I. SUMMARY OF COMMENTS AND AGENCY RESPONSE

Written comments were received during the 45-day comment period in response to the February 19, 2015 public hearing notice, and written and oral comments were presented at the Board Hearing.

Comment Code	Comment Period Received
OP	Comments received during the 45-day comment period of the original proposal, Jan. 2 – Feb. 18, 2015
B	Comments received as written materials during the board hearing , Feb 19, 2015
T	Comments received as testimony at the board hearing, Feb 19, 2015
FF	Comments received during the first 15-day comment period June 4 – June 19, 2015
SF	Comments received during the second 15-day comment period June 23 – July 8, 2015
TF	Comments received during the third 15-day comment period July 31 – August 17, 2015
SB	Comments received as written materials during the second board hearing, September 24, 2015
ST	Comments received as testimony at the second board hearing on September 24, 2015

The comment letters were coded by the order and the comment period in which they were received, and also tagged LCFS, and the name of the organization or individual commenting. For instance, below, 01-OP-LCFS-CNGVC is the first comment received during the 45-day comment period, and is an LCFS comment sent by the California Natural Gas Vehicle Coalition. Listed below are the organizations and individuals that provided comments during the 45-day comment period:

Several comment letters were directed at both the LCFS rulemaking and the Alternative Diesel Fuel (ADF) rulemaking. The comments directed at the LCFS rulemaking are responded to below. The comments directed at the ADF rulemaking are responded to in the ADF Final Statement of Reasons.

California Natural Gas Vehicle Coalition

NGVAMERICA
Natural Gas Vehicles for America

THE COALITION FOR RENEWABLE NATURAL GAS

1_OP_LCFS_CNGVC

January 21, 2015

Richard Corey
Executive Officer
California Air Resources Board
1001 "I" Street
Sacramento, CA 95814

Re: Additional Comments on the Low-Carbon Fuel Standard and Revisions to the CA-GREET Model

Dear Executive Officer Corey:

The California Natural Gas Vehicle Coalition (CNGVC), NGVAmerica (NGVA), and the Coalition for Renewable Natural Gas (RNGC) are pleased to provide these latest joint comments regarding ARB's proposed reauthorization of the Low Carbon Fuel Standard (LCFS) regulation and proposed update to the CA-GREET model (CA-GREET 2.0). For more information about our three organizations and respective memberships, please refer to the previous formal comment letters (dated October 24 and December 15, 2014) that we uploaded to the ARB LCFS comments website.

As stated in those letters, we continue to strongly support ARB's re-authorization of the LCFS regulation. We are committed to continue working closely with ARB staff. Like ARB, we want to ensure that the proposed CA-GREET 2.0 model is based on the most up-to-date, accurate methodologies and data available at the time of its expected adoption in July 2015. LCFS 1-1

Recent Cooperative Efforts and Progress by ARB Staff

Our three organizations greatly appreciate the time and effort put forth by ARB staff over the last 60 days to meet with our representatives and address our specific concerns. We are pleased that ARB has made changes that corrected erroneous information and updated obsolete inputs found in early drafts of CA-GREET 2.0. LCFS 1-2

We also appreciate your general willingness to work with our industry. Most recently (January 11, 2015), you sent a cooperative, positive email communication to CNGVC President Tim Carmichael. In that email, you confirmed ARB's intent to continue working with California NGV industry stakeholders towards the following specific goals:

- Conduct further discussions to better quantify lifecycle GHG emissions;
- Understand and incorporate new research results as they become available over the next 12 months; LCFS 1-3
- Continue to engage with all stakeholders on CA- GREET 2.0, right up until the Board meeting in July 2015 at which the LCFS item will be heard (although, you noted that no "additional workshops" have yet been planned or scheduled);
- Incorporate any further updates to CA-GREET 2.0 through ARB's normal 15-day change rulemaking process; and

- Draft proposed "resolution" language for the Board's consideration at its February meeting; this resolution will confirm the previous bullet. LCFS 1-3 cont.

Ongoing Concerns Needing Resolution

Notwithstanding the significant cooperative efforts by ARB staff and the clear progress that has been made, our organizations and respective members continue to have significant and substantive concerns with Staff's direction towards finalizing LCFS recommendations to the Board for the July 2015 meeting. Our concerns fall within two general areas: 1) unresolved technical issues with the CA-GREET 2.0 model; and 2) the lack of a formal, transparent process for stakeholders to provide inputs and/or new information to help correct such problems. Addressing both issues will improve the CA-GREET model's accuracy and enhance the LCFS Program's fidelity, credibility and defensibility.

Within this context, our specific concerns are described below.

1. Unresolved Technical Issues

There are several major issues associated with the current CA-GREET model's natural gas pathways that remain unresolved to our satisfaction. These unsettled technical issues each relate to the critical parameter of fugitive methane emissions (both upstream and downstream). All issues were originally described in the two detailed letters and reports[1] that we previously submitted to ARB via the formal LCFS comment process. The following summarizes our updated technical concerns.

a) Tailpipe Methane Slip Emission Factors – This is our industry's most-important technical concern with the current version of CA-GREET 2.0. As we have described in past letters, the model's methodology and the data used to calculate methane tailpipe emission factors (EFs) were inaccurate in the first iteration of the proposed CA-GREET 2.0. We appreciate that ARB staff were responsive to our comments and made adjustments to the model, which then emerged in the current working draft of CA-GREET 2.0. Unfortunately, the quality of the subsequent data and methodology for tailpipe methane emissions in CA-GREET 2.0 remains poor. The new methodology utilizes modeled emission factors for gasoline and diesel from an outdated version of the EPA MOVES model, combined with unreferenced scaling factors to convert conventional fuel EFs to natural gas EFs. This approach is not scientifically defensible, and the resulting estimates for methane emissions are not consistent with recent vehicle testing and engine certification data for heavy-duty vehicles. LCFS 1-4

   We continue to strongly recommend that ARB incorporate the most up-to-date tailpipe methane methodology and emissions factors based on actual NGV emissions data. Peer-reviewed sources include SCAQMD's report from West Virginia University on in-use testing of heavy-duty vehicles (July 2014), and the soon-to-be released Argonne National Lab (ANL) Heavy Duty Vehicles report. Notably, the methane slip values in the ANL report for Class 8 heavy-duty trucks are four to six times lower than those currently being used by ARB staff. It appears that ARB staff already have an advanced copy of the ANL report, as it is referenced in the December 16, 2014 CA-GREET 2.0 Supplemental Document.

b) Methane Leakage from RNG Production Facilities – We appreciate that ARB staff responded to our concerns and reduced (from two to one percent) the assumed methane leakage factor for facilities LCFS 1-5

[1] This refers to the ICF International report commissioned by our organizations and submitted to ARB with our October 24, 2014 letter. Additional technical comments about CA-GREET based on this report were submitted to ARB with our December 15, 2014 letter.

that capture landfill gas. However, the current draft of the CA-GREET 2.0 continues to neglect the fact that a leakage rate of even one percent is both unfounded and inconsistent with existing Federal and state level regulations to control methane leakage at landfills, which require industry best practices to comply. The ANL reports and methodology cited by ARB are based on European studies for anaerobic digester facilities; they are simply not applicable to U.S. RNG production from landfill gas. U.S. landfills are subject to New Source Performance Standard (NSPS) operational requirements for collection and control systems. Moreover, California landfills are subject to more-stringent landfill methane rules requiring leak testing of any components that contain landfill gas under pressure. This includes the entire upgrading and treatment system. Specifically, California regulation 17 CCR 95464 (b)(1) sets very stringent leakage limits of 500 ppmv[2] and would translate into less than 0.1 percent leakage. Under Federal law, 40 CFR 60.753 prohibits <u>any</u> leakage of gas from landfill collection and processing systems. Consequently, we continue to support the position that the methane leakage rate at RNG production facilities located at any North American landfill is effectively *zero*. We see no credible or defensible basis for staff's position that a leakage rate of one percent must be assumed. LCFS 1-5 cont.

c) <u>Methane Leakage from Conventional Natural Gas Processes and Transport</u> – Assumptions currently in CA-GREET 2.0 for this category of methane leakage are based on a national-level EPA methodology. Inputs come from the 2014 national GREET model. These leakage rates are lower than the 2013 version of the national GREET model, and reflect the downward trend in methane emissions from the natural gas supply chain over the last 24 years (during very significant increases in natural gas production). Our concern is that using these emissions rates in the current CA-GREET 2.0 model is clearly not representative of California's natural gas distribution systems or the primary gas-producing basins supplying natural gas to California. ARB's ISOR (Appendix D) acknowledges that the release of more up-to-date studies on system leakage are imminent; these will <u>include California-specific data</u>. While we concur with ARB staff's apparent decision to wait for release of these studies before revising leakage values, we want to emphasize the importance of incorporating this new data set before CA-GREET 2.0 is finalized and implemented. LCFS 1-6

To further improve the accuracy of model inputs and outputs, we continue to recommend that ARB develop a California-centric assessment of natural gas systems and supplies, similar in concept to the OPGEE model used to calculate CI values for petroleum fuels. Our organizations and members are ready to assist by providing inputs for this model. For example, Southern California Gas Company reports that modernization efforts over the last 20 years have reduced leakage rates in its territory to levels <u>20 to 80 percent lower than those assumed in the currently proposed CA-GREET 2.0 model</u>. Other utilities and natural gas producers indicate that actual leakage rates attributable to California gas supply are significantly lower than assumed in the proposed CA-GREET update. We strongly urge ARB to work with these industry resources to incorporate and account for unique attributes of the California natural gas system. LCFS 1-7

d) <u>Methane Leakage as a User Modifiable CA-GREET Input</u> – We request that ARB make methane leakage rate a user-modifiable input in the CA-GREET model. This will enable fuel producers *that are able to provide supporting documentation* to submit site-specific values for methane leakage. LCFS 1-8

e) <u>Double Counting of Methane Leakage During Pipeline Distribution</u> – In the current draft of the CA-GREET 2.0 model, methane leakage during pipeline distribution (i.e., via lower-pressure pipelines) is LCFS 1-9

[2] Parts per million, by volume

erroneously being double counted. We have made ARB staff aware of this issue, and expect that the error will be corrected before ARB finalizes and implements the CA-GREET 2.0 model. LCFS 1-9 cont.

2. Concerns with the Stakeholder Review Process

We have the following significant concerns regarding the process used by ARB staff to work with our industry (and other stakeholders) in revising the LCFS and updating the CA-GREET model. While we appreciate the time and attention staff has taken to meet with us thus far, these meetings have been more on an ad-hoc basis and at the request of the NGV industry. Building on the productive dialogue to date, we see opportunity for further improvement of the science, assumptions and calculations being used in the CA-GREET model.

Further, commitments have been made by ARB staff during past ad hoc meetings that have not been reflected in subsequent releases of the CA-GREET model and/or other LCFS Program supporting documentation. An example is provided below in item 2.a). LCFS 1-10

It is for these reasons that we believe a more formal process is warranted. Such a process will help ensure that the best-available data and science are used in updates to the LCFS Program. It will establish a clear, transparent and formal record for stakeholder engagement on these issues, thereby resulting in defensible and credible updates for the revised CA-GREET model and LCFS Program.

a) Publication of CI Values in the ISOR - In our formal joint letter of October 14, 2014, we urged ARB to refrain from publishing preliminary CI values for any fuel pathway, including those for CNG, LNG and RNG. We pointed out that much uncertainty exists with key parameters that dictate CI values; this is especially true regarding fugitive methane emissions during both upstream and downstream processes. Furthermore, more-robust data on such critical issues will emerge over the next six to twelve months; it is highly likely that some of this will be available to ARB staff well before the Board considers adoption of the revised LCFS in July 2015. We emphasized that CI values are an important determinant for end-user fleets when considering a potential switch to NGVs, and publishing interim values would only serve to introduce confusion into the marketplace. This could potentially destabilize the LCFS credit trading market, delay or halt investment plans developed to comply with the LCFS, and/or create hesitation among end users as they consider the adoption and use of lower-carbon transportation options for their fleets. Given the ability for an end-user fleet to make strong investments in NGVs and fueling infrastructure today, and transition these operations to very-low-CI RNG in the future (if not immediately), it is extremely important for the State to encourage rather than hinder such adoption in the market. Given these facts, we requested that ARB continue to use existing CI numbers from the still-active CA-GREET model (1.8b), until better and newer data are available. LCFS 1-11

During a meeting on December 12, 2014 at ARB headquarters, your staff indicated it would be necessary to publish updated CI values, even if preliminary. Staff cited the need to include “illustrative scenarios” in the ISOR for various fuel pathways. In follow-up discussions, Staff communicated that ARB management was willing to compromise by using a combined CI (70 g/mj) for conventional natural gas (fossil CNG and LNG), and a CI range (15 to 25 g/mj) for RNG. Our NGV industry team accepted that approach – although our clear preference has been that ARB not publish any new CI values. We have been consistent that continued use of existing CI values from CA-GREET 1.8b makes the most sense; meanwhile, ARB could note that they would most likely change upon implementation of the revised LCFS program (2016).

Unfortunately, for illustrative scenarios in the actual ISOR (Appendix B), Staff used a single CI of 25 for RNG rather than the range of 15 to 25, to which Staff had committed. While this change may have been inadvertent, our concern is that Staff did not follow through on an important commitment, upon public release of the ISOR and its appendices. This type of disconnect is a key reason that we are requesting a more formal process for obtaining, documenting and responding to stakeholder inputs (see the next item).

The ramifications to such process breakdowns can be significant. The ISOR language notes that "these values approximate the average CIs expected to be applied to these fuels." As such, we are very concerned that publishing only RNG's upper CI value (which is itself a place holder) will have a lasting and negative effect on decisions to make capital investments in California RNG infrastructure and related vehicle deployments. We strongly believe that the draft ISOR should have incorporated the range of 15 to 25 per the agreement made with Staff during our December 12 meeting.

LCFS 1-11 cont.

b) Lack of a Transparent, Effective Process to Incorporate Stakeholder Input – Issues such as the one described above (the CI range for RNG) point to the need for a more effective and transparent process for ARB staff to work with stakeholders to revise this very important regulation and supporting model. As previously stated in our formal letters and during meetings with Staff, we believe it is essential that ARB implements an improved process to obtain and document public input, as well as provide a timely and iterative approach to reviewing and integrating the latest technical information. This should include establishment of an ARB-industry working group that can convene several times within the period between the February 19-20th and July 23-24th board meetings. This will help ensure that legitimate stakeholder concerns and questions are addressed, while also improving the pipeline of useful technical inputs from industry to ARB staff.

This need for stakeholders to make CA-GREET 2.0 inputs during a more formal, transparent process is of paramount importance to our industry. We have been repeatedly assured by ARB staff that "nothing is cast in stone" for CA-GREET 2.0, and that changes can routinely be made by ARB right up until the Board considers adoption in July 2015. However, much of the critical details remain a mystery. For example, we have been told by Staff that after the LCFS issue comes before the Board at its February 2015, "the public record will be closed" until the LCFS Program is again heard at the July 2015 board meeting.

LCFS 1-12

Thus, under a worst-case scenario, our industry assumes that: 1) no formal meetings could take place between the February and July board meetings, 2) ARB staff would not continue to meet with our industry on these issues, 3) no additional data could be considered, and 4) no public testimony could be heard at the July board meeting. If this is the case (we do not have formal clarification and confirmation), we have very significant concerns that ARB's process will not be able to accommodate further industry inputs needed for important CA-GREET 2.0 model modifications. Again, adoption of a more formal and public process that can accommodate critical emerging information will help make this program better for ARB, program stakeholders and the general public.

As noted earlier, we do appreciate your recent email to CNGVC President Tim Carmichael that pledges ARB staff to "continue to engage with stakeholders" up to the July Board meeting. We urge you to now act on this, through the establishment and scheduling of an NGV industry working group. We recommend convening this group for up to three full-day working sessions before Staff finalizes its recommendation to the Board. Our organizations stand ready to engage in such a working group to support ARB staff in the development of a CA-GREET model that incorporates the best-available methodology and data inputs.

Summary of Conclusions and Recommendations

Our three organizations continue to strongly support reauthorization of the LCFS regulation. We genuinely appreciate the cooperation that ARB staff have shown in working with our industry representatives to improve the program, especially the critically important CA-GREET model. Leading up to the February and July Board meetings, we urge you to 1) expeditiously address unresolved technical issues in the current draft CA-GREET 2.0 model, as identified in this letter; 2) fully integrate critical new information that is likely to emerge in the coming months, and 3) plan, schedule and implement a robust public workshop process over the next several months that includes establishment of a natural gas industry working group.

1_OP_LCFS_CNGVC Responses

1. Comment: **LCFS 1-1**

   This comment supports the re-adoption of the LCFS regulation.

   Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

2. Comment: **LCFS 1-2**

   This comment supports the revisions to and re-adoption of the LCFS regulation.

   Agency Response: ARB staff appreciates support for the recommended changes to the California-modified Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (CA-GREET) 2.0 model.

3. Comment: **LCFS 1-3**

   This comment supports ARB staff's efforts in working with stakeholders toward additional goals with the LCFS regulation.

   Agency Response: Staff committed to continue working with California Natural Gas Vehicle Coalition, NGVAmerica, Coalition for Renewable Natural Gas, and other natural gas vehicle industry stakeholders towards the goals specified in above comment. Staff held a workshop on April 3rd, 2015 to discuss CA-GREET 2.0 updates and natural gas and biomethane CI values, and will continue to periodically refine CIs to reflect latest science.

4. Comment: **LCFS 1-4**

   The comment states concerns regarding the quality of the data and methodology for tailpipe methane emissions in CA-GREET 2.0.

   Agency Response: As the commenter has suggested, ARB staff has reviewed the publication, "The GREET Model Expansion for Well-to-Wheels Analysis of Heavy-Duty Vehicles," (Argonne National Laboratory, May 25, 2015) and adopted emission factors from this report in CA-GREET 2.0 to estimate methane (CH_4) and nitrous oxide (N_2O) emissions from heavy duty natural gas vehicles (NGV). Light duty NGV emission factors are calculated using data from GREET1_2014. GREET1_2014 data is drawn from a variety of sources which are referenced in the 2015 Initial Statement of Reasons (ISOR) Appendix C. Fuel consumption data by vehicle class, obtained from the U.S. Energy Information Administration (EIA) and the 2014 LCFS Reporting Tool Database, is used to determine a weighted average emission factor which represents all LNG vehicles operating in California, and a separate emission factor representing the CNG fleet. Staff has recorded the details of these changes since the ISOR in the CA-GREET 2.0 Supplemental Document, which was added to the record in the first round of 15-day changes to the regulation and available for review here: http://www.arb.ca.gov/fuels/lcfs/ca-greet/ca-greet.htm.

5. Comment: **LCFS 1-5**

The comment asserts that CA-GREET 2.0 neglects that methane leakage from RNG production facilities at a rate of one percent is not consistent with state and federal guidelines.

Agency Response: The one percent factor represents leakage during processing (purification to pipeline quality) of landfill gas (LFG), not fugitive emissions from landfills. Fugitive emissions that escape collection at the landfill (estimated to be 10-25 percent) are considered to be outside of the system boundary for LFG fuel pathways, because under the alternative reference case (business-as-usual scenario) where LFG is captured and flared, the same amount of methane is assumed to escape to the atmosphere. Therefore, CA-GREET 2.0 is consistent with the federal regulation of landfill methane emissions because it does not debit the pathway for leakage during the LFG recovery stage, and assesses a credit for avoided flaring.

California regulation 17 CCR 95464 (b)(1) requires leak testing on collection and control as well as gas processing systems and specifies a 500 ppmv limit; however, this limit represents a detectable concentration at one point in time, which is not sufficient to quantify methane emissions as a fraction of throughput.

No studies have been identified by ARB staff or by stakeholders that are relevant to leakage in LFG processing. The biogas studies used to develop the one percent leakage factor were considered to be representative of leakage during LFG processing, as the biogas produced by anaerobic digestion and by landfills have similar methane concentrations and impurities, implying that processing methods and equipment would be similar.

In response to stakeholder feedback and due to the uncertainty and lack of data on these operations, ARB staff has agreed to make methane leakage in renewable natural gas (RNG) processing a user-modifiable input. Regular leak testing, the use of calibrated revenue meters, and third-party verification are among the requirements that applicants will have to meet to substantiate the user-input value. ARB staff will consider results of future peer-reviewed studies and revise the default leakage factor as appropriate in future rulemakings.

6. Comment: **LCFS 1-6**

The commenter states that the emission rates in CA-GREET 2.0 are not representative of California's natural gas distribution system.

Agency Response: Limited data was available in 2009 to estimate leakage from natural gas life cycle stages, and only 0.58 percent of natural gas was presumed to be lost in recovery, processing, and transmission and distribution. This is now considered to be a significant underestimate. ARB staff cannot propose the use of a value that is known to be incorrect. Future studies may show that leakage across the supply chain is higher or lower than the 1.15% leakage currently estimated over the natural gas life cycle; however, studies such as Brandt et al (2014) indicate this is a reasonable estimate.

Methane leakage from natural gas recovery, processing, and transmission and distribution systems is an evolving area of research and current literature estimates can vary significantly. The proposed factors are based on the U.S. EPA Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2012 (2014) and have been used in many state-level GHG inventories. Additional studies may not confirm the commenter's expectation that leakage is lower, but ARB staff will remain attentive to emerging studies and will consider updates to methane leakage factors for the whole supply chain in future rulemakings, allowing ample opportunity for stakeholder review and feedback.

Staff recognizes this is an ongoing area of study and plans to closely monitor progress in understanding and controlling this source of emissions. Staff will consider updating these parameters as appropriate in future rulemakings.

7. Comment: **LCFS 1-7**

The commenter suggests a California-centric assessment of natural gas systems to be developed.

Agency Response: A contract for the development of a California-centric assessment of natural gas, similar in concept to the OPGEE model is being explored.

8. Comment: **LCFS 1-8**

The commenter requests that ARB make methane leakage rate a user-modifiable input to CA-GREET.

Agency Response: ARB staff does not believe that all leaks across the entire natural gas supply chain can be detected and more accurately quantified by any given pathway applicant. Given the uncertainty associated with this parameter, and to avoid the potential for conflicting data from various applicants about the same portions of the natural gas supply chain, this is a parameter that will remain common to all applicants.

9. Comment: **LCFS 1-9**

The commenter asserts that methane leakage is currently double-counted in the CA-GREET model.

Agency Response: Transmission leakage is a distance-dependent parameter (g CH4 per MMBtu per mile), but distribution is expressed as a flat value (g CH4 per MMBtu of natural gas). No double counting occurs as long as users enter only the transmission distance in this field (as it is labeled in the model) and not transmission and distribution as one value. Maps of the natural gas (NG) transmission pipeline system are available to assist in making these estimates.

The user input distance only applies to NG transported by pipeline for use as a vehicle fuel. The upstream impacts of natural gas used in power plants and stationary sources are calculated separately, using the national average transmission distance of 680 mi (ISOR, p. C-72 Table 42).

10. Comment: **LCFS 1-10**

The comment requests a more formal process by which updates are made to the LCFS regulation and the GREET model in particular.

Agency Response: Including preliminary carbon intensity (CI) values is part of the LCFS regulatory process for re-adoption. Such CI values were derived from the most up-to-date scientific data and the Argonne GREET 2013 model.

Based on stakeholder feedback received over the last several years and advances in lifecycle analysis, ARB updated our CA-GREET to CA-GREET-2.0. Future changes will be made as needed through the process set forth in the APA, which is an open, public process.

11. Comment: **LCFS 1-11**

The comment requests that ARB refrain from publishing CI values, due to the uncertainty of them.

Agency Response: Publication of preliminary CI values is essential for any meaningful stakeholder review. All of the CI values given in the ISOR, Appendix B, Table B were assumed point estimates of CI, rather than ranges. The high-end of the range determined for renewable natural gas (RNG), 25 gCO_2e/MJ, was selected for the compliance scenarios as a conservative value, to provide greater confidence that the expected compliance was achievable and not overly optimistic.

The commenter's request for a "more effective and transparent" public process is at odds with its request to hold industry-only working groups and refrain from publishing preliminary CI values.

12. Comment**: LCFS 1-12**

The commenter requests more transparency in regulatory development, by way of the creation of an LCFS working group.

Agency Response: The LCFS re-adoption public process was complete, extensive, and robust. As part of this public process, ARB staff met with all stakeholder groups, including the California Natural Gas Vehicle Coalition (CNGVC), upon request. Staff has been available and responsive to each request for meetings with the CNGVC and all other stakeholders.

Workshops for the proposed CA-GREET-2.0 were conducted throughout the year in the months of March, April, May, August, October, and November of 2014.

During the April 2014 public meeting, it was announced that the CA-GREET-2.0 would be based on a publicly available GREET-1 2013 model from Argonne Laboratory. In May, the two-tiered framework for pathway applications was presented. In August, a preliminary CI comparison was released. Finally, an early draft of the CA-GREET-2.0 model was released in October, along with a comprehensive table of all the parameter decisions reached up to that point.

In April of 2015 an additional workshop was held with a heavy focus on the issues raised by the natural gas vehicle industry.

Phone Number: 916-273-8320
Affiliation: The Auto Channel

Subject: Low Carbon Standard
Comment:
If I was to write a kind response to your Low Carbon Standard initiative I would say, "Shucks, looks like you missed the mark again."

The problem with that response is that I would be dishonest. The honest response is to say that once again the California government and it's self-interested appointee organizations is about to level another scam that milks and bilks the working public of its hard-earned income.

If CARB or CALSTART really had any interest in low-carbon fuels; freeing us from foreign oil dependency; and trying to make the environment healthier; they would have long ago mandated the use of the two fuels that are available to do the job. These two fuels are compressed natural gas (CNG) and ethanol. Instead, they continue to favor electric power, a solution that won't be affordable and in meaningful availability for 2, 3, 4, 5 maybe 6 decades from now.

CNG and ethanol is available right now - today - and can be used by the overwhelming majority of passenger vehicles that are currently on the road; and in the case of ethanol, these vehicles would not even require any engine conversions to use the fuel. Starting immediately we could make an enormous reduction in harmful emissions, while saving the public billions of dollars. LCFS 2-1

Nearly three years ago, to the day, California's Air Resources LCFS 2-2

Board unanimously approved a package of new emissions rules that they claimed would save drivers money, create jobs, and cut smog and greenhouse gases under what was labeled "The Advanced Clean Car Program."

This program only referred to electric. They never talked about the contribution that ethanol and CNG could make. What was particularly ironic was that the report from CARB stated that they relied in part on Ron Cogan and his GREEN CAR JOURNAL to help them make their decision to support their electric car program. But there was a problem with this: they never consulted Ron Cogan, and Mr. Cogan was not in favor of CARB's program. I know this because I discussed it with him at the Los Angeles Auto Show that convened a few months later. LCFS 2-2 cont.

Even more interesting was the fact that just prior to CARB unveiling this program, Mr. Cogan had bestowed (one again) his company's Green Car Of The Year Award on the Honda Civic GX, car powered exclusively by CNG. Honda won this award for virtually the same vehicle just a few years earlier.

In addition, although CNG has received great press in the past couple of years, California continues its refusal to allow existing gasoline-powered passenger vehicles to be converted to CNG. If you purchase a vehicle that was legally converted to CNG in another state, and bring it into California, you can not register the vehicle. CNG conversions are performed everyday around the rest of the world. If there was a danger in doing so, we would be hearing terrible stories about this everyday, rather than the terrible stories we do hear everyday caused by people who are supported by oil dictators.

Moreover, although today's CALSTART article finally does mention CNG, they never said anything about the dearth of available new CNG powered cars. For the past several years only Honda is regularly producing CNG-powered vehicles - that is, if you can describe annual production runs of about 2,000 vehicles to be regular. The auto manufacturers make more electric vehicles per year than that, and that low number is just a totally meaningless. If California (and the EPA) removed their unjustified restrictions on CNG conversions, at least millions of cars could be converted even if there is no increase in the production of new CNG vehicles. LCFS 2-3

Not only is the number of electric cars being produced meaningless, they are too expensive: for the consumers and for the auto manufacturers. Consumers who purchase an electric car are paying a significant premium over the true value of the car, and auto manufacturers lose thousands of dollars on every electric car they sell. Sergio Marchione, CEO of Chrysler-Fiat says it best: "Our electric Fiat 500 is great, but please don't buy them; we lose too much money." LCFS 2-3 cont.

Added to the cost and availability problems with electric cars is the fact that battery production makes us dependent on China. At present, there's little to suggest that reliance on China is any better than reliance on foreign petroleum oil.

Incidentally, 100% of our CNG and ethanol supply is produced domestically, and none of the ethanol producers are owned by foreign or terrorist controlled regimes. No American serviceman or woman have ever been killed defending the domestic production and distribution of ethanol. LCFS 2-1 cont.

So when CARB, CALSTART, Jerry Brown and the California Legislature say "Let's Keep Going," what they mean is let's keep milking and bilking the working public; let's keep padding our staffs with additional friends, relatives and campaign donors.

Board Comments Home

This page intentionally left blank.

2_OP_LCFS_TAC Responses

13. Comment: **LCFS 2-1**

    The commenter suggests CNG and ethanol as a method of compliance for the LCFS.

    Agency Response: ARB staff agrees that ethanol is a method of compliance. Because the LCFS allows fuel producers to choose what fuels to produce and how to comply, including using ethanol, there is no need to change the proposed LCFS.

14. Comment: **LCFS 2-2**

    The commenter discusses the Advanced Clean Car program, and that it only addresses electric cars, and not ethanol or CNG.

    Agency Response: This comment is outside the scope of the proposal.

15. Comment: **LCFS 2-3**

    The commenter does not appreciate that California refuses “to allow existing gasoline-powered passenger vehicles to be converted to CNG.”

    Agency Response: This comment is outside the scope of the proposal.

Commenter: George Sterzinger

Affiliation: American Waste to Energy

The following letter was submitted to the LCFS Docket during the 45-day comment period.

This page intentionally left blank.

CLERK OF THE BOARD
COMMENTS ON STAFF REPORT:
INITIAL STATEMENT OF REASONS
FOR PROPOSED RULEMAKING

3_OP_LCFS_AWTE

OFFERED BY AMERICAN WASTE TO ENERGY

George Sterzinger
American Waste to Energy
gsterzinger@gmail.com
202-255-8119

1. American Waste to Energy (AWE) appreciates the opportunity to offer these comments to the Air Resources Board as part of its consideration of the Staff Report: Initial Statement of Reasons for the Proposed Rulemaking.
2. AWE currently directs substantial effort towards developing and commercializing innovative technologies to reduce the carbon intensity of the fossil fuels produced, refined and distributed in California. AWE supports the ARB use of permits (and the financial support the permits would provide) to attract existing and innovative programs to lower the carbon intensity particularly of the fossil fuel sector of California.
3. AWE supports both the Low Carbon Fuel Standard and the Cap-and-Trade Program. AWE supports the simultaneous application of these two programs. Basically, any program that complies with the Cap-and Trade Program can also contribute to compliance with the LCFS provided the specific action leads to a reduction in the carbon intensity of the fuel supply. LCFS 3-1
4. AWE's comments focuses on two closely related points.
    a. First, the Cap-and Trade program and the LCFS are two programs that are meant to be consistent. A program that meets the requirements of the Cap-and-Trade bill to lower carbon intensity can also lower the carbon intensity of the sectors related to fossil fuels. If those conditions are met

then the programs will be awarded permits under both the Cap-and-Trade and the LCFS program. This is intentional. The Air Resources offers this as an incentive to encourage actions to lower carbon intensity under both the Cap-and-Trade and the LCFS.

b. Second, those same principles should be extended to the Innovative Technologies for Crude Oil Production program outlined in the Proposed Rulemaking. Ant Innovative Technology that can achieve a sustained commercial breakthrough should be eligible for inclusion under the Cap-and-Trade and the LCFS programs. Any decision to limit access to or eligibility under the LCFS program is counter-productive. It reduces the incentives to support the innovation and will ultimately harm the LCFS program. LCFS 3-2

5. AWE supports the basic simultaneous access to the Cap and Trade (C&T) program and the Low Carbon Fuel Standard (LCFS). The Staff responses to issues raised by the Department of Finance underlines the important this consistency. The Staff states: <u>"The LCFS and the Cap-and-Trade program are designed to complement one another. Investments made to comply with one of the programs will result in reduced compliance requirements for the other program. Reductions in the carbon intensity of fuel due to the LCFS reduce compliance obligations under the Cap-and-Trade Program. Similarly, selling cleaner fuels to comply with Cap-abd-Trade helps meet the requirements of the LCFS." (Title 17. California Air Resources Board: Notice of Public Hearing to Consider a Low Carbon Fuel Standard, pg. 24)</u> LCFS 3-3

6. AWE's strongly supports this. The Staff properly finds that any program that meets the requirements of both the Cap-and Trade and the LCFS should be recognized and benefit from both programs. Such programs should receive tradable permits under BOTH the Cap-and-Trade and the LCFS programs. This consistency is emphasized by the Staff as an important way to provide potentially important financial support for efforts undertaken to lower the carbon intensity of the fossil fuel sectors of the California economy. LCFS 3-4

7. AWE's point here is to extend this basic consistency between the Cap-and Trade and the LCFS. It should logically be extended to include Innovative Technologies that have not yet achieved full commercial breakthrough. LCFS 3-2 cont.
8. AWE is particularly urges the ARB to recognize the potential of technological innovation with biomass-based fuels to lower the carbon intensity under the Cap-and-Trade and the LCFS. AWE stresses that this recognition is nothing more than the recognition of a potential. If the potential cannot be realized, i.e. the technology cannot be brought to commercial status, then nothing happens. From the viewpoint of the ARB this recognition of the potential does not have a downside. On the other hand, the premature decision to reject any biomass based technology innovation removes a potential benefit for no reason.
9. AWE is aware that the ARB Staff has considered and rejected the use of 'biomass steam, heat, and electricity production as innovative methods'. AWE urges ARB to reconsider this across-the-board rejection for general and specific reasons. As a general proposition, ARB's broad rejection of the use of biomass will exclude potential technology innovations that have not yet been developed. Going back to AWE's initial point: such a rejection only serves to unnecessarily eliminate potential breakthroughs. Broad rejection unnecessarily removes a potential. Allowing the possibility of a breakthrough is a cost-free benefit that deserves the possibility to prove itself. The Staff also raises several specific concerns about biomass based LCFS fuels. Specifically that: LCFS 3-5
    a. <u>Combustion of waste biomass will produce excess 'criteria pollutants'.</u> The innovations being considered do not rely on combustion but instead use a variety of gasification and even enzymatic processes. Moreover, if any method violated air standards on criteria pollutants the technology will not be permitted. LCFS 3-6
    b. <u>Waste biomass is not generated as part of the 'life cycle of crude oil production' and will result in the 'shuffling' of biomass among other competing uses.</u> The simplest point here is that the same would hold true for solar steam generated in Concentrating Solar technologies. The second LCFS 3-7

point is that under current California Energy Commission rules, waste biomass cannot be used to produce renewable qualified electricity. LCFS 3-7 cont.

c. <u>The standard applies to biomass produced anywhere 'in the world' which would raise difficult to impossible monitoring requirements.</u> This concern is easily addressed. To qualify under Cap-and-Trad and the LCFS biomass must be evaluated using the ASTM D 6866 test. That test determines the organic carbon faction of the biomass fuel. That test must be applied to any biomass regardless of point of origin. The tests must be done as random samples. Tests must be done on a regular basis and resukts must be reported to the ARB. LCFS 3-8

d. <u>Finally, greenhouse gases from biomass will exceed emission reductions expected from 'solar or wind power' and for that reason should be rejected.</u> First, this conclusion is not supported with evidence. But more importantly, the LCFS standard is not offered as the 'best' options. (All our children cannot be above average.) The challenge for the LCFS and for the Cap-and-Trade program is to reduce CO2 emissions and intensity as much as possible. Any and all measures that produce a marginal, positive reduction will help reach that goal and should be accepted under the Cap-and-Trade and the LCFS. LCFS 3-9

10. Under the Cap-and-Trade program the ARB has issued Final Orders specifically defining materials that qualify as biomass and specified the American Society of Tests and Measures (ASTM) to determine the percent of the organic carbon-based materials to qualify as biogenic CO2 emissions. Biogenic CO2 emissions must be reported but do not require permits to cover the emissions. Thee standards should be required for any Innovative Technology option seeking commercial status. Here are the specific standards required by the ARB: LCFS 3-10

ARB Definition of Biomass (From the Final Order)

(31) "Biomass" means non-fossilized and biodegradable organic material originating from plants, animals, and microorganisms, including products, by-products, residues, and waste from agriculture, forestry,

and related industries as well as the non-fossilized and biodegradable organic fractions of industrial and municipal wastes, including gases and liquids recovered from the decomposition of non-fossilized and biodegradable organic material. For the purpose of this article, biomass includes both California Renewable Portfolio Standard (RPS) eligible and non-eligible biomass as defined by the California Energy Commission.

Article 5: CALIFORNIA CAP ON GREENHOUSE GAS EMISSIONS AND
MARKET-BASED COMPLIANCE MECHANISMS, pg A-8.

§ 95852.2. Emissions without a Compliance Obligation.
Emissions from the following source categories and fuel types as identified in sections 95100 through 95199 of the Mandatory Reporting Regulation count toward applicable reporting thresholds but do not count toward a covered entity's compliance obligation set forth in this regulation article unless those emissions are reported as Other Biomass CO2 under MRR. These source categories Emissions without a compliance obligation include:

LCFS 3-10 cont.

Combustion emissions from the folowing biomass-derived portion of biomass-derived fuels (except biogas
from digesters) from the following
sources:

(1) Solid waste materials, including the biogenic content of solid waste materials that are not 100 percent biomass, as determined by methodology specified in ASTM D6866, based on exhaust sampling or fuel sampling (and fuel usage record keeping) at the specified frequency and tires which may use alternative tests.

3_OP_LCFS_AWTE Responses

16. Comment: **LCFS 3-1**

    The comment expresses support for the re-adoption of the LCFS regulation.

    Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

17. Comment: **LCFS 3-2**

    The comment requests that any emission reduction technology should qualify for credit under the LCFS Innovative Crude Production Method provision.

    Agency Response: The LCFS may recognize emissions reductions that occur at crude oil production facilities in two different ways. First, the LCFS will recognize all emissions reduction efforts employed at crude production facilities through calculation of a reduced carbon intensity (CI) for the crude. Second, the LCFS may award credit for emissions reductions achieved through methods deemed innovative. The innovative crude production method provision was designed to promote those technologies that are truly innovative. Technologies included in the provision have been proposed by stakeholders and vetted through a deliberative process involving workshops, stakeholder feedback, and Board consideration. In conclusion, all emission reduction efforts at crude facilities are recognized under the LCFS through a reduced crude CI, but only those deemed to be truly innovative are approved for credit generation under the innovative method provision because this provision is expressly designed to encourage development and use of innovative methods.

18. Comment: **LCFS 3-3**

    The comment supports the goals of the Cap-and-Trade program as well as the LCFS regulation.

    Agency Response: ARB staff appreciates the support for both the Cap-and–Trade Program and the LCFS regulation.

19. Comment: **LCFS 3-4**

    The comment states that Cap and Trade and LCFS should have tradable “permits” or offsets that can work in either program.

Agency Response: ARB thanks the commenter for their support of the statements in the Staff Report regarding the complementary nature of the Cap-and-Trade and LCFS programs. While investments made to comply with one program will generally result in reduced compliance obligations for the other program, there is no central permit shared between the two programs. The LCFS credit and Cap and Trade allowance markets are intentionally distinct with different "currencies" and rules that govern the markets. Unlike Cap and Trade, the LCFS requires development and use of low-carbon fuels that will be necessary in the long term for future GHG and criteria pollutant reductions. Moreover, changes to the Cap-and-Trade Regulation are outside the Scope of the current rulemaking.

20. Comment: **LCFS 3-5**

The commenter requests that ARB recognize the potential of biomass use under the Innovative Crude Production Method provision.

Agency Response: As part of the current LCFS re-adoption process, ARB staff considered direct biomass combustion to produce steam, heat or electricity for inclusion as an innovative crude production method. ARB staff's rationale for rejecting biomass combustion as an innovative method is discussed in the Initial Statement of Reasons (ISOR) on page II-19. Staff does not believe those technologies that employ direct combustion of waste biomass meet the qualifications of an innovative crude method. See response to **LCFS 3-2**.

If the commenter has a specific technology that they would like considered for inclusion under the innovative crude provision, ARB staff welcome a discussion and a deliberate public process for consideration in next related regulatory amendment process.

21. Comment: **LCFS 3-6**

The commenter states that new non-combustion technologies for biomass usage such as gasification and enzymatic processes are being considered.

Agency Response: See response to **LCFS 3-5**.

As part of the current LCFS re-adoption process, ARB staff considered direct biomass combustion to produce steam, heat or electricity for inclusion as an innovative crude production method. Staff became aware of the biomass gasification technology and enzymatic processes proposed by the commenter in the 45-day comment period, and will fully evaluate them in future regulatory proposals.

22. Comment: **LCFS 3-7**

Commenter disagrees with the claim expressed in the staff report concerning biomass resource shuffling.

Agency Response: See response to **LCFS 3-5**. ARB staff is concerned about shuffling of waste biomass under competing uses because staff wants to ensure that GHG emissions reductions credited under the innovative crude method provision are additional. Development of a solar steam project at a crude production facility meets this criterion. Shuffling of biomass from producing energy under one emissions reduction program to producing energy under the LCFS does not meet this standard.

23. Comment: **LCFS 3-8**

The commenter requests biomass testing at the point of origin to be used to satisfy ARB's concern regarding source of biomass.

Agency Response: See response to **LCFS 3-5**.

The American Society for Testing and Materials (ASTM) test recommended by the commenter can be used to determine the organic carbon fraction of the biomass fuel; however it does not determine whether the biomass is waste. ARB staff's concern expressed in the ISOR is that it would be very difficult to ensure that biomass fuel used in many parts of the world would be waste biomass.

24. Comment: **LCFS 3-9**

The commenter disagrees with ARB staff's conclusion that GHG's from combustion of biomass for steam or electricity production will exceed those from solar or wind power. The commenter also argues that any technology that produces even marginal emission reductions should be included under the innovative crude provision.

Agency Response: See response to **LCFS 3-2** and **LCFS 3-5**.

ARB staff believes that, as a whole, evidence supports the conclusion that direct combustion of biomass to produce steam, heat, or electricity is more emissions-intensive than solar or wind-based processes. While there may be some sources of waste biomass that compete with solar or wind with regard to GHG emissions, this is generally only possible if not using the waste biomass can be proven to result in generation of greenhouse gases more potent than CO2 (e.g., the waste biomass would otherwise be deposited in an uncontrolled landfill and decompose anaerobically over a relatively short time horizon to generate methane). Moreover, the innovative crude provision is intended to promote technologies that produce significant, not marginal, GHG emissions reductions as compared to the industry norm. While marginal emission reduction efforts at crude facilities are recognized under the LCFS through a reduced crude CI, only those deemed to be truly innovative are approved for credit generation under the innovative method provision.

25. Comment: **LCFS 3-10**

The comment suggests that LCFS use the same ASTM methods and regulatory language as Cap-and-Trade to provide credit for biogenic CO_2 emissions under the innovative crude provision.

Agency Response: See responses to **LCFS 3-2**, **LCFS 3-5**, and **LCFS 3-8**.

February 9, 2015

Mary Nichols, Chairman
California Air Resources Board
1001 I Street, PO Box 2815
Sacramento, CA 95812

Re: Support for LCFS

Dear Chairman Nichols and Members of the Air Resources Board:

On behalf of the Board of Directors and member companies of the Silicon Valley Leadership Group, I am writing to offer our support of the California Air Resources Board's continued leadership on our state's pioneering climate policies and to urge the swift re-adoption of the Low Carbon Fuel Standard (LCFS). The Silicon Valley Leadership Group, founded in 1978 by David Packard of Hewlett-Packard, represents almost 400 of Silicon Valley's most respected educational institutions and high-tech, bio-tech, and clean-tech employers; our members collectively provide nearly one of every three private sector jobs in Silicon Valley.

We support the LCFS and believe it is an important component of the state's overall strategy to reduce greenhouse gas and other harmful air emissions and drive clean tech innovation. Further, we believe that continuing the transition to lower carbon transportation fuels helps:

- **Diversify the state's fuel supply mix and drive innovation.** From 2011 to 2013 alternative fuels comprised a steadily increasing share of transportation energy use in California[i] and the clean fuels market has grown faster than anticipated. [ii] LCFS 4-1
- **Save consumers money.** Introducing choice in the market drives competition which will help California households save money on their transportation fuel bills. This is complemented by other policies such as more fuel efficient cars and mass transit. LCFS 4-2
- **Improve air quality**. The LCFS has already cut carbon emissions by about 9 million metric tons, the equivalent of removing almost 2 million passenger cars from the road each year.[iii] By 2020, it is estimated the LCFS can help reduce emissions by 35 million metric tons, the equivalent of removing about 7 million passenger cars from the road per year.[iv] LCFS 4-3
- **Improve public health.** It is estimated that the LCFS will result in $1.4 to $4.8 billion in societal benefits by 2020, accruing from reduced air pollution.[v] The benefits could be even greater, $10.4 billion by 2020 and $23.1 billion by 2025, when other state fuels policies are included.[vi] LCFS 4-4
- **Secure California's cleantech market leadership.** California has approximately 40,000 businesses serving advanced energy markets, employing roughly 431,800 people.[vii] It is estimated that the LCFS could contribute up to 9,100 new jobs, and potentially many more if the state continues to attract more clean fuel providers.[viii] LCFS 4-5

We believe that there is a strong business case for clean fuels, and that clean air and a growing economy go hand-in-hand. We applaud your leadership and urge you to re-adopt the LCFS.

Sincerely,

Mike Mielke
Senior Vice President, Environment and Energy
Silicon Valley Leadership Group

5_OP_LCFS_UCS

February 12, 2014

Chairman Mary Nichols and board members
California Air Resources Board
1001 "I" Street
Sacramento, CA 95814

Dear Chairman Nichols and board members,

On behalf of our 73,000 supporters in California, the Union of Concerned Scientists (UCS) urges you to support moving forward with the re-adoption process for the Low Carbon Fuel Standard (LCFS) at the Air Resources Board (ARB) meeting on February 19th.

A year ago more than 100 leading California climate scientists and economists sent the attached letter urging the Governor and Legislature "to adopt a science-based, heat-trapping emissions target for 2030 that puts California on a path to meeting our 2050 goals." The letter also highlighted the need for additional policies that "promote renewable energy, low carbon fuels, and cleaner transportation." LCFS 5-1

The LCFS is a critical element in the comprehensive approach California has taken to achieve the state's climate goals while continuing to thrive economically. Readopting the LCFS will address some technical and legal obstacles that have slowed progress on developing and deploying clean fuels and put California back on track for a 10 percent reduction in carbon intensity by 2020. The LCFS also provides critical support for the Governor's call last month to cut petroleum use in cars and trucks in half by 2030.

Resolving these legal and technical issues with the current LCFS is critical, but to create a sustainable and stable market for clean fuels, state policy should focus on a time horizon longer than 5 years. We therefore urge the ARB to begin developing the next phase of the LCFS out to 2030. Such long-term policy support in conjunction with similar polices enacted by Pacific Coast Collaborative partners in Oregon, Washington and British Columbia will create a large, stable and steadily growing market for clean fuels that will support investment and innovation and bring down the cost of clean fuels. LCFS 5-2

UCS supports several important technical changes have been proposed to strengthen the LCFS including: (1) an update of the lifecycle analysis based on the best available science, (2) innovative crude and refinery provisions that will encourage the oil industry to reduce emissions from its own supply chain, and (3) a cost containment mechanism that will maintain a stable investment climate for low carbon fuel production while ensuring that any unforeseen delays will not destabilize the policy or hurt California consumers. LCFS 5-3

UCS has been performing analysis and providing technical feedback on the LCFS since its inception, and we are confident that diverse sources of low carbon fuel are available to LCFS 5-4 achieve the 10 percent carbon intensity target by 2020. I am attaching a recently released study on LCFS compliance from the consulting firm Promotum that UCS commissioned together with the Natural Resources Defense Council and the Environmental Defense Fund. The study finds that compliance is indeed feasible through 2020 and beyond. The study also demonstrates that in order to ensure investment in the cleanest fuels it is important to establish regulatory stability out beyond 2020. LCFS 5-4 cont.

It is also important to ensure that the cap price in the cost containment mechanism is not so low that is discourages investment in the cleanest fuels. The proposed $200 per ton cap is a minimum to ensure the clean fuels industry has a strong incentive to make the large investments needed to scale up the clean fuels needed to keep moving forward beyond 2020. LCFS 5-5

Thank you for your consideration. I am also attaching several recent UCS publications that discuss how the LCFS fits into the broader suite of transportation policies, recent progress in cellulosic biofuel commercialization, and the latest developments on indirect land use change. Please let me know if you have any questions about our analysis.

Sincerely,

Jeremy Martin, Ph.D.

Union of Concerned Scientists

An Open Letter on Climate Change
from California Climate Scientists and Economists

May 19, 2014

Dear Governor Brown and California State Legislators:

California's leadership is needed now more than ever to address the risks of a dangerously warming climate. We urge the state's policy makers to adopt a science-based, heat-trapping emissions target for 2030 that puts California on a path to meeting our 2050 goals.

The science is clear that human activity is the dominant cause of warming over the last half century.[i] If global emissions continue to rise, the scope and severity of impacts will accelerate. Already communities across California are being forced to cope with many risks, including increased wildfires, more frequent and extreme heat waves, a strained water management system, growing risks to high value agricultural commodities, greater summer electricity demand, and more coastal flooding.[ii]

While we must adapt to the impacts of a changing climate, California must also take ambitious steps to reduce heat-trapping emissions that would cause much more devastating impacts in the decades to come. We are well-positioned to lead the world in this effort. The state has a goal of 80 percent reduction in global warming emissions below 1990 levels by 2050, established by Executive Order S-3-05. More importantly, California's policy makers deserve tremendous credit for adopting and implementing the California Global Warming Solutions Act of 2006 (AB 32) and numerous coordinated sustainability actions. The state has brought innovative climate policies off the drawing board and into practice, spurring investment, innovation, and jobs in a growing "green technology" sector. Moreover, the state's progress demonstrates that it is possible for a growing major economy to reduce emissions substantially at very modest cost.

California must continue to play a leadership role and to serve as a model for much-needed federal and international action. Maintaining a price on carbon dioxide and other global warming pollutants is key, but not sufficient to adequately reduce emissions. Policies that promote renewable energy, low carbon fuels, and cleaner transportation are also critical.

Yet as we approach 2020, we need medium-term targets to continue the progress we have begun. To achieve the steep reductions necessary to limit the worst impacts of climate change, lawmakers and regulators should adopt and implement enforceable emissions caps for 2030 and beyond. Every sector involved in addressing climate change, from energy to transportation, will need sufficient time to prepare to meet new targets. The longer we wait the harder and more costly it will be. Please begin now to set a science-based, heat-trapping emissions target for 2030.

California's Low Carbon Fuel Standard:
Evaluation of the Potential to Meet and Exceed the Standards

Promotum
10 Chauncy Street
Cambridge, MA
02138

February 2, 2015

Contents

1. Regulatory Background

California's adoption of the Global Warming Solutions Act of 2006, also known as Assembly Bill (AB) AB32, set in motion a series of policies to reduce greenhouse gas (GHG) emissions in the state to 1990 levels by 2020 – roughly a 20 percent reduction – while also protecting public health. Under AB32, the California Air Resources Board (ARB) developed a series of GHG reduction strategies as part of a Scoping Plan for achieving the 2020 goal. For the transportation sector, the key programs ARB adopted include standards for cleaner, more efficient cars and trucks; a clean fuels standard; a cap-and-trade regulation; and established targets to reduce emissions through more sustainable, transit friendly and walkable communities.

The state's clean fuels standard, known as the Low Carbon Fuel Standard (LCFS), was adopted in 2009 as an early-action measure under AB32 and in furtherance of Executive Order S-01-07 by then Governor Arnold Schwarzenegger. In addition, in his recent fourth inaugural address, current Governor Jerry Brown provided targets for a series of new environmental goals for 2030, including reducing current petroleum use in cars and trucks by 50 percent.[1]

California's LCFS is a performance-based standard requiring petroleum refiners and other fuel providers to reduce the carbon-intensity of transportation fuels used in California by 10 percent by 2020. The carbon-intensity of each fuel is measured on a full lifecycle basis, which includes accounting for GHG emissions from production of a feedstock, transport, refining, distribution, and end-use combustion. Because the standard is technology-neutral, companies can earn LCFS "credits" any number of ways, including improving their processes or through switching to renewable feedstocks and inputs. Each LCFS credit nominally represents one metric ton of reductions in GHG emissions. The LCFS is designed to include market-based features that allow LCFS credits to be sold, banked, or utilized to help meet the requirements.

2. Project Scope

To inform the dialogue about the re-adoption of the LCFS and establishment of revised annual compliance requirements, Promotum Inc., an independent technical and management consulting firm focused on fuels and chemicals, was commissioned by the Natural Resource Defense Council (NRDC), Union of Concerned Scientists (UCS) and the Environmental Defense Fund (EDF) to evaluate likely scenarios for compliance and the impact of credit values on incentivizing greater production and volumes of low Carbon Intensity (CI) fuels to the state.[2]

Promotum reviewed and analyzed fuel availability, prior supply studies, data from obligated parties (fuel suppliers) quarterly reporting to the ARB, California Energy Commission (CEC)

[1] http://gov.ca.gov/news.php?id=18828
[2] The conclusions and views contained herein are solely those of the consultant and do not necessarily reflect those of NRDC, UCS, and EDF.

information, U.S. Energy Information Administration (EIA) data, and consulted with a wide number of industry participants with specific sector expertise to develop a forecast of supplies and a model of future low carbon fuel production.

As part of the creation of these scenarios we sought to incorporate the latest technology and commercialization developments. For example, 2014 saw the startup of the first two commercial scale cellulosic ethanol facilities in the U.S. with a third scheduled for launch in early 2015. We sought to understand how likely advances in technology would impact future cost of production. Ultimately, we looked at the impact of LCFS credit value both producing additional lower CI fuels in California, and on moving them into California.

For analytical purposes the study evaluated two scenarios: a Reference Case and Low Case.

- The Reference Case assumes the value of credits within the LCFS market remains at roughly $100 per metric ton reduction ($100/MT) over the 2015 to 2025 timeframe. This case is consistent with the estimate currently included in ARB's assessment under its regulatory analysis, provided as part of its 2014 staff report
- The Low Case assumes an LCFS Credit Value below $50/MT. This case is consistent with credit values observed throughout 2014.[3]

3. Key Findings

The key findings of this study are:

Supply Potential

- **The petroleum industry can meet current LCFS compliance requirements through 2020 by taking advantage of the program's performance-based incentive for reducing greenhouse gas (GHG) emissions.** The LCFS credit system provides obligated parties sufficient incentive to reduce their carbon emissions in a timely manner. Promotum's analysis shows that a $100 per MT credit value, (an amount utilized by ARB for their regulatory proposal), provides sufficient incentive to achieve a 10% reduction in fuel carbon-intensity by 2020 through three mechanisms: (1) providing greater volumes of alternative fuels in California, (2) reducing the carbon-intensity of traditional fuels, and (3) reducing emissions at refineries and throughout the petroleum value chain.

- **Diesel substitutes, lower carbon-intensity (CI) ethanol, and reductions in the carbon footprint across the petroleum value chain are primary pathways for meeting a 10% target.** Shifts toward lower-carbon feedstocks, including recycled fats and oils and the

[3] http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs2015.htm

production of cellulosic ethanol, including ethanol made from agricultural residue will reduce carbon intensity. Using electricity as fuel for cars and trains will also significantly contribute to meeting the LCFS.

- **California can extend the LCFS beyond a 10% carbon-intensity (CI) reduction in 2020 to 15% in 2025.** At $100/MT there is sufficient biofuel supply and incentive to support an additional one percent per year reduction from 2020 through 2025.

- **Even under relatively low LCFS credit values, below the historical 2012 and 2013 credit value, California can meet existing requirements through 2020.** However, sustained low credit values may be insufficient to provide the enough incentive to achieve a15% reduction by 2025.

Benefits

- **The LCFS program will contribute significantly to meeting California's goal of cutting petroleum use in half by 2030.** Alternative fuels use is increasing, up from supplying only 6% of transportation energy to 14% by 2020 and 20% by 2025. For diesel, much of the growth in demand for cleaner, alternative fuels will be met through biodiesel, renewable diesel, as well as natural gas including biomethane. Growth on the gasoline side will occur largely through increases in lower CI ethanol and electricity.

- **The LCFS is estimated to result in over 70 million metric tons of GHG emission reductions over the next five years through 2020**. Increasing the requirements to 15% by 2025 could generate 183 MMT CO_2e of reductions over the next ten years through 2025, equivalent to the emissions of nearly five coal fired plants operating for ten years.[4]

Reduction Opportunities, Value Creation, and Economics

- **The petroleum industry can achieve a significant portion of the standard by reducing the carbon-intensity of gasoline and diesel through improvements at petroleum refineries and crude oil production facilities.** Just as alternative fuel companies can achieve reduced overall carbon-intensity though efficient production and processing, the petroleum sector has significant potential to reduce the CI of gasoline and diesel through energy efficiency improvements, integration of renewable energy inputs such as biomethane, and use of innovative technologies including solar thermal. This study estimates these three measures alone will result in a 1.5% reduction in carbon-

[4] U.S. EPA Greenhouse Gas Equivalencies Calculator. http://www.epa.gov/cleanenergy/energy-resources/calculator.html

intensity across petroleum-based gasoline and diesel by 2020, growing to a 3% reduction in CI by 2025.

- **Under the Reference Case of $100 per metric ton value, energy efficiency projects at refineries would be significantly more attractive to fuel suppliers.** Based on information generated by energy efficiency audits for California refineries' past and currently proposed projects, the LCFS credit value could more than double the operating savings at the facilities.[5] In addition to garnering operational savings associated with energy efficiency investments, refineries would be further incented under the LCFS to reduce the carbon-intensity of fuel products, such improvements also allow fuel producers to forgo purchasing pollution permits under the state's cap-and-trade regulation.

- **Biomethane use at refineries and crude oil facilities to displace fossil natural gas use is a potentially attractive option to reduce carbon-intensity or gasoline and diesel. Such uses are in addition to use of biomethane in natural gas vehicles.** At the end of the Fall 2014, the LCFS incentive had resulted in an increase in the use of biomethane for natural gas vehicles to 40% of the mix, primarily from biogas capture at landfills.[6] However, a much greater volume of natural gas in California is currently consumed by refineries and crude oil facilities. Full substitution of this end-use with biomethane going forward would represent a potential of 12 MMT of reductions of carbon annually, such that even partial substitution could meet a significant portion of the LCFS.

- **Future capital and operating costs for cellulosic ethanol will decrease over time.** While it is possible for California entities to import hundreds of millions of gallons of ultra-low CI cellulosic ethanol at some point in the future, it is difficult to predict exactly when those gallons will be available. However, cellulosic technology providers have successfully reached commercial scale at some plants and the first wave build out is well underway. Future validation of the first wave of cellulosic production facilities will pave the way for financing of the second and third wave of cellulosic plants. It is widely expected, based on industry experience and learning, that the second wave and later facilities will have lower capital costs and improved efficiency.

- **Even remaining conservative on the timing and volumes for cellulosic ethanol in 2020, given the uncertainty of the second wave of production plants, other low-carbon fuels and technologies can provide sufficient credits under the scenarios**

[5] Air Resources Board (2013), *Energy Efficiency and Co-Benefits Assessment of Large Industrial Sources Refinery Sector Public Report*, Issued June 6, 2013. http://www.arb.ca.gov/cc/energyaudits/eeareports/refinery.pdf
[6] Air Resources Board (2014), *Low Carbon Fuel Standard Reporting Tool Quarterly Summaries*, http://www.arb.ca.gov/fuels/lcfs/lrtqsummaries.htm.

evaluated. Since the LCFS is technology-neutral and performance based standard, and also includes an ability for parties to "bank" or save credits, regulated entities have enormous flexibility to comply. No single technology is required to generate the reductions needed.

- **Over-compliance over the 2015 to 2018 period will allow for compliance in later years through 2020**. The so-called "banking" provisions of the LCFS allow companies to flexibly utilize credits generated in earlier years to comply with future years. As of the end of 2014, parties registered within the LCFS have registered an over-compliance of approximately six million metric tons, with those credits banked for use in future years.[7]

Potential Barriers Moving Forward

- **The LCFS needs underlying regulatory stability to achieve a 10% reduction by 2020 and a 15% level by 2025.** As a result of lawsuits brought against the state by oil and corn ethanol industry groups, the current LCFS reduction mandate has remained at a 1% CI reduction level since 2013, resulting in significant over-compliance with the standard. As the same time, LCFS credit prices have dropped from nearly $80 per ton in December of 2013 to $26 per credit in December of 2014.[8] Under a scenario where LCFS credit prices remain under $50/ton for 2016 and beyond, the sustained low credit price causes an insufficient market signal, with the overall LCFS market generating annual deficits beginning in 2018 and regulated industries fully using all banked credits by 2020. In 2020 and beyond, the LCFS would experience net cumulative deficits. Accordingly, for the LCFS to achieve full compliance, sufficient regulatory certainty must exist to provide a sufficient market signal to spur additional alternative fuel supplies.

- **Reductions in the carbon-intensity on the gasoline side will be slower than on the diesel side unless greater expansion of E15 and E85 occurs.** While credit values at $100/ton will be sufficient for production of low CI ethanol, further capital investments are needed to develop the next wave of cellulosic ethanol facilities. Furthermore, additional infrastructure investments will be needed to expand the use of low CI ethanol beyond E10 (e.g. E15 or E85) and allow the industry to achieve a larger reduction. This includes ethanol producers overcoming limitations due to lack of upgraded ethanol infrastructure including tankage and blender pumps.

[7] Air Resources Board (2014), *Low Carbon Fuel Standard Regulation: Initial Statement of Reasons*. December 31, 2014. http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs2015.htm
[8] Information based on reporting of the credit values by ARB. http://www.arb.ca.gov/fuels/lcfs/lrtqsummaries.htm.

- **Long-term regulatory stability and firm commitment with both the Low Carbon Fuel Standard and the federal Renewable Fuels Standard is necessary for financing of new facilities**. Major investors are sensitive to regulatory instability and require long-term time horizons before financing major capital projects. Ensuring forward momentum will, at minimum, require the LCFS credit value to be sufficiently robust to achieve compliance.

4. Methodology

Promotum developed spreadsheets for each fuel technology. Where available we developed supply inputs based on prior studies, and discussions with industry experts and stakeholders. The modeling evaluated a Reference Case and Low Case, with calculations and accounting following ARB's methodology as presented in its regulatory analysis.[9]

For consistency we adopted ARB's baselines for gasoline and diesel CIs; forecasts for gasoline and diesel consumption; the proposed compliance curve from 2015 to 2020; and the banked LCFS credits estimated for 2014. For assumptions on CI, we used the CI look up table from ARB's *Initial Statement of Reasons* (ISOR) Appendix B "average annual CI assumptions." Using the CI values and forecasts, we calculated the overall compliance credits and deficits annually to evaluate compliance each year. Where available we utilized obligated party reporting (2013 and 2014) to ground the model, information that ARB makes publicly available.[10]

The fuel volume tables for the 2015 to 2025 period of study assume that refiners and fuel importers must reduce the lifecycle GHGs produced from gasoline and diesel. This includes crude oil production, transportation, refining, distribution, and combustion. LCFS deficits can be offset by blending lower CI gasoline and diesel substitutes, purchasing credits, utilizing banked credits, or generating credits directly from refinery investment projects or applying innovative technologies at crude oil production facilities. In cases where producers use blending as a compliance strategy, they will largely use ethanol and biodiesel. Additional credits accrue from electric vehicles, both fossil-based and bio-based natural gas (or biomethane), and hydrogen used for fuel cell vehicles. These categories are currently small but growing in their contributions to meeting the standard.

For each case we developed biofuel supply curves for 2015 to 2025. There are many pathways and approved biofuels, but the major substitutes include:

Major Gasoline Substitutes and Technologies	Major Diesel Substitutes and Technologies
Ethanol (Corn, Sorghum/Wheat, Sugar, Cellulosic)	Biodiesel (Soy, Corn Oil, Waste Grease/Used Cooking Oil, Animal Tallow)
Electricity	Renewable Diesel (similar feedstocks)
Petroleum Improvements	Compressed Natural Gas or Liquefied Natural Gas, (Fossil and biomethane)
Renewable Gasoline	Petroleum Improvements

[9] http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs2015.htm
[10] http://www.arb.ca.gov/fuels/lcfs/lrtqsummaries.htm

This report also examined potential GHG reductions in the petroleum value chain. Promotum believes there is significant opportunity to reduce the overall CI of traditional gasoline and diesel, principally by utilizing steam derived from biogas or solar thermal energy sources for Enhanced Oil Recovery (EOR) operations at the well head, substituting biomethane for fossil natural gas at refineries, and utilizing off-the-shelf energy efficiency technology and improved operations at refineries. Promotum did not evaluate use of carbon capture and sequestration (CCS) at petroleum facilities.

5. Scenarios

Promotum created two hypothetical cases to evaluate the effects of credit prices on potential achievement of LCFS targets. For each case, we calculated the LCFS deficits (MT CO_2e generated) produced by the petroleum value chain and the combustion of traditional gasoline and diesel. To this obligation, we added back the LCFS credits produced (MT CO_2e reduced) by substituting in biofuels and through reductions in emissions from the petroleum value chain. We then added previously banked credits before comparing the annual and cumulative total against ARB's compliance curve.

For purposes of the study, we assumed steady state average pricing for Low Carbon Fuel Standard credits. Based on these prices, we evaluated how much low carbon fuel could be produced or imported to California for each fuel type.

The basic strategy was to add as much low CI substitute biofuel as possible, taking into account limitations in available supply or potential new capacity, and then backfilling with the best available corn ethanol and biodiesel. We used compliance data filed quarterly with ARB to set starting levels of blended ethanol and biodiesel. The starting blend rate for ethanol was 10.6% (by volume) and about 2% for biodiesel.

To calculate the GHG reductions currently required by the LCFS, we used the currently proposed compliance schedule for 2016 through 2020 in ARB Staff's *Initial Statement of Reasons.* According to the analysis, by 2020 the LCFS requirements would effectively require enough credits to reach a 10% reduction in carbon-intensity for gasoline and diesel.

To calculate the GHG reductions required under an LCFS that extended to 20205, we extended the LCFS requirements to a 15% CI reduction, increasing at an additional rate of 1% per annum. Figure 1 shows the compliance requirements used for both scenarios.

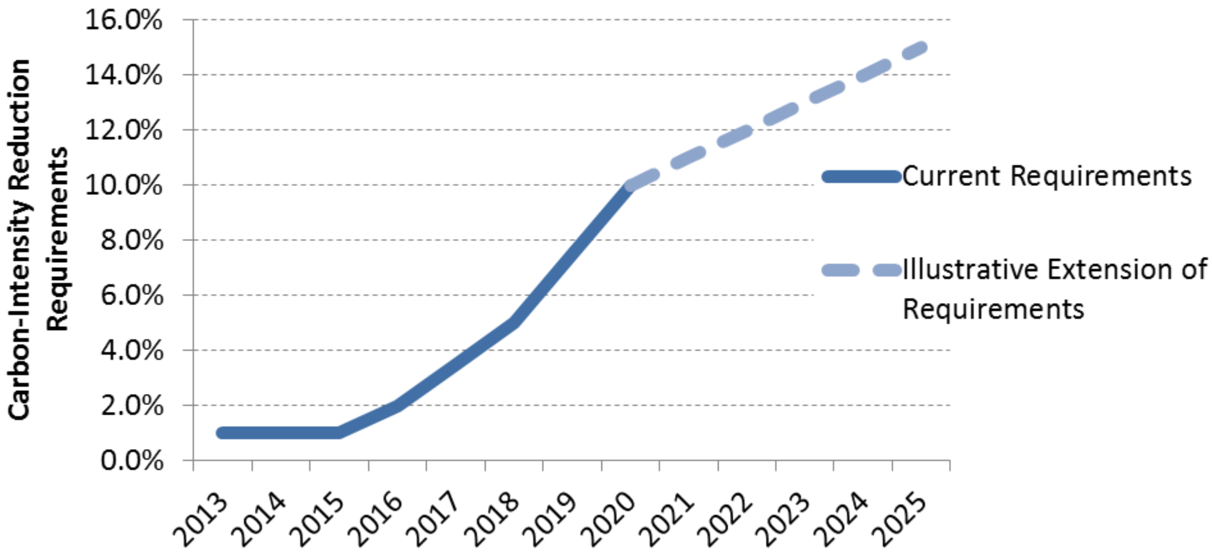

Figure 1: Current proposed requirements achieving 10% by 2020 and extension of requirements to 15% by 2025.

6. Issues and Considerations

Assessing the feasibility of LCFS reductions and differential credit values and the effect of those credit values on biofuel supplies is a considerable and complicated subject. We describe some of the complexities in the following section.

A. Internal LCFS Market Conditions

Since the program's inception, the credit values have experienced market fluctuations. Commodity market experts, such as at Argus, suggest the reasons for volatility encompass a number of factors[11]:

- Regulatory and legal uncertainty in the initial three years,
- Over-compliance occurring due to the low standard—1%—maintained since 2013,
- A short spot market due to producers banking surplus credits in expectation of future shortfalls, and
- A thin LCFS credit market due to a limited numbers of buyers, sellers, and volumes of credits able to be bought and sold.

[11] *Argus White Paper: California Environmental Markets: Factors that Affect LCFS and GHG Trading,* Argusmedia.com

B. Combined Effects of the LCFS and the Renewable Fuel Standard

In addition, understanding the implications of the California GHG reduction measures must account for the federally mandated Renewable Fuel Standard (RFS) managed by the U.S. Environmental Protection Agency (EPA). The RFS requires increasing volumes of biomass-based fuels, with specific volumetric requirements for different categories of fuels meeting GHG reduction thresholds. Fuels that qualify are eligible to generate Renewable Identification Numbers (RINs), a serial number that both allows for tracking of fuel and allows for trading among parties. Like LCFS credits, RINs have a market value for those that own them. In addition, RINs become separable after biofuels are blended - meaning producers can choose to buy and retire RINs instead of blending biofuels themselves.

As a result, if the LCFS credit value plus RIN value exceeds transportation cost to California for a given gallon of biofuel, this should provide enough incentive for producers to make more biofuels and sell them into the California market. Figure 2 demonstrates how RINs and LCFS credit work in tandem to increase supplies of the biofuel.[12]

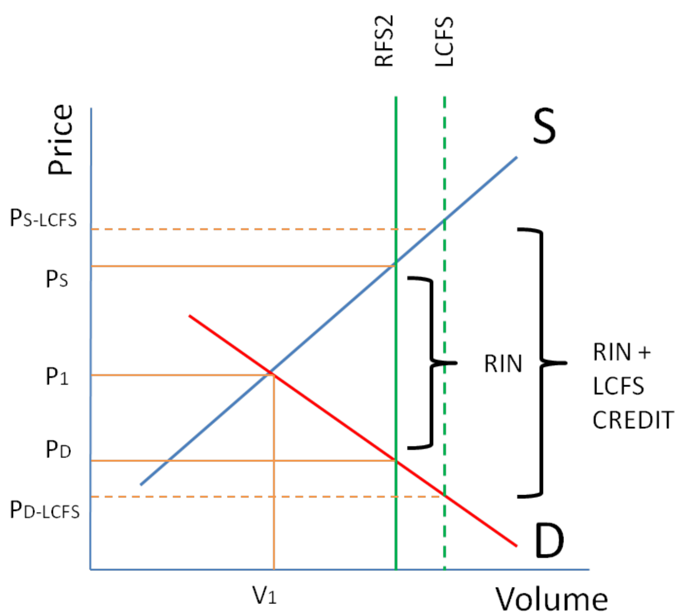

Figure 2: Illustrative figure of the value of RINs and LCFS credits

[12]N. Miller et al (2013), *Measuring and addressing the investment risk in second-generation biofuels* industry, International Council on Clean Transportation, 2013. http://www.theicct.org/addressing-investment-risk-biofuels

S = Supply curve
D = Demand curve
RFS2 = Federal mandate
V_1 = Equilibrium volume w/o RFS or LCFS
P_1 = Equilibrium price w/o RFS or LCFS
P_S = Supply price at RFS mandate
P_D = Demand price at RFS mandate
P_{S-LCFS} = Supply price a LCFS mandate
P_{D-LCFS} = Demand price at LCFS mandate
Redrawn from Miller, Christensen, Park, Baral, Malins, Searle

C. Technology and infrastructure development

Notwithstanding the impact of overlapping LCFS and RIN credit prices, the market signal for Low-CI fuel development gets more complicated when considering the stages of technology development and production capacity for many low CI fuels (i.e. advanced biofuels). Based on present market conditions, it remains evident that much of the nation's prospective supply of low-CI fuels is still maturing. Significant infrastructure issues need to be addressed for many biofuels before the market is truly efficient with high price elasticity.

Under these circumstances technology developers are making investments in technology and capacity based on market expectations, including the future of the RFS and the LCFS programs in terms of regulatory certainty and the RIN and LCFS credit markets. The diagram below based on biofuel supply curves generated by Nathan Parker at UC Davis describes the situation graphically.[13] For our purposes we assumed that LCFS credit values will signal prospective suppliers in anticipation of a future efficient market.

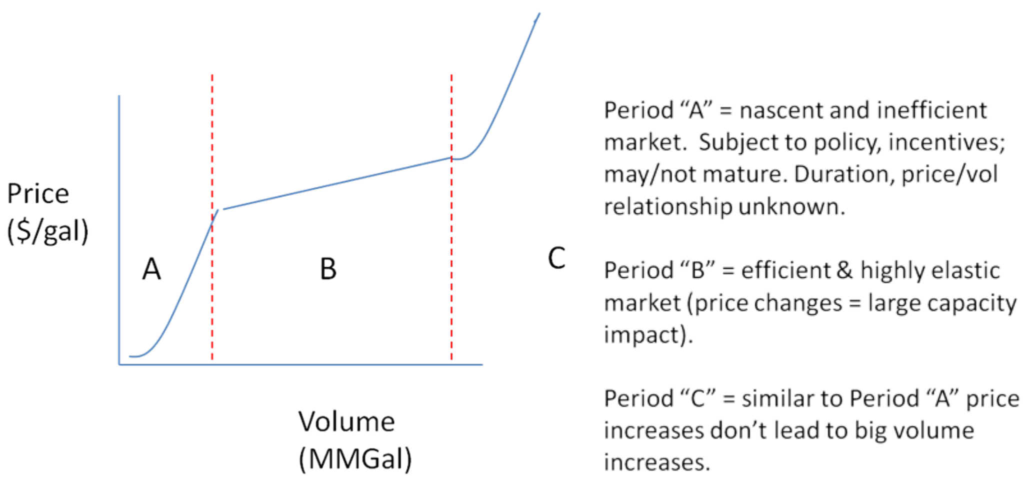

Figure 3: Biofuel supply at varying price points

[13] N. Parker (2011), *Modeling Future Biofuel Supply Chains Using Spatially Explicit Infrastructure Optimization*, Dissertation, Univeristy of California, Davis. http://www.its.ucdavis.edu/research/publications/publication-detail/?pub_id=1471

For each of our cases we estimated the biofuels volumes, which after analysis we believed would be available in California based on the LCFS credit value, constrained by our understanding of the current state of technology, infrastructure and US or global forecast capacity. To understand the value of each biofuel to California we calculated how much each fuel resulted in reduced carbon dioxide emissions and then what additional value was associated with the fuel, on a dollar per gallon gasoline or diesel equivalent energy basis ($/gge or $/dge), depending on which fuel they substituted for.

D. LCFS incentive value for alternative fuels

Figure 4 translates LCFS credit value for gasoline and diesel substitutes to a dollar per gallon gasoline equivalent basis. The range represents a low of $50/MT to a high of $150/MT.

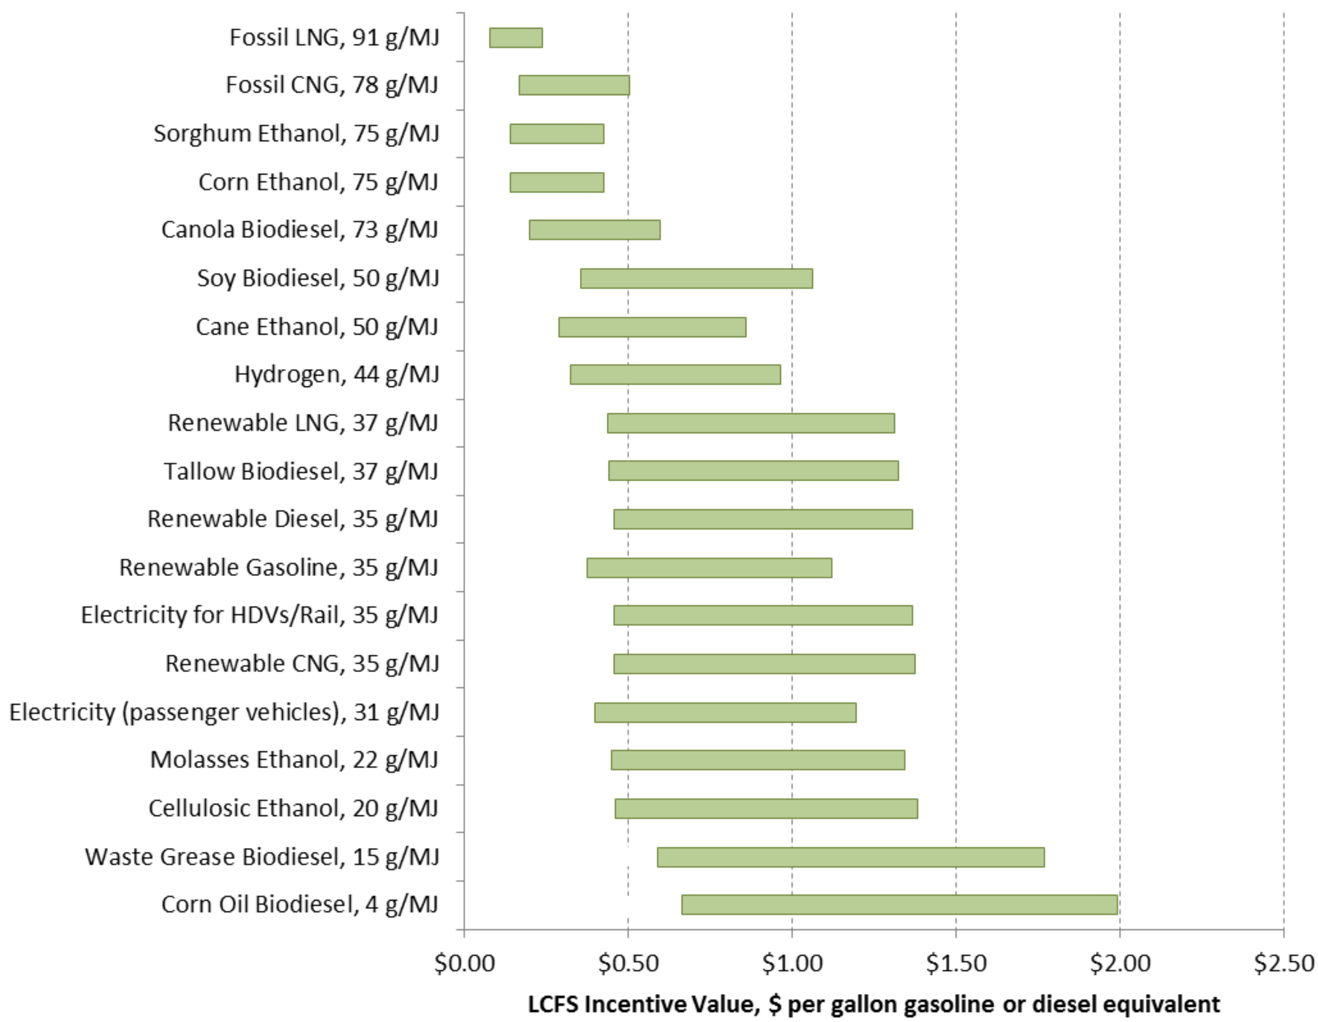

Figure 4: Incentive value provided by the LCFS. Range represents $50 to $150 per MT CO2e reduction.

As shown in Figure 4, the Reference Case of $100 per MT carbon dioxide reduction, translates into $0.92/gallon for cellulosic ethanol. Theoretically, as long as the LCFS credit value together with the associated cellulosic RIN prices exceed transportation costs, we should see producers ramping up capacity and selling into California as well as California producers expanding and increasing production.

An important distinction to make is that RINs and LCFS credits are not production credits, but are instead blender credits, i.e. it is the obligated party, who creates and captures the value upon blending. While producers do not benefit directly from these credits there is some sharing of rents within the value chain. .

In the Low Case ($50/MT reduction), the value for cellulosic ethanol translates to $0.46/gallon in addition to the RIN value. Higher LCFS credit values, of course, are possible and would theoretically provide greater incentive for domestic production or greater importation. However, other factors, such as the state of technology development and availability for financing of new facilities, may be more critical in establishing necessary volumes than the incentive value of RINs and LCFS credits.

E. LCFS incentive value to reduce petroleum sector emissions

The LCFS also provides incentives and returns credit value to petroleum companies that choose to reduce lifecycle oil and gas emissions directly. These companies may generate credits by reducing the CI of crude oil production and refineries through greater use of energy efficiency, innovative technologies, or renewable inputs. Like other fuels, these investments can yield LCFS credits which have higher or lower value based on the overall credit price.

One example of the value of the LCFS for petroleum company investments can be extrapolated from self-reported data on energy efficiency investments by California petroleum refineries to the ARB. [14] As reported, there are over four hundred past and planned energy efficiency and co-generation projects at refineries in California, with a total capital cost of approximately $2,600 million - resulting in annual energy savings of about $200 million for refineries and 2.8 million metric tons of reduced GHGs.

Using past projects identified to ARB as an illustration, if refineries were to invest in future energy efficiency improvements that resulted in an additional 2.8 million metric tons of reductions and achieved the same annual operating savings, the additional LCFS credit value generated could be between $140 to $280 million dollars annually (at a $50 to $100/ton credit price respectively). In addition California refineries would avoid having to purchase permits, or allowances, within the state's cap-and-trade regulation to cover their remaining CO_2 emissions, yielding an additional cost saving of about $35 million annually, assuming current permit prices

[14] http://www.arb.ca.gov/cc/energyaudits/eeareports/refinery.pdf

of just over $12 per ton. These savings, in theory, would increase the overall annual savings from $200 million (energy savings) to $375 to $515 million annually at refineries with the additional LCFS credit value and avoided need to purchase cap and trade pollution permits. While further analysis in this area is warranted to provide finer resolution on a project-specific basis, initial calculations suggest that the LCFS could more than halve the payback period for investments in energy efficiency projects in some cases, making these projects significantly more attractive for petroleum companies.

7. Key Outputs

Promotum's analysis incorporates three major mechanisms that drive reductions in the carbon intensity of transportation fuels. The first is to increase the volume of renewable fuels we currently use (grow the market); the second is to improve the carbon-intensity (CI) of the fuel (improve the fuel in the market); and the third is reduce emissions directly at refineries and crude oil production facilities using energy efficiency, renewable energy, and innovative technologies. To achieve the greatest reductions, California will likely need to spur all three mechanisms to varying degrees.

