reductions sought by CARB in 2009 through the LCFS regulation are now assured by those other programs, the LCFS regulation has been rendered largely superfluous from an environmental perspective, even though it imposes huge financial burdens on the regulated community and requires a large commitment of resources by CARB. As a threshold matter, CARB should therefore carefully and fully consider whether, based on regulatory and program developments related to GHG emission control since 2009, there is any continuing need for the LCFS regulation. *See* pp. 8-14 below.

Part III of this submittal explains that, to the extent that the CARB staff finds any continuing need for the LCFS regulation to control GHG emissions, that need could be met instead through a simple modification of the cap-and-trade regulation. Taking that step -- modifying the cap-and-trade regulation -- would fully eliminate any conceivable remaining need for the LCFS regulation, while doing nothing to alter CARB's overall regulatory strategy to

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

address GHG emissions from the California transportation sector. The GHG emissions reductions benefits of the LCFS program would be fully realized from the suite of other GHG regulations adopted federally and in California since 2009, and by the modification of the cap-and-trade program. The direct regulatory costs of the LCFS program are borne primarily by the California motor vehicle fuels marketing industry, which can to some extent pass those costs to its retail customers. Insofar as the LCFS program imposes costs on California businesses and consumers, the alternative presented here (relying on the cap-and-trade program) would not materially alter the allocation of costs and would at the same time reduce regulatory costs by eliminating an entire regulatory program (the LCFS regulation). Judging from the strong concern about the LCFS regulation expressed by oil industry stakeholders, the regulatory relief and reform proposed here warrants full consideration and further development. *See* pp. 14-20 below.

Part IV of Growth Energy's submittal recommends specific next steps that CARB should consider, including full involvement by the Chief Counsel's Office to ensure compliance with the APA. As will be apparent throughout this submittal, Growth Energy's analysis of regulatory alternatives can be no more detailed than the publicly available information about (i) the new version of the LCFS regulation that the CARB staff is considering for proposal to the Board, and (ii) the information that the CARB staff has provided about the benefits that it is attributing to the LCFS program. Contrary to the position taken in communications to Growth Energy by CARB's Transportation Fuels Section on this subject, very little information on the new version of the LCFS regulation or its estimated benefits -- which are critical to an effective SB 617 process -- has been provided to the public to date. In order to achieve substantial compliance with the APA, the CARB staff needs to provide the public with a full picture of its proposed new

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

LCFS regulation, and in particular describe any new features of the regulation intended to reduce compliance costs. The CARB staff also needs to completely identify for the public all benefits that it is attributing to the LCFS regulation that would bear on an SB 617 alternatives analysis. Then, after the public has had sufficient time to analyze the relevant information from CARB, the public should be permitted to provide updated regulatory alternative analyses, which the CARB staff should fully consider and address in the Standardized Regulatory Impact Assessment required by 1 C.C.R. § 2002. That approach would ensure compliance with the APA, without conflicting or otherwise undermining any other mandates or obligations applicable to the LCFS regulation. *See* pp. 20-24 below.

I. The Statutory Framework for the Regulatory Alternatives Analysis under SB 617

The CARB staff is seeking submittals from the public on regulatory alternatives to the LCFS regulation because it has a legal obligation to do so. For many years, section 11346.3 of the APA has provided in part as follows:

> (a) State agencies proposing to adopt, amend, or repeal any administrative regulation shall assess the potential for adverse economic impact on California business enterprises and individuals, avoiding the imposition of unnecessary or unreasonable regulations or reporting, recordkeeping, or compliance requirements. ...
>
> (2) The state agency, prior to submitting a proposal to adopt, amend, or repeal a regulation to the office, shall consider the proposal's impact on business, with consideration of industries affected including the ability of California businesses to compete with businesses in other states. For purposes of evaluating the impact on the ability of California businesses to compete with businesses in other states, an agency shall consider, but not be limited to, information supplied by interested parties.

Cal. Gov't Code § 11346.3(a)(2). Based on evidence that rulemaking agencies did not adequately consider the burdens that regulations impose on the public, in SB 617 the Legislature added a requirement that rulemaking agencies prepare a detailed assessment of the costs and benefits of any proposed major regulation, for review by the California Department of Finance

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

("the Department") ***before*** initiating the traditional informal rulemaking process. *See id.* § 11346.3(c). Those detailed assessments are called Standardized Regulatory Impact Assessments (or "SRIAs."). *See id.* § 11346.36. The Legislature also made it clear in SB 617 that the obligation to consider and use early public input on regulatory impacts could not be met by merely going through the formalities of seeking public input.[2]

The Department completed work on regulations to implement SB 617 in the fall of 2013. The Department's regulations require, among other steps, the following:

> The [rulemaking] agency shall also seek public input regarding alternatives from those who would be subject to or affected by the regulations ... prior to filing a notice of proposed action with OAL unless the agency is required to implement federal law and regulations which the agency has little or no discretion to vary. An agency shall document and include in the SRIA the methods by which it sought public input.

1 C.C.R. § 2001(d). As the rulemaking file for the Department's regulations implementing SB 617 shows, many state regulatory agencies, CARB not excepted, recognized that SB 617 (as implemented by the Department) would mean the end of "business as usual" in the California rulemaking process.[3]

In responding to objections from rulemaking agencies concerning the obligations created by its SB 617 regulations, the Department explained that "[i]nvolving the Department and affected parties early in the [rulemaking] process could result in the discovery of additional and

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

---

[2] Thus, SB 617 deleted text from section 11346.3(a)(2) of the APA that, up to 2011, had provided that the APA's public-input requirements were not "inten[ded]" to "impose additional criteria on agencies" engaged in rulemaking. *See* Stats. 2011, c.496 (SB 617), subd. (a); Cal. Office of Admin. Law, *California Rulemaking Law under the Administrative Procedure Act* (2012) 57 (legislative history of section 11346.3).

[3] Several rulemaking agencies filed sharp objections to the Department's proposed regulations to implement SB 617 on the ground that the regulations would require major changes in the timing used by the agencies to develop regulations and to obtain public input. *See, e.g.,* Dep't of Finance, *Regulations to Implement SB 617 Re Major Regulations, Responses to 45-day Comment Period (Chart A)* (hereinafter "Chart A"), available at http://www.dof.ca.gov/research/economic_research_unit/SB617_regulation/documents/Response%20to%20Comments%20Chart A.pdf. The Department dealt fully with all those objections and made no material changes in its proposed regulations to implement SB 617.

perhaps more cost-effective alternatives to [a] proposed major regulation, consistent with the intent of SB 617."[4] Similarly, when rulemaking agencies (including CARB) objected to the burdens of preparing the early regulatory analyses of costs and benefits needed for an effective SB 617 process, the Department correctly concluded that the amended APA "clearly contemplates that an agency will have considered [regulatory] alternatives prior to filing a notice of a proposed action" with the Office of Administrative Law and publication of the regulatory notice for further public comment.[5] The Department also made it clear that under the SB 617 process, the "no action" alternative to regulation -- which is an outcome seldom if ever seen in a major California rulemaking -- had to receive full and fair consideration at the beginning of the rulemaking process.[6]

In requiring significant change in the California rulemaking process, the statute and the implementing regulations are salutary. The LCFS regulation in 2009 was typical of major rulemakings affecting the motor vehicle fuels industries in California. Beginning in 2008, CARB had convened a series of public consultation meetings prior to its formal proposal for rulemaking in March 2009. Not until publication of the Initial Statement of Reasons for the LCFS regulation, however, was the public given any opportunity to review the economic analysis of costs and benefits for the proposed regulation; the written comments on economic issues were due a scant 45 days later (in April 2009), and at the Board's April 2009 public hearing, most private-sector speakers were limited to five minutes to make a presentation to

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

[4] *See* Chart A at 24.

[5] *Id.* at 27.

[6] *Id.* at 47-48.

CARB. The public cannot have a significant role in serious economic analysis of a major regulation within such a constrained process.

Unsurprisingly, major economic assumptions and issues were not fully addressed within the time frame for written comments in March to April 2009, nor at the Board hearing. Among the assumptions and factors that could not as a practical matter be "pressure-tested" in the public comment process was the CARB staff's belief that advanced ethanol production methods would eventually drive down gasoline costs at the retail level and make the LCFS program cost-neutral for California consumers or even generate savings of up to $11 billion.[7] That assumption was unsound in 2009, and has since been disproven by experience.[8] Likewise, in the 2009 rulemaking, the CARB staff gave little attention to the ability of the federal RFS program to accomplish the same goals and purposes of the LCFS regulation, and offered largely opaque comparisons between the GHG reductions that the two programs could achieve. Now in its fifth year of implementation, the LCFS regulation has made little or no impact on the supply of lower-GHG fuels in California.[9] SB 617 and the Department's implementing regulations require the Board to improve the quality and depth of the economic analysis for major regulations like the LCFS program.

---

7 Air Resources Board, *Proposed Regulation to Implement the Low Carbon Fuel Standard -- Staff Report: Initial Statement of Reasons* (hereinafter "ISOR") at ES-26.

8 As the ISOR itself noted, "Economic factors, such as tight supplies of lower-carbon-intensity fuels ... could result in overall net costs, not savings, for the LCFS." The fact that the cost savings forecast in 2009 proved ephemeral is implicit in the CARB staff's decision, less than two years after the regulation went into effect, to develop "cost reduction" features for the LCFS regulation, which would assist "regulated parties ... unable to meet their compliance obligations ... due to limited supplies of low carbon fuels or LCFS credits in the market." Air Resources Board, *Low Carbon Fuel Standard 2011 Program Review Report* (Dec. 8, 2011) (hereinafter "2011 Program Review") 16.

9 There have been substantial increases in the efficiency of Midwest corn ethanol production facilities since CARB first embarked on the LCFS rulemaking, and those increases have reduced the lifecycle GHG emissions of those facilities under some analyses; but those reductions in GHG emissions have been caused by market forces (the need to reduce energy consumption in order to remain competitive), not by virtue of the LCFS regulation. *See* note 25 below.

II. Factors Affecting the Regulatory Alternatives Analysis

According to the CARB staff, the goal of the LCFS regulation in 2009 was, and still remains, to "reduce the carbon intensity of transportation fuels used in California by at least 10 percent by 2020 from a 2010 baseline," and also to "support the development of a diversity of cleaner fuels with other attendant co-benefits."[10] Growth Energy sought clarification of the staff's description of the goals of the regulation for purposes of its input in the SB 617 process.[11] Lacking greater specificity or clarification, Growth Energy can only turn to the 2009 rulemaking, in which CARB quantified the "10 percent" target as being a reduction of 16 million metric tons of carbon dioxide equivalent ("MMTCO2eq") GHG emissions associated with combustion of transportation fuels in California, along with a 7 MMTCO2eq reduction in "upstream" emissions, yielding a total 23 MMTCO2eq reduction in worldwide annual GHG emissions in 2020.[12] As explained below, achieving the direct GHG emissions reduction attributed to the LCFS regulation in 2009 -- the 16 MMTCO2eq -- no longer requires the existence of the LCFS regulation.

A. Changes in the Regulatory Baseline Since 2009

The most significant development in the regulatory baseline since 2009 has been the adoption and full implementation of the federal renewable fuels standard program under the Energy Independence and Security Act of 2007, pursuant to a Final Rule adopted by the U.S.

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

[10] The staff identified that goal on June 5, 2014, well after the period for preparation of SB 617 public input had begun, in response to a specific request from Growth Energy. *See* Letter from D. Bearden to K. King, May 30, 2014 (included here as Attachment 1) *and* Letter from M. Waugh to D. Bearden, June 5, 2014 (included here as Attachment 2).

[11] *See* Letter from D. Bearden to M. Waugh, June 11, 2014 (included here as Attachment 3). To date, no response to Mr. Bearden's letter of June 11, 2014, has been received.

[12] *See* ISOR at VII-1. According to the 2009 ISOR, "These reductions account for a 10 percent reduction of the GHG emissions from the use of transportation fuel." *Id.* That 10 percent target, which the CARB staff also sometimes cites, originates in Executive Order S-01-07 of January 18, 2007. *See* Executive Order S-01-07, § 1, available at http://www.arb.ca.gov/fuels/lcfs/eos0107.pdf.

Environmental Protection Agency in 2010.[13] The federal RFS program assures an adequate supply of low-cost renewable fuel for California, *i.e.*, ethanol produced from corn starch at biorefineries located mainly in the Midwest.[14] Because ethanol produced by any method from any renewable feedstock has the same physical and chemical properties when used in motor fuel, gasoline blended with 10 percent ethanol will achieve the same reduction in exhaust or "tailpipe" GHG emissions regardless of the production process or renewable feedstock used to create the ethanol. Consequently, the portion of the 16 MMTCO2eq reduction in GHG emissions from the California transportation fleet operated on gasoline can and will be obtained by virtue of the federal RFS program.[15] Oil companies will continue to buy and blend ethanol into gasoline sold in California under the federal program even if there were no LCFS program, in order to comply with the federal RFS program. The portion of the California fleet operated on diesel fuel can also achieve its part of the 16 MMTCO2eq reduction in GHG emissions by virtue of the federal RFS

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

---

13 *See* U.S. EPA, *Regulation of Fuels and Fuel Additives: Changes to Renewable Fuel Standard Program; Final Rule*, 75 Fed. Reg. 14,669 (Mar. 26, 2010).

14 The RFS program, which in its early stages was effectively non-binding on ethanol usage, has begun to cause substantial increases in biofuel production. Total production of biofuels has increased steadily over the last year and a half, reaching approximately 16 billion gallons in the 12 months through April 2014. *See* http://www.epa.gov/otaq/fuels/rfsdata/.

15 The term "fleet," as used here, includes off-road vehicles and engines in other equipment.

When the CARB staff considered the matter in 2009, it made a number of assumptions about the efficacy of the federal RFS program that need to be reconsidered. The most significant assumption, which was empirically unsupported, was that the federal program (which at the time was still under development) would provide only 30 to 40 percent of the GHG reductions that the staff predicted for the LCFS program. That assumption appears to have been based on a belief that without the LCFS regulation, only 11.3 percent of the advanced or cellulosic biofuels required nationwide by the RFS program would be consumed in California, while a substantially higher amount of those fuels would be drawn from the nationwide fuel pool to California as the result of the LCFS regulation. The advanced biofuels required by the RFS regulation that would be drawn to California by the LCFS program would have been used elsewhere in the absence of the LCFS program, leading to the same reductions in GHG emissions. To the extent that the cellulosic ethanol industry has experienced limits on achieving full commercial launch, those are national and even global economic and technical factors that the existence of the LCFS regulation has not to date, and will not in the future, be able to change or influence.

program, because the federal program results in blending biodiesel and renewable diesel into diesel fuel produced from petroleum.[16]

As for the portion of the California fleet powered in whole or in part with electricity or hydrogen, there is similarly no continuing need for the LCFS program, owing to other changes in the regulatory baseline since 2009. The Advanced Clean Cars program now assures that electricity and hydrogen will be full participants in the California transportation fuel pool. In 2009, CARB's baseline for the alternatives analysis of the LCFS regulation included the then-current version of the Board's regulations to control GHG emissions from new motor vehicles that had been adopted in 2004, and that set GHG emission standards for 2009 to 2016 model-year new vehicles, sometimes called the "Pavley standards." In addition, the baseline also included the then-current provisions of the agency's Zero Emission Vehicle ("ZEV") standards which require manufacturers offer electric and/or hydrogen fuel cell vehicles for sale in California. CARB has now adopted new-vehicle GHG standards applicable to 2017 to 2025 model-year new vehicles and has made significant revisions to the ZEV standards as part of the ACC rulemaking in 2012.[17]

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

---

[16] One reason why California is assured of receiving an adequate supply of ethanol is that ethanol for use in gasoline commands a higher price -- the so-called "California premium" -- in California than in other parts of the United States, as can be readily seen from data available under contract or license from the Oil Price Information Service ("OPIS"). While there are many reasons why the "California premium" exists, one major reason is that refineries producing finished gasoline products for the California retail market tend to have higher production costs than other refineries.

[17] In its 2009 LCFS alternatives analysis, the CARB staff assumed that manufactures would sell more electric vehicles than required by the ZEV standards, as they existed in 2009. Vehicle manufacturer compliance with the ZEV, new vehicle GHG, and criteria emission standards is determined on a "fleet-average" basis. What this means is that to the extent that manufacturers sell more ZEVs than required, they can in turn sell greater numbers of less fuel efficient or higher emitting vehicles provided that they remain in compliance on average. In addition, manufacturers that over comply can sell "credits" to manufacturers that would not otherwise be in compliance. Therefore, even if the LCFS regulation might lead to greater demand and use of electric vehicles, there would be no net reduction in GHG emissions.

CARB has also taken and is taking a number of actions to reduce GHG emissions associated with the use of diesel fuel in heavy-duty vehicles which also need to be taken into account in the baseline for the 2014 LCFS analysis. The relevant measures include California's Tractor-Trailer regulation adopted in 2008 which requires use of aerodynamic improvement devices and low-rolling resistance tires, as well as the Phase I and the soon-to-be proposed Phase II heavy-duty GHG regulations that impose specific GHG emission requirements on new heavy-duty vehicles beginning with the 2014 model-year.[18]

B. Necessary Information for Development of a Detailed Alternative Program

In addition to properly defining the baseline for the alternatives analysis, it is important to have a clear and complete picture of the revised LCFS program that the CARB staff plans to propose. In addition to full information concerning the estimated benefits of the LCFS program (both in terms of GHG reductions and in any other relevant aspect), the currently unknown elements of that program include the following:

- Updated carbon intensity values for transportation fuels that will be included in the proposed 2014 LCFS regulation.
- The detailed form of any proposed "cost-containment" provisions which could allow parties subject to the LCFS regulation to comply with the program's standards, without actually achieving the CI reductions required under the regulation.
- CARB staff's current analysis of the manner in which regulated parties will most likely attempt to comply with the proposed 2014 LCFS.

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

[18] In addition to ensuring that the GHG emissions reductions associated with those regulations are properly accounted for in the baseline for the 2014 LCFS, CARB staff must also ensure that they properly account for the fact that compliance with the latter regulations is determined on a manufacturer fleet average basis in order to avoid improper assignment of GHG reductions to the 2014 LCFS regulation.

- A full description of any other intended goals of the LCFS regulation, such as stimulating "fundamental" changes in the "transportation fuel pool," along with the metrics to be used to measure progress and success in meeting those other goals.[19]

Contrary to the position taken in the CARB staff's recent correspondence with Growth Energy and in related postings on the CARB website, none of those elements have been disclosed to the public at present. In addition to providing that undisclosed information concerning its analysis, the CARB staff should address the following other pertinent questions, which follow from the foregoing review of changes in the regulatory baseline since 2009:

- Does the CARB staff agree that the federal RFS program would, in the absence of an LCFS regulation, assure some level of reductions in GHG exhaust emissions from the California in-use vehicle population that is operated on gasoline? If not, why not; and if so, what would be that level of GHG emissions reductions, on an annual or some other specific basis, if the LCFS program were to be discontinued at the end of 2015?
    - Does the staff have any disagreement with the position that the federal RFS program and the "California premium" (*see* note 15 above) would cause Midwest corn ethanol producers to continue preferentially to deliver ethanol to California, and cause the California gasoline marketing sector to blend that Midwest corn ethanol into gasoline up to the current 10 percent limit, even in the absence of the LCFS regulation? If so, what are the specific reasons why the staff disagrees?
    - Does the staff believe that the LCFS regulation would result in wider usage of E85 in California than the federal RFS program would cause, and if so, what is the empirical basis for that view?
    - Would a possible need for a diesel component to an LCFS program justify an unnecessary gasoline component for an LCFS program, and if so, why?
- The 2009 regulatory analysis predicted that ultra-low-CI fuels would be available and would bring the costs of the LCFS program down to the point where the program would be cost-neutral at the consumer level, or would result in savings of up to $11 billion.[20]

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

---

[19] *See* Air Resources Board, *California's Low Carbon Fuel Standard -- Final Statement of Reasons* (hereinafter "FSOR") 24.

[20] *See* ISOR at ES-26.

Does that remain the CARB staff's position? If not, what will be the consumer costs of the staff's proposed revised LCFS regulation, predicted annually or in some other manner? What uncertainties and assumptions affect those cost estimates?

- Are the ACC program and other vehicle-based GHG reduction programs adopted to implement AB 32 designed to obtain, and will they obtain, the maximum technologically feasible and cost effective reductions in GHG emissions from the new vehicles that are subject to those standards? (*See, e.g.*, Cal. Health & Safety Code § 38562(a).) If not, why not? With the ACC program and other non-LCFS regulations discussed above in Part II. A. now in place, would the LCFS program actually produce any incremental increase in the displacement of liquid motor vehicle fuels by electricity in ZEVs or hybrid electric vehicles or hydrogen in fuel cell vehicles? If so, what are the relevant increases, and on what assumptions do the predicted increases depend? Why would a vehicle manufacturer that over-achieved the ZEV requirement not use the credit gained from the overachievement by selling a higher-emitting conventional vehicle fleet? To what extent would the staff attribute to the LCFS program any displacement of vehicle miles traveled in conventional vehicles by vehicles powered by fuel cells, and what is the basis for that prediction?

- The CARB staff sometimes refers to Executive Order S-07-01 as a basis for maintaining the LCFS regulation. Should the requirements of Executive Order S-07-01 be reconsidered in the current rulemaking process insofar as the Executive Order called for creation of the LCFS regulation? Does Executive Order S-07-01 limit in any way CARB's discretion in adopting and enforcing measures to implement AB 32? Does AB 32 require adoption and enforcement of the LCFS regulation, if the same GHG reductions that the LCFS regulation can achieve could be achieved by other means?

- To the extent that the LCFS program is still intended to stimulate "fundamental changes in the transportation fuel pool" in California,[21] to what extent had the program succeeded in its first five years? Is achieving that objective consistent with the potential "cost reduction" mechanisms under consideration for a revised LCFS regulation? How should the Department and the public try to weigh that objective against the potential costs for California consumers and businesses in meeting that objective?

Having now presented the above questions to the CARB staff, Growth Energy believes that the staff should address them in the SRIA for the Department, or concurrently in a separate submittal to the Department made available to the public, if the staff does not intend otherwise to respond to those questions. Each question bears on the need for the LCFS regulation, the costs and benefits of the LCFS regulation, or the legal authority that would limit the analysis of regulatory

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

[21] *See* note 19 above.

alternatives. If the CARB staff does not believe that one or more of the above questions are relevant to the evaluation of regulatory alternatives, Growth Energy requests that the CARB staff explain why, with respect to each such question.

III. Regulatory Alternatives

The CARB regulations adopted since 2009 and the federal RFS program adequately provide for full control of the direct GHG emissions from the California vehicle fleet that the LCFS regulation may have been intended to control. In 2009, CARB claimed that the LCFS regulation would provide additional GHG reductions on a lifecycle basis; the "upstream" component of the GHG benefits attributed to the LCFS regulation in 2009 was 7 MMTCO2eq in 2020.[22]

Putting to one side the question whether CARB has legal authority to adopt and enforce a regulation to control GHG emissions occurring outside California, there are several reasons to question whether the LCFS regulation actually achieves any reduction in upstream emissions. As CARB has recognized, the LCFS regulation has to date caused "fuel shuffling" -- ethanol that might have been sold in California prior to the LCFS regulation is still being produced, and is sold somewhere else.[23] Ethanol production processes and pathways that have putatively higher upstream emissions have, at this point, neither terminated nor curtailed operations as a result of the LCFS regulation.[24] In addition, many Midwest corn ethanol biorefineries have qualified for

22 *See* ISOR at VII-1.

23 *See* FSOR at 477 ("Without the wider adoption of fuel carbon-intensity standards, fuel producers are free to ship lower-carbon-intensity fuels to areas with such standards, while shipping higher-carbon-intensity fuels elsewhere. The end result of this fuel 'shuffling' process is little or no net change in fuel carbon-intensity on a global scale.") The "wider adoption" of LCFS-type standards to which CARB referred in the 2009 FSOR has not occurred.

24 That is not to say, however, that the LCFS regulation is not injurious to the national market in ethanol, nor neutral in its impact on lifecycle GHG emissions. By causing fuel shuffling, the LCFS regulation disrupts the national market in ethanol, imposes costs, and increases transportation-related GHG emissions. Eventually, by effectively banning Midwest corn ethanol from California (if, for example, the LCFS for 2015 established in

lower-carbon-intensity LCFS "pathways" since 2009, on a scale that the CARB staff has admitted was "not expected in 2009."[25] Moreover, the estimates of upstream emissions attributed to Midwest corn ethanol in 2009 were grossly inflated: no one, including CARB, is still prepared to defend the indirect land-use change emissions factors accepted by CARB in 2009, and the current literature demonstrates that the "science" of indirect land-use change is too unreliable to be used as a basis for regulation.[26]

To the extent there is any remaining basis for attributing upstream GHG emissions reduction benefits to the LCFS regulation, those benefits certainly do not warrant the continuation or re-adoption of the LCFS regulation. The more efficient approach would be to adjust the cap-and-trade regulation in Title 17 of the *California Code of Regulations* to account for whatever increment of GHG emissions reductions would be forgone by eliminating the LCFS regulation.[27] To the extent necessary, modifications to the cap-and-trade regulation would be

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

2009 were to be enforced), the LCFS regulation will leave California with no commercially viable method of complying with the standard; the staff appears to recognize this problem to some extent, with the currently ill-defined "cost reduction" features that it plans to propose. *See* Air Resources Board, *Low Carbon Fuel Standard Re-Adoption Concept Paper* (March 2014) at 6-7. The reduction in nationwide demand for Midwest corn ethanol will then also impose serious economic harm on the Midwest ethanol industry.

25 *See* 2011 Program Review at 169. The Midwest ethanol production facilities that have qualified for lower-carbon-intensity LCFS pathways have not done so through modifications in their production processes intended to obtain those special LCFS pathways: they have a competitive incentive to increase efficiency, and would have done increased their efficiency in the absence of the LCFS regulation. A Growth Energy member has demonstrated this point in the ongoing *Rocky Mountain* litigation involving some aspects of the LCFS regulation. *See* Declaration of Erin Heupel, P.E. (included here as Attachment 6) ¶¶ 5-6. Notably, in the *Rocky Mountain* litigation, CARB offered no competent evidence to the contrary. As Ms. Heupel also demonstrated, the specific features of the LCFS regulation will eventually force even the highest-efficiency Midwest corn production facilities out of the California market. *See id.* ¶¶ 9-11.

26 The CARB staff has begun to revise and to reduce the indirect land-use change emission factors that were included in the 2009 LCFS regulation. *See* letter from G. Cooper to K. Sideco, April 9, 2014, available at http://www.arb.ca.gov/fuels/lcfs/regamend14/rfa_04092014.pdf. It remains Growth Energy's position that the modeling methods used by CARB to generate indirect land-use change values are too unreliable for use in a regulation intended to comply with AB 32. *See* Letter from D. Bearden to J. Goldstene, May 10, 2010 (included here as Attachment 4).

27 In 2009, CARB received substantial comments on the relative inefficiency of the LCFS approach from one of its independent peer reviewers, who urged that CARB consider a cap-and-trade alternative. *See*, e.g., FSOR at 24 (review by Dr. John Reilly); *see also id.* (summarizing Dr. Reilly's review as stating, "The economic analysis

simple and straightforward. Initially, CARB should determine what, if any, upstream GHG reductions should be attributable to the LCFS regulation, using a scientifically reliable process. CARB would also need an appropriate estimate of the total GHG emissions expected from the use of gasoline and diesel fuel in 2020. A CARB emissions forecast prepared in 2010[28] indicates that total GHG emissions from gasoline and diesel fuel use in California are expected to be approximately 175 million metric tons in 2020 under business as usual conditions. Assuming that the generally required 22 percent reduction in emissions in 2020 under the cap-and-trade program[29] applies to gasoline and diesel fuel use, total 2020 emissions without the LCFS program would be about 135 million metric tons.

Continuing the analysis, and by way of example, suppose that the cap-and-trade regulation had to cover the entire annual 16 MMTCO2eq of GHG emissions that the CARB staff identified as the benefit of the LCFS regulation for 2020. That level of GHG control could be achieved by amending the cap-and-trade regulations to require providers of gasoline and diesel fuel to submit 151 (135+16) million metric tons of allowances – or in other words requiring gasoline and diesel fuel suppliers to surrender 1.11 (151/136) allowances for every ton of GHG emissions they report from the fuels they supply.[30]

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

[for the LCFS regulation] was done incorrectly. It does not meet [the] technical standards of economics. The baseline assumptions are mutually inconsistent, and if these assumptions were executed in a proper model it would show that the LCS was unnecessary.") CARB stated in 2009 that it would consider the role of cap-and-trade further in addressing the objectives of the LCFS program once the cap-and-trade regulations were completed. *See* FSOR at 452.

28 *See* Air Resources Board, "California GHG Emissions -- Forecast 2008-2020 (updated Oct. 28, 2010), available at http://www.arb.ca.gov/cc/inventory/data/tables/2020_ghg_emissions_forecast_2010-10-28.pdf

29 This is based on the general percentage reduction requirements established by CARB for total allowances issued. *See* Air Resources Board, "Overview of ARB Emissions Trading Program (October 2011), available at http://www.arb.ca.gov/newsrel/2011/cap_trade_overview.pdf

30 The cap-and-trade regulation already begins to take effect for the gasoline and diesel fuel marketing sector in 2015.

The modifications to the existing text of the cap-and-trade regulation would be minor and limited to section 95852(d) of the regulation.[31] Further, the CARB staff at its discretion could also create a compliance offset program in order to incentivize low- carbon intensity fuels similar to those in place which incentivize other innovative GHG reduction strategies.[32] Insofar as one goal of the APA is to eliminate unnecessary regulation, this approach would well-serve the goals

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

---

[31] Thus, the text of section 95852(d), with the modification shown in italics, and assuming that the full 10 percent GHG emission reduction attributed to the LCFS regulation would be covered by cap-and-trade, would provide as follows:

> Suppliers of RBOB and Distillate Fuel Oils. A supplier of petroleum products covered under sections 95811(d) or 95812(d) has a compliance obligation *equal to 1.x allowances* for every metric ton CO_2e of GHG emissions included in an emissions data report that has received a positive or qualified positive emissions data verification statement or for which emissions have been assigned that would result from full combustion or oxidation of the quantities of the following fuels that are removed from the rack in California, sold to entities not licensed by the California Board of Equalization as a fuel supplier, or imported into California and not directly delivered to the bulk-transfer/terminal system as defined in section 95102 of MRR, except for products for which a final destination outside California can be demonstrated:

(1) RBOB;
(2) Distillate Fuel Oil No. 1; and
(3) Distillate Fuel Oil No. 2.

> *The value of "x" above will be established by Executive Officer by the prior October 31 for each year beginning with 2015 to ensure that actual GHG emissions from the use of RBOB and Distillate Fuel Oil No. 1 and Distillate Fuel Oil No. 2 are reduced to the level that would have been achieved had the Carbon Intensity of those fuels been reduced according to the following schedule relative to 2010.*

Required Carbon Intensity Reduction Relative to 2010	
Year	Reduction
2015	2.7%
2016	3.7%
2017	5.2%
2018	6.7%
2019	8.2%
2020	10.0%

As illustrated above for 2020, the value of "x" would be 0.11 and the compliance obligation for suppliers of gasoline and diesel fuels would be 1.11 times the number of tons of CO_2e emissions reported.

[32] *See* Air Resources Board, "Climate Change Programs -- Compliance Offset Program" (updated June 11, 2014), available at http://www.arb.ca.gov/cc/capandtrade/offsets/offsets.htm

of the APA. By eliminating the LCFS regulation, CARB would also free the California transportation fuel sector from continuing uncertainty about the availability and cost of ultra-low-carbon-intensity alternative fuels necessary for future compliance with the LCFS. As the Western States Petroleum Association ("WSPA") has stated:

> The LCFS, as envisioned by Governor Schwarzenegger in his Executive Order and as developed by the ARB, is infeasible. ... [S]taying the course now could result in disruptions in the transportation fuels markets. ... A successful fuels policy must protect against fuel supply disruptions, severe job losses in the state's refining industry and unacceptable economic harm to California and its citizens.[33]

While Growth Energy believes that its proposal has sufficient merit without endorsement by other organizations, the concerns expressed by WSPA are important. One benefit of the change that Growth Energy is proposing, and a benefit that is particularly important to Growth Energy and the enterprises it represents, is that elimination of the LCFS regulation would eliminate a major conflict between regulations adopted by California and the federal RFS program, a conflict that will only increase if the LCFS regulation is re-adopted.