In our estimate, compliance with the LCFS will result in the alternative fuels market growing to 14% of the transportation energy mix by 2020 and 20% by 2025. Constraints on growth include the E10 blendwall as well as the rate at which biodiesel can expand and be utilized in California. We will need more ethanol and biodiesel to achieve compliance. This means California will need to accelerate E15 and E85 deployment as well as biodiesel blends above B5 levels.

In terms of improving the carbon-intensity of fuels, achieving the LCFS will require migration toward lower-carbon feedstocks; improvements at the biofuel plant and at the agricultural level. The LCFS is already sending a market signal, but regulatory certainty is necessary to ensure sufficient value for technology improvements to continue.

Improvements along the petroleum value chain remains, to date, one of the largest untapped areas of potential for CI reductions across the existing fuel pool. While alternative fuels will increase in market share, the large majority of transportation fuels will remain petroleum-based over the timeframe. Even small changes in CI, when spread across large fuel volumes, will lead to significant reductions.

The analysis of the effects of credit prices demonstrates three findings. First, the LCFS credit value is an important factor in increasing low-carbon fuel supply and reductions in GHG emissions we can achieve. Second, ARB's regulatory analysis, showing credit prices around $100/ton, would be sufficient to allow for a 10% requirement to be met by 2020 while extending the standard to a 15% level by 2025. Third, if credit values remain low – as we saw in the past year, due to regulatory uncertainty– then sufficient incentive will not exist for low-carbon fuel production, and compliance beyond 2020 will be unlikely to occur.

Beyond the recent decreases in oil prices, the most significant barrier to the supply of low CI fuels in California remains uncertainty with the regulatory environment. Oil companies, alternative fuel companies, and other energy investors make large capital commitments and require enough time to achieve acceptable returns.

LCFS Reference Case:

Figure 4 demonstrates annual and cumulative credit balance over time for the Reference Case.

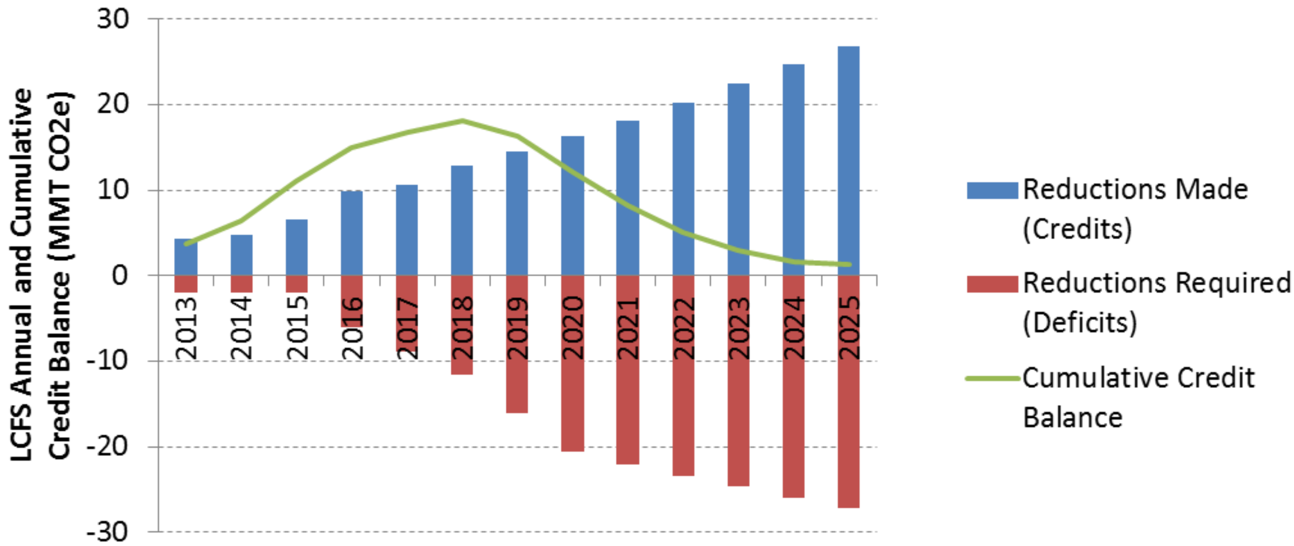

Figure 3: LCFS Annual Credit and Deficits, with the Cumulative Credit Balance (LCFS Reference Case)

The LCFS Reference Case is comprised of the following scenario:

- An LCFS credit value of $100/MT
- Assumes that the current requirement of 10% CI reductions by 2020 is increased to 15% CI reductions by 2025
- Biomass-based diesel, including biodiesel and renewable diesel, become a principal tool of compliance, taking advantage of underutilized production capacity and RIN and LCFS credit values to utilize waste greases, animal tallow, corn oil, and soy oil among other feedstocks.
- Blend rates of biodiesel grow to a 7% by volume mix in diesel (B7) by 2020 taking into account existing infrastructure constraints and restrictions on increased NOx. Blend rates increase to B12 in 2025 as the new NO_x control technologies on trucks are phased in by 2023.
- Direct emission reduction from the petroleum value chain make significant contributions to LCFS compliance
- Electricity used in passenger vehicles, as well as for off-road mobile and truck applications, also make significant contributions.

- Credit value is sufficient to incent the production and import of low CI cellulosic and sugarcane ethanol from existing facilities, but other factors related to investment and financing of new facilities, distribution infrastructure, and other issues limit availability.

The LCFS Low Case:

Figure 5 demonstrates annual and cumulative credit balance over time for the Low Case.

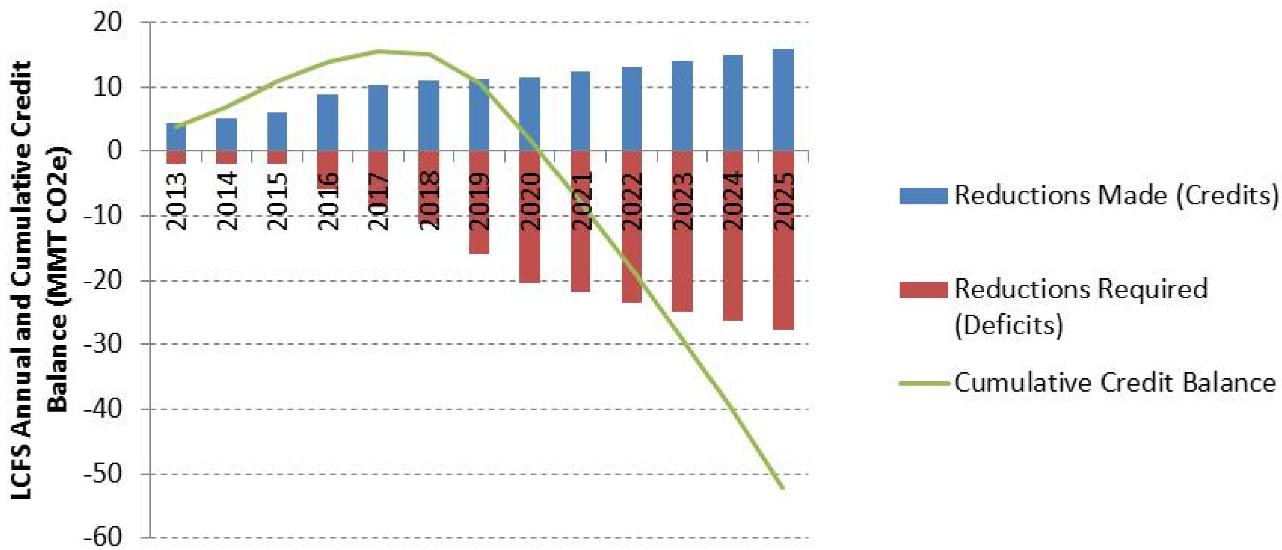

Figure 4: LCFS Annual Credit and Deficits, with the Cumulative Credit Balance (LCFS Low Case)

The LCFS Low Case is comprised of the following scenario:

- LCFS credit value below $50/MT
- Assumes that the current requirement of 10% CI reductions by 2020 is increased to 15% CI reductions by 2025
- Inexpensive and local waste based fuels come to the fore, which is positive, but under this scenario the incentive amount is not sufficient to persuade waste based biodiesel and renewable diesel producers to sell much more than the 2013/2014 volumes currently utilized in the state.
- California's LCFS market may achieve the Low Case scenario in the near term, but soy biodiesel (and other existing seed or vegetable oils) are not sufficiently incented to drive compliance.
- Absent large amounts of credits generated from diesel substitutes as in the Reference Case, greater ethanol demand occurs. In this scenario, a blend rate of 19% ethanol,

including 2.5 billion gallons of mid-CI ethanol (e.g. corn, sorghum, wheat-based) would be required to achieve compliance in 2020.

- While there is enough ethanol production capacity, under a Low Case, significant investments in ethanol infrastructure to support E15 or E85 distribution are needed, including investments in storage tankage and retail blend pumps.
- In the Low Case, the LCFS incentives would be insufficient to allow for compliance beyond 2020.

Tables and additional descriptions of the compliance pathways are provided in the Appendices.

Appendix A: Description of compliance pathways

Reference Case ($100 per ton credit value)

Ethanol - Prior to the LCFS, requirements for reformulated gasoline to reduce smog – together with the federal RFS volume requirement – have effectively led to the growth in the use of ethanol to E10 levels. Corn-based ethanol has been the primary biofuel utilized in California. The LCFS has driven improvements in the carbon-intensity of the ethanol mix over the past three years. ARB has approved many ethanol pathways and the CIs of ethanol produced as well as imported into California continue to drop significantly. In our Reference Case we see a tapering of corn ethanol consumption starting in 2015, dropping steadily to 650 MMG in 2025 as other lower CI ethanol feedstocks and fuels become available.

Traditionally the US receives 50% to 60% of Brazil's cane ethanol exports and despite current challenges in the Brazilian marketplace, we expect imports of this low CI fuel to continue. These challenges, including sugar versus corn pricing and Brazil's domestic policies, will likely temper California's imports. Ultimately, we see consumption growing to 300 million gallons per year (MMGY) by 2020.

While it is easy to envision the importation of hundreds of million gallons of ultra-low CI cellulosic ethanol into California, it is difficult to predict exactly when those quantities will be available. Cellulosic ethanol (c-etoh) volumes remain highly uncertain.

Cellulosic technology providers have successfully reached commercial scale and the first wave build out is well underway. Based on separate estimates from Bloomberg New Energy Finance (2014) and Environmental Entrepreneurs (2015), about 220 million gallons per year of capacity of cellulosic ethanol is already built or forecasted to be completed by end of 2015, with about 100 million gallons of this capacity located in the U.S.[15] We expect availability of c-etoh to emerge in 2015 with the launch of the Abengoa, POET and DuPont facilities in the U.S. However, capacity utilization will likely be modest for the early years. Based on a healthy LCFS credit value and discussions with c-etoh technology providers, we expect a significant fraction of the available pool to make its way to California.

Coming validation will pave the way for financing of the second and third wave of cellulosic plants. At this time the facilities are more expensive and smaller than first generation ethanol plants. However, both capital and operating expenditures will decrease significantly over time as technology and operations improve. Cost of production estimates for cellulosic ethanol abound. Promotum reviewed publically available studies and analysis by academics as well as government agencies that incorporate theoretical cost models. In addition, Promotum spoke directly to several technology providers . We incorporated available data into our supply curves

[15] Bloomberg New Energy Finance data (http://about.bnef.com/). Environmental Entrepreneurs (2015), *Advanced Biofuel Market Report 2014*.

for the Reference Case and Low Case and this informed our thinking. We believe the estimates are conservative but reasonable.

US c-etoh facilities will largely be green field construction, scaling in modular fashion from 25 million gallons per year capacity followed by 50 and 75 MMGY plant capacities. Given issues around herbaceous feedstock transportation, achieving 100 MMGY capacity in any one plant is doubtful. Based on conversations with cellulosic ethanol technology providers we believe the price of cellulosic ethanol will fall on a fully loaded basis from $2.75/gallon today to about $1.70/gallon in 2030, including the cost of capital.

Electricity and Hydrogen –While internal combustion engine vehicles remain the current predominant technology on the road, automakers are rapidly investing in fuel efficient technologies, including various combinations of electric-drive vehicles, from plug-in hybrids to full battery electrics, even offering initial hydrogen fuel cell vehicles. As electric-drive vehicle sales continue to displace gasoline powered vehicles, demand for low CI electricity will increase and credits will be generated. We see electricity consumption almost quadrupling from 0.44GWhr in 2015 to 1.6GWhr in 2020 and nearly 4.4GWhr in 2025. For hydrogen, we believe the opportunities for fuel cell vehicles are good, but we have conservatively kept consumption at modest levels in the study, given potential hydrogen infrastructure constraints. We also note that improvements in the CI of electricity and hydrogen are expected, particularly if California meets targets to reach 50% renewable by 2030 in addition to the existing 33% Renewable Portfolio Standard requirements by 2020. To be conservative, however, we kept CI constant, as assumed in ARB Staff's *Initial Statement of Reasons*.

Petroleum Supply Chain Improvements – This study estimates GHG emission reductions in the petroleum value chain, including at the well head and refinery level will make up a significant percentage of overall compliance in the Reference Case.

Three technologies were included in this assessment using a study by TetraTech/NRDC (2014) as a starting point. These include use of solar thermal for steam generation in enhanced oil recovery, broader use of energy efficiency at refineries, and use of biomethane by the petroleum industry. These estimates may be conservative given the wider array of technologies available as well as industry experience with some of these technologies already.

For solar thermal, it is assumed that approximately 10% of the fossil natural gas used for steam injection projects is displaced in California by 2025. These estimates do not include an assessment of the potential for crude oil imported into the state, which currently represent 63% of the mix used in California, to utilize this technology. We estimate that by 2025, just over 0.7 MMT of reductions annually can be generated.

For refinery energy efficiency (EE) investments, it is assumed that at $100/ton, the incentive is sufficient to more than double the payback of EE, such that a reduction of 1.5% per year improvement in GHG emissions at refineries across the industry. We estimate that reductions from EE investments grow linearly from 2017 to 2025, reaching 4.3 MMT in annual reductions by 2025.

In terms of renewable energy inputs, we consider the use of biomethane to replace fossil natural gas at crude oil facilities, a fuel consumed at refineries, and a feedstock for hydrogen production utilized by refineries. We assume that 15% of the natural gas used by California crude oil and refining facilities could be displaced via biomethane purchases by 2020, growing to nearly 40% by 2025. The reductions would grow to 1.1 MMT annually by 2020 and 2.8 MMT annually by 2025. Significant volumes of biogas, which can be cleaned and processed into biomethane, are currently emitted, flared, or captured from landfills, dairy digesters, and waste-treatment facilities throughout the U.S.[16]

The study projects CI reductions, applied as credits for crude oil producers or refineries respectively, would be approximately 1.5% by 2020 and 3% by 2025 over the entire lifecycle of petroleum gasoline and diesel. This CI reduction level corresponds to 16% and 32% of the standard in 2020 and 2025 respectively being met in those years from direct petroleum supply measures. We believe the current environment of relatively low oil prices also lends itself to implementation of downstream projects, including refinery energy efficiency and GHG reduction projects, as other capital investments in the upstream and midstream are reduced in the U.S.

When combined, we see opportunities for 4.2MM MT of GHG reduction in 2020 reaching 8.8MM MT in 2025 from these three categories of technologies.

Renewable Diesel – We see opportunities for renewable diesel (R-Diesel) to play an important role in California's biofuel portfolio, based on existing domestic and international plant capacity, reaching 400 MMGY in 2020. This represents almost 50% of the ~850 million gallon global capacity, but is consistent with the estimates by the Air Resources Board staff in their regulatory analysis.[17] To some extent we have concerns with regard to the sustained availability of international supplies (~650 million gallons per year) and the high cost of new capacity. We do believe domestic capacity for hydrotreating waste oils will be constrained. We also believe there will be considerable competition for this capacity with military aviation fuel. Continued uncertainty around the US production tax credit will also inhibit financing capacity expansion.

Biodiesel – Biodiesel is a primary driver of compliance in the Reference Case. In California and the United States there are hundreds of millions of gallons of underutilized biodiesel production capacity. The technology is simple and mature, utilizes low carbon feedstocks and produces a low CI diesel substitute. We see an important opportunity to grow the blend rate beyond the currently anemic 2% levels by volume. Waste grease (used cooking oil),increasing volumes of corn oil biodiesel and soy biodiesel will contribute. We see total biodiesel consumption reaching 265 MMGY in 2020 and more than 500 MMGY in 2025.

[17] http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs2015.htm

Availability of corn oil depends primarily on the penetration of necessary unit operations within corn wet mills. Starting from approximately 59% in 2015 we see penetration increasing to ~90% by 2025. We forecast 68 million gallons of inedible corn oil biodiesel reaching California in 2020 out of an estimated US pool of 475 million gallons and greater than 100 million gallons in 2025.

Biodiesel from used cooking oil (waste grease) will continue to make an important contribution to the BD pool. We estimate 51 million gallons will be available to California in 2020 and 77 million gallons in 2025. While the very low CI makes it particularly attractive, community collection by its nature will remain a constraint.

Swing biodiesel feedstock will come in the form of soy oil. While often spurned because of its nominal association with food, soy oil is separated, from soy protein prior to utilization. A healthy LCFS credit value overcomes traditional soy pricing problems, which have mothballed many biodiesel facilities and left many others operating below capacity. With an improving CI profile we predict 51 million gallons of soy biodiesel in the California market in 2020 and 77 million gallons in 2025. We do not see a big role for canola based biodiesel in the US or California.

Natural Gas – We expect natural gas usage in fleets to increase and be utilized to comply with the LCFS. We also assume that an increasing share will come from biomethane captured from landfills and other sources, including anaerobic digestion and waste-treatment facilities. We find approximately 170 million diesel gallon equivalents of liquefied natural gas will be utilized by 2025 and 306 million diesel gallon equivalents of compressed natural gas being utilized. We assume approximately 80% of these volumes will be derived from biomethane sources by 2025, given the increased value for biomethane producers and current levels in California approaching 40%.

Low Case (less than $50 per ton credit value)

Ethanol – In a Low Case scenario, inexpensive corn, wheat, or sorghum based ethanol becomes the primary tool of compliance. Instead of the tapering we saw in the Reference Case, a dramatic increase in these feedstocks occurs, reaching blending level of 2.5 BGY in 2020, together with an additional 140 MMGY of low-CI ethanol. This represents an effective blend rate of 19%-21% in the years 2020-2025.

Electricity and Hydrogen – We find that similar levels of electricity and hydrogen consumption for the transportation sector will occur between the LCFS Reference and Low Case. However, we have not analyzed the use of electricity credits by utilities and the effects on the market, given the lack of current data.

Petroleum Supply Chain Improvements – Lower credit values decrease the incentive for refinery and well head improvements. Significant reductions still occur, reaching 2.1MMT in 2020 and 5 MMT in 2025, but the pace of implementation is slower.

Renewable Diesel – R-Diesel remains relatively expensive from 2015 to 2025 and lower LCFS credit values mean blending remains stuck at circa 2015 levels, approximately 100MMGY.

Natural Gas – While we find that NGV usage and natural gas demand for transportation to remain at similar levels to the Reference Case, we see a significant drop in biomethane use to only double from current levels, growing to only 30 MMGY (diesel equivalent).

8. About Promotum

Promotum is a technology based management consulting working at the convergence of fuels, chemicals and biologics. We are a team of standout engineers, scientists and accomplished MBAs, who are as passionate about science and technology as we are about business. By focusing on the convergence of energy, materials, and biology we deal daily with complex issues and disciplines. Promotum is growth focused helping clients enter new markets, evaluate or create them. Our expertise allows us to maximize results for our clients around the world. Promotum is headquartered in Cambridge, Massachusetts.

Driving Progress, Fueling Savings

How California Is Tackling Global Warming, Cutting Oil Use, and Saving Drivers Money

CALIFORNIA DRIVES PROGRESS

California has implemented a suite of practical strategies to reduce carbon emissions from cars and trucks, benefiting state residents in many ways. In addition to helping prevent the worst impacts of global warming and spurring investment and innovation in clean transportation technologies, the state's clean vehicle and fuel policies are reducing oil use, saving consumers money, and improving public health—particularly in communities most affected by air pollution.

Oil companies, however, are trying to stop this progress, using misinformation and scare tactics to weaken public support for state climate policies. But California's climate policies are working—and setting an example for other states and the federal government to follow—and it's critical that the state keep moving toward a clean transportation future.

The California Global Warming Solutions Act of 2006, also known as Assembly Bill (AB) 32, is a ground-breaking law that calls for reducing the state's global warming emissions to 1990 levels by 2020, laying the foundation for a low-carbon future. Since the bill's passage, the California Air Resources Board (CARB) has implemented a suite of practical policies to meet this target—including reducing emissions from cars and trucks, which represent the single largest source of the state's carbon pollution. California has enjoyed many benefits related to these policies, from reduced consumer spending on gasoline and improved public health in communities affected by air pollution, to increased private-sector investment and innovation in the next generation of climate-friendly technologies.

Perhaps not surprisingly, oil companies are standing in the way of progress. Despite the fact that transportation accounts for nearly 40 percent of California's emissions (see Figure 1), the oil industry wants to be exempt from California's climate policies (CARB 2014a). They are using scare tactics, such as skyrocketing gas prices, to avoid accountability for their carbon emissions and delay the transition to cleaner fuels. Californians should not be fooled by the oil industry's misleading claims. The state's climate policies are working—bringing lower transportation costs, cleaner air, and more transit choices to communities.

© iStock/mccaig

A major focus of California's climate policies is reducing emissions from transportation, the largest source of emissions in California.

The Benefits of California's Clean Transportation Solutions

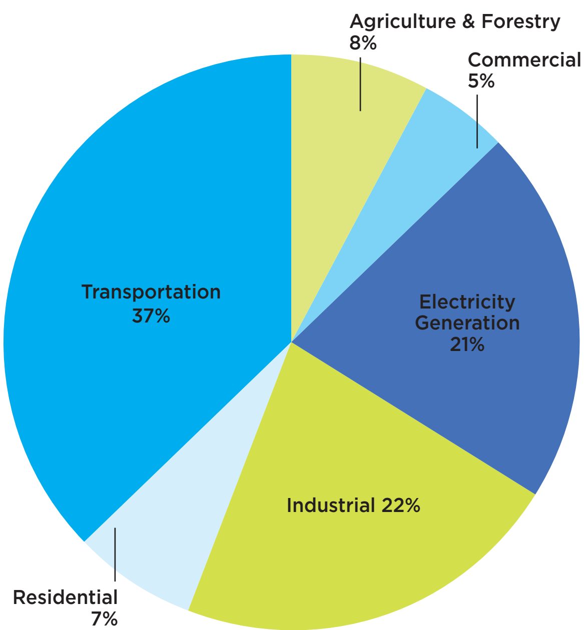
California has pursued successful strategies to reduce carbon emissions from cars and trucks. These include a flexible market-based cap on carbon emissions (see Box 1), stringent emissions standards for new vehicles, a requirement that automakers produce electric cars and other advanced-technology vehicles, a policy to scale up the use of clean fuels, and improved land-use and transportation planning to improve walkability and access to transit in local communities. In addition to reducing the state's carbon emissions, these policies are delivering important benefits to Californians.

REDUCING OIL USE

The price of gasoline has historically had large fluctuations, but has tended to go up over the long run. In California, the average per-gallon price of gasoline climbed from $2.47 in 2009 to $3.89 in 2013 (see Figure 2), and the average California driver spent $2,475 on gasoline in 2013 (CEC 2014a). Oil companies like to point to taxes and regulations as a reason for high fuel prices, but the majority of the cost of gasoline actually comes from the cost of the oil itself: for every $50 spent to fill up a vehicle's gas tank within the past five years, $30 went to pay for the crude oil that was turned into gasoline while $9 went to refining, distribution, and marketing (UCS 2013a).

The real solution to high and volatile gasoline prices is simply to use less oil. Fortunately, California's low-carbon transportation policies are making progress toward this goal. Oil consumption fell 12 percent from 2006 to 2012, helping Californians save money on fuel and reduce emissions (EIA 2014). Going forward, gasoline consumption is forecast to decline—by about 2 billion gallons annually in 2022 compared with 2012—thanks primarily to the state's requirements for less-polluting, more-efficient vehicles (CEC 2014b). In

FIGURE 1. California Global Warming Emissions by Sector, 2012



Transportation is the largest source of heat-trapping global warming emissions in California, accounting for nearly 40 percent of the state's total annual global warming emissions.

Note: Emissions are measured in terms of carbon dioxide equivalent. Electricity generation includes in-state and imported generation.

SOURCE: CARB 2014A.

BOX 1.

Transportation Fuels and California's Cap-and-Trade Program

A cornerstone policy in California's effort to tackle global warming is a market-based program to limit carbon emissions, known as cap-and-trade. The program creates economic incentives for major carbon polluters—oil refineries, electric utilities, and other large industries—to cut their emissions. Cap-and-trade encourages companies to find the least-expensive ways to reduce their emissions, either by upgrading their facilities and equipment or purchasing carbon permits.

The central framework is a declining cap on global warming emissions that requires major carbon polluters to acquire a permit, known as an "allowance," for every ton of carbon pollution they emit. The total level of carbon pollution collectively emitted by the covered entities cannot exceed the number of allowances available under the cap, which declines 2 to 3 percent each year through 2020.

By including gasoline and diesel fuel in the program, California is holding oil companies accountable for their global warming pollution. Any exemption or delay in accounting for fuel emissions under the cap-and-trade program would undermine California's ability to meet its carbon-reduction goals.

addition, the state's Low Carbon Fuel Standard (LCFS) is helping drive production of non-petroleum-based vehicle fuels such as electricity and advanced biofuels. In 2012, alternative fuels accounted for more than 7 percent of fuel used by cars and trucks, and the share of transportation powered by cleaner alternatives is rising as electricity, advanced biofuels, and other clean fuels scale up (CEC 2014b).

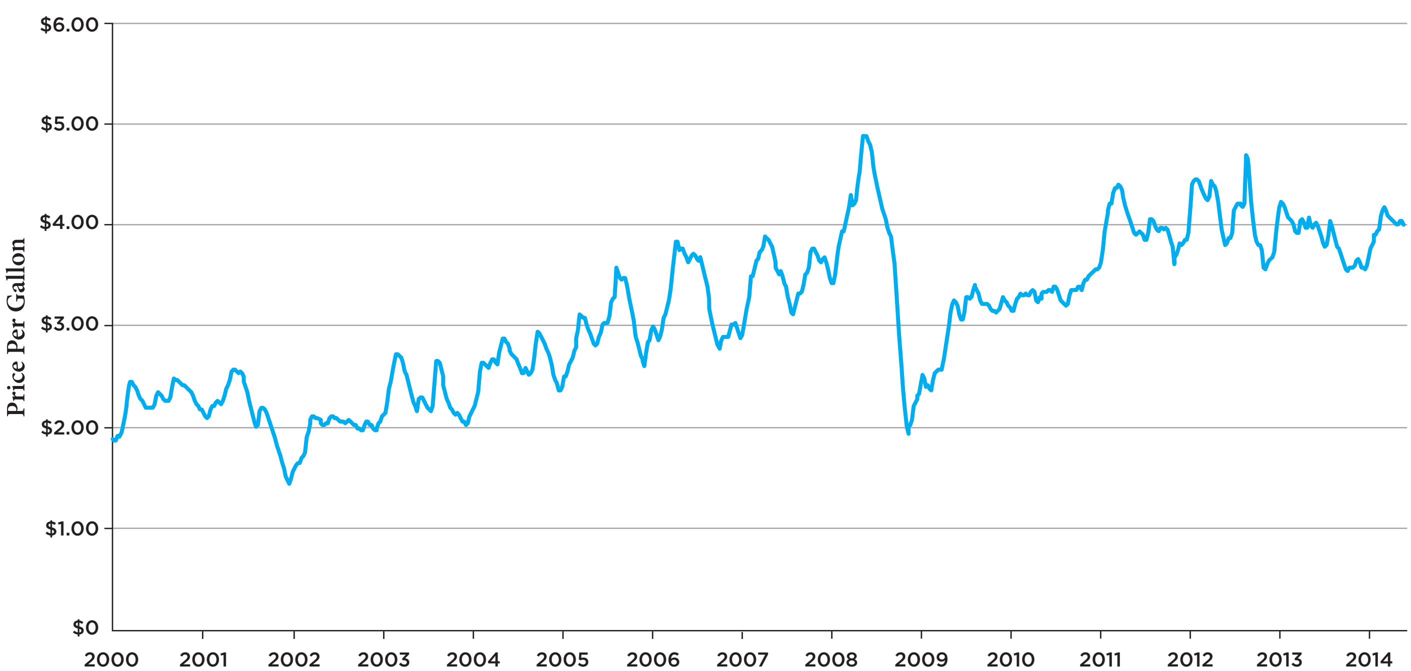
REDUCING PAIN AT THE PUMP

California's cleaner fuels and vehicle policies are saving consumers money. A California driver who purchases an average new model year 2015 car, for example, can expect to save an estimated $3.90 each week over the life of the vehicle, compared with a driver who purchased a new vehicle in 2008 (see Figure 3).[1] The comparative savings grow to $5.20 per week for the owner of a new vehicle in 2020 and $9.00 per week for someone buying a new vehicle in 2025. California's low-carbon transportation policies will also help those looking to purchase a used vehicle; according to UCS analysis, a 10-year-old used car in 2025, for example, will save its driver $7.50 a week, or nearly $400 a year, over the remaining lifetime of the vehicle compared with a 10-year-old used car purchased in 2015.[2]

IMPROVING PUBLIC HEALTH AND SUPPORTING DISADVANTAGED COMMUNITIES

California's transportation system is the primary source of smog-forming nitrogen oxide and diesel particulate matter emissions in the state (CARB 2013)—emissions that do not affect all Californians equally. Low-income communities are more likely to live in close proximity to transportation corridors, and therefore face greater exposure to diesel particulate matter and other toxic air pollutants (Hricko et al. 2014). Fortunately, the state's carbon-fighting strategies are improving air quality, both in these vulnerable communities and statewide. A recent study found that California's LCFS and cap-and-trade programs will save $8.3 billion in health costs between now and 2025 by reducing

FIGURE 2. California Gasoline Prices, 2000–2014



Gasoline prices have increased significantly since 2000, and are vulnerable to extreme volatility.

Note: Year markers represent per-gallon prices on the first Monday in January of that year. Historic gas prices have been adjusted for inflation.

SOURCE: BLS 2014, CEC 2014A.

asthma attacks, hospitalizations, and other health impacts associated with poor air quality (EDF/ALAC/TT 2014).

In addition, at least one-quarter of the proceeds from the sale of carbon permits in the cap-and-trade program are being invested to benefit communities that are disproportionately impacted by air pollution. In California's 2014–2015 fiscal year, more than $200 million will be spent to benefit disadvantaged communities. This funding includes investments in public transit and advanced freight technologies such as electric trucks and buses.

CLEAN TRANSPORTATION INVESTMENT AND INNOVATION

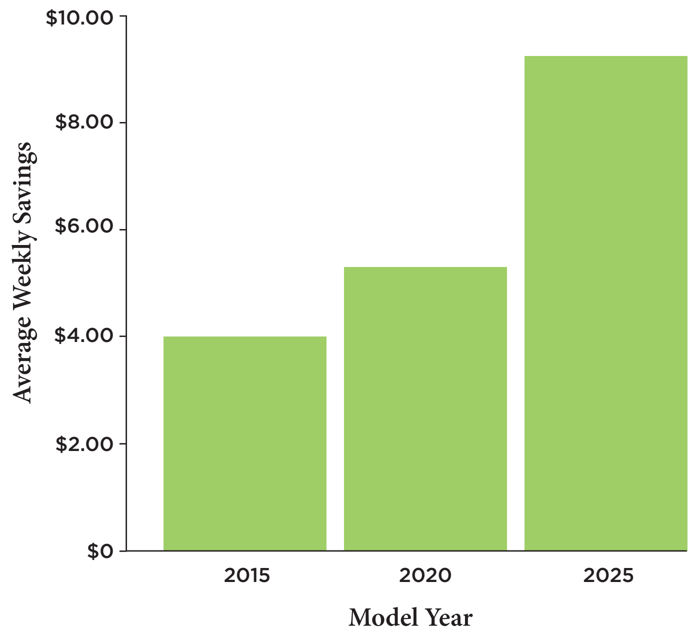
California's climate policies are driving a clean technology boom in the state. More than $5 billion in venture capital was invested in California's clean transportation sector between 2006 and 2013 (NXT 2014) and California's share of total U.S. patent registrations in this sector nearly doubled, jumping from 4.9 percent in 2006 to 9.4 percent in 2011 (Collaborative Economics Inc. 2013). In 2012 and 2013, California had the most or second-most new patents among states for battery, hybrid-electric, and fuel cell systems, and for biofuel and biomass technologies. Clean technology investments are also leading to more jobs; employment in California's clean transportation sector more than doubled between 2002 and 2012, to 8,500 jobs (NXT 2014).

Overcoming Oil Industry Opposition

Chevron, Exxon-Mobil, and other large oil companies lead the list of major carbon polluters, responsible for most of the carbon that has been emitted into the atmosphere over the last 150 years (Heede 2013). These companies make huge profits from the status quo and have a significant interest in ensuring oil continues to be the dominant transportation fuel. It is not surprising, therefore, that the oil industry is fighting California's climate policies.

> ***At least one-quarter of the proceeds from the sale of carbon permits in the cap-and-trade program are being invested to benefit communities that are disproportionately impacted by air pollution.***

FIGURE 3. Average Weekly Savings Over Lifetime (vs. Model Year 2008 New Vehicle)



California's clean transportation policies save drivers money over the lifetime of the vehicle, and as vehicles become more fuel-efficient these savings will grow.

Note: This figure represents the net savings over the lifetime of an average new vehicle purchased in 2015, 2020, and 2025 compared with a new vehicle in 2008, and reflects costs from California's global warming emissions and zero-emissions vehicle standards, Low Carbon Fuel Standard, and cap-and-trade program. For our methodology, see *www.ucsusa.org/ab32saves*.

Oil companies are attempting to weaken public support for California's clean transportation policies by focusing on the price of gasoline. But as UCS analysis has shown, the savings from more efficient vehicles more than offset the modest costs of improving fuel efficiency and producing cleaner fuels. The industry also seeks to obscure the fact that the only long-term solution to rising gas prices is to use less oil—which is precisely what California's clean transportation policies will achieve— while also downplaying the consequences of climate change (see Box 2) and lobbying against long-term emissions reductions.

California's climate policies are reducing carbon emissions, saving consumers at the pump, cutting oil use, and cleaning our air. It's a clean transportation future that works for *all* Californians, and sets a leading example for other states—and ultimately, our federal government—to follow. It's critical that the state keep moving forward toward this goal.

BOX 2.

The Costs of Inaction

Communities across California are already coping with many impacts of climate change, which are certain to worsen without strong action to reduce emissions.

Wildfires. California is experiencing hotter, drier conditions, which are contributing to larger wildfires and longer wildfire seasons. The wildfire season in the Western United States has grown from five months, on average, in the 1970s to seven months today, and the annual number of large wildfires has increased by more than 75 percent over the same time period (UCS 2013b). California has suffered seven of the 10 most costly wildfires in the nation, including three that cost between $1.6 billion and $2 billion in insured losses (UCS 2014).

Drought. Rising temperatures, reduced snowpack, and earlier snowmelt have exacerbated drought conditions in California. As temperatures have warmed over the past century, the prevalence and duration of drought has increased in the American West (Andreadis and Lettenmaier 2006). Droughts can be devastating for ecosystems and the economies that depend on them. A study by the University of California–Davis found that, during the summer of 2014, drought directly cost the state's agriculture industry nearly $1.5 billion, mostly due to having to leave many fields fallow (Howitt et al. 2014). Droughts can also lead to increased energy costs for California ratepayers as relatively inexpensive hydropower is lost. During the 2007–2009 dry period in California, ratepayers were charged an additional $2 billion to cover the purchase of electricity from natural gas plants, which was needed to replace diminished hydropower generation (Christian-Smith, Levy, and Gleick n.d.).

Heat waves. Global warming is increasing the frequency and duration of heat waves in California—and not just during daytime hours. Recent modeling finds that extreme heat waves with high nighttime temperatures are at least five times more likely in California now than 40 years ago (Mera, Mote, and Allen 2014). Heat waves with a strong nighttime component exacerbate the impact of daytime heat, possibly increasing mortality rates. Extreme heat brings greater risk of death from dehydration, heat stroke, heart attack, and other heat-related illnesses, particularly for vulnerable populations. An extended California heat wave in 2006 contributed to more than 650 deaths (Hoshiko et al. 2010).

Coastal flooding. Rising temperatures are leading to increased sea levels due to thermal expansion of warming oceans as well as melting land ice (glaciers, ice caps, and ice sheets). The risks of rising seas include tidal flooding, shoreline erosion, saltwater intrusion, larger storm surges, and permanent inundation. California currently has at least 260,000 people and $50 billion in property vulnerable to a 1-in-100-year coastal flood (a flood that has a 1 percent chance of occurring in any single year). As early as 2050, given current projections of sea-level rise, today's 100-year storm could occur once every year. By the end of this century, rising seas could put around 480,000 people (nearly half a million) at risk from a 1 in 100-year coastal flood (CEC 2009).

Photo credits: © U.S. Forest Service (wildfire); © Peter Gleick (drought)

California is already dealing with harmful consequences of climate change, including larger wildfires and exacerbated drought. Climate policies enacted as a result of AB32 are reducing the heat-trapping emissions that are primary cause of global warming.

ENDNOTES

1 A model year 2008 vehicle is used as the basis for ownership cost comparisons because California's global warming emissions vehicle standards first came into effect with model year 2009.

2 For all underlying assumptions related to this analysis, see www.ucsusa.org/ab32saves.

Low Carbon Fuels: How Clean Fuels Can Power the West Coast and Beyond

February 2, 2015 ***Jeremy Martin, senior scientist, Clean Vehicles***

UCS-commissioned research released today is the latest to find that, with stable policies, we can achieve ambitious clean fuels goals. Recent publications from UC Davis, the International Council on Clean Transportation and E4Tech have drawn similar conclusions. As California prepares to readopt their 2010 Low Carbon Fuel Standard, we are seeing clear evidence that diverse types of clean fuel can be make a significant contribution to cutting oil use and transportation carbon pollution.

A year ago more than one hundred leading California scientists and economists sent an open letter on climate change to Governor Jerry Brown and the California Legislature urging them to maintain California's leadership on climate change. These experts said that a clear price on carbon is "key, but not sufficient to adequately reduce emissions. Policies that promote renewable energy, low carbon fuels, and cleaner transportation are also critical." Policymakers should look beyond the current policies, and prepare now to reach emissions targets between 2020 and 2030.

> *"Every sector involved in addressing climate change, from energy to transportation, will need sufficient time to prepare to meet new targets. The longer we wait the harder and more costly it will be. Please begin now to set a science-based, heat-trapping emissions target for 2030."*

California is taking up this challenge. In addition to policies that put a price on carbon, California has a comprehensive suite of policies that will clean up transportation including a low carbon fuel standard (LCFS) that shifts the market steadily towards cleaner fuels. And the state is starting to look beyond 2020. Governor Brown recently set a 2030 goal of cutting oil use in half, making it clear that 2020 is just the first step. The steady growth of clean fuels is key to meeting this goal.

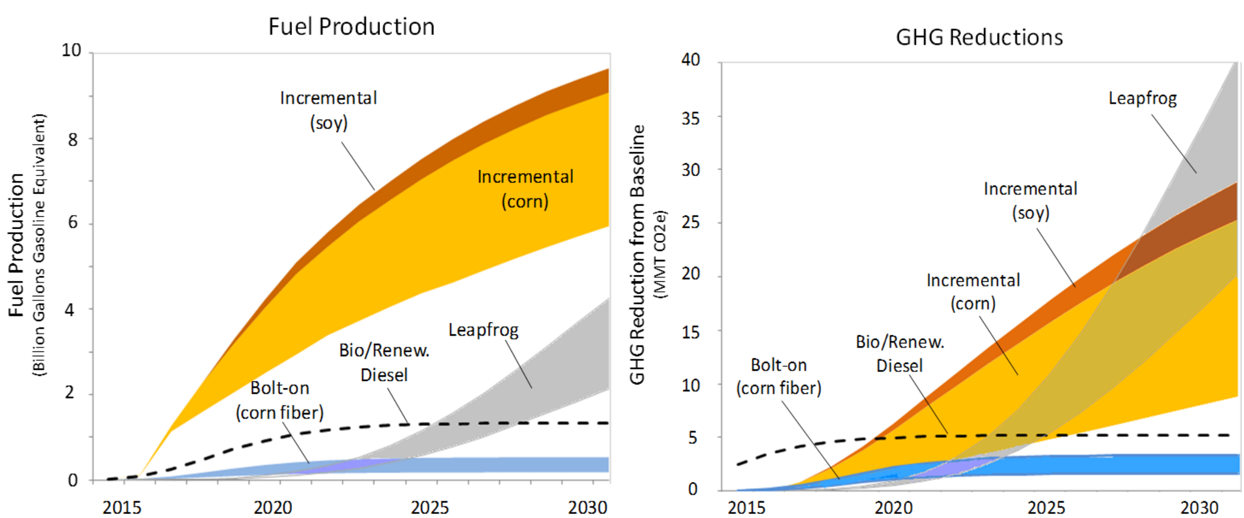
Three recent studies look into the potential for clean fuels in the US, the West Coast and California, and together illustrate why the future for clean fuels is bright, provided the policies are in place to support them.

California kicked off a transition to clean fuels with its LCFS in 2010, and later this month the California Air Resources Board will consider the readoption of the LCFS, making technical updates, resolving legal issues and getting the policy back on track to cut carbon pollution from transportation fuels by 10% per unit of energy by 2020. As they do so, they need to start planning for the next phase, from 2020 to 2030.

Accelerating the transition to clean fuels now will support innovation, cutting oil use and reducing transportation emissions and ensuring that investments in the clean fuels of the future replace dead end investments in ever dirtier sources of oil.

National: UC Davis NextSTEP's study
Experts at UC Davis' Institute for Transportation Studies examined three distinct ways cleaner biofuels of different types are emerging across the United States (recently published in Energy Strategy Reviews).

- First, *incremental* progress is being made at existing biofuel facilities, as they adopt cleaner and more efficient production processes.
- Second, *transitional* progress is being made as existing corn ethanol biorefineries start making cellulosic ethanol from corn fiber together with corn ethanol at existing corn ethanol facilities.
- Finally, *leapfrog* progress is being made as firms build new facilities specifically to make cellulosic biofuel.

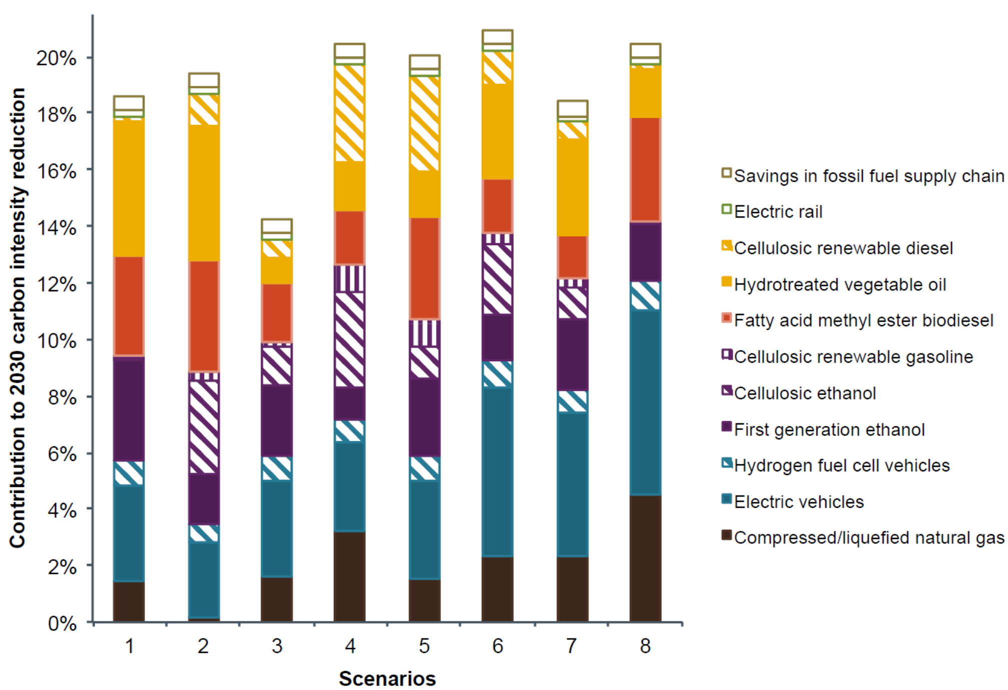


Notice that the incremental approaches are likely to come on more quickly between now and 2020. But the leapfrog approach is the one with the potential to deliver the largest oil savings and emissions reductions by 2030. The transitional route also plays an important role in building early experience with cellulosic biofuel technology in a context that is less risky and capital intensive. This lower risk learning is especially important today, with policy uncertainty delaying investment in the most ambitious projects.

The bright future described in this study is by no means guaranteed. Strong policy support is needed to scale up low carbon fuels. These policies lead to steadily increasing production, which accelerates learning and brings down the costs of cellulosic biofuel over time. And the broader the market for the fuels, the faster this learning will accumulate. While US policy is stalled, the west coast is working on creating a large and steadily growing clean fuels marketplace.

West Coast: ICCT and E4tech

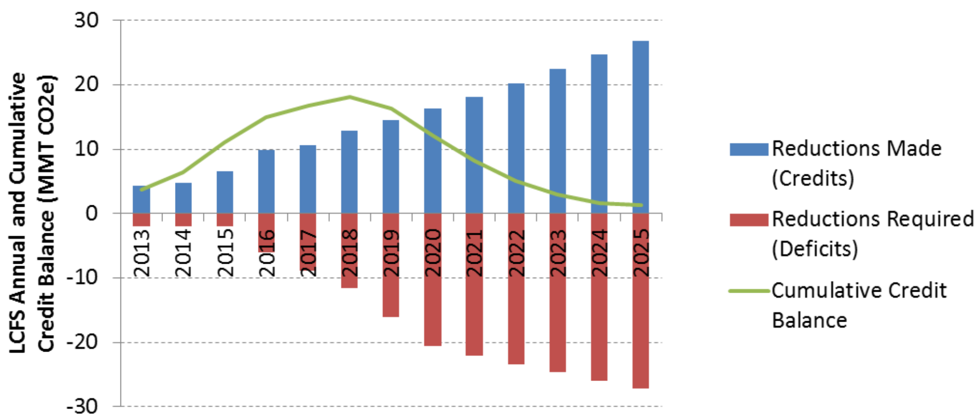
Last month the International Council on Clean Transportation and E4tech released a study on the potential low-carbon fuel supply to the Pacific Coast region of North America. They find that California, Oregon, Washington and British Columbia, acting in concert to create coordinated clean fuels policies, can triple the use of low carbon fuels and replace a quarter of the region's gasoline and diesel use by 2030. That's a massive reduction in carbon pollution and oil use. The report also highlights the diversity of potential fuels and pathways, with eight distinct scenarios and different amounts of low carbon fuels emerging as electricity, renewable natural gas, ethanol, biodiesel, and other low-carbon fuels ramp up at different rates.



Their study reinforces that there are many routes to a low carbon future, and with a flexible policy framework like a low carbon or clean fuel standard, policy makers are committing to the outcome, rather than picking specific fuels or technologies needed to get there. I've written in the past about the importance of flexibility in clean fuels policies, and my colleague Josh just posted a blog on how Oregon's clean fuels program is making it work for them.

California: NRDC/UCS/EDF Promotum Study

Today UCS, the Natural Resources Defense Council and the Environmental Defense Fund released a study of compliance options for the California Low Carbon Fuels Standard over the next ten years. The study was conducted by Promotum and addresses endless oil industry claims that moving to cleaner fuels is infeasible. Our study examines where clean fuels can come from to meet both a 10% reduction in carbon intensity (carbon pollution per unit of energy) by 2020 that California adopted back in 2010, and looks beyond 2020, to a 15% standard in 2025.



The oil industry likes to focus on whether biofuels or Electric Vehicles (EVs) are ready to scale up quickly enough to meet ambitious targets. This study indicates that they are, and also that the oil industry can meet 15% of its clean fuel obligations in 2020 by improving efficiency and integrating renewable energy inputs into the production of oil and the refining of gasoline and diesel. Promotum evaluated the impact of credit prices of $100 a ton (LCFS credits are measured by ton of avoided emissions), and found that the available options would exceed the requirements of the policy in 2020, and allow compliance with steadily increasing targets that hit 15% in 2025.

2020 is just the beginning

It took more than a century to build today's oil industry, and it will take longer than five or ten years to scale up the clean fuels industry that will succeed it. The three studies provide a roadmap for successfully achieving low carbon goals the states are setting today, which will create a steadily growing regional marketplace for clean fuels. When you consider that the combined economies of California, Oregon, Washington and British Columbia would rank fifth in the world, behind Germany and ahead of France, it is clear this marketplace can provide major step forward towards a clean transportation future.

About the author: Jeremy Martin is a scientist with expertise in the technology, lifecycle accounting, and water use of biofuels. He is working on policies to help commercialize the next generation of clean biofuels (made from waste and biomass rather than food) that can cut U.S. oil dependence and curb global warming. He holds a Ph.D. in chemistry with a minor in chemical engineering.

The Latest on Biofuels and Land Use: Progress to Report, but Challenges Remain

January 23, 2015 ***Jeremy Martin, senior scientist, Clean Vehicles***

Carbon pollution caused indirectly by the increasing use of crops to produce biofuels has been a contentious topic for the last 7 years. In this post I look back at what we have learned since then about indirect land use change (ILUC) emissions, as this phenomena is generally called. The headline 7 years ago – that crop-based biofuels are far worse than fossil fuels – no longer holds.

Both the studies and the world have changed. Agricultural markets are more flexible, deforestation has fallen in some key areas (Brazil in particular) and biofuels production is getting more efficient. The overall result is that biofuels are getting cleaner over time, and most biofuels are cleaner than gasoline. But the central importance of reducing biofuels impact on food and forests has been reaffirmed. Expanding the production of food-based fuels will not deliver the low carbon fuels we need to cut projected oil use in half and address climate change, and will cause many other problems. Fortunately we have better options.

What are indirect land use change emissions and why do they matter?

Prior to 2008, biofuels were considered a guilt-free energy source: cleaner than gasoline, good for farmers that produced the feedstocks, and available domestically at seemingly limitless scale. In February 2008 that changed when important papers in Science Magazine, particularly one by Searchinger and coauthors, raised the specter that as US corn ethanol consumed an ever greater share of U.S. crop production, cropland overseas was expanding to fill the void in food markets. Most concerning was the conversion of tropical forests to farmland. Since deforestation is itself a major source of carbon emissions, this shift undermines the potential climate benefits of crop-based biofuels. Searchinger and coauthors estimated that emissions from ILUC for corn ethanol were higher than the total emissions of using gasoline, leaving no potential for corn ethanol or other crop based biofuels in a low carbon transportation future. This concept resonated powerfully, reinforced by the related concern that using food for fuel could make food more expensive and aggravate food insecurity. Since then ILUC emissions have become an important and contentious part of the lifecycle analysis of biofuels and in the administration of fuel regulations that are based on such analyses.

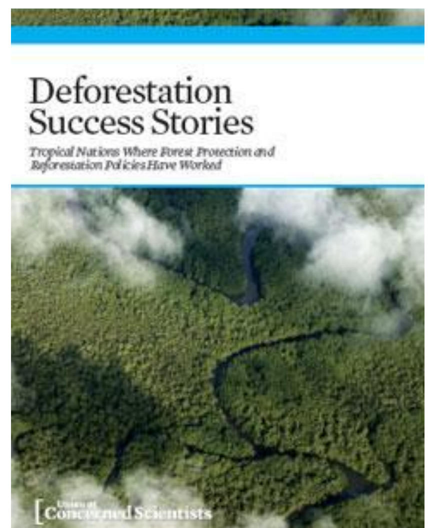
Experts across the country have been hard at work on this topic for the last 7 years, and have learned a great deal about ILUC. The headline conclusion of the 2008 paper, that corn ethanol's emissions are much higher than gasoline, has not survived careful scrutiny. Subsequent analyses found more flexibility in the agricultural system to expand production without large increases in deforestation, and deforestation in Brazil has slowed. California's most recent analysis finds ILUC emissions of about 20 grams of CO_2equivalent carbon pollution per megajoule of energy for the fuel produced (g /MJ), about 80% lower than the Searchinger's result. Nailing these numbers down remains challenging, and an uncertainty analysis finds plausible estimates range from 11 g/MJ to 37 g/MJ. However, these revised values mean that – when ILUC emissions are combined with all other emissions – corn ethanol produced at an average Midwestern facility using natural gas as a source of process heat is 20% cleaner than gasoline, and the cleanest facilities are better still.

Expanding agriculture to make more biofuels has real costs

However, the underlying notion that biofuels expansion is profoundly impacting agriculture has only gotten clearer. Numerous studies have looked at how biofuels expansion impacts land use, crop prices, food consumption, livestock, and the use of irrigation. The global food and agricultural system is complex, to say the least, and incorporating these modelling approaches into a regulatory framework is and will remain a major challenge. But every credible study finds that biofuels are a major player in global agricultural markets. It is clear that, going forward, sustainable biofuels must not only cut oil use and reduce emissions, but also protect food security and complement the agricultural system. For reasons ranging from climate change to water pollution to food price stability, expanding biofuels by moving more and more grain and vegetable oil into fuel markets is not smart transportation policy or smart food and agricultural policy.

Biofuels don't need to drive deforestation

Much of the analysis of ILUC has focused on corn ethanol and soybean biodiesel produced in the US and its link to deforestation in Brazil. This makes sense since the US and Brazil are the largest producers of ethanol and soy biodiesel and the largest producers of corn and soybeans, and Brazil is historically among the largest sources of carbon emissions from deforestation. But what was just starting to come into focus in 2008 was how much of an improvement Brazil was making in reducing deforestation. As my colleagues have described in their recent report, Deforestation Success Stories, Brazil has cut the rate of deforestation by three quarters and they have done this even as soybean and cattle production continue to grow.



Strategies for reducing deforestation are working in a variety of places. Understanding these success stories can help us turn them into a global success story.

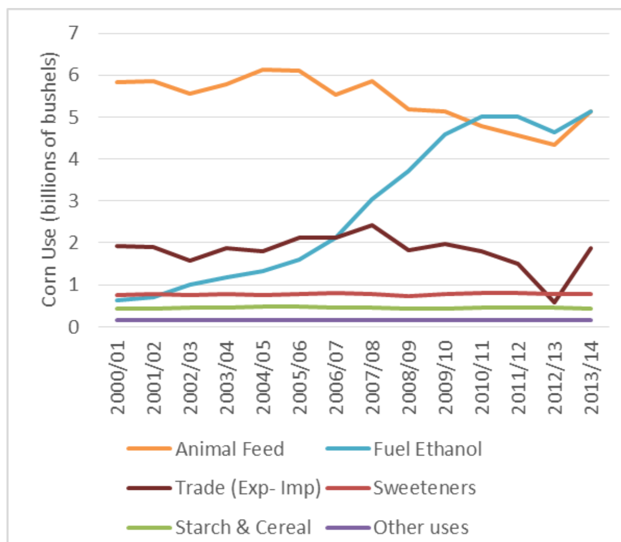
California's latest ILUC analysis suggests that most Brazilian cropland expansion is likely to come from pasture land , as cattle producers raise more cattle on fewer acres. Another important shift is *where*expansion is occurring, with cropland and pasture expansion occurring on previously cleared land in response to more robust forest protection. And recent analysis from Iowa State has shown that much of the increased production in Brazil from 2004 to 2012 came from farmers growing two or more crops per season, or harvesting more of what they plant. The progress in protecting forests together with these opportunities for intensification mean that the magnitude of deforestation associated with corn, soybeans and beef expansion is going down, which is great news.

The bad news is that deforestation in Southeast Asia is still a major concern, particularly driven by the expansion of palm oil production.Because of this, California's recent analysis found that palm oil biodiesel has ILUC emissions of 71 g/MJ, more than twice as high as soybean biodiesel and more than three times as high as corn ethanol. This means that palm oil-based biodiesel is more polluting than petroleum diesel. In the U.S. we don't use a lot of palm oil for biodiesel, but my colleagues are putting pressure on the major companies that use palm oil in household products and foods to stop the expansion of palm oil onto forests. And they are succeeding in getting important commitments from major U.S. companies (for example Hershey, General Mills and Proctor & Gamble) and global agricultural traders (for example Wilmar and Bunge).

Increasing biofuels production and supply chain efficiency

When assessing the performance and potential of a biofuel, it's important to look at ILUC alongside other factors. In 2008 when the ILUC debate got going, the general understanding (based on a model called GREET from Argonne National Lab) was that corn ethanol from a typical Midwestern facility would reduce emissions by about 20% compared to gasoline. Adding 103 g/MJ as Searchinger and coauthors suggested made corn ethanol far worse than gasoline, and even the 30 g/MJ (~30%) California's 2010 analysis found, was enough to make corn ethanol from a typical facility equal to or a little worse than gasoline. But corn ethanol production has been getting more efficient, and an updated version of GREET that reflects these efficiency gains finds that the direct emissions for Midwestern corn ethanol produced using natural gas are about 60 g/MJ or 40% cleaner than gasoline. Adding 20 g/MJ to account for ILUC emissions still leaves typical corn ethanol about 20% cleaner than gasoline. And for corn ethanol producers that adopt the most efficient technology in their production process, for example installing efficient combined heat and power systems, the emissions can come down even further.

Just because corn ethanol can be cleaner than gasoline doesn't mean we need more



While ILUC is just one factor of the lifecycle, the lifecycle itself is still just part of the story for biofuel impacts. And where corn ethanol is concerned, we have to talk about scale. U.S. corn ethanol production expanded rapidly over the last decade, as ethanol changed its role from a minor blending component (an oxygenate required to address air quality problems in some key regions) to its present role as a source of octane in E10 (a 10% ethanol gasoline blend) that is the main type of gasoline sold in the U.S. today. As consumption of corn for ethanol increased by 400 percent in just a decade, ethanol went from being a relatively minor use of corn to being the single largest use worldwide.

Continuing this expansion will make things worse, starting with the harm corn ethanol expansion has caused to water quality, but also the damage to the long term productivity of our agricultural system. My colleagues have outlined the need for a more balanced approach to farming, and for both dietary and environmental reasons, doubling down on corn won't help us get there.

The future of clean transportation is fueled by better biofuels (and electricity)

While more corn won't get us where we need to go, the good news is that we have a lot of biomass resources that are a better choice. These are waste materials from our cities andagricultural residues like corn stalks, as well as environmentally friendly perennial grasses. With these materials we can make enough cellulosic biofuel to easily double or triple biofuels production in the next twenty years, and these non-food based cellulosic biofuels can cut emissions up to 90% compared to gasoline. Just as important, these cellulosic biofuels can scale up while moving our agricultural system in a healthy and sustainable direction. Cellulosic biofuel production is coming on line now, and with policies that support the best biofuels, as well as more electric vehicles and continued efficiency improvements across the transportation sector, we can keep moving towards our goal ofcutting oil use in half in the next twenty years.
My conclusion after working in this area for 7 years is that we need to focus on three distinct areas

- **Make biofuels cleaner:** Move to more efficient and lower carbon production processes to reduce direct emissions along the whole supply chain.
- **Make biofuels out of better biomass:** Make a transition from food crops to sustainable sources of biomass.
- **Scale matters for food and forests:** Sources of waste fats and oils are available to produce a billion gallons of biodiesel a year but cause problems at 2 billion. Corn ethanol is already problematic at its current scale of more than 10 billion gallons a year, but would be catastrophic at 20 billion. And as biomass based fuels scale to more than 10 billion gallons a year, which will take a decade of steady growth, we'll need to calibrate their scale to not just meet our fuel needs, but to protect land for food, forests, and other needs as well.

Policy Matters: Why Clean Fuels Forecasts Come Up Short

October 27, 2014 ***Jeremy Martin, senior scientist, Clean Vehicles***

Cellulosic biofuel facilities are opening this year to much fanfare and a renewed promise that we can look forward to a quickly increasing supply of clean, non-food biofuels. At the same time, forecasts about the future of cellulosic biofuel have recently gotten more pessimistic, with the Energy Information Administration forecasting a plateau once these first plants open. What to believe? I use a simple model to show how progressive, consistent clean fuels policies will lead to lower costs over time.

Learning by doing drives costs down

Experience with production brings many small improvements that reduce costs. Photo Credit: The Henry Ford Foundation.

As with any other new industry, scale-up issues have emerged for the cellulosic industry that were not apparent in the lab or at pilot scale. The pace of learning always accelerates dramatically once you spend hundreds of millions or even billions of dollars to start commercial scale production. This is exactly what I saw when we visited the Poet DSM and DuPont facilities in Iowa this summer. Everything from how to stack bales to the enzyme cocktail to the filter press that cleans the water at the end of the line are in a state of optimization. In theoretical treatments they call this process "learning by doing," and across a broad range of industries it has been observed that when you first start making something, whether it is a Model T or a solar cell, the cost per unit drops as cumulative experience with production rises (see this article in the Economist for some background).

Experience with production brings many small improvements that reduce costs. Photo Credit: The Henry Ford Foundation.

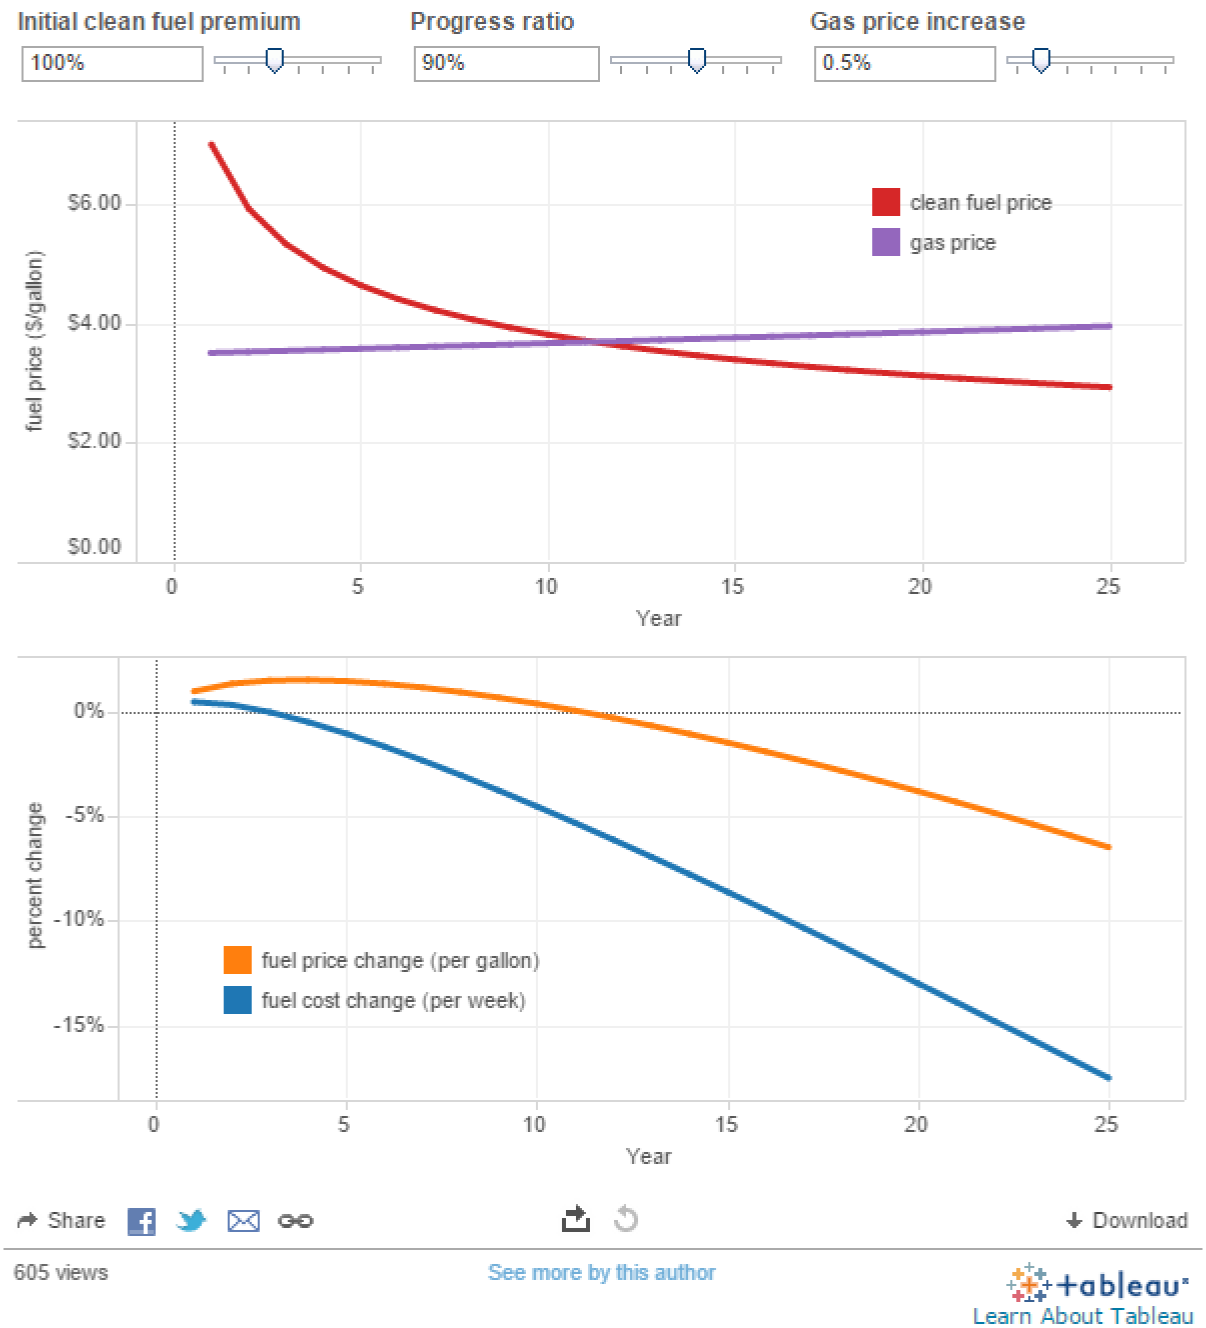
Predicting the future is hard

Fuel markets are complex, as are the models used to forecasts them – yet ultimately the predictive power of the models is rather poor. One of the most authoritative models about fuel that we all rely on is the Annual Energy Outlook published each year by the Energy Information Administration (EIA). It is really a collection of linked models that examine how policies, infrastructure, and economic factors in the vehicles, fuels, and the rest of the world interact. A complex model is needed to help think through complex questions, but the complexity can make it hard to see the big picture. Some key dynamics are best illustrated with simple model with just a few parameters.

Building a simple model

To see what this means for clean fuels, let's construct a simple model of a Low Carbon Fuel Standard. Let's assume we have just two kinds of fuel, ordinary gasoline that costs $3.50 a gallon, and super-duper clean gasoline, which is carbon neutral and currently sells at a 100% premium or $7/gallon. At twice the price, demand for clean fuel is quite low until a low carbon fuel standard (LCFS) is adopted. The LCFS requires fuel producers to reduce emissions from their fuels by 1% each year, and in our simple model this means replacing 1% of the fuel with clean fuel in the first year, 2% the second, etc.

You might think that switching gradually from $3.50/gallon to $7.00 a gallon fuel would get expensive, but remember, the producers of clean fuel have a lot of room for improvement, and as the volume of production rises, experience starts to bring down prices. I put this into a simple model below so you can see the results for yourself. For illustration I started with a 100% initial price premium for clean fuel and used a simple model of learning where each doubling of cumulative production brings prices to 90% of their previous level, called the progress ratio (in other words prices fall by 10%). Finally we assume that gasoline prices rise by 0.5% annually. You can choose different values for these three parameters using the tabs at the top of the chart.



Results that speak for themselves

What you see is that while clean fuel prices start high, they fall rapidly. And since the policy ramps up the share of clean fuel gradually, the net result is that the per gallon price of blended fuel rises slightly for the first few years, peaks 1.5% above the baseline on the 4thyear, and then starts falling. And taking into consideration that cars are getting more efficient, so that average fuel consumption is falling by 0.5% a year, total fuel cost (the blue line) drops steadily almost from the beginning. Changing the parameters will change the numbers, but across a broad range of reasonable values the basic outline of the story remains the same.

Back in the real world, there are a lot of other details that matter. One important fact to keep in mind is that there are more than two types of fuels. Some of today's clean fuels, likeelectricity, are already less expensive than gasoline. And different vehicles and infrastructure constraints also complicate the story, which is why more complex models are necessary. But it remains true that the **cost of producing clean fuels will fall as volumes rise and firms get more experience.** This is an uncontroversial point, based on both theory and empirical observation.

Policy matters—it is the dog that wags the clean fuel tail

So why then, does EIA have such a pessimistic view of the future? Their model evaluates the current state of technology and policy and suggests that in EIA's view, current policy is not adequate to support the investment in production and distribution infrastructure needed to get clean fuels to a scale at which they can compete effectively. It does not anticipate various scenarios under which the policy environment has changed, so cannot paint a rosier picture than a current snapshot.

This creates a negative feedback loop: uncertainty about the future of clean fuel policies is delaying additional investment in the industry; the delayed investment is fueling (pun intended) uncertainty about whether the clean fuel policies are realistic. The oil industry is amplifying this negative feedback, arguing that policy makers should wait until the clean fuels are cheap and plentiful before moving forward with policies that support these fuels. But this cynical tactic is letting the tail wag the dog. Instead, policy makers in California, Oregon, and Washington should move boldly to support clean fuels production, and policy-makers in DC should resolve the uncertainty in the federal fuels policy landscape to reestablish the stable policy framework needed to support investment in clean fuels.

5 Things I Learned in Iowa about Biofuels

August 12, 2014 ***Jeremy Martin, senior scientist, Clean Vehicles***

In July my colleagues and I, together with the Great Plains Institute, organized a Cellulosic Summit in Iowa. We brought together experts in clean transportation (many from California) with experts in sustainable agriculture (many from Iowa) to see for themselves the latest developments in cellulosic biofuel commercialization.

Cellulosic biofuels are a key element of our strategy to help cut projected oil use in half in 20 years, and today we're at a critical juncture, with the long-awaited commercial production of millions of gallons of cellulosic biofuel beginning this year.

I'll be thinking about what I saw and learned for months to come, but here are the top five things I learned:

1. Big refineries signal technological breakthrough

The Poet-DSM and DuPont cellulosic biofuels facilities poised to open this year are a big deal for clean transportation and sustainable agriculture. These early facilities, which represent hundreds of millions of dollars of investments, will work through the technology and logistics challenges of producing cellulosic biofuel at commercial scale, and serve as a proving ground for the technology. Walking through these huge, complex biorefineries is awe-inspiring, and a testament to the innovative spirit and technological know-how being brought to bear to meet our energy challenge.

2. Lots of corn = Lots of biomass

It is well known that Iowa grows a lot of corn—more, in fact, than all but three countries. But a harvested corn plant is only about 50 percent corn grain, and the other half is cellulosic biomass (the stalks, leaves and cobs, called stover). While it's important to leave some stover behind to protect the soil, we can harvest enough to add a billion gallons of ethanol production in Iowa, without using another kernel of corn. Other states throughout the country also produce large amounts of agricultural residues and manure, which can be made into biofuels, renewable electricity and biogas.

Andy Heggenstaller, DuPont Pioneer in front of corn stover bales. Photo credit Brendan McLaughlin.

3. … Yet lots of corn = Lots of problems

90 percent of Iowa is farmland, and 70 percent of that land is planted with just two crops:corn and soybeans. Common farming methods leave bare soil exposed most of the year to increasingly severe weather. Storms can wash tons of Iowa's famous black soil into waterways in just a few days, and fertilizer coming off farm fields (and through subsurface drainage) creates major pollution problems both in Iowa and downstream in the Gulf of Mexico.

Photo showing soil erosion after five inches or more of rain fell in one hour across portions of Western Iowa in 2013. Photo credit USDA NRCS.

4. Smart biofuels means smart farming

The only way to make sustainable biofuels is to practice sustainable farming. Iowa State University and companies like AgSolver are employing complex modeling tools to help farmers make smart economic decisions on their land: where to plant corn, where it makes sense to use part of their corn stover to make ethanol, and where they should plant perennial grasses (highly productive sources of cellulosic biomass) instead or corn. Not only can this make the farmers' operations more profitable, it can keep pollution out of the water, reduce erosion, and someday soon, produce biomass for cellulosic biofuel.

Cereal rye cover crop planted into corn stubble. Photo credit USDA NRCS.

5. Perennial crops have a big role to play

For the foreseeable future, Iowa will continue to grow a lot of corn and soybeans, but integrating perennial grasses into the system can provide benefits far in excess of the land they occupy. Scientists from the STRIPS research team (Science-based Trials of Row-crops Integrated with Prairie Strips) have shown that by strategically converting as little as 10 percent of a row-cropped field to perennial prairie—in narrow patches along contours and foot slopes—farmers and landowners can reduce soil erosion and fertilizer runoff by 85-95 percent. As cellulosic biofuel production scales up, there will be a growing market for these clean, sustainable crops.

Professor Matt Helmers from Iowa State showed us around the STRIPS project. Photo credit Amanda Bilek.

To cut oil use and carbon emissions from transportation and make our agricultural system more resilient and sustainable, we need to change the way we produce fuel and the way we farm. Experts in Iowa are hard at work making that happen. Seeing the beginning of large-scale production of corn-stover based cellulosic biofuel is exciting: the technology is working, and sets us up well to begin growing and harvesting perennial crops to feed the growing industry. It's an important milestone on the road to clean fuels and sustainable agriculture.

About the author: Jeremy Martin is a scientist with expertise in the technology, lifecycle accounting, and water use of biofuels. He is working on policies to help commercialize the next generation of clean biofuels (made from waste and biomass rather than food) that can cut U.S. oil dependence and curb global warming. Production Begins At Second Cellulosic Biofuel Facility

October 17, 2014 ***Jeremy Martin, senior scientist, Clean Vehicles***

You don't often hear Kansas and Spain mentioned in the same sentence. Yet today Spanish company Abengoa is bringing another big cellulosic biofuel facility online in Hugoton, a small community in the Southwest corner of the state. This is the second big plant starting up this year, showing that after some predictable yet highly scrutinized delays, the cellulosic fuel industry is truly beginning to establish itself and making critical contributions to oil savings and climate goals.

Abengoa's plant in Hugoton Kansas will produce 25 million gallons of cellulosic biofuels and 21 MW of electricity per year – enough to power the plant and sell some back to the local Stevens County community. Photo credit: Abengoa

It wasn't long ago that cellulosic biofuels were the punchline of a joke: a phantom fuel that could not be economically produced in large volumes. Fast forward to today, and we see headlines like "Advanced Ethanol Makers Are Trying to Give Big Oil a Run for Its Money."

I wrote recently about the two cellulosic biofuels facilities we visited in Iowa, and about the use of landfill and dairy digester gas to power compressed natural gas and electric vehicles. The Abengoa plant will double the production capacity on line for cellulosic ethanol, and do it without consuming a kernel of corn. The Abengoa plant is also worth noting because it represents an investment in America's clean energy future by a major international company, and it is by no means the only one.

Large companies making big investments

Major companies from all over the world have come to the US to invest in cellulosic biofuel as the result of our smart people, our abundant biomass resources, and a policy environment committed to steady growth in clean fuels. Yet the US is certainly not the only place that cellulosic biofuels are coming on line. There is also a major cellulosic biofuels facility in Italy, and a cellulosic biorefinery just started up in Brazil, which has a longstanding commitment to renewable fuels.

Beta Renewables' cellulosic ethanol facility in Crescentino, Italy opened in October of 2103, and uses enzymes made by Novozymes to produce ethanol from wheat straw and perennial grasses. Photo credit: Novozymes

The cellulosic plant that opened in Iowa in August is a collaboration of Poet, a major US ethanol company, and Royal-DSM, a company from the Netherlands (they are not kidding about the royal part either: King Willem-Alexander of the Netherlands was there for the grand opening). Another major player in cellulosic biofuels is Danish firm Novozymes, which makes enzymes to power cellulosic biofuel production and has major facilities in Nebraska and North Carolina.

It is worth pointing out that major international companies, not just Royal-DSM and Novozymes but also Beta Renewables that just started the cellulosic facility in Brazil, are investing both in Brazil and the United States. And as the U.S. policy landscape has looked less attractive, investment is moving to Brazil. The question is no longer whether or not cellulosic biofuels will arrive; it's how big a part in the industry our country will play.

GranBio started up Brazil's first commercial scale cellulosic ethanol facility in in Alagoas, where sugarcane straw and bagasse are made into ethanol and renewable electricity. Photo credit: GranBio

Policy instability = Lost investment

Seven years ago, we set a course to cut oil use by improving the efficiency of our vehicles and by expanding the use of renewable fuels. The Renewable Fuel Standard, which calls for increasing biofuels production steadily over time, is central to that plan. Yet as opposition to the standard (driven largely by the oil industry) has increased, what was once a stable policy landscape has begun to shift.

I disagree with some biofuels supporters who suggest that any adjustments to the RFS will spell the end of investment in advanced biofuels. I have been arguing for a couple years that a more flexible approach to RFS is needed, and that EPA was right to make some adjustments. I am less concerned about exactly what production volume target EPA sets for 2014 or 2015 than with how they reset the policy in the timeframe 2016 to 2022 and beyond. Establishing policy stability over the next 5 to 10 years is what will support the next round of investment. And strong regional policies like the California Low Carbon Fuels Standard and related clean fuels policies in Oregon and Washington can accelerate the trend further, drawing investment in clean fuels technology from around the world to the US and to these states in particular.

Steady progress on cutting oil use

Oil use has been steadily growing for about 100 years, so our half the oil plan was never going to be something we could execute overnight, but the progress to date is very encouraging: vehicle efficiency is improving and biofuel production has doubled since the RFS was signed in 2007.

The bulk of the oil savings so far have come from technology that was available and ready to scale up rapidly. But to make the deep reductions in oil use and carbon emissions we need to respond to climate change, we need to move on to more advanced technologies like electric vehicles and cleaner biofuels made from abundant and environmentally friendly sources of biomass.

The progress of the policies put in place in 2007 is encouraging, and also a reminder that it takes time to move technology from labs, to pilot plants, to full-scale production. The Abengoa plant opening is the latest evidence that these advanced technologies are making progress also.

About the author: Jeremy Martin is a scientist with expertise in the technology, lifecycle accounting, and water use of biofuels. He is working on policies to help commercialize the next generation of clean biofuels (made from waste and biomass rather than food) that can cut U.S. oil dependence and curb global warming. He holds a Ph.D. in chemistry with a minor in chemical engineering.

5_OP_LCFS_UCS Responses

30. Comment: **LCFS 5-1**

    The comment supports the re-adoption of the LCFS regulation.

    Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

31. Comment: **LCFS 5-2**

    The commenter supports the goals of the LCFS program but states the timeline should be longer than five years.

    Agency Response: The regulation recommended to the Board retains the requirement for a 10 percent carbon intensity reduction in 2020 and beyond. Additionally, further reductions are feasible beyond 2020. Staff will return to the Board with a proposal for additional reductions beyond 2020 if the Board so directs.

32. Comment: **LCFS 5-3**

    The commenter supports several technical updates which strengthen the LCFS regulation.

    Agency Response: ARB staff appreciates the support for the proposed changes to the lifecycle analysis and the innovative crude provision and the support for the inclusion of the refinery investment and cost containment provisions.

33. Comment: **LCFS 5-4**

    The commenter supports the LCFS regulation and 2020 goals and recommends that the time-frame for the regulation extend beyond 2020.

    Agency Response: See response to **LCFS 5-2**.

34. Comment: **LCFS 5-5**

    The comment supports the cost-containment provisions in the LCFS regulation.

    Agency Response: ARB staff appreciates the support for the cost containment provisions.

Honorable Chairman Mary D. Nichols and Honorable Board Members
California Air Resources Board
1001 I Street
P.O. Box 2815
Sacramento, CA 95812

Re: SUPPORT for Re-Adoption of the Low-Carbon Fuels Standard

Dear Chairman Nichols and Honorable Board Members:

The California Electric Transportation Coalition (CalETC) appreciates the opportunity to comment in support of re-adoption of the Low Carbon Fuels Standard (LCFS). CalETC is a non-profit association with a board of directors that includes: Los Angeles Department of Water and Power, Pacific Gas & Electric, Sacramento Municipal Utility District, San Diego Gas & Electric and Southern California Edison. Our membership also includes major auto makers and we work closely with our colleagues in the alternative fuels community.

First, we laud the California Air Resources Board (CARB) in the design and implementation of the LCFS. The regulation sets a standard for the regulated industry and allows the industry to determine how best to meet that standard, providing flexibility in an industry long constrained by the transportation sector's near-total dependence on only one fuel. The LCFS program has resulted in unanticipated innovation in both fuels and vehicles and expanded consumer choice. In the first years of implementation of the LCFS, industry is over-complying, credits are being generated from unanticipated and innovative sources, and consumers are responding to expanding choices in fuels and vehicles. LCFS 6-1

We respectfully submit the following comments:

- CalETC appreciates the addition of forklifts and fixed guideway systems in the LCFS program. The definition of transportation fuel in LCFS includes non-road uses of transportation fuel. Including forklifts and fixed guideway systems ensures that expanded transportation fuel opportunities are available for both the regulated industry and the fuel providers. LCFS 6-2
- CalETC supports the staff's proposal to stay the course and meet a ten percent (10%) reduction in the carbon content of fuels sold in California by 2020. This is essential to providing market certainty for alternative fuel providers, particularly given the overwhelming market advantage the predominant fuel has in the transportation fuels sector. LCFS 6-3
- CalETC supports the staff's proposal for a credit clearance option to cost containment. We respectfully suggest that additional analysis be conducted to determine the appropriate maximum price per credit in the clearance market. Establishing a maximum price which is too low may have negative implications, such as stifling innovation and inhibiting the market. LCFS 6-4

We also respectfully suggest that additional analysis be completed to develop a minimum price per credit, or price floor, for LCFS credits. Certainty for the regulated parties and credit generators can be achieved through both cost containment and price floor mechanisms. LCFS 6-5

In closing, CalETC supports re-adoption of this groundbreaking and essential regulation. Thank you for your consideration and ongoing leadership. LCFS 6-6

Regards

Eileen Wenger Tutt, Executive Director
California Electric Transportation Coalition

EWT/kmg

6_OP_LCFS_CalETC

35. Comment: **LCFS 6-1**

The comment supports the cost-containment provisions in the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

36. Comment: **LCFS 6-2**

This comment supports the inclusion of forklifts and fixed guideway systems provisions in the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the inclusion of forklifts and fixed guideway systems provisions.

37. Comment: **LCFS 6-3**

This comment supports the proposed compliance curves in the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the proposed compliance curves.

38. Comment: **LCFS 6-4**

This comment gives support for the credit clearance option in the cost containment provision. Additionally, it was suggested to perform additional analysis before the price ceiling has been determined.

Agency Response: ARB staff appreciates the support for the credit clearance option to the cost containment provision.

ARB staff proposes that the cost containment threshold for 2016 be set at $200 per metric ton of carbon dioxide-equivalent (MTCO2e) and adjusted annually using a Consumer Price Index deflator to keep pace with inflation and remain at a constant price, in real terms. Staff is further proposing that any compliance debt (in $MTCO_2e$) that is carried over into the next compliance year after the annual credit clearance process has been completed be assessed a five percent interest on that debt until such time that the debt is paid off. Furthermore, all deferred deficits must be repaid within five years. These provisions will encourage regulated parties to erase any compliance debts that they may accrue as soon as possible.

Reducing both these sources of uncertainty is anticipated to increase the incentives for investment. Potential investors may be hesitant to invest in low-CI fuel production facilities given conditions of undue uncertainty, particularly because production facilities for low-CI fuels are typically capital-intensive projects with relatively long payback periods.

39. Comment: **LCFS 6-5**

The comment suggests ARB staff perform additional analysis to develop a price floor.

Agency Response: ARB staff analyzed the potential benefits of a price floor to send a stronger price signal to increase investments in low-CI fuels and to further reduce market uncertainty and credit price volatility. Staff chose not to move forward with this concept in this rulemaking because we believe the compliance curve will send appropriate signals for investment and because of the challenges in setting an appropriate value for the floor. Staff appreciates the ongoing dialogue with, and feedback from, stakeholders regarding whether this topic should be proposed as a future LCFS amendment.

40. Comment: **LCFS 6-6**

This comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

RE: comments regarding the proposed Alternative Diesel Fuel (ADF) Regulations and the Low Carbon Fuel Standard

Dear Chairwoman Nichols:

As California's largest in-state producer of biodiesel (we utilize used cooking oil and distiller's corn oil to produce an ultra-low carbon alternative diesel fuel with an average quarterly carbon intensity for 2013 and 2014 of 12 to 16.5) , we are naturally very interested in the proposed Alternative Diesel Fuel (ADF) Regulations and the Low Carbon Fuel Standard (LCFS). Any proposed ADF regulations and/or changes to LCFS could have a profound impact on the California biodiesel market and on the ultimate viability of our Bakersfield biodiesel plant. The Crimson team would like to thank members of the ARB staff and Board Members for their hard work on this rulemaking and their ongoing willingness to engage with us and other industry stakeholders. We greatly appreciate the time that ARB staff members have taken and the positive relationships they've encouraged.

Economic Impact

Before getting into our comments on the proposed ADF regulations and the future direction of LCFS, I would like to provide some additional information about our biodiesel production facility in Bakersfield, California. Specifically, I hope this information will provide the Air Resources Board and its affiliated regional air districts a context to better understand the economic impact of proposed ADF regulations and LCFS.

Our biodiesel production facility in Bakersfield currently has 25 full time employees, and an additional 6 long term, full-time contractors. The plant was built in order to serve the market for very low carbon fuels created by the LCFS.s Based on our spending in 2014, our annual direct economic contribution was $40 million, of which approximately 87% was spent within California and significant portion of this was spent in Bakersfield and other parts of the Central Valley. The average annual 2014 compensation per person employed at the plant not including the senior management positions is approximately $64,000. Furthermore, several of our plant employees came to us without the full range of experience that is required and we have invested significantly in their training.

We are also currently in the midst of an expansion project that began in early 2014 and will be completed in summer 2015 entailing a total investment of nearly $10 million. The first phase of this project was completed in May 2014 enabling us to increase our annualized production rate from 9.5 mil gal/yr to 14mil gal/yr. Upon completion, our plant capacity will grow to 22 mil gal/yr. At that point, the plant will make a direct economic contribution of $70 - $90 million per year (depending on raw material prices) with 89-93% of this being spent within California, and 36-38 full time employees and long-term contractors.

ADF 7-1

Thus we believe that our biodiesel production facility is making a strong and growing economic and job creation contribution locally (which is also considered an economically disadvantaged area) and within California. However, it is important to note that we are but one plant out of 5 current biodiesel producers. The California Energy Commission estimated that in 2014 biodiesel production within California will be approximately 40 million gallons. Based on our Bakersfield plant's spending this year, this would come out to a total direct economic contribution of approximately $122 million in 2014. The CEC has projected in-state biodiesel production to grow to 55 million gallons in 2016, representing an economic contribution of approximately $200 million. These figures deserve serious

Fax: (720) 475-5399

acknowledgement given the fact that the ADF Rulemaking will reduce the market opportunity for biodiesel in California and this would be disproportionately felt by in-state producers such as Crimson, especially given the markedly higher costs of operating in California as compared to elsewhere in the U.S. or internationally. The same is true if the ARB decides to push back the timeline for LCFS carbon reductions.

ADF 7-1 cont.

Emissions / Health Benefits

As we and other stakeholders have pointed out previously to ARB staff, biodiesel is a solution to very specific problems associated with petroleum diesel's emissions profile – namely the well-known toxics, particulates, and carcinogens that are currently causing unacceptable levels of respiratory illness in California, especially in the Central Valley, the areas surrounding the Port of Long Beach and Port of Los Angeles, and especially among California's children and elderly and its economically disadvantaged communities (such communities tend to be concentrated near industrial areas where truck traffic is disproportionately higher than in other communities). Indeed, "Biodiesel's reduction in PM emissions and associated risks" were acknowledged in the ARB staff presentations at previous ADF Rulemaking Workshops and some air districts in California are out of compliance for PM reductions. Besides PM reduction, biodiesel also provides significant reductions in polycyclic aromatic hydrocarbons (PAHs), nitrated PAHs, and the ozone potential of spectated hydrocarbons. According to the Union of Concerned Scientists and the American Lung Association (http://www.ucusa.org/clean_vehicles/trucks_and_buses/page.cfm/pageID=1429), PM and other hydrocarbon emissions within California are responsible for an estimated 3,000 premature deaths , 2,700 cases of bronchitis, and 4,400 hospital admissions, ultimately creating additional healthcare costs totaling $21+billion.

Biodiesel also provides very large reductions in carbon/GHG emissions (85-95% reduction in carbon/GHG for biodiesel made from used cooking oil and distiller's corn oil from ethanol plants) that are critical to meeting LCFS carbon reduction requirements. According to ARB, in Q1/2014 biodiesel provided 18% of all LCFS credits generated.

Thus we strongly urge the ARB to consider the PM, hydrocarbon toxics, and carbon/GHG reductions and associated health benefits when evaluating any ADF regulatory proposal. Additionally, we urge the ARB to consider that the proposed ADF regulations would be in effect during a period when New Technology Diesel Engines (NTDEs, which reduce all tailpipe NOx emissions by 90% regardless of type of fuel) are being phased in due to existing California law.

ADF 7-2

Comments on LCFS Reauthorization and Specific Aspects of the Proposed ADF Regulations

We ask that ARB Members consider the following points as it continues deliberations on LCFS reauthorization and the proposed ADF regulations.

1. LCFS is working as intended – ARB reporting on LCFS credit generation and deficits from 2011 through Q3/2014 shows 9.80 mil MT credits generated and 5.84mil MT in deficits, creating excess credits of 3.96 mil MT. This data is consistent with original ARB staff projections for the rate of credit generation at this point in the program. Clearly the LCFS has created sufficient market signals to attract the necessary volumes of alternative fuels. Our plant in Bakersfield is but one example among many of how LCFS has influenced investment decisions to create alternative fuel production capacity.

LCFS 7-1

2. LCFS carbon reduction timelines – We strongly urge the ARB and its Members to maintain the original LCFS CI reduction at 10% by 2020. We further encourage the ARB to establish stronger compliance curves to continue progress beyond 2020. Maintaining the 10% reduction is 2020 is absolutely critical to send the right market signals to encourage the availability of large volumes of alternative fuels, development of new low carbon fuel technologies, and incentivize significant alternative fuel utilization. Any pushing back of this timeline would send the opposite signal, devalue alt fuel investments made thus far, and discourage future investment. We believe the 10% reduction is fully achievable in 2020. We agree with the findings in the 2/2/15 Promotum report sponsored by the National Resource Defense Council, stating a $100/MT LCFS credit price will incentivize sufficient volumes of alt fuels to be produced and imported into California and reducing CI intensity of petroleum based fuels. Using alternative diesel fuels as a case in point, there is sufficient excess industry-wide production capacity to greatly increase the volumes of biodiesel and renewable diesel

LCFS 7-2

CRIMSON
RENEWABLE ENERGY, LP

17731 Millux Road
Bakersfield, CA 93311
Tel: (661) 617-8610
Fax: (720) 475-5399

imported into California (the National Biodiesel Board reports 2.5 bil gal of current U.S. biodiesel production capacity vs actual 2014 domestic production of 1.6 bil gal). LCFS 7-2 cont.

3. LCFS Program integrity – In line with creating transparent and predictable market rules, ARB should adopt rule proceedings in the event that fraudulent credit trades or other invalid activities are discovered. We would recommend that ARB carefully consider the experience of the US Environmental Protection Agency in its enforcement of the Renewable Fuel Standard (RFS). Delayed prosecutions and a lack of concern for collateral damage caused to good faith market participants undermined respect for the RFS program and the value of RFS credits. We would encourage ARB to insulate good faith market participants from disproportional impacts and to avoid wholesale invalidation of credits. Due to the complex and novel nature of environmental attribute markets, ARB must invest in sufficient resources and personnel to ensure effective enforcement. LCFS 7-3

4. Impact of ADF Regulations on California Biodiesel Industry – From a California biodiesel producer's perspective the proposed ADF regulations are not ideal for the simple fact that, despite the various economics , emission and health benefits offered by biodiesel, limits will be placed on biodiesel usage in California. However, we do believe that the proposed ADF regulations reflect input from the biodiesel industry and many other stakeholder groups. ARB Staff was really done outstanding job in reaching out to all stakeholders for consistent engagement. As such we feel that the biodiesel usage limits prescribed by the proposed ADF regulations are not unreasonable. They are workable and will achieve the desired goals for NOx management while retaining the ability to meaningfully take advantage of the significant benefits offered by biodiesel blending in California. ADF 7-3

5. ADF Regulation implementation timeline – The proposed ADF regulations will require significant change within the industry, including new labeling at each retail dispenser and the joint development of new compliance and tracking mechanisms. Other agencies such as the Division of Weights and Measures will require time to adapt their biodiesel related regulations (there may be a need to change the current California labeling requirements at retail dispensers).Thus we believe the implementation timelines as stated in the proposed ADF regulations are reasonable and necessary. ADF 7-4

6. Mitigation options - We applaud the ARB's understanding that DTBP additive is not an ideal mitigation option for several safety, financial and operational reasons, and thus preserved in the proposed ADF regulations the ability to approve other NOx mitigation additives. We would only add that we hope ARB staff will diligently pursue this in a timely manner in partnership with the biodiesel industry, and consider the use of current commercially available cetane enhancers. ADF 7-5

7. Accounting for NTDE and Sunset Provisions -. NTDE vehicles which reduce NOx by 90%+ already make up 25%+ of the current heavy duty diesel fleet in California and will grow to 95% by 2023 as required by ARB fleet turnover regulations. In light of this, we believe it is completely reasonable and appropriate that the ADF regulations will sunset when vehicle miles travelled by NTDE heavy duty vehicles reach 90% of the total miles travelled by the California heavy-duty diesel vehicle fleet. ADF 7-6

We greatly appreciate this opportunity to comment. Please feel free to contact me should you have any questions.

Sincerely yours,

Harry Simpson
President

7_OP_LCFS_CRE Response

41. Comment: **LCFS 7-1**

This comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

42. Comment: **LCFS 7-2**

The comment strongly suggests that ARB continue the LCFS timeline beyond 2020.

Agency Response: See response to **LCFS 5-2**.

43. Comment: **LCFS 7-3**

The comment urges ARB to monitor the LCFS program to retain program integrity and to insulate good faith market participants.

Agency Response: ARB staff agrees that monitoring, auditing and enforcement of the LCFS Program are critical to ensure the emission benefits of the program are realized. The ARB's Enforcement Division is authorized to enforce the regulations adopted by our Board. Enforcement and LCFS Program staff persons coordinate efforts to ensure that rules are fully followed. Additionally, LCFS Program management has paired with Cap-and-Trade Program management to create a branch within ARB that verifies the underlying data used to create credits. The new branch will facilitate a consistent agency approach regarding transportation fuels.

ARB staff is aware of the voluntary quality assurance plan provisions that the U.S. Environmental Protection Agency (U.S. EPA) has adopted in the Renewable Fuel Standard (RFS) Program. ARB staff has had discussions with U.S. EPA staff regarding their implementation experience with this recently-adopted provision, as the RFS uses a similar "buyer-beware" approach. The RFS Program requires that all retired credits which are found to be invalid must be offset by valid credits with real emission benefits. Currently, LCFS market participants can do their own due diligence to ensure the validity of the LCFS credits, and these efforts will be taken into consideration if invalid credits are found.

If fraud is discovered, the Health and Safety Code and a host of other state and federal statutes may apply and provide civil and criminal consequences. ARB staff will investigate the most culpable party available to replace invalid credits and face other legal consequences; however, because identifying and locating a “most culpable” party is sometimes difficult or impossible, staff does not deem it wise to immunize other parties who hold or previously held invalid credits. To do so would be to risk losing the programs benefits in cases where the culpable party could not be found or compelled to replace credits. This “buyer beware” policy should also incent all parties to perform appropriate due diligence prior to purchasing credits.

RENEWABLE FUELS ASSOCIATION

8_OP_LCFS _RFA

February 16, 2015

Mary Nichols
Chairwoman
California Air Resources Board
1001 "I" Street
Sacramento, CA 95812

Dear Chairwoman Nichols,

The Renewable Fuels Association (RFA) appreciates the opportunity to provide comment on the California Air Resources Board's (CARB) Initial Statement of Reasons (ISOR) regarding re-adoption of the Low Carbon Fuel Standard (LCFS). While the proposal for re-adoption marks a slight improvement over the current regulation, we remain deeply concerned by several aspects of the proposal and believe it threatens the long-term durability of the LCFS program. Thus, RFA believes the ISOR needs significant revision before it can be presented to the Board for approval.

Grain-based ethanol has made a substantial contribution to LCFS compliance in the first four years of the program. Indeed, ethanol has accounted for **59% of total credits** generated from 2011Q1 through 2014Q3, and 95% of the ethanol used for compliance has been grain-based ethanol, according to CARB reporting data. If not for the LCFS credits generated by grain-based ethanol, deficit generation would have certainly outpaced credits by now, and compliance with the program would be extremely difficult, if not impossible. Thus, it is not an exaggeration to state that the LCFS has endured so far **only because of the contributions of grain ethanol**. Yet, the ISOR proposes to continue punitive carbon intensity (CI) penalties for grain ethanol and other crop-based biofuels based on purported indirect land use change (ILUC) emissions. If finalized, the proposed re-adoption regulation will make the use of most grain ethanol infeasible for compliance as early as 2016. Why would CARB use flawed and prejudicial analysis to purposely diminish the compliance viability of the low-carbon fuel that has provided the largest volume of credits to date? LCFS 8-1

As the attached comments show, CARB's ILUC analysis remains technically and methodologically flawed, and grossly overstates the land use impacts associated with biofuels expansion. A November publication by the Center for Agricultural and Rural Development (CARD) at Iowa State University makes a remarkably important contribution to the debate over ILUC modeling. The report marks the first time that actual land use changes over the past decade (i.e., the period in which commodity crop prices rose to record levels) have been quantified and discussed in the context of CARB's ILUC modeling results. The CARD/ISU paper, which is discussed in detail in the attached comments, found that "[t]he pattern of recent land use changes suggests that **existing estimates of greenhouse gas emissions caused by** LCFS 8-2

land conversions due to biofuel production are too high because they are based on models that do not allow for increases in non-yield intensification of land use." In essence, the authors found that the primary response of the world's farmers to higher crop prices "…**has been to use available land resources more efficiently rather than to expand the amount of land brought into production**." LCFS 8-2 cont.

The CARD/ISU research was submitted to CARB in early December. However, CARB's ISOR fails to even mention or acknowledge the work in any way. For the first time, we have real-world data that provides important insight into actual market responses to increased biofuels demand and higher crop prices. As described in the attached comments, we believe CARB must take into account the new CARD/ISU research and use it to immediately re-calibrate the GTAP model. LCFS 8-3

We appreciate CARB's consideration of our attached comments, which also address CA-GREET model revisions and assumptions used in CARB's illustrative compliance scenarios. We welcome further dialog on this subject and look forward to responses to any of the comments offered in the attached document.

Sincerely,

Geoff Cooper

Geoff Cooper

RENEWABLE FUELS ASSOCIATION

COMMENTS OF
THE RENEWABLE FUELS ASSOCIATION
IN RESPONSE TO THE CALIFORNIA AIR RESOURCES BOARD
STAFF REPORT: INITIAL STATEMENT OF REASONS
TO CONSIDER
RE-ADOPTION OF THE LOW CARBON FUEL STANDARD (LCFS)

The Renewable Fuels Association (RFA) offers the following comments in response to the California Air Resources Board's (CARB) release of its Initial Statement of Reasons (ISOR) proposing re-adoption of the Low Carbon Fuel Standard (LCFS)

I. Indirect Land Use Change Analysis

CARB continues to rely on a fundamentally flawed approach to predicting indirect land use change (ILUC) that favors hypothetical modeling results over empirical data, real-world observations, and improved assessment methods.

Nearly six years have passed since CARB originally adopted the LCFS, which included carbon intensity (CI) penalties for certain biofuels for predicted ILUC. In the intervening years since the program was adopted, the scientific understanding of land use change has significantly progressed. Retrospective analyses of global agricultural land use have been conducted, actual market responses to increased demand and higher commodity prices have been observed and characterized, the reliability of predictive economic models has been improved, and new data has emerged to better guide certain modeling assumptions.

Yet, in spite of these advances in the science, CARB continues to rely on the narrow—and completely unsubstantiated—view that "[a] sufficiently large increase in biofuel demand in the U.S. would cause non-agricultural land to be converted to cropland both in the U.S. and in countries with agricultural trade relations with the U.S." LCFS 8-4

CARB's entire approach to ILUC is founded on the notion that farmers are limited to only two responses to increased demand for crops. While CARB recognizes four potential market responses to heightened demand for crops, its predictive modeling framework essentially allows only two of these responses to play out. The four potential market responses acknowledged by CARB are shown below.

- **Response 1**: "Grow more biofuel feedstock crops on existing crop land by reducing or eliminating crop rotations, fallow periods, and other practices which improve soil conditions";
- **Response 2**: "Convert existing agricultural lands from food to fuel crop production";
- **Response 3**: "Convert lands in non-agricultural uses to fuel crop production"; or
- **Response 4**: "Take steps to increase yields beyond that which would otherwise occur."

CARB theorizes that there is essentially no crop yield response to increased demand (Response 4 above), and an artificially low elasticity value is used to reflect this belief in CARB's economic model. Further, the CARB modeling framework does not allow double-cropping or reduction of fallow/idle cropland; thus, Response 1 above is also eliminated. *As a result, CARB assumes increased demand for crops can only be met through displacement of animal feed and conversion of non-agricultural lands to crop production (Responses 2 and 3 above).* Not coincidentally, Responses 2 and 3 have the most significant GHG impacts.

CARB has produced no evidence whatsoever that such land conversions have actually occurred on a meaningful scale in response to the LCFS or growth in U.S. biofuels demand. Indeed, empirical evidence suggests that demand growth has been primarily met through Responses 1 and 4 above, which are effectively excluded from CARB's modeling framework. LCFS 8-4 cont.

Instead of tuning the modeling framework to reflect these observed market responses, CARB continues to rely on conjectural assumptions and model predictions to penalize biofuels for hypothetical market outcomes. In essence, CARB is using the exact same approach to estimating ILUC emissions that it used six years ago, making only minor adjustments to certain model parameters based on "judgment calls."

RFA believes the principles of sound policymaking and regulation demand that CARB recognize and incorporate the best available science and data in the LCFS process, particularly when empirical data is available to fill important knowledge gaps.

a. A New Publication by Babcock & Iqbal Has Important Implications for CARB's ILUC Analysis. CARB Should Give Serious Consideration to the Findings of the Paper, and Adjust its ILUC Estimation Methodology Accordingly

In mid-November, Babcock & Iqbal at the Center for Agricultural and Rural Development (CARD) published Staff Report 14-SR 109, "Using Recent Land Use Changes to Validate Land Use Change Models."[1] The paper (Attachment 1) makes a remarkably important contribution to the debate over ILUC modeling. The report marks the first time that actual global land use changes over the past decade (i.e., the period in which commodity crop prices rose to record levels) have been quantified and discussed in the context of CARB's ILUC modeling results. <u>The report was submitted to CARB staff in early December 2014, yet there is not a single mention of the paper (nor is there a response to its findings) in the ISOR.</u> LCFS 8-5

Babcock & Iqbal examined historical global land use changes from 2004-2006 to 2010-2012 and determined that "…the primary land use change response of the world's farmers from 2004

[1] Babcock, B.A. and Z. Iqbal (2014), Using Recent Land Use Changes to Validate Land Use Change Models. Center for Agricultural and Rural Development Iowa State University Staff Report 14-SR 109. Available at: http://www.card.iastate.edu/publications/synopsis.aspx?id=1230

to 2012 has been to use available land resources more efficiently rather than to expand the amount of land brought into production."[2] Among other important revelations, the paper shows that key regions where CARB's GTAP analysis predicts biofuels-induced conversion of forest and grassland have actually experienced substantial *losses* of cropland.

Unfortunately, CARB's GTAP analysis does not take into account the methods of intensification (e.g., double-cropping, increases in the share of planted area that is harvested, return of fallowed land to production) that have been observed in the real world over the past decade. According to Babcock & Iqbal, GTAP and other models "…do not capture intensive margin land use changes so they will tend to ***overstate land use change at the extensive margin and resulting emissions***."[3] This finding is corroborated by Langeveld et al (2013) (Attachment 2), who found GTAP and other models have "…limited ability to incorporate changes in land use, ***notably cropping intensity***," and "[t]he increases in multiple cropping have often been overlooked and should be considered more fully in calculations of (indirect) land-use change (iLUC)."[4]

LCFS 8-5 cont.

Ultimately, the Babcock & Iqbal work calls into question the plausibility of CARB's GTAP results and demonstrates that CARB's ILUC results are directionally inconsistent with real-world data and observed market behaviors in many regions. The data and discussion presented in the paper challenge the very underpinnings of CARB's analysis and are simply too important for the agency to ignore. Thus, as described more fully in the comments below, <u>we believe CARB should move immediately to calibrate its GTAP model using the real-world land use data made available by Babcock & Iqbal</u>.

b. Countries and regions where cropland has decreased and/or forestland and grassland have increased over the past decade should be presumed to not have converted pasture or forest to crops in response to biofuel-induced higher prices. CARB should calibrate its GTAP model to reflect the absence of extensive land use change in these countries and regions.

At the outset, it is important to note that the lack of a "counterfactual case" to compare to the real-world data (i.e., the *ceteris paribus* principle) is not sufficient reason to ignore the Babcock & Iqbal results. CARB has stated that comparing GTAP results to real-world data is "not productive," because it is not possible to compare real-world data to a counterfactual case in which biofuel expansion did not occur. Appendix I to the ISOR further states:

LCFS 8-6

> GTAP-BIO is not predicting the *overall aggregate* market trend—only the incremental contribution of a single factor to that trend. If GTAP-BIO projects reduced exports, for example, this should be understood to mean that exports will be lower than what they would have been in

---
[2] *Id,* Executive Summary.
[3] *Id,* Executive Summary. (emphasis added)
[4] Langeveld, J. W.A., Dixon, J., van Keulen, H. and Quist-Wessel, P.M. F. (2014), Analyzing the effect of biofuel expansion on land use in major producing countries: evidence of increased multiple cropping. Biofuels, Bioprod. Bioref., 8: 49–58. doi: 10.1002/bbb.1432. (emphasis added)

> the absence of the effect being modeled (increased ethanol production, in this case). It is the difference between predicting an absolute change and a relative change.[5]

This statement by CARB seems to misunderstand the recommendation from stakeholders to consider and integrate empirical data and observed outcomes into CARB's modeling work. *RFA and other stakeholders fully understand that CARB's GTAP modeling exercise is meant to isolate only the impacts of biofuels expansion on land use.* However, empirical data can be useful for checking the directional consistency and general reasonableness of model predictions. According to the Babcock & Iqbal, "…the historical record of land use changes can be used to provide insight into the types of land that were converted…"[6]

Comparing empirical land use data to GTAP predictions is particularly useful in regions where cropland has contracted over the past decade. That is, if cropland in a certain region *decreased* according to historical data, then there is no justification for asserting—as GTAP does—that biofuel expansion caused extensive margin conversion of natural forest and grassland in that region. In other words, if there was no cropland expansion resulting from biofuels expansion *and all other factors combined* (i.e., in aggregate), then there certainly is no rationale for arguing that biofuels expansion in isolation of other factors led to cropland expansion.

That is not to say, however, that biofuels expansion did not have an impact on land use in the region. Indeed, cropland may have contracted *even more* in a "world without biofuels" (i.e., the counterfactual case). In other words, some additional cropland might have gone out of production in the absence of biofuels, and the function of biofuels demand may have been to keep that cropland engaged in production. Thus, the appropriate question for regions that have experienced cropland *contraction* over the past decade is whether there was foregone sequestration because of biofuels—***not*** whether there was extensive conversion of forest and grassland and soil carbon loss because of biofuels. According to Babcock & Iqbal:

> The countries in Figure 8 that either had negligible or negative extensive land use changes **should be presumed to not have converted pasture or forest to crops in response to biofuel-induced higher prices**. Rather, the presumption should be that **any predicted change in land used in agriculture came from cropland that did not go out of production**.[7]

Figure 8 from Babcock & Iqbal is embedded below. Note that many countries and regions for which CARB's latest GTAP analysis predicts extensive change from forest and grassland to crops actually showed cropland losses or no change. This includes Canada, EU, Japan, China, India, Russia, the U.S., and Oceania. Further, the amount of corn ethanol-induced conversion of

LCFS 8-6 cont.

[6] Babcock, B.A. and Z. Iqbal (2014) at executive summary.
[7] *Id*. at 26.

forest and grassland in the U.S. predicted by CARB's GTAP model is two to four times larger than the actual extensive land use change in the U.S. driven by ***all factors in aggregate***.

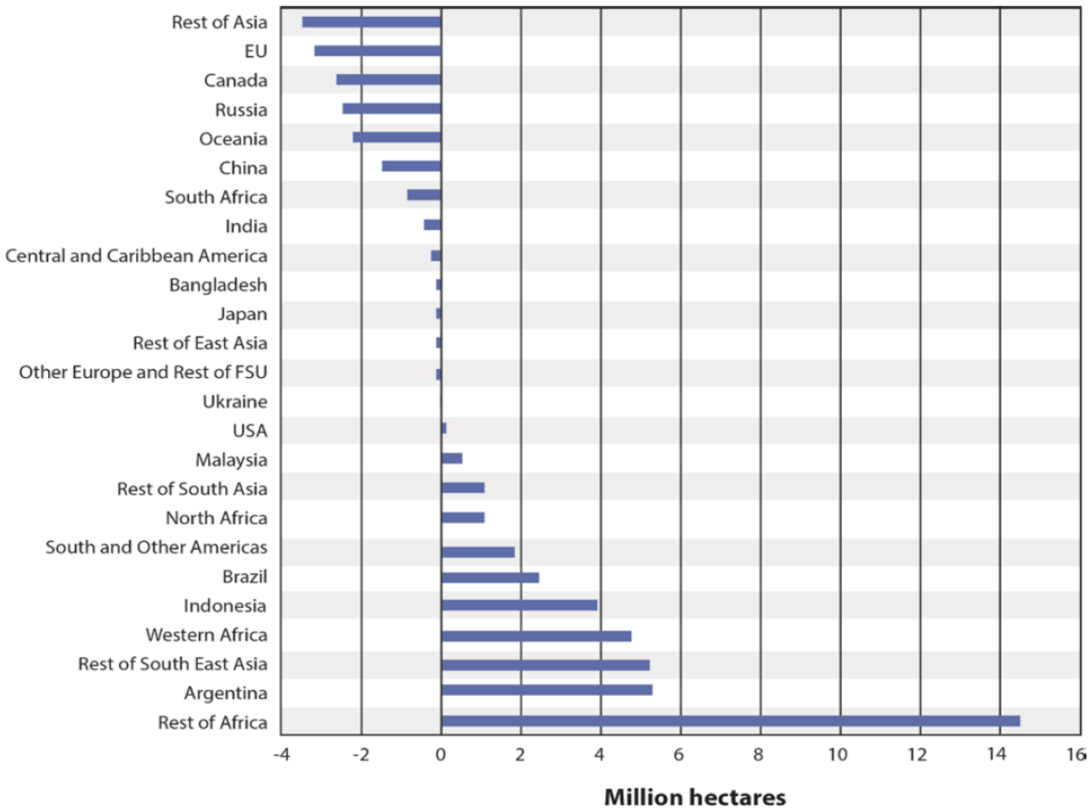

Figure 8. Change in Arable Land Plus Permanent Crops: 2004–2006 to 2010–2012

According to Babcock & Iqbal, the land use emissions implications in countries and regions where cropland decreased or stayed the same are that:

> …the type of land converted to accommodate biofuels was not forest or pastureland but rather **cropland that did not go out of production**. Calculation of foregone carbon sequestration depends on what would have happened to the cropland if it did not remain in crops which, in turn, depends on where the cropland is located and the potential alternative uses. **The magnitude of the change in estimated CO2 emissions from cropland that is prevented from going out of production relative to forest that is converted to cropland is potentially large.**[8]

Unfortunately, CARB's GTAP analysis suggests there was conversion of forest and grassland to crops in regions where real-world data show cropland actually contracted. The disagreement

LCFS 8-6 cont.

[8] *Id.*

between GTAP predictions and real-world data highlights the implausibility of GTAP results for certain regions. CARB can—and should—correct its analysis to better align with real-world land use patterns. The following section provides a method for calibrating CARB's GTAP model to better reflect observed land use changes. LCFS 8-6 cont.

c. CARB should use data from Babcock & Iqbal (2014) to immediately calibrate its GTAP model to reflect real-world land use change patterns in key regions.

LCFS 8-7

As stated in the Babcock & Iqbal paper, CARB should not presume that higher crop prices have caused conversion of forest and grassland to crops in countries and regions where cropland has actually decreased over the past 10 years. Thus, we believe CARB should calibrate its GTAP model to disallow forest and grassland conversion in AEZs and regions for which empirical data show forest or grassland expansion and/or cropland contraction. This can be easily accomplished by excluding GTAP predicted land conversions for the countries in Figure 8 of Babcock & Iqbal that show negative extensive change (i.e., loss of cropland). A more detailed method for accomplishing this calibration is available in comments submitted to CARB by Air Improvement Resource on Dec. 4, 2014.[9]

It could be argued that these countries should still be subject to emissions penalties for foregone sequestration, in that biofuels demand may have caused some cropland to remain in production that may otherwise have transitioned to some other use. But this should only be done if it can be demonstrated that the alternative use of the land would have resulted in carbon sequestration that is greater than the sequestration achieved if the land remained engaged in crop production.

For the countries in Figure 8 that *do* show extensive land use change over the past 10 years, CARB can continue to rely on GTAP predictions, but should also conduct more intensive research to better understand the precipitating causes of land conversions at the extensive margin in those countries. For example, while Sub-Saharan Africa (excluding South Africa) shows significant extensive change over the past decade, it is likely unrelated to biofuels expansion in the U.S. According to Babcock & Iqbal, "The extent to which extensive expansion in African countries was caused by high world prices is likely small for the simple reason that higher world prices were not transmitted to growers in many African countries."[10]

In the longer term, CARB should migrate to the soon-to-be-released dynamic version of GTAP that contains updated baseline economic data. Further, CARB should closely monitor efforts to validate and back-cast the new version of GTAP and be prepared to consider new results from these exercises.

d. CARB's GTAP Analysis Should Adopt CA-GREET2.0 Assumptions for Co-products Displacement Rates

LCFS 8-8

[9] Air Improvement Resources comments available at: http://www.arb.ca.gov/fuels/lcfs/regamend14/air_12042014.pdf
[10] Babcock, B.A. and Z. Iqbal (2014) at 16.

The recently released CA-GREET2.0 model correctly assumes that distillers grains from ethanol production displace both corn and soybean meal in livestock and poultry rations.[11] The total mass of corn, soybean meal, and urea displaced by 1 pound of distiller grains is 1.111 pounds. While this assumption has modest impacts for the direct emissions associated with corn ethanol's lifecycle, the impacts on land use are significant. We have detailed these impacts in many previous comments to CARB, dating back to 2008.

Unfortunately, CARB's GTAP analysis continues to assume 1 pound of distillers grains displaces only 1 pound of corn. This is problematic for at least two reasons: 1) CARB's assumptions and boundary conditions for estimates of direct and indirect emissions should be consistent and uniform, 2) CARB's current GTAP assumptions on distillers grains displacement are simply inconsistent with the reality of how distillers grains are fed.

LCFS 8-8 cont.

We are fully aware that there is no simple method for setting displacement ratios in GTAP, as interactions amongst the various sectors in the model are characterized in terms of economic values (e.g., expenditures, receipts, etc.). However, the economic values representing ethanol co-products in CARB's GTAP model are based on the 2004 database. Obviously, there have been significant changes in the distillers grains market since 2004; the ways in which these co-products are traded, priced, and fed have evolved dramatically. As we have discussed in previous comments to CARB, the agency can better reflect real-world feeding practices (i.e., some displacement of soybean meal) by adjusting the economic values associated with co-product trade in GTAP. RFA believes CARB must make this adjustment to ensure consistent boundaries and assumptions across its direct and indirect emissions analysis.

e. CARB <u>Still</u> Has Not Justified its Proposal to Use a Yield-Price Elasticity Value That is Lower than Recommended by Both Purdue and CARB's Own Expert Work Group. CARB Should Use 0.25 as the Central Value, Not the Proposed Value of 0.185.

Despite new data and published scientific papers supporting the use of a range for YPE of 0.14-0.53, CARB continues to propose using a range of 0.05-0.35. CARB staff has continued to ignore input from stakeholders, academia, and its own Expert Work Group on this parameter, instead relying on input from paid contractors at UC Davis and its own "expert judgment."

LCFS 8-9

In Appendix I, CARB states that "[a]n expert from UC Davis, contracted to conduct a review and statistical analysis of data from a few published studies also concluded that YPE values were small to zero." Yet, it is quite clear from the brief (and somewhat unclear) report from the UC Davis contractor that the YPE response was examined only over the short term (i.e., 1-2 years).

This is inappropriate and scientifically indefensible, as demonstrated by previous stakeholder comments and remarks from Purdue University. For example, during the March 11 workshop on

[11] The latest version of CA-GREET2.0 is available at: http://www.arb.ca.gov/fuels/lcfs/ca-greet/ca-greet.htm

ILUC, Purdue University Prof. Wally Tyner explained why it is inappropriate to include short-run estimates in the range used for CARB's analysis, stating:

> The yield-price elasticity is a *medium-term elasticity*…and we normally think of that as about 8 years. I personally think, and our group thinks, that any of those papers in the literature that represent one year are *totally irrelevant* to this. They may be fine for a one-year estimate, but a one-year estimate is totally irrelevant. Most of the short-term estimates are very low and most of the medium-term [estimates] were much higher—in the range of the 0.25 that we currently use.[12]

Tyner underscored this point again in a note to CARB following the March 11 workshop: "The yield to price elasticity does not measure changes over one crop year. In fact, ***any estimate done over one year would be totally inappropriate for GTAP and should be excluded from consideration in determining appropriate values for the parameter***."[13]

Babcock and other members of the Expert Work Group's Elasticity Subgroup agreed that the use of a short-run elasticity is inappropriate for the purposes of CARB's GTAP scenario runs: LCFS 8-9 cont.

> …to the extent that existing studies provide reliable one-year estimates, they underestimate the long-run response of yields to price. There are sound theoretical reasons for believing that there are lags in the response to higher crop prices. Farmers have an incentive to adopt higher-yielding seed technologies and other management techniques with higher prices. Switching from one seed variety or technology such as seed-planting populations, may require more than a single season to accomplish. And there are likely five to 15 year lags involved in developing new seed varieties and new management techniques that may be only profitable under high prices.[14]

The Schlenker work, which has served as the basis of CARB's use of inappropriately low YPE values, was critiqued by the EWG's Elasticities Subgroup. The subgroup raised several concerns with the Schlenker data, none of which (to our knowledge) have been adequately addressed by CARB staff. In short, the Elasticities Subgroup found that, "[t]he Roberts and Schlenker (2010) results provide ***no evidence that there is not a price-yield relationship***,

[14] ARB Expert Work Group. 2011. "Final Recommendations from the Elasticity Values Subgroup." Available at: http://www.arb.ca.gov/fuels/lcfs/workgroups/ewg/010511-final-rpt-elasticity.pdf

they just find evidence that any short-run price yield relationship is overwhelmed by variations in yields caused by weather."[15] LCFS 8-9 cont.

f. The GTAP model's inability to explicitly consider double-cropping further justifies the use of a higher range of price-yield elasticity values.

As explained by CARB's EWG, "…higher prices give farmers a greater incentive to double crop."[16] Indeed, Babcock & Iqbal adds to the body of empirical evidence that double-cropping has significantly increased during the recent period of higher commodity prices (see also Babcock & Carriquiry[17]). Unfortunately, GTAP simulations do not explicitly allow increased demand for agricultural commodities to be satisfied through increased double-cropping. <u>While we believe the best way to account for the impact of double-cropping is to calibrate the GTAP model to the Babcock & Iqbal data (as described in previous sections), and alternative method would be to raise the yield-price elasticity in regions where double-cropping is known to occur</u>. LCFS 8-10

The EWG Elasticities Subgroup recommended that the price-yield elasticity parameter could be used to partially account for double-cropping responses. In its final report, the subgroup explained that "the reality of double cropping" *by itself* justified the use of a positive (i.e., non-zero) value for the price-yield elasticity.[18] The subgroup recommended that "…for countries that have the opportunity to double crop, such as the U.S., Brazil, Argentina, and some Asian rice producing countries such as Thailand…an additional increment should be given to the price-yield elasticity."[19] To date, CARB staff has failed to account for increased double-cropping in its GTAP modeling scenarios. At a minimum, 0.25 should be used as an average value, and an additional increment of 0.1 should be added (total = 0.35) for regions where double-cropping is known to occur.

II. The New CA-GREET2.0 Model Marks a Major Improvement Over CA-GREET1.8b. However, Certain Improvements to CA-GREE2.0 Are Still Needed to Better Reflect the Direct Carbon Intensity of Ethanol Pathways

In general, RFA supports CARB's decision to revise and update its CA-GREET model based on the Argonne National Laboratory GREET1_2013 model. We believe Argonne's GREET1_2013 model contains a number of important improvements and updated inputs that more accurately reflect the current CI performance of corn ethanol and many other fuel pathways. Much has changed since CARB released the original CA-GREET model more than six years ago; ethanol and feedstock producers have rapidly adopted new technologies and practices that have significantly reduced the fuel's lifecycle CI impacts. Thus, it is encouraging to see the CA- LCFS 8-11

[19] *Id.*

GREET model finally catching up to the actual state of the industry. However, we believe the CA-GREET2.0 model could be further improved by adopting the recommendations below. LCFS 8-11 cont.

a. CARB Should Reduce Denaturant Content in Fuel Ethanol to 2.49% to Reflect Real-World Conditions

In order to comply with Federal requirements, ethanol producers limit the denaturant content of commercial fuel ethanol to 2.49% or less. GREET1_2013, upon which CA-GREET2.0 is based, appropriately assumes denaturant content is 2%. However, Appendix C to the ISOR specifies that CA-GREET2.0 assumes the non-ethanol content of denatured fuel ethanol is 5.4%, with 2.5% being denaturant, 1% being water, 0.5% being methanol, and 1.4% being "other." While denatured fuel ethanol does contain trace amounts of water (1% or less), methanol and "other" components are generally absent from the fuel or present in amounts below those specified by CARB. Further, CARB assumes that all non-ethanol constituents of denatured fuel ethanol—including *water* and "other"—have the same carbon intensity as CARBOB. This is an unsubstantiated and unfair assumption. CARB should fix the denaturant content at 2.49% and treat any remaining non-ethanol constituents (which would be mostly water) as having the same CI as the ethanol. LCFS 8-12

b. CARB Should Include the GREET1_2013 Default Value for Enteric Fermentation Impacts in the Corn Ethanol Pathway

For the CA-GREET2.0 model, CARB is proposing to exclude the GREET1_2013 credit for methane emissions reduction resulting from feeding DDGS. We strongly disagree with this proposal and CARB's rationale for the exclusion. We recommend that CARB adopt the GREET1_2013 methane emissions reduction credit for use in CA-GREET2.0.

CARB states that an "expanded system boundary" would be required for inclusion of methane emission reductions resulting from feeding DDGS to livestock. This implies that CARB views methane emissions reductions as a potential indirect or consequential effect. It could be argued that reduced methane emissions from livestock are a direct effect of corn ethanol expansion (via increased DDGS feeding). Nonetheless, even if we accept the argument that methane emission reductions are an *indirect* effect, CARB has no defensible reason for excluding these emission reductions. That is because CARB *already has expanded the boundary conditions for its corn ethanol pathways to include consequential/indirect effects such as purported land use changes*. CARB has also proposed to include indirect emissions associated with irrigation constraints, and at one point CARB was considering inclusion of hypothetical emissions that would indirectly result from "holding food consumption constant." Thus, CARB is proposing to include a number of potential indirect/consequential emissions sources in the corn ethanol lifecycle, but plans to selectively exclude potential emissions reductions (i.e., credits). This reflects inconsistent and asymmetrical boundary conditions (and possible bias) in CARB's analysis of corn ethanol emissions. LCFS 8-13

III. CARB's Compliance Scenario Assumptions Regarding the Availability of Sugarcane Ethanol and Related Credit Generation Seem Highly Implausible

CARB's new compliance scenarios continue to grossly over-estimate the amount of imported sugar-derived ethanol that is likely to be available to the U.S. and California marketplace in the future. As a result, CARB adopts an overly optimistic view of potential LCFS credit generation in the 2015-2020 timeframe.

In Appendix B, CARB states that its sugarcane ethanol estimate is derived from the Food and Agricultural Policy Research Institute's (FAPRI) World Agricultural Outlook. It should be noted that due to budget constraints, FAPRI has not produced a comprehensive World Agricultural Outlook report since 2011. It is unfathomable that CARB would rely on the 2011 FAPRI publication for its projections of sugarcane ethanol availability when more current projections are available from multiple sources.

Indeed, FAPRI itself continues to publish annual "Projections for Agricultural and Biofuel Markets."[20] These projections are published in March of every year. Much has changed in the Brazilian and world sugar and ethanol sectors since 2011, and FAPRI has since significantly revised its outlook for U.S. imports of sugarcane ethanol.

FAPRI's 2014 projections include yearly estimates of U.S. ethanol imports through 2023. FAPRI projects that U.S. ethanol imports will average **182 mg per year** in the 2015-2023 timeframe, with exports never exceeding 197 mg in any single year. *Importantly, these projections include the effects of the California Low Carbon Fuel Standard*. According to FAPRI: LCFS 8-14

- "Sugarcane ethanol imports from Brazil continue to decline in 2014 before leveling out."
- "Lower RFS requirements for advanced biofuel could imply reduced ethanol imports."
- "However, *low-carbon fuel requirements in California provide some incentive for continued ethanol imports*."

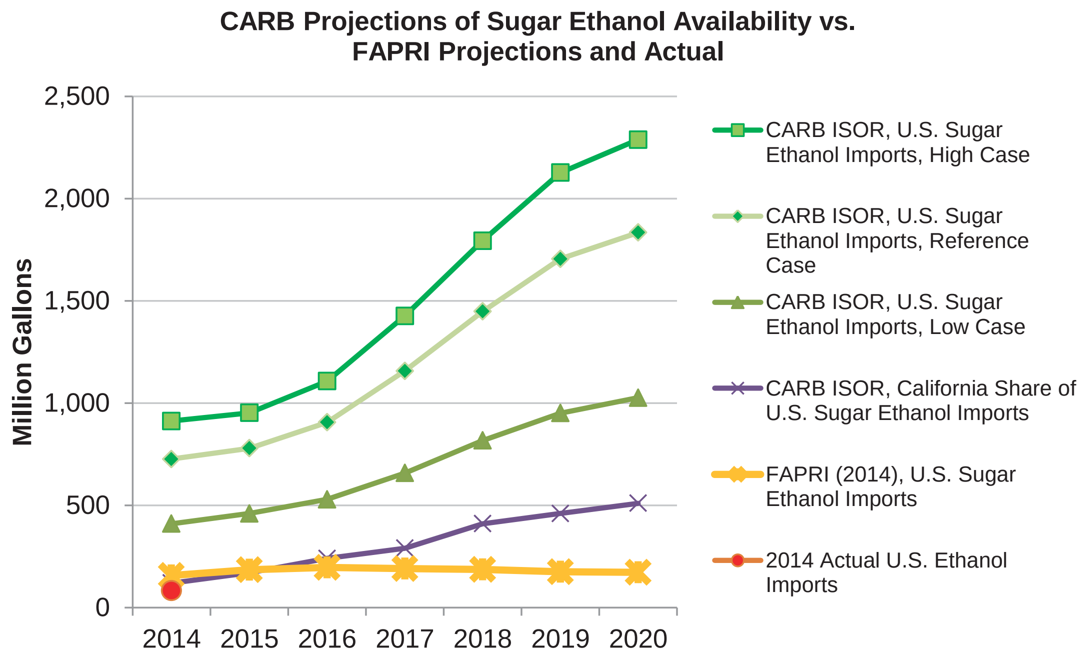
<u>Thus, CARB's current 2020 projections (Appendix B reference, high and low cases) of sugarcane- and molasses-based ethanol are roughly 6-13 times higher than FAPRI's current outlook, which *do* take into the account the likely "pull" from the LCFS.</u> Further, total ethanol imports to the entire United States (most of which were sugar-derived) were just 84 million gallons in 2014, compared to CARB's compliance scenario assumption of 410-912 million gallons. In fact, CARB's projection that California would receive 120 million gallons of sugar-related ethanol in 2014 is 42% larger than actual imports to the <u>entire U.S.</u> Of the 84 million gallons imported by the U.S., only 7.96 million gallons—or 9.5% of the U.S. total—entered through California ports. Thus, actual California imports in 2014 were equivalent to just <u>6.6%</u> of the volume anticipated by CARB.

[20] 2014 FAPRI Baseline available here: http://www.fapri.missouri.edu/outreach/publications/2014/FAPRI_MU_Report_02_14.pdf

Similarly, CARB's projection that California will receive 510 million gallons of sugar-derived ethanol in 2020 compares to FAPRI's projection that the entire U.S. will receive only 172 million gallons of sugar ethanol that year.

CARB has suggested that higher LCFS credit values could lure larger volumes of sugar ethanol to California than projected by FAPRI. However, empirical data from the past four years show no discernible relationship between credit values and sugarcane ethanol imports to California.[21] It is also worth noting that Brazil is soon increasing its ethanol blend rate, which will further reduce the amount of sugarcane ethanol that is available to export.

LCFS 8-14 cont.



We strongly recommend that CARB refine its estimates of sugar-related ethanol and use FAPRI's latest projections of sugarcane ethanol availability when conducting its analysis of potential fuel availability.

* * * * *

Thank you for considering RFA's comments on the ISOR for the re-adoption of the LCFS. We would be pleased to address any questions you may have regarding the contents of these comments or any other issues related to ethanol's role in the LCFS.

Executive Summary

Economics models used by California, the Environmental Protection Agency, and the EU Commission all predict significant emissions from conversion of land from forest and pasture to cropland in response to increased biofuel production. The models attribute all supply response not captured by increased crop yields to land use conversion on the extensive margin. The dramatic increase in agricultural commodity prices since the mid-2000s seems ideally suited to test the reliability of these models by comparing actual land use changes that have occurred since the price increase to model predictions. Country-level data from FAOSTAT were used to measure land use changes. To smooth annual variations, changes in land use were measured as the change in average use across 2004 to 2006 compared to average use across 2010 to 2012. Separate measurements were made of changes in land use at the extensive margin, which involves bringing new land into agriculture, and changes in land use at the intensive margin, which includes increased double cropping, a reduction in unharvested land, a reduction in fallow land, and a reduction in temporary or mowed pasture. Changes in yield per harvested hectare were not considered in this study. Significant findings include:

- In most countries harvested area is a poor indicator of extensive land use.
- Most of the change in extensive land use change occurred in African countries. Most of the extensive land use change in African countries cannot be attributed to higher world prices because transmission of world price changes to most rural African markets is quite low.
- Outside of African countries, 15 times more land use change occurred at the intensive margin than at the extensive margin. Economic models used to measure land use change do not capture intensive margin land use changes so they will tend to overstate land use change at the extensive margin and resulting emissions.
- Non-African countries with significant extensive land use changes include Argentina, Indonesia, Brazil, and other Southeast Asian countries.
- Given the lack of a definitive counterfactual, it is not possible to judge the consistency of model predictions of land use to what actually happened in each country. Some indirect findings are that model predictions of land use change in Brazil are too high relative to other South American countries; and model predictions of increasing extensive land use that are larger than what actually occurred are consistent with actual land use changes only if cropland was kept from going out of production rather than being converted from forest or pasture.

The contribution of this study is to confirm that the primary land use change response of the world's farmers from 2004 to 2012 has been to use available land resources more efficiently rather than to expand the amount of land brought into production. This finding is not necessarily new and it is consistent with the literature that shows the value of waiting before investing in land conversion projects; however, this finding has not been recognized by regulators who calculate indirect land use. Our conclusion that intensification of agricultural production has dominated supply response in most of the world does not rely on higher yields in terms of production per hectare harvested. Any increase in yields in response to higher prices would be an additional intensive response.

Using Recent Land Use Changes to Validate Land Use Change Models

In the mid-2000s prices for major agricultural commodities began a long, sustained increase. Prices increased dramatically due to growth in demand for food and biofuel producers, underinvestment in agricultural infrastructure and technology, and poor growing conditions in major producing regions. Figure 1 shows the percent change in inflation-adjusted prices received by US producers for corn, soybeans, wheat, and rice relative to the previous five-year average.[1] The predominance of negative changes shows that since 1960 average real prices for these commodities have dropped. These figures show that the commodity price boom in the early 1970s resulted in the largest increase in real prices, but the recent increase in prices since 2006 resulted in the longest sustained increase, especially for corn and soybeans. For wheat and rice, real prices increased sharply in the mid-2000s and have stayed high even though the year-over-year increases were not as long lasting as for corn and soybeans. The magnitude of these real price increases after such a prolonged and sustained period of flat or falling prices presents a unique opportunity to quantify how world agriculture responds to incentives to produce more.

The United States, California, and the EU have enacted regulations based in part on model predictions of agricultural supply response to price increases induced by increased biofuel production. The model predictions of land use changes are called indirect land use changes because the predicted changes are due to a modeled response to higher market prices rather than a direct response to the need to grow more feedstock for biofuel production. Thus, for example, the corn used to produce corn ethanol in the United States was met by US corn production; however, the diversion of corn from other uses increased corn prices and crop prices of other commodities that compete with corn for market share and land. Because corn and other commodities are traded on world markets, prices in other countries also increase. The response in the US and in other countries to these higher prices is what the models measure.

[1] Prices are average annual prices received by US farmers adjusted by the US CPI.

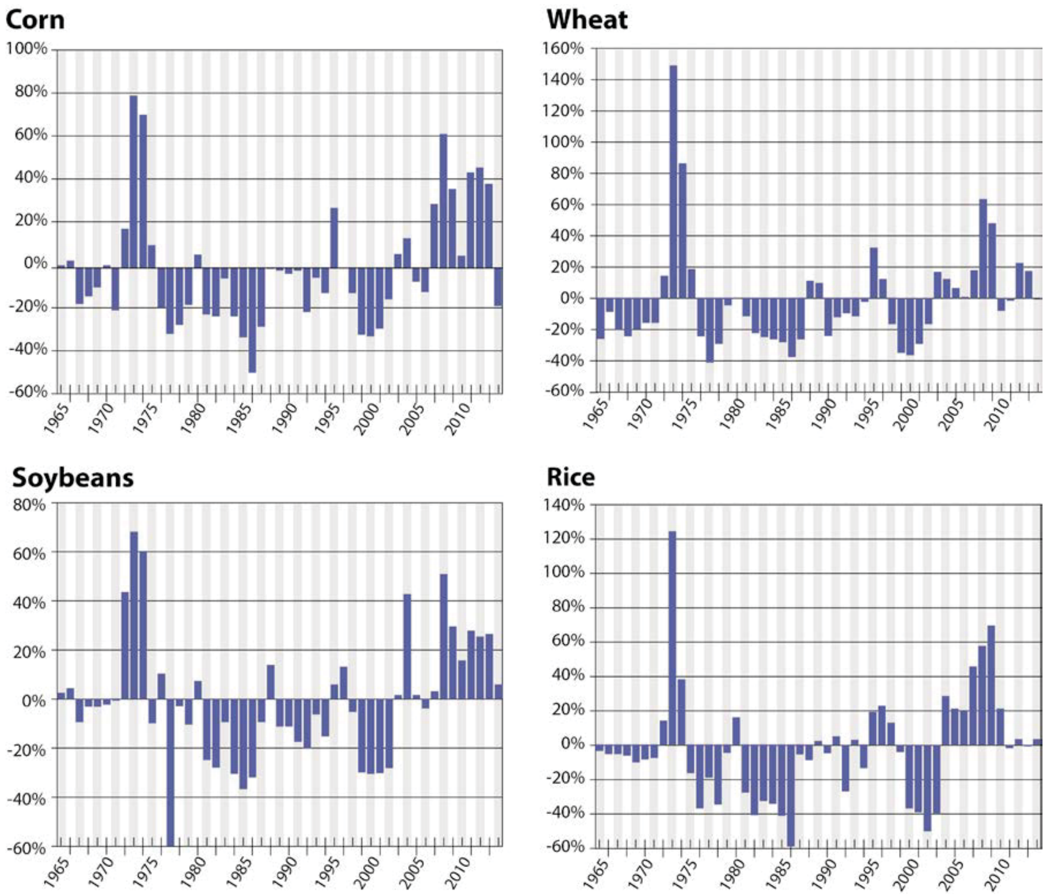

Figure 1. Deviations in Real US Commodity Price Levels from Lagged Five-Year Average Measuring World Land Use Changes

Some portion of the higher prices since the mid-2000s was caused by increased biofuel production. For example, Fabiosa and Babcock (2011) estimate that 36% of the corn price increase from 2006 to 2009 was due to expanded ethanol production. Carter, Rausser, and Smith (2010) estimate that 34% of the corn price increase between 2006 and 2012 was due to the US corn ethanol mandate. This implies that a portion of the actual response of land use since this price increase is due to US ethanol production. Other factors such as crop shortfalls and other sources of increased demand account for the rest of the price increase.

Because indirect land use is a response to higher market prices, model predictions of land use change should be similar whether the higher prices came from increased biofuel production, increased world demand for beef, or from a drought that decreased supply in one or more major producing areas. This implies that the pattern of actual land use changes that we have seen since the mid-2000s should be useful to determine the reliability and accuracy of the models that have been used to measure indirect land use. The purpose of this paper is to look at what has happened over approximately the last 10 years in terms of land use changes and to determine whether and how these historical changes can provide insight into the reliability of model-predicted changes in land use. We address the following questions in this paper:

- How has cropland changed around the world in approximately the last 10 years?
- What were the major drivers of observed land use changes?
- When can actual land use changes be compared with model predictions?
- What can be said about the types of land that were actually converted?

How Has Harvested Area Changed Since 2004?

The most complete source of data on annual cropland is from the Statistics Division of FAO (FAOSTAT), which measures annual harvested area by crop and country. These data have been widely used to measure the impact of biofuel production on expansion of land used in agriculture (Roberts and Schlenker 2013) and to calibrate the land cover change parameter in the GTAP model (Taheripour and Tyner 2013). Figure 2 shows the change in harvested land according to FAO. The data are smoothed by calculating the change in harvested area as the average in 2010, 2011, and 2012 minus the average in 2004, 2005, and 2006. The earlier period measures harvested area before the large increase in price. The later period represents harvested area after prices had increased substantially. India, China, Africa, Indonesia and Brazil had the largest increase in harvested land. These data seem to suggest that these countries had the largest increase in land conversion; however, harvested land is not equal to planted land. Harvested land will deviate from planted land when a portion of planted land is not harvested and when a portion of land is double or triple cropped.

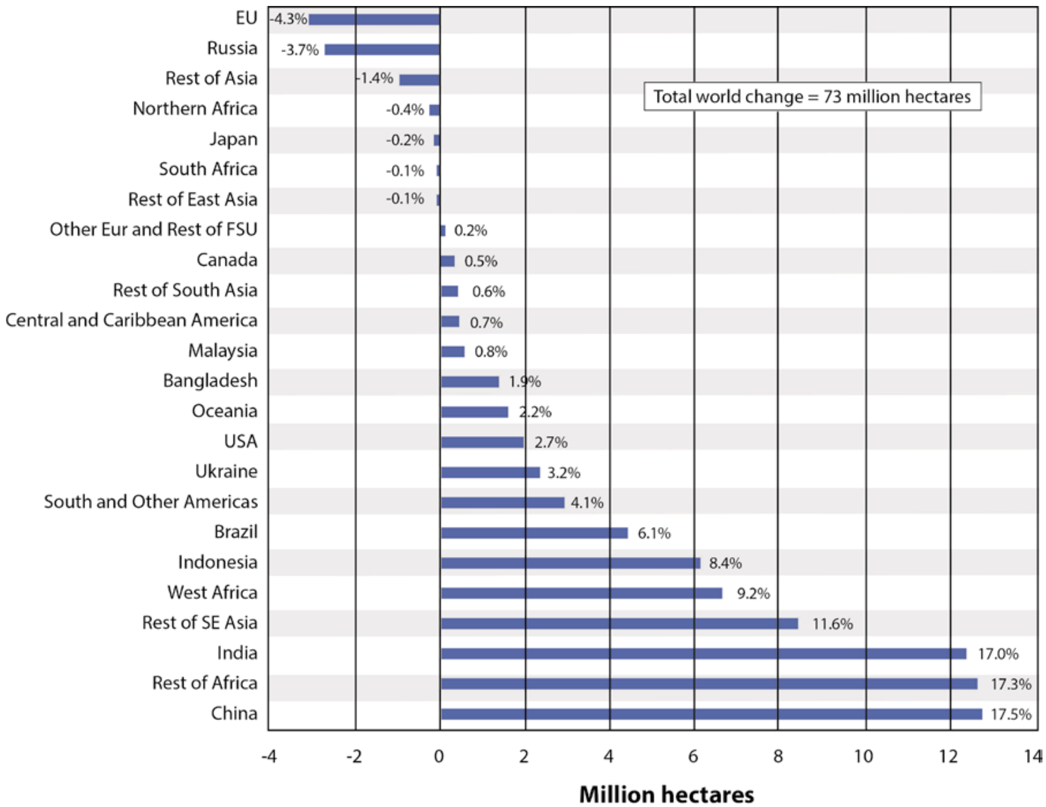

Figure 2. Change in Harvested Land 2010–2012 Average Minus 2004–2006 Average and Country's Share of Total World Change
Source: FAOSTAT

Suppose that a portion of land that is planted to a first crop is not harvested and that a portion of first crop land that is harvested in a country is double-cropped, which simply means that a second crop is planted on land that was already planted to a crop in the same year.[2] By definition, total harvested land, H, equals total harvested land from the first crop, H_1, plus total harvested land from the second crop, H_2. Total harvested land from the first crop equals total land planted to the first crop, P_1 minus land that was planted but not harvested, a_1. Thus we have in any year t

$$P_{1,t} = H_t - H_{2,t} + a_{1,t}$$

[2] Throughout this article land the phrase double crop should be interpreted as two or more crops being grown on a single parcel of land.

For the purpose of greenhouse gas emissions from land use changes, it is most relevant to calculate the change in planted area between two time periods $t = T$ and $t = 0$. Thus, we have

$$P_{1,\mathrm{T}} - P_{1,0} = (H_T - H_0) - (\mathrm{H}_{2,\mathrm{T}} - H_{2,0}) + (a_{1,\mathrm{T}} - a_{1,0})$$

If second crop acreage has increased over time, then use of FAO data on total harvested land overstates land use change by this amount. If the change in first crop land that is not harvested also increases over time, then at least some portion of this upward bias in measuring land use change is overcome. If, instead, the amount of unharvested land has decreased over time then the upward bias is increased. A more in-depth examination of data available for a few countries gives insight into the extent to which use of FAO harvested area data provides a good indication of land use changes.

United States

Figure 3 illustrates that reliance on harvested area as an indicator of land use change can lead to a large bias, and shows annual changes in harvested and planted land to corn in

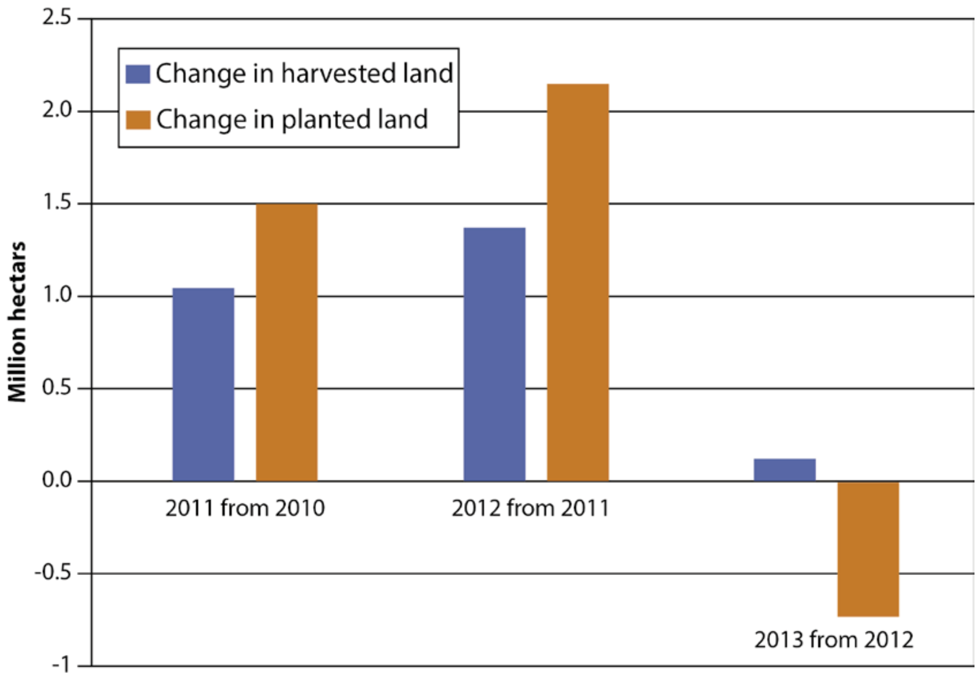

Figure 3. Annual Change in Harvested and Planted Corn Land in the United States

the United States from 2011 to 2013. A widespread drought in the United States resulted in an increase in the amount of planted land that was not harvested. Thus in 2012, use of harvested land to measure land use change understates land use change, whereas in 2013, it overstates land use change. Taking average changes over some time period will reduce the impact of an outlier like 2012, but it will not eliminate it. Thus, use of 2012 harvested data in the United States will tend to understate land use change relative to an earlier period and overstate it relative to a later period. Because data on US planted land is available from USDA's National Agricultural Statistics Service, it makes much more sense to use these data rather than FAO harvested land data.

Brazil

Brazil is another country that collects data on both harvested and planted land.[3] In addition, Brazil collects data on land that is double cropped. Figure 4 shows total harvested land and total harvested land from double cropped land. The axes have been set to the same scale to show that a large proportion of the increase in Brazilian harvested land is a result of increased double cropping. The change in total harvested land from 2004–2012 is 5.4

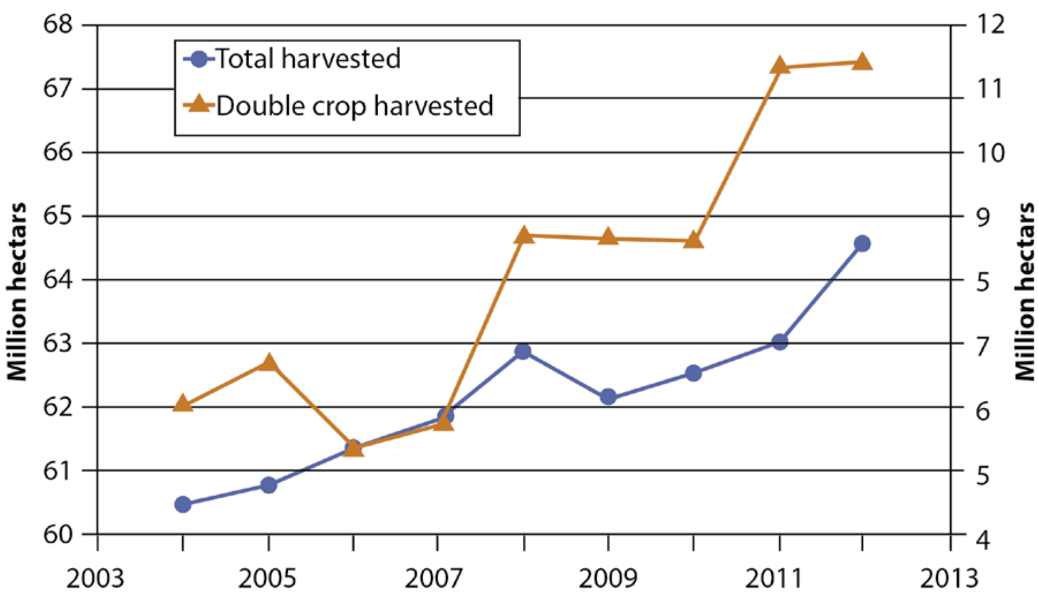

Figure 4. Brazil Harvested Land Data

[3]Brazilian IBGE data is available at http://www.sidra.ibge.gov.br/bda/pesquisas/pam/default.asp?o=27&i=P

million hectares. The change in double cropped land is 4.1 million hectares. Thus, more efficient use of land accounts for 76% of the change in harvested land in Figure 4.

India

Figure 2 shows that India increased harvested area by 6.8% from 2004–2006 to 2010–2012 which is 12.4 million hectares. Given India's long agricultural history it seems unlikely that so much land would be suitable for conversion to crops in such a relatively short time. India collects data on both planted and harvested land as well as double cropped land (India Ministry of Agriculture). Figure 5 shows that the variation in multiple crop area explains most of the variation in total planted area, which includes double cropped area. Subtracting double cropped area from total planted area shows that net planted area decreased by 147,000 hectares between 2004–2006 and 2010–2012. What then accounts for the increase in harvested area? Figure 6 shows that the proportion of planted area that is harvested has increased dramatically over this time period. An examination of previous years' data shows that the wide gap between planted and harvested

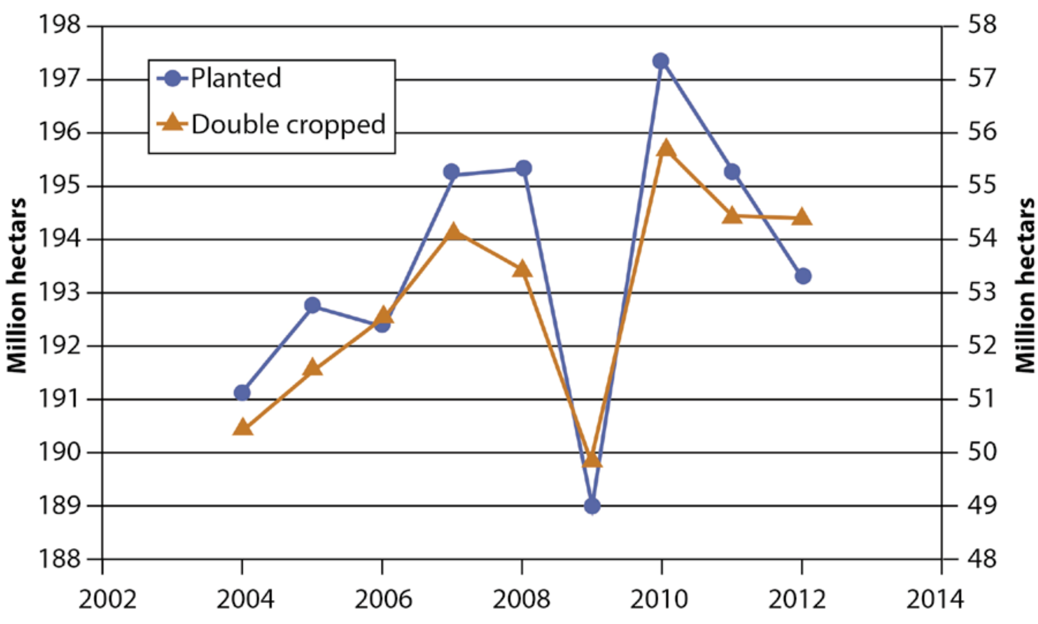

Figure 5. Total Planted and Multiple Crop Area in India

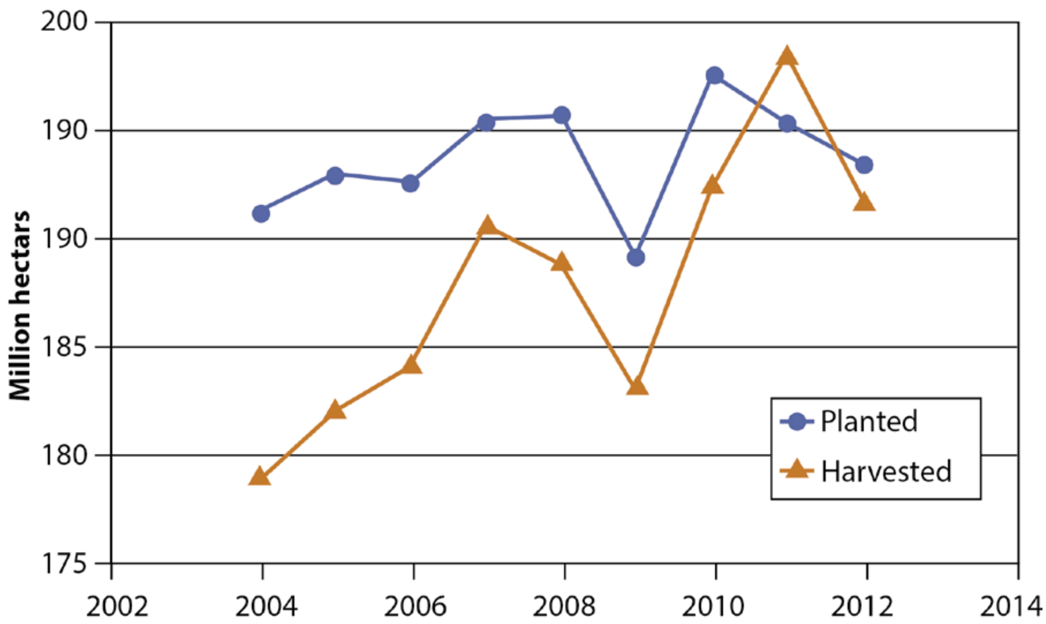

Figure 6. Total Planted and Harvested Area in India

area shown in Figure 6 from 2004 to 2006 was typical. For example, the 2004–2006 gap averages 10.6 million hectares, and the gap from 1992 to 2000 averages 10.4 million hectares. The average gap in 2010 and 2012 is 3.4 million hectares. Thus, an increase in double cropped area accounts for about 3.5 million hectares of the increase in harvested area, and a decrease in non-harvested area accounts for another 7 million hectares. Thus, all of the increase is harvested area is accounted for by intensification of land use. One reason why non-harvested area has increased so much is the 6 million hectare increase in irrigated area from 2004 to 2011. More irrigation allows a greater proportion of planted area to grow to maturity, thereby making it worth harvesting. In addition, India increased support prices and input subsidies in the mid-2000s to combat stagnant growth in the agricultural sector. These actions, combined with the expansion of irrigation, increased the opportunity cost of not harvesting land.

China

FAO harvested area data shows an increase of 8% from 160 million hectares to 173 million hectares from 2004–2006 to 2010–2012. Figure 2 in Cui and Kattumuri (2012) shows that total cultivated land in China dropped from about 130 to about 122 million hectares from 1996 to 2008. The four reasons cited for the loss of agricultural land are urbanization, natural disasters, ecological restoration, and agricultural structural adjustment, with restoration and urbanization accounting for about 80% of losses. Cui and Kattumuri (2012) claim that the loss of agricultural land slowed down in 2004 and 2005 only because of "…stringent land protection policies" (p. 14). Based on this conclusion, it seems that economic forces in China were trying to reduce cultivated land, not increase it, in the mid-2000s. If correct, then it seems highly unlikely that a significant portion of the increase in harvested area was caused by an increase in the amount of land cultivated. If both FAO harvested area data and data used by Cui and Kattumuri (2012) are correct, then at least 38 million hectares of harvested area came from double cropped land in 2004–2006 and 51 million hectares of harvested area came from double cropped areas in 2010–2012.

Sub-Saharan African Countries

Figure 2 shows that sub-Saharan African countries have been large contributors to increases in harvested land. With some exceptions, much of African crop production is carried out by small-scale producers without use of modern technologies. While differences exist between countries, typically most production is consumed domestically and most commercial trade occurs between adjoining African countries (Minot 2010). Sub-Saharan African countries account for 34 of the top 50 countries in the UN data base in terms of population growth rates in 2010.[4] The average population growth rates for these 34 countries in 2010 was 2.93%. Leliveld et al. (2013) show that food production in Tanzania has just about matched population growth and that almost all of the food production increase has been due to an increase in the amount of land planted. Although it is possible to plant more than one crop in many African countries by developing shorter-season varieties and better management (Ajeigle et al. 2010), a lack of access to technology and capital is one defining characteristic of traditional agriculture in sub-Saharan Africa, so there is no evidence that double cropping is widely adopted. Thus, the change in harvested land shown in Figure 2 for African countries is likely a better measure of the change in planted land than in other countries.

[4] Population growth rates are available at http://data.worldbank.org/indicator/SP.POP.GROW/countries?display=default

Indonesia

Figure 7 shows the change in area harvested from 2004–2006 to 2010–2012 for the top eight crops and for all other crops in Indonesia according to FAOSTAT. As shown most of the expansion has occurred in rice and palm oil fruit. Because perennial crops do not generally produce more than one crop per year, the extent to which FAO harvested land data overstates the change in planted land is limited. Adding the change in harvested land of palm, rubber, coffee, coconuts, and cocoa together accounts for 54% of the change in harvested area. According to USDA-FAS (2012) the availability of suitable rice-growing land is severely restricted in Indonesia. Most of the increase in harvested rice area that has been achieved has come about from investment in irrigation facilities that allow two or three crops of rice to be planted on the same land rather than a single crop. The extent to which intensification explains the 1.4 million hectare increase in rice harvested area shown in Indonesia cannot be determined by harvested area data alone. However, given that Indonesia is one of the world's most densely populated countries, and 1.4 million hectares represents a 12% increase in harvested production, it is unlikely that a significant portion of this 1.4 million hectares is new land. According to USDA-FAS (2012) about

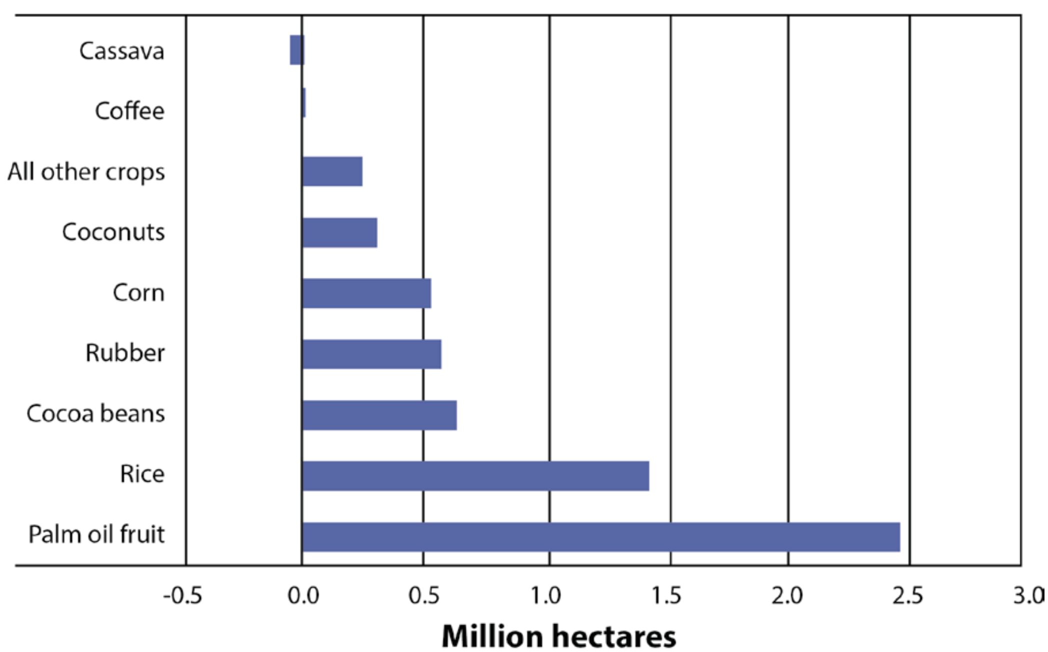

Figure 7. Change in Harvested Area by Crop for Indonesia as Reported by FAO

50% of Indonesian rice area grew rice in both the rainy and dry seasons in 2011, which implies that there is significant room for harvested area growth with greater irrigation. Thus it is likely that most of the increased rice area in Indonesia is accounted for by increased double and triple cropping.

Swastika et al. (2004) explain that most corn production in Indonesia is grown on land that produces two crops. Corn is typically grown with tobacco, cassava, another corn crop, or sometimes with rice. Given land constraints in Indonesia and the significant expansion of palm oil production, which has been accomplished by converting forestland and cropland (Susanti and Burgers 2013; Koh and Wilcove 2008), it is likely that a significant portion of the corn production increase came about by increasing double cropped area.

An Alternative Measure of Land Use Change

Use of harvested area to measure land use change can lead to a large bias in estimates of how much land has been converted to crops from other uses. While this may be an obvious point, it is too often missed in analysis of land use changes. Reliable country-specific data, such as in the United States, that can measure the change in net planted area should be used when available. Where it is not available, land cover data can be used. For global coverage FAOSTAT data on arable land and land planted to permanent crops are available. The FAO definition of arable land is "the land under temporary agricultural crops (multiple-cropped areas are counted only once), temporary meadows for mowing or pasture, land under market and kitchen gardens, and land temporarily fallow (less than five years). The abandoned land resulting from shifting cultivation is not included in this category."[5] This definition is different than the common meaning of arable land—land that is capable of producing a crop rather than land that is actually in crop production. Adding FAO's measure of arable land to land that is in permanent crop provides a measure of land use that is appropriate to use in determining the amount of new land that has been brought into production. Figure 8 reproduces Figure 2 using this measure with the exception of the United States, for which USDA's NASS planted area data is used. For the United States, total planted area of principal field crops minus double crop area is

[5] http://faostat.fao.org/site/375/default.aspx

used instead of FAOSTAT data because FAOSTAT reports a 9 million hectare loss in total cropland because of a sharp reduction in temporary pasture.

The implications of Figure 8 are strikingly different than Figure 2. Furthermore the Figure 8 data is much more consistent with the country-specific data in China, India, Brazil, Indonesia, and Africa. Figure 8 data suggest that the net change in global cropland over this period is 24 million hectares. African countries increased cropland by 20 million hectares. Other countries with more than a million-hectare increase include Argentina, Indonesia, Brazil, Rest of Southeast Asia, Rest of South Asia, and South and Other Americas. Countries with significant reductions in cropland include the EU, Canada, China, Russia, and South Africa.

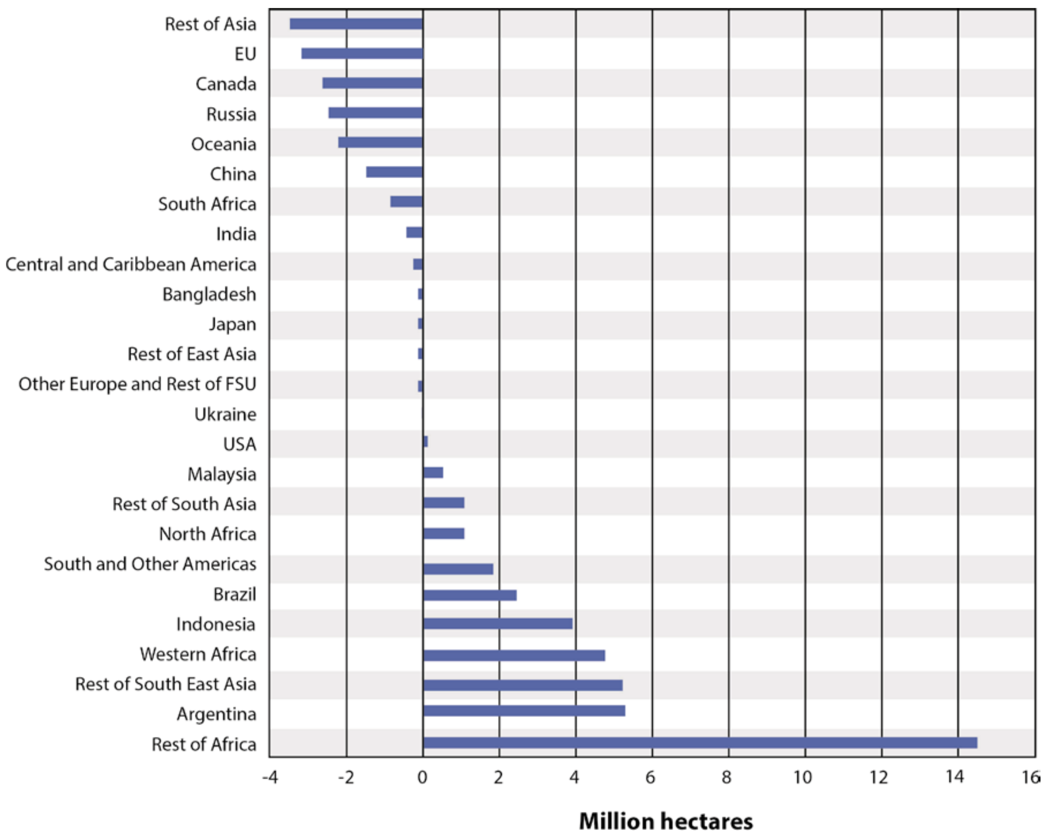

Figure 8. Change in Arable Land Plus Permanent Crops: 2004–2006 to 2010–2012

The data in Figures 2 and 8 can be used to determine the relative importance of land use changes at the intensive and extensive margin. Intensive margin changes are changes in double cropped area and a reduction in land that is available to plant but that is not harvested. The total change in harvested area in Figure 2 is the sum of extensive changes and intensive changes to land use. Thus, intensive changes equal the total change in harvested area from Figure 2 minus the changes in cropland given in Figure 8.[6] Both intensive and extensive changes are shown in Figure 9. Countries are sorted from the left according to their level of extensive acreage changes.

Most of the change in land use in African countries and Argentina is at the extensive margin. Most or all of the response in the developed world, India, China, South Africa, and the rest of Asia is at the intensive margin. The response in Indonesia and Brazil is mixed.

Major Drivers of Recent Land Use Changes

Broadly speaking, the land use changes shown in Figure 9 are consistent with a model of the world in which countries that have available land to convert to agriculture will have relatively more extensive land use change than countries that have long histories of agricultural development and limitations on available land. Thus, one major driver of recent land use changes is the availability of land to convert to agriculture. Most developed countries, along with China and India, have little land available, however, countries in Africa and South America have abundant land resources. There are striking differences, however, in land use indicated by Figure 9 that must be due to other drivers.