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

In considering Growth Energy's proposal, and in addition to the questions presented in Part II of this submittal, the CARB staff should in the SRIA address the following questions:

- The CARB staff's May 23, 2014, notice soliciting public input for the SRIA sought "alternative LCFS approaches." (See Attachment 5.) Does the CARB staff believe the alternatives analysis for the SRIA and public submittals related to the SRIA must be confined to regulatory alternatives that include or would preserve in some form the LCFS regulation? If so, what is the basis for such a limitation?

- Other than emissions created in generating electricity for delivery in California, does AB 32 give CARB the authority to regulate upstream emissions occurring outside California, or to account for upstream emissions occurring outside

[33] The reference is to Executive Order S-01-07, with its "10 percent" by 2020 goal, which according to the CARB staff remains the target for the LCFS regulation. *See* Letter from G. Grey to K. Sideco, June 13, 2014 at 2, available at http://www.arb.ca.gov/fuels/lcfs/regamend14/wspa_06132014.pdf. WSPA has also stated that modification of the LCFS program through "cost reduction" provisions would "simply penalize fuel suppliers for not meeting an infeasible standard." *See* Letter from C. Reheis-Boyd to K. Sideco, April 11, 2014 at 10, available at http://www.arb.ca.gov/fuels/lcfs/regamend14/wspa_04112014.pdf.

California in adopting regulations to meet the statewide greenhouse gas emissions limit? (*See* Cal. Health & Safety Code § 38505(m), (n); 38562(a).) If AB 32 authorizes CARB to regulate or consider out-of-state GHG emissions attributed to ethanol production, does AB 32 also authorize CARB to address those emissions through the cap-and-trade regulation?

- Can the California cap-and-trade regulations be modified to provide the same numerical reductions in GHG emissions as the LCFS regulation? If not, why not?

- If the CARB staff is concerned that the state measures to control GHG emissions and the federal RFS program might not be fully implemented and enforced at some time in the future, would adoption of a revised LCFS regulation as a "backstop" measure, to be implemented only if those other programs are not meeting defined objectives, address that concern? If not, why not?

- If the CARB staff believes some regulated parties might prefer to comply with a revised LCFS regulation rather than a modified cap-and-trade regulation, could that issue be addressed by including a revised LCFS as a part of a regulatory alternative (with appropriate opt-in provisions) that would be an option for parties that did not wish to comply with a modified cap-and-trade regulation?

- What are the current and expected future levels of resources at CARB, in terms of personnel and other resources, that are allocated to the LCFS regulation? What would be the budgetary impact for CARB if the LCFS program were eliminated? What would be the budgetary impact for CARB caused by the change in the cap-and-trade regulation proposed here?

- To the extent the CARB staff would attribute other beneficial impacts, different from GHG emissions reductions, to the LCFS regulation, to whom do those benefits accrue? With regard to those other beneficial impacts, are California consumers benefitted and, if so, how and to what extent? With regard to those other beneficial impacts, are California businesses benefitted and if so, how and to what extent? Do those other beneficial impacts justify or support continuation of the LCFS regulation, and if so, what is the basis for CARB's authority to adopt and enforce the LCFS regulation to obtain those benefits? If those other beneficial impacts include the possibility that sources for alternative fuels will be increased or diversified, are there any peer-reviewed or other studies that support such a proposition? If not, what is the staff's basis for attributing such benefits to the LCFS regulation? Could those benefits be realized through the development of a compliance offset program under the cap-and-trade regulation?

As with the questions presented in Part II, the CARB staff's responses to these questions are important in understanding its evaluation of Growth Energy's proposal. If the CARB staff does not believe that one or more of the above questions are relevant to the evaluation of

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

regulatory alternatives, Growth Energy requests that the CARB staff explain why, with respect to each such question.

IV. Next Steps

As noted at the outset of this submittal, Growth Energy's analysis of alternatives to the LCFS regulation can be no more detailed than the available information about the staff's intended revised LCFS regulation. If CARB does nothing further to facilitate the public input into the SB 617 process for use in the SRIA, it will not have substantially complied with the APA as amended by SB 617 and implemented in the Department's regulations.

In the CARB staff's first notice that it was ready to receive public input on regulatory alternatives, published on May 23, 2014, the staff set a deadline for that input of June 6, 2014 -- nine business days later. The staff indicated in that notice that the public should, among other things, "submit the quantities of low-CI fuels used each year" in the proposed alternative to the LCFS regulation, "as well as the associated cost and benefit information, and their sources." [34] According to the May 23 notice, that information was needed "to enable comparison of economic impacts."[35] The May 23 notice stated that the objective for public input should be to provide "alternative LCFS approaches," meaning "any approach that may yield the same or greater benefits than those associated with the proposed regulation, or that may achieve the goals at lower cost."[36]

The "proposed regulation" to which the May 23 proposal referred (i) had not been provided to the public for review as of May 23, nor (ii) has it been provided at any time since

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

[34] *See* Attachment 5.

[35] *Id.*

[36] *Id.*

May 23.[37] The May 23 notice was not accompanied by any information that provided the CARB staff's own prediction of "the quantities of low-CI fuels [that would be] used each year" under the CARB staff's proposed regulation, nor the benefits that the CARB staff attributed to the LCFS regulation. Growth Energy requested that the CARB staff give the public the information needed to prepare a complete SB 617 submission and requested that the public be given additional time to prepare SB 617 analyses after the necessary information was released.[38]

The CARB staff responded by extending the deadline for public submittals that would be addressed in the SRIA to June 23, 2014 (31 days after the May 23 notice), but did not provide any of the information requested by Growth Energy and needed to provide the type of input sought in the May 23 notice, and necessary under the Department's SB 617 regulations. Instead, the staff referred to the GHG emissions reductions targeted in the 2009 rulemaking, to a March 2014 "Concept Paper" that discussed the staff's approach to revision of the LCFS regulation, and to material provided to the public in connection with regulatory workshops held in ARB's offices.[39] The March 2014 Concept Paper raises more questions about the staff's approach than it answers: it included, for example, a general description of two different "cost reduction" concepts without indicating how either of them would work, how they would reduce costs, or how they would affect the GHG emissions reduction benefits of the LCFS program. If the March 2014 Concept Paper provided a basis for preparing SB 617 submittals, then there is no reason why the CARB staff should have waited until May 23 to solicit public input under the Department's regulations. Had the staff informed the public when it released the Concept Paper

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

---

[37] The CARB staff has released some draft regulatory text for their proposed revised LCFS, but that partial text does not include, for example, the "cost reduction" feature intended for the new regulation, nor the carbon intensity values to be assigned to each alternative fuel.

[38] *See* Attachment 1.

[39] *See* Attachment 2.

and discussed the Concept Paper at one of its March 2014 regulatory workshops that the Concept Paper was intended to provide a basis for SB 617 input, Growth Energy (and perhaps other stakeholders) would have pointed out at that time that the Concept Paper was inadequate for that purpose; in that event, perhaps the CARB staff would have been able to provide the necessary information for public input into the SRIA.

The materials provided in connection with the regulatory workshops -- including the partial regulatory text released on May 28, after the staff had launched the public input process -- likewise do not provide the necessary information for detailed public submittals consistent with SB 617 and the Department's regulations. Growth Energy has studied those materials carefully, and with the greatest respect, would challenge the CARB staff to indicate where in those materials the staff identifies GHG emissions reduction targets for a revised LCFS regulation; where the staff identifies any other putative benefits of the LCFS regulation; and where in those materials the staff provides specific and concrete information about the impact of the "cost reduction" concepts on the quantities of alternative fuels that would be used in order to comply with the revised LCFS regulation, or permits a quantification of costs and benefits of a revised LCFS regulation that includes a cost-reduction feature.

Finally, it is important to address comments by the CARB staff at one recent workshop, which suggested that the timing of the current regulatory effort has been affected by the Board's need to comply with the mandate in litigation under the APA and the California Environmental Quality Act ("CEQA").[40] In that litigation, the Superior Court has allowed CARB all the time

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

[40] The case is *POET LLC et al. v. California Air Resources Board*, Case No. 09 CE CG 04659 (Sup'r Ct., Fresno County). The Writ of Mandate in that proceeding does not require CARB to commence or conclude rulemaking by a particular date, but to proceed in good faith without delay. The Writ of Mandate was issued more than six months ago, by which time CARB presumably knew that it had to comply with the Department's SB 617 regulations.

that the Board has requested in order to comply with the mandate. If CARB needs more time in order to conduct the SB 617 process in a manner that allows sufficient time for effective public input into the preparation of an SRIA, CARB should so inform the Superior Court. (Notably, in its filings with the Superior Court, CARB has not adverted to SB 617 or the Department's implementing regulations.) In addition, the CARB staff would surely agree that even before issuance of the mandate in that litigation, it was aware that it had major program review obligations for the LCFS regulation in 2014.[41] Particularly in light of those program review obligations, the CARB staff's inability to provide more information now to the public, needed to participate fully in the SB 617 process, seems inexcusable.

Against that backdrop, Growth Energy urges the CARB staff to reconsider its present approach to the SB 617 process, and specifically the staff's approach to obtaining public input for the SRIA. As the staff might expect, if one response to Growth Energy's proposed regulatory

Reproduction of Pages 191 - 218 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-195 through LCFS 46-232

---

[41] In 2009, when it first adopted the LCFS regulation, the Board directed the CARB staff to conduct and to present by January 1, 2015 a "review of implementation of the LCFS program" that was to "include, at a minimum, consideration of the following areas:

"(1) The LCFS program's progress against LCFS targets;
"(2) Adjustments to the compliance schedule, if needed;
"(3) Advances in full, fuel-lifecycle assessments;
"(4) Advances in fuels and production technologies, including the feasibility and cost-effectiveness of such advances;
"(5) The availability and use of ultralow carbon fuels to achieve the LCFS standards and advisability of establishing additional mechanisms to incentivize higher volumes of these fuels to be used;
"(6) An assessment of supply availabilities and the rates of commercialization of fuels and vehicles;
"(7) The LCFS program's impact on the State's fuel supplies;
"(8) The LCFS program's impact on state revenues, consumers, and economic growth;
. . .
"(12) Significant economic issues; fuel adequacy, reliability, and supply issues; and environmental issues that have arisen; and
"(13) The advisability of harmonizing with international, federal, regional, and state LCFS and lifecycle assessments."

17 C.C.R. § 95489(a).

alternative is that Growth Energy's proposal lacks a detailed comparison with the costs, benefits, and cost-effectiveness of the staff's proposal in the SRIA, Growth Energy will attribute its lack of specificity to the staff's failure to provide the information needed to offer a more specific regulatory analysis. Because this is one of the first major rulemakings at CARB that is required to comply with SB 617 and the Department's SB 617 regulations, it is also important for the Department to take a proactive role in providing guidance to CARB, the stakeholders, and other members of the public interested in the LCFS program.

NOX IMPACT OF SOY- AND ANIMAL-BASED BIODIESEL FUELS: A RE-ANALYSIS

Table of Contents

List of Tables

List of Figures

1. EXECUTIVE SUMMARY

1.1 Background on the Proposed Rule

The California Air Resources Board (CARB) has proposed regulations on the commercialization of alternative diesel fuel (ADF) that were to be heard at the December 2013 meeting of the Board. The proposed regulations seek to "... create a streamlined legal framework that protects California's residents and environment while allowing innovative ADFs to enter the commercial market as efficiently is possible."[1] In this context ADF refers to biodiesel fuel blends. Biodiesel fuels are generally recognized to have the potential to decrease emissions of several pollutants, including hydrocarbons (HC), carbon monoxide (CO), and particulate matter (PM), but are also recognized to have the potential to increase oxides of nitrogen (NOx) unless mitigated in some way. NOx emissions are an important precursor to smog and have historically been subject to stringent emission standards and mitigation programs to prevent growth in emissions over time. A crucial issue with respect to biodiesel is how to "... safeguard against potential increases in oxides of nitrogen (NOx) emissions."[2]

The proposed regulations are presented in the Staff Report: Initial Statement of Reasons (ISOR) for the Proposed Regulation on the Commercialization of New Alternative Diesel Fuels[3] (referenced as ISOR). Chapter 5 of the document describes the proposed regulations, which exempt diesel blends with less than 10 percent biodiesel (B10) from requirements to mitigate NOx emissions:

> There are two distinct blend levels relative to biodiesel that have been identified as important for this analysis. Based on our analysis to date, we have found that diesel blends with less than 10 percent biodiesel by volume (<B10) have no significant increase in any of the pollutants of concern and therefore will be regulated at Stage 3B (Commercial Sales not Subject to Mitigation). However, we have found that biodiesel blends of 10 percent and above (≥B10) have potentially significant increases in NOx emissions, in the absence of any mitigating factors, and therefore those higher blend levels will be regulated under Stage 3A (Commercial Sales Subject to Mitigation).[4]

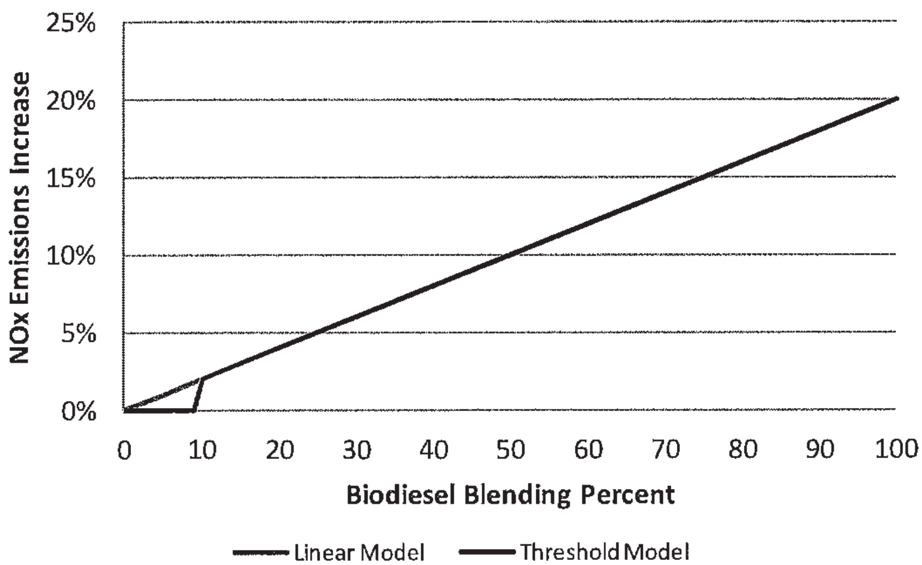
[2] Ibid. p. 3.

[3] "Proposed Regulation on the Commercialization of New Alternative Diesel Fuels. Staff Report: Initial Statement of Reason." California Air Resources Board, Stationary Source Division, Alternative Fuels Branch. October 23, 2013. http://www.arb.ca.gov/regact/2013/adf2013/adf2013isor.pdf

[4] Ibid, p. 22.

Existing research on the NOx emission effects of biodiesel has consistently been conducted under the hypothesis that the emission effect will be linearly proportional to the blending percent of neat biodiesel (B100) with the base diesel fuel. The Linear Model that has been accepted by researchers is shown as the blue line in Figure 1-1. The Staff position cited above is that biodiesel fuels do not increase NOx emissions until the fuel blend reaches 10% biodiesel. This so-called Staff Threshold Model departs from the Linear Model that underlies past and current biodiesel research by claiming that NOx emissions do not increase until the biodiesel content reaches 10 percent.

Figure 1-1
Linear and Staff Threshold Models for Biodiesel NOx Impacts



Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

The Staff Threshold model is justified by the statement: "Based on our analysis to date, we have found that diesel blends with less than 10 percent biodiesel by volume (<B10) have no significant increase in any of the pollutants of concern." Other portions of the ISOR state that Staff will track "... the effective blend level on an annual statewide average basis until the effective blend level reaches 9.5 percent. At that point, the biodiesel producers, importers, blenders, and other suppliers are put on notice that the effective blend-level trigger of 9.5 percent is approaching and mitigation measures will be required once the trigger is reached."[5] Until such time, NOx emission increases from biodiesel blends below B10 will not require mitigation.