Growing demand for soybean imports was a major driver of land use decisions in Argentina, Brazil and the United States. The increased demand for soybeans resulted mainly from China's decision to meet its domestic needs for soybeans through imports rather than domestic production. This decision freed up resources in China to devote to production of other commodities and led to much higher soybean area in Argentina, Brazil, and the United States. Higher demand for high-protein foods in China and other developing countries increased the demand for soybean meal.

[6]One other use of this measure as an indicator of the amount of land that is used in agriculture is OECD-FAO (2014) when total agricultural land is discussed.

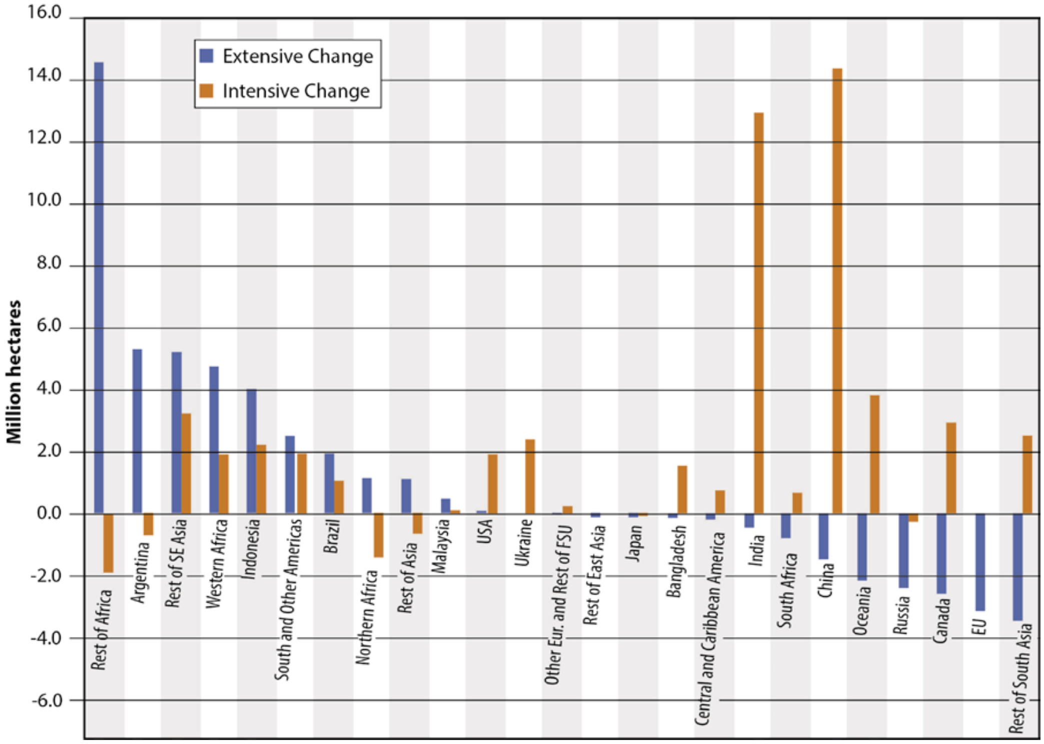

Figure 9. Extensive and Intensive Land Use Changes: 2004–2006 to 2010–2012

Increased demand for vegetable oils for food production, cooking, and biodiesel increased the demand for soybean oil.

Brazil responded to this increased soybean demand by expanding soybean area, however, a second crop of corn was planted on a good portion of expanded soybean acreage. This expansion in double cropping reduced the amount of corn area planted to the first crop of corn. Thus, Brazil expanded at both the extensive and intensive land use margins.

Argentina also expanded soybean area, but it did so at the extensive margin rather than by intensifying land use. The prime soybean production areas in Argentina are farther south than in Brazil, which shortens the time period available for double cropping. However, a second crop of soybeans can be planted in Argentina after winter wheat is harvested in December. One explanation for a lack of intensification is that Argentine area planted to wheat has declined from about 6 million hectares in 2005 to 3.6 million hectares in 2012. This decline simply means that there is less land available for double cropping soybeans after wheat. Therefore, if soybean area needs to increase, less wheat land means less land available for double cropping, thus, soybean first crop area by definition must increase. The decline in wheat area has been mainly driven by government policy interventions in the form of export taxes and export subsidies that were implemented in a way that favored soybeans over corn and wheat (Nogues 2011). This suggests that government policy is what caused a lack of an intensive land use response in Argentina, in contrast to the significant intensive response shown in Figure 9 in Brazil and other South American countries.

As discussed, Indonesian expansion of palm production was accomplished at least in part at the extensive margin. This expansion resulted from increased investment drawn to the industry due to higher profit margins caused by higher prices and higher yields. The higher prices resulted from an overall increase in demand for vegetable oil, driven by increased demand for food production, cooking oil, biodiesel, and other uses. The data show that Indonesian expansion of rice and corn harvested area was done at the intensive margin because the area devoted to perennial crops in Figure 7 is greater than the total extensive expansion shown in Figure 9.

Sugarcane and soybeans account for nearly all of the land expansion in Brazil. Increased sugarcane production was used to meet growing demand for sugar and to meet growing domestic demand for ethanol. The number of flex vehicles in Brazil grew by 20 million from 2005 to 2012. If all of these vehicles used ethanol, Brazilian consumption of ethanol in 2012 would have exceeded 24 billion liters just from these vehicles, and additional consumption would have come from the 15 million gasoline vehicles in Brazil. Actual consumption in Brazil was about 18 billion liters.[7] These figures demonstrate that the growth in sugarcane area was primarily driven by the Brazilian government policy that increased the sales of flex vehicles in Brazil. The expansion in Brazilian soybean area was driven by increased world demand for soybean imports, which was mainly driven by China, as previously discussed. The ability to plant a second crop of corn after soybean due to adoption of shorter-season soybeans and agronomic advances reduced the amount of new land that was needed to accommodate this expansion.

[7] All figures on Brazilian vehicle numbers and ethanol consumption were obtained from UNICA: http://www.unicadata.com.br/?idioma=2

In China, India, and most of the developed world, agricultural land resources are limited. Limited land resources means that expansion at the extensive margin is costly relative to expansion at the intensive margin. Thus, we see a large response in both China and India at the intensive margin rather than the extensive margin. Cui and Kattumuri (2012) argue that Chinese intensification would have been even greater but for the government policy objective of maintaining a minimum of 120 million hectares of land in agriculture. India's intensification was facilitated by government investment in irrigation facilities and price subsidies that increased agricultural profitability (OECO-FAO 2014).

The lack of a large extensive response in Ukraine, Russia, and other FSU countries is somewhat surprising given the availability of land. The lack of response at the extensive margin could be due to a lack of investment in the agricultural sectors of these countries.

How much of the changes in land use shown in Figure 9 can be attributed to high commodity prices cannot be known precisely without observing an alternative history in which the run-up in commodity prices did not occur. Economic theory suggests that some portion of the changes in Figure 9 came about because of high prices in those countries where high world prices were transmitted to farmers. However, some of the changes in land use would have occurred even if prices had remained constant at their 2004–2006 levels.

The extent to which extensive expansion in African countries was caused by high world prices is likely small for the simple reason that higher world prices were not transmitted to growers in many African countries. Minot (2010) concludes that domestic grain prices in Tanzania bear little relationship to world prices. In a more complete study, Minot (2011) studies price transmission in multiple markets in Ethiopia, Ghana, Uganda, Zambia, Mozambique, Tanzania, Kenya, South Africa, and Malawi. Of the 62 markets studied, he found that only 13 showed a statistically significant long-run relationship with world prices. He found some evidence of a linkage in large urban centers and in coastal markets, which is consistent with markets in cities and in coastal ports being more integrated with world markets. However, given his overall findings, these limited linkages to world prices did not find their way through to rural areas where most crops are grown. With such weak evidence supporting price transmission to rural areas one can conclude that the main driver of land expansion in many African countries was not higher world prices.

Empirical Measures of Land Use Changes

Aggregating land use changes across all countries, the aggregate world extensive change was a net increase of 24 million hectares from 2004–2006 to 2010–2012. The aggregate world intensive land use change was 49.1 million hectares. Thus, across all countries, more intensive use of existing land was double the change from more extensive use of land. Outside of African countries, the aggregate intensive change in land use was almost 15 times as large as extensive changes. This wide disparity between more intensive use of land and more extensive use means that the reliability of current models used to estimate indirect would be dramatically increased if they were modified to account for non-yield intensification of land use.

The recent historical changes in land use can provide some guidance about the effect of dramatically higher prices on land use change over an eight-year period. An estimate of the amount of extensive land use change that can be attributed to higher commodity prices can be made under fairly restrictive assumptions.

First is assuming that land use change at the extensive margin due to high prices is zero in those countries or regions in Figure 9 that had negative extensive changes. This assumption implies that the forces that caused countries to lose agricultural land during this time would have caused the same amount of loss even without the high prices. Clearly, it would seem that at least some land in these countries was kept in production from the high prices, so this assumption understates land use change at the extensive margin. From a greenhouse gas perspective, this assumption is equivalent to saying that the net amount of carbon sequestration that would have occurred on land that was kept in production by high prices in these countries is negligible.

Second is assuming that all the extensive margin changes in Figure 9 in countries and regions that have positive changes are due to high world prices. This too is an extreme assumption because some land would have been brought into production even if commodity prices had not increased. Thus this assumption overstates the response of land use at the extensive margin.

If we include extensive changes in Africa, then world extensive land use changes equals 41.2 million hectares, which represents a 2.68% increase over the average level of land in production in 2004–2006. If we assume that the extensive land use changes in

Africa were primarily caused by internal domestic food demand from growing populations and income, and they would have occurred even without high world commodity prices, then the extensive land use increase equals 20.7 million hectares or 1.35%.

It is instructive here to make a rough estimate of the response of the world extensive margin to aggregate higher commodity prices. The average real prices of corn, soybeans, wheat, and rice received by US farmers increased by 123%, 85%, 59%, and 47% respectively in 2010–2012 relative to 2004–2006. A simple average of these price increases is 78%. With this real price increase, the elasticity of the world extensive margin is 0.034 if African extensive response is included, and 0.017 if the African extensive response is not included.

Similarly, if the intensive response in countries and regions where the response is negative is set to zero, then the aggregate intensive response to high prices is 49.1 million hectares if we attribute all the intensive response to higher prices. Without the African country response, the aggregate response is 47.2 million hectares. The resulting elasticities of intensive response are 0.041 and 0.039. Thus, if we attribute all the African extensive land use changes to high prices, then the world intensive elasticity is 19% higher than the extensive elasticity. If none of the African response is attributed to higher prices than the non-African intensive elasticity is almost three times as great as the extensive response.

These rough estimates demonstrate that the primary land use change response of the world's farmers in the last 10 years has been to use available land resources more efficiently rather than to expand the amount of land brought into production. This finding is not new and is consistent with the literature that finds significant option value in waiting to convert land (Song et al. 2011). OECD-FAO (2009) recognized that intensive land use change has been the driving force behind higher production levels, however, this finding has not been recognized by regulators who calculate indirect land use. Note that our measure of more efficient land use does not include higher yields in terms of production per hectare harvested. Any increase in yields would be an additional intensive response. Rather the intensive response measured here is due to increased multiple cropped area, a reduction in unharvested planted area, a reduction in fallow land, and a reduction in temporary pasture. Because greenhouse gas emissions associated with an intensive response are much lower than emissions caused by land conversions (Burney, Davis, and Lobell 2010), ignoring this intensive response overstates estimates of emissions associated with land use change because most of the land use change that has occurred is at the intensive rather than extensive margin.

Comparison of Actual Land Use Changes with Model Predictions

Model predictions of land use change from increased biofuel production are conceptually appealing. This is because the effects of higher biofuel production on land use are measured in isolation—the effects of everything else that influences agriculture are held constant. Thus, the effects of biofuel production alone can, at least conceptually, be measured. The way that the models assume increased production impacts land use is through higher prices. Thus, if the actual changes in land use in Figure 9 were the result of a response to the large increase in commodity prices that actually occurred, then it seems reasonable to compare model predictions to the actual changes that occurred. However reasonable this seems, we simply do not know with certainty what land use changes would have occurred without the increase in commodity prices. What needs to be compared to model predictions is the difference in land use with the commodity price increase relative to what it would have been without the commodity price increase.

What information then can be gleaned from a comparison of model predictions with actual changes? At one extreme, if none of the observed changes in extensive land use were the result of high prices, then we know that indirect land use is not empirically important because land use changes are caused by other forces. At the other extreme, if extensive land use would have stayed constant at base period levels if prices had not increased then all of the observed changes resulted from high prices. In this case it would be valid to judge the accuracy of model predictions with observed changes, because both would be caused by price responses. Reality likely falls somewhere in between these two extremes in that land use in 2012 would have been different than in 2004 even without the price increase, and that at least some portion of the observed changes we see can be attributed to higher prices. Taheripour and Tyner (2013) use observed land use changes as a guide to selection of a key model parameter in GTAP in an attempt to reconcile model predictions with observed changes. Hence, they assume that observed changes in land use are a useful guide to determine how the GTAP model should predict how land use changes in response to a change in commodity prices.

The two most widely used international models used in the United States to predict land use changes associated with increased biofuel production are GTAP and FAPRI (Gohin 2014). Both models allowed crop yields to respond to higher prices, and neither model allowed land use intensity, as measured here, to increase. Given that the primary way that non-African countries have increased effective agricultural land was through intensification, both models have an upward bias in their predictions of land use change at the extensive margin in non-African countries.[8]

Figure 10 shows the predicted increases in cropland from the FAPRI model that was used by the Environmental Protection Agency to determine greenhouse gas emissions

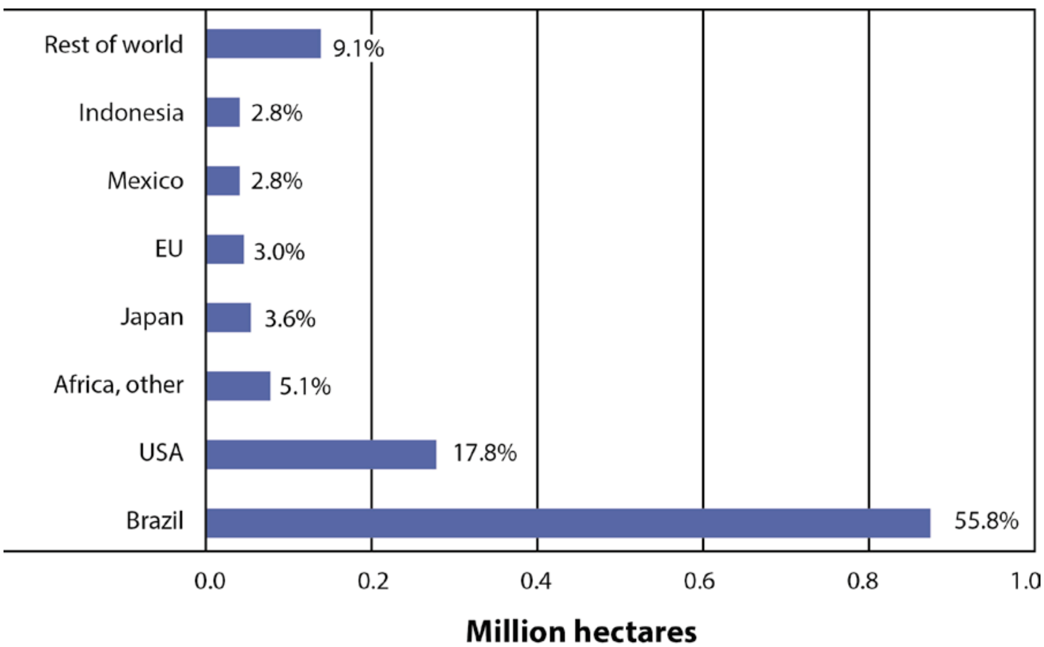

Figure 10. Predicted Land Use Change in EPA "All Biofuel" Scenario: Hectares and Share of World Total

[8] One way that production per unit of agricultural land can increase in the GTAP model is through its yield elasticity, therefore at least some of the upward bias in GTAP's prediction of extensive land use changes is offset by using a yield elasticity value that is higher than can be supported empirically.

associated with land use changes from increased biofuels. What is illustrated is the difference between EPA's "Control Case" that includes levels of biofuels in the RFS and EPA's "AEO Reference Case," which contains lower levels of biofuels (EPA 2010). This scenario simulated increases in many different biofuels including biodiesel made from vegetable oil and waste greases, corn ethanol, sugarcane ethanol, and cellulosic ethanol. How these land use changes were calculated is that the FAPRI predictions of land use in the AEO Reference Case were subtracted from the predictions in the Control Case. The total predicted world change in land use is 1.45 million hectares.

What is striking about Figure 10 is the concentration of predicted land use change in Brazil and the United States. These two countries account for almost 75% of the total predicted change in land use, with Brazil alone accounting for more than half of all change in the world at the extensive margin. In the AEO Reference Case total cropland in Brazil is increasing, thus the predicted increase in area must come from conversion of land that would have been devoted to other uses.

The first valid comparison that can be made between the CARD-FAPRI model prediction and what actually occurred is that the predicted land use change in Brazil due to higher prices is far too high relative to land use changes that actually occurred at the extensive margin in Argentina and other South American countries. As shown in Figure 9 Argentina and other South American countries together increased land use at the extensive margin by almost four times as much as did Brazil. The CARD-FAPRI model results used by EPA predicted almost no land use change in Argentina and other South American countries due to higher prices. It is notable that the CARD-FAPRI model predicted that growth in Brazil cropland from 2002 to 2009 would be about 9.1 million hectares, whereas Argentina's growth would be 3.7 million hectares in the Reference Case. Thus, the larger increase in agricultural area in Argentina that actually occurred cannot be attributed to the model being right about predicting a larger baseline increase in Argentina than in Brazil. The first conclusion one can draw from this comparison is that the CARD-FAPRI model dramatically over-predicted land use change in Brazil relative to Argentina and other South American countries.

The CARD-FAPRI prediction that the United States would account for about 18% of the world's increase in extensive land use seems inconsistent with the large changes that occurred in African countries and Argentina. The only way that the US land use prediction is consistent with the historical record is if cropland in the United States would have dropped by a large amount in the absence of the large price increase. The CARD-FAPRI model predicted that US crop area would decline in both the Reference and Control Cases.

The CARD-FAPRI model includes some South African production and a limited number of other crops in a limited number of African countries. The CARD-FAPRI model implicitly assumes that most of African agricultural production of major crops is isolated from world markets. As discussed above if this isolation is in fact a correct characterization of African agriculture, then the large land use changes in African countries shown in Figure 9 would have occurred even without the high commodity prices. The only other conclusion that can be drawn regarding African countries is that the CARD-FAPRI model underpredicts land use changes there to the extent that land use in African countries responded to world prices.

The commodity price increases that led to the Figure 10 predicted changes in land use were a 3.1% increase in corn prices and a 0.8% increase in soybean prices. These simulated price changes are dwarfed by the actual price changes that have occurred as shown in Figure 1. The FAPRI model prediction of a small increase in extensive land use in Japan and the EU due to small changes in price seems inconsistent with the fact that land use in Japan has been largely unchanged over the last 10 years and the EU has experienced a decline in land use. Again, it is not possible to know the extent to which a small increase in world commodity prices would have kept a small amount of land in production in the EU.

The small model-predicted change in Indonesia in extensive land use is generally consistent with observed changes if we assume that no changes would have occurred except for the higher market prices that actually occurred and not from government development priorities.

Figure 11 shows predicted land use changes by the GTAP model. [9] GTAP predicts that 38% of land use changes occur in the United States. As discussed, although

---

[9] GTAP model predictions of land use changes associated with biofuels vary across publications. Figure 11 land use change predictions were taken from Hertel et al. (2009) which were published about the same time that California's Air Resources Board was making their determination of greenhouse gas emissions from land use change that relied on GTAP model predictions. For the purposes of this paper, we assume that the

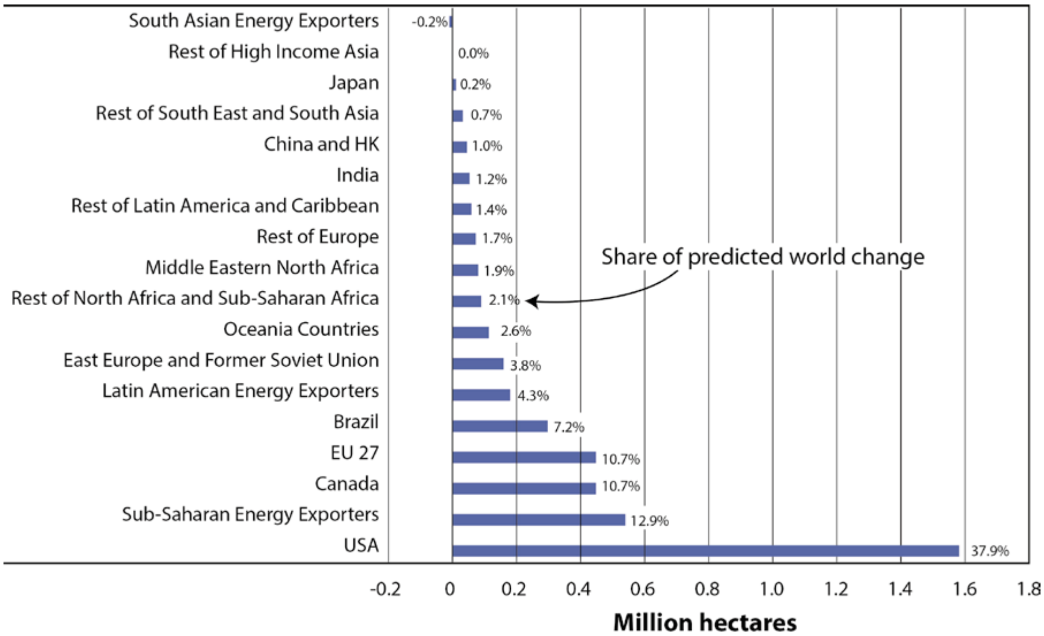

Figure 11. GTAP Predictions of Indirect Land Use Change from Corn Ethanol
Source: Hertel et al. (2009)

this seems like a large over-prediction of the US contribution, it is not possible to say this prediction is inconsistent with the recent historical data given that we cannot observe what land use would have been without the price increase. However, for this prediction to be true, the fairly small price increase simulated by GTAP would have kept a sizeable amount of land in production in the United States.

As with the CARD-FAPRI model, GTAP over-predicts the land use change for Brazil relative to other Latin American countries assuming that the baseline in Hertel et al. (2009) shows Brazil's area increasing more than agricultural area in the rest of Latin America. This baseline level of data was not available for inspection but GTAP's baseline was developed using 2001 data that incorporates land use changes that occurred in previous years. Brazil's agricultural land was expanding in this prior period, so it is reasonable to assume that Brazil's land use in the baseline was increasing more than in

Figure 11 land use changes are consistent with those used by California. There exist many GTAP-based estimates of land use change due to biofuels. An alternative estimate was provided by Tyner (2010). First and Second Generation Biofuels: Economic and Policy Issues, Presented at the Third Berkeley Bioeconomy Conference, June 24, 2010, http://www.berkeleybioeconomy.com/wpcontent/uploads//2010/07/TYner%20Berkeley%20June%202010.pdf.

other South American countries. This would imply that the predicted change in Brazil relative to the rest of Latin America is too large.

Despite the large discrepancies between model predictions and the actual land use changes that have occurred since 2004 it simply is not possible to conclude with certainty that the model predictions have been proven wrong and should be disregarded. For example, the Hertel et al. (2009) prediction that large land use changes from output price increases resulting from US corn ethanol production would occur in the United States, Europe, and Canada seems inconsistent with the fact that cultivated land decreased in the EU and Canada and stayed constant in the United States despite price changes that were many times larger than those predicted by the model. However, it could be that the amount of actual land reduction that would have occurred in the EU and Canada would have been much larger without the commodity price boom and that if actual land use changes were calculated relative to what would have happened without the price impact then the GTAP model predictions would be consistent with what we observe. Thus, without being able to observe the alternative history that did not contain the commodity price boom, it is not possible to conclude with certainty that the model predictions are wrong. As Babcock (2009) pointed out, economists who run models to predict future land use changes are in the enviable position that skeptics of the predictions will find it difficult to use the actual land use change data to prove that the model predictions were wrong. However the historical record of land use changes can be used to provide insight into the types of land that were converted assuming that the model predictions are correct.

Using the Historical Record to Guide Estimates of Land Conversion

Table 1 below presents some GTAP results that were used by California's Air Resources Board to calculate CO_2 emissions associated with land conversion due to corn ethanol production. By regressing emissions on the amount of land converted, it is possible to obtain a rough estimate of how each of the four land conversions affect estimated emissions separately. Table 2 provides the regression results.

An increase in land conversion increases GTAP's estimates of emissions. Conversion of a million hectares of forest increases emissions much more than conversion of pasture. How to interpret these coefficients is that a one million hectare increase in, for

example, US pasture to crops, leads to a 6.17 increase in emissions measured by grams CO_2 per MJ of gasoline energy replaced by corn ethanol. Across all seven scenarios the average prediction of forest conversion in the United States is 0.58 million hectares.

Multiplying 0.58 by 22.69, which is the coefficient relating conversion of forest to emissions, results in an estimate of the average contribution of US forest conversion to the final CO_2 emission number. The result is that GTAP estimates that conversion of US forests contributes 13.06 gCO_2/MJ or 43% of total estimated emissions.

As shown in Figure 8, US cropland did not appreciably increase at the extensive margin in response to higher prices on average in 2010–2012 relative to 2004–2006.[10] As

[10] A more detailed examination of US data is provided in the next section, which shows there is some evidence of an increase in planned area to be planted from 2007 to 2013. The 2004–2006 and 2010–2012 time periods were used to make US data consistent with available data for other countries.

discussed in the previous section, it is not possible to conclude whether the GTAP model prediction that US cropland would be 1.6 million hectares higher due to higher prices is inconsistent with what actually happened, because it could be that US cropland would have declined from 2004 to 2012 if the higher prices had not occurred. For example, if US cropland would have declined by 5 million hectares if the high prices had not occurred, then the GTAP prediction that 1.6 million of these hectares would have been kept in production is consistent with the historical record. More formally, a necessary condition for consistency of the model prediction of an increase in US cropland due to higher prices is that US cropland would have declined by at least the amount of the model prediction were it not for the higher prices that actually occurred.

So suppose that there would have been a 5 million hectare decline in US cropland were it not for the higher prices and the GTAP prediction is correct that 1.6 million hectares of this land would have been kept in production because of higher prices caused by corn ethanol production. This means that the type of land converted to accommodate biofuels was not forest or pastureland but rather cropland that did not go out of production. Calculation of foregone carbon sequestration depends on what would have happened to the cropland if it did not remain in crops which, in turn, depends on where the cropland is located and the potential alternative uses. The magnitude of the change in estimated CO_2 emissions from cropland that is prevented from going out of production relative to forest that is converted to cropland is potentially large. For example, from Table 2, converting one million hectares of grassland instead of forest would reduce land-based CO_2 emissions by 11.3 gCO_2e/MJ in the rest of the world and by 16.5 gCO_2e/MJ in the United States. If foregone carbon sequestration is less than the amount of carbon lost from converting pasture to crops then the magnitude of the emission reduction would be larger.

The countries in Figure 8 that either had negligible or negative extensive land use changes should be presumed to not have converted pasture or forest to crops in response to biofuel-induced higher prices. Rather, the presumption should be that any predicted change in land used in agriculture came from cropland that did not go out of production. From Figure 11 this would include Canada, the EU, Russia, the Ukraine, and India.

The countries in Figure 8 that had significant extensive land increases cannot be presumed to have only kept cropland in production because of biofuels. Whether the expanded cropland due to the portion of the actual price increase attributable to biofuels expansion came from cropland that would have gone out of production or from pasture is an accounting decision. For these countries that expanded extensive land use, the historical pattern of where in the country the land use expansion occurred provides insight into the type of land that was converted to crops.

Brazil is one country that expanded extensive land use and has data on where this expansion occurred. Figure 12 shows each state's share of extensive land use change in Brazil measured by the change in the 2010–2012 average from the 2010–2012 average.[11] Not surprisingly extensive land use increased the most in Mato Grosso. Expansion of sugarcane area in Sao Paulo explains its increase. The states of Goias, Maranhao,

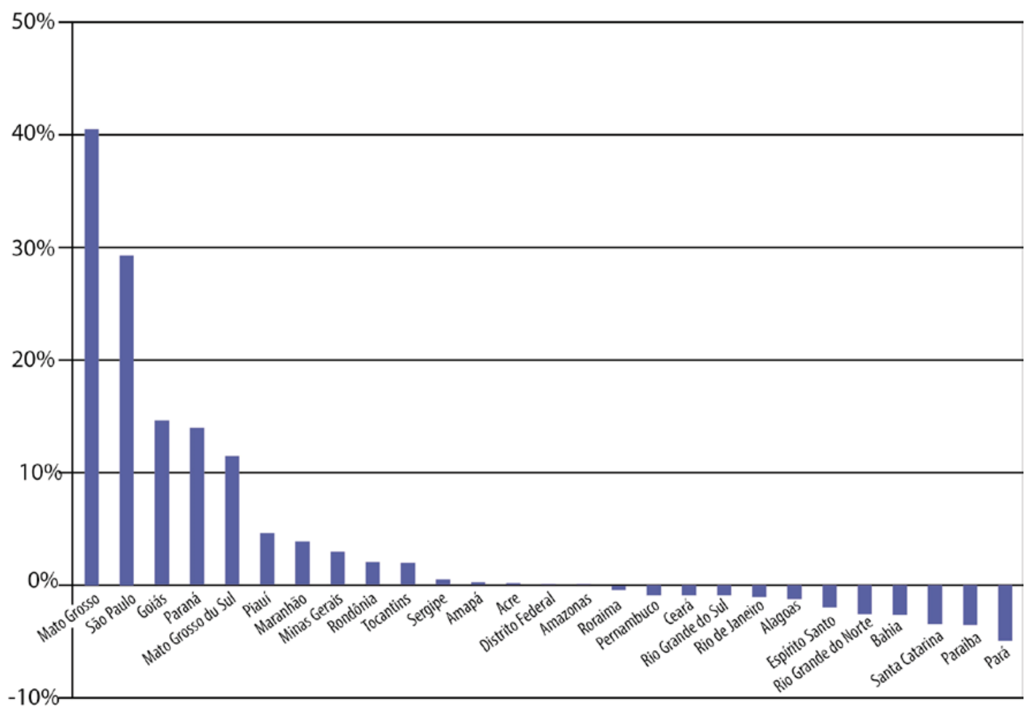

Figure 12. State Share of Brazil's Change in Extensive Land Use from 2004–2006 to 2010-2012.

[11]Only land that was planted to crop was considered in calculating each state's share of extensive land use change. The cropland planted data comes from the IBGE website: http://www.sidra.ibge.gov.br/bda/acervo/acervo9.asp?e=c&p=PA&z=t&o=11. Total planted cropland in Brazil is less than FAOSTAT data on arable land plus permanent crops that was used to determine extensive and internsive land use changes in Figure 10 and 11.

Tocantins, and Piaui all have large land areas in the vast Brazilian Cerrado biome which has also seen large-scale development (The Economist). Rondonia is the only state in the Amazon biome that shows an increase in cropland. Where cropland has expanded in Brazil (and in other countries where data allows) can be used as a guide to determine if model predictions of the type land converted are accurate.

A More Detailed Look at US Extensive Area Data

Figure 13 shows what has happened to one measure of US cropland from 1993 to 2013. This measure is area planted to US principle crops as measured by USDA-NASS, less double cropped harvested area, plus fallow cropland. This measure reached its peak in 1996. In 2007, this measure increased after a long downturn, suggesting some impact of higher prices. However, in 2010 it fell below 130 million hectares before increasing in 2011 and 2012. It is somewhat surprising that total land in agriculture has not increased more than indicated since 2006 because land enrolled in the Conservation Reserve

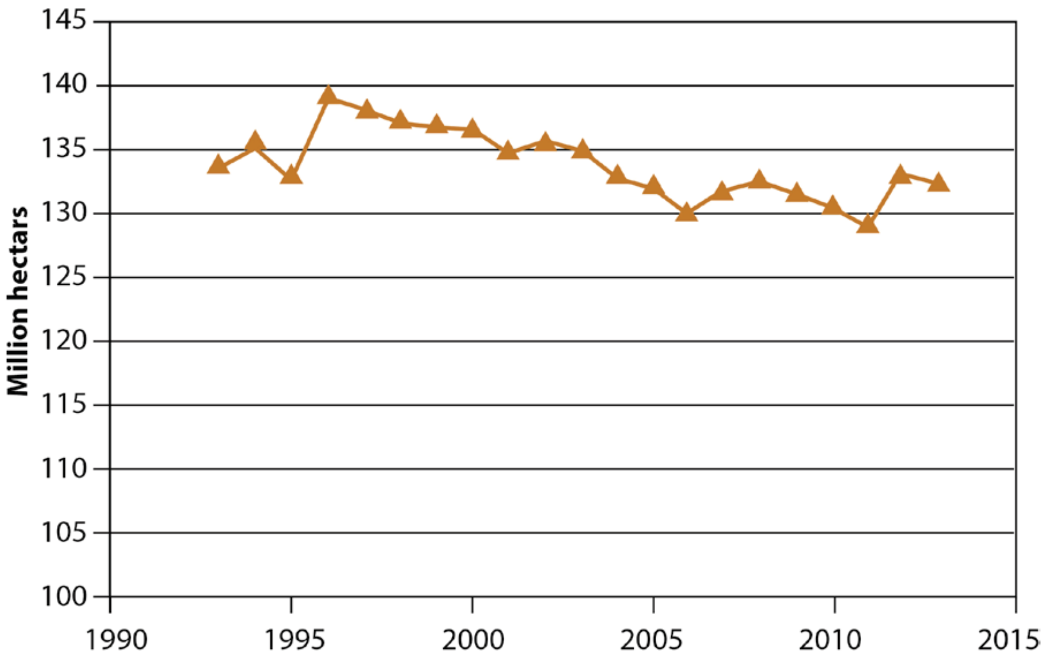

Figure 13. US Cropland Since 1993

Program (CRP) declined by 4 million hectares from 2007 to 2013. One explanation for a lack of response in this measure of land use could be an increase in area that is reported as prevented planting area.

The US crop insurance program creates an incentive for farmers to report area that they had planned to plant but were not able to due to adverse weather. This land is called prevented planted acres. Farmers who buy crop insurance receive a crop insurance payment on these acres. Aggregate data on the amount of prevented planted acres can be added to the Figure 13 data to measure how much land US farmers intend to plant each year. Data on the area designated as prevented planting area are available since 2007.[12] Figure 14 shows the change in CRP land since 2007 (grey line), the change in US cropland since 2007 (blue line calculated from Figure 13), and the change in intended planted land since 2007 (orange line). It is striking how close the change in intended

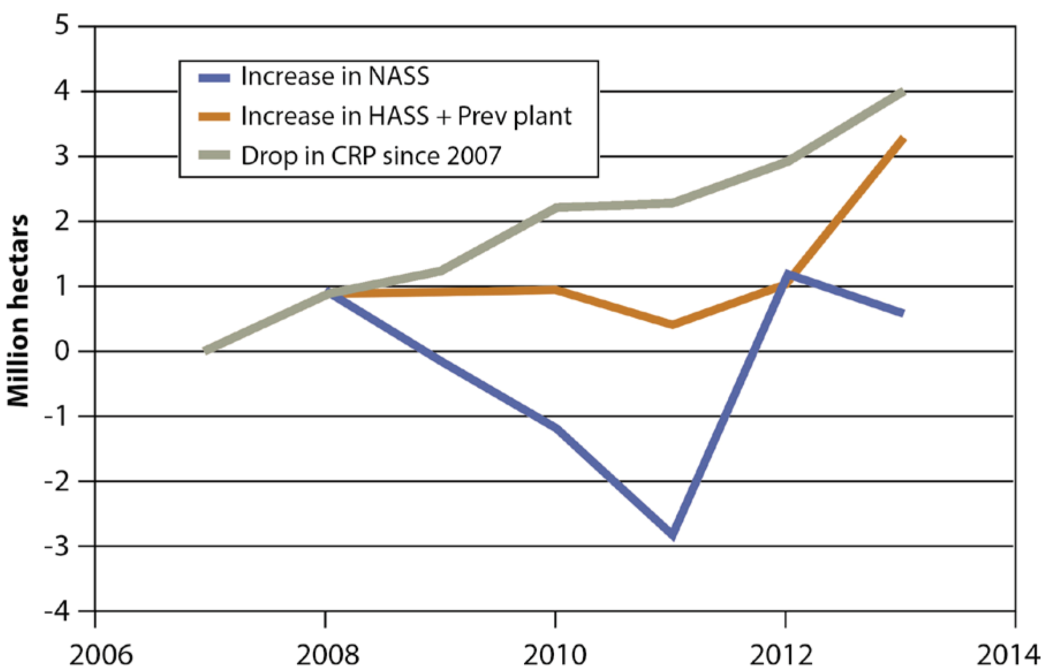

Figure 14. CRP Land Showing up as Increased Prevented Planting Acres

[12] Prevented planting has been part of the US crop insurance program before 2007 but data on total area designated as prevented planting are not readily available.

planted land is to the reduction in CRP, and it is also striking how little of the land that is no longer enrolled in CRP shows up as land in production.

What can be concluded from this more detailed examination of extensive land use in the United States is that the data seem to indicate a reversal of a long-term trend of declining total US cropland since 1996 beginning in 2007—the first crop planted in response to significantly higher prices for US corn and soybeans. The large reduction in land enrolled in CRP is much greater than the amount of land that is reported as being in productive use in crop production. This suggests that there is an abundance of ex-CRP land that is available for planting or that a large proportion of ex-CRP land has not yet been available for crop production and is being reported as having been prevented from being planted. The data are consistent with any increase in extensive land use since prices increased in 2006 as coming from a stock of available land that had been planted to crops previously or from land that was enrolled in CRP. This finding is consistent with USDA (2013), which found that the only net contributor to US cropland from 2007 to 2010 was a reduction in CRP land. There was no net increase in cropland from conversion of forests, from conversion of urban land, or from conversion of pasture.

Conclusions

That countries primarily responded to higher world prices by intensifying land use rather than by converting land from forests and pastures should not be surprising. Many countries, such as China and India, simply do not have available land to bring into agriculture. In countries with land suitable for crops, the investment and other transaction costs of developing new land make the process quite costly relative to the cost of increasing the intensity of land use. In addition, the value of waiting to invest in land conversion projects is large, which leads to a significant delay in land conversions.

The pattern of recent land use changes suggests that existing estimates of greenhouse gas emissions caused by land conversions due to biofuel production are too high because they are based on models that do not allow for increases in non-yield intensification of land use. Intensification of land use does not involve clearing forests or plowing up native grasslands that lead to large losses of carbon stocks.

The recent data on land use changes reveals the importance of policy in determining land use decisions. In Argentina, higher export taxes and quotas on corn and wheat relative to soybeans caused soybean area to increase and wheat area to decrease. The drop in wheat area limits the availability of land on which soybeans can be double cropped which means that expansion of soybeans can only take place by replacing existing crops or by expanding onto new lands. In Brazil, increased enforcement of laws restricting clearing of forests and the resulting drop in the rate of deforestation is consistent with Brazil expanding land use at both the intensive and extensive margin.

It might be argued that recent data are a poor indicator of what we should expect to happen if more time passes because supply response is always larger in the long-run than in the short-run. Land conversion takes time but the time gap used here to measure land use change is long enough to allow a significant amount of change to happen. In addition, the incentive to expand agricultural supply between 2006 and 2012 was as strong as any period since at least 1960. Furthermore, if the recent sharp declines in commodity prices continue then the incentive to expand supplies in the future will be muted.

We plan on extending our analysis of land use changes by attempting to develop a statistical model to explain more systematically why some countries expanded land use more at the extensive margin and others expanded more at the intensive margin. Such a model could provide better insights into the role that policy, price transmission, and resource availability plan in determining agricultural supply response. Improved understanding could be useful to future attempts at estimating greenhouse gas emissions caused by extensification of agricultural production.

Abstract: Estimates on impacts of biofuel production often use models with limited ability to incorporate changes in land use, notably cropping intensity. This review studies biofuel expansion between 2000 and 2010 in Brazil, the USA, Indonesia, Malaysia, China, Mozambique, South Africa plus 27 EU member states. In 2010, these countries produced 86 billion litres of ethanol and 15 billion litres of biodiesel. Land use increased by 25 Mha, of which 11 Mha is associated with co-products, i.e. by-products of biofuel production processes used as animal feed. In the decade up to 2010, agricultural land decreased by 9 Mha overall. It expanded by 22 Mha in Brazil, Indonesia, Malaysia, and Mozambique, some 31 Mha was lost in the USA, the EU, and South Africa due to urbanization, expansion of infrastructure, conversion into nature, and land abandonment. Increases in cropping intensity accounted for 42 Mha of additional harvested area. Together with increased co-product availability for animal feed, this was sufficient to increase the net harvested area (NHA, crop area harvested for food, feed, and fiber markets) in the study countries by 19 Mha. Thus, despite substantial expansion of biofuel production, more land has become available for non-fuel applications. Biofuel crop areas and NHA increased in most countries including the USA and Brazil. It is concluded that biofuel expansion in 2000–2010 is not associated with a decline in the NHA available for food crop production. The increases in multiple cropping have often been overlooked and should be considered more fully in calculations of (indirect) land-use change (iLUC). © 2013 Society of Chemical Industry and John Wiley & Sons, Ltd

Introduction

Increased biofuel production has led to criticism and concerns about food availability while it is feared that rising demand for cropland will lead to deforestation, grassland conversion and increased Greenhouse Gas (GHG) emissions from these land use changes. The main criticism is based on expected impacts of biofuel production following the introduction of dedicated biofuel targets and policies.[1–3]

Commonly used economic models in biofuel policy evaluation include multimarket partial equilibrium models such as the FAPRI-CARD, ESIM, and IMPACT model, and computable general equilibrium (CGE) models such as the Global Trade Analysis Project (GTAP), LEITAP and the Modeling International Relationships in Applied General Equilibrium (MIRAGE) model. Most models were originally developed to evaluate agriculture or climate policies and were later adapted to incorporate biofuel production.[4–6] This has consequences for the way the models have been implemented. Early applications, for example, did not consider generation of co-products (by-products of the biofuel production process which are mostly used as animal feed)[1,7] while second-generation biofuel production technology, at least in early applications, was not included.[4]

Other restrictions include limited ability to adjust to accelerations in yield improvement[7] or to changes in crop rotation.[9] Most models do not consider double-cropping (cultivation of two or more crops on the same plot within a given year), while changes in fallow or other unmanaged land can only be accommodated to a limited extent,[8] which is considered a significant drawback of model results.[7] Changes in programs offering farmers compensation for not cultivating arable land (Conservation Reserve Program (CRP) in the USA and Set-Aside in the EU), for example, were often not adequately represented. Further, models do not fully incorporate impacts of trade policies (e.g. preferential biofuel imports[8]), crop tillage,[10] or agro-ecological conditions in crop production areas.

While the exact consequences of these limitations remain unclear, there is a risk that relevant changes in crop production patterns, partly triggered by biofuel policies, may not be sufficiently covered in the analysis. Scenarios for future crop production published by the Food and Agriculture Organization (FAO) suggest that increasing cropping intensity will be an important source of additional crop biomass. According to Nachtergaele *et al.*,[11] cropping intensity is projected to increase by a total of 4% in developing countries between 2006 and 2050. For developed countries, however, the forecast increase is 7%. Global average is projected to increase by 6%.

Central to the debate on the impact of biofuel production is the question to what extent current policies are causing alienation of land from food and feed production. At the core is the way increased biomass requirements are to be met by area expansion, yield improvement or by increased cropping intensity. Bruinsma[12] estimated that 80% of the projected growth in crop production in developing countries up to 2050 would come from intensification in the form of yield increases (71%) and higher cropping intensities (8%). Higher shares are projected in land-scarce regions such as South Asia and the Near East/North Africa where increases in yield would need to compensate for the expected decline in the arable land area. Arable land expansion will remain an important factor in crop production growth in many countries of sub-Saharan Africa and Latin America; although less so than in the past.

Given the large (albeit possibly temporary) increases in crop prices, the general expectation that biofuels will permanently push up demand for food crop biomass plus the fact that farmers in the past have shown to be able to respond effectively to changes in crop demand might have to be moderated. Especially the projected increases in cropping intensity may be on the low side. Using data for 1962–2007, OECD-FAO[13] for example calculated that half of the realized increases in the harvested area were attributable to increased cropping intensity (the other half have been related to area expansion).

More recently, reduction of (fodder and) CRP area and increased double-cropping have been reported for the USA.[14] For example, about 16% of 2008 corn and soybean farms had brought new acreage into production since 2006. This new, formerly uncultivated, land accounted for approximately 30% of the reported farm's expansion in total harvested acreage. Most acreage conversion came from uncultivated hay. Some 15% of corn and soybean farms reported a harvested acreage (summing up all crops) exceeding their arable area in 2008, implying an increase in double-cropping. These farms reported greater expansion in harvested biofuel crop acreage than other farms, suggesting double-cropping is a quick and effective strategy to generate additional biofuel crop biomass.

Given the above limitations, economic model impact assessments of biofuel policies should be considered with care. Consequences of the limitations on the modeling outcome are difficult to assess but they may be considerable. The introduction of co-products in a GTAP evaluation of US and EU biofuel policies, for example, was

© 2013 Society of Chemical Industry and John Wiley & Sons, Ltd

assessed to reduce the need for land conversion with 27%.[6] According to Croezen and Brouwer,[15] scenarios including second-generation biofuel technologies resulted in land-use requirements that were 50% lower as compared to scenarios which did not include lignocellulosic biofuel conversion technologies.

In summary, the use of estimates of biofuel scenarios based on incomplete information could generate misleading estimates. Another risk is the inadequate input use, which could give an incorrect impression with respect to day-to-day crop management practices such as input use efficiency. Consequently, perspectives for (sustainable) biomass production for biofuel and food/feed applications may be estimated incorrectly.

With a view to improving the accuracy of data for evaluations of biofuel policy impacts, this paper assesses data from different sources of biomass production of eight major biofuel producers. We analyze biofuels and feedstock increases of major biofuel feedstocks between 2000 and 2010, and their impacts on land use in Brazil, the USA, the EU, China, Indonesia, Malaysia, South Africa, and Mozambique. Together, these countries represent a large majority of global biofuel production. Local conditions for crop and biofuel production will be described in a generalized way. In order to determine the impact of biofuel policies, production volumes will be compared to those of 2000, clearly before most countries introduced biofuel-related policy measures. An important distinction will be made between the amount of biomass (crop feedstocks) that is used to generate biofuels, the amount of land that is needed to produce the biomass, and the average number of harvests that can be generated from arable land (resulting from the prevalence of fallow and double-cropping in a given region). The paper will make use of the following concepts:

- Harvested area: the crop area that is harvested in a country or region in a given year. This differs from the amount of arable land, as land may be harvested several times, while fallow land is not harvested at all.
- Agricultural area in a given country or region. This includes arable land (cultivated with arable crops, i.e. food and feed crops), permanent grassland and agricultural tree crops (fruits, beverages, stimulant crops)
- Cropping intensity: the ratio of harvested crop area to the amount of arable land.*

The relation between these concepts is the following equation:

- Harvested area = arable area * cropping intensity (1)

In our analysis, we estimate land and biomass balances. Based on the volume of biofuels produced, the equivalent amount of biomass and the required area of land is calculated. These estimates are based on detailed material collected and analyzed for a book on biofuel crop production systems currently in preparation. The review is organized as follows. First, it describes available land resources in the study countries. Next, it presents biofuel production in 2010 which is compared to that in 2000. Implications of biofuel expansion for land use are given, as are other changes in land use that have been observed. This is followed by a discussion and some conclusions.

Land resources

An overview of land cover and land use in the study countries is presented in Table 1. China, Brazil, and the USA are the largest countries, Brazil having the largest forest area (nearly 40% of the study countries total). Agricultural area is high in China, the USA and (on a relative scale) the EU, Mozambique, and South Africa. Most arable land is found in the USA, China, and the EU, permanent grasslands being important in China (hosting more than one-third of the study area grassland), the USA, and Brazil. We calculated cropping intensity, expressed as the sum of all harvested crop area during a given year divided by the total arable land (the Multiple Cropping Index or MCI). MCI was originally introduced as a measure for cropping intensity of tropical farming systems,[16] but can be calculated for temperate regions as well.[12] MCI in the study countries varies between 0.53 in South Africa, 1.45 in China. It is around 0.8 in Brazil, the USA, and the EU.

Biofuel production

Sugarcane is the predominant feedstock for ethanol production in tropical regions (Table 2). In temperate areas, ethanol is mostly made from cereals (corn in the USA and China, wheat in the EU and China). Main biodiesel feedstocks are soybean (Brazil, USA), rapeseed (EU), and oil palm (Indonesia and Malaysia). There are other feedstocks of minor importance, such as castor beans in Brazil, sunflower in the EU and Jatropha in Mozambique, but these are not included in the analysis.

Large differences exist in the way fields are prepared for biofuel production. There are a number of practices which

*Note: this is not similar to the intensity of crop production (amount of inputs used per ha or amount of yield realized per ha).

Table 2. Biofuel production chains included in the analysis.

Region	Feedstock	Biofuel	Field preparation	Input use
Brazil	Sugarcane	Ethanol	Pre-harvest burning is phased out	Moderately low
Brazil	Soybean	Biodiesel	Mostly no-till	Low
USA	Corn	Ethanol	Mostly plowed	High
USA	Soybean	Biodiesel	Half under no-till	Moderately low
EU	Wheat	Ethanol	Plowing	High
EU	Rapeseed	Biodiesel	Plowing	High
EU	Sugarbeet	Ethanol	Plowing	Moderately high
Indonesia and Malaysia	Palm oil	Biodiesel	Pre-harvest burning	Moderately low
China	Corn	Ethanol	Plowing	Very high
China	Wheat	Ethanol	Plowing	Very high
Mozambique	Sugarcane	Ethanol	Pre-harvest burning	Moderately high
South Africa	Sugarcane	Ethanol	Pre-harvest burning	High

determine the performance of the biofuel production chain including pre-harvest burning of sugarcane leaves and plowing for arable crops. Burning leaves of sugarcane is common practice before manual harvesting in order to avoid injuries to laborers. This causes a considerable loss of leaf material and soil organic matter, while emissions of particulate matter cause a threat to the laborers' lungs. This practice is gradually being phased out in Brazil where mechanical green harvesting is becoming more common. Plowing arable fields, causing loss of soil carbon, is common in the EU and in China, but less so in the Midwest of the USA and soybean cultivation in Brazil, who have adopted conservation agriculture. Use of fertilizers and agro-chemicals is highly variable. Input use in feedstock production is low to moderately low in Brazil and in the USA (corn), Indonesia, Malaysia and Southern Africa. It is high in the production of cereals (USA, EU, and China) and rapeseed. Sugarbeet holds an intermediate position.

The main output data are presented in Table 3. Crop yield is high for sugarcane (Brazil, South Africa), sugarbeet, and oil palm. Cereal yields are high for corn in the USA, but less so for corn and wheat in the EU and China. Rapeseed and soybean yields are modest. Ethanol yields are highest for sugarbeet, and sugarcane (Brazil). Highest biodiesel yields were observed for oil palm (Indonesia, Malaysia). Generation of co-products is also quantified, as these can be applied in the livestock industry. Major biofuel crops are well established feed crops, which holds especially for corn and soybean. Co-products considered in this study include dried distillers' grains with solubles (DDGS), soy meal, rapeseed meal, beet pulp, and palm meal. It was decided to use a simple mass balance approach to distinguish between crop biomass used for biofuel production and for feed applications. Biofuel land claims were calculated by allocating a share of total land use according to the ratio of total crop feedstocks used for biofuels. Co-product yields were calculated using conversion data and converted into tons per ha equivalent

which allows better comparison. Co-product yields are high for corn (USA), oil palm, and sugarbeet. Yields are low for rapeseed and soybean, while no co-products for the food or feed market are generated by sugarcane-ethanol.

Ethanol production in the study countries, amounting to 17 billion litres in 2000, rose to 86 billion litres in 2010 (Table 4). Most of the increase was realized in the USA, which was responsible for a production of 50 billion litres in 2010. Brazil is the second-largest producer with 28 billion litres, followed by the EU and China. Increases have been relatively high in China, the USA, and the EU. Biodiesel production rose from 0.8 to 15 billion litres. The EU is the highest producer, followed by Brazil and the USA. Indonesia, Malaysia, Mozambique, or South Africa are not producing significant amounts of biofuels, although they may be important producers in their respective regions. Biofuel production in the study countries (86 and 15 billion litres of ethanol and biodiesel, respectively) represents 97% and 77% of the global total production level. Thus, conclusions of global significance can be drawn from the analysis of the study countries.

Table 4. Biofuel production in the study countries (billion l).

	Ethanol			Biodiesel		
	2000	2010	Increase	2000	2010	Increase

Notes: N.i. = not included; Neg. = negligible.

Land use

Land used for biofuel expansion was calculated by dividing increased biofuel production presented in Table 4 by biomass to biofuel conversion rates taken from literature. Since 2000, biofuel expansion in the study countries has claimed an additional 25 million ha of cropland (Table 5). As 11 million ha is allocated to co-products, net biofuel expansion amounts to 14 million ha. Over 85% of area expansion occurred in the USA, where increased biofuel production has occupied over 5 million ha, and in the the EU and Brazil. Co-product generation is relatively high in the USA and the EU. The main crops used to produce biofuels (corn, wheat, soybean, and rape), are dominant feed crops whose nutritive characteristics have long been known. Low co-product ratio in Brazil is explained by the high share of sugarcane, whose residues are mostly used in the production of biofuels or electricity (co-generation). Vinasse is recycled and used as fertilizer.

Since 2000, countries of the study area have seen a net decline in agricultural area by 9 million ha. Loss of agricultural area in the USA, the EU, China, and South Africa amounted to 31 million ha, which is mostly compensated

China	2.2	0.4	1.8	–13.4	20.3	5.1
Mozambique	0.13	0.03	0.1	1.3	0.9	2.0
South Africa	0.12	0.04	0.1	–2.7	–1.2	–4.0
All	24.9	11.4	13.5	–9.0	41.5	19.0
Global total				–47.8	91.5	

by expansion of agricultural land in Brazil (plus 12 million ha), Indonesia/Malaysia (plus nine million ha), and Mozambique. Net global loss of agricultural area amounted to 48 million ha. In many cases, loss of agricultural area has been much larger than net expansion of biofuel area. This was the case in the EU, China, and South Africa. It is only in the USA that biofuel expansion is the dominant cause of agricultural land use loss.

Increasing the cropping frequency on arable land – reflected by an increase of the MCI – allows farmers to increase the harvested area on shrinking agricultural areas. This has facilitated *additional* crop harvests equivalent to 42 million ha. More than half of this expansion was realized in China, where government policy has been oriented toward improving (maintaining) food production capacity. MCI also added considerable harvested areas in the USA, Brazil, the EU, Indonesia, and Malaysia. The role of MCI in improving agricultural output since 2000 can hardly be overemphasized. Global increases, equivalent to 92 million ha of harvested crops, have been more than sufficient to compensate for losses of agricultural area.

Improvement of MCI in all but one case is more than sufficient to compensate for expansion of biofuel area: this is the case in Brazil (where MCI generated 5 million ha while biofuels required 3 million ha – a positive balance of nearly 2 million ha), the USA (11 *vs.* 5 million ha), EU (0.2 million ha balance), Indonesia/Malaysia (plus 2 million ha), China (19 million ha) and Mozambique (0.8 million ha). South Africa, which noted a decline of MCI, is the exception to the rule of increased cropping intensity.

The combined effect of biofuel expansion, changes in agricultural area, and improvement of MCI generally is positive. Together, countries included in the study increased harvested area for non-biofuel purposes of 19 million ha. This increase allowed improved availability of crop production for traditional food, feed, and fiber (FFF) markets. Net FFF area increased in most of the cases, except for the EU and South Africa.

Discussion

Following changes in biofuel policies in the course of the first decade of the twenty-first century, a strong expansion in biofuel production was observed in the USA, the EU, China, and many other countries. The 34 study countries realized an increase in ethanol production of 68 billion litres and 14 billion litres of biodiesel in 2010 as compared to 2000. These increases, however, were not sufficient to fully satisfy biofuel policy objectives in the USA and the EU. China, Indonesia, and Malaysia have adjusted policies in response to substantial consumption of food cereals and high palm oil prices, respectively. For the near future, further expansion of biofuel production is expected especially in the USA, Brazil, Argentina, and the EU. Smaller, but significant, development may be expected elsewhere.

Land devoted to biofuel production was calculated at 32 million ha in 2010, an increase of 25 million ha as compared to 2000. Of this increase, 11 million ha can be allocated, using standard conversion rates, to co-products. This means that nearly half of the increase in biofuel area in fact is used to generate crop biomass for the livestock feed market. Clearly, ignoring co-product generation in early biofuel impact assessments has led to an overestimation of land requirements, in most cases by 40% or more. The contribution of feed co-products is relatively high in the USA, China, and the EU due to the large share of cereals with high feed yields. It is low in Brazil where ethanol production is dominated by sugarcane which generates no

© 2013 Society of Chemical Industry and John Wiley & Sons, Ltd

feed co-products. However, it should be noted that the co-generation of electricity from sugar cane residues has not been included in the calculations.

Biomass used for biofuel production, calculated from biofuel literature and FAO statistics, amounted to 527 million ton in 2010. This is an increase of 334 million ton, of which 80 million tons is for co-product generation. Biofuel expansion therefore required 254 million tons of crops. Area expansion, amounting to 25 million ha (including co-products), has been relatively stronger due to a shift from high yielding (ton per ha) sugarcane to cereals like corn and wheat and to oil crops like soybean and rapeseed all which have much lower yields than sugarcane. Implications for land use will, however, also depend on the role of yield improvement. In literature, different assumptions on yield improvement can be found. For US corn, for example, Searchinger *et al.*[19] assumed a maximum of 20% yield improvement in 30 years. Others have suggested that a considerable share of corn used in biofuels in the USA could be generated by yield improvements.[20] One should be extremely careful comparing crop yields as these tend to show large year-to-year variations. However, US corn yields calculated from FAOSTAT data suggest that a significant part of these yield improvements already has taken place between 2000 and 2010. Indicative yield improvements (3-year averages) during this period of sugarcane in Brazil and wheat in the EU have been 17% and 11%, respectively.

The changes in land use that were reported are most revealing. The loss of agricultural area due to urbanization, etc., in industrial countries (USA, EU, South Africa) is two times larger than biofuel expansion (31 *vs.* 14 million ha). Expansion of agricultural area in other countries (Brazil, Indonesia, Malaysia, and Mozambique) amounted to 22 million ha. Changes in intensification of arable cropping are even larger. On a global scale, the MCI increased by 7% in a period of ten years. This may not seem high, but as it applies to an area of 1.4 billion ha, the implications are enormous. In the study area, improvement of cropping intensity has been variable. It rose by 14% in China, 10% in Brazil and Mozambique, and 4% in the EU. Other countries take an intermediate position.

For the entire study area, 42 million ha of crop harvested area has been generated. Consequently, the reduction of unutilized arable land (CRP in the USA, set-aside in the EU plus fallow) and an increase in double-cropping has been sufficient to generate nearly three times the amount of biofuel land expansion. Both fallow reduction and double-cropping seem to have been largely ignored in the debate so far which is a serious omission. Improved MCI was identified as a major source of increased harvested area by OECD-FAO,[12] but the consequences for land availability vis-à-vis future biofuel expansion tend to have been overlooked. Bruinsma[11] focused mainly on yield improvement. Economic models used in evaluation of biofuel policies appear to have neglected the potential contribution of MCI.

In the future, MCI may be expected to show further increases. The magnitudes will, however, depend on crops and farming systems. Tropical regions have a larger potential for double-cropping (provided sufficient water is available). Cereals and pulses, having relatively short growing cycles, provide good perspectives. Sugarcane, occupying land year round, has limited potential for increased MCI. Climate change may, however, also offer new opportunities for temperate regions, for example, when temperatures in spring allow early harvesting of winter cereals.[17]

The approach that was followed has a number of advantages. Calculating full biomass balances allowed the assessment of biofuel feedstocks available for animal feed and – consequently – gives a realistic assessment of the amount of feedstocks required for biofuel production. Requirements of biofuel production for biomass and land resources were calculated with local data, thus incorporating a realistic assumption of cultivation practices, crop rotations, yields, and conversion efficiencies. The use of full land balances has put land demand for biofuels in perspective, integrating many processes which affect land requirement and changes in land use. Limitations of the approach are related to the large number of data that are needed. Data on crop rotations and cultivation practices often have a local nature which makes it difficult to obtain a more generic picture at the national level. Data on double-cropping and biomass to biofuel conversion are extremely difficult to obtain while the exact relation between biofuel production and increased MCI needs to be investigated. Calculations, finally, have been restricted to major biofuel feedstocks.

Notwithstanding these limitations, the implications of the findings are substantial. The impact of the increases in cropping intensity can hardly be overemphasized. On the one hand, observed MCI improvement since 2000 demonstrates that projected biofuel crop areas (estimated up to 50 million ha in 2050) can easily be compensated. In one decade, enhanced cropping intensity generated as much as 92 million ha of extra harvested crops worldwide. This is surprisingly high, and the consequences are clear. While biofuel production may occupy a significant amount of crop land in the future, there are strong drivers of crop area expansion which may be able to generate similar – or larger – additional harvested areas

© 2013 Society of Chemical Industry and John Wiley & Sons, Ltd

in biofuel countries. Thus, there is little reason to expect that biofuel expansion will lead to substantial reductions of area of food/feed production. For the first decade of the twenty-first century, net harvested area for traditional (non-biofuels) biomass markets in the study area increased by 19 million ha.

The outcomes of this study are relevant to the debates related to biofuel production. Our review clearly shows that biofuel expansion has not been the major factor causing land-use change. Loss of arable land due to urbanization, etc., has claimed over twice as much land. This loss is almost certainly permanent, which is not the case for biofuel production. Further, increased intensity of arable land use has generated more than sufficient harvested area to fully compensate biofuel expansion. This makes claims of land-use changes caused by biofuel expansion (as caused by biofuel policies) less convincing.

Consider, for example, projected land use change caused by EU biofuel policies. In 2020, an additional area of 0.5 million ha has been projected to be devoted to biofuels in Brazil.[2] Only 15% of this is associated with deforestation. These are small figures, which suggest that the role of biofuel expansion as a major driving force for deforestation in Brazil needs to be reconsidered (26 million ha of forest was lost since 2000). Projected land-use change due to EU policies should also be compared to the increase of MCI observed in Brazil, generating almost (five million ha or) *ten* times the amount lost to EU biofuel exports in just one decade. In the light of these figures it is hard to imagine that biofuel policies alone are the dominant source of land-use change or deforestation.

The food *versus* fuel debate, further, needs to be enriched. While biofuel expansion in the study area has claimed 14 million ha of arable land, this area is more than compensated for by increased cropping intensity. FAOSTAT data clearly show that harvested area for food/feed markets has increased. They also show that biomass availability for food and feed applications has gone up. Further, it is not biofuel expansion but loss of agricultural land due to urbanization, etc., that is the major threat to land (biomass) availability. All this needs to be considered in the debate. The outcomes of this study show that it is essential for policy impact analyses to use statistical data to check model projections. Further, the analysis should be based on full – and not partial – biomass and land balances. Initial restrictions in model applications, ignoring co-product generation, seem to have given strongly misleading conclusions. Excluding double-cropping or cropping intensity in biofuel policy analysis has been another limitation which has had a major impact on the results. It is suggested, therefore, to incorporate local and national data on crop cultivation (e.g. crop rotations) in assessment studies of biofuel policies.

Keeney and Hertel[8] indicated that forecasting environmental impacts of biofuel policies requires both careful model formulation as well as sufficient empirical knowledge of supply and demand. Currently, only a few key parameters (e.g. yield elasticity, acreage response elasticity) determine the outcome of land-use change modeling studies. It should be checked to what extent popular analytical models correctly predicted adjustments in crop production and land-use practices. Essential elements that may have been lacking include changes in fallow and double-cropping, accelerations in yield improvement, and loss of agricultural land due to urbanization, infrasructure and industry.

Special attention is merited for cropping intensity, as well as non-biofuel crop yield improvement.[7] In this process, predicted changes in crop production and land use should be critically evaluated. Keeney and Hertel,[8] for example, predicted an increase of crop production to coincide with a reduction of forest and pasture areas in the USA, the EU, and Latin America. FAO statistics have shown that, during the last decade, forest area in the USA and EU has *increased* while grassland area remained constant in the USA and in Brazil.

The implication of this analysis for estimations of GHG emissions from biofuel production is potentially substantial. Very high assessments of carbon releases due to indirect land-use changes[2,18] have been used to underpin adjustments in biofuel policies in the EU. This review shows that a careful reconsideration of the generally assumed view that biofuels are important causes of indirect land use change is in place. Whereever feasible, this should be done using observed – rather than modeled – data.

Conclusion

This review addressed the impact of increased biofuels production on land use in major biofuel producing countries using full land balances based on land and crop statistics. Biofuel expansion is often considered a major threat for biomass availability for food and feed production and an important source of land use change. However, this analysis based on FAO statistics on crop production and land use in the period 2000 to 2010 shows that the impact of biofuel expansion on land use has been limited. An increase of 14 million ha was noted in 34 major biofuel producing nations over a period of a decade.

© 2013 Society of Chemical Industry and John Wiley & Sons, Ltd

During the same period, increased cropping intensity generated over 42 million ha of extra crop land – three times the biofuel expansion. Further, an area of 31 million ha of agricultural area was lost (amongst other due to urbanization) in the USA, the EU, China, and South Africa. Consequently, there are strong drivers for expansion of land availability for traditional food and feed markets which has led to increased food and feed crop area. With the exception of the USA, biofuel expansion has not made up more than a quarter of the total loss of agricultural land.

This information should be considered in discussions on food vs. fuel debate and land-use change caused by biofuel policies. Existing frameworks need to be reconsidered. For example, biofuels *cannot* be identified as the most important or single global cause of land-use change. Other drivers have caused more (and more permanent) loss of agricultural area including process of urbanization, infrastructure development, tourism and even conversion into nature (an additional 8 million ha of forest have been established in the USA and the EU since 2000). Observed changes in land use caused by biofuel policies are very small in comparison to other changes.

Models used to evaluate biofuel policies should be enriched by incorporating more and better information on (changes in) land use and local cropping patterns, as well as differences in current and potential productivities in different agro-ecologies and farming systems. Finally, the relation between increased multiple cropping and biofuel production should be further investigated.

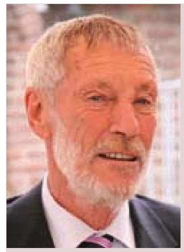
Hans Langeveld

Hans Langeveld, agronomist, develops and evaluates bioenergy and biobased production chains. His main focus is on feedstock availability, land use change, soil carbon dynamics and GHG emissions. He studied sustainable land use in five continents and co-authored many scientific papers as well as books on farming systems and the biobased economy.



Herman van Keulen

Herman van Keulen was trained as a soil scientist and production ecologist at Wageningen University. During his carreer, he wrote many crop growth models. Herman developed innovative concepts in soil water modelling and sustainability research and has been an expert on crop growth, animal production systems and sustainable land use for over four decades.

John Dixon

John Dixon is Principal Regional Adviser, Asia and Africa, Australian Centre for International Agricultural Research. He has over 30 years of developing country experience with agricultural research and development, including cropping systems, economics and natural resource management with the CGIAR system and the FAO UN.

Foluke Quist-Wessel

Foluke Quist-Wessel is senior agronomist and director of AgriQuest. She holds an MSc. in Tropical Crop Science (Wageningen University) and focuses on agricultural production systems, rural development, food security and chain development. Previously, she worked at Plant Research International (Wageningen UR), and Biomass Research.

8_OP_LCFS_RFA Responses

44. Comment: **LCFS 8-1**

The comment alleges that the LCFS has enjoyed success thus far, in large part, due to the contributions of grain ethanol, however it also states that the LCFS penalizes grain ethanol with a higher CI due to land usage issues.

Agency Response: The LCFS uses the most accurate information available to quantify the full lifecycle emissions, including the indirect land use change (iLUC), of fuel pathways. Therefore, the LCFS is not penalizing corn ethanol, but accurately assesses its emission impacts. The existence of iLUC effect and corresponding emissions related to biofuel expansion has been demonstrated by scientific and academic research. The U.S. Environmental Protection Agency (U.S. EPA) has included iLUC emissions in their lifecycle analysis of biofuels for their Renewable Fuel Standard (RFS). A peer review conducted in 2009 agreed on the need to include iLUC emissions to fully account for the effects of additional feedstock demand for biofuel production. The Board, in 2009, recognizing the need to account for all effects in the evaluation of GHG emissions from transportation fuels approved the inclusion of iLUC emissions in the evaluation of crop-based biofuels. Following the Board's directive in 2009, staff convened experts in land use science, economics, agriculture, carbon emissions, etc. to review and recommend modifications to iLUC. This group, called the Expert Working Group, acknowledged the need to include iLUC emissions in the lifecycle analysis of crop-based biofuels. Studies and reports since 2009 have also supported the existence of such effects from crop-based biofuels.

The comments related to flawed analysis or prejudicial treatment for corn ethanol is not warranted. The analysis methodology used for corn ethanol is the same approach used for the other crop-based biofuels in the current regulation such as sugarcane ethanol, soy biodiesel, sorghum ethanol, palm oil biodiesel, and canola biodiesel. In 2009, the Board recognized that the use of the GTAP model to estimate iLUC was scientifically defensible, and not flawed as suggested by the commenter. They approved iLUC values for the LCFS regulation in 2009. Since 2009, ARB staff has made several refinements to the methodology to account for improved data, advancements in land use science and advances in modeling methodologies. The current set of iLUC values are determined using the average of 30 scenario runs and have utilized the same modeling approach for all six biofuels. The approach used by ARB staff has been harmonized for all biofuels and is therefore not prejudicial to any particular biofuel. This is also supported by the results of the independent peer review which demonstrate, that staff continues to make every effort to use the best science in evaluating ilUC emissions.

It is worth noting that other commenters have stated that ARB staff's choice of data has resulted in a corn ethanol value that is too low.

45. Comment: **LCFS 8-2**

The commenter states that ARB staff's iLUC analysis is "technically and methodically flawed."

Agency Response: The iLUC analysis conducted by ARB staff is based on numerous scientific studies and reports as referenced in the Initial Statement of Reasons (ISOR) and is not technically or methodologically flawed. Outputs of the model are driven by a few critical parameters and ARB staff, after conducting a comprehensive review of scientific literature, used a range to values to reflect the findings from the review conducted. The land conversions outputs are realistic and ARB staff believes that our modeling methodology for land conversions is appropriate for the six biofuels. The comment that staff's approach does not account for non-yield intensification is not valid. The economic modeling accounts for crop switching, crop rotations and other agricultural practices by accounting for them implicitly using calibrated elasticity parameters. For modeling iLUC, an input to the GTAP model included a specific volume of biofuel which constituted a 'shock' (e.g., for corn ethanol, the input shock was 11.54B gallons which was derived from 15B gallons, a RFS2 mandate, minus 3.46B gallons of ethanol production that already existed in 2004, the baseline year for the GTAP model).   When the model is shocked, the response represents the summation of decisions taken by growers to maximize profits.

46. Comment: **LCFS 8-3**

The commenter states that CARD/ISU data was submitted in December 2014, and is puzzled that those analyses were not reflected in the ISOR.

Agency Response: Since refinements to iLUC values used in the current ARB analysis are not based on the Center for Agricultural and Rural Development at Iowa State University (CARD/ISU) report. Therefore, ARB staff did not perceive the utility of citing this report just to acknowledge its availability. Preliminary review of the CARD/ISU report indicated that additional data would be required to fully evaluate issues raised, that the report comments on previous-older ARB analysis, and that it does not comment on the latest analysis as proposed for this rulemaking. Because there was insufficient time for ARB staff to collect and evaluate data in order to complete a comprehensive review of this report, analysis of the issues highlighted in the report was not included in the ISOR. Furthermore, the existing structure of the Global Trade Analysis Project (GTAP) model could not accommodate the evaluation of some of the issues raised. Staff continues to follow developments in iLUC measurement and modeling so that future improvements can be considered and incorporated in future amendments as appropriate.

47. Comment: **LCFS 8-4**

The comment alleges that ARB's iLUC is fundamentally flawed especially with respect to conversion of non-agricultural land.

Agency Response: See response to **LCFS 8-1**.

ARB's iLUC methodology and models are peer-reviewed, scientifically sound, and use the most up-to-date data available. Land use change effects occur when the acreage of agricultural production is expanded to support increased biofuel production. Lands in both agricultural and non-agricultural uses may be converted to the cultivation of biofuel crops. Some land use change impacts are indirect or secondary. When biofuel crops are grown on acreage formerly devoted to food and livestock feed production, supplies of the affected food and feed commodities are reduced. These reduced supplies lead to increased prices, which, in turn, stimulate the conversion of non-agricultural lands to agricultural uses. The land conversions may occur both domestically and internationally as trading partners attempt to make up for reduced imports from the United States. The land use change will result in increased GHG emissions from the release of carbon sequestered in soils and land cover vegetation. These emissions constitute the iLUC impact of increased biofuel production. Since 2009, there have been numerous peer-reviewed literature and scientific reviews of iLUC for biofuels. Empirical data, real-world observations, updated modeling methodology, and improved assessment methods have all been considered in these scientific publications. ARB staff has reviewed such articles and implemented appropriate modifications to the methodology for the current iLUC analysis.

The GTAP model includes elements to capture all of the potential effects specified in the four “responses”. The model accounts for crop switching, crop rotations and other agricultural practices by accounting for them implicitly using calibrated elasticity parameters. When the model is shocked, a response represents the summation of all decisions (Response 1) taken by growers to maximize profits. This includes decisions that result in increasing yields beyond average (Response 4) that could result from the increased use of fertilizers and other agricultural chemicals. The analysis by ARB staff uses a range of Yield Price Elasticity (YPE) values and accounts for potential increase in yields (YPE values spanning the range 0.05 to 0.35) and <u>does not use a single low elasticity value</u> as mentioned by the commenter. The baseline crop production data includes double cropping information. Increase in crop production and yields implicitly ensure that these effects propagate through the model results. The ARB modeling approach also includes the effects of converting lands that are either idle, or from other uses, to agricultural production.

The iLUC analysis conducted by ARB staff is based on numerous scientific studies and reports as referenced in the ISOR. The current version of the model has also been tuned using new data and updated land use science. Though the approach to iLUC analysis is the same as used for the 2009 analysis, significant updates to data and modeling methodology have been incorporated into the current analysis. The datasets are recent and obtained from sources such as the U.S. Department of Agriculture (USDA), the Food and Agricultural Organization of the United Nations (FAO), the International Monetary Fund (IMF), and other national and international repositories on agriculture and trade information.

48. <u>Comment</u>: **LCFS 8-5**

The comment directs ARB to a new publication by Babcock and Iqbal, which they feel has “important implications for CARB’s iLUC analysis.”

<u>Agency Response</u>: See response to **LCFS 8-3**.

The Babcock and Iqbal report attempts to utilize actual land use change into the analysis of an iLUC model. However, the complexities of real-world impacts do not allow for an accurate assessment of just the impact of increased crop demand. In the real-world, a decrease or increase in cropping area in a region is the sum totality of numerous factors (i.e., population and economic growth, weather conditions, drought, flooding, reforestation, GHG reduction incentives for agriculture, etc.), not just increased demand for feedstocks used for the production of biofuels. Some factors may increase cropping area and some may decrease the overall need for cropland. The results of the GTAP analysis presented by ARB staff includes only the impacts related to the increased production of biofuels and not the results of all of the activities that could effect changes in cropland at various regions of the world. Though the current version of ARB's GTAP model is capable of estimating the effects of biofuels expansion, it is incapable of modeling the impacts of all other activities in the global marketplace. In the future, if appropriate modifications can be made to the model to estimate the effects of all global activities, it may allow for comparison of model outputs to the totality of observed changes in land cover.

The GTAP model includes in it a parameter (Yield Price Elasticity) to account for intensification effects directly resulting from increases in prices of agricultural commodities. However, data related to reversal of fallow land to crop production and changes in share of planted to harvested area are not available for many regions of the world. Therefore, this analysis cannot be performed with the current version of the model. At a future date, when data becomes available, staff may incorporate appropriate modeling structures and parameters to account for such effects in the iLUC analysis.

The database used in the GTAP model includes in it double cropping data for appropriate regions of the world. Therefore, outputs from the model implicitly include impacts from double cropping, though we do not explicitly disaggregate contributions from such effects. A preliminary review of agricultural data for the U.S. has concluded that double cropping is small and not expected to contribute significantly to 'intensification effects' as mentioned in the Babcock paper. As for other regions of the world, significant work has to be completed to collect and disaggregate data to provide accurate information on double cropping across the world. When detailed data becomes available, ARB staff will consider updates to modeling structure to explicitly account for double cropping in the analysis. It should also be noted that double cropping benefits are offset by increased use of fertilizers and pesticides and these impacts also need to be accounted in the analysis (not included in the current ARB analysis).

Current predictions by the GTAP model are similar to that reported by Babcock. As discussed in comment **LCFS 8-2** above, GTAP estimates reflect the impacts related only to the increased production of biofuels but real-world data is the net result of all global activities (i.e., population growth, agriculture, deforestation for mining, etc.). Considering that GTAP estimates reflect the impacts related to a single sector, but real-world data reflects the combined impacts of all activities and sectors, it will be highly challenging to match GTAP outputs with the totality of land cover changes and market behaviors across the world.

Calibration of the model with real-world data assumes that the model is capable of evaluating the effects of all factors that affect real world behavior. The current version of the ARB GTAP model is capable of estimating the effects related to one factor, biofuel expansion. No model currently available contains the modeling structures and data to model all activities in the global economy that could impact land conversions across all regions and doing so would be outside the scope of this rulemaking.

49. Comment: **LCFS 8-6**

The comment asks ARB staff to calibrate the GTAP model "to reflect the absence of extensive land use change" in countries or regions where grassland or forestland has increased over the past decade.

Agency Response: ARB does not agree with comment that in regions where cropland contracted, demand for biofuel crops had no effect on land use. In the real-world, changes in cropland, forest, and grassland in a region is the sum totality of numerous factors (i.e., population and economic growth, weather conditions, drought, flooding, reforestation, GHG reduction incentives from agriculture, etc.) and not just increased demand for feedstocks used for the production of biofuels. Some factors may increase the requirements from these types of land cover and some may decrease the overall need for land. The net result may be negative or positive. The results of the GTAP analysis by ARB includes only the impacts of one factor, increased production of biofuels, and not the results of all of other activities that could affect changes in land in various regions of the world. See also response to **LCFS 8-5** and **LCFS 8-7**.

50. Comment: **LCFS 8-7**

The commenter contends that CARB should have used the information contained within Babcock and Iqbal report, published December 4, 2014, to calibrate its GTAP model.

Agency Response: ARB staff does not agree with the comment that in regions where there has been no change in cropland, demand for biofuel crops had no effect on land use. See response to **LCFS 8-6**.

An assessment of emission penalties on countries for foregone sequestration is not a provision under the LCFS. Determination of alternative use of land in a country is also not a provision under the LCFS. Indirect Land Use Change (iLUC) serves to estimate GHG emissions from land conversions in regions of the world resulting from an increased demand for biofuel feedstocks.

ARB staff will complete comprehensive testing of a dynamic version of the model when it becomes available to validate model behavior and response. ARB staff remains committed to evaluating new data and updates to land use science when it becomes available and accordingly refining iLUC analysis in the future.

51. Comment: **LCFS 8-8**

The commenter points out that the DDGS -- corn displacement ratio in CA-GREET 2.0 differs from the ratio in GTAP, a difference that the commenter finds problematic

Agency Response: The different ratios are appropriate because the GTAP is based on past land conversions for the period 2004-2010. The relevant land conversions have already occurred. On the other hand, CA-GREET 2.0 is intended to represent current practices.

52. Comment: **LCFS 8-9**

The commenter contends that ARB has not justified the use of their Yield Price Elasticity value, which is lower than the commenter's recommended value.

Agency Response: YPE is one of the most important parameters within the GTAP model and has significant impacts on the outputs of the model. ARB staff used a multi-dimensional approach to considering YPE that includes:

- Conducting a comprehensive review of literature for YPE,
- Contracting with Steve Berry at Yale University and a statistical expert at UC Davis to analyze data related to YPE, and
- Considering recommendations on YPE by the Expert Working Group (EWG).

Literature reviews concluded that there is likely a wide range of values for YPE and this has been detailed in Appendix I of the ISOR. The EWG recommended using a reasonable increment between values (0.05) for the short-run elasticity to account for long-run effects. The members suggested using an average value between 0.1 and 0.25.

A review of studies and data from some of the studies by a statistical expert at UC Davis concluded that yield prices elasticities are generally small. Steve Berry's findings support zero to small values for YPE based on his analysis of data. The net conclusion is that there is a wide range of likely values based on econometric/statistical treatment applied to estimate YPE. To include impacts from a range of likely values for YPE, ARB staff used a range between 0.05 and 0.35 in the scenario analysis for each biofuel. Also, most of the available data is for corn grown in the U.S. and may not represent behavior of other crops grown in the U.S. and worldwide.

Use of YPE to accommodate double cropping as suggested by stakeholders is not possible with the present version of the model. It will require more detailed land data for each location and modeling of YPE for each case. In the absence of data, YPE as currently structured for use in the model, cannot replicate double cropping in model simulations. When complete data sets for double or triple cropping are available by crop and region, appropriate structural modifications could be considered to account for such cropping patterns.

53. Comment: **LCFS 8-10**

The comment points out perceived weaknesses in the GTAP model, as a justification for using a higher price-yield elasticity value.

Agency Response: The database used in the GTAP model includes double cropping data for appropriate regions of the world. Outputs from the model, therefore, implicitly include impacts from double cropping. The contributions from such effects cannot be explicitly disaggregated. Regarding the use of YPE to accommodate double cropping, see response to **LCFS 8-9**.

The elasticity sub-group of the EWG consisted of members who are not GTAP experts. Experts of the GTAP model (academics at Purdue University who developed the model), however, were not in favor of using ad-hoc adjustments to YPE until detailed data was available to conduct comprehensive testing of model responses was completed. However, the commenter's requested value of 0.35, proposed by the commenter, was included in the range of values for YPE in the scenario analysis conducted by ARB staff for all of the biofuels. See also response to **LCFS 8-9**.

54. Comment: **LCFS 8-11**

The comment states that although the CA-GREET 2.0 is an improvement, more work is needed on the CI of ethanol pathways.

Agency Response: ARB staff appreciates the support for the proposed revisions to the CA-GREET model. See responses to **LCFS 8-12 and 8-13** to address specific concerns.

55. Comment: **LCFS 8-12**

The comment directs ARB to reduce denaturant content in ethanol to reflect "real-world" conditions.

Agency Response: ARB did consider real-world conditions and changed the proposal to reflect current industry practice of using up to 2.5% denaturant by volume. ARB has reviewed producer data confirming that blending 2.5% denaturant by volume represents standard industry practice. Rather than use a fixed constant CI for denaturant, the formula for denaturant CI now in CA-GREET 2.0 factors in the CI of the ethanol to yield an appropriate value in each instance. A more detailed spreadsheet calculator (http://www.arb.ca.gov/fuels/lcfs/ca-greet/ca-greet.htm) is available to help clearly demonstrate and document the data sources and assumptions used in determining this result.