Section 6 of the ISOR presents a Technology Assessment that includes a literature search the Staff conducted to obtain past studies on the NOx impact of biodiesel in heavy-duty

[5] Ibid, p. 24.

engines using California diesel (or other high-cetane diesel) as a base fuel. Section 6.d presents the results of the literature search with additional technical information provided in Appendix B. The past studies include the Biodiesel Characterization and NOx Mitigation Study[6] sponsored by CARB (referenced as Durbin 2011).

The results of the Staff literature search are summarized in Table 1-1, which has been reproduced from Table 6.1 of the ISOR. For B5 and B20, the data represent averages for a mix of soy- and animal-based biodiesels, which tend to have different impacts on NOx emissions (animal-based biodiesels increase NOx to a lesser extent). For B10, the data represent an average for soy-based biodiesels only. Staff uses the +0.3% average NOx increase at B5 in comparison to the 1.3% standard deviation to conclude:

> Overall, the testing indicates different NOx impacts at different biodiesel percentages. Staff analysis shows there is a wide statistical variance in NOx emissions at biodiesel levels of B5, providing no demonstrable NOx emissions impact at this level and below. At biodiesel levels of B10 and above, multiple studies demonstrate statistically significant NOx increases, without additional mitigation.[7]

B20	3.2%	2.3%

Source: Table 6.1 of Durbin 2011
Notes:
[a] Represents data using biodiesel from soy feedstocks.

<u>The Staff conclusion is erroneous because it relies upon an apples-to-oranges comparison among the blending levels</u>. Each of the B5, B10, and B20 levels include data from a different mix of studies, involving different fuels (soy- and/or animal-based), different test engines, and different test cycles. The B5 values come solely from the CARB Biodiesel Characterization study, while the B10 values come solely from other studies. The B20 values are a mix of data from the CARB and other studies. The results seen in the table above are the product of the uncontrolled aggregation of different studies that produces incomparable estimates of the NOx emission impact at the three blending levels.

[6] "CARB Assessment of the Emissions from the Use of Biodiesel as a Motor Vehicle Fuel in California: Biodiesel Characterization and NOx Mitigation Study." Prepared by Thomas D. Durbin, J. Wayne Miller and others. Prepared for Robert Okamoto and Alexander Mitchell, California Air Resources Board. October 2011.
[7] ISOR, p. 32.

As will be demonstrated in this report, the Staff conclusion drawn from the data in Table 1-1 is not supported by past or current biodiesel research, including the recent testing program sponsored by CARB. In fact, past and current studies indicate that biodiesel blends at any level will increase NOx emissions in proportion to the blending percent unless specifically mitigated by additives or other measures.

1.2 Summary and Conclusions

The following sections of this report examine the studies cited by CARB one-by-one. As evidenced from this review, it is clear that the data do not support the Staff conclusion and, indeed, the data refute the Staff conclusion in some instances. Specifically:

- There is no evidence supporting the Staff conclusion that NOx emissions do not increase until the B10 level is reached. Instead, there is consistent and strong evidence that biodiesel increases NOx emissions in proportion to the biodiesel blending percent.

- There is clear and statistically significant evidence that biodiesel increases NOx emissions at the B5 level in at least some engines for both soy- and animal-based biodiesels.

Considering each of the six past studies obtained from the technical literature and their data on high-cetane biodiesels comparable to California fuels, we find the following:

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

1. None of the six studies measured the NOx emissions impact from biodiesel at blending levels below B10. Only two studies tested a fuel at the B10 level. All other testing was at the B20 level or higher. Because none tested a B5 (or similar) fuel, none of them can provide direct evidence that NOx emissions are not increased at B5 or other blending levels below B10.

2. These studies provide no data or evidence supporting the validity of the Staff's Threshold Model that biodiesel below B10 does not increase NOx emissions. In fact, all of the studies are consistent with the contention that biodiesel increases NOx emissions in proportion to the blending percent.

3. Two of the studies present evidence and arguments that the NOx impact from biodiesel is a continuous effect that is present even at very low blending levels and will increase at higher levels in proportion to the blending percentage.

Considering the CARB Biodiesel Characterization report, we find that:

4. For the three engines where CARB has published the emission values measured in engine dynamometer testing, all of the data demonstrate that biodiesel fuels significantly increase NOx emissions for both soy- and animal-based fuels by amounts that are proportional to the blending percent. This is true for on-road and off-road engines and for a range of test cycles.

5. Where B5 fuels were tested for these engines, NOx emissions were observed to increase. NOx emission increases are smaller at B5 than at higher blending levels and the observed increases for two engines were not statistically significant by themselves based on the pair-wise t-test employed in Durbin 2011.[8] However, the testing for one of the engines (the 2007 MBE4000) showed statistically significant NOx emission increases at the B5 level for both soy- and animal-based blends.

By itself, the latter result is sufficient to disprove the Staff's contention that biodiesel blends at the B5 level will not increase NOx emissions.

Based on examination of all of the studies cited by CARB as the basis for its proposal to exempt biodiesels below B10 from mitigation, it is clear that the available research points to the expectation that both soy- and animal-based biodiesel blends will increase NOx emissions in proportion to their biodiesel content, including at the B5 level. CARB's own test data demonstrate that B5 will significantly increase NOx emissions in at least some engines.

Based on data in the CARB Biodiesel Characterization report, soy-based biodiesels will increase NOx emissions by about 1% at B5 (and 2% at B10), while animal-based biodiesels will increase NOx emissions by about one-half as much: 0.45% at B5 (and 0.9% at B10). All of the available research says that the NOx increases are real and implementation of mitigation measures will be required to prevent increases in NOx emissions due to biodiesel use at blending levels below B10.

Reproduction of
Pages 167 - 204
Consisting of
Comments ADF B3-146
through ADF B3-92

Finally, we note that CARB has not published fully the biodiesel testing data that it relied on in support of the Proposed Rule and thereby has failed to adequately serve the interest of full public disclosure in this matter. The CARB-sponsored testing reported in Durbin 2011 is the sole source of B5 testing cited by CARB as support for the Proposed Rule. Durbin 2011 publishes only portions of the measured emissions data in a form that permits re-analysis; it does not publish any of the B5 data in such a form. It has not been possible to obtain the remaining data through a personal request to Durbin or an official public records request to CARB and, to the best of our knowledge, the data are not otherwise available online or through another source.

CARB should publish all of the testing presented in Durbin 2011 and any future testing that it sponsors in a complete format that allows for re-analysis. Such a format would be (a) the measured emission values for each individual test replication; or (b) averages across all test replications, along with the number of replications and the standard error of the individual tests. The first format (individual test replications) is preferable because that would permit a full examination of the data including effects such as test cell drift over time. Such publication is necessary to assure that full public disclosure is achieved and that future proposed rules are fully and adequately informed by the data.

---

[8]As discussed in Section 3.3, the pair-wise t-test is not the preferred method for demonstrating statistical significance.

1.3 Review of 2013 CARB B5 Emission Testing

In December 2013, after the release of the ISOR and in response to an earlier Public Records Act request, CARB released a copy of new CARB-sponsored emission testing conducted by Durbin and others at the University of California CE-CERT[9]. The purpose of the study was "... to evaluate different B5 blends as potential emissions equivalent biodiesel fuel formulations for California."[10] Three B5 blends derived from soy, waste vegetable oil (WVO), and animal biodiesel stocks were tested on one 2006 Cummins ISM 370 engine using the hot-start EPA heavy-duty engine dynamometer cycle. A preliminary round of testing was conducted for all three fuels followed by emissions-equivalent certification testing per 13 CCR 2282(g) for two of the fuels. As noted by Durbin: "[t]he emissions equivalent diesel certification procedure is robust in that it requires at least twenty replicate tests on the reference and candidate fuels, providing the ability to differentiate small differences in emissions."[11]

Soy and WVO B5 Biodiesel

The B5-soy and B5-WVO fuels were blended from biodiesel stocks that were generally similar to the soy-based stock used in the earlier CARB Biodiesel Characterization Study (Durbin 2011) with respect to API gravity and cetane number. In the preliminary testing, the two fuels "...showed 1.2-1.3% statistically significant [NOx emissions] increases with the B5-soy and B5-WVO biodiesel blends compared to the CARB reference fuel."[12] The B5-WVO fuel caused the smaller NOx increase (1.2%) and was selected for the certification phase of the testing. There, it "... showed a statistically significant 1.0% increase in NOx compared to the CARB reference fuel"[13] and failed the emissions-equivalent certification due to NOx emissions.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

Animal B5 Biodiesel

The B5-animal derived fuel was blended from an animal tallow derived biodiesel that was substantially different from the animal based biodiesel used in the earlier Durbin study, and was higher in both API gravity and cetane number. The blending response for cetane number was also surprising, in that blending 5 percent by volume of a B100 stock (cetane number 61.1) with 95% of CARB ULSD (cetane number 53.1) produced a B5 fuel blend with cetane number 61.

In preliminary testing, the B5-animal fuel showed a small NOx increase which was not statistically significant, causing it to be judged the best candidate for emissions-equivalent certification. In the certification testing, it "...showed a statistically

[12] Ibid, p. 8.

[13] Ibid, p. 9.

significant 0.5% reduction in NOx compared to the CARB reference fuel"[13] and passed the emissions-equivalent certification. The NOx emission reduction for this fuel blend appears to be real for this engine, but given the differences between the blendstock and the animal based biodiesel blendstock used in the earlier Durbin study it is unclear that it is representative for animal-based biodiesels in general..

Summary

The conclusions drawn in the preceding section are not changed by the consideration of these new emission testing results. For plant-based biodiesels (soy- and WVO-based), the new testing provides additional and statistically significant evidence that B5 blends will increase NOx emissions at the B5 level. The result of decreased NOx for the B5 animal-based blend stands out from the general trend of research results reviewed in this report. However:

- The same result – reduced NOx emissions for some fuels and engines – has sometimes been observed in past research, as evidenced by the emissions data considered by CARB staff in ISOR Figure B.3 (reproduced in Figure 2.1 below). As shown, some animal-based B5 and B20 fuels reduced NOx emissions while others increased NOx emissions with the overall conclusion being that NOx emissions increase in direct proportion to biodiesel content of the blends and that there is no emissions threshold.

- Increasing cetane is known to generally reduce NOx emissions and has already been proposed by CARB as a mitigation strategy for increased NOx emissions from biodiesel[14]. The unusual cetane number response in the blending and the high cetane number of the B5-animal fuel may account for the results presented in the recently released study.

Considering the broad range of plant- and animal-based biodiesel stocks that will be used in biodiesel fuels, we conclude that the available research (including the recently released CARB test results) indicates that unrestricted biodiesel use at the B5 level will cause real increases in NOx emissions and that countermeasures may be required to prevent increases in NOx emissions due to biodiesel use at blending levels below B10.

[14] For example, see Durbin 2011 Section 7.0 for a discussion of NOx mitigation results through blending of cetane improvers and other measures.

2. CARB LITERATURE REVIEW

The Staff ISOR explains that the Appendix B Technology Assessment is the basis for CARB's conclusion that biodiesels below B10 have no significant impact on NOx emissions. The assessment is based on data from seven studies (identified in Table 2-1) that tested high-cetane diesel fuels. The first study (Durbin 2011) is the Biodiesel Characterization Study that was conducted for CARB, while the others were obtained through a literature search.

Table 2-1

soy-based biodiesels are shown to increase NOx emissions by approximately 1% at B5, 2% at B10, and 4% at B20. Animal-based biodiesels are shown to increase NOx emissions by about one-half as much: 0.45% at B5, 0.9% at B10, and 1.8% at B20. Although there is substantial scatter in the results, these data do not appear to support the Staff Threshold Model that biodiesel does not increase NOx emissions at B5 but does so at B10.

We will examine the Durbin 2011 study at some length in Section 3. In this section, we look at each of the other studies cited by the Staff to find out what the studies say about NOx emissions impacts at and below B10.

2.1 Review of Literature Cited in the ISOR

The Staff literature search sought and selected testing that used fuels with cetane levels comparable to California diesel fuels; the Staff does not, however, list those fuels or provide the data that support the tables and figures in Appendix B of the ISOR. Therefore, we have necessarily made our own selection of high-cetane fuels in the course of reviewing the studies. The key testing and findings of each study are summarized below, with a specific focus on what they tell us about NOx emission impacts at B10 and below.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

2.1.1 Clark 1999

This study tested a variety of fuels on a 1994 7.3L Navistar T444E engine. Of the high-cetane base fuels, one base fuel (Diesel A, off-road LSD) was blended and tested at levels of B20, B50, and B100. NOx emissions were significantly increased for all of the blends. The other base fuel (CA Diesel) was tested only as a base fuel. Its NOx emissions were 12% below that of Diesel A, making it is unclear whether Diesel A is representative of fuels in CA. This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below.

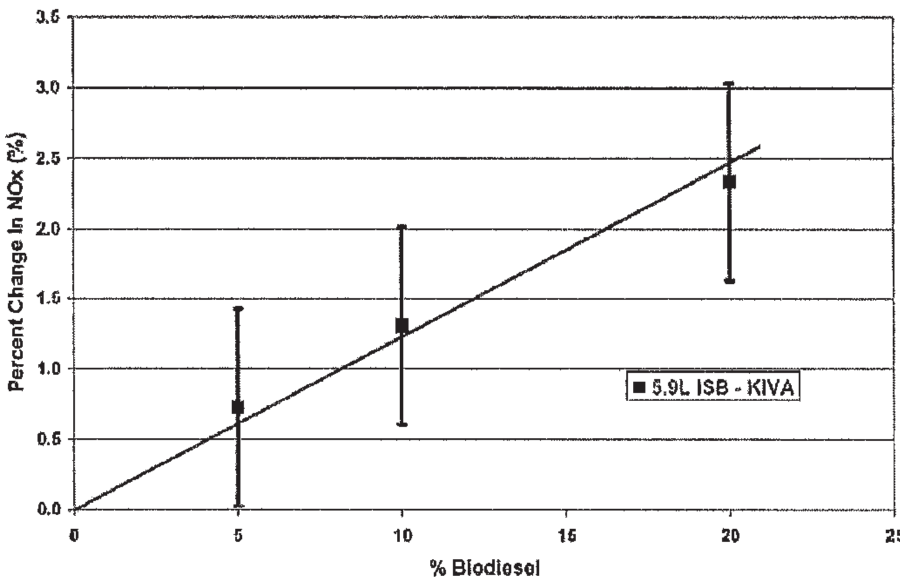
2.1.2 Eckerle 2008

This study tested low and mid/high-cetane base fuels alone and blended with soy-based biodiesel at the B20 level. The Cummins single-cylinder test engine facility was used in a configuration representative of modern diesel technology, including cooled EGR. Testing was conducted under a variety of engine speed and load conditions. FTP cycle emissions were then calculated from the speed/load data points. The test results show that B20 blends increase NOx emissions compared to both low- and high-cetane base fuels. This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below.

The study notes that two other studies "show that NOx emissions increase nearly linearly with the increase in the percentage of biodiesel added to diesel fuel." Eckerle's Figure 21 (reproduced below as Figure 2-2) indicates a NOx emissions increase at B5, which is the basis for the statement in the abstract that "Results also show that for biodiesel blends containing less than 20% biodiesel, the NOx impact over the FTP cycle is proportional to

the blend percentage of biodiesel." The authors clearly believe that biodiesel fuels have NOx emission impacts proportional to the blending percent at all levels including B5.

Figure 2-2
Impact of Biodiesel Blends on Percent NOx Change for the 5.9L ISB Engine Operation Over the FTP Cycle



Source: Figure 21 of Eckerle 2008

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

2.1.3 McCormick 2002

This study tested low- and mid-cetane base fuels alone and blended with soy- and animal-based biodiesel at the B20 level. The testing was conducted on a 1991 DDC Series 60 engine using the hot-start U.S. heavy-duty FTP. NOx emission increases were observed for both fuels at the B20 level. Mitigation of NOx impacts was investigated by blending a Fisher-Tropsch fuel, a 10% aromatics fuel and fuel additives. This study conducted no testing of the NOx emissions impact from commercial biodiesels at the B10 level or below.

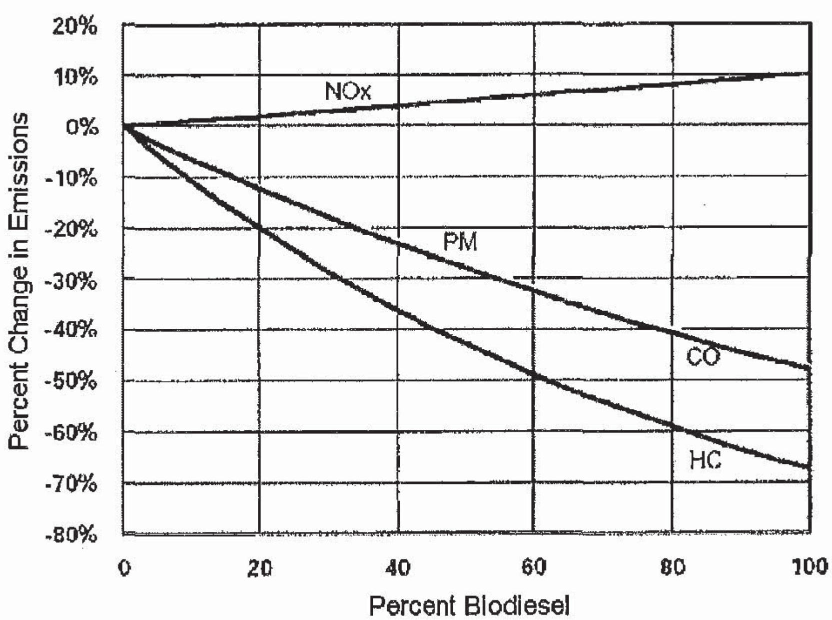
This study also tested a Fisher-Tropsch (FT) base fuel blended at the B1, B20, and B80 levels. Although the very high cetane number (≥75) takes it out of the range of commercial diesel fuels, it is interesting to note that the study measured higher NOx emissions at the B1 level than it did on the FT base fuel and substantially higher NOx emissions at the B20 and B80 levels. While the B1 increase was not statistically significant given the uncertainties in the emission measurements (averages of three test runs), it is clear that increased NOx emissions have been observed at very low blending levels.

2.1.4 McCormick 2005

This study tested blends of soy- and animal-based biodiesels with a high-cetane ULSD base fuel at B10 levels and higher. Two engines were tested – a 2002 Cummins ISB and a 2003 DDC Series 60, both with cooled EGR. The hot-start U.S. heavy-duty FTP test cycle was used. The majority of testing was at the B20 level with additional testing at the B50 and B100 levels. One soy-based fuel was tested at B10. The study showed NOx emission increases at B10, B20, and higher levels. The study also investigated mitigation of NOx increases. This study conducted no testing of the NOx emissions impact from biodiesels below the B10 level.

The authors present a figure (reproduced as Figure 2-3) in their introduction that shows their summary of biodiesel emission impacts based on an EPA review of heavy-duty engine testing. It shows NOx emissions increasing linearly with the biodiesel blend percentage.

Figure 2-3
Trend in HC, CO, NOx and PM Emissions with Biodiesel Percent



Source: McCormick 2005

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

2.1.5 Nuszkowski 2009

This study tested five different diesel engines: one 1991 DDC Series 60, two 1992 DDC Series 60, one 1999 Cummins ISM, and one 2004 Cummins ISM. Only the 2004 Cummins ISM was equipped with EGR. All testing was done using the hot-start U.S. heavy-duty FTP test cycle. The testing was designed to test emissions from fuels with and without cetane-improving additives. Although a total of five engines were tested, the base diesel and B20 fuels were tested on only two engines (one Cummins and one DDC Series 60) because there was a limited supply of fuel available. NOx emissions increased on the B20 fuel for both engines. A third engine (Cummins) was tested on B20 and B20 blended with cetane improvers to examine mitigation of NOx emissions. This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below.

2.1.6 Thompson 2010

This study examined the emissions impacts of soy-based biodiesel at the B10 and B20 levels relative to low-cetane (42), mid-cetane (49), and high-cetane (63) base fuels using one 1992 DDC Series 60 engine. The emissions results were measured on the hot-start U.S. heavy-duty FTP cycle. The study found that NOx emissions were unchanged (observed differences were not statistically significant) at B10 and B20 levels for the low- and mid-cetane fuels. NOx emissions increased significantly at B10 and B20 levels for the high-cetane fuels. This study conducted no testing of the NOx emissions impact from biodiesels at levels below B10.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

2.2 Conclusions Based on Studies Obtained in Literature Search

From the foregoing summary of the studies cited by Staff, we reach the conclusions given below.

1. None of the six studies measured the NOx emissions impact from commercial-grade biodiesel at blending levels below B10, and only two studies tested a fuel at the B10 level. All other testing was at the B20 level or higher. Because none tested a B5 (or similar) fuel, none is capable of providing direct evidence regarding NOx emissions at B5 or other blending levels below B10.

2. These studies provide no data or evidence supporting the validity of Staff's Threshold Model that biodiesel below B10 does not increase NOx emissions. In fact, all of the studies are consistent with the contention that biodiesel increases NOx emissions in proportion to the blending percent.

3. Two of the studies present evidence and arguments that the NOx impact from biodiesel is a continuous effect that is present even at very low blending levels and will increase at higher levels in proportion to the blending percentage. One study tested a Fischer-Tropsch biodiesel blend at B1 and observed NOx emissions to increase (but not by a statistically significant amount).

###

3. CARB BIODIESEL CHARACTERIZATION STUDY

3.1 Background

CARB sponsored a comprehensive study of biodiesel and other alternative diesel blends in order "… to better characterize the emissions impacts of renewable fuels under a variety of conditions."[15] The study was designed to test eight different heavy- duty engines or vehicles, including both highway and off-road engines using engine or chassis dynamometer testing. Five different test cycles were used: the Urban Dynamometer Driving Schedule (UDDS), the Federal Test Procedure (FTP), and 40 mph and 50 mph CARB heavy-heavy-duty diesel truck (HHDDT) cruise cycles, and the ISO 8178 (8 mode) cycle. Table 3-1 (reproduced from Table ES-1 of Durbin 2011) documents the scope of the test program. Because the Staff relied only on engine dynamometer testing in its Technology Assessment, only the data for the first four engines (shaded) are considered here.

Table 3-1
A Breakdown of the Test Engines for the Different Categories of Testing

2006 Cummins ISM[a]	Heavy-duty on-highway	Engine dynamometer

through ADF B3-92

[15] Durbin 2011, p. xxiv.

The original goal of this report was to subject all of the NOx emission testing in Durbin 2011 to a fresh re-analysis. However, it was discovered that Durbin 2011 did not report all of the data that were obtained during the program and are discussed in the report. The chassis dynamometer testing was conducted at the CARB Los Angeles facility. Emission results for the chassis dynamometer testing are presented in tabular and graphical form, but the report does not contain the actual emissions test data. For the engine dynamometer testing, some of the measured emission values are not reported even though the emission results are reported in tabulated or graphical form. Requests for the missing data were directed to Durbin in a personal request and to CARB through an official records request. No information has been provided in response and we have not been able to obtain the missing data from online or other sources.

For this report, we have worked with the data in the forms that are provided in Durbin 2011 as being the best-available record of the results of the CARB study. Because Staff used only data obtained in engine dynamometer testing, the analysis presented in this report has done the same. Nevertheless, the results of the chassis dynamometer testing are generally supportive of the results and conclusions presented here. Durbin 2011 notes:

> "... The NOx emissions showed a consistent trend of increasing emissions with increasing biodiesel blend level. These differences were statistically significant or marginally significant for nearly all of the test sequences for the B50 and B100 fuels, and for a subset of the tests on the B20 blends."[16]

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

Durbin notes that emissions variability was greater in the chassis dynamometer testing, which leads to the sometimes lower levels of statistical significance. There was also a noticeable drift over time in NOx emissions that complicated the results for one engine.

3.2 Data and Methodology

Table 3-2 compiles descriptive information on the engine dynamometer testing performed in Durbin 2011. The experimental matrix involves four engines, two types of biodiesel fuels (soy- and animal-based), and up to four test cycles per engine. However, the matrix is not completely filled with all fuels tested on all engines on all applicable test cycles. The most complete testing is for the ULSD base fuel and B20, B50, and B100 blends. There is less testing for the B5 blend, and B5 is tested using only a subset of cycles. For this reason, we first examine the testing for ULSD, B20, B50, and B100 fuels to determine the overall impact of biodiesels on NOx emissions. We then examine the more limited testing for B5 to determine the extent to which it impacts NOx emissions.

This examination is limited by the form in which emissions test information is reported in Durbin 2011. A complete statistical analysis can be conducted only for the two on-road engines for which Appendices G and H of Durbin 2011 provide measured emissions, and for a portion of the testing of the Kubota off-road engine for which Appendix I provides

[16] Durbin 2011, p. 126.

measured emissions. The data needed to support a full re-analysis consist of measured emissions on each fuel in gm/hp-hr terms, which are stated in Durbin 2011 as averages across all test replications along with the number of replications and the standard error of the individual tests. With this information, the dependence of NOx emissions on biodiesel blending percent can be determined as accurately as if the individual test values had been reported and the appropriate statistical tests for the significance of results can be performed.

Regression analysis is used as the primary method of analysis. For each engine and test cycle, the emission averages for each fuel are regressed against the biodiesel blending percent to determine a straight line. The regression weights each data point in inverse proportion to the square of its standard error to account for differences in the number and reliability of emission measurements that make up each average. The resulting regression line will pass through the mean value estimated from the data (i.e., the average NOx emission level at the average blending percent), while the emission averages for each fuel may scatter above and below the regression line due to uncertainties in their measurement. The slope of the line estimates the dependence of NOx emissions on the blending percentage.

Where the data points closely follow a straight line and the slope is determined to be statistically significant, one can conclude that blending biodiesel with a base fuel will increase NOx emissions in proportion to the blending percent. The regression line can then be used to estimate the predicted emissions increase for a given blending percent. The predicted emissions increase is the value one would expect on average over many measurements and is comparable to the average emissions increase one would expect in a fleet of vehicles.

The same level of analysis is not possible for the testing on B5 fuel, which is reported as a simple average for the on-road engines and is not reported at all for the off-road engines. For the B5 fuel, Durbin 2011 presents emission test results in a tabulated form where the percentage change in NOx emissions has been computed compared to ULSD base fuel. This form supports the presentation of results graphically, but it does not permit a proper statistical analysis to be performed. Specifically, the computation of percentage emission changes will perturb the error distribution of the data, by mixing the uncertainty in measured emissions on the base fuel with the uncertainties in measured emissions on each biodiesel blend, and it can introduce bias as a result of the mixing. Further statistical analysis of the computed percent values should be avoided because of these problems. Therefore, a more limited trend analysis of the NOx emissions data for B5 and the John Deere engine is conducted.

3.3 2006 Cummins Engine (Engine Dynamometer Testing)

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

Table 3-3 shows the NOx emission results for the 2006 model-year Cummins heavy-duty diesel engine based on a re-analysis of the data for this report. As indicated by highlighting in the table, the relationship between increasing biodiesel content and increased NOx emissions for soy-based biodiesel is statistically significant at >95% confidence level[17] in all cases. For the animal-based biodiesel, the relationship is statistically significant at the 92% confidence level for the UDDS cycle, the 94% confidence level for the 50 mph cruise, and the >99% confidence level for the FTP cycle.

For the soy-based fuels, the R^2 statistics show that the emissions effect of biodiesel is almost perfectly linear with increasing biodiesel content over the range B20, B50, and B100. Although not as high for the animal-based fuels (because the emissions effect is smaller and measurement errors are relatively larger in comparison to the trend), the R^2 statistics nevertheless establish a linear increase in NOx emissions with increasing biodiesel content over the same range. The linearity of the response with blending percent is well supported by the many NOx emissions graphs contained in Durbin 2011.

The table also gives the estimated NOx emission increases for B5 and B10 as predicted by the regression lines. For soy-based fuels, the values are 1% for B5 (range 0.8% to 1.3% depending on the cycle) and 2% for B10 (range 1.6% to 2.6% depending on cycle).

[17] A result is said to be statistically significant at the 95% confidence level when the p value is reported as $p \leq 0.05$. At the $p \leq 0.01$ level, a result is said to be statistically significant at the 99% confidence level, and so forth.

Table 3-3 Re-Analysis for 2006 Cummins Engine (Engine Dynamometer Testing) Model: NOx = A + B · BioPct Using ULSD, B20, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A	BioPct Slope B		Predicted NOx Increase for B5	Predicted NOx Increase for B10
			Value	Value	p value	Pct Change	Pct Change
Soy-based							
	UDDS	0.997	5.896	0.0100 [a]	0.001	0.8%	1.7%
	FTP	0.995	2.024	0.0052	0.003	1.3%	2.6%
	40 mph	1.000	2.030	0.0037	<0.0001	0.9%	1.8%
	50 mph	0.969	1.733	0.0028	0.016	0.8%	1.6%
Animal-based							
	UDDS	0.847	5.911	0.0021 [b]	0.080	0.2%	0.4%
	FTP	0.981	2.067	0.0031	0.001	0.7%	1.4%
	50 mph	0.887	1.768	0.0011	0.058	0.3%	0.6%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.
[b] Orange highlight indicates result is statistically significant at the 90% confidence level or better.

For animal-based fuels, the values are approximately one-half as large: 0.4% for B5 (range 0.2% to 0.7%) and 0.8% for B10 (range 0.4% to 1.4%). These predicted increases are statistically significant to the same degree as the slope of the regression line from which they are estimated. That is, the NOx increases predicted by the regression line for soy-based fuels are statistically significant at the 95% confidence level (or better) on all cycles and the predicted NOx increases for animal-based fuels are statistically significant at the 90% confidence level (or better) on all cycles and at the >99% confidence level for the FTP.

Because the limited data on B5 were not used to develop the regression lines for each cycle, and no test data on B10 are available, use of the lines to make predictions for B5 and B10 depends on their linearity over the range between ULSD and B20. Based on the R^2 statistics and the graphs in Durbin 2011, the slopes observed between ULSD and B20 are the same as the slopes observed between B20 and B100 for each of the test cycles. We believe that the linearity of the response with blending percent for values over the range ULSD to B100 would be accepted by the large majority of researchers in the field, as would the use of regression analysis to make predictions for B5 and B10.

The Durbin 2011 report takes a different approach for determining the statistical significance of NOx emission increases for each fuel. For each fuel tested, it computes a percentage change in emissions for NOx (and other pollutants) relative to the ULSD base fuel. It then determines the statistical significance of each observed change using a conventional t-test for the difference of two mean values (2-tailed, 2 sample equal

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

variance t-test). The t-test is conducted on the measured emission values before the percentage emission change is computed.

The t-test would be the appropriate approach for determining statistical significance if only two fuels were tested. However, it is a simplistic approach when three or more fuels are tested because it is applied on a pair-wise basis (B5 vs. ULSD, B20 vs. ULSD, etc.) and does not make use of all of the data that is available. It will have less power than the regression approach to detect emission changes that are real. This limitation is in one direction, however, in that the test is too weak when 3 or more data points are available, but a finding of statistical significance is valid when it occurs. As long as the linear hypothesis is valid, the regression approach should be the preferred method for analysis and for the determination of whether biodiesel blending significantly increases NOx emissions.

Because emission changes will be smallest for B5 (because of the low blending volume), the pair-wise t-test is most likely to fail to find statistical significance at the B5 level. In cases where the pair-wise t-test for B5 says that the emission change vs. ULSD is not statistically significant – but slope of the regression line is statistically significant – the proper conclusion is that additional B5 testing (to improve the precision of the emission averages) would likely lead to the detection of a statistically significant B5 emissions change using the t-test. In this case, the failure to find statistical significance using the t-test is not evidence that B5 does not increase NOx emissions.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

For this engine, soy-based B5 was tested on the 40 mph and 50 mph cruise cycles and animal-based B5 was tested on the FTP. To examine this matter further, Table 3-4 reproduces NOx emission results reported in Tables ES-2 and ES-3 of Durbin 2011. Soy-based B5 was shown to increase NOx emissions on the 40 mph cruise cycle, but not on the 50 mph cruise cycle. Animal-based B5 was shown to increase NOx emissions on the FTP. Durbin 2011 noted (p. xxxii) that "[t]he 50 mph cruise results were obscured, however, by changes in the engine operation and control strategy that occurred over a segment of this cycle." Therefore, we discount the 50 mph cruise results and do not consider them further. Neither of the remaining B5 NOx emission increases (for the 40 mph Cruise and FTP cycles) were found to be statistically significant using the t-test, although the 40 mph cruise result for soy-based fuels comes close to being marginally significant (it would be statistically significant at an 86.5% level). The NOx emission increases at higher blending levels were found have high statistical significance (>99% confidence level).