56. Comment: **LCFS 8-13**

The commenter wishes for ARB to include the GREET1_2013 default value for enteric fermentation impacts resulting from the co-product distillers grains with solubles (DGS) in the corn ethanol pathway.

Agency Response: Based upon the reasoning below and the contents of ISOR Appendix C on this topic, ARB will not include a credit for avoided enteric fermentation. ARB staff did not intend to imply or suggest that methane emission reductions from feeding distillers grains with solubles (DGS) to cattle are an indirect (consequential) lifecycle analysis (LCA) effect; however, such effects may be considered if staff included DGS-fed animals in the LCFS LCA system boundary. The commenter argues that this credit is warranted by drawing a parallel between it as an indirect effect and the iLUC values applied to corn ethanol. The commenter does not address other aspects discussed in Appendix C of the LCFS ISOR related to the incomplete LCA surrounding the enteric methane emissions credit or the complexity of applying this credit to all grain ethanol LCFS pathways.

ARB staff did not include the direct or consequential (indirect) emissions for specific types of animals in the existing LCFS LCA DGS credit determination (CA-GREET 1.8b). Under the existing regulation (CA-GREET 1.8b basis), the transportation of DGS to the animal feedlot, the emissions related to feeding the many types of animals that are fed DGS, and any aspect related to the DGS co-product credit or emissions (reduced or increased) of specific groups of animals were not considered. In the current and proposed LCFS regulations, the LCA boundary stops at displacing primary agricultural products used to feed these animals. For example, a credit for transportation of feedstock to the ethanol plant is granted as part of the DGS co-product credit. This distance relates to the transport of the primary agricultural crop to the ethanol plant, as if the ethanol plant never received this displaced feedstock, and in the proposed regulation, the transportation credit applies to both feedstocks and urea. The transportation credit does not include the distance required to transport the primary agricultural crop to the actual animal feedlot, which could be in China. Therefore, the boundary of the DGS credit does not extend to the animal, but stops on the farm where the displacement occurs regardless of what the ultimate fate of the DGS is (ARB staff does not track spoiled DGS, poor quality DGS, actual use of DGS for feeding livestock, etc.).

In CA-GREET 2.0, ARB staff is using the aggregated displacement ratio for U.S. and export markets for DGS, which are used in GREET1 2013 (see LCFS ISOR, Appendix C) because staff cannot determine what sub-markets ethanol plants will sell their DGS into over the lifetime of the applicant’s LCFS fuel lifecycle pathway. Similarly, staff cannot determine if a specific applicant will sell their DGS into the necessary market (e.g., cattle) for the duration of their LCFS fuel pathway to obtain the reduced enteric methane emissions credit, assuming the LCA of the animals being fed was as complete, as current research indicates that it is not. This incomplete analysis is explained in Appendix C of the LCFS ISOR. Staff also explains in Appendix C that overall emissions may not be reduced if animals were considered in the LCA. Specifically, the LCA presented in GREET1 2013 (and earlier versions) appears incomplete based on a review of current scientific literature. ARB staff or the scientific community may be able to conduct a LCA that would evaluate the body of scientific literature in this area of research. Staff understands there are challenges posed for fuel pathway analyses in areas where scientific research is ongoing and consensus has not yet been reached. This is also discussed by staff in Appendix C.

It is unclear whether the commenter suggests that all grain ethanol pathways that produce DGS should receive the credit based upon the incomplete LCA used in GREET1 2013 and earlier GREET models. Appendix C explains that ARB staff believes there is significant work to be done in order to assess credits or deficits at the animal feeding level through digestion, excrement, the ultimate fate of the animals (or rather the DGS embodied in the animals) and any indirect effects. In the absence of monitoring and verification requirements for LCFS fuel pathways, further research into the areas of uncertainty is needed before ARB staff can thoroughly evaluate and consider providing a DGS credit in LCFS.

57. Comment: **LCFS 8-14**

The comment suggests that the compliance scenario assumptions made by ARB are highly implausible, with regard to availability of sugarcane ethanol and related credit generation.

Agency Response: ARB staff disagrees that the available supplies of cane ethanol will be insufficient to provide the levels presented in the illustrative compliance scenario. Staff recognizes that the level of cane ethanol imports to California in 2014 was very low relative to the two previous years, and staff has adjusted the estimates of 2014 credit generation from this fuel accordingly. However, this low level of imports was simply reflective of conditions in place in 2014. These included low LCFS credit prices, low prices for corn ethanol, no need for federal Renewable Identification Number (RIN) credits from cane ethanol, and adequate LCFS credits from other sources. The ability of Brazilian producers to export considerable volumes of ethanol will continue as will the capability to ship and import the volumes envisioned in the illustrative compliance scenario. As the LCFS becomes more stringent the attractiveness of cane ethanol will increase and imports are expected to rise. As with all of the fuel volumes presented in the illustrative compliance scenario, these are not *predictions* of the future; the level of actual use of cane ethanol could be higher or lower than presented, depending on the price and availability of other credit generating fuels as well as other market factors.

Mary Nichols, Chairman
California Air Resources Board
1001 I Street
Sacramento, CA 95812

RE: LCFS Re-adoption

Chairman Nichols,

National Sorghum Producers (NSP) is a trade association representing the interests of over 50,000 sorghum producers on issues related to legislative and regulatory policy in Washington as well as various state capitals. NSP led efforts to secure an advanced biofuel pathway for sorghum under the RFS2 and has performed extensive analysis on several models and datasets over the last four years, including several datasets similar to those used by the Argonne National Laboratory as well as the ARB in modeling the CI of sorghum ethanol.

NSP applauds the ARB for undertaking an extensive update of the LCFS and is very appreciative of the time committed by ARB staff to ensure not only the integrity of the data used but their representativeness of real-world conditions as well. NSP also generally supports the data underlying the sorghum portions of CA-GREET 2.0 and thanks the ARB for its special attention to sorghum iLUC, sorghum fertilizer requirements and N_2O emissions from sorghum stover. In addition to these areas, NSP strongly recommends that the ARB focus attention on information related to sorghum root:shoot ratios, and as it becomes available, incorporate this information into future versions of CA-GREET.

LCFS 9-1

LCFS 9-2

Thank you for the opportunity to provide feedback. We feel with this re-adoption, sorghum ethanol can play an even larger role in helping California meet the greenhouse gas reduction goals set by the LCFS while at the same time promoting the use of water-sipping crops like sorghum.

Please do not hesitate to let me know if you have any questions.

Regards,

J.B. Stewart
Chairman
National Sorghum Producers
4201 N. Interstate 27
Lubbock, TX 79403
Phone: (806) 749-3478

9_OP_LCFS_NSP Responses

58. Comment: **LCFS 9-1**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

59. Comment: **LCFS 9-2**

The commenter appreciates ARB's special attention to sorghum in CA-GREET 2.0 but recommends that the ARB focus attention on information related to sorghum root:shoot ratios, and as it becomes available, incorporate this information into future versions of CA-GREET.

Agency Response: ARB staff continues to build upon and improve our knowledge base of fuel lifecycle analyses, including the effect of grain sorghum (typically S. bicolor) root shoot ratios and the impact of those ratios on the agricultural lifecycle phase of grain sorghum biofuel pathways. Staff will consider incorporating the root shoot ratio information and its effect on the fuel lifecycle pathway for grain sorghum in future rulemakings to the extent it can be accurately quantified, monitored and verified. ARB staff plans to make regular updates to the CA-GREET model on a periodic basis, currently envisioned to be no less than once every three years. The periodic update to CA-GREET will consider changes to all fuels and feedstocks and would not be limited to grain sorghum. Nevertheless, staff appreciates the commenters calling attention to this important LCA parameter for grain sorghum and staff will review additional information as it is made available.

COMMENT 10 FOR LOW CARBON FUEL STANDARD 2015 (LCFS2015) - 45 DAY.

First Name: Lyle
Last Name: Schlyer
Email Address: lschlyer@calgren.com
Phone Number: 5597301154
Affiliation: Calgren Renewable Fuels

Subject: Comments on LCFS Readoption
Comment:
Dear Chairman:

Calgren Renewable Fuels is a California ethanol producer that desires to use more grain sorghum as feed stock. Sorghum is low-water and, we believe, will help us reduce the carbon intensity of our fuel ethanol. We are in close touch with the National Sorghum Producers (NSP) and understand they will also submit comments.

While bemoaning the fact that others in the ethanol industry saw the need to file suit against the ARB regarding the LCFS, we applaud the ARB's reaction - re-authorizing the LCFS and working to improve the accuracy of carbon intensity scores sends the right message. LCFS 10-1

As will the NSP, we thank the ARB for paying special attention to sorghum iLUC, sorghum fertilizer requirements, and nitric oxide emissions from sorghum stover. We would ask that the ARB be alert for future information on sorghum root;shoot ratios and incorporate it into future versions of CA-GREET. LCFS 10-2

Lyle Schlyer
President, Calgren Renewable Fuels

February 17, 2015

California Air Resources Board
1001 I Street
Sacramento, CA 95812

Dear Member of the Air Resources Board,

We applaud your continued work to implement and improve the Low Carbon Fuel Standard (LCFS). E2 encourages you to vote to re-adopt the LCFS. As a direct result of the LCFS, California is leading the world in the effort to establish commercially-viable fuel options that will contribute to lower greenhouse gas (GHG) emissions from transportation. LCFS 11-1

E2 is a nonpartisan, national community of business leaders who promote sound environmental policies that grow the economy. We are entrepreneurs, investors, and professionals from every sector of the economy who collectively have been involved in the financing, founding or development of more than 1,700 companies that have created more than 570,000 jobs. Our members manage billions of dollars in venture and private equity capital that will flow over the next several years into new companies in Oregon and beyond.

Importantly, the LCFS is already driving tangible and valuable business activities in California. Companies are investing in infrastructure to expand retail availability of the low carbon-intensity (CI) fuels they are currently selling in the state. Meanwhile, California is the focus both for efforts to pioneer additional low CI fuel options and for investments to reduce the CI of conventional fuels such as petroleum and ethanol.

We have helped develop, implement and refine the LCFS since its conception. Over the years we have seen the market grow in some unpredicted ways, such as the rise of natural gas and renewable diesel. What we did expect was the array of alternative fuels that would all scale to meet the standard, and now have proof positive that the standard is working as intended. To date, we have seen the flexibility of the LCFS encourage credit trading from dozens of fuel types, and expect even more fuel diversity by 2020.

E2 conducts an annual assessment of the domestic advanced biofuel industry. According to our 2014 report, North America's advanced biofuel industry reached a production capacity of more than 800 million gallons in 2014, almost double the capacity in 2011. This is roughly enough to fill an entire lane of Interstate 5 from Seattle to San Diego with nothing but large tanker trucks filled with advanced biofuel.

The report, "E2 Advanced Biofuel Market Report 2014," projects that by 2017, as many as 180 companies are expected to produce 1.7 billion gallons of advanced biofuel, doubling current capacity.[1] Additionally, the work recently completed by ICCT shows how advanced biofuels will

combine with other alternative fuels to meet or exceed 2020 reduction targets, especially if the standard is expanded into Oregon and Washington. Overall, low-carbon fuels could reduce the carbon intensity of on-road transportation fuels across the Pacific coast state by 14-21% by 2030.[2]

As the Air Resources Board (ARB) considers re-adoption of the LCFS, E2 recommends that the program be strengthened in ways that will increase and accelerate private sector investment activities. To that end, we wish to identify certain elements of the re-adoption proposal that will help strengthen the program, and propose additional considerations for staff to develop in the future:

1. E2 strongly supports ARB's proposal to keep LCFS compliance at 10% in 2020. The ARB should maintain this compliance curve through 2020 and establish stronger compliance curves to continue progress beyond 2020. Compliance curves will be the foundation for investment in infrastructure and in innovative production strategies in California. LCFS 11-2

2. Adoption of a Credit Clearance Market will protect markets in the event of a lack of liquidity in supply of either low CI fuels or LCFS credits. The ARB should adopt transparent and predictable market rules to ensure that temporary challenges in the supply of low CI fuels or LCFS credits will not disrupt the market. LCFS 11-3

3. E2 supports ARB staff's recommendation to include petroleum emission reductions from refineries. This supports the technological neutrality and carbon reduction goals of the program, and provides obligated parties with additional compliance flexibility. LCFS 11-4

Future staff proposals and considerations should include:

4. In complement to the proposed Credit Clearance Market, a credit price floor may serve to secure additional investment in low carbon fuels, thus helping ARB maximize emission reductions in a cost effective manner. The purpose of a LCFS credit price floor would be to reduce uncertainty in the minimum value of credits, to spur investment into new low-carbon fuel projects, and thereby further AB 32's goal to reduce greenhouse gas emissions in California. LCFS 11-5

5. In line with creating transparent and predictable market rules, ARB should more clearly define the penalty and enforcement provisions in the event fraudulent credit trades are discovered in the market. Clearly defined rules regarding the nature and scope of violations, culpable parties, and penalties will help deter violators, enable market participants to operate within demarcated compliance boundaries, and may facilitate the discovery of fraudulent credits by ARB. LCFS 11-6

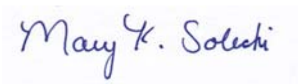
6. Since lifecycle analysis is a continuously developing science, carbon intensity pathways will be updated on an ongoing basis. Providing a clearly defined process and timeline by which new science is considered and incorporated into pathways will provide more investor certainty, and inform alternative fuel project development. LCFS 11-7

[2] Malins et al. Potential Low Carbon Fuel Supply to the Pacific Coast Region of North America. International Council on Clean Transportation. Available on the web at: http://bit.ly/PacificLCF

7. Expanding the credit trading market to third parties in parcel with developing an exchange can: increase credit price transparency and frequency of trades; alleviate long-term staff resources to broker a credit market; allow ARB to focus on the regulation of credit transactions and credit verification; and provide a platform by which other states may easily harmonize with the LCFS credit market. LCFS 11-8

The future program considerations we have outlined may be integrated at a later date. **Today, we encourage the Board to re-instate the LCFS by voting to re-adopt the program.** We commend the Board for your collective leadership and guidance on this landmark regulation.

Sincerely,



Mary Solecki
E2 Western States Advocate

11_OP_LCFS_E2 Responses

62. Comment: **LCFS 11-1**

    The comment supports the re-adoption of the LCFS regulation.

    Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

63. Comment: **LCFS 11-2**

    The comment urges ARB to establish stronger compliance curves for the LCFS program beyond 2020.

    Agency Response: See response to **LCFS 5-2**.

64. Comment: **LCFS 11-3**

    The comment supports the credit clearance provision as part of the re-adoption of the LCFS regulation.

    Agency Response: ARB staff appreciates the support for the inclusion of the credit clearance provision.

65. Comment: **LCFS 11-4**

    The comment supports the refinery investment provision as part of the re-adoption of the LCFS regulation.

    Agency Response: ARB staff appreciates the support for the inclusion of the refinery investment provision.

66. Comment: **LCFS 11-5**

    The comment suggests a credit price floor would reduce uncertainly and maximize emissions reductions in a cost effective manner.

    Agency Response: See response to **LCFS 6-5**.

67. Comment: **LCFS 11-6**

    The commenter suggests ARB should more clearly define the penalty and enforcement provisions in situations of fraudulent transactions.

    Agency Response: See response to **LCFS 7-3**, **LCFS 32-20**, and **LCFS 40-41**.

68. <u>Comment</u>: **LCFS 11-7**

The comment requests ARB review the program and make updates at regular intervals, as the state of the science improves.

<u>Agency Response</u>: ARB staff seeks to maintain a balance between the latest science and market certainty. To do so, staff will update the model at predictable intervals to be determined, likely every three years.

69. <u>Comment</u>: **LCFS 11-8**

<u>Agency Response</u>: ARB staff agrees with the commenter's suggestion to evaluate possible expansion of the credit market to third parties as a consideration for a future rulemaking.

Subject: LCFS and Sorghum ILUC
Comment:
Chairman Nichols,

Western Plains Energy, LLC (WPE) is a Kansas-based sorghum ethanol producer. WPE feels that sorghum has an important role to play in helping California meet the greenhouse gas reduction goals set by the LCFS and reducing water usage on irrigated acres.

We have a strong affiliation with the National Sorghum Producers (NSP) and understand they are submitting comments as well. As NSP does, we applaud the ARB for its update of the LCFS and appreciate its special attention to sorghum iLUC, sorghum fertilizer requirements and N2O emissions from sorghum stover. We also recommend that the ARB focus attention on information related to sorghum root:shoot ratios, and as it becomes available and incorporate this information into future versions of CA-GREET.

LCFS 12-1

LCFS 12-2

Thank you for the opportunity to comment.

With Kindest Regards,
Derek Peine
Chief Executive Officer

COMMENT 13 FOR LOW CARBON FUEL STANDARD 2015 (LCFS2015) - 45 DAY.

First Name: Matt
Last Name: Durler
Email Address: matt.durler@conestogaenergy.com
Phone Number: 620-626-2053
Affiliation: Conestoga Energy Partners

Subject: Conestoga Energy Partners Comments on LCFS Re-adoption
Comment:
Chairman Nichols,

As I stated in the previous comment period, Conestoga Energy Partners owns and operates 3 ethanol plants in Southwest Kansas and the Texas panhandle. I believe that sorghum plays an important role in helping California reach its greenhouse gas reduction goals and our company to improve the sustainability or agriculture in our production region by reducing water usage.

I would like to echo the comments of the National Sorghum Producers applauding the ARB for its update of the LCFS and am particularly supportive of the attention given to the sorghum production systems. LCFS 13-1 I would however encourage ARB to continue to focus attention on sorghum root:shoot ratios and as the information becomes available incorporate it into future versions of CA-GREET. LCFS 13-2

I appreciate the opportunity to comment, and your continued efforts in GHG reduction.

Sincerely,

Matt Durler

Re: SUPPORT for Re-Adoption of the Low-Carbon Fuel Standard

Dear Chairman Nichols and Board Members:

CALSTART supports the re-adoption of the Low Carbon Fuel Standard (LCFS) and we applaud the leadership of the Board Members and staff in developing and implementing this important policy.

CALSTART is a nonprofit organization focused on supporting the growth of the clean transportation technologies industry. CALSTART has nearly 150 member companies working to bring about a cleaner, lower carbon transportation future. Based on our work with our membership, we believe that policies like the LCFS – together with AB 32, incentives, and other complementary policies – are needed to support the transition to cleaner vehicles and fuels. We encourage the Board to support re-adoption and we look forward to continuing to work with you on implementation of California's climate and clean transportation policies.

LCFS 14-1

The LCFS is working as intended. Fuel providers are making investments and carbon intensities are dropping. Though the mix of fuels may differ from what was expected when the policy was put in place, this is to be expected. The structure of the LCFS – a flexible, performance-based standard – allows for a mix of fuels to contribute to goals and encourages innovation. The contributions of some of the diesel substitutes, including renewable diesel, have exceeded expectations. To ensure continued progress, it will be important to maintain clear market signals and ensure that the program reflects the best science. These goals can be achieved within the framework of the existing policy.

LCFS 14-2

Targets are achievable through 2020 and beyond with the right policies in place. Multiple independent studies have shown a range of compliance pathways for the 2020 LCFS targets. Moreover, a recent study from the International Council on Clean Transportation and E4Tech looking at the Pacific Coast region of North America showed that low-carbon fuels can reduce the overall carbon intensity of on-road transportation fuels in the Pacific Coast region by 14%–21% by 2030. The key is to ensure strong policy and market signals, and this is the role of the LCFS.

LCFS 14-3

OFFICES IN:
48 S. Chester Ave PASADENA, CA 91106 • 626.744.5600 • FAX: 626.744.5610 | 14062 Denver West Pkwy Suite 300 LAKEWOOD, CO 80401-3188 • 303.825.7550 • FAX 626.744.5610
501 Canal Blvd., Suite G RICHMOND, CA 94804 • 510.307.8700 • FAX: 510.307.8706 | 68 Jay Street, Suite 201 BROOKLYN, NY 11201 • (860) 729-5700

Additional market and regulatory certainty is needed. CALSTART supports re-authorizing the LCFS with the 10% carbon reduction target for 2020. Maintaining this goal is crucial for providing signals to the market. Additionally, our discussions with industry leaders suggest that we could see even greater investment and innovation with more certainty over credit values. Staff is proposing a cost-containment mechanism that provides certainty as to the upper bound of credit prices. We believe it would be beneficial to continue investigation of a minimum price, or price floor, which can provide additional certainty to investors and fuel providers. LCFS 14-4

In conclusion, CALSTART supports re-authorization of the LCFS. This is a vitally important regulation and it is functioning as intended. LCFS 14-2 cont. Indeed, we believe now is the time to begin discussions about longer term targets and plan to continue the progress being made in California. We would like to thank both the board and the staff for the hard work and leadership to date. LCFS 14-3 cont.

Sincerely,

Jamie Hall
Policy Director

14_OP_LCFS_CALSTART Responses

74. Comment: **LCFS 14-1**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

75. Comment: **LCFS 14-2**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the continued support for the LCFS regulation.

76. Comment: **LCFS 14-3**

The comment directs ARB to extend the program past 2020.

Agency Response: See response to **LCFS 5-2**.

77. Comment: **LCFS 14-4**

The commenter supports the 10 percent carbon reduction target in 2020 and requests for ARB to consider a price-floor for credits, to ensure market and regulatory certainty.

Agency Response: ARB staff appreciates the support for the compliance targets and the cost containment provision.

With respect to the portion of the comment pertaining to the price-floor concept, please see response to **LCFS 6-5**.

February 17, 2015

Mary Nichols, Chairman
California Air Resources Board
1001 I Street, PO Box 2815
Sacramento, CA 95812

Dear Chairman Nichols and Members of the Board:

The undersigned businesses, associations and organizations are writing to support the California Air Resources Board's continued strong, steady leadership on the state's pioneering clean energy and climate policies and to urge the Board's swift re-adoption of the Low Carbon Fuel Standard, or LCFS, in 2015. We believe that clean fuels, clean air and a growing economy can go hand-in-hand, and add our voices to the tens of thousands of Californians who support the LCFS.

Transitioning to lower carbon transportation fuels benefits all Californians by:

- **Diversifying the state's fuel supply and increasing independence from fluctuating oil prices that create market and economic uncertainty.** The LCFS is already working. From 2011 to 2013 alternative fuels comprised a steadily increasing share of transportation energy use in California. An abundance of alternative fuels exists—enough to meet the LCFS by 2020—and the market has grown faster than anticipated. Furthermore, available low carbon fuels could grow to replace up to 400,000 barrels [16.8 million U.S. gallons] of gasoline and diesel use *per day*, reducing the overall carbon intensity of on-road transportation fuels in California and the Pacific Northwest by 14% to 21% by 2030. LCFS 15-1
- **Making consumers less vulnerable to price swings at the pump, saving money in the long run, and keeping transportation fuel dollars at home to grow the local economy.** California households are expected to save, on average, over $800 annually by 2020, growing to over $2,000 annually by 2030 in their transportation fuel bills, thanks to a combination of state policies that will spur more efficient cars and diverse fuel choices, and more walkable communities with transit. When consumers spend less on fuel, they have more to spend in their communities. LCFS 15-2
- **Benefitting society by spurring greater use of clean alternative fuels and vehicles.** The LCFS will result in $1.4 to $4.8 billion in societal benefits by 2020 from reduced air pollution and increased energy security. The benefits could be even greater, $10.4 billion by 2020 and $23.1 billion by 2025, when other state fuels policies are also included. LCFS 15-3
- **Helping to cut air pollution and improve public health.** To date, the LCFS has cut carbon emissions by about 9 million metric tons – that's equivalent to removing about 1.9 million passenger cars from the road for a year. Looking forward, from 2016 to 2020, the state estimates the LCFS will cut emissions by 35 million metric tons – the equivalent of removing about 7.4 million passenger cars from the road for a year. LCFS 15-4
- **Retaining the state's innovation leadership in a domestic clean fuels industry**. California is home to more than 40,000 businesses serving advanced energy markets, employing roughly 431,800. The LCFS, alone, could contribute at least 9,100 new jobs, and potentially many more if the state attracts more clean fuel production facilities and technology providers. LCFS 15-5

The science is clear: the time to act is now. We applaud your commitment to ensuring a healthy and economically vibrant California today and for future generations.

Subject: Low Carbon Fuel Standard Energy Economy Ratio Update

Dear Michael Waugh and LCFS Staff,

Thank you for the opportunity to provide comments on the Low Carbon Fuel Standard (LCFS) program. We strongly support the goals of the LCFS program and applaud programs within the California Air Resources Board (ARB) that provide needed incentives to reduce the carbon intensity of fuels to help achieve California's health based air quality standards and aggressive greenhouse gas emission goals. LCFS 16-1

Proterra is the leading U.S. manufacturer of zero-emission commercial transit solutions and makes the world's first all-electric, fast-charge public transit bus. These buses are currently in service in California at Foothill Transit and Stockton RTD, as well as many locations throughout the country. Proterra's buses charge along their routes in less than 10 minutes with an automated roof top charger and then continue on their routes all day long, offering functionally unlimited range. Proterra's CATALYST bus achieves 21+ miles per gallon equivalent performance, 500%+ better than diesel and CNG buses. In addition, Proterra's advanced technology reduces carbon emissions by 70% or more compared to CNG or diesel buses. Zero-emission transit buses provide the opportunity for all Californian's to ride an electric vehicle and realize the health and other associated benefits.

We appreciate ARB updating the Energy Economy Ratio (EER) for heavy-duty battery electric vehicles and request ARB increase the EER to adequately reflect the miles per diesel equivalent of fast-charge battery electric compared to diesel transit buses. The proposed EER of 4.2 for heavy-duty battery electric buses does not accurately represent the real ratio between new fast-charge battery electric buses and new diesel transit bus fleets. The proposed EER for heavy-duty battery electric buses averages the EER among battery electric buses – Proterra and BYD. To help ensure an equal comparison, we recommend averaging the fuel economy across all similar Altoona-tested diesel buses, including Gillig and Nova—in addition to New Flyer. Based on the Altoona testing for the most recent 40ft, low-floor, diesel buses over the three test cycles identified by ARB (Central Business District, Arterial, and Commuter), the Gillig bus averages 4.74 MPG, Nova 2.97 MPG, and New Flyer 4.82 MPG, generating an overall overage of 4.18 MPG. Using the average 20.33 MPG diesel equivalent for battery electric transit buses and the average 4.18 MPG for diesel transit buses, we respectfully request updating the EER to at least 4.86 for heavy-duty, battery electric vehicles in LCFS 16-2

PROTERRA
FUTURE-PROOF YOUR FLEET

www.proterra.com

order to provide an equal comparison of battery electric and diesel transit buses and accurately recognize the significant fuel efficiency and air quality benefits of zero-emission transit buses. LCFS 16-2 cont.

But even an EER of 4.86 does not accurately capture the unique fuel efficiency gains associated with Proterra's fast-charge technology. Therefore, we further request the consideration of a separate LCFS category for fast-charge, battery-electric buses, similar to ARB's additional incentive for fast-charge in the Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project (HVIP), in order to recognize the technology's functionally unlimited range, efficiency, and greater miles per gallon diesel equivalent. Charging along the route in less than 10 minutes allows the fast-charge, battery-electric buses to operate continuously – similar to a fuel cell or other long-range advanced technology. In addition, the buses have greater efficiency and MPG equivalent due to their light weight and advanced technology, as the fast-charge, battery-electric transit buses have fewer batteries and less weight on-board the vehicle. <u>Therefore, we strongly encourage recognizing a separate LCFS category for fast-charge, battery electric buses with an EER of 5.2—using the 21.72 MPG diesel equivalent achieved at Altoona under three identified test cycles and the average diesel transit bus at the same test cycles of 4.18 MPG.</u> LCFS 16-3

We thank you for the opportunity to provide comments on the Low Carbon Fuel Standard, and appreciate the efforts of the California Air Resources Board to reduce the carbon intensity of fuels to support California's climate goals, help clean the air, and promote clean, low-carbon fuels to improve California's energy security and energy independence.

Sincerely,

Eric J. McCarthy
VP Government Relations & General Counsel

16_OP_LCFS_Proterra Responses

83. Comment: **LCFS 16-1**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

84. Comment: **LCFS 16-2**

The comment requests ARB staff to update EERs to reflect the significant fuel efficiency and air quality benefits of zero emissions busses.

Agency Response: The proposed EERs for electric buses are based on testing of 3 different buses (including 2 electric buses operating in California: Proterra Electric Bus Model BE-35, and BYD Motors Electric Bus and 1 diesel bus – New Flyer of American Model XD40) performed at the Altoona Pennsylvania Transportation Institute (PTI) at Penn State Test Track. The testing was conducted using a Transit Coach Operating Duty Cycle that comprises of 3 Central Business District (CBD) phases, 2 Arterial (ART) phases and 1 Commuter (COM) phase. All necessary data, including total miles traveled and total energy consumed while driving and charging were recorded. As such, staff believes sufficient testing data were used to establish the EERs for electric buses.

When developing the proposed EERs for electrical buses, staff preferred to have the diesel buses that are most likely to be purchased by transit services as the baseline of fuel efficiency comparisons. As a result, New Flyer of American Model XD40 was selected as the most representative of new buses that could be purchased by transit services.

85. Comment: **LCFS 16-3**

The commenter encourages staff to add another LCFS category for fast-charge electric battery busses.

Agency Response: Staff prefers to keep the EERs generic for categories of vehicles, not for a specific make/model. Staff acknowledges that the electric bus technologies will continue to improve, and as a result, the EERs for electric buses will continue to increase. Staff commits to reevaluate electric bus EER as newer testing data become available.

Submitted via electronic mail.

Re: Written comments from the National Biodiesel Board on proposed Regulations for the Commercialization of Alternative Diesel Fuels and a Low Carbon Fuel Standard.

Dear Chair Nichols:

Thank you for the opportunity to comment on these regulations. We sincerely value the job you and all ARB board members and staff undertake in protecting the state's environment and public health.

By way of background, the National Biodiesel Board (NBB) serves as the trade association for the U.S. biodiesel and renewable diesel industries. The NBB represents more than 90 percent of domestic biodiesel and renewable diesel production. In addition to governmental affairs activities, the association coordinates the industry's research and development efforts.

Before delving briefly into a few key regulatory areas, I would like to express our appreciation to the Air Resources Board (ARB) for the cooperation we have received over the past several years. Biodiesel has encountered unique regulatory challenges as a result of the fact that it is the first alternative diesel fuel to ascend to commercial scale. I am pleased to report that, in each situation we have encountered, ARB staff have diligently worked through whatever issues were present with great skill, integrity, and professionalism. It has been a pleasure to work with staff on numerous matters of precedent-setting importance. LCFS 17-1

Alternative Diesel Fuel Regulation (ADF)

Speaking candidly, and strictly from a practical standpoint, we view NOx mitigation for biodiesel as unnecessary. This view is based on anticipated levels of biodiesel use in the marketplace and air quality modeling studies sponsored by the National Renewable Energy Laboratory and others. These studies show no measurable impacts on ground level ozone from widespread use of B20 due to the fact that small NOx increases are overwhelmed by large decreases in PM and other pollutants. ADF 8-1

That said, the NBB and its member companies fully support the ADF regulation as drafted. While ARB staff may have chosen a more conservative approach than our industry would have, in a perfect world, preferred, the regulation is clearly underpinned by robust data and technical analysis. Moreover, we view ARB's conservative mindset as appropriate in light of its statutory mission. ADF 8-2

In the final analysis, the ADF regulation should be viewed as an enhancement to the Low Carbon Fuel Standard (LCFS) because it provides much-needed regulatory certainty for California's biodiesel industry and it identifies a clear, certain, and rational path forward, both for biodiesel and other "new" fuels. Importantly, we also believe the regulation provides strong assurances to stakeholders that use of biodiesel under the LCFS will only result in air quality benefits.

ADF 8-2 cont.

Production and Feedstock Growth

Because of the LCFS, every biodiesel producer in the state is in some phase of expansion, waste feedstock collection rates are higher than they have ever been, and California is developing into a hub for "next generation" feedstock research and development with companies such as REG Life Sciences and Solazyme. These investments by environmental entrepreneurs are being made based on the promise of a stable, long-term GHG reduction policy. For this reason, we support maintaining the 10 percent by 2020 carbon intensity reduction requirement.

LCFS 17-2

Implementation Schedule

After careful analysis, we believe the overarching 10 percent by 2020 objective is workable. Certainly, there can be no question that the diesel requirement is achievable since more than 1.4 billion gallons of biodiesel and renewable diesel have been produced domestically each of the past two years. In light of these fuels' widespread availability and attractive pricing (typically the same as, or less than, petroleum), we see diesel substitutes as a highly attractive early compliance option. In addition, we are bullish on the growth prospects for the California biodiesel and feedstock industries. Continued in-state growth and development will make long-term compliance even easier, even less expensive, and even more beneficial to the state's economy.

LCFS 17-3

Biodiesel Fuel Pathways

We are in general agreement with the technical analysis that underpins the changes in lifecycle assessment for soybean oil, canola oil, and inedible corn oil. Of course, every scientist and stakeholder will, to some extent, have differing views on such inherently complex matters but, on the whole, ARB staff have done a superb job in integrating the most advanced science into these fuel pathways.

LCFS 17-4

Thank you, in advance, for your consideration of our views on these important matters. If I may be of any assistance, please feel free to contact me at any time at (573) 635-3893.

Sincerely,

Shelby Neal
Director of State Governmental Affairs

Re. ABBI's comments on the Proposed Re-Adoption of the Low Carbon Fuel Standard

Dear Sirs,

The Brazilian Industrial Biotechnology Association (*Associação Brasileira de Biotecnologia Industrial* – "ABBI") welcomes this opportunity to provide comments on the Proposed Re-Adoption of the Low Carbon Fuel Standard – LCFS (the "Proposed Re-Adoption"), published on December 30, 2014 by the Air Resources Board – ARB, a body within the California Environmental Protection Agency.

ABBI is a non-profit organization based in São Paulo, Brazil, established with the purpose of acting in a global level to promote the country's biochemical and biofuels industry. The Association is composed of leading global and local industrial biotechnology companies, acting together towards the biotechnology-based industry's sustainable development.

As further detailed below, the adoption of the Brazilian average electricity mix, based on outdated and inaccurate electricity generation data, as established in Table 9 of the CA-GREET 2.0 Supplemental Document and Tables of Changes (page C-22) for the calculation of Carbon Intensity (CI) credits derived from the export of electricity to the grid, if approved as proposed, shall adversely affect Brazilian ethanol producers which already – or plan to – export ethanol to potential off-takers in the State of California. LCFS 18-1

1. Introduction:

The proposed CA-GREET 2.0 adopts the electricity mixes associated with the 26 eGRID subregions, based on the US EPA's Emissions & Generation Resource Integrated Database (eGRID), instead of the 2010 10-region North American Electric Reliability Corporation (NERC) regions, which was used in the replaced GREET1 2013. In addition, the ARB is proposing to create a Brazilian average electricity mix, based on EIA's Country Analysis Brief website report for Brazil, as provided in Table 9 – 2010 Brazil Electricity Resource Mix (page C-22 of the of the CA-GREET 2.0 Supplemental Document and Tables of Changes): LCFS 18-2

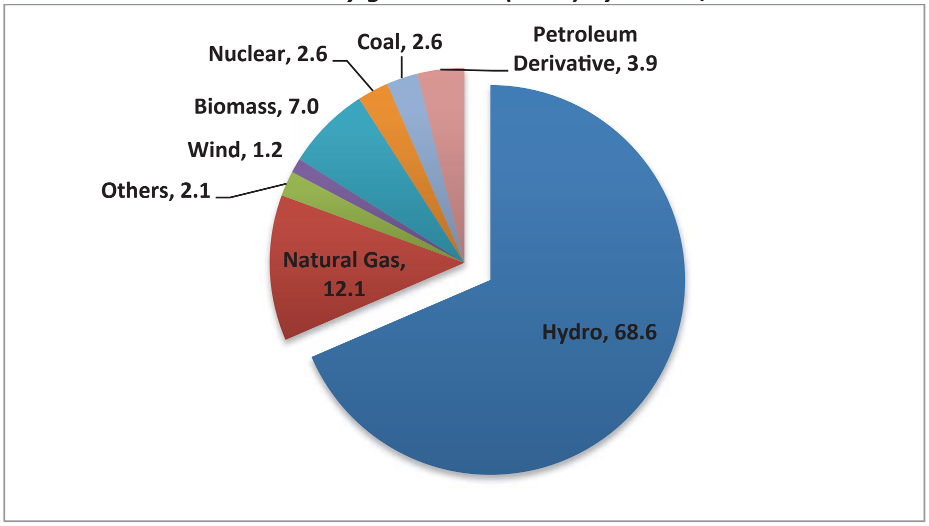
A9trica%202014.pdf

Chart 2: Brazil 2013 electricity generation (GWh) by source, %



Source: Brazilian Energy Research Company (EPE), 2014 Statistical Yearbook of Electricity

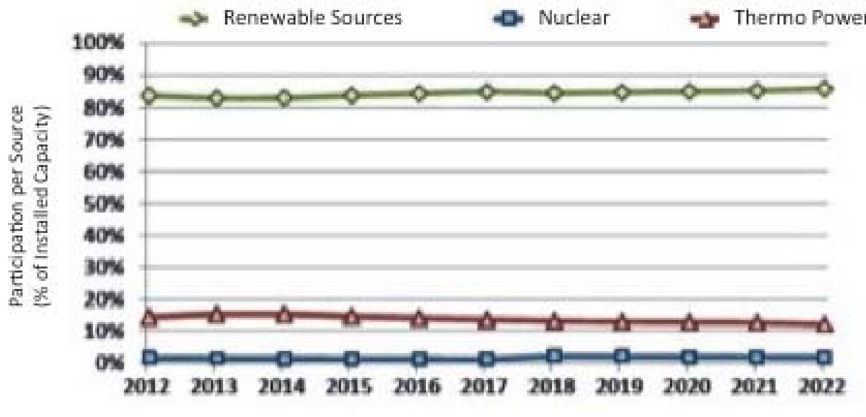
LCFS 18-2 cont.

As seen above (chart 2), the Brazilian electricity mix is still heavily dependent on the generation of electricity from hydro power plants, which includes large plants, such as Itaipú (with an installed capacity of 14,000 MW) and Tucuruí (with an installed capacity of 8,370 MW), as well as small hydroelectric plants (*Pequenas Centrais Hidrelétricas – PCHs*), which are limited to 30 MW capacity each. Hydro power installed capacity in Brazil is currently 89,224 MW and, if all new hydro power plants start operations according to the schedule, by 2021 and additional hydro power capacity of 21,774 MW shall be added to the national grid.

However, due to hydrological crisis which affects Brazil since 2010/2011, the capacity of the hydro power plants' reservoirs are currently below 20% (twenty percent) in the Southeast and Northeast regions[3] (which represents 69% of Brazil's total electricity consumption), meaning that the existing hydro power plants have been operating far below their installed capacity and the additional capacity to be delivered by the new hydro power plants shall not be sufficient to reduce the participation of fossil sources plants in the Brazilian electricity mix, which installed capacity shall account to 14.2% (fourteen point two percent) in 2016 and 12.3% (twelve point three percent) in 2022, according to official estimates prepared by the EPE, as shown in the charts below:

[3] Hydro power plants reservoirs status on Jan 12, 2015: Southeast and Center West regions: 19.29%; South region: 70.04%; Northeast region: 17.9% and North region: 35.06% (Source: ONS);

Chart 3: Development of sources participation on SIN's installed capacity

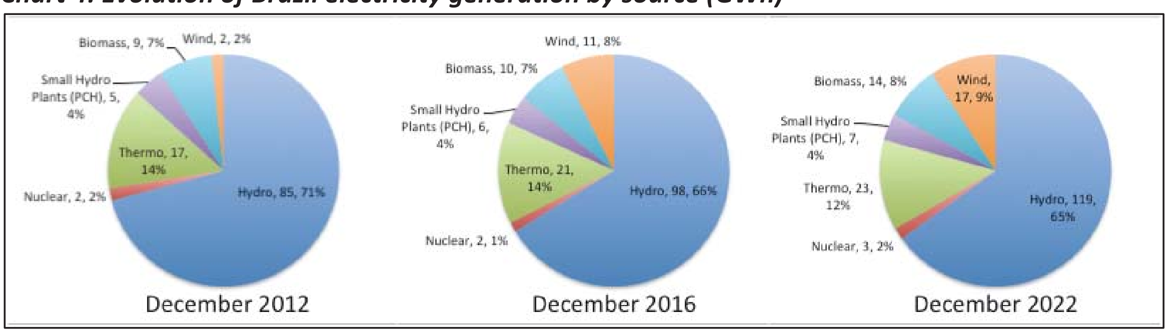


Source: Brazilian Energy Research Company (EPE)

The Brazilian electricity system is connected through the National Interconnected System (*Sistema Interligado Nacional – SIN*), which is monitored by the National Operator of the Electricity System (*Operador Nacional do Sistema Elétrico – ONS*), a non-profit organization regulated by the National Electricity Energy Agency (*Agencia Nacional de Energia Elétrica - ANEEL*). Under the SIN, the hydropower plants, which have lower operational costs as compared to the other sources, operate in full capacity, while fossil sources plants (i.e. natural gas, petroleum products and coal), which have higher operational costs, operate "on demand", by means of the so-called dispatch orders issued by the ONS, according to the system's needs.

LCFS 18-2
cont.

Chart 4: Evolution of Brazil electricity generation by source (GWh)[5]



Source: Ten-Year Plan for Energy Expansion – PDE, Brazilian Energy Research Company (EPE)

Periodically, two reports are prepared by the ONS: (i) the Energy Operation Planning (*Planejamento de Operação Estratégica – POE*), with the purpose of presenting a 5-year planning for the electricity generated to and consumed from the SIN; and (ii) Annual Electricity Operation Planning (*Planejamento de Operação Elétrica Anual – POEA*), a study which offers the diagnosis of the SIN performance and provides a forecast of the generation and consumption of electricity in a 1-year

[5] http://www.epe.gov.br/pdee/forms/epeestudo.aspx

period. The POEA is the study that subsidies ANEEL's decisions to increase or reduce the electricity to be generated by the fossil sources plants within a certain period of time.

Due to (i) the increase of electricity demand over the years; (ii) the severe hydrological crisis which affects the sector since 2011 (as explained above); and (iii) the lack of sufficient investments in new projects; the fossil source plants have been registering, since 2008, the highest increases in installed capacity in Brazil (see Chart 5 below) and, since 2011, have been operating close to full capacity to meet the system's needs.

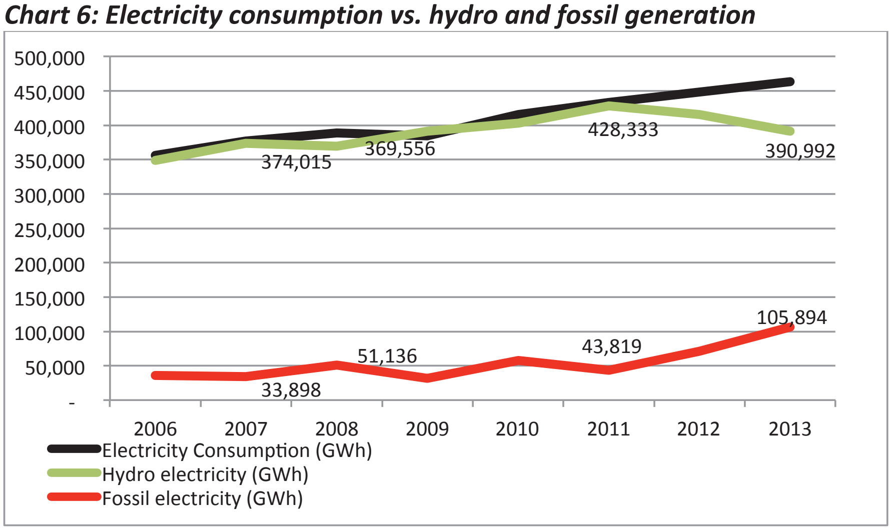
Chart 5: Start-up of new electricity plants (in MW)

	2008	2009	2010	2011	2012	2013	Total	%
Thermal (fossil + biomass)	1.243,90	2.224,00	3.762,80	2.125,54	1.670,08	3.717,35	14.743,67	57,57
Hydro	822,84	1.074,18	2.060,97	1.575,47	1.856,64	1.525,17	8.915,27	34,81
Wind	91,30	266,93	325,60	498,35	456,19	313,19	1.951,56	7,62
							25.610,50	**100**

Source: National Electricity Energy Agency - ANEEL

Until 2010/2011, the generation of hydro electricity was capable of meeting most of Brazil's electricity demand, and other sources of electricity were used only for brief periods of hydro electricity shortages imposed by water scarcity during dry seasons or consumption peaks. As from 2011, the hydro electricity became no longer capable to meet the national needs and the fossil sources' plants started playing a critical role in the Brazilian electricity sector, increasing the electricity generation from 43,819 GWh in 2011 to 105,894 GWh in 2013, as shown below: LCFS 18-2 cont.

Chart 6: Electricity consumption vs. hydro and fossil generation



Source: EPE, prepared by ABBI

The tables and charts above and Chart 7 below prove the reduction of the participation of hydropower plants and the increase of fossil sources plants in the Brazilian electricity mix, from 79.8% and 11.04%, respectively, in 2008, to 68.6% and 18.6% in 2013. They also evidence how dependent is Brazil on the electricity generated by the fossil sources plants (i.e. natural gas, petroleum and coal).

As explained by Vahl and Casarotto Filho, whose study suggests that by 2022 thermal plants shall be the main source of electricity in Brazil, surpassing the hydropower market share, ***"dispatch orders and the energy mix follow seasonal demand peaks in the Brazilian grid. In order to meet demand during peak seasons, especially in summer (from December through March), the Brazilian operator*** **[i.e. ONS]** ***has hired an increasing amount of energy from thermo power plants, which are currently the primary contingency plan for the maintenance of supply and system reliability. Such strategy increases significantly the amount of GHG emissions "***[6].

They continue saying that ***"electricity production from thermal power plants has increased 694% in the Brazilian energy mix from 2005 to 2012, a pace much higher than consumption. Also, the strategy of dispatching energy from thermal power plants only in situations of low hydro energy stored no longer applies for Brazilian scenarios, since the yearly average has also grown regardless of hydro energy stored. Such plants are indeed becoming important suppliers in order to maintain balance between electricity supply and demand***[7]. The recent exploitation of petroleum in the pre-salt area, part of them with massive quantities of natural gas, also poses as a potential factor to increase even further the electricity generation from such source.

Year over year, the hydroelectric capacity has declined while fossil fuel generation has grown. This trend clearly indicates that the marginal power generation resource is from fossil fuels. In other words, as the fossil sources plants are the only ones with capacity to increase production in Brazil, they work as a marginal resource to balance the national electricity supply and demand and should therefore be considered, for any purpose, as the only sources of electricity to compose the Brazilian marginal resource mix.

LCFS 18-2 cont.

Chart 7: Electricity generation 2008 x 2013

Type	Source	2008	% (per source)	% (per type)	2013	% (per source)	% (per type)

3. GREET 2.0 Electricity mix methodology: average mix vs. marginal resource mix

The ARB says in the CA-GREET 2.0 Supplemental Document and Tables of Changes (page C-2) that "*Staff has adopted the mixes associated with the 26 eGRID subregions. Average rather than marginal subregional mixed are used*" and continues saying that "*Staff selected average electricity resource mixes primarily due to the uncertainty in determining the marginal resource mix accurately for each subregion*".

ABBI appreciates the difficulties to determine which type of energy should be considered as marginal for the purposes set out in the CA-GREET 2.0 in the US, in view of the different sources of electricity suppliers with availability to increase production to attend the demand. However, that is not applicable to Brazil. As demonstrated above, the only source of electricity that has been substantially increasing in Brazil since 2008 and that has installed capacity and flexibility to increase production in the short or medium term is the fossil energy, primarily from natural gas. LCFS 18-3

Therefore, the fossil energy (i.e. generated by natural gas, petroleum products and coal) should be considered the Brazilian marginal resource mix for any purposes, including for the calculation of Carbon Intensity – CI credits derived from the export of electricity to the grid by Brazilian ethanol producers.

4. Conclusion

In view of the above, ABBI hereby urges the ARB to adopt in GREET 2.0, for the calculation of Carbon Intensity – CI credits derived from the export of electricity to the grid:

(i) The actual marginal resource mix of the region where the respective mill is located. In this case, the Brazilian marginal resource mix should be composed exclusively of natural gas, petroleum and coal power plants; or alternatively, LCFS 18-3 cont.

(ii) the natural gas based electricity mix (i.e. 2010 10-region North American Electric Reliability Corporation (NERC) regions), which was used in GREET1 2013 and previous CA_GREET models, which are the measures that most accurately reflect the savings of GHG emissions caused by the export of electricity to the grid. LCFS 18-2 cont.

ABBI would be glad to provide any further information or document as deemed necessary by the ARB and renew its assurances of full support and the most distinguished consideration for the work carried out by the ARB.

Respectfully submitted,

____

91. Comment: **LCFS 18-1**

The commenter states that the Brazilian average electricity mix in CA-GREET will adversely affect ethanol producers in the country.

Agency Response: With regards to the comment on the incorrect mix of electrical generating assets specified in the draft California-modified Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (CA-GREET) v2.0 life cycle analysis model, ARB staff concurs with the commenter that the proposed mix had incorrectly grouped several fossil-fueled generating resources (such as petroleum fuel-based generation) with natural gas-based generation. CA-GREET 2.0 was amended to reflect electricity generation data from the Brazilian government.

With regards to the broader comment that the average electricity mix will adversely impact ethanol producers in Brazil, see the response to **LCFS 18-3** below.

92. Comment: **LCFS 18-2**

The comment is an informative display of the historical electrical energy production and usage in Brazil, from 2006 to 2012.

Agency Response: In response to the comment, ARB staff changed the mix of electrical generating assets. The resulting mix is based on data provided in the annual Brazilian Energy Balance[1] prepared by the Ministry of Mines and Energy, Government of Brazil. The correction was made as a 15-day change to the regulation to consider the re-adoption of an updated Low Carbon Fuel Standard (LCFS). Staff thanks the commenter for sharing the average Brazilian mix data.

[1] The average portfolio of electrical generating assets is based upon the Brazilian Energy Balance for years 2010-2012, published by the Empresa de Pesquisa Energetica (EPE) agency of the Ministry of Mines and Energy (http://www.mme.gov.br).

15-day Change to the Average Electrical Generation Mix for Brazil

Electric Generation Mixes: Data Table for Use in GREET (From Annual Energy Outlook 2013)	29-Brazillian Mix	
	Transportation	Stationary
Residual oil	3.4%	3.4%
Natural gas	7.9%	7.9%
Coal	1.9%	1.9%
Nuclear power	2.6%	2.6%
Biomass	7.0%	7.0%
Renewable sources (w/o hydro) and others	77.3%	77.3%

93. Comment: **LCFS 18-3**

The comments states that the marginal electricity use in Brazil has been derived primarily from fossil-based energy sources and request that ARB staff update CA-GREET 2.0 to reflect it.

Agency Response: ARB staff concurs with the commenter that the marginal electrical energy use in Brazil in recent drought-affected years may have been derived primarily from fossil-based energy resources. However, Staff's proposal requires the use of average electricity resource mixes for both grid power consumption and for displacement credit for generated power for pathways submitted under CA-GREET 2.0. Under this framework grid electricity users and exporters to the grid use the same values. This decision was made primarily due to challenges in accurately determining the marginal electricity resource mix for each U.S. subregion or international subregion as explained in Appendix C of the ISOR.

It is challenging to define and distinguish marginal electricity sources accurately. To conduct this type of analysis with the highest degree of certainty requires the use of sophisticated dispatch modelling imposing consistent assumptions across all regions.

Further, different types of self-generation may operate in different modes and have different abilities to displace various grid resources (i.e., intermittent renewables are different from baseload combined-heat-and power, which is also different from dispatchable self-generation). Staff does not have access to robust and comparable marginal unit analysis across all regions and does not have the resources to conduct such an analysis currently.

Staff determined that the simplest, most equitable and defensible method for the current rulemaking is to apply the regional average across all pathways.

COMMENT 19 FOR LOW CARBON FUEL STANDARD 2015 (LCFS2015) - 45 DAY.

First Name: Eileen
Last Name: Tutt
Email Address: eileen@caletc.com
Phone Number:
Affiliation:

Subject: Support for LCFS re Adoption
Comment:
Dear Honorable Chairman Nichols and Members of the Board:

Please consider the attached documents supporting the California Electric Transportation Coalition comments which were submitted on February 13, 2015:

1. An assessment by ICF International characterizing the macroeconomic impacts and associated co-benefits of LCFS compliance. LCFS 19-1

2. An assessment by ICF International in cooperation with industry leaders and investors showing the alternative fuels market has evolved much faster than anticipated and the Low Carbon Fuel Standard is exceeding expectations. The report analyzes recent developments in the transportation sector and presents three scenarios that ratchet down the carbon intensity of transportation fuels 10 percent, to meet the goal of California's Low Carbon Fuel Standard by 2020. All three projections point to an increasingly diverse fuel supply, with more innovation leading to more renewable fuels and advanced vehicles. LCFS 19-2

3. An assessment by TIAX, LLC demonstrating that electricity consumption in on-road and off-road applications has the potential to produce a significant quantity of LCFS credits. LCFS 19-3

4. A powerpoint summarizing a related assessment by ICF LCFS 19-4

International and E3 which demonstrates the benefits of transportation electrification for all Californians, whether or not they drive electric. These benefits extend beyond the air quality and greenhouse gas benefits to include benefits to ratepayers. The full reports are available online at www.caletc.com. LCFS 19-4 cont.

Thank you for your consideration.
Regards,
Eileen Wenger Tutt, Executive Director
California Electric Transportation Coalition

California Low Carbon Fuel Standard (LCFS) Electric Pathway – On-Road and Off-Road

Presentation to:

California Electric Transportation Coalition (CalETC)

November 14, 2012

TIAX LLC
35 Hartwell Avenue
Lexington, MA
02421-3102

www.TIAXLLC.com

© 2012 TIAX LLC

Electric Credits in the California Low Carbon Fuel Standard

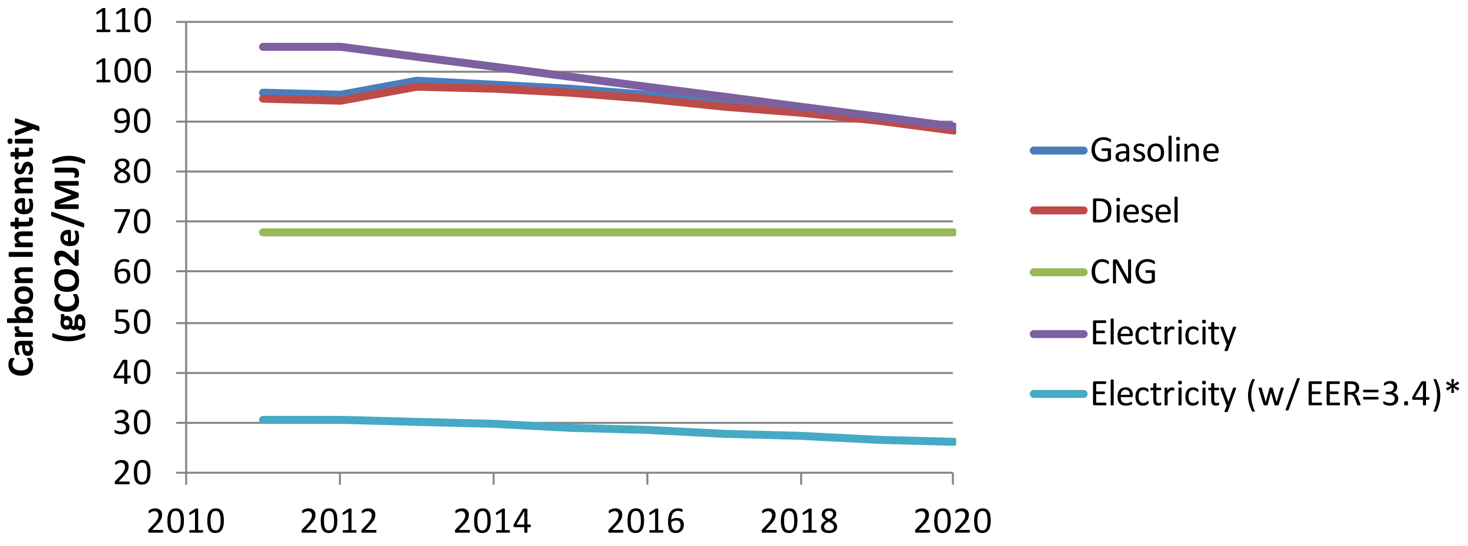
- Electricity consumption in on-road and off-road applications has the potential to produce a significant quantity of LCFS credits
- On-road applications include light-duty plug-in electric vehicles (PEVS) such as battery electric vehicles (BEVs) or plug-in hybrid vehicles (PHEVs)
- Off-road applications include electric passenger rail, electric forklifts and E-transport refrigeration units (e-TRUs)

Not included in this Analysis

- In several ways this analysis is conservative because GHG reductions from several existing and potential segments for electric transportation were excluded
  - Medium and heavy duty PHEVs and BEVs (including over-head wire options)
  - Most of the off-road applications including
    - electric airport ground support equipment,
    - electric golf carts,
    - electric personnel / burden carriers,
    - electric industrial tow tractors,
    - electric sweepers, scrubbers and burnishers
    - electric lawn and garden equipment
    - shore-side electric equipment (cold ironing)
    - electric port cargo handling equipment
    - truck stop electrification
    - electric freight rail and high speed rail
    - expanding market share for electric forklifts and electric TRUs.
- Also this analysis does not count the GHG reductions from PHEVs when they travel in gasoline mode (317,000 tons reduced per year in 2020 for 780,000 PHEVs)

Carbon Intensities

- Gasoline and diesel carbon intensities are the standard values, decreasing from 2011 to 2020, using the September 17, 2012 15 Day Modified Regulatory Order
- CNG carbon intensity stays the same
- RPS regulation has stair-step renewable requirements for electricity between 2013 and 2020; modeled electricity carbon intensity decreasing linearly from 2012 (21.3% renewables; balance natural gas) to 2020 (33% renewables; balance natural gas) for simplicity

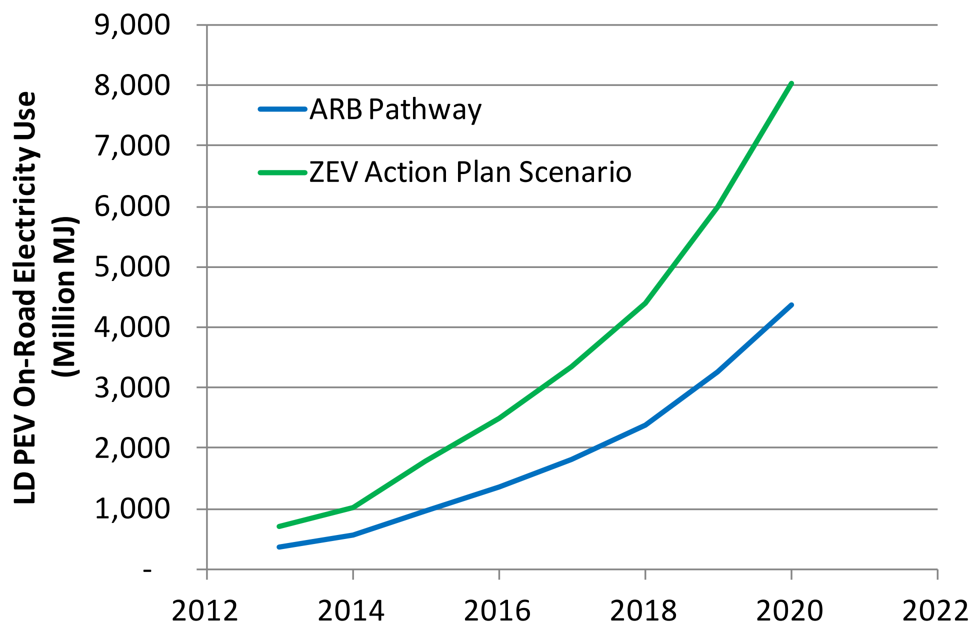


*Taking into account the EER allows for a comparison based on per unit of energy of the replaced fuel (e.g. gasoline or diesel)

On-Road Electrification – LD PEVs (40% PHEV Miles in Electric Mode)

- Electricity consumption based on ARB Illustrative Pathways – 544,000 plug-in vehicles in 2020, 22% of which are BEVs; PHEVs – 40% miles in Electric Mode
- ZEV Action Plan Scenario is 1 million plug-in vehicles in 2020, 22% BEVs and 40% PHEV miles Electric Mode similar to ARB Illustrative Pathways
- ARB Pathway: EER - 3.4; VMT All Vehicles (2020) – 12,000

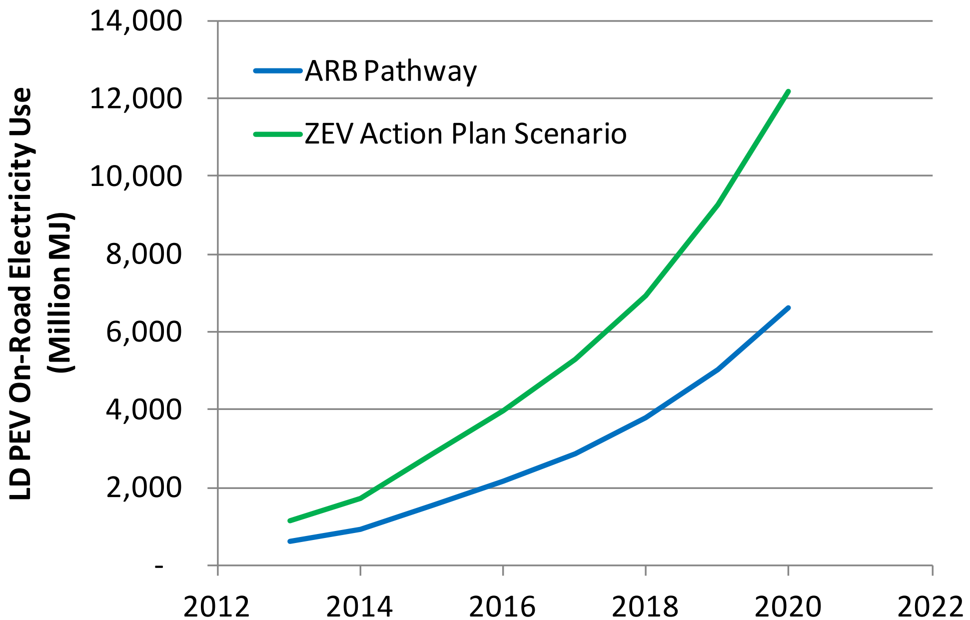
$$(CI^{Gasoline}_{Standard} - CI^{Elec} / EER^{Elec}) * (E^{Elec} * EER^{Elec}) * C = Credits$$



On-Road Electrification – LD PEVs (75% PHEV Miles in Electric Mode)

- Electricity consumption based on ARB Illustrative Pathways – 544,000 plug-in vehicles in 2020, 22% of which are BEVs; PHEVs – 75% miles in Electric Mode
- ZEV Action Plan Scenario is 1 million plug-in vehicles in 2020, 22% BEVs and 75% PHEV miles Electric Mode similar to ARB Illustrative Pathways
- ARB Pathway: EER - 3.4; VMT All Vehicles (2020) – 12,000

$$(CI^{Gasoline}_{Standard} - CI^{Elec} / EER^{Elec}) * (E^{Elec} * EER^{Elec}) * C = Credits$$

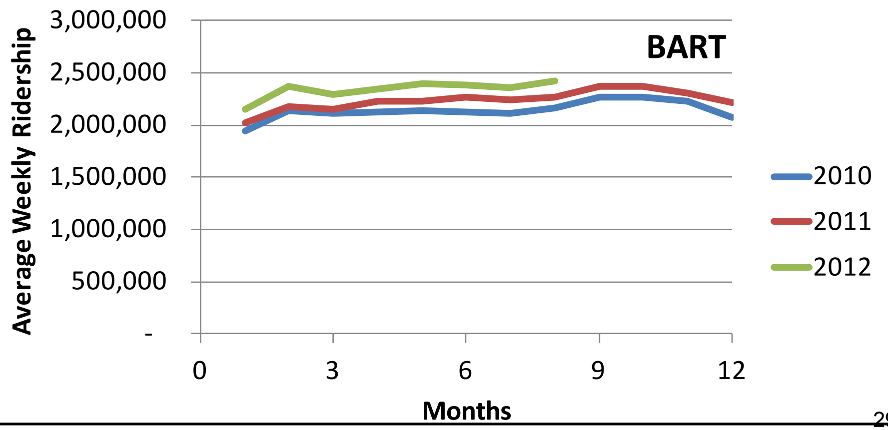


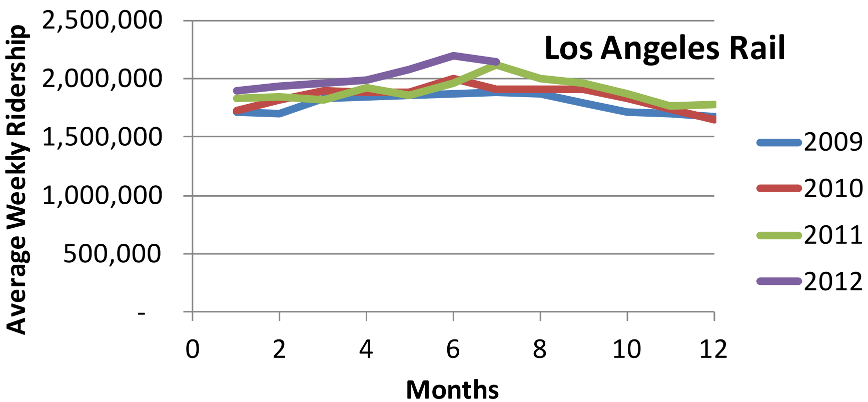
Electric Passenger Rail

- Data from the National Transit Database was used to calculate kWh/mi and MJ/mi for electric rail in California and their corresponding transit bus fleet, rail passenger miles and rail track length in 2010

	Electric Rail		Transit Bus		Rail Passenger Miles	Track Length (mi)
	kWh/mi	MJ(e-)/mi	Fuel	MJ/mi		
Los Angeles HR	0.37	1.34	CNG	3.82	231,935,841	34.1
Los Angeles LR	0.29	1.04	CNG	3.82	333,334,394	116.3
Sacramento	0.42	1.52	CNG	5.54	82,500,482	73.4
San Diego	0.21	0.74	CNG	5.68	186,509,312	102.6
BART	0.20	0.73	Diesel	3.25	1,390,909,655	267.6
San Francisco	0.38	1.36	Diesel	3.25	239,829,549	103.5
Santa Clara	0.45	1.61	Diesel	4.00	50,000,272	79.6

- LA Metro and BART data show ridership has been increasing since 2010 and confirm the use of 2010 data for passenger miles as a conservative assumption



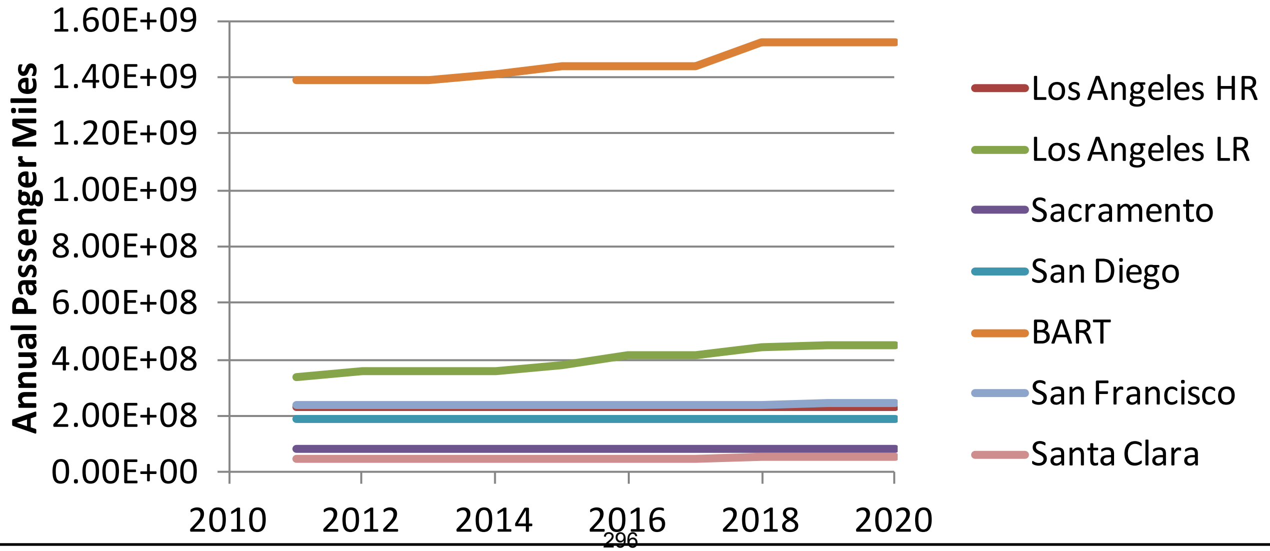


Electric Passenger Rail (cont.)

- Planned and implemented rail expansions taken into account by assuming ratio of passengers to track miles is constant for each transit

2012-2020	Electric Rail Expansion (mi (yr))
Los Angeles HR	none
Los Angeles LR	8.6 (2012); 6.6 (2015); 11 (2016); 8.5 (2018)
Sacramento	1.1 (2012)
San Diego	none
BART	3.2 (2014); 5.4 (2015); 16 (2018)
San Francisco	1.7 (2019)
Santa Clara	10 (2018)

- Increased Passenger-miles based on implemented and planned track increases



Electric Passenger Rail (cont.)

- Used Two (2) Methodologies For Comparison
  - Displacing Light-duty Auto Miles
  - Displacing Transit Bus Miles
- Displacing Light-Duty Auto Miles
  - Used EMFAC fleet average fuel economy (~23.3 mpg) and 1.1 Passenger's per vehicle to calculate MJ/mi (~4.64MJ/mi)

$$\left[(CI_{\text{Standard}}^{\text{Gasoline}} * (MJ / pass-mile)^{Gasoline}) - (CI^{Elec} * (MJ / pass-mile)_{Rail}^{Elec}\right]$$
$$* \; pass-miles_{rail}^{annual} * C = Credits$$

Electric Passenger Rail (cont.)

- Displacing Transit Bus Miles
  - Use MJ/mi from NTD and corresponding fuel Carbon Intensity (CNG or Diesel) for each transit agency
  - Diesel

$$\left[(CI^{\mathrm{Diesel}}_{\mathrm{Standard}} * (MJ / pass - mile)^{Diesel}_{TransitBus}) - (CI^{Elec} * (MJ / pass - mile)^{Elec}_{Rail} \right]$$

$$* \; pass - miles^{annual}_{rail} * C = Credits$$

  - CNG

$$\left[(CI^{\mathrm{CNG}} * (MJ / pass - mile)^{CNG}_{TransitBus}) - (CI^{Elec} * (MJ / pass - mile)^{Elec}_{Rail} \right]$$

$$* \; pass - miles^{annual}_{rail} * C = Credits$$

Electric Forklifts

- Electric forklift population based on US factory shipments of electric rider (Class 1&2) and motorized hand (Class 3) forklifts from 2000-2010[A] (Industrial Truck Association); used year 2000 shipments as a surrogate for 2011 assuming forklifts have an 11 year lifetime and 2011 shipments replace 2000 shipments
- Pro-rated California share of 12% (2010 Census Population Data)
- Split Electric Rider into Class 1 & 2 using the World Industrial Truck Statistics for America[A] in 2009 and 2010 (60% Class 1, 40% Class 2)
- Conservatively estimate current population equals 2013 – 2020 population

	Class 1+2	Class 3
2000-2010 US Shipments	488,853	458,502
CA Share	58,662	55,020
CA Class 1 (60%)	35,197	
CA Class 2 (40%)	23,465	

[A] – Industrial Truck Association http://www.indtrk.org/market-intelligence

Electric Forklifts (cont.)