This format, used throughout Durbin 2011 to report emission test data and to show the effect of biodiesel on emissions, is subject to an important statistical caveat. The percent changes are computed by dividing the biodiesel emission values by the emissions measured for the ULSD base fuel. Therefore, measurement errors in the ULSD measurement are blended with the measurement errors for each of the biodiesel fuels. The blending of errors in each computed percent change can bias the apparent trend of emissions with increasing biodiesel content. As will be shown in Section 3.3.2, we can see this problem in the animal-based B5 test data for this engine.

Table 3-4 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 2006 Cummins Engine (Engine Dynamometer Testing)						
	Soy-based Biodiesel				Animal-based Biodiesel	
	40 mph Cruise		50 mph Cruise		FTP	
	NOx % Diff	p value	NOx % Diff	p value	NOx % Diff	p value
B5	1.7%	0.135	-1.1%	0.588	0.3%	0.298
B20	3.9% [a]	0.000	0.5%	0.800	1.5%	0.000
B50	9.1%	0.000	6.3%	0.001	6.4%	0.000
B100	20.9%	0.000	18.3%	0.000	14.1%	0.000

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on the pair-wise t-test.

3.3.1 NOx Impact of Soy-based Biodiesel at the B5 Level

Figures 3-1a and 3-1b display the trend of NOx emissions with blending percent for the soy-based biodiesel on the 40 mph cruise cycle. Figure 3-1a plots the percentage increases as reported by Durbin 2011 in contrast to two different analytical models for the relationship:

- The Linear Model shown by the blue line; and
- The Staff Threshold model (black line), in which the NOx emission change is zero through B9 and then increases abruptly to join the linear model.

In Figure 3-1a, the linear model is an Excel trendline for the computed percent changes. While the data violate a key assumption for the proper use of regression analysis, this approach is the only way to establish a trendline given the form in which Durbin 2011 tabulates the data and presents the results of its testing.

Figure 3-1b plots the actual measured emission values in g/bhp-hr terms in contrast to the same two analytical models. Here, the linear model line is determined through a proper use of regression analysis, in which each emission average in g/bhp-hr terms is weighted inversely by the square of its standard error, using the data for ULSD, B20, B50 and B100 (i.e., excluding the B5 data point). In the case of this engine and biodiesel fuel, both forms of assessment show generally the same trend for NOx emissions as a function of blending percent. Although the NOx emission increases for B5 may fail the t-test for significance, emissions are increased at B5 and the B5 data point is fully consistent with the Linear Model. The Threshold model is clearly a less-satisfactory representation of the test data.

Figure 3-1a
Durbin 2011 Assessment: 40 mph Cruise Cycle NOx Emissions Increases for Soy-Biodiesel Blends (2006 Cummins Engine)

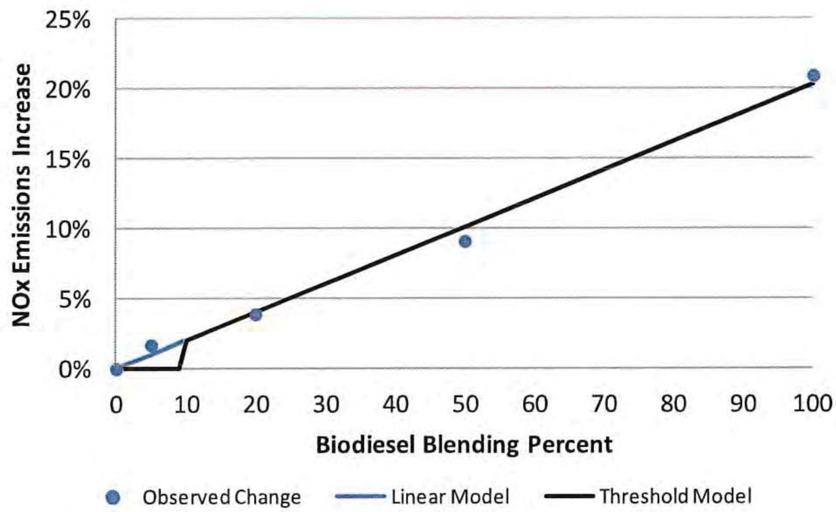

Figure 3-1b
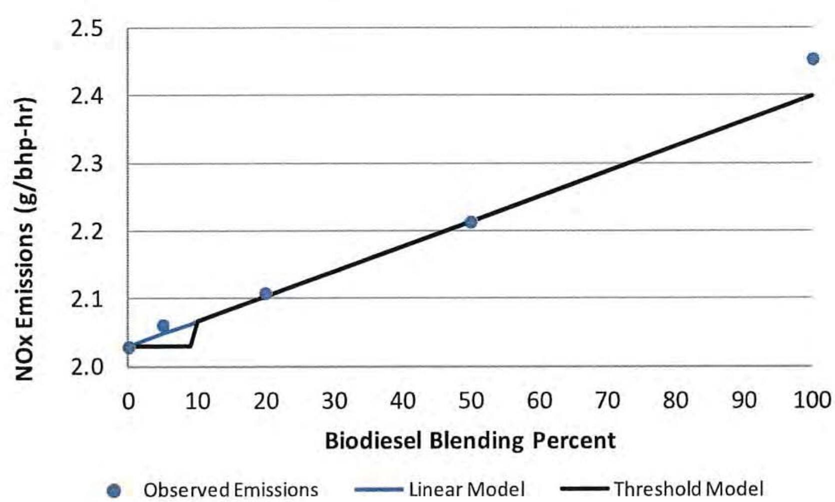
Re-assessment of 40 mph Cruise Cycle NOx Emissions Increases for Soy-Biodiesel Blends (2006 Cummins Engine)



Note that the slope of the trendline (Figure 3-1a) is greater than the slope of the regression line (Figure 3-1b). In the latter figure, the B100 data point stands above the regression line, which passes below it. The regression line (but not the trendline) is fit in

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

a manner that accounts for the uncertainties in each data point, so that the line will pass closer to points that have smaller uncertainties and farther from points that have greater uncertainties. For these data, the B100 data point has the largest uncertainty (±0.026 g/bhp-hr) followed by the B20 data point (±0.025 g/bhp-hr). The other three data points (ULSD, B5, and B50) have uncertainties less than ±0.001 g/bhp-hr. The B20 data point happens to fall on the line, but the B100 data point is found to diverge above. Because the regression analysis can account for the relative uncertainties of the data points, it provides a more accurate and reliable assessment of the impact on NOx emissions.

3.3.2 NOx Impact of Animal-based Biodiesel at the B5 level

Figures 3-2a and 3-2b display the trend of NOx emissions with blending percent for the animal-based biodiesel on the FTP test cycle as reported by Durbin 2011 and as re-assessed in this report using regression analysis, respectively. As Figure 3-2a shows, the NOx percent change values reported by Durbin 2011 appear to follow the Staff Threshold model in that NOx emissions are not materially increased at B5, but are increased significantly at B20 and above. As a result, the blue trendline in the figure (fit from the B20, B50 and B100 data points) has a negative intercept.

Figure 3-2b paints a very different picture from the data. Here, the ULSD and B5 data points stand above the weighted regression line (blue) developed from the data for ULSD, B20, B50 and B100. In the data used to fit the regression line, the ULSD data point has the largest uncertainty (±0.013 g/bhp-hr) while the other three data points (B20, B50, and B100) have uncertainties of ±0.002 g/bhp-hr (one case) and ±0.001 g/bhp-hr (two cases). Considering all of the data, the B5 data point has the second highest uncertainty (±0.007 g/bhp-hr). The regression line closely follows a linear model with a high R^2 (0.981) considering the weighted errors, while the ULSD and B5 points lie above it.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

Because the ULSD data point is subject to more uncertainty and appears to be biased high compared to the regression line, the NOx percent changes computed by Durbin 2011 are themselves biased. The trendline result in Figure 3-2a that appeared to be supportive of the Staff Threshold model now appears to be the result of biases in the ULSD and B5 emission averages.

Two important conclusions can be drawn from the foregoing:

1. Accurate and reliable conclusions regarding the impact of B5 on NOx emissions cannot be drawn from the computed percent changes that are reported in Durbin 2011. Nor can accurate and reliable conclusions be drawn from visual inspection of graphs that present such data. Weighted regression analysis of the measured emission values (g/bhp-hr terms) must be performed so that the uncertainties in emissions measurements can be fully accounted for.

2. When a weighted regression analysis is performed using the testing for this engine, there is no evidence that supports the conclusion that B5 blends will not increase NOx emissions. In fact, the data are consistent with the conclusion that biodiesel increases NOx emissions in proportion to the blending percent.

3.4 2007 MBE4000 Engine (Engine Dynamometer Testing)

To analyze the data for the 2007 MBE4000 engine, it has proved necessary to remove two data points, one for the soy-based B20 fuel on the 50 mpg cruise cycle and one for the animal-based B50 fuel on the FTP test cycle:

- Appendix H reports the 50 mph cruise emission average for soy-based B20 to be 0.014 ± 0.020 g/bhp-hr. This value is implausible and wholly inconsistent with the NOx emission change of +6.9% reported in Table ES-4 of Durbin 2011, which would imply a NOx emission average of 1.21*1.069 = 1.30 g/bhp-hr.

- Appendix H reports the FTP emission average for the animal-based B50 fuel to be 2.592 ± 0.028 g/bhp-hr, which stands well above the other test data on animal-based biodiesel. This value is also inconsistent with the NOx emission change of +12.1% reported in Table ES-4 of Durbin 2011, which would imply a NOx emission average of 1.29*1.121 = 1.45 g/bhp-hr.

We believe these reported values are affected by typographical errors and have deleted them from the dataset used here.

With these corrections, Table 3-5 shows the results of the NOx emissions analysis for the 2007 model-year MBE4000 heavy-duty diesel engine. As indicated by highlighting in the table, the relationship between increasing biodiesel content and increased NOx emissions is statistically significant at >99% confidence level in two cases for soy-based biodiesel (the UDDS and FTP cycles) and at the 90% confidence level in one case (the 50 mph cycle). For the animal-based biodiesel, the relationship is statistically significant at the 96% confidence level for the UDDS cycle, the 98% confidence level for the FTP cycle, and >99% confidence level for the 50 mph cycle.

Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

Durbin 2011 again notes a problem with the 50 mph cruise test results, saying (p. xxxii) that "[the NOx] trend was obscured, however, by the differences in engine operation that were observed for the 50 mph cruise cycle." Therefore, we will focus the discussion on the UDDS and FTP results.

For the soy-based fuels, the R^2 statistics show that the emissions effect of biodiesel is almost perfectly linear with increasing biodiesel content over the range from ULSD to B20, B50, and B100 for all cycles (including the 50 mph cruise). That is, the NOx emissions increase between ULSD and B20 shares the same slope as the NOx emissions increase between B20 and B100. For the animal-based biodiesel, the R^2 statistics also establish a linear increase in NOx emissions with increasing biodiesel content over the same range. The linearity of the response with blending percent is also well supported by the many NOx emissions graphs contained in Durbin 2011.

Table 3-5 Re-Analysis for 2007 MBE4000 Engine (Engine Dynamometer Testing) Model: NOx = A + B · BioPct Using ULSD, B20, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A Value	BioPct Slope B Value	BioPct Slope B p value	Predicted NOx Increase for B5 Pct Change	Predicted NOx Increase for B10 Pct Change
Soy-based							
	UDDS	0.989	2.319	0.0090 [a]	0.005	4.6%	9.1%
	FTP	0.998	1.268	0.0049	0.006	2.5%	5.0%
	50 mph	0.979	1.198	0.0054 [b]	0.092	2.7%	5.5%
Animal-based							
	UDDS	0.913	2.441	0.0036	0.044	2.0%	4.0%
	FTP	0.999	1.288	0.0038	0.020	2.5%	5.0%
	50 mph	0.994	1.205	0.0049	0.003	2.5%	5.0%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.
[b] Orange highlight indicates result is statistically significant at the 90% confidence level or better.

The table also gives the estimated NOx emission increases for B5 and B10 as predicted by the regression lines. For soy-based fuels, the values are ~3.5% for B5 (range 2.5% to 4.6% depending on the cycle) and ~7.5% for B10 (range 5.0% to 9.1% depending on cycle). For animal-based fuels, the values are approximately two-thirds as large: ~2.3% for B5 (range 2.0% to 2.5%) and ~4.5% for B10 (range 4.0% to 5.0%). The predicted increases are statistically significant to the same degree as the slope of the regression line from which they are estimated. That is, the predicted NOx increases are statistically significant at the >99% confidence level for soy-based fuels on the UDDS and FTP cycles and at the >95% confidence level for animal-based fuels on all cycles. The predicted NOx increase is statistically significant at the 90% confidence level for soy-based fuels on the 50 mph cruise cycle.

For this engine, soy- and animal-based B5 were tested on the FTP. Table 3-6 reproduces the NOx emission results reported in Tables ES-4 and ES-5 of Durbin 2011. While there are caveats on use of the pair-wise t-test, the FTP test data for this engine show NOx emissions at the B5 level for both soy- and animal-based fuels that are statistically significant at the 99% confidence level (or better) in this case. That is, <u>the test data for this engine as reported by Durbin 2011 refute the Staff Threshold Model that biodiesel blends below B10 do not increase NOx emissions</u>.

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on pair-wise t-test.

Figures 3-3a and 3-3b below compare the FTP data for this engine to the regression line representing the linear model (blue) and the Staff Threshold model (black) for both soy- and animal-based biodiesel. In both cases, the regression line was developed using the data for ULSD, B20, B50, and B100 (i.e., excluding the B5 data point). For both soy- and animal-based biodiesels, the data point for B5 falls on the established line, while the Staff Threshold model is inconsistent with the data. For this engine, it is clear that soy- and animal-based biodiesels increase NOx emissions at all blending levels.

3.5 1998 Kubota TRU Engine (Engine Dynamometer Testing)

The 1998 Kubota V2203-DIB off-road engine was tested on the base fuel (ULSD) and soy-based biodiesel at four blending levels (B5, B20, B50, B100) in two different series using the ISO 8178 (8-mode) test cycle. Appendix I reports the measured emissions data only for the first series (ULSD, B50, B100). Using this subset of data, Table 3-7 summarizes the results of the re-analysis for this engine.

As for the other engines, the results of the analysis demonstrate the following:

- The high R^2 statistic shows that the emissions effect of biodiesel is almost perfectly linear over the range B50 and B100. That is, the slope from ULSD to B50 is the same as the slope from B50 to B100. The slope of the regression line is statistically significant at the 99% confidence level.

- NOx emissions are estimated to increase by 1.0% at the B5 level and by 2.1% at the B10 level. These estimated NOx emission increases are statistically significant to the same high degree as the regression slope on which they are based.

Table 3-7 Re-Analysis for 1998 Kubota V2203-DIB Engine (Engine Dynamometer Testing) Model: NOx = A + B · BioPct Using ULSD, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A Value	BioPct Slope B Value	p value	Predicted NOx Increase for B5 Pct Change	Predicted NOx Increase for B10 Pct Change
Soy-based	ISO 8178	0.999	12.19	0.0256 [a]	0.01	1.0%	2.1%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.

The second test series involved ULSD, B5, B20, and B100 fuels. Measured emissions data are not given in Appendix I, so we must work with the calculated percent changes in NOx emissions tabulated in Durbin 2011. Table 3-8 reproduces the NOx emission results reported in Table ES-8 of Durbin 2011 for the two test series. For the second test series, biodiesel at the B5 level increased NOx emissions, but the result fails the pair-wise t-test for statistical significance. The NOx emission increase at the B20 level was statistically significant at the 90% confidence level, and the increase at the B100 level was statistically significant at the >99% confidence level. The significance determinations use the pair-wise t-test, which is subject to caveats, but this is the only method available to gauge significance because re-analysis of the computed percentage changes is not possible.

Table 3-8 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 1998 Kubota TRU Engine (Engine Dynamometer Testing)				
	Soy-Based Biodiesel Series 1 ISO 8178		Soy-Based Biodiesel Series 2 ISO 8178	
	NOx % Diff	p value	NOx % Diff	p value

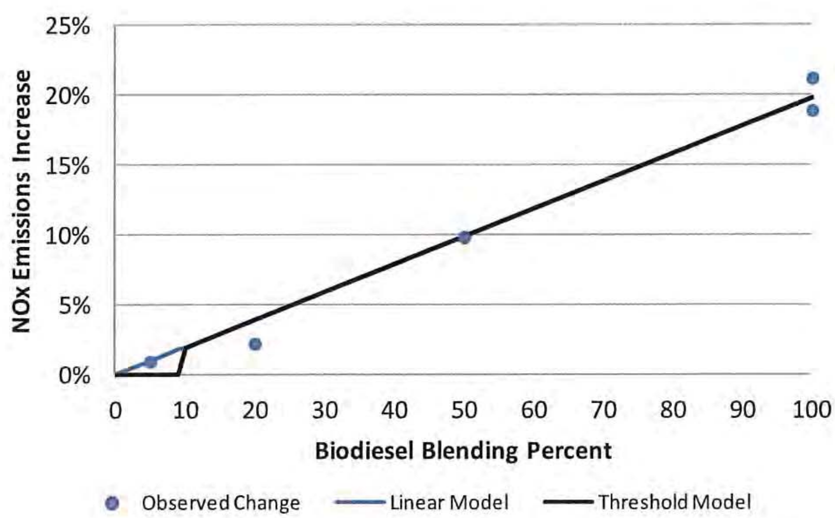
Figure 3-4 displays the trend of NOx emissions with blending percent for the first and second test series combined. As the figure shows, the available data points scatter around the trendline determined from the emission change percentages (not from regression analysis). The B20 data point falls below the trend line while the two B100 data points bracket the trend line. It is not possible to explain the divergence of the B20 data point

Figure 3-4
Durbin 2011 Assessment: ISO 8178 Cycle NOx Emissions Increases for Soy-based Biodiesel Blends (1998 Kubota Engine, Test Series 1 and 2 Combined)



Reproduction of Pages 167 - 204 Consisting of Comments ADF B3-146 through ADF B3-92

because the emissions data for the second test series are not published in Durbin 2011. The B5 data point clearly supports the Linear Model and is inconsistent with the Staff Threshold Model.

3.6 2009 John Deere Off-Road Engine (Engine Dynamometer Testing)

The only information on the 2009 John Deere off-road engine comes from the tabulation of calculated percentage emission changes. Table 3-9 reproduces these data from Table ES-7 of Durbin 2011. For the soy-based biodiesel, NOx emissions are significantly increased at the B20 and higher blend levels. The increase for B20 is statistically significant at the 90% confidence level and the increases for B50 and B100 are statistically significant at the >99% confidence level based on the pair-wise t-test. A soy-based B5 fuel was not tested.

Table 3-9 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 2009 John Deere Engine (Engine Dynamometer Testing)				
	Soy-Based Biodiesel ISO 8178		Animal-Based Biodiesel ISO 8178	
	NOx % Diff	p value	NOx % Diff	p value
B5	Not tested		-3.82	0.318
B20	2.82% [a]	0.021	-2.20	0.528
B50	7.63%	0.000	Not tested	
B100	13.76%	0.000	4.57	0.000

Source: Table ES-7 of Durbin 2011, p. xxxviii
Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on pair-wise t-test.

For animal-based biodiesel, the testing shows the unusual result that B5 and B20 appear to decrease NOx emissions, while B100 increases NOx. The B5 and B20 decreases are not statistically significant, while the B100 increase is statistically significant at the >99% confidence level. Durbin 2011 concludes:

> The animal-based biodiesel also did not show as great a tendency to increase NOx emissions compared to the soy-based biodiesel for the John Deere engine, with only the B100 animal-based biodiesel showing statistically significant increases in NOx emissions.[18]

Durbin 2011 does not discuss these results further and does not note any problems in the testing, making further interpretation of the results difficult. Figure 8-1 of Durbin 2011 presents the NOx results for this engine with error bars. First, we note that the figure appears to suggest that NOx emissions were increased on the B20 fuel in contradiction to the table above. Second, it is clear that the error bars are large enough that no difference in NOx emissions can be detected among ULSD, B5, and B20 fuels. Overall, this result could be consistent with the Staff Threshold Model through B5, but the failure to detect a NOx emission increase at B20 is not. Without further information, it is not possible to determine whether the result seen here is a unique response of the John Deere engine to animal-based biodiesel or is the result of a statistical fluctuation or an artifact in the emissions data.

3.7 Conclusions

The Biodiesel Characterization report prepared by Durbin et al. for CARB is an important source of information on the NOx emissions impact of biodiesel fuels in heavy-duty engines. It is the sole source of information on the NOx impact of B5 blends cited in the ISOR. When the engine dynamometer test data are examined for

Reproduction of

Comments ADF B3-146
through ADF B3-92

[18] Durbin 2011, p. xx.

the three engines for which emissions test data have been published, we find clear evidence that biodiesel increases NOx emissions in proportion to the blending percent. Where B5 fuels were tested for these engines, NOx emissions are found to increase above ULSD for both soy- and animal-based blends in all three engines and by statistically significant amounts in one engine.

Specifically, a re-analysis of the NOx emissions test data demonstrates the following:

1. For the 2006 Cummins engine, biodiesel fuels are found to significantly increase NOx emissions for both soy- and animal-based blends by amounts that are proportional to the blending percent. This result indicates that biodiesels will increase NOx emissions at blending levels below B10. When B5 fuels were tested, NOx emissions were observed to increase but by amounts that fail to reach statistical significance according to the pair-wise test.[19] Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

2. For the 2007 MBD4000 engine, biodiesel fuels are found to significantly increase NOx emissions for both soy- and animal-based blends by amounts that are proportional to the blending percent. This result indicates that biodiesels will increase NOx emissions at blending levels below B10. When B5 fuels were tested, NOx emissions were observed to increase and by amounts that are found to be statistically significant using the pair-wise t-test.[13] This result alone is sufficient to disprove the Staff Threshold Model. Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

3. For the 1998 Kubota TRU (off-road) engine, soy-based biodiesel fuels are found to significantly increase NOx missions. Animal-based biodiesel was not tested. When a soy-based B5 fuel was tested, NOx emissions were observed to increase but by amounts that fail to reach statistical significance according to the pair-wise test.[13] Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

The measured emissions test data for the other off-road engine (2009 John Deere) are not contained in the Durbin 2011 report and CARB has not made them publicly available. Thus, a re-analysis was not possible. Based on the tables and figures in Durbin 2011, soy-based biodiesel fuels were shown to significantly increase NOx emissions at B20 levels and higher, but B5 was not tested. Testing of animal-based blends shows no change in NOx emissions at B5 and B20 levels, but B100 is shown to significantly increase NOx emissions. Durbin 2011 discusses this result only briefly, and it is unclear what conclusions can be drawn from it.

APPENDIX A

RESUME OF ROBERT W. CRAWFORD

Education

1978 Doctoral Candidate, ScM. Physics, Brown University, Providence, Rhode Island
1976 B.A. Physics, Pomona College, Claremont, California

Professional Experience

1998-Present Independent Consultant

Individual consulting practice emphasizing the statistical analysis of environment and energy data with an emphasis on how data and statistics are properly used to make scientific inferences. Mr. Crawford provides support on statistical, data analysis, and modeling problems related to ambient air quality data and emissions from mobile and stationary sources.

Ambient Air Quality and Mobile Source Emissions – Mr. Crawford has worked with Sierra Research on elevated ambient CO and PM concentrations in Fairbanks AK and Phoenix AZ, including the effect of meteorological conditions on ambient concentrations, the relationship of concentrations to source inventories, and the use of non-parametric techniques to infer source location from wind speed and direction data. Ongoing work is employing Principal Components Analysis to elucidate the relationship between meteorology and $PM_{2.5}$ concentrations in Fairbanks. In the past year, this work led to creation of the AQ Alert System, a tool used by air quality staff to track $PM_{2.5}$ monitor concentrations during the day and to prepare AQ alerts over the next 3 days based on the meteorological forecast.

In past work for Sierra, he has also conducted studies of fuel effects on motor vehicle emissions for Sierra. For CRC, he determined the relationship between gasoline volatility and oxygen content on tailpipe emissions of late model vehicles at FTP and cold-ambient temperatures. For SEMPRA, he determined the relationship between CNG formulation and tailpipe emissions of criteria pollutants and a range of air toxics. Other work has included the design of vehicle surveillance surveys and determination of sample sizes, development of screening techniques similar to discriminant functions to improve the efficiency of vehicle recruitment, the analysis of vehicle failure rates measured in inspection & maintenance programs, and the statistical evaluation of data collected on freeway speeds using automated sensors.

Stationary Source Emissions – Over the past 5 years, Mr. Crawford has worked with AEMS, LLC on EPA's MACT and CISWI rulemakings for Portland Cement plants, in which significant issues related to data quality, data reliability, and emissions variability are evident. Key issues include the need to properly account for uncertainty and emissions variability in setting emission standards. He also supported AEMS in the

current EPA rulemaking on reporting of greenhouse gas emissions from semiconductor facilities, where the proper characterization of emission control device performance was a key issue. He is currently supporting AEMS in a regulatory process to re-determine emission standards for an industrial facility where the new standard will be enforced by continuous emissions monitoring (CEMS). At issue is how to set the standard in such a way that there will be no more than a small, defined risk that 30-day emission averages will exceed the limitations while emissions remain well-controlled .

Advanced Combustion Research – In recent work for Oak Ridge National Laboratory, Mr. Crawford conducted a series of statistical studies on the fuel consumption and emissions performance of Homogenous Charge Compression Ignition (HCCI) engines. One of these studies was for CRC, in which fuel chemistry impacts were examined in gasoline HCCI. In HCCI, the fuel is atomized and fully-mixed with the intake air charge outside the cylinder, inducted during the intake stroke, and then compressed to the point of spontaneous combustion. The timing of combustion is controlled by heating of the intake air. If R&D work can demonstrate a sufficient understanding of how fuel properties influence engine performance, the HCCI combustion strategy potentially offers the fuel economy benefit of a diesel engine with inherently lower emissions.

1979-1997 Energy and Environmental Analysis, Inc., Arlington, VA. Director & Partner (from 1989).

Primary work areas: Studies of U.S. energy industries for private and institutional clients emphasizing statistical analysis, business planning and computer modeling/forecasting. Responsible for the EEA practice area that provided strategic planning and forecasting services to major energy companies. Primary topical areas included: U.S. energy market analysis and strategic planning; gas utility operations; and natural gas supply planning.

U.S. Energy Market Analysis

During 1995-1997, Mr. Crawford directed EEA's program to provide comprehensive energy supply and demand forecasting for the Gas Research Institute (GRI) in its annual Baseline Projection of U.S. Energy Supply and Demand. Services included: development of U.S. energy supply, demand, and price forecasts; sector-specific analyses covering energy end-use (residential, commercial, industrial, transportation), electricity supply, and natural gas supply and transportation; and the preparation of a range of publications on the forecasts and energy sector trends.

From 1989 through 1997, he directed the use of EEA's Energy Overview Model in strategic planning and long-term market analysis for a client base of major energy producers, pipelines, and distributors in both the United States and Canada. The Energy Overview Model was used under his direction as the primary analytical basis for the 1992 National Petroleum Council study The Potential for Natural Gas in the United States. Mr. Crawford also provided analysis for clients on a wide range of other energy market issues, including negotiations related to an LNG import project intended to serve U.S. East Coast markets. This work assessed the utilization and economic value of seasonal

gas deliverability in order to develop LNG pricing formulas and evaluate the project's viability.

Other topical areas of work during his period of employment with EEA include:

Gas Load Analysis and Utility Operations – Principal investigator in a multi-year research program for the Gas Research Institute (GRI) that examined seasonal gas loads, utility operations, and the implications for transmission and storage system reliability and capacity planning.

Gas Transmission and Storage – Principal investigator for a study of industry plans for expansion of underground gas storage capacity in the post-Order 636 environment, including additions of depleted-reservoir and salt-formation storage, an engineering analysis of capital and operating costs for the projects, and unbundled rates for new storage services.

Natural Gas Supply Planning – Mr. Crawford was EEA's senior manager and lead analyst on gas supply planning issues for both pipeline and distribution companies, which included technical and analytic support in development and justification of gas supply strategies; and identification of optimal seasonal supply portfolios for Integrated Resource Planning proceedings.

Transportation Systems Research

Mr. Crawford also had extensive experience in motor vehicle fuel economy and emissions while at EEA. He participated for five years in a DOE research program on fuel economy, with emphasis on the evaluation of differences between laboratory and on-road fuel economy. His work included analysis of vehicle use databases to understand how driving patterns and ambient (environmental) conditions influence actual on-road fuel economy. He also developed a software system to link vehicle certification data systems to vehicle inspection and testing programs and participated in a range of studies on vehicle technology, fuel economy, and emissions for DOE, EPA, and other governmental agencies.

BEFORE THE
CALIFORNIA AIR RESOURCES BOARD

In re:	)
	)
Proposed Regulation on the Commercialization of Alternative Diesel Fuels (Public Hearing Scheduled for March 20, 2014)	)
	)

Declaration of James M. Lyons

I, James M. Lyons, declare and state as follows:

1. I am an engineer with training and expertise in motor vehicle fuels, automotive emissions control, and automotive air pollution. I am a Senior Partner of Sierra Research, Inc. ("Sierra"), an environmental consulting firm located at 1801 J Street, Sacramento, California. Sierra specializes in research and regulatory matters pertaining to air pollution control, and does work for both governmental and private sector clients. I have been employed at Sierra Research since 1991. I received a B.S. degree in Chemistry from the University of California, Irvine, and a M.S. Degree in Chemical Engineering from the University of California, Los Angeles. Before joining Sierra in 1991, I was employed by the State of California in the Mobile Source Division of the California Air Resources Board ("CARB").

Reproduction of Pages 211 - 224 Consisting of Comments ADF B3-93 through ADF B3-105

I. Introduction, Qualifications, and Materials Considered

2. I have prepared this Declaration and the analysis it contains for Growth Energy. I hold the opinions expressed in this Declaration with a reasonable degree of engineering and scientific certainty. I plan to request an opportunity to testify before CARB at the public hearing scheduled for this matter, so that I may answer any questions concerning my opinions and the analysis and sources on which I have based those opinions. I also request that CARB review and

respond to each part of the analysis and opinions presented in this Declaration before deciding what action to take on the CARB staff's proposed alternative diesel fuel ("ADF") regulation.

3. During my career, I have worked on many projects related to the following areas: (1) the assessment of emissions from on- and non-road mobile sources, including ships and locomotives; (2) analyses of the unintended consequences of regulatory actions; and (3) the feasibility of compliance with air quality regulations. I have also studied how the use of biodiesel fuels can influence exhaust emissions of oxides of nitrogen ("NOx") when used in vehicles and engines operated in California, and I have prepared and filed declarations regarding that issue in *POET LLC et al. v. California Air Resources Board*, an action in which I was a co-petitioner.

Reproduction of Pages 211 - 224 Consisting of Comments ADF B3-93 through ADF B3-105

4. I have testified as an expert under state and federal court rules in cases involving CARB regulations for gasoline, Stage II vapor recovery systems and their design, combustion chamber system design, and issues related to emissions from heavy-duty vehicles and engines. While at Sierra I have acted as a consultant on automobile air pollution control matters for CARB and other governmental organizations. I am a member of the American Chemical Society and the Society of Automotive Engineers and have co-authored nine peer-reviewed monographs concerned with automotive emissions, including greenhouse gases and their control. In addition, over the course of my career, I have conducted peer-reviews of numerous papers related to a wide variety of issues associated with pollutant emissions and air quality. My résumé is attached as Attachment A.

5. I have reviewed a report being filed along with this Declaration by Growth Energy that has been prepared by Mr. Robert Crawford of Rincon Ranch Consulting, entitled *NOx Emissions Impact of Soy- and Animal-based Biodiesel Fuels: A Re-Analysis* (December

2013). I have also studied the CARB Initial Statement of Reasons ("ISOR" or "Staff Report") released to support the proposed ADF regulation, and the studies cited in the ISOR that are pertinent to Mr. Crawford's analysis. The additional materials I have considered to prepare this Declaration are identified as references.

6. Mr. Crawford's report examines the empirical basis for the CARB staff's claims that the use of biodiesel in California is unlikely to warrant environmental mitigation, and that the use of biodiesel blends below the ten percent blend level (B10) in California pursuant to the proposed ADF regulation will not result in increases in NOx emissions.