- EER of 3.0; Assume a diesel standard
- Class 1 and Class 2 estimated battery size of 43.6 kWh[A]
- Class 3 estimated battery size of 12.5 kWh[B]
- 3,150 hrs/yr of operation per forklift[C] (50% single shift; 25% each double and triple shift)
- Assume 80% depth of charge and full battery usage per shift resulting in an average load of 4.36kW for Class 1 and 2 and 1.25 kW for Class 3

$$(CI^{Diesel}_{\text{Standard}} - CI^{Elec} / EER^{Elec}) * (E^{Elec} * EER^{Elec}) * C = Credits$$

[A,B] – Based on spec sheets for Nissan and Crown Class 1 and 2 Forklifts, http://www.crown.com, http://nissanforklift.com/

[C] – Based on TIAX Phase 2 Report for CalETC communications with SCE and industry members

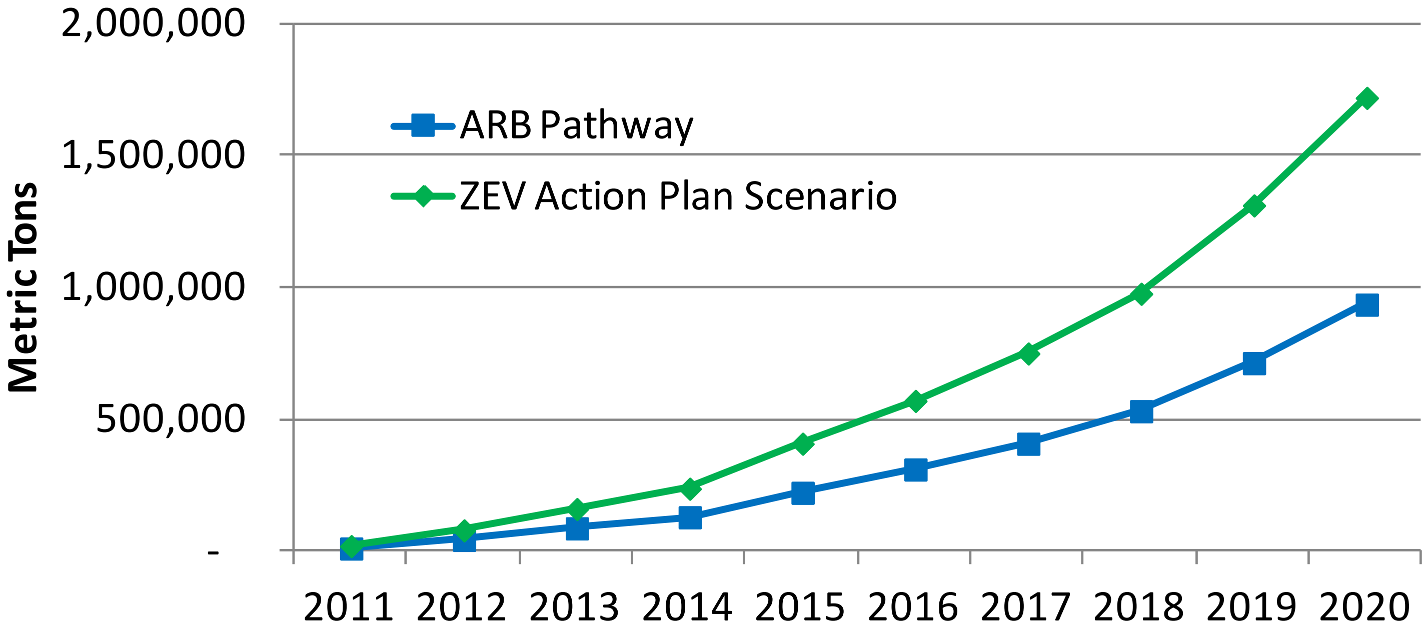
E-Transport Refrigeration Units

- Data Supplied by ARB:
  - 2,100 registered hybrid eTRUs in California
  - Conservatively estimate current population equals 2013 – 2020 population
  - Operate 3hrs/day, 6 days/wk, 52 wks/yr
  - Motor rating of 8 kW and a load factor of 0.75
  - Estimated 11.7 million kWh of electricity consumed each year by e-TRUs
  - Offset diesel consumption
  - EER = 3.0

$$(CI_{\mathrm{Standard}}^{Diesel} - CI^{Elec} / EER^{Elec}) * (E^{Elec} * EER^{Elec}) * C = Credits$$

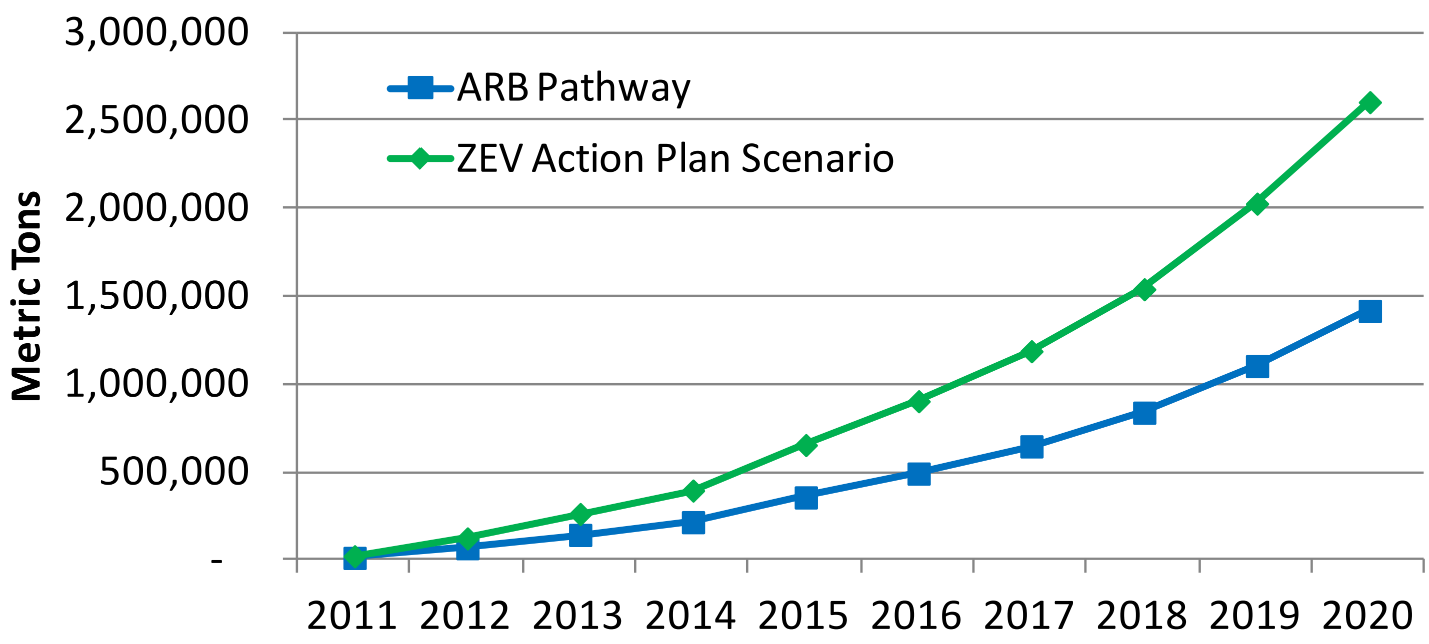
2013-2020 Potential Credits (40% PHEV Miles in Electric Mode)

- LD PEV on-road electrification yields almost 1 million credits in 2020 for the ARB Pathway and over 1.7 million credits in the ZEV Action Plan Scenario with 40% PHEV miles in electric mode



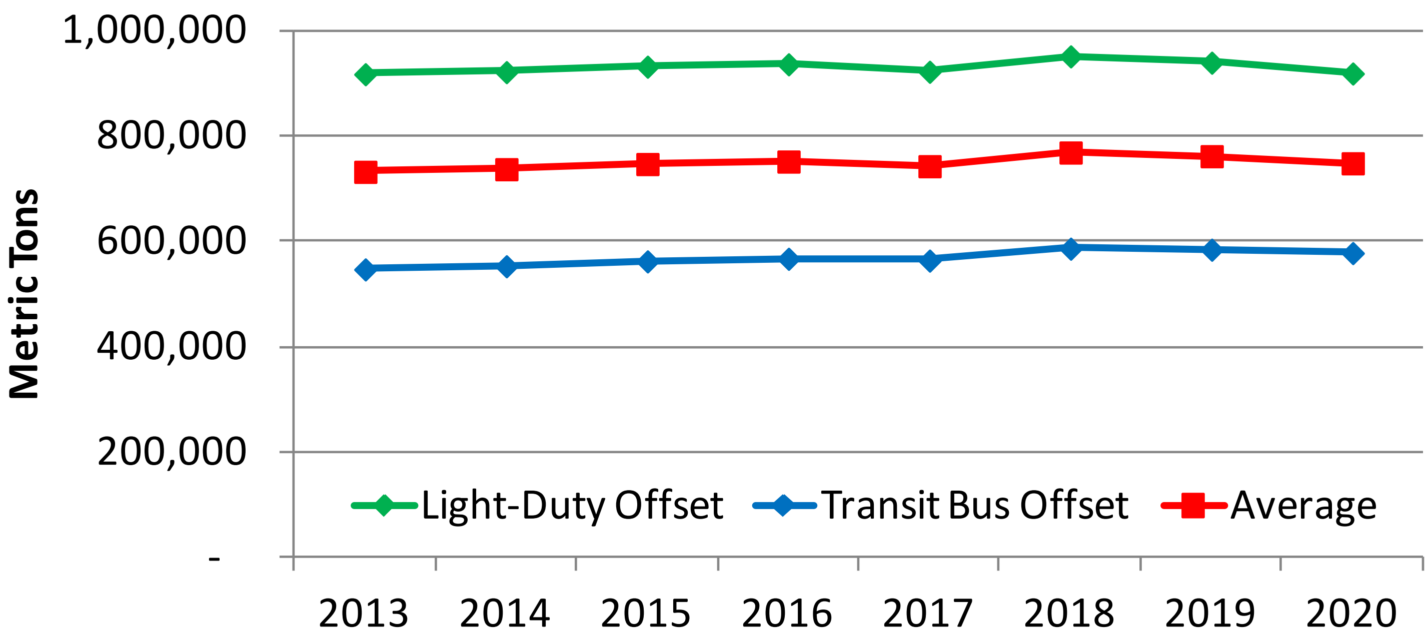
2013-2020 Potential Credits (75% PHEV Miles in Electric Mode)

- LD PEV on-road electrification yields almost 1.5 million credits in 2020 for the ARB Pathway and over 2.5 million credits in the ZEV Action Plan Scenario with 40% PHEV miles in electric mode



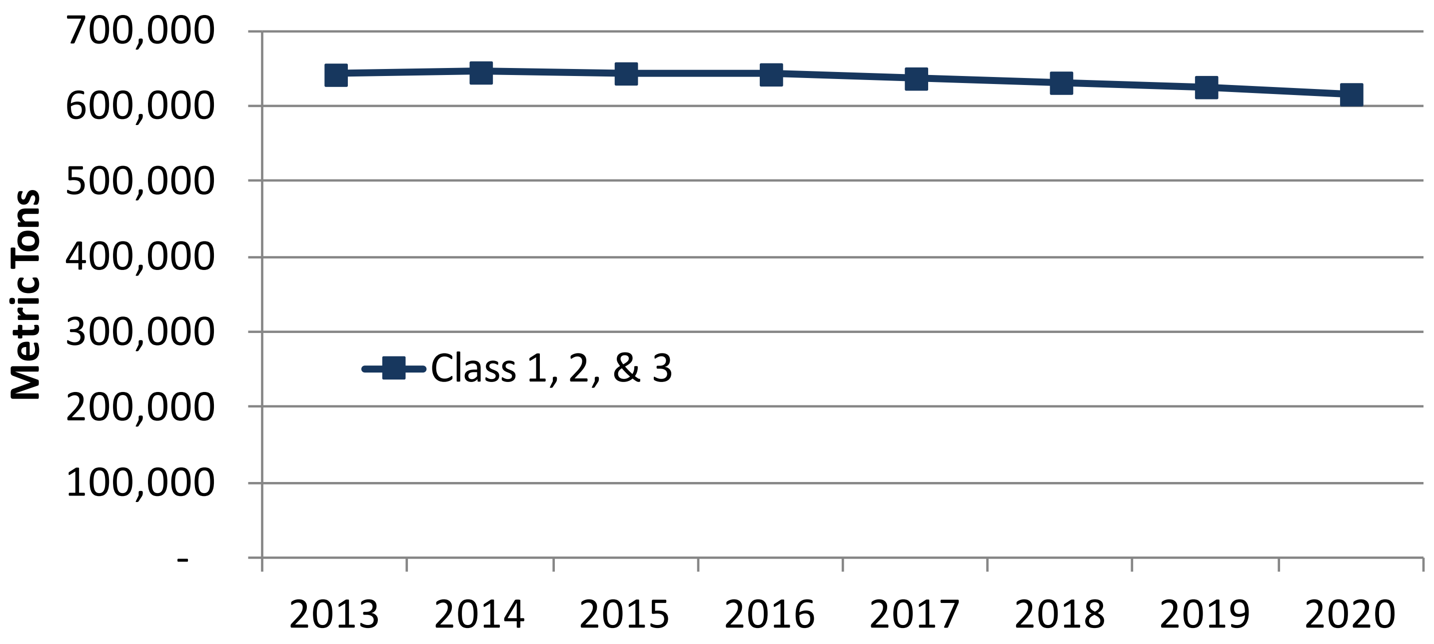
2013-2020 Potential Credits

- Displacing light-duty vehicles yields 910,000-950,000 metric tons of credits per year
- Displacing transit bus usage yields between 540,000-570,000 metrics tons of credits per year
- Average of both methodologies yields between 730,000-770,000 metric tons of credits per year



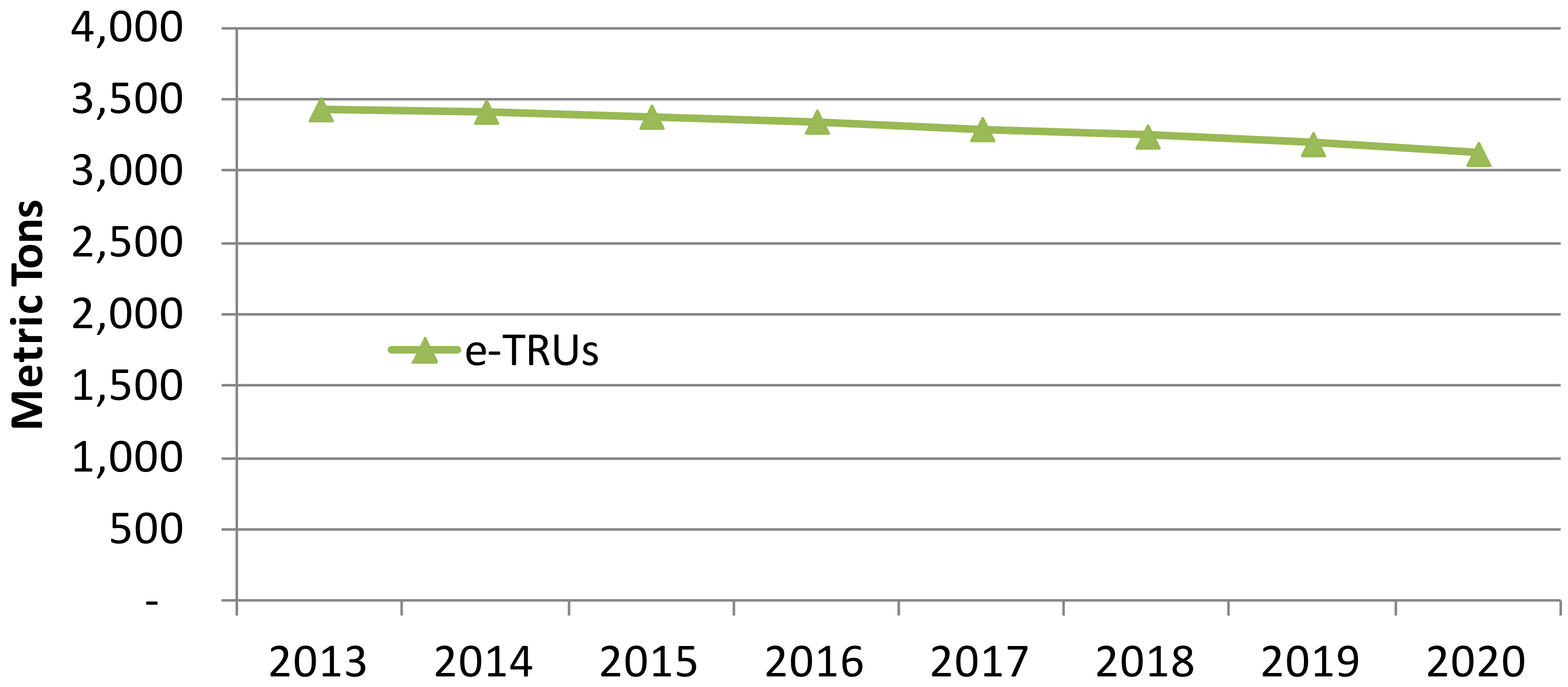
2013-2020 Potential Credits

- E-Forklifts yield over 600,000 metric tons of credits with the estimated current population



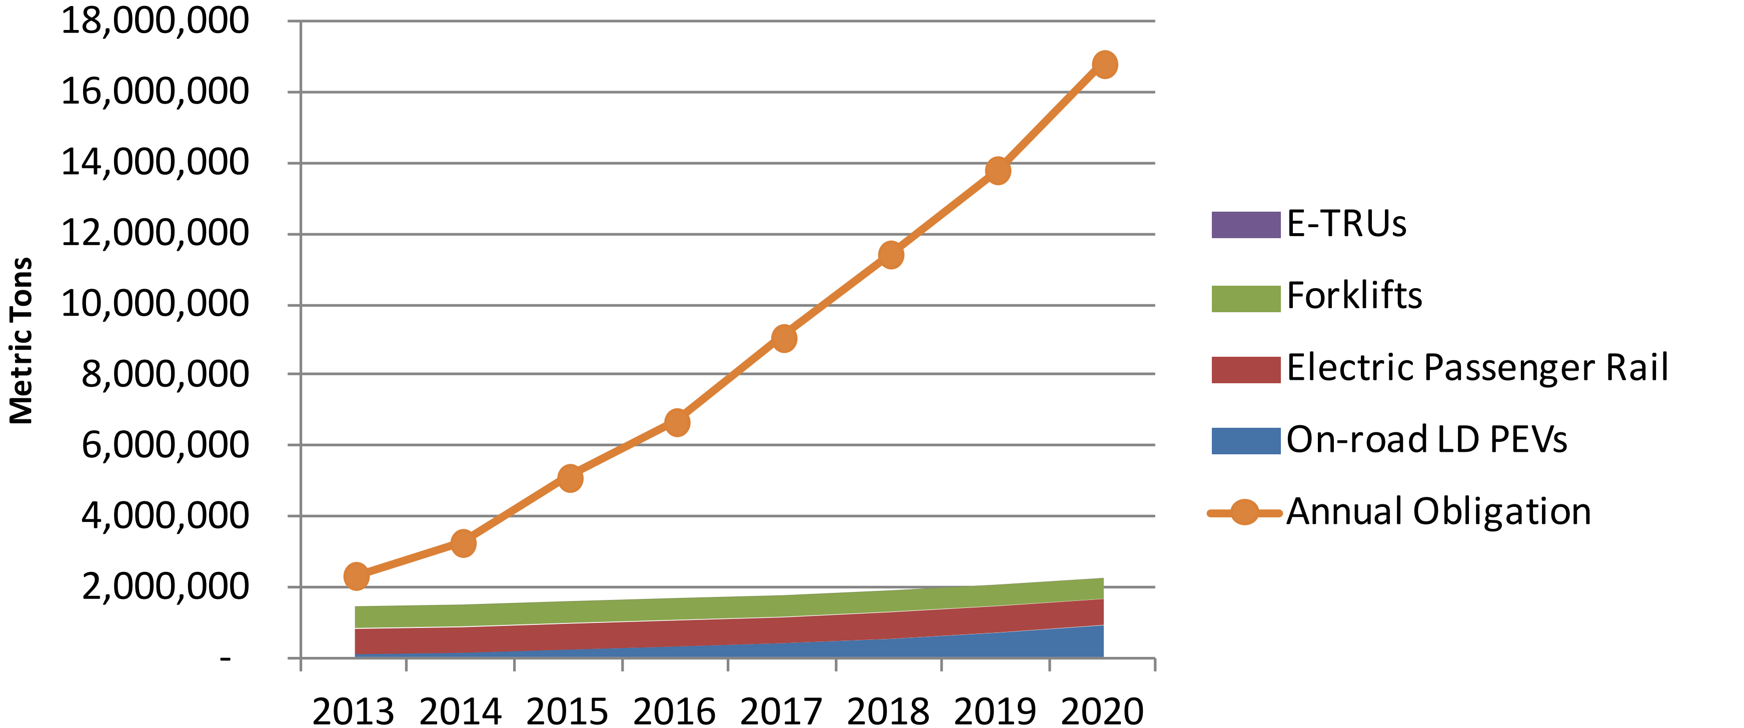
2013-2020 Potential Credits

- E-TRUs yield over 3,000 metric tons of credits per year



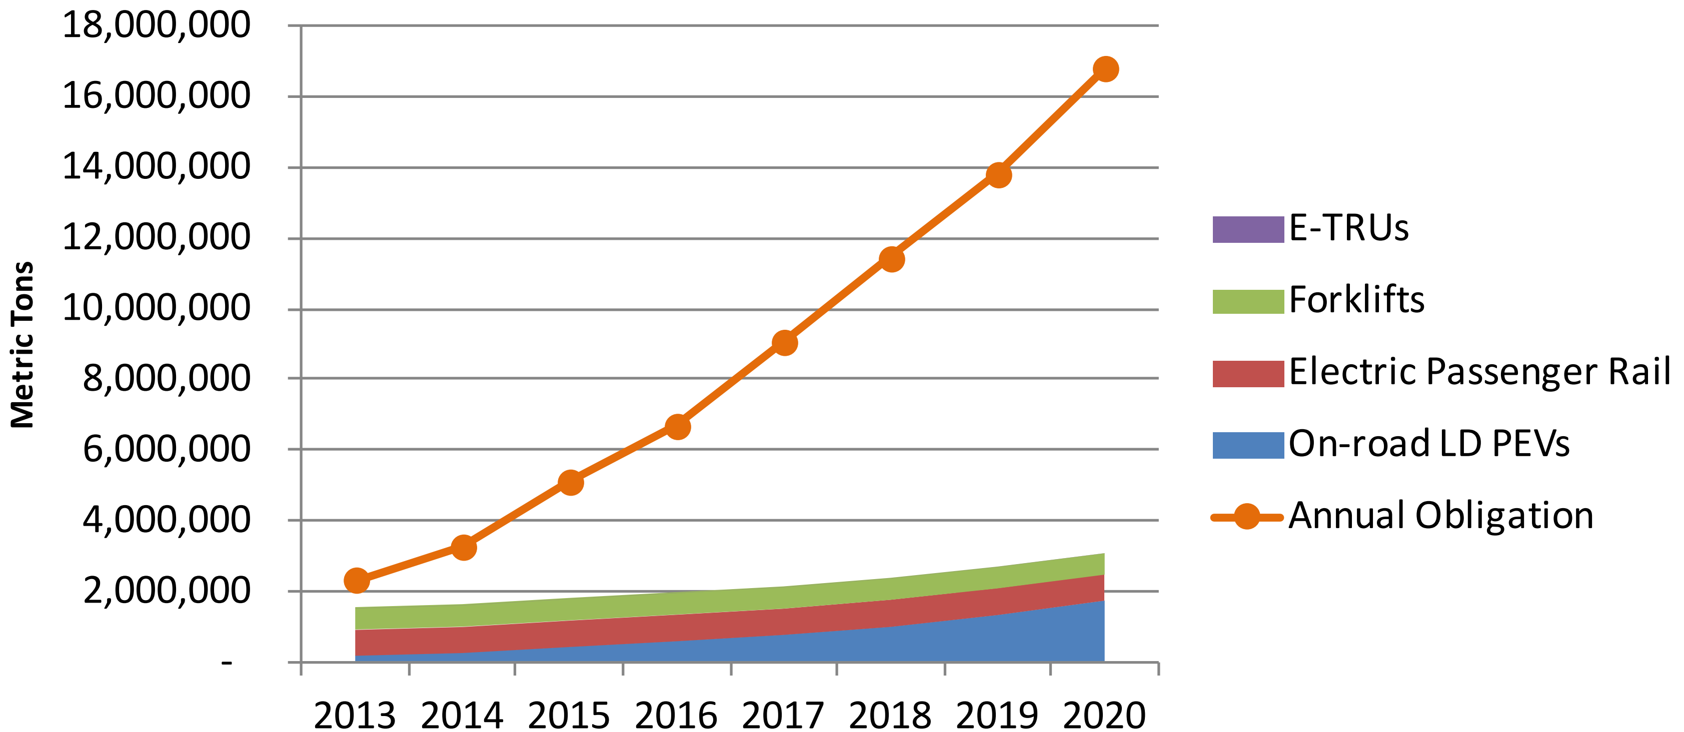
2013-2020 Potential Credits (40% PHEV Miles in Electric Mode)

- Annual obligation and on-road credits in the figure below based on ARB illustrative pathways and 40% PHEV miles in electric mode
- Electric passenger rail credits based on average of light-duty and transit bus offsets



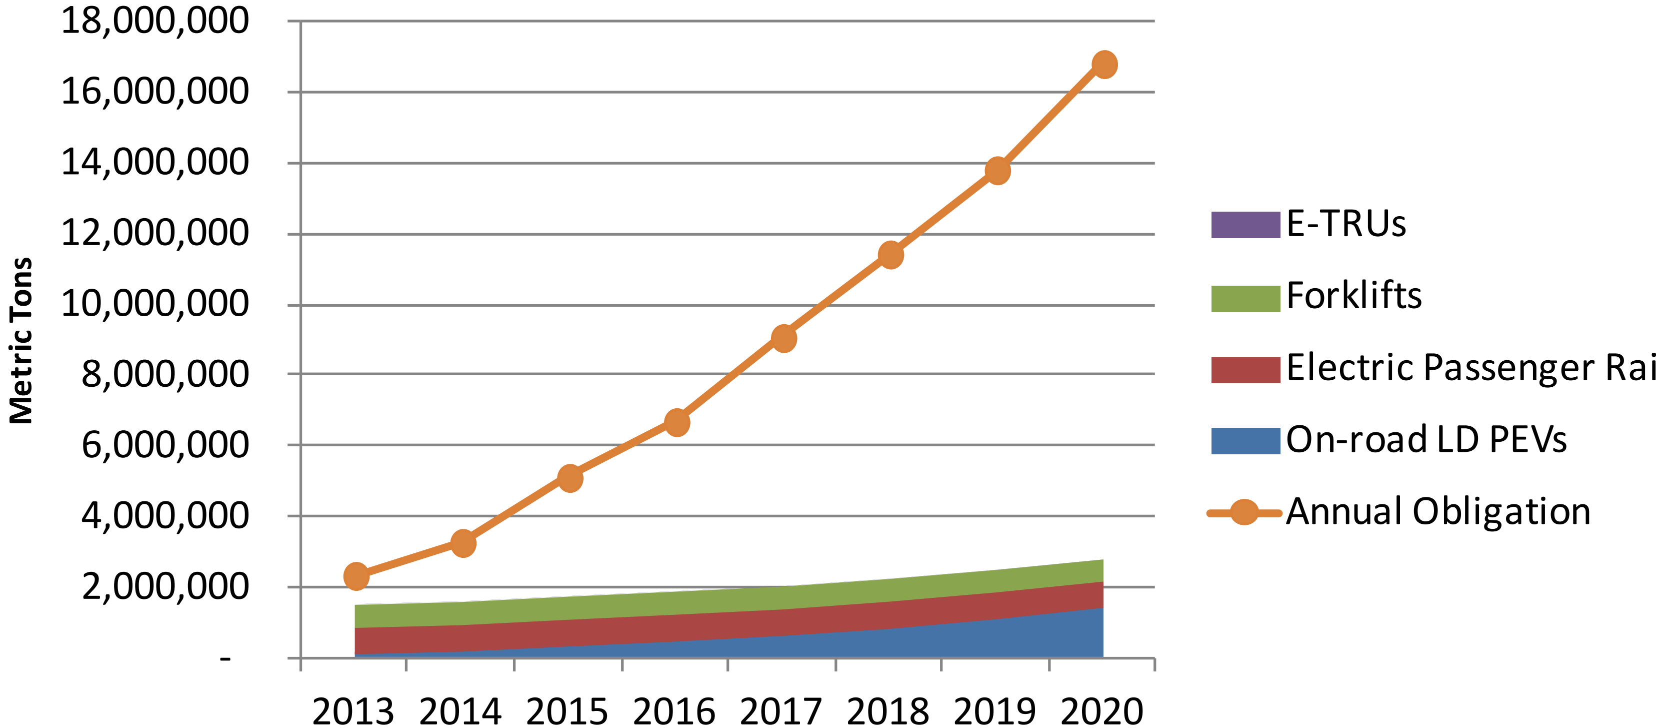
2013-2020 Potential Credits (40% PHEV Miles in Electric Mode)

- Annual obligation in the figure below based on ARB illustrative pathways
- On-road credits based on ZEV Action Plan Scenario and 40% PHEV miles in electric mode
- Electric passenger rail credits based on average of light-duty and transit bus offsets



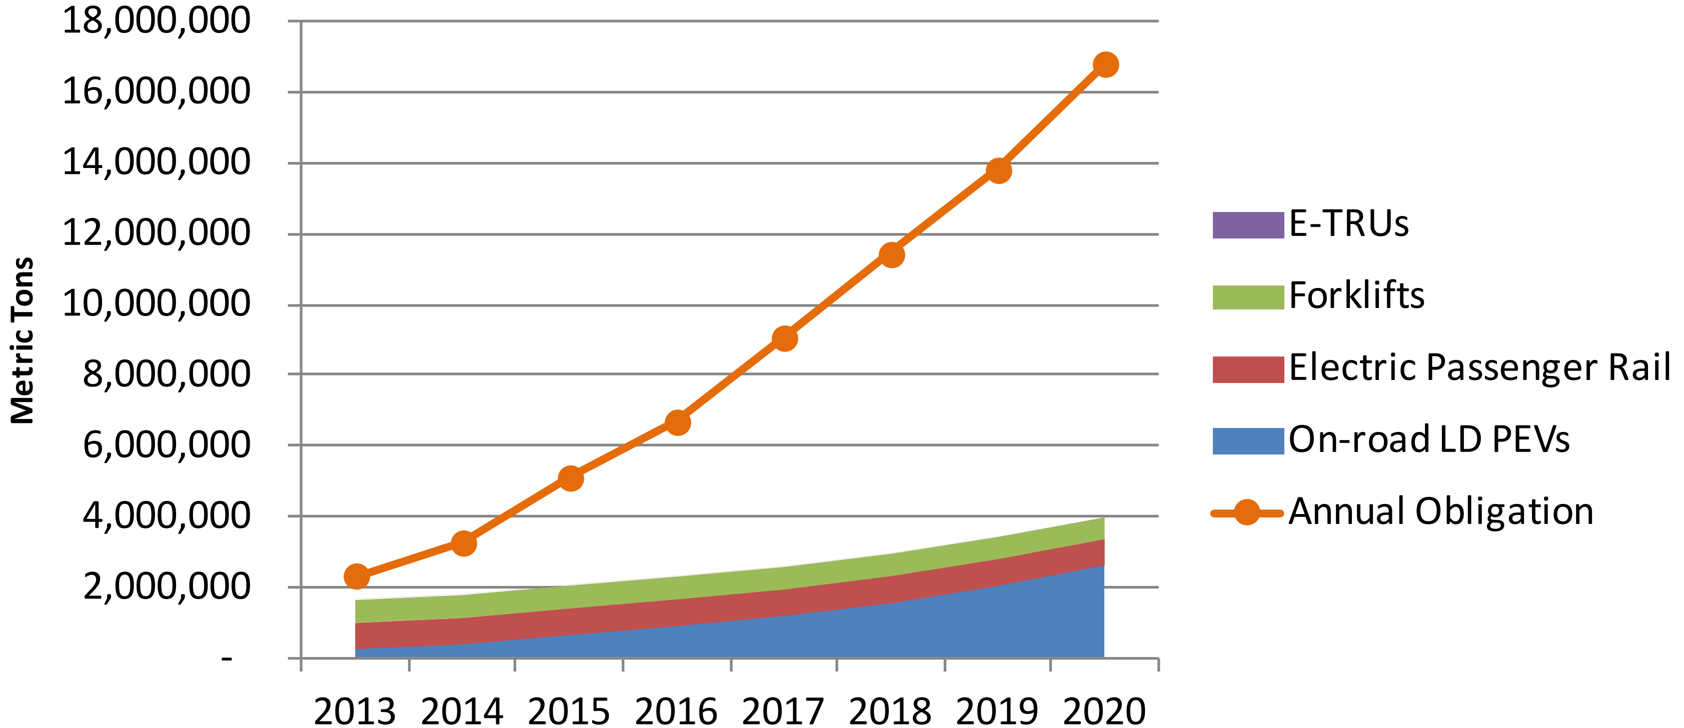
2013-2020 Potential Credits (75% PHEV Miles in Electric Mode)

- Annual obligation and on-road credits in the figure below based on ARB illustrative pathways and 75% PHEV miles in electric mode
- Electric passenger rail credits based on average of light-duty and transit bus offsets



2013-2020 Potential Credits (75% PHEV Miles in Electric Mode)

- Annual obligation in the figure below based on ARB illustrative pathways
- On-road credits based on ZEV Action Plan Scenario and 75% PHEV miles in electric mode
- Electric passenger rail credits based on average of light-duty and transit bus offsets



ICF INTERNATIONAL

Transportation Electrification Assessment

Prepared for:

California Electric Transportation Coalition

Energy+Environmental Economics

December 19, 2014

Overview

- Introductions – Organizations & Key Staff
- Introduction to the Transportation Electrification Assessment
- Cost and Benefits of Electrification Technologies
- PEV Forecasts for Grid Impacts Modeling
- Market Gaps and Barriers and Potential Solutions
- Grid Impacts Modeling

Introduction

Overview of Project

Project Objectives

ICF and E3 are providing analytical support to CalETC and its members to characterize the benefits of electrification technologies. Two key aspects of the study:

- **Utility Coordination**: This project includes active coordination and collaboration from utilities – PG&E, SCE, SDG&E, SMUD, City of Palo Alto, LADWP, and CMUA members. Engagement of so many utilities demonstrates the collective commitment of the industry to develop a coordinated plan related to electrification.

- **Changing landscape**: With the new OIR from the CPUC, there is a change in the landscape for electrification. Generally speaking, the current trajectory in California, as it pertains to electrification, will achieve one class of benefits. This study seeks to determine: What *could* the trajectory be and what benefits are we leaving on the table? And what is the course of intervention to change the current trajectory?

Work Flow (1 of 2)

Phase 1 of Transportation Electrification Assessment

- **Assess existing studies**: Literature review of transportation electrification opportunities. Dozens of reports reviewed. Focusing on 18 segments.
- **Market sizing**: Segment-by-segment forecasting for 2020 and 2030.
- **Cost and benefits of selected segments**: Reviewing the costs and benefits of selected TE segments. Considering incremental up-front costs, the incremental infrastructure costs, incremental benefits including lower operational costs for TE vehicles and equipment, and cost savings from lower electricity fuel costs.
- **Identify market gaps/barriers and potential solutions to address gaps/barriers:** Focusing on mitigation recommendations that could be implemented for whole or partial gaps and barriers. Identifying the party or parties that would be responsible for implementing the solution or corrective action necessary to address the gap or barrier. Keeping in mind that there may be some market gaps barriers for which there is no immediate mitigating solution.

Work Flow (2 of 2)

Phase 2 of Transportation Electrification Assessment

- **Grid impacts of light duty plug-in electric vehicles:** Considering a variety of impacts including generation, energy, transmission/distribution, ancillary services, losses, increased RPS procurement.

Potential Future Work (Phase 3)

- CalETC considering targeting future analysis of the grid impacts of off-road technologies with the largest potential impact (e.g., forklifts)

Costs and Benefits of Electrification Technologies

Electrification Technologies

Detailed Forecasting Update and Cost Analysis	Detailed Forecasting Update	Projection to 2030 from Previous Forecast
• *PEVs (PHEVs and BEVs)* • Forklifts • Truck Stop Electrification • Transportation Refrigeration Units	• Shore Power • Port Cargo Handling Equipment • Airport Ground Support Equipment • High Speed Rail • Light (including trolley buses) and Heavy Passenger Rail (BART, LA Metro, SDMTS) • Commuter Rail (Caltrain) • Dual Mode Catenary Trucks on I-710/SR60 • Medium- and Heavy-Duty Vehicles	• Lawn & Garden • Sweepers/Scrubbers • Burnishers • Tow Tractors/Industrial Tugs • Personnel/Burden Carriers • Turf Trucks • Golf carts

Detailed Forecasting

- **Detailed forecasting includes the following:**
  - Literature review to reassess the current market and future market conditions
  - Contacting industry and government experts (including ARB, CEC and EPA) to characterize the future market conditions and regulatory drivers
  - Forecasting future populations and GWh of electricity consumption for three cases:
    - "In Line with Current Adoption" is a low case based on anticipated market growth, expected incentive programs, and compliance with existing regulations; for build/no-build projects like HSR and I-710 catenary could be zero
    - "Aggressive Adoption" is a high case based on aggressive new incentive programs and/or regulations and make sure the high cases are tangibly aggressive and not simply hypothetical maximum
    - "In Between" is a medium case that will fall somewhere in the middle and will vary by technology
  - A working group consisting of utility representatives helped review the electrification forecasts prior to calculation of benefits and costs

Costs and Benefits of Electrification Technologies

- **Based on the projected GWh and populations for each technology and their comparison conventional fuel technologies, the following societal benefits were calculated for all technologies:**
  – GHG emission reductions
  – Criteria pollutant emission reductions
  – Petroleum displacement

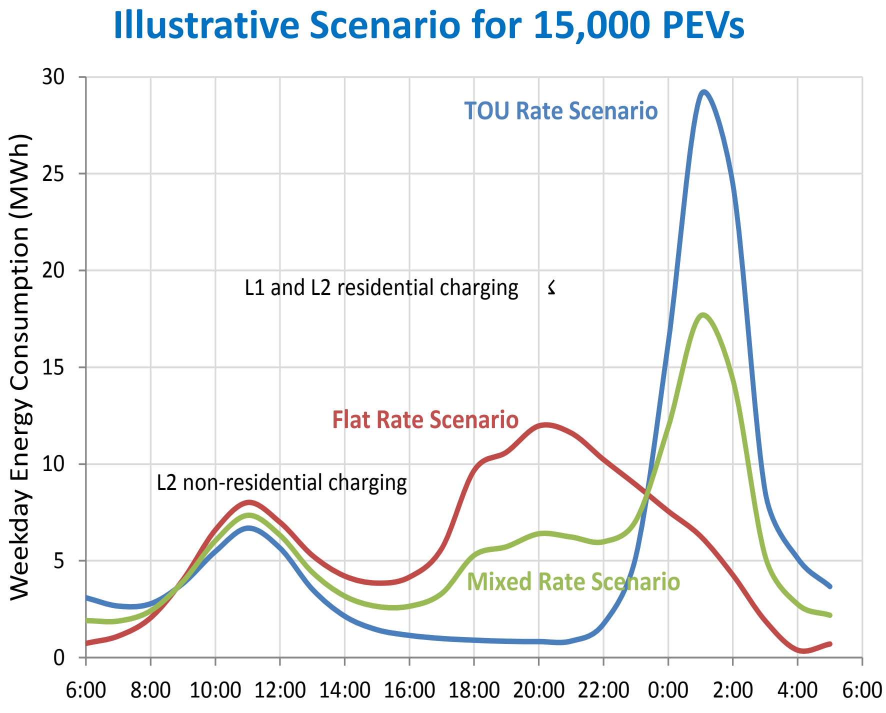
- **The lifecycle cost or savings of electric technologies were analyzed by including the following aspects of lifecycle cost:**
  – Equipment costs
  – Infrastructure costs
  – Operations and maintenance
  – Fuel costs
  – Equipment lifetime

Light-duty PEV Forecasts

Background and Assumptions for
a) Cost-Benefit Analysis and b) Grid Impacts Modeling

Developing scenarios

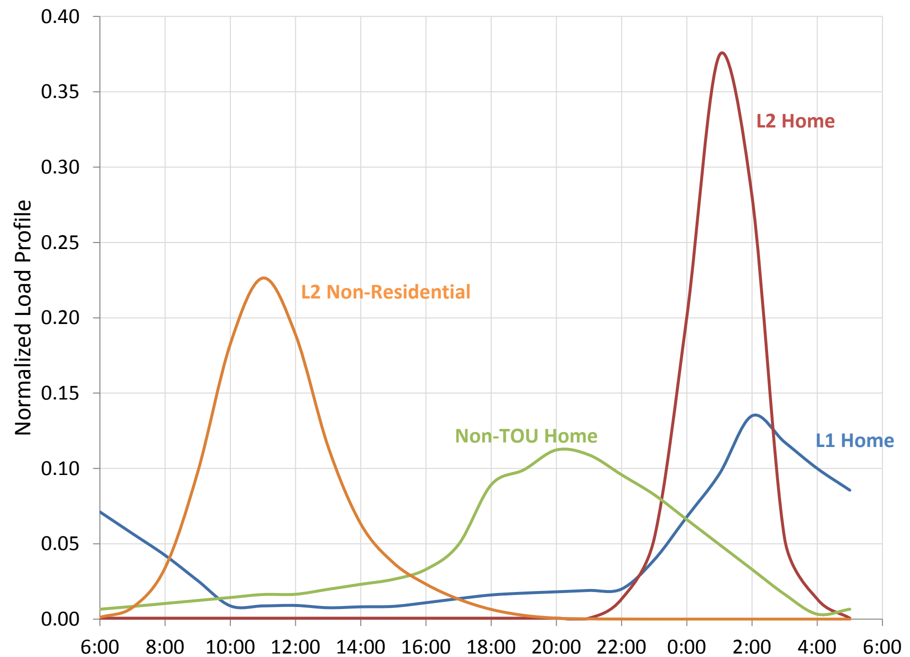
- **Multiple Scenarios**
  - TOU Rate Scenario
  - Domestic Rate Scenario
  - Mixed Rate Scenario
- **Each scenario is developed considering**
  - Load shapes
  - Level of charging: L2 and L1
  - Location: residential and non-residential
  - Vehicle Forecasts: Number and Type (PHEV vs BEV)
  - Energy Consumption



322

Load shapes

- **L2 residential charging, TOU rate:** Level 2 charging at home is a proxy for BEV or PHEV40 charging.
- **L1 residential charging, TOU rate:** Level 1 charging at home is a proxy for charging of PHEVs with smaller batteries, like the PHEV10 or PHEV20. The normalized profile is based on a similar start time as L2 charging; however, it is stretched out over a longer period.
- **Residential charging, Domestic rate:** Residential charging in the non-TOU case is a modified version of what is reported in the EV Project for Nashville, Tennessee – a region without a TOU rate. The modifications were made based on the at-home arrival times (at home) reported in the National Household Transportation Survey (NTHS).
- **L2 non-residential charging:** The non-residential charging is a proxy for workplace charging (weekdays) and public charging (weekends) and is used in the TOU scenario and the Flat Rate Scenario (described in more detail below) and scaled incrementally in a modification to each scenario.

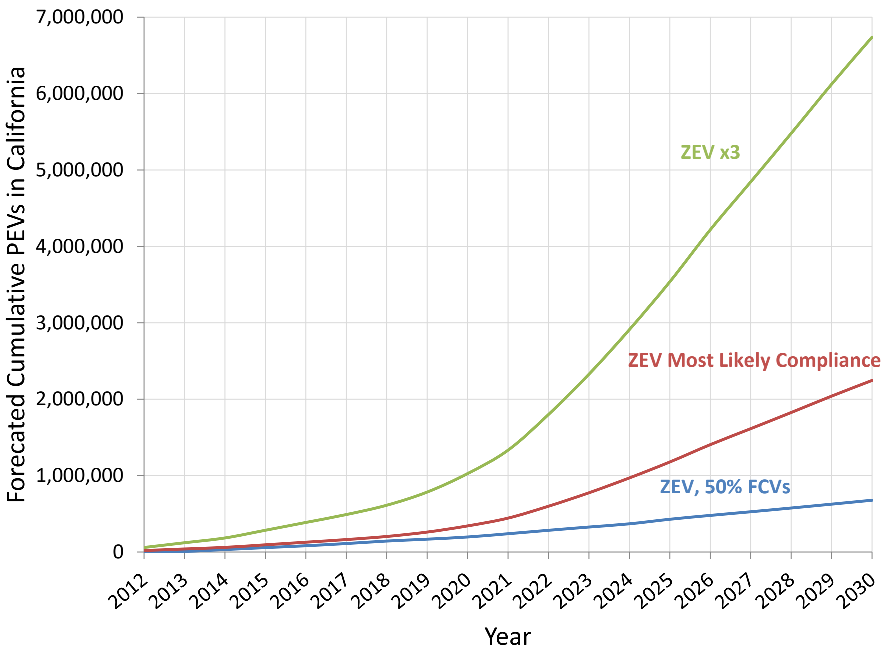


PEV Forecasts – Three Scenarios representing range of adoption

- **ZEV Program with 50% Compliance from FCVs:** Compliance with the Zero Emission Vehicle Program and modifying the most likely compliance scenario to achieve 50% compliance from FCVs.

- **ZEV Program "Most Likely Compliance Scenario" from CARB:** In the development of the Zero Emission Vehicle Program, CARB staff developed a most likely compliance scenario. There were some modifications to this scenario to reflect recent PEV sales data.

- **ZEV Program Scenario x 3:** This scenario is a factor of three larger than the ZEV program's most likely compliance scenario.



Energy Consumption

Vehicle Type	VMT		eVMT		Energy Consumption (kWh)					
					Daily			Annual		
	Daily	Annual	Daily	Annual	Res	NonRes	Total	Res	NonRes	Total
PHEV10	41.0	14,965	10.0	3,650	2.8	0.7	3.5	1,022	256	1,278
PHEV20			20.0	7,300	5.6	1.4	7.0	2,044	511	2,555
PHEV40			30.6	11,169	8.6	2.1	10.7	3,127	782	3,909
BEV	29.5	10,768	29.5	10,768	8.3	2.1	10.3	3,016	754	3,770

Developed modification for each scenario whereby the eVMT for each PEV-type is increase by one mile per day per year, not to exceed 39 daily VMT. Additional charging is assumed to happen on commercial circuits.

Overview of Results

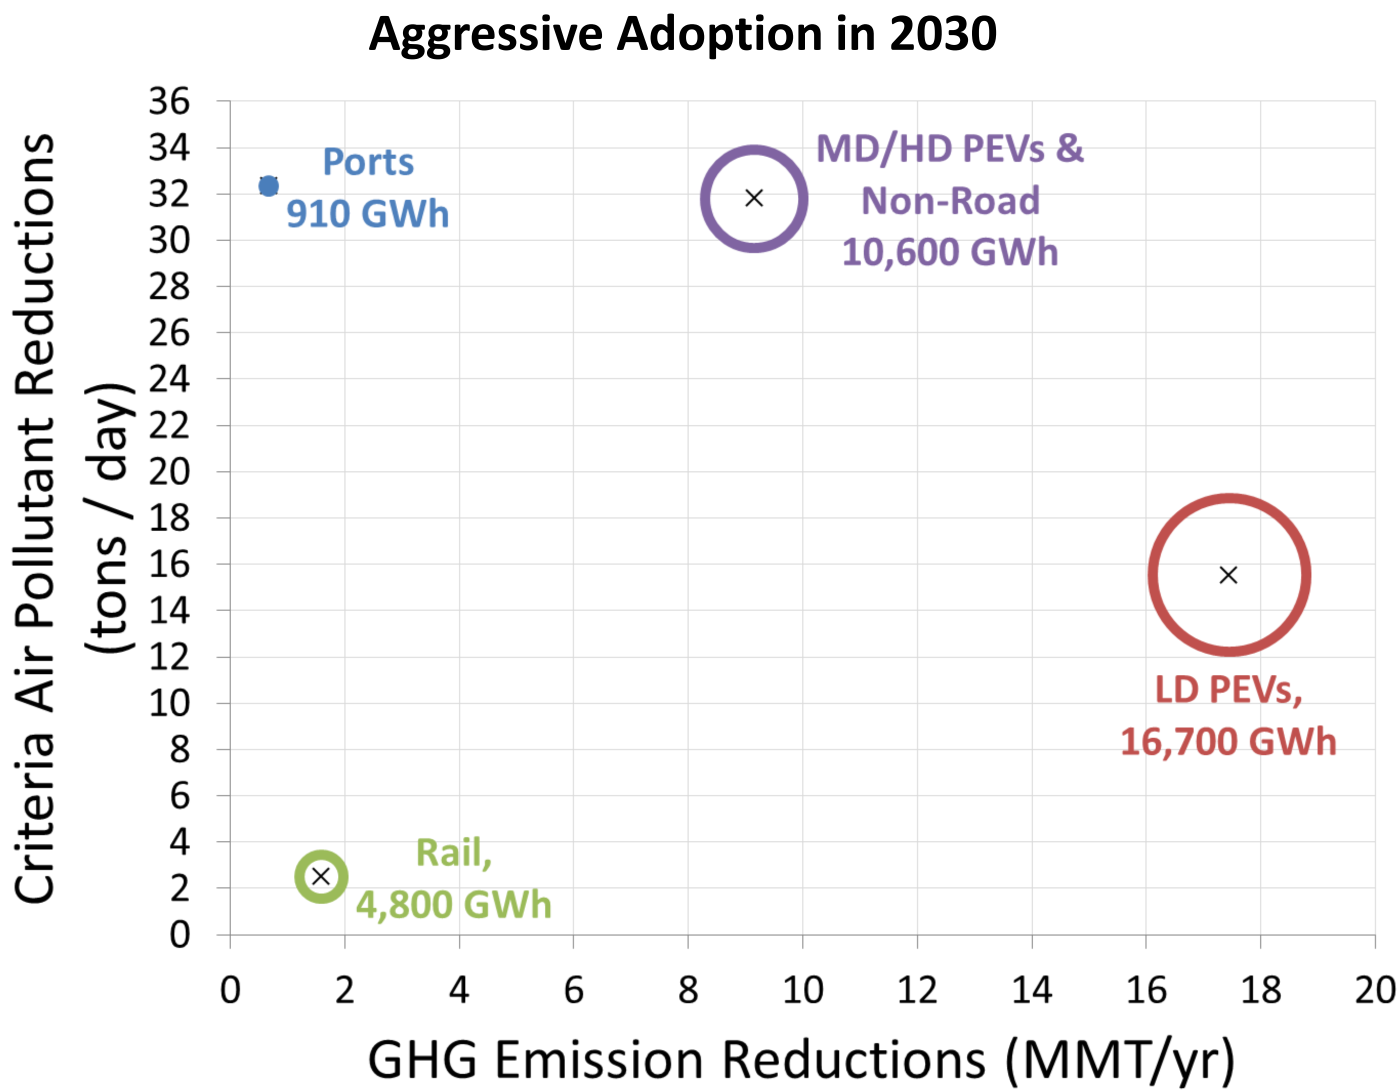
329

Comparison of Transportation Electrification Segments in 2030



330

Market Gaps and Barriers and Potential Solutions

Potential Solutions to Maximize PEV Adoption

Main Areas of Focus (1 of 2)

Market Gaps and Barriers		Potential Solutions
Consumer Costs	• Upfront vehicle costs • Upfront charging infrastructure (EVSE) costs • Vehicle operating costs; need for competitive charging rates for PEVs and shift in traditional billing paradigm	• Increased publicity and continued availability of existing incentives • Creative use of utility LCFS credits or utility developed programs (e.g. battery second life) to reduce the upfront vehicle or EVSE costs • Improved PEV charging rate structures to increase the reduced fuel cost benefits for drivers
Charging Infrastructure	• Lack of information available to single family homeowners seeking to decide between Level 1 and Level 2 charging installation • Little to no progress made in deploying charging at multi-dwelling units; MDU installations are particularly challenging due to technical and logistical issues • Lack of investment in workplace charging infrastructure to date	• Engage MDUs/HOAs, employers and workplace parking providers as a trusted advisor regarding optimal and cost-effective EVSE solutions

Main Areas of Focus (2 of 2)

Market Gaps and Barriers		Potential Solutions
Sustainability of Third-Party Ownership of EVSE Networks	• Sustainability of revenue model is frequently challenged and has not been convincingly demonstrated • Demand for non-home charging is unclear due to several factors: vehicle purchasing behavior, consumer willingness to pay for charging, and charging needs/behaviors	• Alternatives to additional public investment in charging infrastructure • Revisiting the CPUC ruling regarding utility investment in charging infrastructure • Improved evaluation of charging infrastructure deployment
Consumer Education and Outreach	• General lack of PEV awareness and knowledge • Total cost of vehicle ownership is poorly understood • Disparate efforts to improve PEV education	• The utility acting as a trusted advisor in the PEV market • Engage with PEV ecosystem partners
Vehicle Features	• Limited vehicle offerings in marketplace	• Modifications to the ZEV program to incentivize the development of PEVs outside of traditional market segments (e.g. subcompacts or midsize sedans)

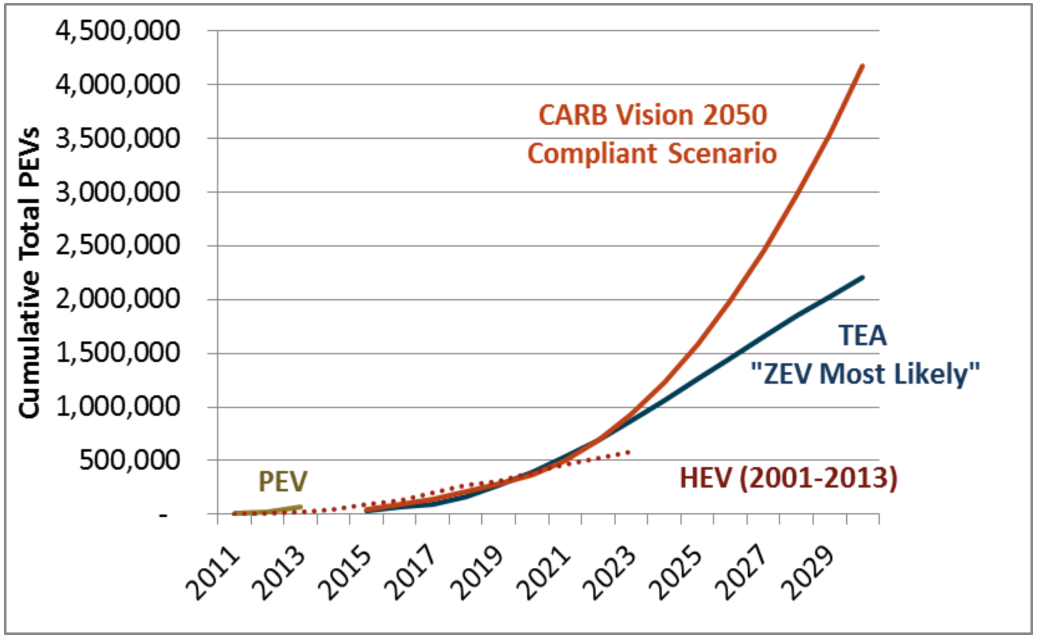
Appendix | Phase 2: Grid Impacts Modeling

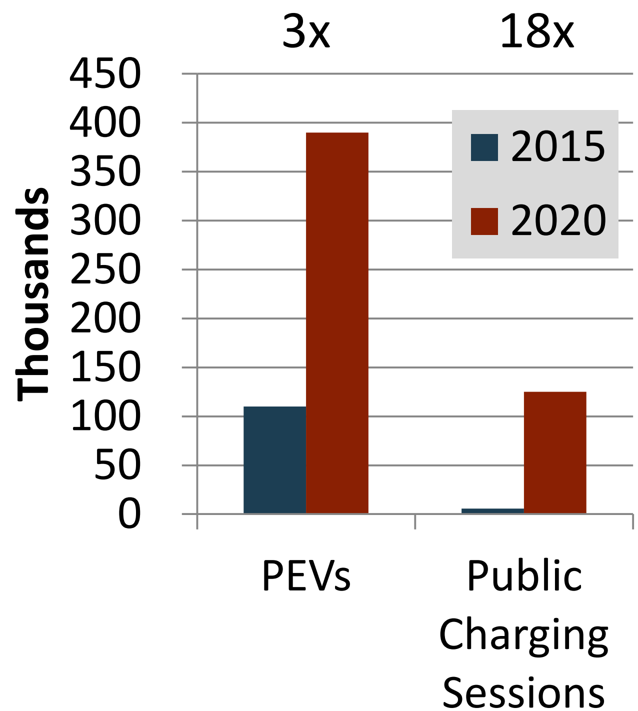
Distributed Energy Resource Modeling

Energy+Environmental Economics

334

Infrastructure Investment Required





- **~90% of car buyers are not familiar with electric vehicles (nationally)**
- **Will saturate early adopter market segment soon**
- **Need to reach beyond single-family home owners**

335

Utility Role in Transportation Electrification

- **Customer, EVSE and utility investment in infrastructure is needed to provide readily accessible charging for higher penetrations of PEVs**

Hearing Room	Board Room
✓ PEVs provide environmental and societal benefits	✓ PEVs increase revenues with "good" load
✓ PEVs will reduce rates for all customers	✓ PEV load creates headroom for capital investment without rate increases
✓ PEVs pass cost-effectiveness tests	✓ PEVs can increase shareholder earnings
✓ Utility investment accelerates PEV adoption	✓ Utility investment provides positive customer engagement

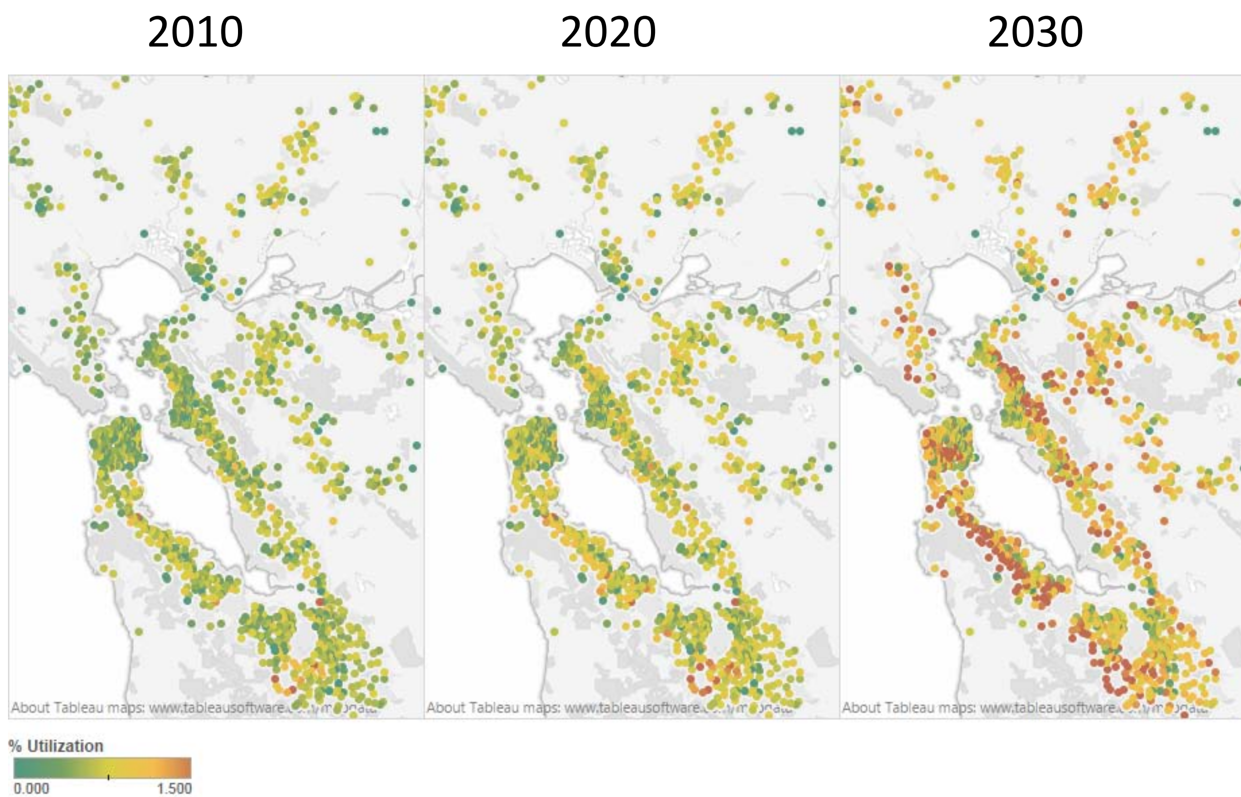
Utility Role in Transforming Transportation

- **Utility planning (Yesterday)**
  - **meet forecasted load with lowest utility costs and emissions**
  - Pass "standard" cost-effectiveness tests

- **Electrifying transportation (Tomorrow)**
  - **meet GHG and criteria pollutant targets at lowest regional cost**
  - Requires rapid adoption of new technologies with cross-sector coordination
  - Requires expanded cost-effectiveness framework with new metrics

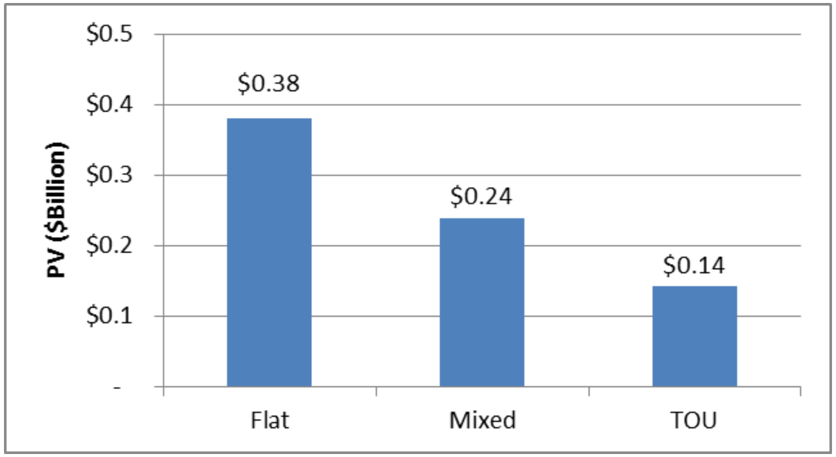
Grid Impact Overview

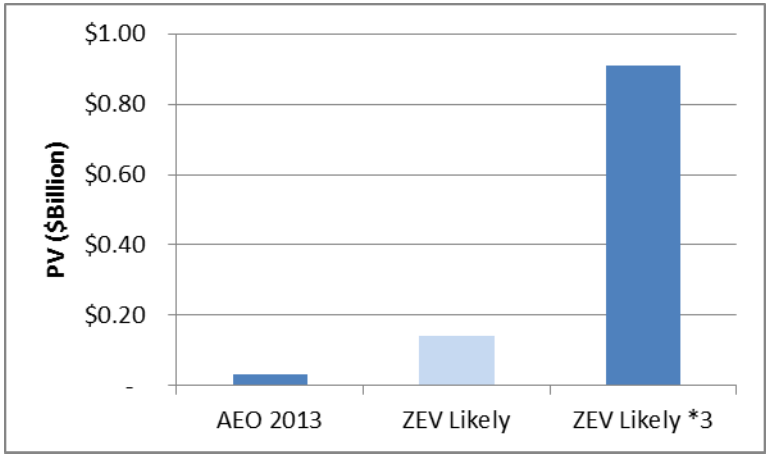
- **Emphasis on quantifying distribution impacts**
- **Map PEV Clusters and load shapes to individual feeders and substations**
- **Utilities provided**
  - equipment rating
  - peak day load shape
  - forecasted load growth
- **Calculate upgrades required at each location**
- **Found minimal upgrade costs even at higher penetration scenarios**



338

Distribution Upgrade Costs





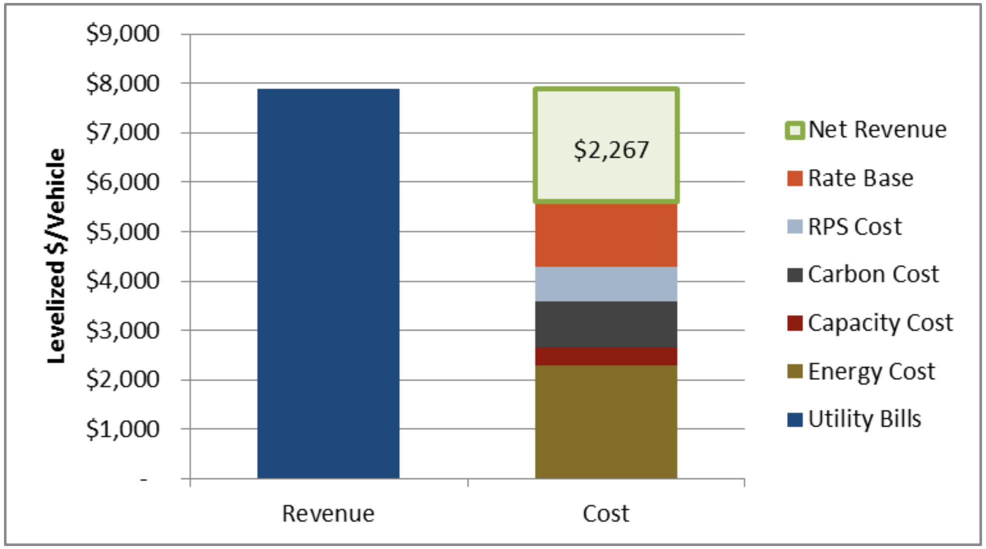
- **Managed charging reduces distribution upgrade costs by 60%**
- **Distribution costs are manageable under current trajectory**

- **Bigger cost challenge: "make-ready" and circuit upgrades for higher concentrations of multi-family, workplace and fast DC charging**

Standard Cost-tests (for EE, DR, DG)

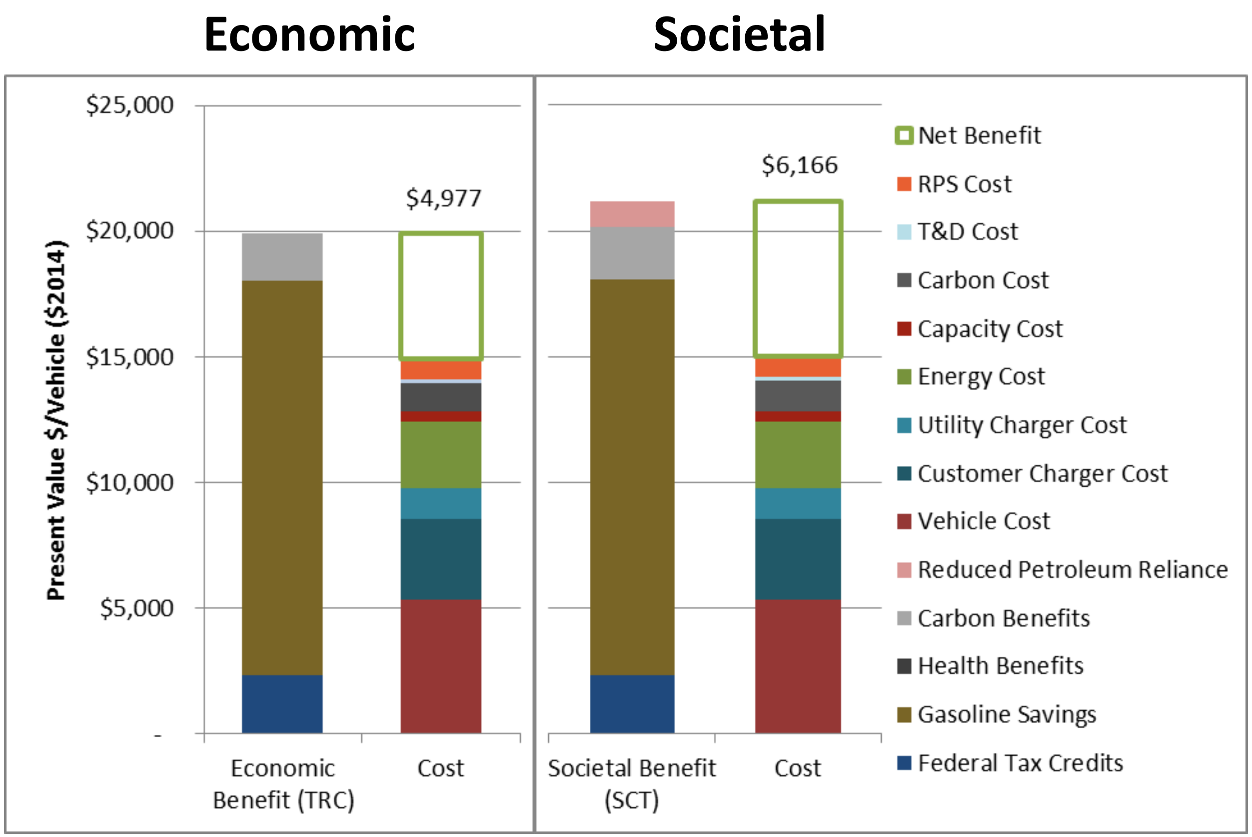
Cost Test		Key Question Answered	Summary Approach
Ratepayer Impact Measure	RIM	**Will utility rates for non PEV owners increase?**	**Comparison of utility infrastructure and supply costs to retail bill revenues**
Total Resource Cost	TRC	**Are there net economic benefits to the region as a whole?**	**Comparison of vehicle, infrastructure and energy costs to reduced gasoline (and GHG) costs and federal tax credit**

PEV Load Benefits to Utility Ratepayers



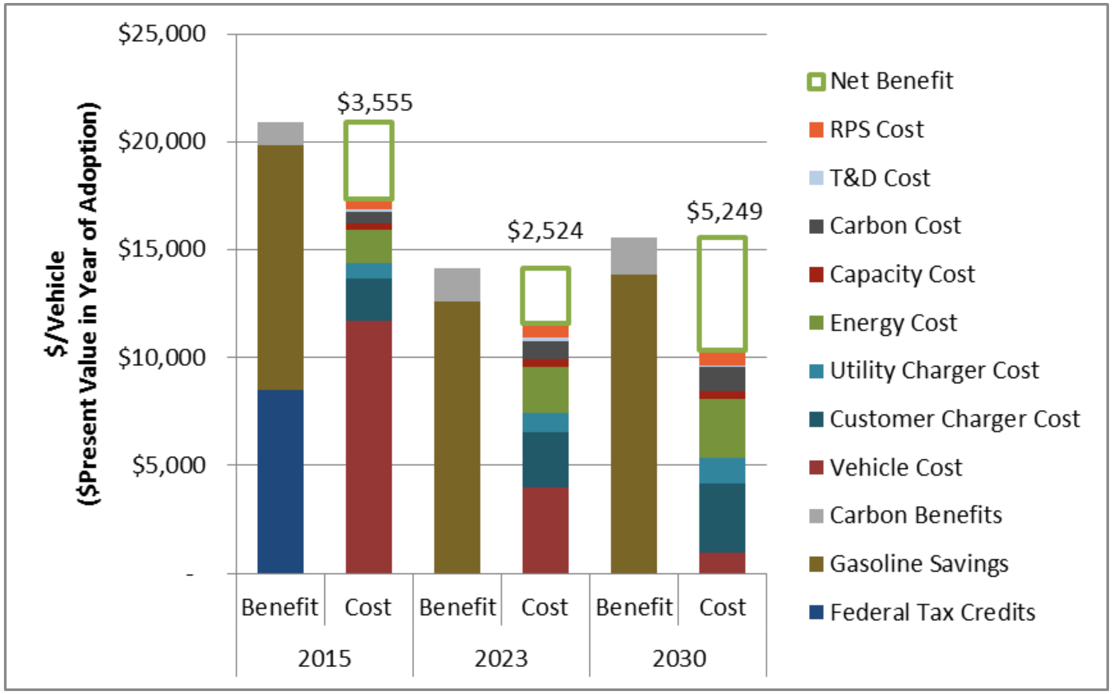
- **Utility rates represent average fixed and variable costs and are higher than the marginal cost of delivered energy in most hours**
- **Typically distributed energy resource programs (EE, DR, DG) reduce customer bills and utility revenues, but increase rates**
- **PEVs are unique in providing environmental benefits while reducing rates**
- **Northwest: true for the region as a whole, but will differ by utility based on BPA Tiered Rate allocation**

TRC and "740.8" SCT Results



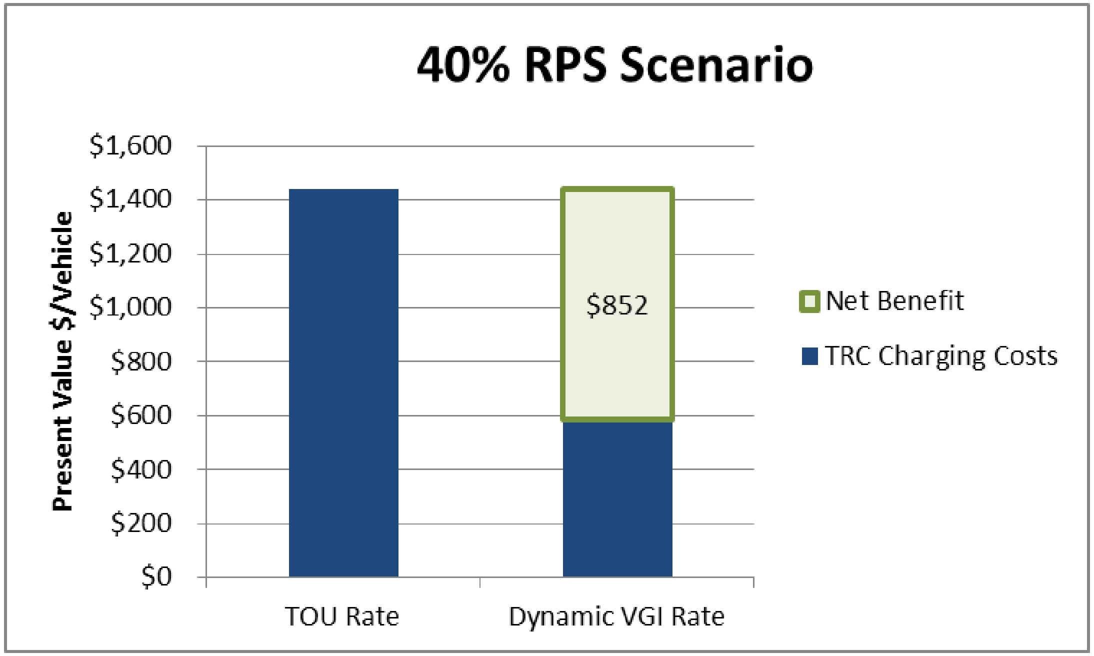
- **"740.8" SCT represents a combination of CARB and CPUC cost-effectiveness methods**
- **Present value net benefits for TRC and "740.8" SCT of $4.7 Billion and $5.8 Billion with ZEV Most Likely vehicle adoption**

How TRC Changes Over Time



- **TRC is positive in 2015 due to federal tax credit**
- **TRC net benefit is lower in 2023 after tax credits presumed to expire**
- **TRC is higher in 2030 with declining incremental PEV costs and higher gasoline prices**

Dynamic Vehicle Grid Integration (VGI) Charging



- **Dynamic VGI charging provides additional benefits, reducing charging costs**
- **TOU Rates discourage charging on-peak**
- **VGI rates encouraging day-time charging during periods of excess renewable generation in Spring and Fall.**

California Utility PEV Applications

SDG&E Vehicle Grid Integration (VGI)	SCE – Charge Ready
$103 Million over 10 years	$355 Million over 5 years
Install up to 5,500 charging stations	Supporting infrastructure for up to 30,000 charging stations
Focus on workplace and multifamily	Focus on expanding availability of long dwell-time infrastructure especially at work places and multifamily dwellings
Day-ahead dynamic hourly VGI rate provides economic incentives to charge when most beneficial for the grid	EV specific TOU rates
Focus on vertically integrated billing and charging solution for customer	Focus on service upgrades needed to install and operate charging infrastructure
Competitively bid, but charging equipment is SDG&E owned.	Host can choose to own and operate charging station

Expanded Cost-tests

- Societal Cost Test (SCT)
  - TRC test plus environmental and societal benefits
  - Benefits include
    - Health and environmental impacts
    - Reduced reliance on petroleum
    - “Social” cost of carbon
  - Included in California Public Utility Code 740.3 and 740.8
  - Combination of public utility and air resources board cost-benefit evaluation

- Cost of meeting GHG and criteria pollutant emission targets
  - Compare costs of alternative strategies (renewables, efficiency, transportation) to reduce emissions

Conclusions

- Distribution system upgrade costs related specifically to PEV charging are manageable in near-term, even under the most aggressive PEV adoption scenario
- **“Make ready” costs for multi-family, public and workplace charging** are larger than distribution upgrade costs and may pose a more significant barrier to PEV adoption
- **Utility investment in enabling technology and infrastructure is needed to accelerate PEV adoption and market transformation**.
- **Such investment may not pass current cost-effectiveness tests in the short-term, but still provide net ratepayer and societal benefits in the long-term**
- Over time, with reduced incremental vehicle costs and increasing gasoline prices, PEVs provide net TRC benefits even without the federal tax credit
- “740.8” SCT as presented here produces net benefits that are 22% higher than the SPM TRC test using health and reduced reliance on imported petroleum benefits

Conclusions

- Current CARB and CPUC cost-effectiveness tests evaluate resource measures largely against "traditional" investments. More comprehensive methods are need to evaluate alternative strategies towards meeting California's ambitious GHG reduction goals
- Over the long-term, PEV rates can be designed to provide sufficient net revenues to more than cover short-term and long-term marginal costs, providing additional fixed cost recovery and lowering average rates for non-PEV owners in the rate class
- The increased benefits provided by TOU rates and VGI charging show that **utility or government programs funding PEV charging infrastructure should also include strong incentives for PEV owners and electric vehicle service entities to engage in managed charging that is responsive to grid needs**

ZEV	Zero Emission Vehicle

Executive Summary

Adopted in 2007, California's Low Carbon Fuel Standard requires a 10 percent reduction in the carbon intensity of transportation fuels by 2020, as measured on a lifecycle basis. The goals of the program are to reduce greenhouse gas emissions from the transportation sector, diversify the transportation fuels sector, and to spur investment and innovation in lower carbon fuels.

The LCFS is designed as a performance-based standard using flexible market-based mechanisms that allow regulated parties to select the most cost-effective pathways to achieve compliance. Fuels that have a lower carbon intensity than gasoline or diesel generate LCFS credits. Regulated parties, such as refiners, have the option of producing or blending low carbon fuels, or purchasing credits from other fuel providers, including, but not limited to biofuel producers, natural gas infrastructure providers, electric utilities, and hydrogen producers.

This report represents the first phase of a two-phase, year-long project assessing the economic and environmental impacts of compliance with California's LCFS out to 2020. This phase focuses on the development of compliance scenarios based on market research, consultation with stakeholders, and market forecasts based on best estimates of fuel availability. These compliance scenarios are used to convey the outcomes of our research and analysis: namely, that the LCFS requirements can be achieved through modest changes in the diversity of transportation fuels supplied to California. The second phase of the work will focus on the economic and environmental impacts of these compliance scenarios, including parameters such as gross domestic product, jobs, and avoided damage costs.

ICF developed two scenarios – Scenario 1 and Scenario 2 – to capture the potential market responses to achieve compliance with the LCFS. ICF emphasized probabilistic outcomes for each alternative fuel type based on market constraints and opportunities: where appropriate, ICF defaulted to more conservative estimates of fuel and vehicle penetrations. A stakeholder panel developed a third compliance scenario referred to as the LCFS Enhanced Scenario, which ICF will also be modeling as part of the second phase of our work. The key highlights of the LCFS compliance scenarios include:

- **Compliance with the LCFS can be achieved through modest changes and a diverse supply of transportation fuels.** Broadly speaking, compliance is achieved through biofuel blending (with both gasoline and diesel) and through the deployment of advanced vehicle technologies that use natural gas, electricity, and hydrogen. In both scenarios, the majority of LCFS compliance is achieved through blending biofuels. However, compliance in Scenario 1 depends on more aggressive forecasts for advanced vehicle technologies than Scenario 2, thereby putting less pressure on the demand for biofuels. Regardless, both scenarios were developed to reflect the market-based flexibility of the regulation and recent market developments.
- **The alternative fuels market is evolving rapidly and in unforeseen ways, and the LCFS is driving investment in low carbon ethanol, biodiesel, renewable diesel, and biogas.** ICF has accounted for a variety of market developments in the compliance scenarios. For instance, the immediate availability of lower carbon biofuels such as biodiesel from corn oil, waste greases, and animal fats; renewable diesel from tallow; and ethanol from molasses. Although cellulosic biofuels have been produced at a slower-than-expected rate, these lower

carbon biofuels are available to California in significant quantities today and supply is forecasted to increase dramatically over the next several years. Each of these fuels has a carbon intensity less than 35 gCO_2e/MJ, representing a more than 60 percent reduction in carbon intensity compared to the LCFS compliance schedule. Apart from biofuels, increasing natural gas supplies and lower fuel pricing than diesel have renewed interest in natural gas in the transportation sector. Meanwhile, although plug-in electric vehicles are being purchased by California drivers at modest rates – in some areas, demand has been high enough to cause vehicle supply shortages – electricity consumption is unexpectedly making contributions towards LCFS compliance in these early years of the program.

- **Over-compliance in early years of the regulation (through 2016, at least) is critical, and a significant number of excess credits have already been generated.** As noted previously, LCFS credits can be banked and traded, and do not lose value. In fact, despite the uncertainty regarding the LCFS (e.g., legal challenges) and a fragile economic recovery, the LCFS market generated nearly 1.3 million excess credits by the end of 2012. Because of the way the LCFS compliance schedule is designed, over-compliance in early years is critical towards meeting compliance in later years (e.g., 2019 and 2020). In Scenario 1 and Scenario 2, for instance, credits are banked through 2017 and 2016, respectively. In subsequent years, the banked credits are drawn down to achieve compliance.
- **The diesel sector will likely generate more than its fair share of credits.** ICF developed scenarios that reflect the flexibility of the LCFS guidelines: namely, credits are fungible. It does not matter if credits are generated using fuels that substitute for gasoline or fuels that substitute for diesel. Forecasted diesel consumption in California indicates that diesel will generate about 20 percent of deficits in the LCFS program. However, fuels that substitute for diesel, including biodiesel, renewable diesel, and natural gas, have the potential to generate 40-55 percent of LCFS credits.
- **Biodiesel can make a significant contribution towards LCFS compliance.** Although biodiesel consumption in California has been modest in recent years, there is significant potential to blend biodiesel at lower levels (e.g., 5 percent to 20 percent by volume) with conventional diesel and generate a substantial number of LCFS credits. Infrastructure providers are already responding to this potential, and based on ICF research and stakeholder consultation, the industry is rapidly increasing the ability to store and blend biodiesel at petroleum terminals and at refineries.
- **Renewable diesel will make a modest contribution towards LCFS compliance, even at low volumes.** With no additional distribution infrastructure or refueling infrastructure costs, and no limitations on consumption in vehicles, renewable diesel is an attractive option for LCFS compliance. Furthermore, it is available in significant quantities today. Even at conservative forecasts of 150 million gallons renewable diesel delivered to California by 2020, renewable diesel could generate about 8 percent of the LCFS credits required to achieve compliance.
- **Natural gas consumption will increase rapidly in California and play a significant role in LCFS compliance.** When the LCFS was first developed in 2008, natural gas was expected to play a niche role in compliance. However, the increase in domestic natural gas supply has helped maintain a persistent price differential between natural gas and diesel. Combined with increased engine offerings in medium- and heavy-duty applications, particularly in the goods movement sector, natural gas consumption in the transportation sector is poised to increase significantly and rapidly. The expansion of natural gas consumption in the transportation sector will also facilitate a transition to biogas from landfills, for instance. With a carbon intensity less than 30 gCO_2e/MJ, even modest

penetrations of biogas (e.g., 10 percent of California’s natural gas consumption) are feasible.

- **Small modifications to the LCFS can have a substantive impact on compliance.** ICF also included estimated credits that can be generated through potential modifications to the LCFS, namely electricity used in fixed guideway applications (e.g., light rail in transit) or forklifts. Even though these credits are modest, they decrease the necessity of blending potentially more costly low carbon biofuels or accelerating the adoption of advanced vehicle technologies.

1. Introduction

1.1. California's Low Carbon Fuel Standard

In 2007 Governor Schwarzenegger signed Executive Order S-01-07 establishing California's Low Carbon Fuel Standard (LCFS), which requires a ten percent reduction in the carbon intensity of transportation fuels by 2020. Carbon intensity is measured in grams of carbon dioxide equivalents (gCO_2e) per unit energy (MJ) of fuel and is quantified on a lifecycle or well-to-wheels basis. In 2009, the California Air Resources Board (CARB) adopted the LCFS regulations. The program has been implemented and enforced since the beginning of 2011.

The LCFS is a flexible market-based standard implemented using a system of credits and deficits: transportation fuels that have a higher carbon intensity than the compliance schedule yield deficits, and fuels that have a lower carbon intensity generate credits. Regulated parties are required to have a net zero balance of credits and deficits annually. Credits can be banked and traded without limitations, and credits do not lose value. Transportation fuels that have a lower carbon intensity than the compliance schedule include ethanol, biodiesel, natural gas, electricity, and hydrogen. CARB quantifies and publishes carbon intensity values for all fuel pathways.

The entities that generate credits and deficits are referred to as regulated parties, an d the entity varies depending on the fuel. For instance, refiners are typically the regulated party for gasoline and diesel. Alternative fuel providers are referred to as opt-in regulated parties. The obligated parties vary considerably, including entities such as fuel producers and fueling station owners.

> **The Nuts and Bolts of LCFS**
>
> **Carbon intensity** is measured on a lifecycle or well-to-wheels basis in units of grams of carbon dioxide equivalent per unit energy of fuel (gCO2e/MJ).
>
> The LCFS is implemented using a system of **credits and deficits**, with each credit representing one metric ton of reduction. Credits are generated by transportation fuels that have a carbon intensity lower than the compliance schedule (ranging from about 98 gCO2e/MJ in 2013 to 89 gCO2e/MJ in 2020) and deficits are generated by gasoline and diesel.
>
> At the end of each year, compliance is achieved by offsetting deficits with credits. Credits can be banked and traded, and they do not lose value over time.

1.2. Scope of Work

ICF was retained by the California Electric Transportation Coalition (CalETC), the California Natural Gas Vehicle Coalition, the National Biodiesel Board (NBB), the Advanced Biofuels Association (ABFA), Environmental Entrepreneurs (E2), and Ceres to assess the macroeconomic impacts of the LCFS, using parameters such as gross domestic product and changes in jobs. The project has two phases:

- In the first phase of work, ICF developed scenarios that represent a range of likely outcomes towards LCFS compliance. These scenarios are intended to capture the range of potential market developments that would lead to LCFS compliance given our current outlook on the transportation fuel marketplace. In any forward-looking exercise, it is important to note that there is some uncertainty associated with the availability of lower carbon transportation fuels.

- In the second phase of work, ICF is using the REMI model to analyze the associated macroeconomic impacts of the LCFS compliance scenarios developed in Phase 1. Furthermore, ICF is quantifying and monetizing the GHG emission reductions, criteria pollutant emission reductions, and petroleum reductions associated with each compliance scenario.

This report focuses on the first phase of our work and includes the following sections:

- **Section 2** outlines the methodology that ICF employed, with information regarding conventional fuel projections, how regulatory overlap was included, and compliance strategies considered.
- **Section 3** provides an overview of LCFS compliance scenarios
- **Section 4** provides a more detailed review of the research, analysis, and market developments that were used to develop the LCFS compliance scenarios.
- **Section 5** provides a brief overview of the project’s next steps, including a more detailed discussion of the macroeconomic modeling ICF is conducting using the REMI model.

2. Methodology: Scenario Development

ICF developed three (3) LCFS compliance scenarios in the first phase of our work to estimate the macroeconomic impacts of the LCFS: Compliance Scenario 1 and Compliance Scenario 2 were developed by ICF in collaboration with a Stakeholder Review Panel. The stakeholder group developed the final compliance scenario, referred to as the LCFS Enhanced Scenario. The following subsections review the methodological issues identified in the process of developing LCFS compliance scenarios.

2.1. Stakeholder Input

The table below highlights the organizations that provided input via the Stakeholder Review Panel, which includes representatives from the utilities, the natural gas industry, and biofuel producers.

Exhibit 1. LCFS Study Stakeholder Review Panel

Stakeholder Review Panel Member	Areas of Expertise
California Electric Transportation Coalition	• Electricity transmission and distribution • Electric vehicles and hydrogen fuel cell vehicles • Renewable energy
California Natural Gas Vehicle Coalition	• Natural gas delivery: compressed, liquefied, and biogas • Natural gas vehicles • Natural gas infrastructure
National Biodiesel Board	• Feedstocks • Biodiesel production • Biodiesel infrastructure
Advanced Biofuels Association	• Biofuel production • Investment in biofuels
Environmental Entrepreneurs	• Biofuel production • Investment in biofuels
Ceres	• Alternative fuel investments

2.2. Fuel Volumes, Forecasts, and LCFS Compliance

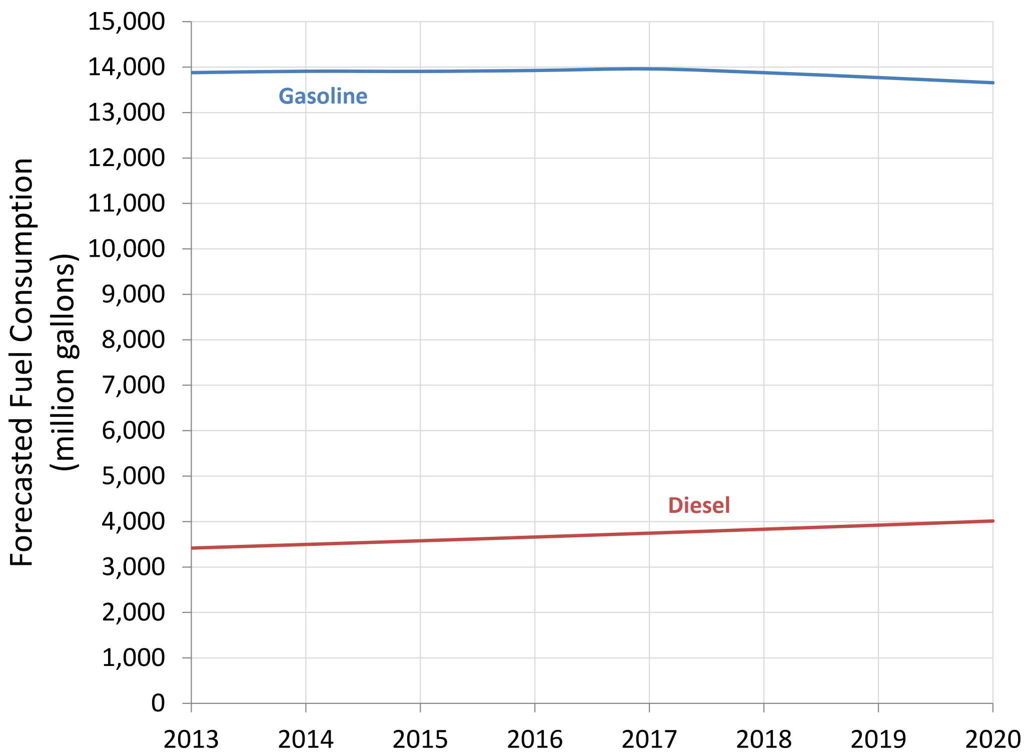
Conventional Fuel Volumes and Forecasts

ICF used a combination of transportation fuel demand forecasts reported by the California Energy Commission (CEC) from the most recent publicly available Integrated Energy Policy Report from 2011[1] and fuel volumes reported to date by regulated parties.[2] The gasoline and

[1] California Energy Commission (CEC). "Transportation Energy Forecasts and Analyses for the 2011 Integrated Energy Policy Report." CEC, August 2011: Available at: http://www.arb.ca.gov/msprog/clean_cars/clean_cars_ab1085/cec-600-2011-007-sd.pdf

diesel demand forecasted trends were applied to actual volumes reported through LCFS reporting from 2011 and 2012. These fuel forecasts account for the most recent fuel economy and GHG tailpipe emission standards for light-, medium-, and heavy-duty vehicles. Although it is likely that there will be additional regulations on medium- and heavy-duty regulations, we only incorporated regulations that have been promulgated into our forecasts.

Exhibit 2. Forecasted Gasoline (blue) and Diesel (red) Consumption in California



Other Regulations Considered in the Analysis

There are many regulations that impact the transportation sector in California. To the extent feasible, ICF accounted for regulatory drivers in the development of LCFS compliance scenarios. Regulatory overlap becomes a more significant issue in the second phase of the project because the attribution of costs associated with LCFS compliance impact the corresponding macroeconomic impacts. This issue is less of a concern in the consideration of LCFS compliance scenarios. Regardless, the following regulatory drivers were considered in the development of LCFS compliance scenarios.

Federal Renewable Fuel Standard (RFS2)

The United States Environmental Protection Agency (EPA) administers the federal Renewable Fuel Standard (RFS2). The RFS2 is a volumetric standard for blending biofuels into the

[2] Yeh, S; Whitcover, J; and Kessler, J. Status Review of California's Low Carbon Fuel Standard, Spring 2013. Available online at: http://tinyurl.com/LCFS-StatusReview2013

transportation fuel mix.[3] Although the RFS2 is a significant driver for biofuel blending nationwide, the regulation does not require a so-called fair-share for California. In other words, because California accounts for about 11 percent of domestic transportation fuel consumption, it would therefore be responsible for the equivalent fair-share of RFS2 obligations. However, regulated parties (e.g., refiners) can in theory comply with the RFS2 without blending biofuels in California. Although regulated parties do comply with the standard by blending biofuels in California, we make the assumption that the RFS2 does not act as a major regulatory driver in California – it plays a role in that it is a complementary regulatory driver for advanced biofuel production. Regulated parties under the LCFS that blend low carbon biofuels will earn credit towards RFS2, however, ICF's analysis assumes that the driver for California consumption is largely the LCFS and not RFS2.

Light Duty Fuel Economy Standards and Tailpipe GHG Standards

Although LCFS focuses on the carbon intensity of transportation fuels, there are other regulatory mechanisms in place in the transportation sector. These other regulations ensure that vehicles are becoming more fuel efficient and that GHG emissions from vehicles are lower. In 2002, California passed AB 1493 (Pavley) which limits light duty vehicle tailpipe GHG emissions. In 2009, the EPA granted California's waiver request, allowing it to regulate vehicle GHG emissions; CARB subsequently adopted amendments to the Pavley standards to reduce light duty tailpipe GHG emissions from new vehicles sold in California from 2009 through 2016. As part of a national agreement with the Obama Administration, agencies, automakers, and other stakeholders, the U.S. Environmental Protection Agency (EPA) and the U.S. National Highway Traffic Safety Administration (NHTSA) issued harmonized GHG and fuel economy standards in partnership with CARB, equivalent to 35.5 mpg by model year 2016.

As part of the AB 32 Scoping Plan, the Plan that describes the approach California will take to reduce GHG emissions to 1990 levels by 2020, CARB began development of the Advanced Clean Cars program. This program is essentially a combination of Low Emission Vehicle III (LEVIII) rulemaking and an update to the Zero Emission Vehicle (ZEV) Program. LEV III reduces tailpipe criteria pollutant and GHG emissions. The GHG portion is referred to as Pavley 2.

The EPA and NHTSA worked in parallel to develop the second phase of the national program, and in 2012 issued new federal light duty GHG and fuel economy standards for model years 2017-2025. EPA's fleet average standard of 163 grams per miles corresponds to 54.5 miles per gallon (mpg) if all reductions are made through fuel economy improvements. As part of the national agreement, CARB allows compliance with the EPA's requirements to serve as compliance with California's standards for those model years.

The light duty fuel economy standards and tailpipe GHG standards were incorporated into gasoline and diesel demand forecasts.

[3] The RFS2 does not include non-biofuels such as electricity, natural gas, or hydrogen. However, the RFS2 does include biogas as an eligible fuel – in a recent proposed rulemaking, the EPA is proposing to amend the biogas pathways to list renewable CNG or LNG as the fuel types and biogas as the feedstock. Furthermore, EPA's recent proposed rulemaking would allow renewable electricity (used in electric vehicles) produced from landfill gas to generate credits under the RFS2. More information is available online at: http://www.epa.gov/otaq/fuels/renewablefuels/documents/nprm-pathways-2-signature-version.pdf

Zero Emission Vehicle Program

ARB adopted the Zero Emission Vehicle (ZEV) Program in 1990 as part of the Low Emission Vehicle (LEV) to reduce criteria pollutant emissions in order to meet health based air quality goals. Today, the ZEV Program requires a certain percentage of light duty vehicles sold in California to be partly or fully zero emitting at the tailpipe. Qualifying technologies include battery electric vehicles (BEVs), plug-in hybrid electric vehicles (PHEVs), and hydrogen fuel cell vehicles (FCVs). ARB recently adopted the changes to the ZEV Program as part of the Advanced Clean Cars Program, with modified requirements over the model year 2014 to 2025 time period. The table below provides light duty vehicle populations for ARB's likely compliance scenario. Note that for the purposes of this study, the so-called transitional zero emission vehicles (TZEVs) are all considered plug-in hybrid electric vehicles (PHEVs).

Exhibit 3. Advanced Vehicle Technology Populations, Most Likely Compliance Scenario for the ZEV Program

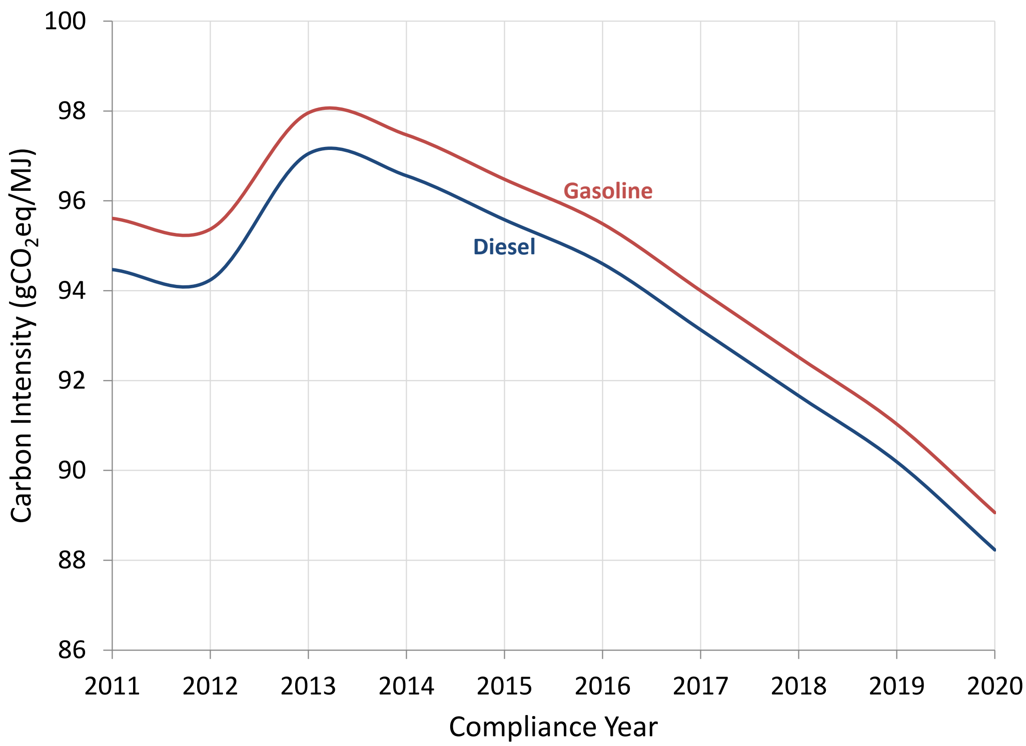
ZEV Type	2017	2018	2019	2020
FCVs	6,337	9,237	15,437	26,037
BEVs	42,832	56,732	84,032	121,732
TZEVs / PHEVs	128,589	189,889	265,189	354,289
Total	177,758	255,858	364,658	502,058

The credits generated by the consumption of electricity and hydrogen in ZEVs to comply with the ZEV Program will generate LCFS credits. ICF considered the credits generated through CARB's most likely compliance scenario as the minimum number of credits for PEVs and FCVs. Any credits generated above and beyond the most likely compliance scenario were attributed to the LCFS and not the ZEV Program.

LCFS Compliance Schedule

The compliance schedule for the LCFS is shown in the figure below.

Exhibit 4. LCFS Compliance Schedule for Gasoline and Diesel



Note that CARB modified the baseline number, which was originally an average of crude oil supplied to California refineries in 2006; the values from 2013 to 2020 reflect the updated average of crude oil supplied to California refineries in 2010.

Note that although there are separate compliance schedules for gasoline and diesel, LCFS credits are fungible across these fuels. For instance, credits generated using a low carbon fuel that substitutes for gasoline can be used to offset deficits generated by diesel. This is an important aspect of LCFS compliance because, based on ICF's research and analysis, there is considerable room for over-compliance in the diesel sector compared to the gasoline sector. There are two prominent reasons for this:

- Firstly, ethanol is already blended into gasoline at a rate of 10 percent by volume. The primary pathway for compliance in the near-term future for gasoline suppliers is simply to blend ethanol from feedstocks with a lower carbon intensity. However, they are blending the same volume of ethanol.
- Secondly, there is very little biodiesel consumed in California today (less than 1 percent by volume in 2010). Biodiesel blends of up to 5 percent (B5) are considered identical to conventional diesel according to the ASTM International. ASTM International is the leading standard-setting organization for fuel in North America and sets science-based standards by consensus of fuel producers, petroleum distributors, original equipment manufacturers, and regulators. As a result, not only can diesel providers blend low carbon biodiesel, they can drastically increase the volume of biodiesel blended and earn credits for those reductions.

2.3. Compliance Options Considered

ICF considered a variety of low carbon fuels to develop representative LCFS compliance scenarios. Furthermore, to determine the balance of deficits and credits in each compliance scenario, ICF made various assumptions regarding how vehicles and fuels will be used in the near-term future towards LCFS compliance. These are distinguished between fuels that substitute for gasoline (the gasoline pool) and fuels that substitute for diesel.

Fuels that Substitute for Gasoline

ICF assumed that ethanol would continue to be blended into gasoline at a rate of 10 percent by volume, consistent with today's reformulated gasoline requirements. ICF limited the blending of ethanol with gasoline at a maximum of 15 percent by volume based on EPA's recently issued waiver for E15 in vehicle model years (MY) 2001 or newer. Although there is no E15 consumed in California today – and very little generally in the United States – ICF anticipates that E15 will be consumed in meaningful quantities in California in the 2017-2018 timeframe as a result of drivers such as LCFS and the RFS2.

ICF considered the following feedstocks for ethanol production:

- **Corn, Conventional**: Corn from conventional processes is typically sourced from the Midwest. Corn has been and continues to be the most common feedstock for ethanol consumed in California. Nearly 1.5 billion gallons of corn ethanol are consumed in California today as an oxygenator in reformulated gasoline.
- **Corn, California-produced**: California currently has seven (7) ethanol production facilities with a combined nameplate production capacity of more than 250 million gallons; however, actual production capacity is close to 200 million gallons annually. For the purposes of this report, we assume that there is potential for modest expansion in California facilities, with a maximum capacity of 220 million gallons. We assumed modest improvements consistent with information provided via consultation with Pacific Ethanol.
- **Corn, low carbon intensity**: There is significant potential to lower the carbon intensity of corn ethanol through a variety of measures. For the purposes of this report, ICF assumed a lower limit of 73 g/MJ for what we term low carbon intensity corn ethanol. There has already been a shift towards more efficient corn ethanol production as a result of the LCFS, with many new lower carbon pathways submitted to and approved by CARB.
- **Sugarcane**: Most sugarcane ethanol is produced in Brazil and shipped via tanker to the United States. In some cases, hydrous ethanol is shipped to a country in the Caribbean Basin Initiative (CBI); the excess water is subsequently removed and the anhydrous ethanol is shipped to the US. This step was more common when the US had a tariff on sugarcane ethanol imported directly from Brazil; the interim step allowed importers to avoid paying the tariff. The ethanol arrives in California in two ways: 1) directly via port or 2) via rail after landing in Texas. For the sake of reference, the United States imported 500 million gallons of sugarcane ethanol in 2012, with an estimated 90 million gallons coming to California.
- **Cellulosic**: Cellulosic ethanol refers generally to ethanol produced from wood, grasses, or other lignocelluosic materials. For the purposes of this report, ICF did not identify feedstocks specifically; rather, we focused on the long-term likelihood (out to 2020) of cellulosic ethanol production and the availability to California.

Although ethanol from various feedstocks is the primary substitute for gasoline today, ICF also considered the following fuels that substitute for gasoline:

- **Renewable gasoline** is a drop-in replacement biofuel for gasoline. To remain conservative in our estimates, ICF assumed that 50% of Energy Information Administration (EIA)-forecasted renewable gasoline production will be available to California, starting in 2015.
- **Electricity** used in plug -in electric vehicles (PEVs), including plug-in hybrid electric vehicles (PHEVs) and battery electric vehicles (BEVs), stands to play an important role towards LCFS compliance, particularly in later years of the regulation as California's Zero Emission Vehicle (ZEV) Program takes full effect. In each of the compliance scenarios, a minimum number of PEVs was deployed to be consistent with CARB' most likely scenario. ICF also considered the potential for a more rapid expansion of the market for PEVs.
- **Hydrogen** consumed in fuel cell vehicles (FCVs) is another aspect of California's ZEV Program that was also considered. Similarly, ICF deployed a minimum number of FCVs using hydrogen to be consistent with CARB's most likely compliance scenario. ICF also considered the potential for a more rapid expansion of the market for FCVs.
- **Natural gas** has significant potential to displace gasoline consumption in medium-duty and light heavy-duty vehicles.

The table below shows the carbon intensity values used for fuels that substitute for gasoline. In most cases, we employed static carbon intensity values; however, in some cases we did decrease the carbon intensity of a transportation fuel to reflect expected advanced in technologies. Unless otherwise noted, the carbon intensity values were taken directly from CARB's look-up tables.

Exhibit 5. Carbon Intensity Values for Fuels that Substitute for Gasoline

Fuel / Feedstock	Carbon Intensity (gCO2e/MJ)
Ethanol, conventional	95.66
Ethanol, CA corn	80.70; decreasing to 70.70 in 2016
Ethanol, Low CI Corn	73.21
Ethanol, Sugarcane	73.40; decreasing to 67.38 by 2020
Ethanol, Cellulosic	21.30 [a]
Renewable Gasoline	25.00 [b]
Compressed natural gas	68.00
Biogas, landfill	11.56
Electricity, marginal [c]	30.80; decreasing to 26.32 by 2020
Hydrogen [d]	39.42

[a] The average of CARB pathways for ethanol from farmed trees and forest ways
[b] Estimated carbon intensity based on stakeholder consultation.
[c] Includes the energy economy ratio (EER) of 3.4 for electric vehicles
[d] Includes the EER of 2.5 for fuel cell vehicles

Fuels that Substitute for Diesel

The fuel volumes in the compliance scenarios represent a combination of ICF research and input provided by the National Biodiesel Board (NBB), with similar biodiesel blending rates and feedstocks: In the development of the compliance scenarios, we considered the following feedstocks for biodiesel:

- **Soybean oil**: Soybean oil is the largest single feedstock for biodiesel production in the United States. It is a well-established crop with a robust commodity market. While most soybeans are grown in the Midwest and a significant amount of biodiesel production capacity exists in the Midwest, soybean oil is also transported to independent biodiesel production facilities in California and elsewhere.
- **Waste grease**: Waste grease is significant feedstock at California production facilities. As a waste feedstock, waste grease has a low carbon intensity. The production process for biodiesel from waste grease is generally more energy intensive than for vegetable oils because there is generally a higher free fatty acid content. This requires an additional acid-catalyzed esterification reaction, thereby increasing the energy inputs.
- **Animal fats**: Animal fats, like waste grease, are also a significant feedstock for biodiesel production and yield a finished product with a low carbon intensity. Typically, animal fats include poultry, tallow, and white grease (or lard).
- **Corn oil**: Corn oil is a byproduct of corn ethanol production and generally requires retrofitting an ethanol plant. It is a feedstock with significant growth potential for the biodiesel industry. Corn oil extraction is a relatively new commodity for the majority of ethanol production facilities, but represents another high-value co-product. Anecdotal evidence indicates that the majority of corn ethanol facilities in the US will have installed equipment to extract corn oil by the end of 2013.
- **Canola oil**: Canola oil is similar to soybean oil as a feedstock; it is more prominent feedstock in the European Union (referred to there as rapeseed). In North America, canola production historically exists primarily in Canada and northern states of the US. It is increasingly being planted as a winter crop is places like Oklahoma and the Carolinas. Existing transportation infrastructure makes Canola a significant feedstock for biodiesel production on the West Coast.

ICF also considered the following alternative fuels:

- **Renewable diesel**: Like biodiesel, there are multiple feedstocks that can be used to produce renewable diesel, including palm oil, canola (or rapeseed) oil, jatropha oil, camelina oil, soy oil, waste greases, and animal fats (i.e., tallow). ICF considered renewable diesel produced from tallow; this pathway is largely based on the availability of renewable diesel produced by Neste Oil in its Singapore production plant using its renewable diesel production process.
- **Natural gas**: ICF considered the potential for natural gas – compressed, liquefied, and biogas – in heavy-duty applications such as short-, medium-, and long-haul trucks, refuse haulers, and transit buses. For the purposes of this report, and after consultation with the California Natural Gas Vehicle Coalition, we assumed that about 85 percent of natural gas in the heavy-duty sector (Class 7 and Class 8 trucks) will be consumed as LNG in spark-ignited engines and 15 percent will be consumed as CNG in spark-ignited engines for medium-heavy and heavy-heavy duty vehicles.

- **Electricity**: Electricity used in fixed guideway applications (e.g., light- and heavy-rail) and forklifts were considered in the analysis, and are discussed in more detail in Section 4.7. Although BEVs and PHEVs have the potential to displace diesel in the medium- and heavy-duty sector, ICF limited the scope of our analysis regarding electric vehicles to light-duty applications.

The table below includes the carbon intensity values used to determine the balance of LCFS deficits and credits in each scenario. Unless otherwise noted, the carbon intensity values were taken directly from CARB's look-up tables.

Exhibit 6. Carbon Intensity Values for Fuels that Substitute for Diesel

Fuel / Feedstock	Carbon Intensity (gCO2e/MJ)
Biodiesel, soy oil	83.25
Biodiesel, waste grease	13.80
Biodiesel, corn oil	4.00
Biodiesel, canola oil [a]	83.25
Renewable diesel, tallow	19.65
Compressed natural gas [b]	75.56
Liquefied natural gas [c]	77.76
Biogas, landfill [b]	12.51

[a] Biodiesel from canola oil is not in the LCFS look-up tables. ICF used a conservative value equivalent to biodiesel from soy oil.

[b] Includes the EER of 0.9 for spark ignition CNG vehicles

[c] Average of LNG pathways with natural gas liquefied in California with 80% and 90% efficiency.

3. Overview of Compliance Scenarios

From a broad perspective, there are two ways to deploy alternative fuels that will help comply with the LCFS. Firstly, biofuels can be blended into conventional gasoline or diesel for consumption in the existing vehicle fleet. Secondly, advanced vehicle technologies can be deployed, which consume alternative fuels such as natural gas, electricity, or hydrogen. ICF maintains that compliance with the LCFS will require a diverse mix of all of these alternative fuels. Due to constraints on how quickly the vehicle fleet can be turned over, however, biofuel blending is and will likely continue to be a major form of LCFS compliance until advanced vehicle technologies are deployed in higher numbers. The scenarios outlined in the following sections highlight the diversity of alternative fuels that are available or forecasted to be available out to 2020.

ICF developed two compliance scenarios in coordination with the Stakeholder Review Panel. As noted above, both scenarios have significant reliance on biofuel blending to achieve compliance – using a mix of so-called first generation biofuels and advanced biofuels, with an emphasis on fuels that we know are available today. Scenario 1, however, reflects a market that is more dependent on advanced vehicle technologies than Scenario 2, thereby decreasing the pressure on biofuel blending.

The Stakeholder Review Panel developed a third compliance scenario, referred to as the LCFS Enhanced Scenario. This scenario has even greater advanced vehicle penetrations than Scenario 1, and includes additional credits generated from off-road electrification and innovative crude extraction processes.

The table below characterizes broadly the scenarios with more detail in the subsequent sections.

Exhibit 7. Overview of LCFS Compliance Scenarios Developed

Scenario	Ethanol	Biodiesel / Renewable Diesel	Natural Gas	Advanced Vehicles (PEVs / FCVs)	Other
Scenario 1	Maintained E10 blend rate until 2018 E15 introduced 2019 and 2020 Cellulosic/advanced biofuels capped at 50% of volumes reported by E2	Limited blend percentages to 20 percent by volume of conventional diesel.	Linear increase from 2012 to 2020 to 1.2 billion gge 10% biogas Based on estimates from CNGVC	220,000 BEVs; 800,000 PHEVs; and 110,000 FCVs in 2020	Only forklifts and rail with no additional credits for displacement
Scenario 2	Maintained E10 blend rate until 2017 E15 introduced 2018-2020 Cellulosic/advanced biofuels capped at 13% of volumes reported by E2	Limited blend percentages to 20 percent by volume of conventional diesel. Increased corn oil BD Increased RD from tallow in 2018-2020	Linear increase from 2012 to 2020 to 900 million gge, 10% biogas Based on estimates from CNGVC	ZEV Program Compliance	Only forklifts and rail with no additional credits for displacement
LCFS Enhanced	Maintained E10 blend rate Brazilian sugarcane capped at less than 350 MGY until 2018	Limited blend percentages to 20 percent by volume of conventional diesel.	Linear increase from 2012 to 2020 to 1.5 billion gge 10% biogas Based on estimates from CNGVC	240,000 BEVs; 960,000 PHEVs; and 110,000 FCVs in 2020	Marginal incremental calculations for forklifts and rail, no displacement when including ports, small non-truck and truck related
Assumption for all Scenarios	Maximum ethanol is E15 FFVs driving 85% of miles on E85. Maximums for ethanol: • Low CI corn at 1 BGPY • Sugarcane at 500 MGPY			40% PHEV VMT is electric	Compliance achieved in 2011 and 2012 Assumed 1 million banked credits at end of 2012

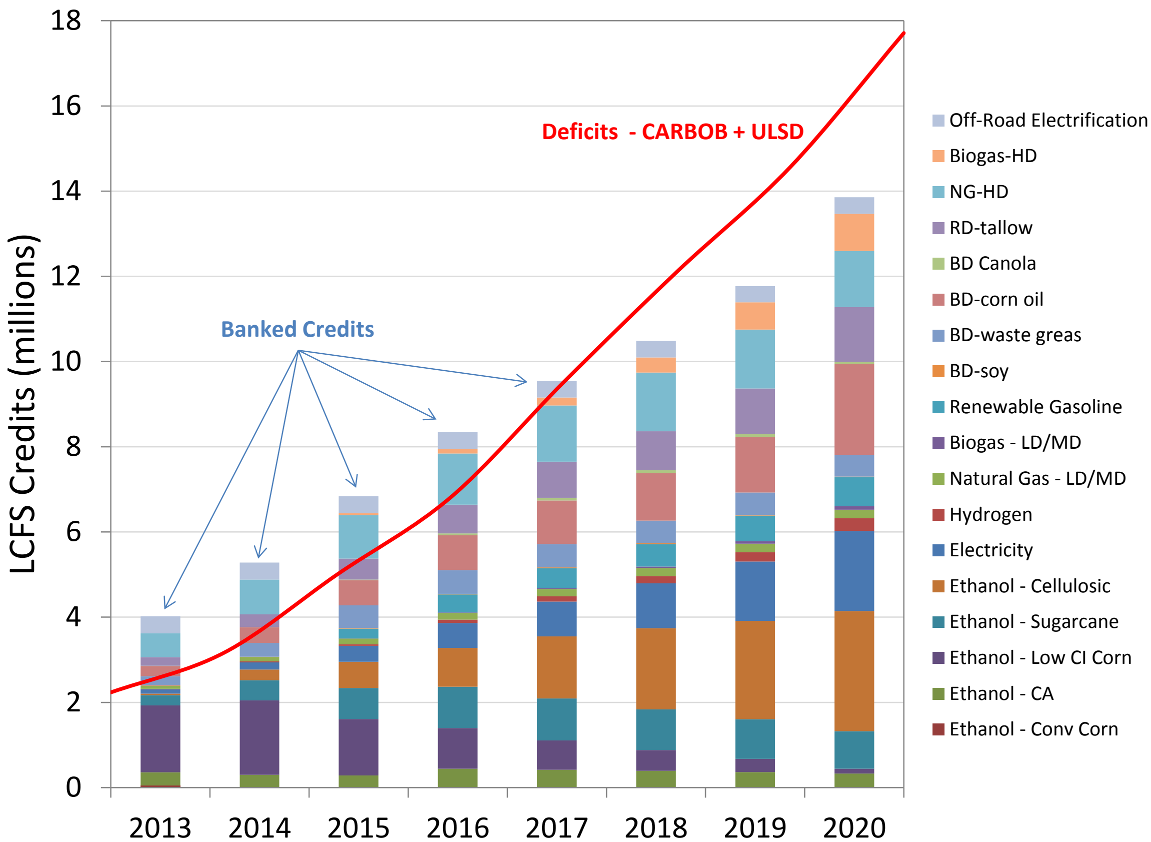
* gge = gasoline gallon equivalent

3.1. Compliance Scenario 1

Summary Overview of Compliance Scenario 1

Exhibit 8 shows the annual balance of credits and deficits (in millions) for Scenario 1. Each colored stacked bar represents credits generated via low carbon fuels; the red line represents the deficits from forecasted CARBOB and ultra low sulfur diesel (ULSD) consumption. When the stacked bars are above the red line (2013-2017) that indicates a year in which more credits are generated than are required to meet compliance. Conversely, in years where the stacked bars are lower than the red line (2018-2020) that indicates a year in which banked credits must be used. The stacked bars are grouped according to the fuel being displaced. The stacked bars at the bottom of the graph are for fuels that displace gasoline; moving up the graph, the stacked bars represent fuels that displace diesel.

Exhibit 8. Balance of LCFS Credits and Deficits in Scenario 1



The table below highlights the deficits generated by forecasted CARBOB and diesel consumption (in millions of deficits) compared to the credits generated by fuels that substitute for gasoline and diesel, respectively. The last two rows of the table show the balance of credits and the number of credits banked after compliance. Note that there is significant over-compliance in the early years of the program. Furthermore, note that although diesel accounts for only about 20 percent of deficits, the fuels that substitute for diesel account for about 45 percent of credits.

Exhibit 9. LCFS Credits and Deficits: Banking in Scenario 1

Fuel		2013	2014	2015	2016	2017	2018	2019	2020
Deficits (millions)	CARBOB	-1.82	-2.55	-4.00	-5.44	-7.62	-9.69	-11.67	-14.24
	ULSD	-0.42	-0.62	-1.01	-1.37	-1.90	-2.43	-2.90	-3.47
Credits (millions)	Gasoline Subs	2.39	3.06	3.73	4.53	5.15	5.72	6.38	7.28
	Diesel Subs	1.63	2.22	3.11	3.81	4.39	4.77	5.39	6.57
	Balance	1.79	2.12	1.83	1.53	0.02	-1.63	-2.80	-3.85
	Banked (Net)	2.79	4.90	6.74	8.27	8.29	6.66	3.86	0.01

Note: The banked balance in 2013 includes one million credits from over-compliance in 2011-2012

Ethanol and Biofuels that Substitute for Gasoline

ICF considered ethanol from the aforementioned feedstocks: corn (with varying production locations and processes), sugarcane, and cellulosic. The table below indicates the volumes (in million gallons) of ethanol broken down by feedstock in Scenario 1.

Exhibit 10. Ethanol Volumes (in million gallons) in Scenario 1

Feedstock	2013	2014	2015	2016	2017	2018	2019	2020
Corn, Conventional	264	0	0	0	0	0	0	0
California Corn	215	220	220	220	220	220	220	220
Low CI Corn	780	884	699	526	408	311	214	87

Biodiesel Blend (%)	1%	2%	4%	5%	7%	8%	10%	12%

Renewable Diesel

The table below shows the volume of renewable diesel consumed in Scenario 1.

Exhibit 12. Renewable Diesel Consumption in Scenario 1 (million gallons)

Feedstock	2013	2014	2015	2016	2017	2018	2019	2020
Tallow	19	29	48	67	86	95	112	139

Natural Gas

The consumption of natural gas is the medium-level of deployment from the CNGVC's estimates and reaches 1,200 million gasoline gallon equivalents (gge) consumed in 2020, as shown in the table below.

Exhibit 13. Natural Gas Consumption in Scenario 1 (million gge)

	2013	2014	2015	2016	2017	2018	2019	2020
NG, medium-duty	20	30	40	49	58	67	74	81
Biogas, medium-duty	-	-	0	1	2	4	6	9
NG, heavy-duty	250	373	491	606	719	821	908	999
Biogas, heavy-duty	-	-	5	12	22	43	79	111
Total	271	403	536	669	802	934	1,067	1,200

Advanced Vehicle Technologies: PEVs and FCVs

Advanced vehicle technologies were deployed at an accelerated rate in Compliance Scenario 1 relative to the minimum level of deployment to comply with the ZEV Program. The table below shows the consumption of hydrogen in FCVs and electricity in PEVs in gasoline equivalent volumes.

Exhibit 14. Hydrogen and Electricity Consumption in ZEVs in Scenario 1 (million gge)

Vehicle	2013	2014	2015	2016	2017	2018	2019	2020
FCVs	0	1	2	5	8	11	15	21

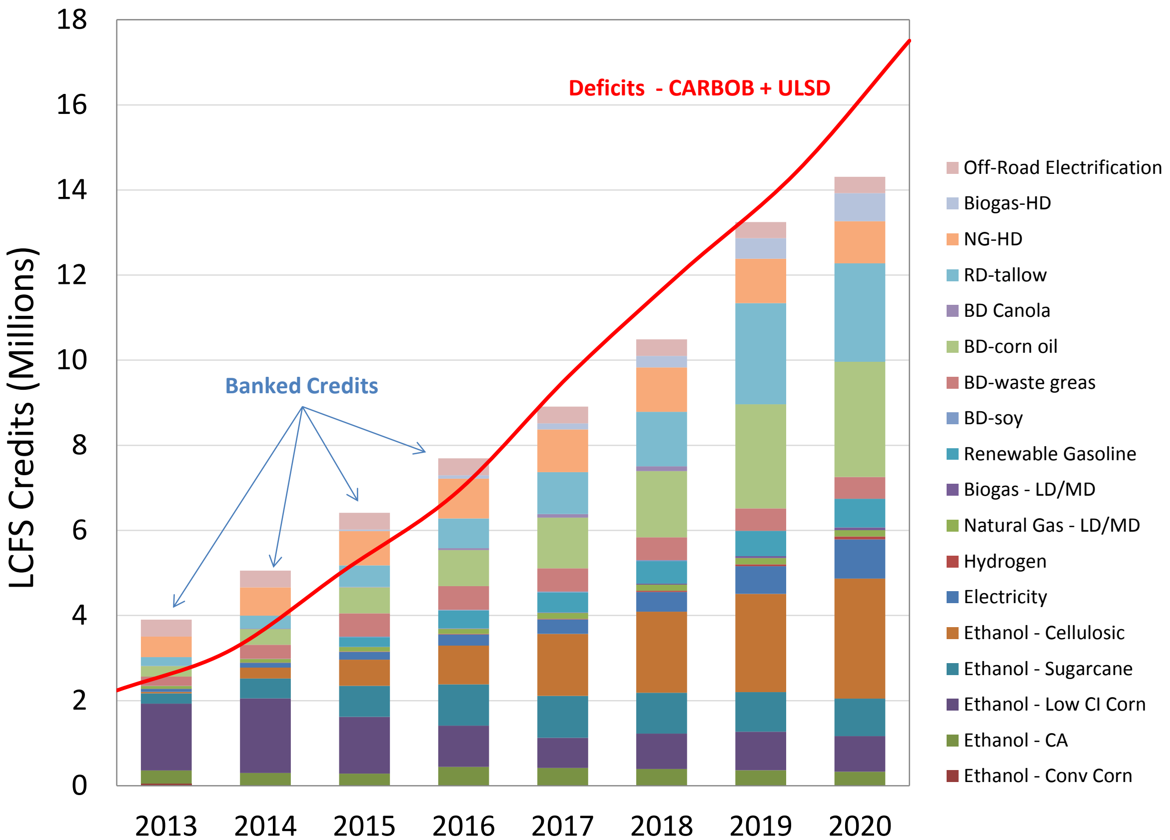
PHEVs	10	16	34	50	69	87	119	153
Total	14	24	51	78	109	141	192	251

3.2. Compliance Scenario 2

Summary Overview of Compliance Scenario 2

Exhibit 15 shows the annual balance of credits and deficits (in millions) for Scenario 1. Each colored stacked bar represents credits generated via low carbon fuels; the red line represents the deficits from forecasted CARBOB and ULSD consumption. When the stacked bars are above the red line (2013-2016) that indicates a year in which more credits are generated than are required to meet compliance. Conversely, in years where the stacked bars are lower than the red line (2017-2020) that indicates a year in which banked credits must be used. The stacked bars are grouped according to the fuel being displaced. The stacked bars at the bottom of the graph are for fuels that displace gasoline; moving up the graph, the stacked bars represent fuels that displace diesel.

Exhibit 15. Balance of Credits and Deficits for Compliance Scenario 2



The table below highlights the deficits generated by forecasted CARBOB and diesel consumption (in millions of deficits) compared to the credits generated by fuels that substitute for gasoline and diesel, respectively. The last two rows of the table show the balance of credits and the number of credits banked after compliance. Note that there is significant over-compliance in the early years of the program. Furthermore, note that although diesel accounts for only about 20 percent of deficits, the fuels that substitute for diesel account for about 50 percent of credits.

Exhibit 16. LCFS Credits and Deficits: Banking in Scenario 2

Fuel		2013	2014	2015	2016	2017	2018	2019	2020
Deficits (millions)	CARBOB	-1.82	-2.55	-4.01	-5.47	-7.69	-9.63	-11.46	-13.85
	ULSD	-0.42	-0.63	-1.03	-1.42	-1.96	-2.47	-2.96	-3.66

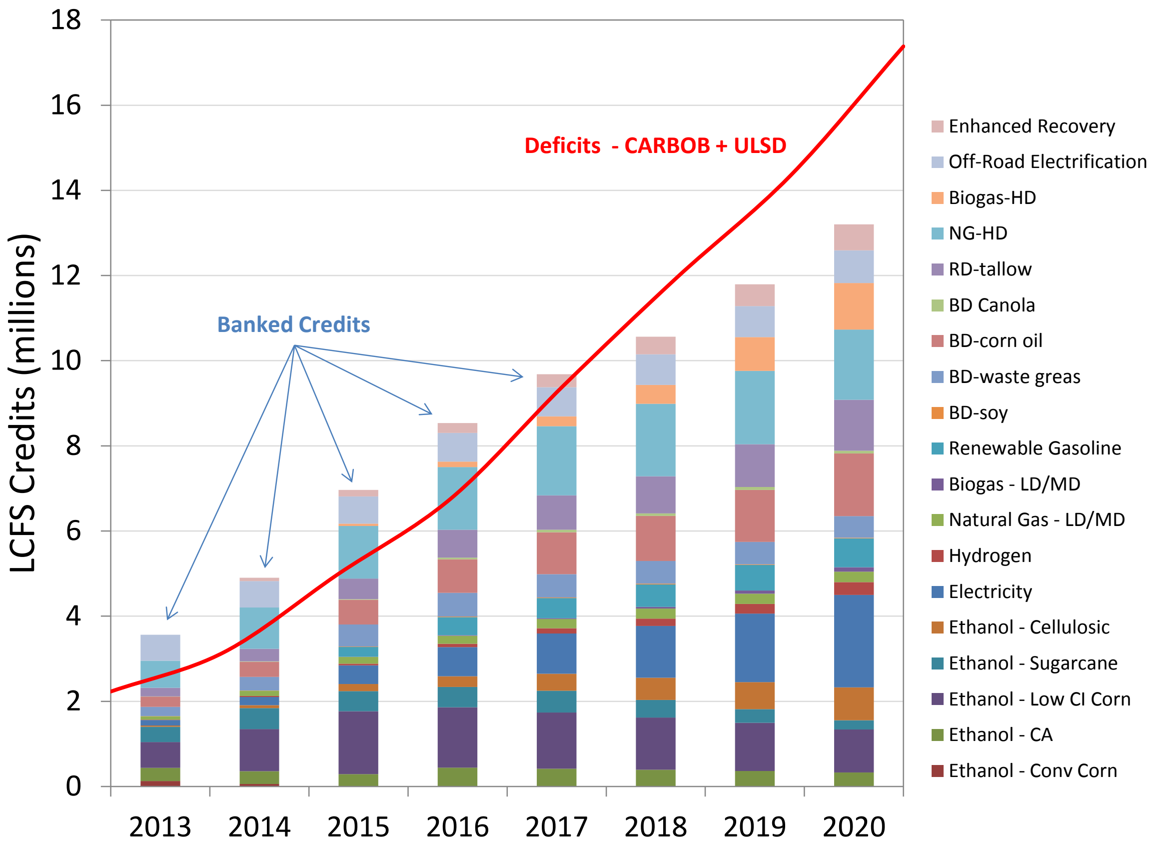
3.3. LCFS Enhanced Scenario

Summary Overview of LCFS Enhanced Compliance Scenario

Exhibit 22 shows the annual balance of credits and deficits (in millions) for the LCFS Enhanced Scenario. Each colored stacked bar represents credits generated via low carbon fuels; the red line represents the deficits from forecasted CARBOB and ULSD consumption. When the stacked bars are above the red line (2013-2017) that indicates a year in which more credits are generated than are required to meet compliance. Conversely, in years where the stacked bars are lower than the red line (2018-2020) that indicates a year in which banked credits must be used. The stacked bars are grouped according to the fuel being displaced. The stacked bars at the bottom of the graph are for fuels that displace gasoline; moving up the graph, the stacked bars represent fuels that displace diesel. Note that the top stacked bar, labeled Enhanced Recovery, includes credits generated by deploying innovative crude recovery technologies. These technologies reduce the carbon intensity of both gasoline and diesel, and are discussed in more detail below.

Exhibit 22. Balance of Credits and Deficits in the LCFS Enhanced Scenario



The table below highlights the deficits generated by forecasted CARBOB and diesel consumption (in millions of deficits) compared to the credits generated by fuels that substitute for gasoline and diesel, respectively. The last two rows of the table show the balance of credits and the number of credits banked after compliance. Note that there is significant over-compliance in the early years of the program. Furthermore, note that although diesel accounts for only about 20 percent of deficits, the fuels that substitute for diesel account for about 50 percent of credits.

Exhibit 23. LCFS Credits and Deficits: Banking in the LCFS Enhanced Scenario

Fuel		2013	2014	2015	2016	2017	2018	2019	2020
Deficits (millions)	CARBOB	-1.82	-2.54	-3.99	-5.43	-7.60	-9.65	-11.62	-14.15
	ULSD	-0.41	-0.61	-0.98	-1.33	-1.82	-2.30	-2.72	-3.23
Credits (millions)	Gasoline Subs	1.65	2.32	3.43	4.20	4.73	5.16	5.71	6.44

	Balance	1.33	1.75	1.99	1.78	0.26	-1.39	-2.55	-4.18
	Banked (Net)	2.33	4.08	6.07	7.86	8.12	6.72	4.18	0.00

Note: The banked balance in 2013 includes one million credits from over-compliance in 2011-2012

Ethanol and Biofuels that Substitute for Gasoline

In the LCFS Enhanced Scenario, cellulosic ethanol was restricted to one quarter of the Scenario 1 and Scenario 2 (or 1/8th of E2's estimated cellulosic ethanol availability). The table below shows the volumes of ethanol consumed in the LCFS Enhanced Scenario.

Exhibit 24. Ethanol Volumes (in million gallons) in the LCFS Enhanced Scenario

Feedstock	2013	2014	2015	2016	2017	2018	2019	2020

Total Adv Vehicles	18	28	61	92	127	165	225	293

Additional Credit-Generating Measures

For the LCFS Enhanced Scenario, additional LCFS credits were calculated for off-road electrification from forklifts and rail for marginal electricity from 2010 consumption. The marginal electricity credits were calculated using the ARB formula which includes diesel displacement. Scenarios 1 and 2 calculated all rail and forklift electricity without diesel displacement. Also, the LCFS enhanced scenario includes additional off-road LCFS credits from ports, small non-road, and truck related applications. These credits were calculated using the base formula which does not include diesel displacement.

ICF also considered LCFS credits that can be earned for purchasing crudes produced using innovative recovery methods, including renewable energy in steam used for extraction and carbon capture and storage.

The table below shows the annual number of credits generated in these two measures.

Exhibit 29. LCFS Credits Earned Through Off-Road Electrification and Innovative Crude Recovery Technologies

	2013	2014	2015	2016	2017	2018	2019	2020

4. Alternative Fuels Market Assessment

The following subsections include more detailed market research and analysis considered in the development of LCFS compliance scenarios.

4.1. Ethanol

Low carbon intensity corn ethanol

The ethanol industry has already responded to the LCFS by investing in technologies that reduce the carbon intensity of products. Corn ethanol producers have submitted to CARB more than two dozen pathway documents for approval, each of which includes distinctive production processes that help achieve a lower carbon intensity score, including:

- Transition to wet distiller grains. Facilities that have wet distiller grains generally have a carbon intensity score nearly 7 g/MJ lower than for facilities that dry their distiller grains.
- Transition to natural gas. Facilities are seeking to displace energy produced from higher carbon sources by transitioning to natural gas. Similarly, some facilities are seeking to use biogas or biomass for on-site energy consumption.
- Cogeneration. Production facilities are increasingly seeking to use cogeneration at production facilities.
- Feedstock switching. Several corn ethanol producers are adding sorghum or milo to their production facilities to help lower the carbon intensity of ethanol produced. Other facilities have applied for approval of pathways that include wheat slurry.

California represents at least 10 percent of domestic gasoline consumption; with such a sizeable market share, and with LCFS-driven price premium, there is a significant incentive for ethanol producers to continue seeking innovative production processes and technologies that reduce their carbon intensity score. Furthermore, given the uncertainty associated with the availability of lower carbon biofuels e.g., from cellulosic feedstocks, regulated parties will seek out cost-effective reductions from corn ethanol producers where available in the near-term future.

California Corn Ethanol

The California ethanol industry has responded to the LCFS by seeking to reduce their carbon intensity significantly. Most California ethanol today is sold at a carbon intensity of around 80 g/MJ; while interviews with California ethanol producers indicate that they seek to reduce the carbon intensity of their products to 70 g/MJ over the next 3-4 years. There is good reason to believe that the LCFS will continue to drive innovation in California's ethanol production; and given the current carbon intensity of the fuel provided, ICF expects California's ethanol facilities to continue supply the domestic market at near-maximum capacity of around 200 million gallons.

For the purposes of this analysis, California ethanol volumes are reported as corn ethanol; however, there is potential for facilities to reduce their carbon intensity through feedstock switching. For instance, Pacific Ethanol reported that in the 3rd quarter of 2012, about 30 percent of its feedstock was sorghum. Furthermore, Pacific Ethanol has partnered with Edeniq to expand production through the installation of Edeniq's Cellunator™ - a technology that has the potential to improve yields at the plant by 2-4 percent. Similarly, Aemetis recently idled its 60 million gallon per year production plant in Keyes, California plant to upgrade the facility so that it can also operate using sorghum as a feedstock for ethanol production. Aemetis has since restarted its facility and announced a multi-year agreement with Chromatin to supply locally grown sorghum.

Edeniq is funded in part by a $3.9 million grant from the CEC's Alternative and Renewable Fuel and Vehicle Technology Program to help existing corn ethanol production facilities upgrade via addition of Edeniq's cellulosic ethanol production technology.

Brazilian sugarcane ethanol

For the purposes of this project, the ICF team sought to limit the import of Brazilian sugarcane ethanol to California at levels of 500 million gallons annually in an effort to minimize dependence on this compliance option. Even though this is a significant increase from the most recent volumes of Brazilian sugarcane ethanol imported to California (at least 90 million gallons in 2012), there are three reasons why our team is confident that Brazilian sugarcane ethanol will continue to play a significant role in compliance: 1) Brazil has sufficient capacity to meet demand for ethanol, 2) the fuel is priced competitively with corn ethanol, and 3) there is potential to lower the carbon intensity of sugarcane ethanol further. These issues are discussed in more detail here.

Brazilian sugarcane ethanol: Export capacity

Firstly, Brazil has sufficient capacity to export significantly higher volumes of ethanol. In 2012, Brazil exported approximately 800 million gallons of sugarcane ethanol, with about two thirds of that (530 million gallons) coming to the United States. The majority of Brazil's ethanol is exported from the Port of Santos and is either delivered to California via Los Angeles or San Francisco. It is also feasible for the ethanol to be imported via Houston and shipped to California via rail; however, it is unclear how common this practice is. The most recent data from EIA for 2013 indicate that fuel ethanol imports to the US are considerably higher than in the same period in 2012. Through the end of April 2013, the US has imported approximately 100 million gallons of fuel ethanol, up from just 23 million gallons over the same period last year. Furthermore, the likelihood of lower sugar prices and an abundant sugarcane crop for 2013 have led most analysts to project Brazilian ethanol production upwards of 7 billion gallons, up from 5.6 billion gallons over the last couple of years.[4]

The figure below highlights the Organisation for Economic Co-operation and Development's (OEC) forecast of Brazil's production, consumption, and net export of ethanol out to 2020.[5] Note

[4] Irwin, S and Good, D. Brazilian Ethanol Imports – Implications for US Ethanol and Corn Demand. Farmdoc Daily, University of Illinois, Dept of Agricultural and Consumer Economics, May 2013. Available online at. http://farmdocdaily.illinois.edu/2013/05/brazilian-ethanol-implications.html

[5] OECD-FAO. "Agricultural Outlook: 2012-2021". OECD-FAO, 2012.

that even though production in 2012 was down from the forecasted 6.8 billion gallons, exports were more than double the forecasted 365 million gallons.

Exhibit 30. OECD Forecast of Brazil's production, consumption and net export of ethanol

	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020
Production	7,284	5,997	6,805	7,495	8,294	9,111	9,896	10,932	11,408	11,987	12,695
Consumption	6,795	5,796	6,440	7,061	7,590	7,761	7,972	8,661	8,797	9,444	10,103
Net export	489	201	365	435	704	1,350	1,924	2,271	2,611	2,543	2,592

It is important to note that there will be other export markets for Brazilian sugarcane ethanol. For instance, the European Commission (EC) issued the Fuel Quality Directive (FQD), which requires a six percent reduction in the lifecycle carbon intensity of transportation fuels by 2020, similar to California's LCFS. The EC also has issued the Renewable Energy Directive (RED), which requires 10 percent renewable energy consumption in the transportation fuels market by 2020. Brazilian sugarcane ethanol is likely to play a significant role towards compliance with both of these directives. ICF recently prepared a report for the EC regarding the impact analysis of one of the key provisions of the FQD – in that work, the EC indicated that their internal forecast for Brazilian sugarcane ethanol consumption in the European Union was upwards of 1.3 billion gallons by 2020. Currently, Brazilian sugarcane ethanol exports to the EU are extremely small to non-existent in large part because of tariffs and increased transportation costs. The EU has an import tariff equivalent to about 50 cents per gallon[6] – considerably higher than the *ad valorem* tax (2.5 percent) that is imposed in the US, which is about 7 cents per gallon.[7] Secondly, ICF estimates that the transports costs to the US will continue to be cheaper than those same costs to the EU. Despite these barriers, it seems likely that exports of Brazilian sugarcane ethanol to the EU will increase to comply with the FQD, in part because of limited

[6] The tariff is €0.102 per liter and was converted using current exchange rates for illustrative purposes.

[7] The ad valorem tax is applied at 2.5percent of the value of the imported product, so the tax paid will fluctuate as a function of ethanol prices paid FOB Santos. The 7 cents per gallon is an average based on data from 2010-2012.

ethanol production capacity in the EU. This is one of the reasons that the team sought to limit the import of Brazilian sugarcane ethanol to California.

Brazilian sugarcane ethanol: Price Competitiveness

Recent spot price spreads between ethanol from Brazil (Santos FOB, $2.65 per gallon) and in California (San Francisco and Los Angeles, $2.86) indicate attractive pricing, even after accounting for transportation and a federally imposed *ad valorem* tariff (of 2.5 percent of the total value of the shipment). Even at LCFS credit prices of $40-45, Brazilian sugarcane ethanol produced from average processes (with a carbon intensity of about 74 g/MJ) would only command an 8-9 cent per gallon premium. When blended at 10 percent by volume with California Reformulated Blendstock for Oxygenate Blending (CARBOB), the additional cost is less than a penny per gallon.

Brazilian sugarcane ethanol: Low carbon ethanol

The GHG abatement potential of Brazilian sugarcane ethanol is significant. Even with an indirect land use change (ILUC) emissions factor of 46 g/MJ to its carbon intensity, the pathways for Brazilian sugarcane ethanol range from 58-79 g/MJ. This is one of the major drivers for Brazilian sugarcane ethanol imports to California because it is one of the most cost-effective compliance pathways for regulated parties. The carbon intensity of the sugarcane ethanol only stands to improve moving forward: By 2014, sugarcane producers in Sao Paolo, for instance, will be required to switch from manual harvesting to mechanized harvesting – a process that reduces local air pollution (the fields are burned before manual harvesting) and reduces the average carbon intensity from 73 g/MJ to 58 g/MJ.

Brazilian sugarcane ethanol consumption will likely be bolstered by the recent recommendation from CARB staff that a molasses-to-ethanol pathway be approved for LCFS compliance. Pantaleon Sugar Holdings is producing ethanol from molasses and estimated a carbon intensity of about 23 g/MJ, less than half of the lowest carbon intensity attributed to sugarcane ethanol using mechanized harvesting because it uses a byproduct of the sugar production process. The Pantaleon facility is based out of Guatemala. Given the demand for low carbon biofuels, it is possible that ethanol production facilities using Brazilian sugarcane ethanol – either in Brazil or in CBI countries – implement similar production capabilities to lower the carbon intensity of their product offerings.

Cellulosic ethanol

ICF developed projections for cellulosic ethanol in coordination with Environmental Entrepreneurs (E2). E2 considered the state of financing of various cellulosic ethanol facilities,[8] the likelihood that facilities would be completed, and their proximity to California to determine the maximum potential for cellulosic ethanol consumption in California.

[8] Solecki, M; Dougherty, A; and Epstein, B. Advanced Biofuel Market Report 2012: Meeting US Fuel Standards. Available online at: http://www.e2.org/ext/doc/E2AdvancedBiofuelMarketReport2012.pdf

- E2 identified 27 facilities that are in some advanced stage of financing. These facilities – if completed as announced – would have a combined production capacity of between 337 and 512 million gallons annually by 2015.
- ICF and E2 developed assumptions regarding increased penetration of cellulosic ethanol beyond the initial 27 facilities, increasing the potential capacity of cellulosic ethanol to slightly less than 600 million gallons by 2020.
- Most cellulosic ethanol plants are outside of California; therefore, ICF made assumptions about the percent of the production capacity that would be available to California refineries considering proximity to a cost-effective distribution infrastructure (e.g., rail) and other regulatory drivers (e.g., RFS2). For instance, INEOS Bio built the Indian River County BioEnergy Center, near Vero Beach, Florida – since it is unlikely that this fuel will be shipped to California, even with an LCFS-driven price premium, ICF did not take this facility into account.

ICF understands that there is considerable uncertainty regarding the availability of cellulosic ethanol to achieve California's LCFS. Cellulosic biofuel projects have been slower to come on-line than expected, falling well short of the volumetric requirements established by Congress in 2007 for the RFS2. CARB's original 2009 illustrative compliance scenarios were based, in part, on aggressive cellulosic ethanol volumes as well (even though the LCFS is performance based and allows the most lowest-cost technology to be utilized). Thus, the slower-than-expected advances in cellulosic biofuel production have dominated the discussion regarding both LCFS compliance and RFS2 compliance; however, the scenarios that ICF has developed highlight that cellulosic biofuels are part of a more diverse solution to GHG reductions in the transportation fuels sector. In this regard, the ICF team sought to limit the dependence of the compliance scenarios on cellulosic ethanol availability.

Despite the slower-than-expected deployment of cellulosic ethanol, there is evidence that the industry is looking up. For instance, Edeniq's cellulosic ethanol demonstration facility in Visalia, CA recently completed 1,000 hours of continuous operation, ahead of schedule and higher than projected production. Meanwhile, Zeachem's demonstration facility in neighboring Oregon has had continuous operation since mid-2012 and is producing 250,000 gallons annually, with plans to ramp up to 25 million gallons by 2014.

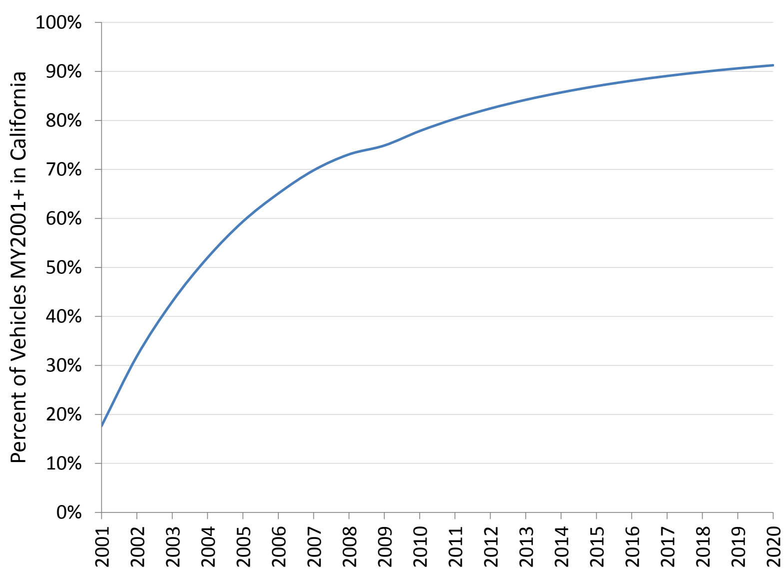
Even in a scenario in which cellulosic ethanol continues to struggle to achieve expected market penetration, innovation is occurring with other waste feedstocks. Most recently, Pantaleon Sugar Holdings applied for a pathway using molasses to produce ethanol with a carbon intensity of 22.75 g/MJ.

Higher blends of ethanol

As noted previously, reformulated gasoline includes 10 percent by volume ethanol. In order to achieve LCFS compliance, ICF considered the potential to move to higher blends of ethanol, including E15 and E85. ICF opted to focus on the introduction of E15 to increase ethanol volumes in California. The US EPA recently approved waivers for E15 consumption in model year 2001 and newer light-duty vehicles. There is considerable uncertainty today regarding the timing of E15 deployment in California. In order for the fuel to be sold in California, CARB would likely initiate a multi-media evaluation and would require modification of the predictive model used for gasoline formulations. Although original equipment manufacturers (OEMs) have strongly expressed hesitation regarding the use of E15 in vehicles, in order for regulated parties (i.e., refiners) to comply with the RFS2, they will likely have to move to higher blends of ethanol such as E15.

ICF used EMFAC2011[9] to estimate the percent of light-duty vehicles (passenger cars and light-duty trucks) that will be model year 2001 (MY2001) or newer by 2020, as shown in the figure below. ICF used this penetration curve to determine the maximum capacity of E15 that could be sold in California. As shown below, by 2018 90 percent of California's light-duty vehicle fleet is anticipated to be MY2001 or newer. An additional 600-650 million gallons of ethanol annually could be blended into gasoline by transitioning to E15.

Exhibit 31. Percent of Light-duty Vehicles MY2001 or Newer in California Fleet



We did not consider the potential for expanded E85 consumption in our scenarios. The potential expansion of the ethanol market via a transition to E15 is similar to the upper limit of an E85 market, assuming that flex-fuel vehicle (FFV) sales were to increase modestly over the next 5 years. Most recently, California drivers have consumed between 10-15 million gallons of E85 in FFVs. There are between 400,000 and 500,000 FFVs on the road in California today. This level of deployment indicates that theoretical consumption would peak around 240 million gallons if FFV drivers were to fuel their vehicles exclusively with E85.

One of the reasons we did not consider E85 more closely is because California drivers do not buy many FFVs. For instance, based on light-duty vehicle sales from 2012 reported by the California New Car Dealers Association (CNCDA), about 115,000-130,000 vehicles sold in California have FFV options. This does not mean that all of these vehicles sold were FFVs; rather, they had FFV models available. This represents about 8-10 percent of the market for

[9] The EMAFC model is issued by CARB and includes the emission factors that represent vehicle fleet, speeds, and environmental conditions associated with a project that are needed to perform project-level air quality modeling. More information is available online at: http://www.arb.ca.gov/msei/modeling.htm

light-duty vehicles and highlights one of the major challenges facing the E85 market: Of the top 10 top selling light-duty vehicles in California for 2012 – Toyota Prius, Honda Civic, Toyota Camry, Honda Accord, Toyota Corolla, Honda CRV, the Ford F-Series, Nissan Altima, Hyundai Sonata, and Toyota Tacoma – only the Ford F-Series offers a FFV model. These 10 models account for nearly 25 percent of the market, and only 7 percent of those sales (or 2 percent of the entire market) has an FFV alternative. In other words, absent changes in vehicle offerings from OEMs such as Toyota, Honda, and Nissan, it is unlikely that California's FFV population will increase significantly over the next 5 years.

4.2. Renewable Gasoline

Renewable gasoline is the term used for biomass-to-liquid processes – such as gasification, pyrolysis, or biochemical processes – that yield a product that can be used as a transportation fuel. The fuel is typically produced in several steps. For instance, fast pyrolysis of biomass yields a bio-oil that needs to be upgraded via hydrotreating; the stabilized oil can then be hydrocracked to produce renewable gasoline. Renewable gasoline is chemically similar to conventional gasoline, and in principle, can be distributed and combusted in the existing infrastructure and vehicles. For the purposes of this analysis, ICF assumed that 50 percent of the forecasted renewable gasoline produced in the United States would be available to California.

Companies such as Dynamic Fuels, KiOR, Sundrop, and UOP all are building commercial plants to manufacture these types of biomass-to-liquid fuels. Similarly, there are other firms, including Ensyn, Sapphire, and Solazyme that are seeking to produce a stable renewable oil from biomass or sugars that can be processed into renewable gasoline, renewable diesel, or renewable jet fuel. The long-term viability of renewable gasoline will be largely dependent on the ability of biofuel producers to reduce the costs of producing a stable oil for processing, which is currently the most expensive production process (see the table below).

Exhibit 32. Renewable Gasoline Production Costs via Pyrolysis (Haq, 2012)

Production Element	Production Costs ($/gallon)		
	2009 State of Technology	2012 Projection	2017 Projection
Feedstocks	$1.33	$0.99	$0.75
Feed drying, sizing, fast pyrolysis	$0.54	$0.52	$0.34
Upgrading to stable oil	$4.69	$2.01	$0.47
Fuel finishing	$0.30	$0.29	$0.11
Balance of plant	$0.82	$0.74	$0.65
Total	**$7.68**	**$4.55**	**$2.32**

Source: Haq, Z; Advanced Biofuels Cost of Production, October 2012. Available online at: http://www1.eere.energy.gov/biomass/pdfs/aviation_biofuels_haq.pdf

Although there have been significant advances in the production cost, the 2017 projections reported in the table above will require significant advances in technology and a stable supply of affordable feedstock. The $0.75 per gallon feedstock projection is equivalent to about $50 per dry ton of biomass; this is a commonly sourced estimate for the cost of biomass for biofuel production. However, ICF urges caution regarding cost projections for waste-based or byproducts because there is so much uncertainty in these markets. This uncertainty is attributable to the markets for many of these products being either emerging or nonexistent; therefore, it is unclear how market pricing will evolve. Despite these notes of caution, ICF's assumptions regarding the availability of renewable gasoline to the California market are conservative, and reach a maximum of about 90 million gallons by 2020.

4.3. Biodiesel

The significant potential for biodiesel to play a key role in LCFS compliance is being realized through a variety of industry investments. As a result of the LCFS and the recent extension of the Biodiesel Mixture Excise Tax Credit, 2013 promises to be a banner year for biodiesel consumption in California.

Biodiesel Production

The biodiesel industry has struggled in recent years with a significant portion of domestic capacity idled as a part of challenging economics. The extension of the tax credit for biodiesel blending will improve the industry's performance for 2013; however, the mid- to long-term outlook is unclear. In California, however, biodiesel consumption is poised to expand rapidly in large part due to very low levels of consumption in recent years (in the range of 20-25 million gallons in 2010, for instance).

There are several significant developments that have and will continue to support increased biodiesel consumption in California. Most notably, the low carbon intensity of biodiesel from corn oil reported by CARB in late 2011 has been a significant driver in the LCFS market to date. To a lesser degree, the low carbon intensity of other feedstocks such as recycled or waste oils has also played an important role in the early stages of LCFS compliance. Biodiesel consumption, mandated through RFS2, was 800 million gallons and one billion gallons in 2011 and 2012, respectively. Biodiesel production has exceeded these targets in both years, however, production volumes were about the same in 2011 and 2012.

As shown in the table below, the production of biodiesel from corn oil and recycled feedstocks were the only two to increase between 2011 and 2012. There is increasing evidence to suggest that these numbers are driven in part by California's LCFS, largely because these feedstocks yield biodiesel with a low carbon intensity. Furthermore, these feedstocks are generally cheaper than soy oil; for instance, corn oil has been selling in the range of 32-38 cents per pound for the past 18 months whereas soybean oil has been selling for closer to 50-55 cents per pound.

Exhibit 33. Feedstock Consumption for Biodiesel Production in the United States, 2011-2012

Feedstock	Feedstock Consumption for Biodiesel (million lbs)		
	2011	2012	Change
Canola Oil	847	787	-60
Corn Oil	304	571	267
Soybean Oil	4,153	4,023	-130
Animal Fats [a]	1,289	840	-449
Recycled Feeds [b]	666	900	234
Total	7,259	7,291	32

a. Includes poultry, tallow, white grease, and other.

b. Includes yellow grease and other.

Source: EIA

The nationwide potential for corn oil is significant: with a yield of approximately 5-7 gallons of corn oil per 100 gallons of corn ethanol, the upper limit of nationwide production is about 720 million gallons in 2020 according to the EIA. By the end of 2011, approximately 40 percent of ethanol production facilities in the US had corn oil extraction in place, and this likely increased further in 2012. ICF research indicates that nearly every corn ethanol production facility that can be retrofitted for corn oil extraction will have done so by the end of 2014. In California, for example, Pacific Ethanol announced plans in November 2012 to install a corn oil extraction system at its Stockton, California plant.

The scenarios developed for our study include 175-240 million gallons of corn oil biodiesel in 2020, representing a maximum of one third of domestic production in the same timeframe. With a carbon intensity of 4 g/MJ and LCFS credits trading at $40-45, the implied premium for corn oil biodiesel today is 47-53 cents per gallon. The LCFS market is likely to remain a strong driver for corn oil biodiesel consumption in California. Given that there is currently no parallel premium for corn oil biodiesel at the national or other state level, our team is confident that our assumptions regarding California consumption of corn oil biodiesel are conservative.

The scenarios also include about 50 million gallons of biodiesel produced from waste grease. Similar to corn oil, with a low carbon intensity and significant potential to expand the biodiesel market in California, we see the LCFS as a significant driver for biodiesel producers that can use feedstocks such as waste grease and animal fats.

In addition, the production of biodiesel in California has been boosted by awards from the CEC's Alternative and Renewable Fuel and Vehicle Technology Program. For instance, the program has awarded:

- Buster Biofuels received a $2.6 million grant for a production facility in the San Diego area that will produce about 5 million gallons per year.

- Eslinger Biodiesel Inc. received a $6 million grant to help build a biodiesel production facility in Fresno with an initial capacity of 5 million gallons per year, with potential expansion up to 45 million gallons per year.
- Springboard Biodiesel LLC received about $760,000 towards the construction of a pilot production facility in Chico with an annual production capacity of about 365,000 gallons.

Biodiesel Infrastructure and Vehicle Compatibility

With regard to infrastructure, pipeline operators and storage terminal operators are expanding storage capacity and biodiesel handling/blending capabilities significantly. As recently as 2010, the CEC reported that biodiesel terminal storage was severely limited.

Kinder Morgan made significant investments to expand biodiesel storage and delivery capacity at its Fresno and Colton terminals, with a reported throughput of 19 to 20 million gallons per year at each facility. As of late last year (2012), Kinder Morgan informed wholesalers that it will only sell B5 (a blend of 5 percent biodiesel with conventional diesel) at its Fresno and Colton facilities. Chevron made a similar announcement regarding the exclusive delivery of B5 at its facility in Montebello. Interviews with industry representatives indicate that at least four (4) refiners within California have proprietary terminals at which they are or have the capacity to blend biodiesel. ICF research indicates that there are at least 230,000 barrels of biodiesel storage capacity in California today. If we assume conservatively that these storage tanks have about 75 turns per year (i.e., the number of times each tank is emptied and filled) and that biodiesel represents about 15 percent of throughput at these facilities, then we estimate a biodiesel blending capacity of around 110 million gallons annually.

Based on ICF analysis and interviews with industry stakeholders, we anticipate storage capacity and blending capabilities in California to continue increasing over the next several years. The low-level biodiesel blend market (B5) will saturate around 200 million gallons per year. There is still significant potential to increase biodiesel blending beyond B5; however, higher blends of biodiesel will require more investment in retail infrastructure and consideration of engine manufacturer warranties, as discussed below.

- **Refueling infrastructure**. Most underground storage tanks (USTs) that are manufactured to store petroleum diesel blends can store B100 (i.e., pure biodiesel);[10] however, it's important to confirm that tank materials such as aluminum, steel, fluorinated polypropylene, and fiberglass make up the tank structure to ensure that degradation does not occur when using biodiesel. These materials must also be used in biodiesel fueling equipment to ensure that piping, spill and release detection equipment, dispensers, and dispenser nozzles are compatible with biodiesel blends.[11] Equipment materials that may lead to oxidation of biodiesel include brass, bronze, lead, zinc, tin, and copper. The U.S. EPA published final guidance on the subject in Volume 76, No. 28 of the Federal Register on July 5, 2011 to assist owners and operators of USTs in complying with the federal UST compatibility requirements promulgated under the authority of Subtitle I of the Solid Waste Disposal Act

[10] Petroleum Equipment Institute, UST Component Compatibility Library, Available online at: http://www.pei.org/PublicationsResources/ComplianceFunding/USTComponentCompatibilityLibrary/tabid/882/Default.aspx

[11] Oregon Department of Environmental Quality, "Biodiesel and Underground Storage Tank Systems", Available online at: http://www.deq.state.or.us/lq/pubs/factsheets/tanks/ust/BiodieselUSTSystems.pdf

(SWDA).[12] This guidance applies to biodiesel blends over 20 percent biodiesel that are stored in USTs. Currently, all newly manufactured USTs are compatible with blends of up to 100 percent biodiesel; however, EPA requires all UST manufacturers to provide a statement of compatibility for their products with biodiesel blends.

- **Engine warranties.** All diesel engine manufacturers selling into the US market provide warranties supporting blends of B20 or higher. The National Biodiesel Board has developed a summary table outlining OEM statements as they pertain to biodiesel blends – with the majority of engine manufacturers indicating that B20 can be used when it meets certain specifications such as ASTM D 6751 or fuel that is sourced from a BQ-9000 accredited producers.[13] Some notable exceptions of vehicle manufacturers that do not warranty above B5 include Kenworth and Peterbilt. Both are divisions of PACCAR Inc., which are still studying approvals for their trucks. It is also noteworthy that the engine manufactures supplying PACCAR have already approved B20.

The CEC has invested a modest amount of funding from the Alternative and Renewable Fuel and Vehicle Technology Program in biodiesel infrastructure, including:

- Pearson Fuels, in partnership with SoCo Group Inc. and InterState Oil Company received $1.8 million in grant funding to build two new biodiesel terminals with in-line blending capabilities.
- Whole Energy Pacific received about $125,000 to design, build, and install a biodiesel blending facility in Richmond, CA.

4.4. Renewable Diesel

Renewable diesel is similar to renewable gasoline in that it is produced via biomass-to-liquid processing. Renewable diesel, however, is currently being produced, primarily via hydrogenation of bio-oils, in commercial quantities and being consumed in California. In terms of chemical and physical properties, renewable diesel meets all the requirements of ASTM D975; in fact, Neste Oil's NExBTL product meets the fuel quality specifications of CARB diesel, meaning no modifications are needed to existing storage and transport infrastructure.

Neste Oil has been the most aggressive producer shipping renewable diesel to California. In 2010, Neste invested billions of dollars to build renewable diesel production plants in Singapore and Rotterdam (the Netherlands), in addition to facilities in Finland. All four of these facilities are operational; the Singapore plant is well situated to deliver renewable diesel fuel to California. It has been estimated that Neste will deliver about 100 million gallons of renewable diesel to consumers in California in 2013. Neste's NExBTL process is capable of using multiple feedstocks: Although the Singapore facility uses palm oil, which does not have a pathway under California's LCFS, the facility also uses tallow from Australia. The tallow based renewable diesel has a carbon intensity of around 33 g/MJ.

The renewable diesel industry will be expanding significantly in the near-term with the completion of Diamond Green's production facility in Norco, Louisiana. Diamond Green – a joint

[12] Federal Register, "Volume 76, No. 2", July 5, 2011, http://www.gpo.gov/fdsys/pkg/FR-2011-07-05/pdf/2011-16738.pdf

[13] Available online at: http://www.biodiesel.org/using-biodiesel/oem-information/oem-statement-summary-chart

venture between Valero and Darling International Inc – has a reported production capacity of 137 million gallons per year. Although the project is behind schedule, the most recent reports indicate that the facility will be online by the second quarter of 2013. Diamond Green has indicated to CARB that it plans to use four feedstocks for renewable diesel production at its facility: soy oil, corn oil, used cooking oil, and animal fat.[14]

4.5. Natural Gas

To develop natural gas projections, ICF consulted with the natural gas transportation fuel industry, analyzed trends within the natural gas market place and used the National Petroleum Councils Future Transportation Fuels Study.[15]

Recent advances in technology used to extract natural gas have drastically changed the landscape for natural gas in many applications. In the transportation sector, ICF considered the potential for increased natural gas consumption given the dramatic increases in supply, an expanding retail fueling infrastructure, and more vehicle offerings. Furthermore, the long-term potential for significant GHG reductions from natural gas in the transportation sector is tied to the deployment of biogas.

Increased Supply of Natural Gas

The increased discovery and production of shale gas reserves in the United States, including the Monterey Shale in the San Joaquin Basin, has decreased the cost of natural gas for all applications including electricity generation and transportation. Natural gas can be used as a transportation fuel as both compressed (CNG) and liquefied (LNG). CNG is favored in medium and light heavy-duty applications where there is a lower VMT per day and refueling can take place each night. This includes many local and regional commercial fleets and transit bus applications. LNG is preferred for heavy-duty applications with higher VMT such as long-haul trucking due to the increased energy density over CNG that requires less refueling.

Natural gas, due to its much lower fuel price, has the potential to contribute significantly to the future transportation fuel mix in California. This is especially true in Southern California where natural gas is required in certain market segments that include refuse applications. The greatest potential market for natural gas is in the medium and heavy duty commercial fleet and transit agency market segments, with significant annual VMT and a heavy emphasis on lifecycle cost. The higher annual VMT takes advantage of the lower fuel price compared to gasoline (medium-duty) and diesel (heavy-duty) and decreases the time needed for payback of the increased vehicle costs.

Expanding Retail Infrastructure

There are still limitations on natural gas as a transportation fuel including infrastructure and vehicle costs. Both CNG and LNG require additional and costly infrastructure to expand access.

[14] More information is available online at: http://www.arb.ca.gov/fuels/lcfs/2a2b/apps/dgd-sum-120112.pdf

[15] NPC Future Transportation Fuels Study: Advancing Technology for America's Transportation Future. Available online at: http://www.npc.org/FTF-80112.html

Natural gas' future in the transportation fuel market is evidenced by significant industry investments in refueling infrastructure. Clean Energy Fuels has teamed up with Pilot Flying J truck stops to create a nationwide network of natural gas refueling stations called America's Natural Gas Highway. As of February, the first 70 of the planned 150+ stations have been constructed. In addition, Clean Energy built 127 stations in 2012 for transit, refuse and airport applications. Shell has an agreement to build refueling stations at as many as 100 TravelCenters of America and Petro Stopping Centers and ENN, a privately held Chinese company, hopes to build 500 filling stations.[16]

To date, the CEC has awarded over $16 million towards natural gas fueling infrastructure through the Alternative and Renewable Fuel and Vehicle Technology Program.

Increased Vehicle Availability

On the vehicle side, UPS is seeking to increase their use of LNG vehicles over seven fold – from 112 to 800 – by the end of 2014, and companies such as Walmart are testing the use of natural gas[17] in their California fleet. Cummins-Westport is the main manufacturer of heavy-duty natural gas engines to date; they recently announced the availability of the Cummins ISX12 G engine, which will be in full production by August 2013. Cummins Westport also announced that it is developing the ISB6.7, a mid-range 6.7 L engine with plans for full production by 2015.

Apart from development in the heavy-duty engine market, there are an increasing number of natural gas vehicle offerings in lower weight categories. For instance, GM introduced the bi-fuel Chevrolet Silverado and GMC Sierra 2500 HD; these packages start at around $11,000. Meanwhile, Chrysler is offering the Ram 2500 CNG to retail customers. Similarly, Westport Innovations now has conversion kits for Ford's F series of medium-duty trucks – one of the top 10 selling vehicles in California during 2012 – at a retail price of $9,500. Wesport's WiNG technology is a bi-fuel system that has been demonstrated and deployed with success in the F-250 and F-350 models; and Westport recently announced that they are expanding the offering to the F-450 and F-550 trucks.

At price increments of $9,500-$11,000 and using current fuel pricing forecasts with natural gas about half to two thirds the cost of diesel, most consumers will see a two-to-three year payback period, which will push sales of natural gas vehicles higher.

Cummins Westport's advances in heavy-duty engines and increased OEM and conversion kit offerings in medium-duty trucks portend significantly higher sales of CNG and LNG in the near-term future. The volumes of natural gas in each of the compliance scenarios only require modest increases in new vehicles sales. For instance, if natural gas vehicles were able to capture 10-15 percent of new vehicles sales by 2020 in targeted vehicle segments, then this would displace upwards of 600 million gge. This would be in addition to California's existing natural gas consumption in the transportation sector of around 120 million gge.

[16] http://www.nytimes.com/2013/04/23/business/energy-environment/natural-gas-use-in-long-haul-trucks-expected-to-rise.html?pagewanted=all&_r=1&

[17] http://www.walmartstores.com/sites/responsibility-report/2012/fleetImprovements.aspx

To date, the CEC has awarded more than $28 million to natural gas vehicles within California through the Alternative and Renewable Fuel and Vehicle Technology Program.[18]

Biogas: Transition to a Lower Carbon Fuel

In the context of the LCFS, another driver for increased use of natural gas is biogas.[19] Biogas converted to CNG and LNG has some of the lower carbon intensity values evaluated by CARB. There is growing interest from regulated parties and natural gas fueling companies to invest in biogas projects since they have the potential to be a significant source of LCFS credits. Based on conversations with industry sources and operational projects sending biogas to California, an estimated 10 percent of natural gas used as a transportation fuel will be coming from biogas due to the LCFS.

4.6. Advanced Vehicle Technologies: PEVs and FCVs

Electricity and hydrogen used PEVs and FCVs, respectively, promise to play significant roles in LCFS compliance, particularly in the later years of program implementation. By 2020, estimated electricity and hydrogen consumption associated with PEV and FCV deployment in CARB's most likely compliance scenario account for nearly five percent of all credits generated.

Vehicle Sales

CARB's most likely compliance scenario yields about 500,000 ZEVs by 2020. Scenario 1 includes 1.13 million ZEVs and the LCFS Enhanced Scenario includes 1.31 million ZEVs by 2020. The projections for Scenario 1 are consistent with the types of sales that would be needed to achieve the long-term goal of the Governor's ZEV Action Plan,[20] which would yield 1.5 million ZEVs on the road by 2025.

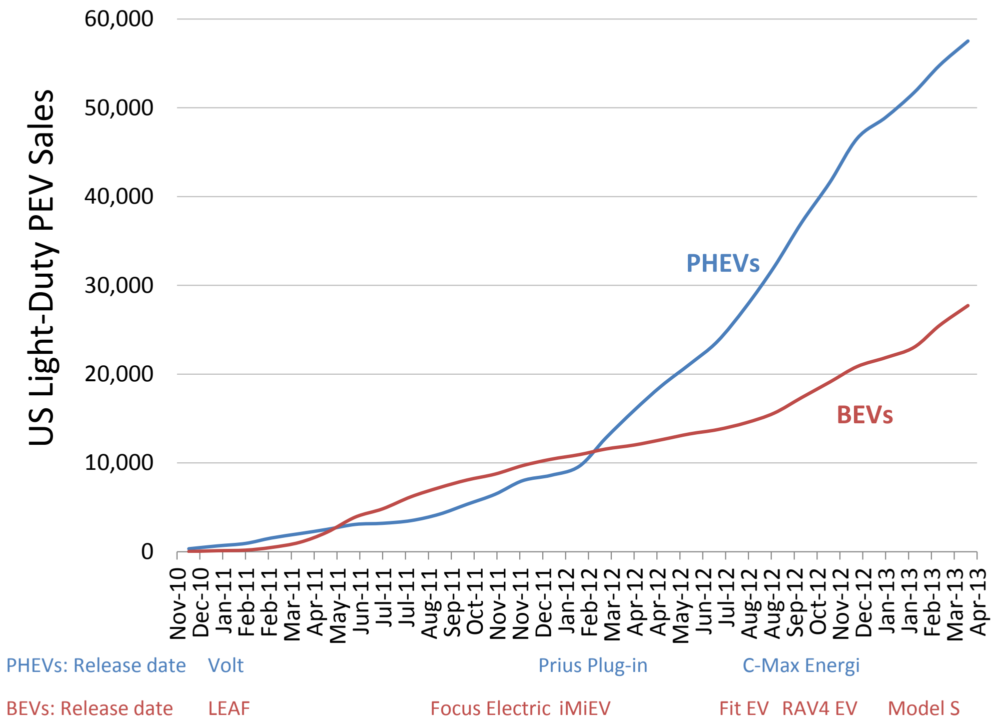
PEV sales in the US have been below some analysts' expectations; however, the initial data indicate that the vehicles are selling at a better rate than the original deployment of hybrid electric vehicles (HEVs) in the early 2000s. Moreover, sales have been bolstered by far more PEV offerings compared to the initial launch of HEVs (see figure below for cumulative PEV sales in the US; the model of vehicles at the bottom of the graph indicate when those became commercially available): Each major OEM is now selling either a PHEV or BEV, and they are competing with upstarts such as Tesla Motors.

[18] http://www.energy.ca.gov/2012publications/CEC-600-2012-008/CEC-600-2012-008-CMF.pdf

[19] Biogas is the gaseous product of anaerobic digestion (decomposition without oxygen) of organic matter.

[20] 2013 ZEV Action Plan: A roadmap toward 1.5 million zero-emission vehicles on California roadways by 2025, Office of Planning and Research. First Draft available online at: http://opr.ca.gov/docs/Governor's_Office_ZEV_Action_Plan_(02-13).pdf

Exhibit 34. Cumulative PEV Sales in the United States through April 2013



Most analysts estimate that about 35-40 percent of PEV sales nationwide are in California. Consumers are drawn to incentives such as rebates of $1,500 for PHEVs and $2,500 for BEVs from the Clean Vehicle Rebate Project (CVRP) and the Green or White Clean Air Vehicle Stickers that provide single occupant vehicles use of high occupancy vehicle (HOV) lanes. The CVRP has been so successful that CARB and CEC recently agreed to add $6 million and $4.5 million respectively to the rebate program's funds to extend the availability of funds until next year's funds are available. Even with the success of the CVRP, conversation with staff at the California Center for Sustainable Energy (CCSE), which administers the CVRP, indicate that there are still a significant number of PEV buyers do not take advantage of the rebate program. CCSE worked with OEMs to determine that in some cases, only 75 percent of owners of select PEVs apply for the rebate.

The PEV deployment scenarios assume that OEMs will continue to have more vehicle offerings at more attractive pricing out to 2020. The more aggressive scenarios include higher penetrations of PHEVs, with more modest increases in BEVs and FCVs. This reflects the automotive industry's focus on PHEV technology. For instance, in a recent survey of automotive industry executives, KPMG reports that 29 percent of OEMs and 23 percent of suppliers are making the biggest investments in plug-in hybrid technology over the next five years, second only to investments in internal combustion engine (ICE) downsizing (see table below).[21]

[21] KPMG's Global Automotive Executive Survey 2013: Managing a multiidimensional business model. Available online at: http://www.kpmg.com/SK/en/IssuesAndInsights/ArticlesPublications/Documents/Global-automotive-survey-2013.pdf.

Exhibit 35. Percentage of OEMs and Suppliers Making Investments in Powertrain Technologies in the Next 5 Years

Powertrain technologies	OEMs	Suppliers
ICE downsizing	31%	24%
Plug-in hybrid	29%	23%
Hybrid fuel systems	18%	11%
Battery (range extender)	10%	18%
Pure battery	6%	13%
Fuel cell	6%	11%
Source: KPMG Global Auto Executive Survey 2013		

Some OEMs have already taken aggressive measures to increase PEV sales. For instance, Nissan LEAF cut the price of the LEAF by $6,400 in 2013, leading to a significant resurgence in sales approaching 5,500 vehicles in the first four (4) months of 2013, or 2.5 times more LEAFs sold in the same period in 2012. Information from Tesla's recent first quarter filings also indicate the competitive nature of the PEV industry. Tesla's first quarter earnings were bolstered considerably by the sale of ZEV credits to other OEMs. Tesla's financial filings indicate sales of $68 million of ZEV credits;[22] each of Tesla's vehicles generated five ZEV credits because their vehicles have a range greater than 200 miles. With estimated sales of 4,900 vehicles, this values the credits at about $14,000 per vehicle. Going forward, there will be a strong financial incentive for other OEMs to develop ZEVs rather than paying out such large sums to competitors like Tesla.

Vehicle sales will likely also be bolstered by decreasing battery prices. Apart from technological improvements and economics of scale, the global capacity of lithium-ion battery manufacturing is drastically over-supplied. For 2013, global production capacity is estimated to be nearly 4,000 MW; however, the demand for batteries is an order of magnitude less – around 400 MW. This over-supply will likely lead to industry consolidation in the next several years and may yield lower battery prices.

CARB and CEC continue to report via surveys of major OEMs that they are planning on rolling out tens of thousands of hydrogen fuel cell vehicles in California over the next 2-4 years. As recently as 2012, OEMs indicated that they plan on achieving sales upwards of 55,000 vehicles by 2017 in California. These numbers are bolstered by action: Hyundai recently announced the limited assembly-line production of its ix35 FCV, and although the vehicle will likely be sold in Europe for the first several years of production, it portends positive developments in the fuel cell vehicle industry.

Fueling Infrastructure for ZEVs

There has been a major push to deploy sufficient infrastructure for PEV and FCV adoption:

[22] Tesla Motors Inc – First Quarter 2013 Shareholder Letter. Available online at: http://tinyurl.com/Tesla1Q

- Level 2 Electric Vehicle Supply Equipment (EVSE) and DC fast charging EVSE are being deployed rapidly around the State of California using grant funding provided by the Department of Energy (DOE) and CEC. Many EVSE were deployed as part of ECOtality's EV Project and Coulomb Technologies' ChargePoint America.
- Furthermore, another $100 million will be spent by NRG as part of a settlement with the California Public Utilities Commission (CPUC) – these funds are dedicated to installing at least 200 so-called Freedom Stations (i.e., DC fast charging EVSE) and 10,000 Make-Readies (i.e., the pre-wiring and conduit required for Level 2 EVSE).
- The CEC is coordinating the deployment of hydrogen fueling stations with funding from the Alternative and Renewable Fuel and Vehicle Technology Program. Current estimates indicate that about 20 publicly available stations will be online by the end of 2013, up from eight today.

4.7. LCFS Enhancements

Electricity Consumed in Non-Road Applications

CARB is actively considering proposed changes to LCFS for electricity used in fixed guideway transportation applications and for forklifts. CARB staff are using a methodology similar to the one developed by ICF staff (previously with TIAX LLC) for CalETC as part of another project.[23]

- For electricity used in fixed guideway applications, the National Transit Database was used to calculate energy consumption per mile for transit agencies in California. These data were coupled with ridership data from Los Angeles Metropolitan Transportation Authority (Metro) and Bay Area Rapid Transit (BART). The research team accounted for planned and implemented rail expansions by holding the ratio of passenger to track miles constant for each transit agency.
- For electricity used in forklifts, the research team developed population estimates based on US factory shipments of electric rider (Class 1 and 2) and motorized hand (Class 3) forklifts from 2000-2010. These shipments were pro-rated (conservatively) based on population statistics to develop California-specific estimates. The potential LCFS credits that could be generated were based on an EER of 3.0, assuming that electricity is replacing diesel, an operational frequency of 3,150 hours per year, and an average daily load of 4.36 kW for Class 1 and Class 2 and 1.25 kW for Class 3.

CARB is actively developing the methodology to present to the Board regarding electricity used in fixed guideway applications and forklifts. These areas have significant potential to increase the number of LCFS credits available and improve the outlook for LCFS compliance.