7. Mr. Crawford's report applies generally accepted methods of data analysis and demonstrates expertise in the subject-matter of the report; Mr. Crawford is an expert in the field in which he opines in his report; and his report is the type of analysis on which experts in the field of automotive emissions control rely.

Reproduction of Pages 211 - 224 Consisting of Comments ADF B3-93 through ADF B3-105

II. Analysis and Opinions

A. Increases in NOx Emissions from Biodiesel Blends Below B10

8. As explained in detail in Mr. Crawford's report, a proper statistical analysis of the available emissions data relied upon by CARB staff in developing the proposed ADF regulation demonstrates that statistically significant increases in NOx emissions will result from biodiesel blends that contain less than ten percent biodiesel, including at the five percent level (B5) and below. In addition, Mr. Crawford's report demonstrates that NOx emissions increase in direct proportion of the amount of biodiesel in a blend and there is not, as CARB staff claims, a "threshold" below which biodiesel use in a blend will not increase NOx emissions. Given this, as I explain below in more detail, CARB staff should be proposing a Significance Level of zero, rather than ten percent, for biodiesel. Given the issues identified with the CARB staff analysis of

biodiesel impacts on NOx emissions by Mr. Crawford, CARB has no credible scientific basis upon which to adopt the ADF regulation as proposed with the biodiesel Significance Level set at ten percent.

9. CARB staff presents, in Figures B.2 and B.3 of the ISOR, regressions of all the available emissions data considered by CARB staff in developing the proposed ADF regulation. Based on Mr. Crawford's findings, the slopes of these regression lines can be used to calculate the increases in NOx emissions expected from the use of soy- and animal-based biodiesel as a function of biodiesel content in the blend. The values calculated for soy- and animal-based biodiesel at selected blends levels over the range from one percent to twenty percent are shown in Table 1.

Reproduction of Pages 211 - 224 Consisting of Comments ADF B3-93 through ADF B3-105

Table 1
Expected Increases In NOx Emissions from Biodiesel Use Based on Available Emissions Data Considered by CARB Staff

Biodiesel Blend Level %	Percentage Increase in NOx Emissions	
	Soy-Based	Animal-Based
1	0.2	0.09
2	0.4	0.18
3	0.6	0.27
4	0.8	0.36
5	1	0.45
10	2	0.90
20	4	1.80

10. As shown in Table 1, the magnitude of the NOx increase for animal-based biodiesel is approximately half that observed for soy-based biodiesel. As also shown in Table 1, the emissions data considered by CARB show that increases in NOx emissions between about one and two percent occur at the proposed B10 significance threshold.

B. The "Effective Blend Level" Concept Provides No Assurance Against Increases in NOx Emissions Due to Biodiesel Use

11. The proposed ADF regulation relies on a concept called the "Effective Blend Level" (EB) for biodiesel to determine when mitigation would be required. The formula proposed by CARB staff for calculating the Effective Blend Level for biodiesel is found in proposed Section 2293.6(a) and is reproduced below.

$$EB = 100 \times \left[\frac{NBV - 0.5LN - 0.73RD - VM - 0.55AB}{TCV}\right]$$

As specified in Section 2293.6(a), the above formula is to be used to compute an annual average statewide value for the Effective Blend Level relative to the total volume of fuel used in compression ignition engines excluding alternative fuels such as natural gas and liquefied petroleum gas ("TCV") in the state during that year.

12. The calculation begins with establishing the net volume of biodiesel of all types used in California *excluding biodiesel used in blends of five percent or less* (NBV) — a step that has no scientific basis, as demonstrated by Mr. Crawford's analysis, and that, on its own, completely invalidates the use of the EB metric for the intended purpose. The NBV value is then further reduced by subtracting 50% of the volume of low NOx Diesel (LN) used statewide and 73% of the volume of renewable Diesel used statewide. The remainder is then further reduced by subtracting the volume of biodiesel of all types used in blends where steps have been taken to voluntarily mitigate NOx increases (VM) and then again by subtracting 55% of the volume of animal-based biodiesel (AB) to account for the smaller magnitude of the NOx emission increases observed with that fuel.[1] The final value is then divided by TCV (i.e., the total volume of fuel

Reproduction of Pages 211 - 224 Consisting of Comments ADF B3-93 through ADF B3-105

1 Those voluntary mitigation measures are assumed to have been taken before the so-called "Significance Level" is reached and mitigation would be required under the staff's proposal. *See* ¶ 13.

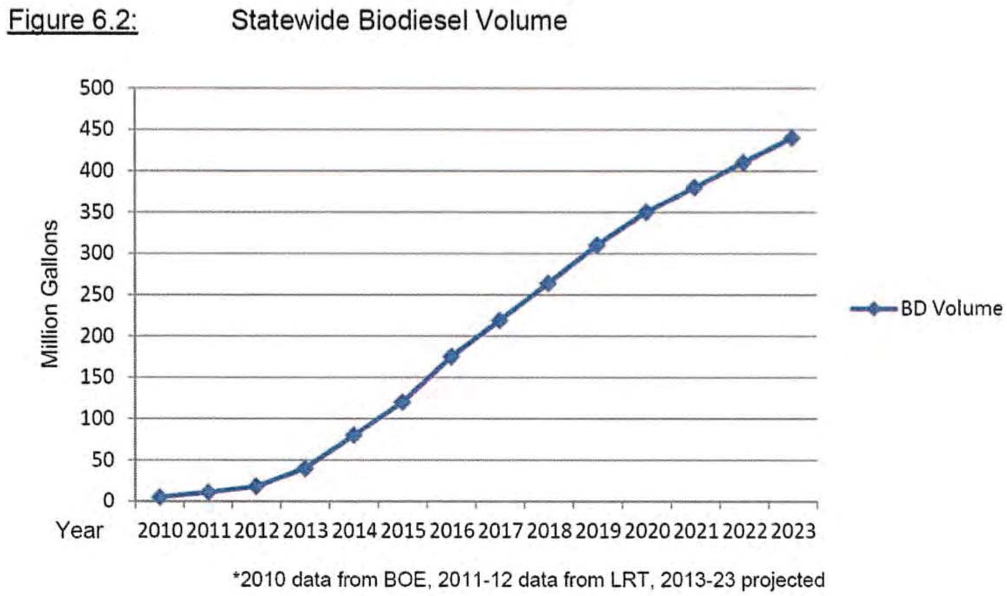
used in compression ignition engines excluding alternative fuels such as natural gas and liquefied petroleum gas in the state during that year) and multiplied by 100 to yield the Effective Blend Level on a percentage basis.

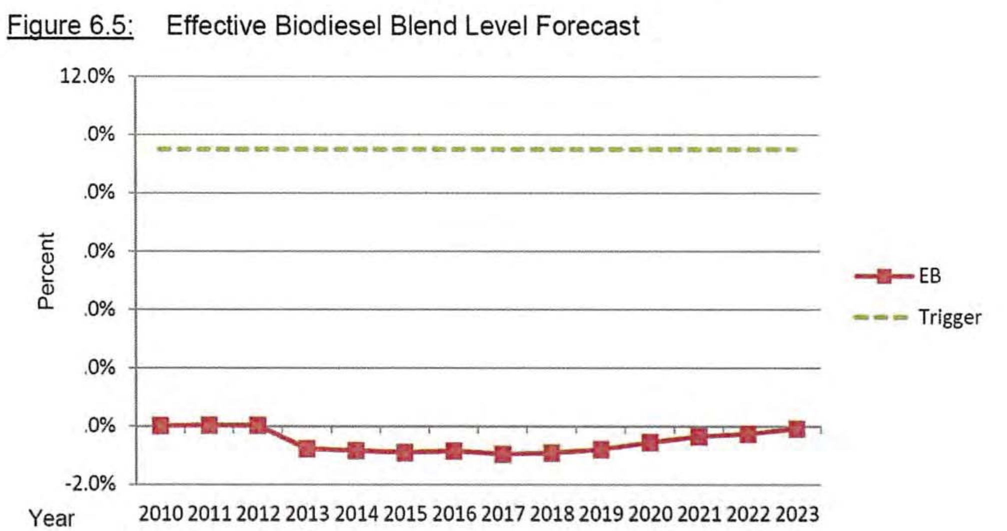
13. As specified in proposed Section 2293.5(c)(4), mitigation of NOx increases associated with biodiesel would be required only when the value of EB reaches 9.5 percent, which is 95% of the 10% Significance Level proposed for biodiesel.

14. There are a number of specific problems with the concept and calculation of the predicted Effective Blend Level that create the potential for significant increases in NOx emissions to result from the use of biodiesel in California; these are explained in detail below and should be addressed by CARB. As an initial matter, however, the overall problem with the EB concept will allow massive increases in the amount of biodiesel used in California without requiring any mitigation of the associated increase in NOx emissions. This can be seen readily by comparing CARB staff's projections of biodiesel use in California (Figure 6.2 of the ISOR) with CARB staff's projections regarding the Effective Blend Level for biodiesel (Figure 6.5 of the ISOR). Those two figures are reproduced below in Figure 1. As can been seen, despite the forecast nine-fold increase in annual biodiesel use in California from 50 million to 450 million gallons from 2013 to 2023 shown in Figure 6.2 of the ISOR, the forecast Effective Blend Level of biodiesel **decreases** to less than zero over virtually all of the period in question — meaning that, under the CARB staff's proposal, no mitigation of the increase in NOx emissions in California from biodiesel use will ever occur. CARB needs to confront and eliminate the EB concept from the staff's proposal, in light of this very simple demonstration of why the EB concept will not protect the environment against increases in NOx emissions.

Reproduction of Pages 211 - 224 Consisting of Comments ADF B3-93 through ADF B3-105

Figure 1. CARB Biodiesel Forecasts





Source: CARB Initial Statement of Reasons. Note that Figure 6.5 is reproduced directly from the ISOR, which is missing some increments on the y-axis.

15. Next, CARB needs to modify the proposed ADF regulation in order to address CARB staff's faulty assumption that biodiesel blends of up to five percent will have no impact on NOx emissions. With respect to five percent blends, CARB staff states on page ES-3 of the Staff

Reproduction of Pages 211 - 224 Consisting of Comments ADF B3-93 through ADF B3-105

Report that "biodiesel used in blends at B9 or below, including the B5 (B0 to B5) in predominant use today, does not increase NOx." The Staff Report also attempts to justify the exclusion of five percent blends from the EB calculation by arbitrarily excluding these blends from the ADF regulation. That assertion is undercut by the Staff Report's frank and correct admission on page 51 that "[g]iven the significant price premium for higher biodiesel blends such as B20 or B100, it is highly unlikely that operators of heavy-duty, legacy diesel fleets would opt to use the more expensive, higher biodiesel blends when comparable, lower cost conventional CARB diesel or B5 blends are readily available."

16. As noted above, Mr. Crawford's analysis demonstrates that statistically significant increases in NOx emissions will occur from the use of five percent biodiesel blends and, as Table 1 shows, the available emissions data relied upon by CARB staff indicate that at the five percent blend level, biodiesel use is expected to increase NOx emission by between about 0.5 and one percent. There is no doubt that unmitigated NOx emission increases of this magnitude have the potential to create significant adverse environmental impacts in areas of California with severe air quality problems.

Reproduction of Pages 211 - 224 Consisting of Comments ADF B3-93 through ADF B3-105

17. It is also important for CARB to understand the import of the staff's prediction that biodiesel blends of five percent or less will be the primary means by which biodiesel will be used in California. As the Staff Report states on page 30:

> Staff has communicated with many of the stations that sell biodiesel as well as the major terminal operators in the state, and has found that the vast majority of the biodiesel currently being sold in California and expected to be sold in the future is sold as blends of B5 or less.

The fact that most biodiesel used in California will be sold as blends of five percent biodiesel or less, coupled with the fact that – as Mr. Crawford has explained – the available data show statistically significant increases in NOx emissions from such blends, means that biodiesel use in

California under the proposed ADF regulation will result in unmitigated increases in NOx emissions. Again, the critical nature of the CARB staff's invalid assumption about the NOx impacts of blends at or below five percent simply cannot be ignored by CARB.

18. Even if it were correct that blends of B5 and less have no impact on NOx emissions, the EB calculation double-counts for the supposedly benign effect of those blends, and therefore makes mitigation even more unlikely. This can be illustrated by noting that CARB staff estimates that 450 million gallons per year of biodiesel will be used in California in 2023. (See Figure 6.2 of the Staff Report.) A recent California Energy Commission forecast[2] for total Diesel use in California in 2023 is about 4 billion gallons. On that basis, and without discounting for low NOx, renewable Diesel, or voluntary mitigation, the actual Effective Blend Level would be 11.25 percent and mitigation would be required for at least some biodiesel blends under the proposed ADF. Under CARB staff's approach, however, if a substantial portion of that biodiesel — for example, 50 percent — is five percent or lower blends, the Effective Blend Level drops to 5.6 percent and no mitigation of any kind is required for any biodiesel blends. That result is clearly incorrect, and the EB calculation must be modified to include, rather than exclude, B5 blends.

19. Another fundamental problem with the proposed EB calculation is that it is based on annual statewide average fuel use. NOx emissions have local and immediate impacts on air quality, with the questions of when and where they occur in the state being of critical importance with respect to the significance of those impacts. It follows directly that mitigation of NOx increases associated with biodiesel use must occur in the same area at the same time if air quality

Reproduction of Pages 211 - 224 Consisting of Comments ADF B3-93 through ADF B3-105

[2] See *http://www.energy.ca.gov/2011publications/CEC-600-2011-007/CEC-600-2011-007-SD.pdf*.

impacts are to be avoided. However, the EB completely fails to provide this assurance because CARB staff has either (1) ignored that reductions in NOx emissions from mitigation must take place at the same time and in the same area as NOx increases from biodiesel use, or (2) without support from anything in the rulemaking file, assumed that mitigation will occur in the same area and at the same time as the increases in NOx emissions.

20. To illustrate the problems the EB creates for mitigation, consider, for example, that under the proposed ADF regulation, increases in NOx emissions could occur from trucks operating on biodiesel in Los Angeles during August and exacerbate already high ambient ozone levels in that area. In turn, this increase in NOx emissions could be "mitigated" by reductions in NOx emissions from trucks operating on renewable diesel in the San Francisco area during December, when high ozone levels are not a problem. In this example, the EB concept would allow residents of Los Angeles to suffer adverse environmental impacts while the residents of San Francisco would realize no environmental benefit. Clearly the approach to mitigation designed into the EB concept by CARB staff makes no sense.

Reproduction of Pages 211 - 224 Consisting of Comments ADF B3-93 through ADF B3-105

C. CARB Staff's Assumption that Biodiesel Use Will not Increase Emissions from New Technology Diesel Engines Is Not Adequately Supported

21. In the Staff Report, CARB staff makes frequent statements regarding the impact of biodiesel on NOx emissions from "new technology diesel engines" (or "NTDEs"). For example, on page ES-3 of the ISOR, the staff states categorically that "use of biodiesel in 2010-compliant engines and other so-called 'New Technology Diesel Engines' does not increase NOx, regardless of the biodiesel blend level." Only one reference, Lammert et al.,[3] is provided in the staff report

[3] Lammert, M., McCormick, R., Sindler, P. and Williams, A., "Effect of B20 and Low Aromatic Diesel on Transit Bus NOx Emissions Over Driving Cycles with a Range of Kinetic Intensity," *SAE Int. J. Fuels Lubr.* 5(3):2012,

(Continued...)

to support this and other, analogous, statements by CARB staff. As CARB staff acknowledges, this single study involved chassis dynamometer testing of only two urban buses with NTDEs, with both engines being the same model produced by the same manufacturer. The extrapolation of that limited testing to the entire population of heavy-duty Diesel vehicles with NTDEs used in different applications and with different engine designs produced by a number of different manufacturers is simply not credible or reliable.

22. In addition, the CARB staff fails to acknowledge the following statement made by the authors of the Lammert study about the measurement of NOx emissions: "For much of the cycle[,] NOx would be at or near the detection limit of the laboratory equipment which resulted in a 95 percent confidence interval that was high relative to the value of the cycle emissions." That effect, which can be clearly seen in Figures 10 and 11 of the Lammert study, renders the claim that there was no statistically significant increase in NOx emissions observed from the use of biodiesel in NTDEs an artifact attributable to the lack of sensitivity of the NOx measurement instrumentation used in the study.