Innovative Crude Recovery Methods

Pursuant to the November Final Regulatory Order for the LCFS, [24]

[23] California LCFS Electric Pathway – On-Road and Off-Road. TIAX LLC, November 2012. Available online at: http://www.caletc.com/wp-content/uploads/2012/12/TIAX_CalETC_LCFS_Electricity_Potential_FINAL.pdf

[24] http://www.arb.ca.gov/fuels/lcfs/CleanFinalRegOrder112612.pdf

> A regulated party may receive credit for fuel or blendstock derived from petroleum feedstock which has been produced using innovative methods. For the purpose of this section, an innovative method means crude production using carbon capture and sequestration or solar steam generation that was implemented by the crude producer during or after the year 2010 and results in a reduction in carbon intensity for crude oil recovery (well to refinery entrance gate) of 1.00 gCO2E/MJ or greater.

Crude oil recovery in California utilizes a significant amount of steam production through its steam flooding and cycling steam injection operations. The California Department of Conservation Oil and Gas production data from January 2011 to June 2012 show 1,300 thousand barrels per day of steam is utilized for crude production. According to the 2009 Annual Report of the State Oil and Gas Supervisor,[25] Forty two percent of steam produced for oil recovery in California comes from cogeneration and the balance from simple once-through steam generator (OTSG). The steam from OTSG is the potential market for renewable steam generation and carbon capture and storage (CCS). ICF estimated the potential credits generated through innovative crude oil recovery based on work that ICF staff (previously working for TIAX LLC) conducted for NRDC.[26] The research included the following assumptions:

- Renewable steam generation technologies such as BrightSource and GlassPoint could offset GHG emissions from combustion and upstream sources while CCS could only sequester those emissions from combustion.
- Based on the Oil Production Greenhouse gas Emissions Estimator (OPGEE) developed by Stanford University for CARB, OTSG requires 401,537 Btu of natural gas/bbl of steam and 1.9×10^8 MMBtu per year of natural gas. From the CA-GREET model, an estimated 66,677 gCO2e/MMBtu are a result of upstream production and transport of natural gas and combustion while 58,350 gCO2e/MMBtu are a result of combustion alone.
- In their analysis, TIAX did not assume an increase in steam production between 2012 and 2020.
- Furthermore, TIAX assumed a maximum total market share of 10 percent of OTSG steam production in 2020 in California is converted to renewable steam generation and CCS and is split equally between them. Because the standard is performance-based, crude production from other regions could also incorporate similar technologies. This potential was not analysed in this study.

Other GHG reduction options along the supply chain for conventional fuels, including reduced venting, flaring, and leakage were not considered. Moreover, improvements to petroleum refinery energy efficiency, the use of combined heat and power, and incorporation of renewable feedstocks or energy inputs at refineries were not included in this analysis. These types of GHG reduction measures are not currently eligible to receive a carbon intensity reduction under the LCFS.

[25] 2009 Annual Report of the State Oil & Gas Supervisor, California Department of Conservation, 2010. Available online at: ftp://ftp.consrv.ca.gov/pub/oil/annual_reports/2009/PR06_Annual_2009.pdf

[26] California Low Carbon Fuel Standard (LCFS): Potential Emission Reductions from Petroleum, TIAX LLC for National Resources Defense Council, February 2013.

5. Next Steps

The first phase of this project has focused on developing LCFS compliance scenarios, harnessing a combination of existing market data with realistic projections of the availability of low carbon fuels out to 2020. These scenarios demonstrate how the LCFS requirements can be achieved through modest changes in the diversity of transportation fuels supplied to California.

5.1. Overview of Macroeconomic Modeling

The second phase of this project focuses on the macroeconomic impacts of the compliance scenarios presented here. ICF is using the REMI model to perform the economic modeling. The REMI model is well suited to assess the dynamic impacts of assessing regulations with impacts into the future, such as California's LCFS. With impacts out to 2020, it is important to have a dynamic model that allows for behavior such as technological change and adaptation. The modeling is performed by determining the changes in economic parameters relative to a reference scenario (or a business-as-usual scenario). Each scenario has associated expenditures in areas such as industry investments required to deploy alternative fuels and consumer expenditures associated with fuel consumption or vehicle purchases. The types of parameters that the macroeconomic impact analysis will consider in detail include the following:

- Changes in gross state/regional product
- Changes in employment and income
- Changes in total economic production
- Inter-industry and aggregate impacts

5.2. Other economic and environmental impacts

Although the second phase of the project focuses on macroeconomic impacts, the ICF team is also assessing the air quality and GHG benefits of the compliance scenarios. Our assessment includes the emission reductions and the corresponding monetization of those benefits. More specifically, our team is investigating the following impacts:

- **Air quality pollutants**: Pollutants are generally considered negative externalities and researchers have attempted to capture the value of avoided emissions in the form of health and environmental benefits. The EPA has developed cost per ton estimates of the health benefits achieved by reducing criteria air pollutant emissions. The health benefits of reducing transportation-related emissions will depend on a large number of local factors, including the overall levels of pollution in the area and the presence of individuals sensitive to air pollution, among others. Further, the unit risk factors, i.e. the estimated health damage per unit of emissions, for several of the emissions are still a matter of research as state and federal agencies differ on their values.
- **GHG emissions**: Recently, estimates have been developed to monetize the benefits of reducing GHG emissions via a parameter termed the social cost of carbon (SCC). The SCC is an economic parameter employed to estimate the economic cost of an addition ton of CO_2-equivalent emissions. More precisely, this term is the "change in the discounted value

of the utility of consumption denominated in terms of current consumption per unit of additional emissions".[27] Most recently, the US government concluded a year-long process to develop a range of values for SCC and these values are to be used in benefit-cost analyses to assess potential federal regulations. In 2007 dollars, the recommended central value is \$21/ton of CO_2 emissions; the final report also recommends conducting sensitivity analyses conducted at \$5, \$35, and \$65.[28]

- **Reduced petroleum dependence**: Paul Leiby at the Oak Ridge National Laboratory (ORNL) estimated the energy security benefits of reduced US oil imports.[29] The research focuses on two components of energy security benefits: monopsony and macroeconomic disruption or adjustment costs. The benefit of displacing imported oil is reported with a mid-point of nearly \$14 per barrel of oil (in 2004 dollars). For the sake of comparison, based on information available from the EIA, about 50% of the oil refined to produce gasoline and diesel is imported. For illustrative purposes, this yields a monetized benefit of reduced U.S. oil imports of about \$0.81 per gallon of diesel or gasoline after adjusting for inflation, with a low/high scenario of \$0.40 and \$1.39 per gallon.

California's Low Carbon Fuel Standard: Compliance Outlook & Economic Impacts

Final Report

April 2014

Prepared for:

California Electric Transportation Coalition

California Natural Gas Vehicle Coalition

Environmental Entrepreneurs

Advanced Biofuels Association

National Biodiesel Board

Ceres

Outline

- Introduction
- Review of Compliance Scenarios
- Introduction to REMI Modeling
- Review of Model Inputs
- Fuel Pricing and LCFS Credit Pricing
- REMI Modeling Results
- Monetized Externalities
- Summary and Conclusions

Introduction

California's Low Carbon Fuel Standard

- In 2007 Governor Schwarzenegger signed Executive Order S-01-07 establishing California's Low Carbon Fuel Standard (LCFS), which requires a ten percent reduction in the carbon intensity of transportation fuels by 2020.
- The LCFS is a flexible market-based standard implemented using a system of credits and deficits:
  - **Carbon intensity** is measured on a lifecycle or well-to-wheels basis in units of grams of carbon dioxide equivalent per unit energy of fuel (gCO2e/MJ).
  - The LCFS is implemented using a system of **credits and deficits**. Fuels with a carbon intensity lower than gasoline and diesel earn credits. Gasoline and diesel generate deficits.
  - At the end of each year, compliance is achieved by offsetting deficits with credits. Credits can be banked and traded, and they do not lose value over time.

Scope of Work

- The objective of this study was to characterize the macroeconomic impacts of LCFS compliance, and the co-benefits. This study had two phases.
- In the first phase of work, ICF developed scenarios that represent a range of likely outcomes towards LCFS compliance.
  - Scenarios are intended to capture the range of potential market developments that would lead to LCFS compliance given our current outlook on the transportation fuel marketplace.
  - In any forward-looking exercise, it is important to note that there is some uncertainty associated with the availability of lower carbon fuels.
- In the second phase of work ICF characterized the macroeconomic impacts and associated co-benefits of LCFS compliance.
  - Macroeconomic impacts were estimated using the REMI model
  - The co-benefits we considered include: GHG emission reductions, criteria pollutant emission reductions, and petroleum reductions.

Review of Compliance Scenarios

Scenario Analysis

- ICF developed a reference scenario and two LCFS compliance scenarios, referred to as Scenario 1 and Scenario 2, in the first phase of our work to estimate the macroeconomic impacts of the LCFS. The stakeholder group developed the final compliance scenario, referred to as the LCFS Enhanced Scenario. The macroeconomic impacts reported are based on the difference between the compliance scenario and the reference scenario.
- A more detailed review of the scenarios, including the fuel volumes, forecasts, compliance options considered, and an alternative fuel market assessment are available in a separate report. That report is available online at: http://www.caletc.com/wp-content/downloads/LCFSReportJune.pdf

REVIEW OF COMPLIANCE SCENARIOS

Summary Table

Scenario	Ethanol	Biodiesel	Adv Biofuels	Electricity / Hydrogen	Natural Gas	Assumptions for all scenarios
Reference Scenario	Limited to E10. Mostly MW corn ethanol.	Very limited; about 25 million gallons	Federal RFS2 identified as only major driver for consumption in California absent LCFS	ZEV Program: most likely compliance scenario; about 500,000 ZEVs on the road by 2020: 26k FCVs, 120k PHEVs, 350k BEVs	Based on CEC projections: about 220 million gallons	Constrained low carbon corn ethanol at 1 billion gallons (200 MGPY in California). Assumed 56% of VMT in PHEVs is electric. Banking/trading of credits is included in our analysis. Over-compliance in early years. Significant room for over-compliance in diesel sector.
Scenario 1	Ethanol blend increased from E10 in 2019-2020. Assume some E15 is consumed. 500 MG sugarcane ethanol.	420 million gallons blended into diesel by 2020: soy, waste grease, corn oil, canola.	410 MG cellulosic ethanol 89 MG drop-in gasoline substitute 125 MG renewable diesel	Proportionally similar distribution to most likely compliance scenario; total of 800k vehicles. Electricity consumed in forklifts and fixed guideway applications included	Aggressive introduction of CNG/LNG in MD/HD sectors. 900 million gallons consumption by 2020. 10% RNG consumption.	
Scenario 2	Limited to E10. 500 MG sugarcane ethanol.	560 MG blended into diesel by 2020: waste grease, corn oil, canola.	430 MG cellulosic ethanol 89 MG drop-in gasoline substitute 220 MG renewable diesel	ZEV Program compliance Electricity consumed in forklifts and fixed guideway applications included	Modest increase in CNG/ LNG consumption. 650 million gallons consumed. 10% RNG consumption.	
LCFS enhanced	Limited to E10. 230 MG sugarcane ethanol	440 MG blended into diesel by 2020: soy, waste grease, corn oil, canola.	50 MG cellulosic ethanol 89 MG drop-in gasoline substitute 130 MG renewable diesel	Accelerated adoption scenario: 1.2 million PEVs on the road by 2020 Electricity consumed in forklifts, fixed guideway, port equipment, e-TRUs, TSE, small non-road applications included	1.1 billion gallons consumption by 2020. 10% RNG consumption.	Includes credits earned through enhanced crude oil recovery techniques e.g., solar powered steam.

Introduction to REMI Modeling

REMI Model Description

ICF employed the REMI Policy Insight Plus v1.4 to measure the wider macroeconomic impacts of the compliance scenarios developed in this study. Some key aspects of the REMI Model:

- Peer reviewed structural economic modeling, forecasting and policy analysis tool
- Dynamic regional economic impact model using a combination of input-output, econometric, and computable general equilibrium techniques
- 70 NAICS-based sectors, 2 regions
- Ability to forecast impacts over time
- All results are presented in 2020 for this study

REMI Model Description, ctd

- REMI can produce a wide variety of economic and demographic outputs:
  - overall employment levels
  - employment by industry sector
  - value added output
  - output by sector
  - changes in income
  - population or demographic shifts.
- This study focused on analyzing the impacts to employment, personal income, and gross state or domestic product (GSP or GDP).
- Inputs to the REMI model for each scenario were derived from the outputs of ICF analysis of each compliance scenario. For example, the compliance scenarios modeled in REMI included expenditures for fuel production, distribution infrastructure (including transportation, storage, retail infrastructure, vehicles, and fuel pricing.

Overview of Model Inputs

Introduction

ICF developed estimates for the investments that would be required to achieve the compliance scenarios. ICF considered three broad types of expenditures:

- **Fuel production / upstream expenditures:** Many of the alternative fuels will require significant investments in expanded production. To the extent feasible, ICF identified production that would happen in California and the rest of the United States.

- **Distribution infrastructure expenditures:** While the compliance scenarios include drop-in fuels that are compatible with existing distribution infrastructure such as renewable diesel and renewable gasoline, other fuels will require infrastructure in storage terminals and refueling equipment. Distribution infrastructure costs were modeled as an increase in exogenous final demand for industries involved in equipment manufacturing or building new infrastructure.

- **Vehicle expenditures:** In the case of electricity, hydrogen, and natural gas, new light- and heavy-duty vehicles will need to be purchased to achieve the levels of fuel consumption included in the penetration scenarios.

Overview of Alternative Fuel Investments

Fuel	Fuel Production	Distribution infrastructure	Vehicle Expenditures
Ethanol	Yes; feedstock specific. Continued CA production, most from Rest of US	E15 infrastructure for S1	N/A; MY2001+ can use E15
Renewable Gasoline	Yes; focused on biomass feedstock. Produced outside of CA	N/A; drop-in fuel	N/A; drop-in fuel
Biodiesel	Yes; feedstock specific. Increased utilization in CA, balance produced in Rest of US	Yes; terminal storage, blending equipment, fueling stations	N/A; overwhelming number of diesel engines warrantied for use up to B20
Renewable Diesel	Yes; focused on tallow. Produced outside of CA	N/A; drop-in fuel	N/A; drop-in fuel
Electricity	Yes; small b/c assumed significant TOU charging and increased utilization of assets	EVSE (L1, L2, DC fast)	PEV cost curves from CalETC study (Roland-Holst 2012) Included federal tax credit
CNG	No; transportation is small fraction of total production	Yes; mix of slow- and fast-fill stations	NGVs in medium-, and heavy-duty sectors
LNG	Yes; mostly liquefied outside of CA	Yes; LNG stations	
Biomethane	Yes; injected in-state and from out-of-state	No; accounted for in CNG and LNG	

Conventional Fuels – Gasoline and Diesel

Overview

LCFS compliance yields varying levels of decreases in gasoline and diesel consumption in California. Although the reduction of petroleum consumption has positive impacts via improved energy security and increased fuel diversity, the decreased consumption of petroleum will also have direct negative impacts on the refining industry – in the same way that the investments in alternative fuels and advanced vehicles will yield positive impacts in the corresponding industries. ICF treated the reduction in gasoline and diesel consumption in the modeling as follows:

- ICF assumed that there were lost margins on 50% of those crude runs that are assumed to be displaced entirely as a result of the LCFS. These margins were estimated based on an ICF analysis of the 3-2-1 crack spread for California-based refiners (estimated at about $15/bbl)

- ICF assumed that the remaining 50% of crude runs representing the reduction in gasoline and diesel consumption in California are exported, rather than displaced entirely. For these exports, ICF assumed a corresponding decrease in revenue in the export markets because of increased freight costs (estimated at $5/bbl).

Fuel Pricing and LCFS Credit Pricing

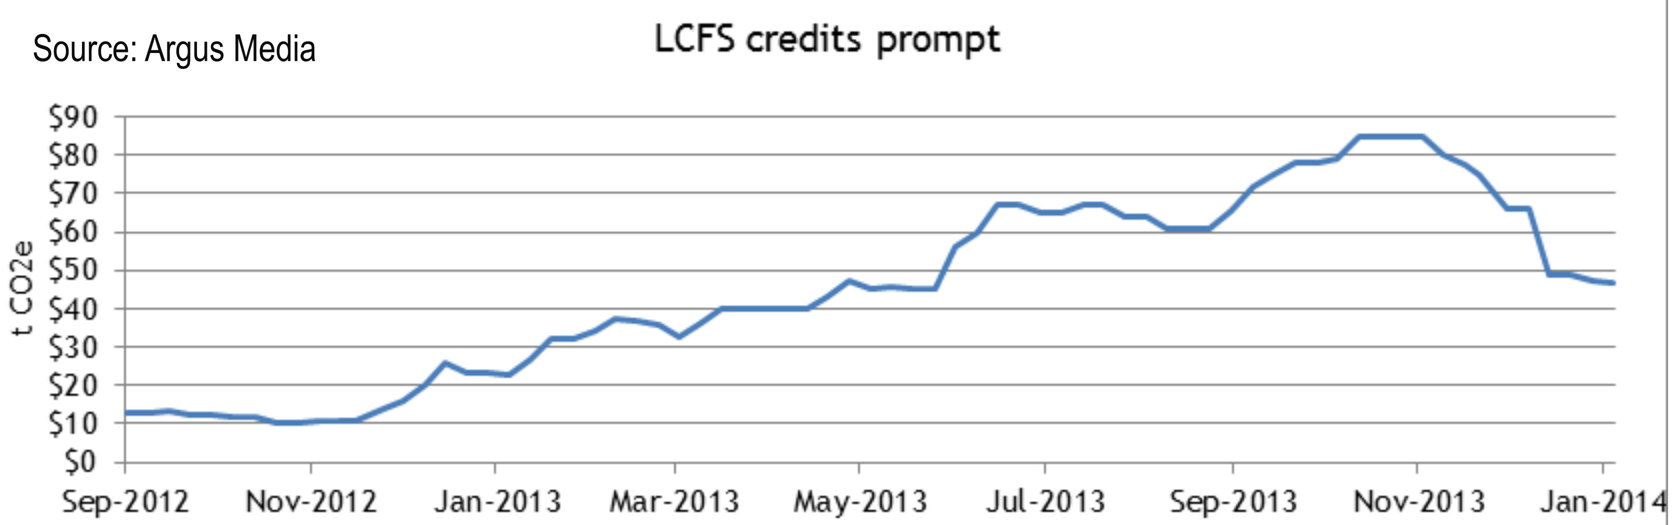
Fuel Pricing

- One of the key limitations of REMI is that it is not explicitly an energy model. Most notably, the model is not designed to predict changes in demand and supply for fuels, or the impacts on fuel pricing. In response, ICF augmented REMI by developing a supplementary estimate of fuel prices through 2020.
- ICF considered several components of fuel pricing as inputs into the REMI modeling. We sought to capture the likely impacts on fuel pricing as a result of LCFS compliance. ICF used fuel pricing forecasts from 2011 Integrated Energy Policy Report (IEPR), adjusted for actual fuel prices reported in California for 2011 and 2012.

Review of LCFS Credit Prices

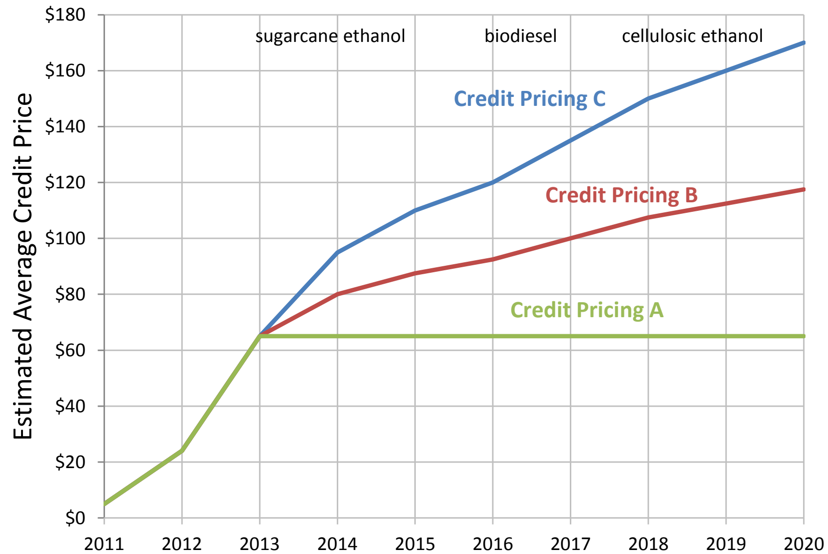
- The LCFS credit market today is relatively illiquid and immature. It is also difficult to determine what is driving credit prices.
  - The majority of credits are being transferred to regulated parties (mainly refiners / importers of fuel), rather than purchased in the LCFS credit market.
  - These credit transfers are currently happening at the point of blending biofuels like ethanol, biodiesel, or renewable diesel into CARBOB or diesel.
  - CARB reports 1.15 million credits have been traded via 271 credit transfers through February 2014. However, over that same period, nearly 6 million credits have been generated.

Source: Argus Media



LCFS Credit Pricing

- Stakeholders identified three credit pricing variations for ICF to model with each compliance option:
  - Pricing A: Future credit prices are fixed at the weighted average of credit prices in 2013, about $65/ton
  - Pricing B: Credit prices are an average of Pricing A (see above) and Pricing C (see below).
  - Pricing C: Credit prices reach a peak of around $170/ton in 2020. The profile for credit increases is a function of what is considered the implied price of carbon based on the premium of the associated alternative fuel. The pricing is largely defined by the premium paid for a) sugarcane ethanol, b) biodiesel (from various feedstocks), and c) cellulosic ethanol.



Treatment of LCFS Credit Prices in REMI

- ICF's treatment of LCFS credit prices was based on the recipient of credits, as outlined by the regulation.
  - For entities that sell the credits or credit generators – such as ethanol producers, biodiesel producers, and natural gas refueling infrastructure owners – ICF modeled credits as a decrease in production costs.
  - ICF modeled credit purchases (made by entities producing or importing CARBOB and ULSD) as an increase in production costs.
  - In the case of credits generated through the use of electricity as a transportation fuel, ICF assumed that the value of the credit would be passed to the consumer, per the requirements of the regulation. There are provisions for entities other than utilities to earn LCFS credits for the use of electricity as a transportation fuel. However, we made a simplifying assumption that the utilities would earn all of the credits generated by electricity consumption.

REMI Modeling Results

Overview

- As noted throughout this report, ICF has generally defaulted to conservative assumptions to enhance the study's credibility. Because the study's assumptions are generally conservative, the results of our modeling likely understate the full magnitude of economic benefits.
- Our results focus on the following changes resulting from the three LCFS compliance scenarios compared to the Reference Scenario:
  - Changes in employment;
  - Changes in personal income; and
  - Changes in gross state product (GSP)
- The following tables report the changes from the Reference Scenario for California:
  - Absolute change
  - Percent change

Employment

Scenarios	Credit Pricing Variations		
	A	B	C
California | EMPLOYMENT, jobs			
Scenario 1	4,100	3,900	3,700
	0.02%	0.02%	0.02%
Scenario 2	-5,300	-6,900	-8,500
	-0.02%	-0.03%	-0.04%
LCFS Enhanced	8,300	8,700	9,100
	0.04%	0.04%	0.04%

REMI MODELING RESULTS

Personal Income

Scenarios	Credit Pricing Variations		
	A	B	C
California | PERSONAL INCOME, $ billions			
Scenario 1	0.44	0.44	0.44
	0.02%	0.02%	0.02%
Scenario 2	-0.28	-0.36	-0.43
	-0.01%	-0.02%	-0.02%
LCFS Enhanced	0.90	0.84	0.89
	0.04%	0.04%	0.04%

REMI MODELING RESULTS

Gross State Product

Scenarios	Credit Pricing Variations		
	A	B	C
California | GSP, $ billions			
Scenario 1	0.43	0.40	0.38
	0.02%	0.02%	0.02%
Scenario 2	-0.50	-0.64	-0.79
	-0.02%	-0.03%	-0.03%
LCFS Enhanced	0.75	0.91	0.95
	0.03%	0.04%	0.04%

Discussion

- There are net positive macroeconomic impacts for each of the three scenarios.

- The macroeconomic impacts, however, are very small.
  - The range of impacts across the parameters considered – employment, income, and GDP/GSP, vary from -0.04% to 0.04%.
  - Despite the significant investments that are necessary to comply with the LCFS, these investments are a small fraction of overall macroeconomic activity.
  - In all cases, economic growth continues – it is not reversed. Even in the case of Scenario 2, in which there are small negative impacts in California, economic growth is not reversed. Rather it is very slightly reduced from its growth trajectory.

Discussion, ctd

- Fuel diversification leads to positive impacts in California.
  - Scenario 1 and the LCFS Enhanced Scenario demonstrate positive impacts in California.
  - The ratio of income/employment (gains), a proxy for the value of the types of jobs added, is nearly double the ratio of income/employment (loss) in Scenario 2 (see next slide). Good indicator that investments towards diversification provide higher value jobs.
  - These scenarios have more significant penetration of electricity and natural gas; but still significant blending of liquid biofuels.
  - Natural gas and electricity help offset some of the higher costs attributed to blending lower carbon biofuels.
  - They also lead to significant investments in infrastructure (charging infrastructure and natural gas stations) and vehicles – both positive drivers in the model.
  - Electric vehicles also benefit from the federal tax credit, which boosts consumer spending by returning money to California.

Discussion, ctd

- Scenario 2 yields small negative impacts in California.
  - Economic growth is not reversed; it is simply slightly reduced from its growth trajectory.
  - The income/employment ratio is lower than Scenario 1 and LCFS Enhanced Scenario – tied to reductions in growth for specific types of jobs.
  - Because ZEVs are deployed at the same level as the baseline case, there is no *incremental* benefit associated with electricity consumption as a transportation fuel or *incremental dollars* flowing to California via the federal tax credit for PEVs.
  - There are some benefits captured from electric forklifts and fixed guideway applications.
  - Scenario 2 has the most significant deployment of liquid biofuels – ethanol, biodiesel, renewable gasoline, and renewable diesel. This leads to two factors:
    - *ICF forecasts – and our data sources such as the EIA and CEC, assume higher near-term costs for liquid biofuels. With less electricity and natural gas consumption to mitigate higher fuel expenditures, this contributes to the small negative impacts.*
    - *ICF assumes that most liquid biofuels will be produced out-of-state.*

Discussion, ctd

- Several sectors consistently show positive economic impacts across all modeling scenarios, with the primary driver(s) in blue:
  - Motor vehicles, bodies and trailers, and parts manufacturing | Increased alternative fuel vehicle sales
  - Chemical manufacturing | Increased biofuel production
  - Utilities | Increased utilization of assets through electric vehicle charging
  - Electrical equipment and appliance manufacturing | EVSE deployment
  - Primary metal manufacturing | Expanded distribution and fueling infrastructure
  - Transportation (via Rail, Marine, Truck) | Liquid biofuel transport
- The Petroleum and Coal Products Manufacturing Sector has the largest percentage decrease in rate of growth in employment across all modeling runs.
  - These impacts are small, ranging from -1.0% to -0.4%.
  - In other words, these impacts are not significant enough to indicate an economic disruption such as a refinery closure.

Monetized Externalities

Introduction

Alternative fuels and advanced vehicles have a variety of benefits and costs. Apart from the traditional financial metrics and macroeconomic impacts associated with alternative fuel use, ICF estimated the environmental benefits and associated monetized value of:

- Reduced GHG emissions
- Reduced criteria air pollutants
- Displaced petroleum

GHG Emission Reductions

- The LCFS will result in significant economic benefits associated with avoiding damages associated with incremental increases in carbon emissions. The monetized value of damages avoided as a result of CO_2 reductions, including changes in net agricultural productivity, human health and flooding, is referred to as the social cost of carbon (SCC).

[1] R_d is the social discount rate used in the modeling exercise; not the discount rate used by ICF in the analysis.

We estimate that the net present value of SCC for LCFS compliance in 2020 ranges from $497 million to $3.26 billion.

The low value corresponds to the LCFS Enhanced scenario using a 7% discount rate (and 5% discount rate for SCC); the high value corresponds to Scenario 2 using a 2% discount rate (and 2.5% discount rate for SCC, see previous slide)

Criteria Air Pollutants

Introduction

- Criteria air pollutants such as nitrogen oxides (NOx) and particulate matter (PM) are considered negative externalities and researchers have attempted to capture the value of avoided emissions in the form of health and environmental benefits. NOx is a precursor to photochemical ozone formation and PM is linked to an array of respiratory problems.

- Two key aspects for consideration in the review of the estimated criteria air pollutant estimates:
  - ICF only considered tailpipe criteria air pollutant emission reductions. It is possible – and in many cases likely – that the criteria pollutant emissions reductions would be larger if our analysis considered lifecycle emission reductions.
  - CARB has developed several programs to reduce criteria pollutant emissions from light-duty and heavy-duty vehicles. The avoided costs reported here are incremental to the benefits of existing CARB programs, such as the Advanced Clean Cars Program (focused on light-duty vehicles) and the Truck and Bus Rule (focused on medium- and heavy-duty vehicles).

Criteria Air Pollutants, ctd

- ICF used damage costs reported by EPA in rulemakings. The magnitude of damage costs (on a dollar per ton basis) for PM2.5 is dependent on the location of emission reductions. Areas with higher population density, for instance, tend to have higher damage costs than less populated areas. ICF developed a population-weighted average for the damage cost of PM2.5 in California, as shown in the table below.

Criteria Pollutant	2015	2020
PM2.5	$1,450,000—1,600,000	$1,600,000–1,740,000
VOC	$1,120–1,220	$1,220–1,320
NOx	$4,675–5,080	$5,080–5,590
The values are shown as ranges; EPA calculated low and high values using 3% and 7% discount rates

359

Low scenario: Includes low value of EPA-reported dollar-per-ton and a discount rate in ICF's analysis of 7 percent.

High scenario: Includes high value of EPA-reported dollar-per-ton and a discount rate in ICF's analysis of 2 percent.

ICF conservatively estimates the monetized benefit of criteria air pollutant emission reductions attributable to the LCFS program in the range of $63 million to $359 million.

Petroleum Displacement / Energy Security

Introduction

- Petroleum displacement by alternative fuels as part of LCFS compliance will lead to improved energy security. As outlined in a report by Paul Leiby from Oak Ridge National Laboratory regarding energy security benefits, energy security concerns arise from three problems:
  - concentrated crude oil supply in an historically unstable region
  - sustained exercise of market power by oil exporting countries
  - the vulnerability of the economy to oil supply shocks and price spikes
- Leiby estimates the benefits of energy security focusing on two components:
  - Monopsony Component: This component reflects the effect of US import demand on the long-run world oil price. The US remains a sufficiently large purchaser of foreign oil supplies that it affects global oil pricing. This demand is characterized as monopsony power.
  - Macroeconomic Disruption / Adjustment Costs: The second component of Leiby's analysis focuses on the effect of oil imports on disruptions such as a sudden increase in oil prices. These price spikes increase the costs of imports in the short run and can lead to macroeconomic contraction, dislocation, and GDP loss.

Petroleum Displacement / Energy Security, ctd

- The most recently available results from Leiby's analysis regarding the monetized benefits of decreasing oil imports are shown in the table below for the years 2013 and 2022. ICF used the mean values and assumed a linear relationship between 2013 and 2022 to calculate the annual discrete values for energy security.

Component	2013 ($/bbl)		2022 ($/bbl)	
	Mean	Range	Mean	Range
Monopsony	11.40	3.83–19.40	9.82	3.27–16.77
Disruption Costs	7.13	3.41–10.35	7.84	3.80–11.30
Total	18.53	10.03–26.74	17.66	9.88–24.99
Source: Leiby, EPA-HQ-OAR-2010-0133-0252, September 2012				

Petroleum Displacement / Energy Security, ctd

ICF INTERNATIONAL

- The monetized energy security premium for each scenario is shown in the table below for two different discount rates – 2 percent and 7 percent. ICF assumed that 50.3 percent of California's crude oil is imported based on data from the California Energy Almanac for 2011 and 2012.
- **The cumulative benefits of increased energy security resulting from the LCFS scenarios ranges from $796 million to $1.23 billion, depending on the discount rate employed in the analysis.**

Scenario		Energy Security Benefits (NPV, $2010 millions)								
		2013	2014	2015	2016	2017	2018	2019	2020	**Total**
2% discount rate	Scenario 1	16	44	82	119	152	185	216	247	**1,059**
	Scenario 2	10	31	57	88	116	177	236	302	**1,017**
	LCFS Enhanced	20	53	95	136	174	211	250	290	**1,230**
7% discount rate	Scenario 1	16	42	74	103	126	145	162	177	**844**
	Scenario 2	10	30	51	77	96	140	177	216	**796**
	LCFS Enhanced	20	50	86	118	144	166	188	207	**980**

Petroleum Displacement / Energy Security, ctd

- The proportion of foreign oil imported to California refineries has increased significantly as California reserves have been drawn down and as the Alaska North Slope production has continued to decline (starting in 1998). As recently as 2005, only 40 percent of crude oil was imported to California refineries from foreign sources. The decrease in domestic production has been offset by increases in foreign crude imports. While it is likely that ICF has under-estimated the percent of crude oil imported, recent domestic developments and the way that the LCFS is implemented give our team pause with regard to any assumptions that foreign imports are likely to increase significantly beyond the 50 percent estimate. For instance:
  - The production of domestic crude oils, such as the Bakken reserve in North Dakota and West Texas Intermediate – both of which are well suited for refining in California based on their respective crude properties – is strong and they are currently priced attractively relative to other crude oils. Similarly, there is significant potential for tight oil in California – with the EIA estimating that the Monterey/Santos Shale in Southern California has 64 percent of the onshore total shale oil resources in the lower 48 States, or about 15 billion barrels of oil.
  - There is a disincentive for refiners to seek out foreign (or domestic) crude oils that have a high carbon intensity because of the way that CARB determines the annual carbon intensity targets of the LCFS. If the carbon intensity of the crude oils that are refined increases, then the carbon intensity targets in subsequent years will be higher, thereby creating more deficits that must be offset by regulated parties.
- **In other words, it is more likely that imported crude oils will decrease more rapidly than domestic crude oils. However, we assumed a uniform petroleum displacement of imported and domestic crude oils. As a result, the range of benefits reported here is likely a low or conservative estimate of the energy security benefits.**

Summary and Conclusions

LCFS Compliance

To date, some analyses show draconian effects associated with California's LCFS.[1] But such studies harnessed assumptions and methods that lacked transparency and disregarded alternative fuel market developments. This study marks an independent effort to evaluate environmental and economic benefits. ICF uses conservative assumptions to enhance the study's credibility. Because the study's assumptions are generally conservative they likely understate the full magnitude of macroeconomic and environmental benefits.

Our analysis of the LCFS program leads to the following key takeaways:

- LCFS compliance is achievable through modest changes to fuel consumption.
  - The scenarios seek to capture the range of compliance possibilities - generally characterized as biofuel blending and advanced vehicle technology deployment.
  - A review of quarterly reports from the program combined with an alternative fuel market assessment leads ICF to conclude that the program is already working – it is driving increased volumes of alternative fuels into California, innovation, and investment.
- The LCFS program will lead to significant investments in fuel production, distribution infrastructure, and advanced vehicle technologies.

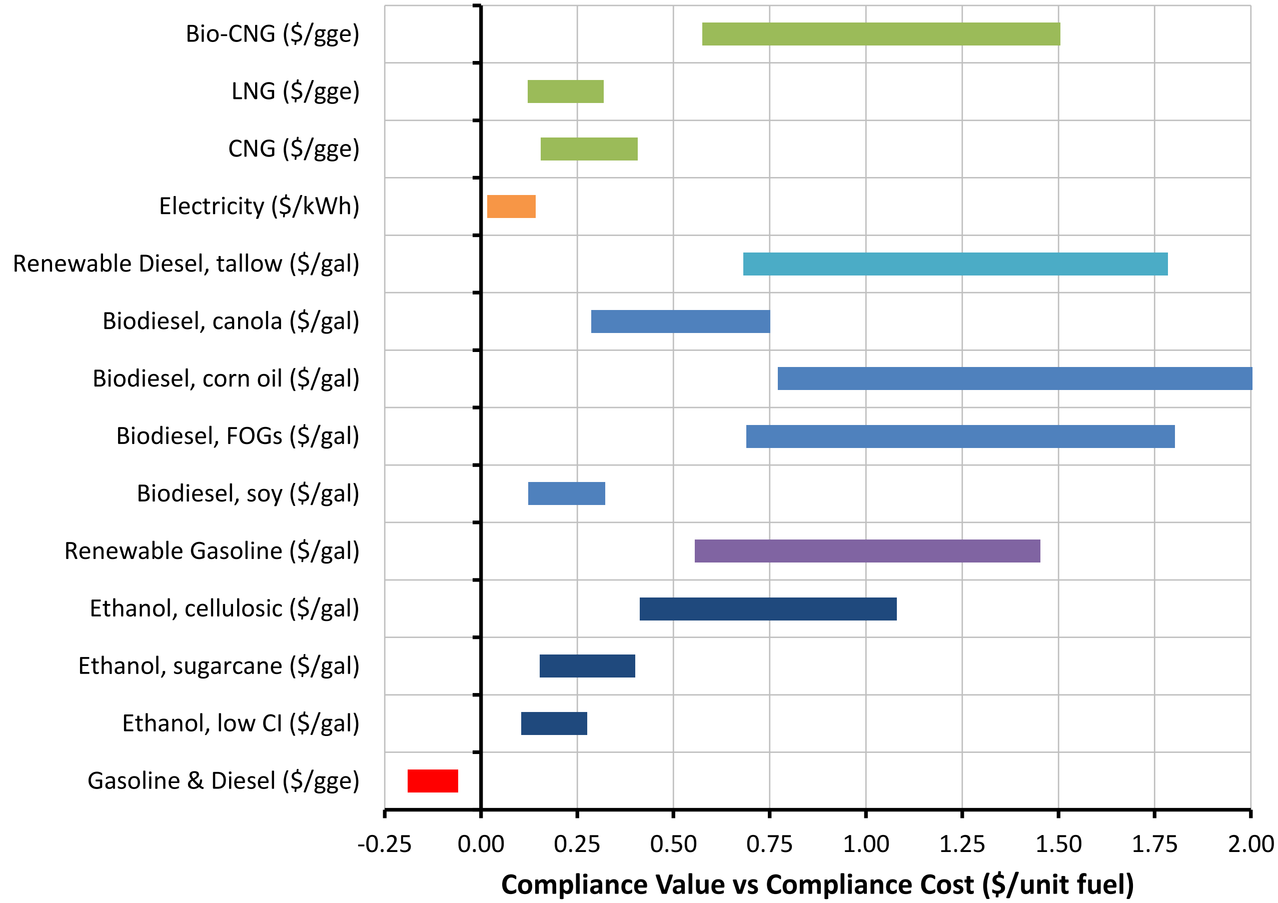
1. For instance: Boston Consulting Group, *Understanding the impact of AB 32*, June 2012 and Andrew Chang & Co, *The Fiscal and Economic Impact of the California Global Warming Solutions Act of 2006*, June 2012.

LCFS Compliance, ctd

- Based on baseline fuel price forecasts from the California Energy Commission (IEPR 2011), the credit pricing variations selected by stakeholders, and ICF's analysis of alternative fuel price forecasts, **the LCFS has a compliance cost ranging from $0.06–$0.19 per gasoline gallon equivalent**. The compliance costs have been normalized to a unit of energy – gasoline gallon equivalent – by accounting for the volumes of gasoline and diesel consumed in each scenario. The range of compliance costs reflects the variation in a) credit pricing and b) likely higher cost of blending low carbon liquid biofuels.
- As a point of comparison, gasoline and diesel prices in California have fluctuated an average of $0.75 per gallon and $0.63 per gallon annually, respectively, since 2010.

LCFS Compliance: Costs vs Value

- The compliance costs for refiners are mirrored by significant value for alternative fuels. The values shown in the graph below represent the LCFS credit range considered: $65-$170/ton



REMI Modeling

- **In all cases, investments in alternative fuels to achieve LCFS compliance yielded net positive macroeconomic impacts in 2020** – including employment, personal income, and gross domestic product (GDP). Total employment increases by up to 9,100 jobs in California.

- **The range of impacts due to the LCFS in California is small,** ranging from -0.04% to 0.04% for all the macroeconomic variables considered across all three scenarios.

- **The scenarios with the highest level of fuel diversity – Scenario 1 and LCFS Enhanced Scenario – yield net positive macroeconomic impacts** across all three credit pricing variations in California.

- **The modeling results from Scenario 2 yield small negative impacts** on employment, personal income, and GDP in California across all three credit pricing variations. This dynamic is largely driven by the fact that compliance in Scenario 2 is more dependent on liquid biofuels, are less likely to generate investment expenditures within California in the timeframe of our analysis (2020).

Research Areas for Further Study

This study's objective is to present an independent macroeconomic assessment of the LCFS. Over the course of our research, ICF has identified three critical areas for further study.

1. **The timeline of our analysis was limited to 2020, which reflects the current implementation timeframe of the LCFS program. Many of the benefits of the LCFS – driven by fuel diversification – are likely to increase significantly in the 2025-2030 timeframe.**
   - For instance, several policy cases examined in *Transitions to Alternative Vehicles and Fuels (2013)*, published by the National Academies Press, do not yield significant monetized benefits until the 2025 timeframe and increase rapidly thereafter.
   - Given that the transportation sector is nearly 95 percent dependent on petroleum-based fuels, it is to be expected that the early stages of a transition to greater alternative fuel use will have some "start-up" costs that do not fully translate into benefits until the post-2020 timeframe. These additional benefits can be attributed to factors such as increased utilization of infrastructure assets, increased competitiveness in fuel markets, increased economies of scale in alternative fuel production, and continued incremental technological improvements.

Research Areas for Further Study, ctd

2. **It is possible to estimate LCFS compliance costs and corresponding fuel pricing impacts using an energy model. The REMI model is not an energy model, and therefore is ill-equipped to forecast fuel pricing changes as a result of increased alternative fuel use. As a result of this limitation, ICF estimated the LCFS compliance costs as exogenous parameters to REMI.**
   - In a more rigorous modeling exercise, a macroeconomic model such as REMI would be paired with an optimization model or fuel/energy pricing model.
   - This is a much more resource intensive exercise, and frankly, ICF is unaware of an off-the-shelf fuel pricing model that is sufficiently sophisticated to capture the dynamics of the LCFS and its interaction with other regulations (e.g., the federal Renewable Fuel Standard).
   - ICF does not think that the pairing of an energy model with the REMI model would materially change the results of our analysis in the 2020 timeframe; however, when considering the LCFS in the post-2020 timeframe (see previous bullet), the pairing of an energy model and the REMI model is strongly recommended to ensure a robust representation of an increasingly competitive fuels market.

Research Areas for Further Study, ctd

3. **ARB is making amendments to the LCFS that are likely to be adopted in 2014 and considering new concepts .**
   - The amendments that require further study include a cost containment provision and revised indirect land use change (ILUC) values for biofuels.
     - *The cost containment mechanism will have an impact on credit pricing in modeling scenarios, thereby changing the macroeconomic impacts and the compliance costs of the regulation.*
     - *The revised ILUC values will change the balance of deficits and credits. These changes will also require modifications to the compliance scenarios because the market demand for some biofuels will likely change significantly.*
   - The new concepts being considered by ARB include GHG emission reductions at refineries, the modification of compliance curves, and modifications to the fuel pathways.
     - *ARB is considering a concept in which refiners can earn credits for GHG reductions at refineries. These types of reductions were not considered in this analysis.*
     - *This analysis assumed a 1% carbon intensity reduction in 2014; however, the carbon intensity reductions for 2015-2020 were based on the existing regulation. Modifications to these will have an impact on the balance of credits and deficits.*
     - *ARB is also considering changing the way fuel pathways are approved. As part of this, they are considering bins for fuels with similar pathways. Depending on the size of these bins, this might have an impact on our analysis.*

Monetized Externalities

The table below aggregates the results of ICF's analysis of the monetized externalities for a) GHG emission reductions, b) criteria air pollutant reductions, and c) increased energy security benefits through petroleum displacement.

Scenario		Monetized Externalities (NPV, $2010 millions)			
		GHG Emissions SCC[1]	Criteria Air Pollutants	Energy Security	Total
Scenario 1	low	$502	$253	$844	$1,599
	high	$3,220	$346	$1,059	$4,625
Scenario 2	low	$502	$63	$796	$1,360
	high	$3,260	$68	$1,017	$4,345
LCFS Enhanced	low	$497	$258	$980	$1,736
	high	$3,204	$359	$1,230	$4,793

[1] For the low SCC estimates, ICF used the values reported at a 5 percent social discount rate; for the high SCC estimates, ICF used the 2.5 percent discount rate

Monetized Externalities, ctd

The monetized environmental and energy security benefits of the LCFS are significant and can be valued in the range of $1.4–4.8 billion out to 2020. The following numbers are shown as cumulative values out to 2020.

- The GHG reductions attributable to LCFS compliance, when monetized using the social cost of carbon, are valued at $497 million to $3.26 billion.
- The criteria pollutant reductions attributable to LCFS compliance, when monetized using avoided damage costs, are valued at about $63–359 million per year.
- The energy security benefits of displacing petroleum consumption – particularly petroleum imports – are valued at $796 million to $1.23 billion per year.

Subject: RE: Deadline for Comments on LCFS?

Thanks much Floyd.

We will not be able to submit formal public comments, unless you can include this email. We are developing CO2 capture technology that will take CO2 directly out of air. This is in a research phase now, but there is already commercial interest in scaling up and evaluating it. The first market is CO2-based enhanced oil recovery wherein the equipment would be installed at the oil field site. The CO2 captured from air and used for this purpose is mostly sequestered, rendering the oil 70-100% carbon free, according to the attached journal paper from the DOE.

It is important the LCFS is flexible enough to allow oil produced in this method to be considered as a LC fuel upon proper review and certification.

LCFS 20-1

Abstract

CO_2 enhanced oil recovery (CO_2-EOR) offers the potential for storing significant volumes of carbon dioxide emissions while increasing domestic oil production. This presentation, based on a recently completed study for DOE/NETL, examines the domestic oil resource amenable to CO_2-EOR, the size of the related market for CO_2, and the benefits to the power sector from CO_2 sales to the EOR industry. The study finds that, depending on future oil prices and the costs for purchasing CO_2 from power plants and other industrial sources, from 39 to 48 billion barrels of oil could be economically recoverable with CO_2-EOR. In addition, the size of the market for CO_2 offered by the EOR industry is on the order of 7,500 million metric tons between now and 2030. With advances in CO_2-EOR and storage technology, the economically recoverable oil resource would increase to 54 to 70 billion barrels.

The market for CO_2 from the EOR industry is examined in depth from the coal-fueled power plant industry's standpoint. The sale of CO_2 emissions captured from new coal-fueled power plants could provide significant revenue offsets to the cost of installing carbon capture technology. It is estimated these revenue offsets along with a value for carbon abatement could enable 40% (48 out of 121 GW) of the new coal-fueled power capacity expected to be built between now and 2030 to install CCS. With advances in CO_2-EOR and storage technology the number of power plants with CCS could increase to 50 to 70 GWs. This would provide significant assistance toward addressing CO_2 emissions from this sector, helping drive down the costs of installing CCS technology. © 2009 Elsevier Ltd. All rights reserved.

1. Introduction

CO_2 enhanced oil recovery (CO_2-EOR) offers the potential for storing significant volumes of carbon dioxide emissions while increasing domestic oil production. Four notable benefits would accrue from integrating CO_2 storage and enhanced oil recovery:

- First, CO_2-EOR provides a large, "value added" market for sale of CO_2 emissions captured from new coal-fueled power plants. The size of this market is on the order of 7,500 million metric tons between now and 2030. Sales of captured CO_2 emissions would help defray some of the costs of installing and operating carbon capture and storage (CCS) technology. These CO_2 sales would support "early market entry" of up to 49 (one GW size) installations of CCS technology in the coal-fueled power sector. With advances in CO_2-EOR and storage technology the market could increase to 10,850 million metric tons which would support up to 70 GW of CCS;
- Second, storing CO_2 with EOR helps bypass two of today's most serious barriers to using geological storage of CO_2 - - establishing mineral (pore space) rights and assigning long-term liability for the injected CO_2;
- Third, the oil produced with injection of captured CO_2 emissions is 70% "carbon-free", after accounting for the difference between the carbon content in the incremental oil produced by EOR and the volume of CO_2 stored in the reservoir. With "next generation" CO_2 storage technology and a value for storing CO_2, the oil produced by EOR could be 100+% "carbon free";
- Fourth, the 39 to 48 billion barrels of economically recoverable domestic oil economically recoverable from storing CO_2 with EOR would help displace imports, supporting a path toward energy independence. It could also help build pipeline infrastructure subsequently usable for storing CO_2 in saline formations.

Various analysts and studies have discussed the potential for storing CO_2 with enhanced oil recovery but have noted (incorrectly) that this option is quite small or is counter productive to reducing CO_2 emissions. For example, the "IPCC Special Report on Carbon Dioxide Capture and Storage", while recognizing that depleted oil fields could provide an attractive, early option for storing CO_2 (particularly with CO_2-EOR), concluded that oil fields would provide only a relatively small volume of CO_2 storage capacity.

The report finds that the opportunity for selling captured CO_2 emissions to the EOR industry and storing these emissions in oil reservoirs using CO_2-EOR is largely providing a market for productive use of CO_2 emissions from the nation's large and growing fleet of coal-fueled power plants.

2. Evaluating the Market for Captured CO_2 Emissions Offered by EOR

The size and value of the market for captured CO_2 emissions offered by enhanced oil recovery rests on three pillars: (1) the size and nature of the domestic crude oil resource base, particularly the large portion of this resource base unrecoverable with existing primary and secondary oil recovery methods; (2) the ability of CO_2-EOR to recover a portion of this currently unrecoverable ("stranded") domestic oil, while efficiently storing CO_2; and (3) the impact of alternative oil prices and CO_2 costs on the volume of oil that could be economically produced.

2.1. The Domestic Oil Resource Base

The U.S. has a large, established oil resource base, on the order of 596 billion barrels originally in-place. About one-third of this resource base, nearly 196 billion barrels, has been recovered or placed into proved reserves with existing primary and secondary oil recovery technologies. This leaves behind a massive target of 400 billion barrels of "technically stranded" oil, Table 1.

Table 1. National In-Place, Conventionally Recoverable and "Stranded" Crude Oil Resources

Basin/Area	OOIP* (Billion Barrels)	Conventionally Recoverable (Billion Barrels)	ROIP** "Stranded" (Billion Barrels)
1. Alaska	67.3	22.3	45.0
2. California	83.3	26.0	57.3

2.2. Technically Recoverable Oil Resources Using CO_2-EOR

Numerous scientific as well as practical reasons account for the large volume of "stranded" oil, unrecoverable with primary and secondary methods. These include: oil that is bypassed due to poor waterflood sweep efficiency; oil that is physically unconnected to a wellbore; and, most importantly, oil that is trapped by viscous, capillary and interfacial tension forces as residual oil in the pore space.

Injection of CO_2 helps lower the oil viscosity and trapping forces in the reservoir. Additional well drilling and pattern realignment for the EOR project helps contact bypassed and occluded oil. These actions enable a portion of this "stranded oil" to become mobile, connected to a wellbore and thus recoverable.

2.2.1. Current CO2-EOR Activity and Production

According to the latest tabulation of CO_2-EOR activity in the U.S., in the 2008 EOR Survey published by the Oil and Gas Journal, approximately 250,000 barrels per day of incremental domestic oil is being produced by 101 CO_2-EOR projects, distributed broadly across the U.S.

2.2.2. Evolution in CO_2 Flooding Practices

Considerable evolution has occurred in the design and implementation of CO_2-EOR technology since it was developed in the 1970's. Notable changes include: (1) use of much larger (up to 1 HCPV*) volumes of CO_2; (2) incorporation of tapered WAG (water alternating with gas) and other methods for mobility control; and (3) application of advanced well drilling and completion strategies to better contact previously bypassed oil. As a result of the changes mentioned above, the oil recovery efficiencies of today's better designed "state-of-the-art" CO_2-EOR projects have steadily improved.

2.2.3. Technically Recoverable Resources

The reservoir-by-reservoir assessment of the 1,111 large oil reservoirs contained in the ARI database amenable to CO_2-EOR shows that a significant volume, 64 billion barrels, of domestic oil may be recoverable with state-of-the-art application of CO_2-EOR. Extrapolating the data base to national-level results indicates that 87.1 billion barrels

(84.8 after subtracting the 2.3 that has already been produced and proven) of domestic oil may become recoverable by applying "state-of-the-art" CO_2-EOR, Table 2.

Table 2. Technically Recoverable Resources from Applying "State-of-the-Art" CO_2-EOR: National Totals

	Technically Recoverable (Billion Barrels)	Existing CO_2-EOR Production/Reserves	Incremental Technically Recoverable (Billion Barrels)
1. Alaska	12.4	-	12.4
2. California	6.3	-	6.3
3. Gulf Coast (AL, FL, MS, LA)	7	-	7
4. Mid-Continent (OK, AR, KS, NE)	10.7	-0.1	10.6
5. Illinois/Michigan	1.2	-	1.2
6. Permian (W TX, NM)	17.8	-1.9	15.9
7. Rockies (CO,UT,WY)	4.2	-0.3	3.9
8. Texas, East/Central	17.6	-	17.6
9. Williston (MT, ND, SD)	2.5	-	2.5
10. Louisiana Offshore	5.8	-	5.8
11. Appalachia (WV, OH, KY, PA)	1.6	-	1.6
Total	87.1	-2.3	84.8

3. Economically Recoverable Resources

3.1. Economically Recoverable Resources: Base Case Scenario

Out of 85 billion barrels technically recoverable using CO_2-EOR technology, 45 billion barrels of incremental oil are economically recoverable in our base case scenario, Table 3. The Base Case evaluates the CO_2-EOR potential using an oil price of $70 per barrel (constant, real) and a CO_2 cost of $45 per metric ton ($2.38 per Mcf) (delivered at pressures around 2,200 psi to the field, constant and real), Table 4. The 40 billion barrels that are not economic to recover in this scenario are contained in reservoirs that cannot provide a sufficient rate of return, 15%, in this scenario, on a CO_2-EOR project's capital costs.

Table 3. Economically Recovemble Resources from Applying "State-of-the-Art" CO_2-EOR: National Totals at Base Case Economics*

Basin/Area	Incremental Technically Recoverable (Billion Barrels)	Incremental Economically Recoverable* (Billion Barrels)
1. Alaska	12.4	9.5
2. California	6.3	5.4
3. Gulf Coast (AL, FL, MS, LA)	7.0	2.2
4. Mid-Continent (OK, AR, KS, NE)	10.6	5.6
5. Illinois/Michigan	1.2	0.5
6. Permian (W TX, NM)	15.9	7.1
7. Rockies (CO,UT,WY)	3.9	1.9
8. Texas, East/Central	17.6	8.3
9. Williston (MT, ND, SD)	2.5	0.5
10. Louisiana Offshore	5.8	3.9
11. Appalachia (WV, OH, KY, PA)	1.6	0.1
Total	84.8	45.0

*Base Case Economics use an oil price of $70 per barrel (constant, real) and a CO_2 cost of $45 per metric ton ($2.38/Mcf), delivered at pressure to the field.

Table 4. Economically Recoverable Resources from Applying "State-of-the-Art" CO_2-EOR: National Totals at Base Case and Alternative Oil Prices/CO_2 Costs

Oil Prices	CO2 Costs			
($ per Bbl)	($ per metric ton)			
	$35	$45*	$55	$60
Lower Prices				
$50	39.1 BBbls			
Base Case				
$70		45.0 BBbls		
Higher Prices				
$90			47.9 BBbls	
$100				48.3 BBbls

*A CO_2 cost of $45 per metric ton (mt) is equal to $2.38 per Mcf. 15% IRR project hurtle rate

4. The Market for Storing CO2 with EOR

Our analysis shows that significant volumes of CO_2 (ranging from 10 to 13 billion metric tons depending on oil price) can be stored with enhanced oil recovery. In general, about 5 to 6 Mcf (0.26 to 0.32 metric tons (mt)) of purchased CO_2 per barrel of oil is injected and stored as part of CO_2-EOR. This is augmented with 5 to 10 Mcf (0.26 mt to 0.52 mt) of recycled CO_2 during the latter stages of a CO_2-EOR process. With incentives for storing CO_2 emissions and "next generation" CO_2 storage technology, considerably larger volumes of CO_2 could be stored.

4.1. Producing "Carbon Free" Domestic Oil

A typical barrel of crude oil contains 0.42 metric tons (mt) of releasable CO_2 (assuming that 3% of the produced and refined oil barrel remains as asphalt or coke). As such, netting the injection and storage of 0.26 to 0.32 mt of CO_2 emissions against the 0.42 mt of CO_2 in the produced oil, makes the domestic oil produced by CO_2-EOR about 70% (62% to 76%) "carbon free".

4.2. Market Demand for CO_2: Power Plant Perspective

The overall demand for CO_2 by the CO_2-EOR industry can be met by three potential sources of CO_2 supply, namely:

- Natural CO_2 supplies already found and defined in geological structures;
- Industrial, high concentration sources of CO_2 (e.g. refineries and fertilizer plants) that are currently being captured and used by the CO_2-EOR industry; and
- The large volumes of low concentration power plant and industrial emissions of CO_2 that needs to be captured and stored to mitigate CO_2 emissions.

Excluding Alaska, which is not projected to build new coal-fueled power plants to any great extent, the demand for CO_2 in the lower-48 states offered by the EOR industry is 9,694 million metric tons (183.4 Tcf)

Table 5 sets forth the net remaining demand for CO_2 by the EOR industry of 7,470 million metric tons for the lower-48 states, after subtracting the 2,224 million metric tons (42.2 Tcf) of CO_2 available, in the next 30 years, from natural CO_2 deposits and high concentration industrial CO_2 sources (e.g., natural gas processing plants, fertilizer plants) already being captured and used for enhanced oil recovery.

The overall conclusion from the analysis is that CO_2-EOR may provide a 7,500 million metric ton market for captured CO2 emissions by the coal-fueled power generation industry, Table 5. While the actual revenues afforded by this market will be established, in the main, by one-on-one negotiations between individual power companies and oil field operators, the potential size of this market could be large.

Using an oil price of $70 per barrel (Base Case), assuming a delivered CO_2 cost of $45 per metric ton, and subtracting $10 per metric ton for transportation and handling, the revenue potential offered by the CO_2-EOR market could reach $260 billion.

Table 5. Economically Feasible Market Demand for CO_2 by EOR: NEMS/EMM Power Generation Regions*

NEMS EMM Region	Purchased CO_2 Requirements (Tcf)	Natural CO_2** (Tcf)	Industrial CO_2** (MMcfd)	Industrial CO_2** (Tcf)	Unmet (Net) Demand for CO_2 (Tcf)	Unmet (Net) Demand for CO_2 (Million mt)

*Base Case: \$70/Bbl oil and \$45/mt CO_2

**Assumed available to be produced and productively used by the CO_2-EOR industry in the next 30 years.

***Less than 0.01 Tcf and thus not included in totals.

5. Using Sale of Captured CO_2 Emission for "Early Market Entry" of CCS Technology

A common feature of EIA carbon management studies is that, in general, CCS is not considered, as of yet, a key part of the solution. The reason, according to EIA's EMM cost model, is that using CCS with coal- or gas-fired power is not economically competitive with other options for generating power with low CO_2 emissions.

However, revenues from selling captured CO_2 emissions into the CO_2-EOR market can change the competitive outlook. For example, as shown in Table 6 and Figure 1, the sale of captured CO_2 emissions at \$25 to \$35 per metric ton can reduce the costs of power generation with CCS by \$17 to \$24 per MWh, significantly offsetting the costs of installing CCS with new coal-fueled power plants.

Table 6. Relationship of CO_2 Sales Price to Cost Offsets in the Coal-Fueled Power Sector (Year 2020)

Sale of CO_2	Sale of CO_2
@ \$25/mt CO_2	@ \$35/mt CO_2
*7,920 btu/kWh x	7,920 btu/kWh x
94 MMmt CO_2/QBtu x	94 MMmt CO_2/QBtu x
90% Capture	90% Capture
Cost Offset: \$16.80/MWh	Cost Offset: \$23.50/MWh

*Advanced Integrated Gasification Combined Cycle (IGCC) plant.

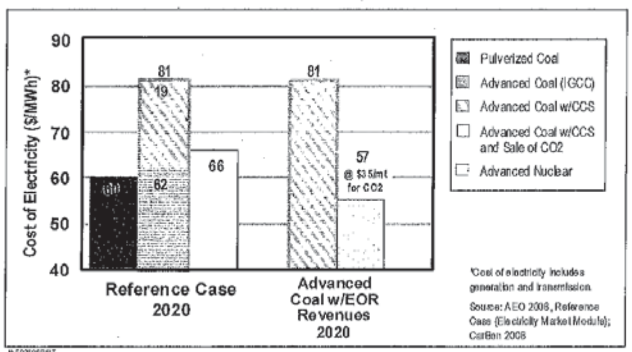

Figure 1. Sale of Captured CO_2 Emissions Can Help Make Coal Plants w/CCS Competitive

The CarBen and EIA EMM models project that 29 new coal-fueled power plants would be placed into operation between 2013 and 2020 in the lower-48. Assuming that half of these power plants are favorably located with respect to oil fields attractive for CO_2-EOR and are able to sell CO_2 at \$35/mt at the plant gate, the integration of CO_2 storage and EOR plus a value for abating CO_2 emissions would support the construction of 15 new advanced coal w/CCS power plants, each with 1 GW of capacity. (A 1 GW advanced coal-fueled power plant built by 2020 is estimated to be able to sell about 5.1 million metric tons of captured CO_2 emissions per year; 15 plants would be able to provide 2,300 million metric tons in 30 years). Sales of captured CO_2 emissions by power plants built after 2020 would support the 33 additional installations of CCS by 2030 for a total of 48 GWs of capacity with CCS.

20_OP_LCFS_Cinc Responses

98. Comment: **LCFS 20-1**

The commenter urges ARB to consider enhanced oil recovery with carbon captured directly from the air at the oil production site.

Agency Response: Under the proposed regulation language, the carbon capture must take place onsite at the crude oil production facilities in order for Carbon Capture with CO_2 Enhanced Oil Recovery to qualify as an innovative crude method. Moreover, carbon capture and storage (CCS) projects must use a Board-approved quantification methodology including monitoring, reporting, verification, and permanence requirements associated with the carbon storage method being proposed for the innovative method. This quantification method is being developed and is expected to be available by 2017. Therefore, the project described by the commenter should qualify as an innovative crude production method, assuming it meets all requirements of the quantification method.

Air Resource Board
California Air Resources Board
1001 "I" Street
Sacramento, CA 95814

The Union of Concerned Scientists has been working with the Air Resource Board (ARB) to develop a science based Low Carbon Fuel Standard (LCFS) since the program's inception, and has joined other organizations on other letters supporting the readoption in general and making several specific recommendations. However, we have been extensively involved in the getting the science right on the important issue of accounting for biofuels indirect land use emissions (ILUC), and wanted to make some more specific comments on that topic.

First thanks to the ARB staff for tireless work to address stakeholder and expert input on ILUC analysis. With the dedicated work of ARB staff and many contractors and collaborators the models used in 2009 have been adapted to more carefully model animal feed markets, to take into consideration irrigation, and to adapt the model structure of both GTAP and the associated emissions factor model to take into consideration considerably more detailed information, especially about the US and Brazil. This process enhanced the technical foundation of the LCFS, and also advanced the state of the art on the study of land use changes associated with expanded biofuels production. The board is on sound footing to adopt updated emissions values as part of the LCFS readoption.

But despite this important progress, there remain important areas for continued investigation. The most critical of these is related to palm oil. Palm oil is one of the most important drivers of deforestation, and a significant global source of biofuel. The emissions from palm oil are relevant not only for palm biodiesel itself, but for fuels made from other fats, oils or oil biproducts that may substitute for palm oil in the marketplace. The interconnected markets for biodiesel and renewable diesel feedstocks are complicated and the data is imperfect. Moreover, as ARB staff has highlighted, there are likely some structural limitations in GTAP that make it difficult to adjust the model to reflect key market dynamics. But this area of inquiry is clearly critically important going forward. Additional investigation is needed to ensure the link between palm and deforestation is understood, and that California fuel regulations do not inadvertently increase deforestation from palm oil. LCFS 21-1

This is particularly important because LCFS compliance may lead to a significant increase in the use of fuels made from oils and fats. I urge the ARB to seek expert input on key land use issues raised by palm oil in particular, and large increases in the use of bio-based diesel in general. ARB certainly has important technical work to continue, refining the GTAP model LCFS 21-2 and associated emissions factor models, but a broader perspective on the drivers of palm oil deforestation is also critical to ensure that California's fuel regulations avoid becoming an indirect driver of deforestation and support deforestation-free fuels. LCFS 21-2 cont.

My comments are focused on palm oil because it is a leading driver of deforestation and a weakness in ARB's otherwise strong analysis, but the other areas identified for further long term work are also very important. The forestry issues associated with the treatment of unmanaged land in GTAP are very important to ILUC for all fuels, and especially palm oil, and deserve further attention. LCFS 21-3 It is also worth understanding the discrepancy between ARB's irrigation results and those of Taheripour, Hertel and Liu (*Energy, Sustainability and Society* 2013, 3:4). LCFS 21-4 Analysis of fertilizer, paddy rice and livestock emissions, and consideration of a dynamic GTAP model is also worthwhile. LCFS 21-5 And as cellulosic biofuels feedstocks scale up and begin to be significant driver of land use change, it will be important to understand their land use impacts. LCFS 21-6

I also wanted to include some comments on recent publications related to ILUC.

Babcock and Iqbal.

At the highest level, the recent white paper by Babcock and Iqbal suggests that calculations of indirect land use change (ILUC) emissions that ARB finalized in 2009 and related studies US Environmental Protection Agency finalized in 2010 may overestimate ILUC emissions. Of course with the updated analysis the 2010 values are indeed being lowered. But of course there is a lot more to it than that, and I want to comment on four specific points.

1. The findings of the Babcock and Iqbal study are strongly connected with the reduced rate of deforestation in Brazil, which is an important success story (see UCS report *Deforestation Success Stories* – also my colleague's papers in *Tropical Conservation Science* and *Solutions Journal*). This success was no means automatic, and reflects not simply the option value of intensification, but also considerable pressure on soybean traders and the Brazilian government to stop deforestation. Fully accounting for emissions associated with deforestation was part of that pressure, and thus reduced deforestation in Brazil is a success that vindicates the importance of land use change emissions accounting.
2. However, while there is an important success to report in Brazilian soy, the Babcock and Iqbal study also demonstrates that for palm oil production just the opposite is true, with substantial expansion on the extensive margin, primarily from deforestation and expansion onto peat, rather than on the intensive margin. This demonstrates the importance of focusing on emissions from palm oil, pushing customers, traders and governments to invest in yield increases and to block expansion into forests and peat. Palm oil is a significant global source of biofuel, and these first ARB estimates to be released require thorough scrutiny before these results will be up to the same standard the corn, sugar and soy results are now. Additional expert work is LCFS 21-7

needed in this area to ensure the links between palm and deforestation are understood. LCFS 21-7 cont.

3. Also, while the Babcock and Iqbal's analysis makes a compelling case that expansion at the intensive margin is important, this kind of intensification can only go so far before the growing season is fully used and the planted land is fully harvested. Furthermore, for perennial tree crops like oil palm, double-cropping is not feasible and increasing the proportion of the planted area that is harvested has very limited potential. So the mechanisms Babcock identified cannot continue if biofuels production grows indefinitely.
4. Finally, the Babcock and Iqbal study concludes with a promise to extend their analysis into a statistical model that could be incorporated into future attempts at estimating greenhouse gas emissions caused by biofuels or other drivers of agricultural production. This forthcoming model may well enhance the next round of analysis performed by ARB or others, but the opportunity for future improvements is no reason to hold up the updates based on work done over the last five years or the regulation in general. The refinement of models is an ongoing process, and further improvement is always possible. The changes regarding intensification, improved treatment of unmanaged land, and more scrutiny of palm and peat are all warranted. But future changes will need to be incorporated into future policy updates. LCFS 21-8

Searchinger and Heimlich

In a recent World Resources Institute report, Tim Searchinger and Ralph Heimlich argue that in light of the looming challenge of producing food and other needs for the world population in 2050, there is no space for any use of crops to produce fuels on a significant scale. The question of whether crop production will succeed or fail to keep up with demand growth over the next 35 years is not a matter of scientific consensus and depends on many non-technical factors. I agree that competition for land with crops, forests and other land uses must be considered in assessing the limits on the productive scale of bioenergy, so it is a mistake to target an arbitrary fraction of future fossil energy demand, whether 10% or 20%.

Searchinger and Heimlich argue that most bioenergy policies are based on faulty accounting that double counts carbon. They propose that the low carbon fuel standard be dropped in favor of other measures in support of electric or hydrogen vehicles or at a minimum they should disqualify biofuels grown on dedicated land from contributing to low carbon fuel standards. The electricity-only focus is too narrow to meet climate goals, and the remedy of disqualifying biofuels seems to reflect a fundamental misunderstanding of how a performance standard works. By definition all fuels must be included in the standard to fully assess the overall average fuel carbon intensity. Moreover, by including an accounting for indirect land use change, the California LCFS has avoided the basic double counting problems associated with Kyoto accounting, as they call it. The last element of so called double counting Searchinger and Heimlich mention is associated with lost food consumption.

Competition of bioenergy uses of crops with food or with land for growing food is an important policy question, although primarily a moral question rather than a matter of carbon accounting. Biofuels use in California seems unlikely to put significant pressure on global food production in the timeframe of the current LCFS (through 2020), but as more ambitious targets are considered, measures to mitigate food versus fuel conflicts may be an appropriate addition to mechanisms to mitigate ILUC emissions.

The Searchinger and Heimlich report suggests that for crop based bioenergy to have real carbon reductions compared to fossil fuels additional carbon uptake is required, which can only arise in highly restricted situations and not from using current crops like maize or soybeans. It is interesting to compare the findings of this report with the findings of Babcock and Iqbal that much of the increased production of major crops in Brazil arose from double and triple cropping and from increasing the fraction of planted acreage that was harvested. These examples point to the real potential for increases in the utilization of existing land, which would meet the theoretical "additional carbon" test proposed by Searchinger and Heimlich. I mention this to highlight that alternative accounting schemes are not necessarily consistent with their claims that carbon mitigation credit can only arise for residues.

Searchinger et al.'s 2008 paper in Science on indirect land use change was in part responsible for initiating a great deal of detailed research on how increased biofuel production would reverberate through the global agricultural system. The understanding of the world represented by the totality of this research is far more nuanced than the zero sum game portrayed by this latest Searchinger and Heimlich report

The practical reality of transportation fuel markets is that biofuels are now a significant component of the fuel system. The administration of a carbon intensity based fuels policy framework like the LCFS requires a credible climate accounting framework that should be based on the best available science rather than an interest to promote or disqualify any particular fuel. The role of agriculture in energy markets and the impact for food and forest protection are important, but the potential contributions of bioenergy to carbon mitigation cannot be dismissed out of hand, no more than can the ultimate constraints on this contribution.

John DeCicco's Liquid Carbon Challenge paper

In a recent review John DeCicco argues that the combination of consequential and attributional lifecycle analysis in what he calls Fuel Cycle Analysis used to administer the LCFS is fatally flawed, and that "emissions from liquid fuels must be balanced by increasing the rate of net carbon fixation." The uncertainty about the carbon benefits of biofuels arises from the question of whether their expansion comes at the cost of carbon stored in forests and soils, rather than to the annual flows into and out of annual crops. Since the primary changes in forest cover occur in the tropics, and the connection to biofuels use is mediated by global agricultural commodity markets, the uncertainty about these benefits can only be resolved by examining the whole system, and especially the impact on forests and other carbon rich ecosystems. This creates a complicated analytical problem, but not one that is necessarily clarified by changing the accounting framework.

DeCicco's argument about the theoretical challenges associated with combining attributional and consequential lifecycle analysis is well taken, and research in different approaches is advisable. But his argument seem to reach beyond methodological issues and argues that the climate benefits associated with biofuels in the analysis underlying California's LCFS stem from analytical errors. It is not at all clear that his theoretical musings support this conclusion and in any case his paper lacks concrete suggestions that would improve the administration of the LCFS.

In conclusion, we applaud the work ARB staff has done these last five years to advance the state of knowledge on indirect land use change emissions. The LCFS regulation is on solid ground for reauthorization through 2020. As the ARB starts to look beyond 2020, it is appropriate to consider whether other analytical approaches, lifecycle frameworks, and protective measures are needed to ensure that California's low carbon fuels meet diverse policy goals. These goals start with carbon mitigation, but must also ensure that California's climate mitigation strategies do not export problems in food markets or forest protection elsewhere in the world. We look forward to continued engagement with ARB on these issues over the next few years.

LCFS 21-9

Sincerely,

Jeremy Martin, Ph.D.

Subject: Promotum Study on LCFS Compliance to 2025
Comment:
Please find attached a study by Promotum, a fuels and chemicals consultancy, that was commissioned by Natural Resources Defense Council, Union of Concerned Scientists, and Environmental Defense Fund.

The study demonstrates that a 10% target by 2020 is achievable using a variety of lower carbon fuels as well as technologies to reduce the carbon-intensity of refining and crude oil production. If the LCFS provides the credit incentive value assessed in ARB staff's proposed ISOR, a 15% reduction target could even be achieved by 2025. LCFS 22-1

Report: Pump Primed for Three-Fold Growth in Clean, Alternative Fuels by 2025
California's Low Carbon Fuel Standard Targets are Achievable and Will Drive Growth

SAN FRANCISCO (February 2, 2015) – California is capable of tripling its use of alternative fuels over the next 10 years, according to a new report by the fuels and energy consulting firm Promotum. The study examined the growth potential for cleaner fuels under California's Low Carbon Fuel Standard (LCFS), a program requiring the oil industry to reduce the carbon intensity of fuels through the production and use of cleaner fuels.

"It's time for the oil industry to send the lobbyists and lawyers home and put their engineers to work," said Dr. Simon Mui, director of NRDC's work on clean vehicles and fuels in California. "Despite their protests, this shows once and for all that industry can meet and exceed the standard by diversifying to cleaner fuels like advanced biofuels, renewable natural gas, and clean electricity. A range of cleaner options is there for the taking."

The report's findings show that the oil industry can meet the LCFS reduction target – a 10 percent decrease in carbon emissions by 2020 – through known, existing fuels and refinery technologies. This includes expanding the use of lower-carbon biodiesel and renewable diesel, biomethane, electricity, and ethanol, as well as improving the carbon-intensity of existing alternative fuels. It also found that existing oil refineries and crude oil production facilities could dramatically cut their carbon footprint by integrating renewable energy, utilizing innovative technologies, and investing in greater energy efficiency.

The study analyzed different scenarios in which the program would encourage cleaner fuels by rewarding producers based on their environmental performance, measured in tons of carbon pollution reduced. The strong, performance-based incentive provided by the LCFS – worth potentially more than a dollar per gallon for ultra-low carbon fuel producers of fuels such as ethanol made from agricultural waste or biodiesel made from recycled oils – will enable the market to expand and diversify.

"A growing body of evidence shows that the LCFS will be a critical tool toward achieving Gov. Brown's new goal of cutting petroleum use in cars and trucks in half by 2030 to help California meet its climate goals," said Dr. Jeremy Martin, Senior Scientist and Fuels Lead at the Union of Concerned Scientists.

"By providing a steadily growing market for clean fuels, the LCFS supports investments that will energize clean transportation for decades to come."

At its February 19 hearing, the California Air Resources Board will consider its staff's proposal for re-adoption of the LCFS together with a series of enhancements to the program. Together with other clean transportation policies, the standard will enable California to continue reducing carbon emissions that contribute to global warming and poor air quality

"The LCFS is working to diversify California's energy mix. Innovation and investments in clean fuels is growing," said Tim O'Connor, Director of EDF's California Climate Initiative. "As part of a suite of smart policies under our clean energy law, AB32, we're seeing more efficient vehicles, more clean fuel options, and better access to transit. Californians will breathe easier, save money at the pump, and reduce their dependence on oil."

Over the next six years, 70 million tons of carbon pollution will be avoided and 280 million barrels oil will be saved. That's equivalent to avoiding the pollution from nearly 15 million cars and trucks in one year.

As California considers more ambitious future targets, this report – along with a growing body of research over the last several years – demonstrates that the state can reduce the carbon intensity of fuels beyond its current 10 percent reduction target by 2020 to 15 percent by 2025. Long-term regulatory stability is key and will help enable the alternative fuels market to steadily grow to supply 20 percent of California's transportation energy, up three-fold by 2025 compared to when the program began in 2011.

The report was commissioned by the Natural Resources Defense Council (NRDC), the Union of Concerned Scientists (UCS), and the Environmental Defense Fund (EDF).

California's Low Carbon Fuel Standard:
Evaluation of the Potential to Meet and Exceed the Standards

Promotum
10 Chauncy Street
Cambridge, MA
02138

February 2, 2015

Contents

1. Regulatory Background

California's adoption of the Global Warming Solutions Act of 2006, also known as Assembly Bill (AB) AB32, set in motion a series of policies to reduce greenhouse gas (GHG) emissions in the state to 1990 levels by 2020 – roughly a 20 percent reduction – while also protecting public health. Under AB32, the California Air Resources Board (ARB) developed a series of GHG reduction strategies as part of a Scoping Plan for achieving the 2020 goal. For the transportation sector, the key programs ARB adopted include standards for cleaner, more efficient cars and trucks; a clean fuels standard; a cap-and-trade regulation; and established targets to reduce emissions through more sustainable, transit friendly and walkable communities.

The state's clean fuels standard, known as the Low Carbon Fuel Standard (LCFS), was adopted in 2009 as an early-action measure under AB32 and in furtherance of Executive Order S-01-07 by then Governor Arnold Schwarzenegger. In addition, in his recent fourth inaugural address, current Governor Jerry Brown provided targets for a series of new environmental goals for 2030, including reducing current petroleum use in cars and trucks by 50 percent.[1]

California's LCFS is a performance-based standard requiring petroleum refiners and other fuel providers to reduce the carbon-intensity of transportation fuels used in California by 10 percent by 2020. The carbon-intensity of each fuel is measured on a full lifecycle basis, which includes accounting for GHG emissions from production of a feedstock, transport, refining, distribution, and end-use combustion. Because the standard is technology-neutral, companies can earn LCFS "credits" any number of ways, including improving their processes or through switching to renewable feedstocks and inputs. Each LCFS credit represents one metric ton of reductions in GHG emissions. The LCFS is designed to include market-based features that allow LCFS credits to be sold, banked, or utilized to help meet the requirements.

2. Project Scope

To inform the dialogue about the re-adoption of the LCFS and establishment of revised annual compliance requirements, Promotum Inc., an independent technical and management consulting firm focused on fuels and chemicals, was commissioned by the Natural Resources Defense Council (NRDC), Union of Concerned Scientists (UCS) and the Environmental Defense Fund (EDF) to evaluate likely scenarios for compliance and the impact of credit values on incentivizing greater production and volumes of low Carbon Intensity (CI) fuels for sale in the state.[2]

[1] http://gov.ca.gov/news.php?id=18828

[2] The conclusions and views contained herein are solely those of the consultant and do not necessarily reflect those of NRDC, UCS, and EDF.

Promotum reviewed and analyzed fuel availability, prior supply studies, data from obligated parties (fuel suppliers) through quarterly reporting to the ARB, California Energy Commission (CEC) information, U.S. Energy Information Administration (EIA) data, and consulted with a wide number of industry participants with specific sector expertise to develop a forecast of supplies and a model of future low carbon fuel production.

As part of the creation of these scenarios we sought to incorporate the latest technology and commercialization developments. For example, 2014 saw the startup of the first two commercial scale cellulosic ethanol facilities in the U.S. with a third scheduled for launch in early 2015. We sought to understand how likely advances in technology would impact future cost of production. Ultimately, we looked at the impact of LCFS credit value both producing additional lower CI fuels in California, and on moving them into California.

For analytical purposes the study evaluated two scenarios: a Reference Case and Low Case.

- The Reference Case assumes the value of credits within the LCFS market remains at roughly $100 per metric ton reduction ($100/MT) over the 2015 to 2025 timeframe. This case is consistent with the estimate currently included in ARB's assessment under its regulatory analysis, provided as part of its 2014 staff report.
- The Low Case assumes a LCFS Credit Value below $50/MT. This case is consistent with credit values observed throughout 2014.[3]

3. Key Findings

The key findings of this study are:

Supply Potential

- **The petroleum industry can meet current LCFS compliance requirements through 2020 by taking advantage of the program's performance-based incentive for reducing greenhouse gas (GHG) emissions.** The LCFS credit system provides obligated parties sufficient incentive to reduce their carbon emissions in a timely manner. Promotum's analysis shows that a $100 per MT credit value, (an amount utilized by ARB for their regulatory proposal), provides sufficient incentive to achieve a 10% reduction in fuel carbon-intensity by 2020 through three mechanisms: (1) providing greater volumes of alternative fuels in California, (2) reducing the carbon-intensity of traditional fuels, and (3) reducing emissions at refineries and throughout the petroleum value chain.

[3] http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs2015.htm

- **Diesel substitutes, lower carbon-intensity (CI) ethanol, and reductions in the carbon footprint across the petroleum value chain are primary pathways for meeting a 10% target.** Shifts toward lower-carbon feedstocks, including recycled fats and oils, and the production of cellulosic ethanol, including ethanol made from agricultural residue, will reduce carbon intensity. Using electricity as fuel for cars, trucks, and offroad sources such as trains will also significantly contribute to meeting the LCFS.

- **California can extend the LCFS beyond a 10% carbon-intensity (CI) reduction in 2020 to 15% in 2025.** At $100/MT there is sufficient biofuel supply and incentive to support an additional one percent per year reduction from 2020 through 2025.

- **Even under relatively low LCFS credit values, below the historical 2012 and 2013 credit value, California can meet existing requirements through 2020.** However, sustained low credit values may be insufficient to provide enough incentive to achieve a15% reduction by 2025.

Benefits

- **The LCFS program will contribute significantly to meeting California's goal of cutting petroleum use in half by 2030.** Alternative fuels use is increasing, up from supplying only 6% of transportation energy to 14% by 2020 and 20% by 2025. For diesel, much of the growth in demand for cleaner, alternative fuels will be met through biodiesel, renewable diesel, as well as natural gas including biomethane. Growth on the gasoline side will occur largely through increases in lower CI ethanol and electricity.

- **The LCFS is estimated to result in over 70 million metric tons of GHG emission reductions over the next five years through 2020**. Increasing the requirements to 15% by 2025 could generate 183 MMT CO_2e of reductions over the next ten years through 2025, equivalent to cutting the emissions of nearly five coal fired plants operating for ten years.[4]

Reduction Opportunities, Value Creation, and Economics

- **The petroleum industry can achieve a significant portion of the standard by reducing the carbon-intensity of gasoline and diesel through improvements at petroleum refineries and crude oil production facilities.** Just as alternative fuel companies can achieve reduced overall carbon-intensity though efficient production and

[4] U.S. EPA Greenhouse Gas Equivalencies Calculator. http://www.epa.gov/cleanenergy/energy-resources/calculator.html

processing, the petroleum sector has significant potential to reduce the CI of gasoline and diesel through energy efficiency improvements, integration of renewable energy inputs such as biomethane, and use of innovative technologies including solar thermal. This study estimates these three measures alone could result in a 1.5% reduction in carbon-intensity across petroleum-based gasoline and diesel by 2020, growing to a 3% reduction in CI by 2025.

- **Under the Reference Case of $100 per metric ton value, energy efficiency projects at refineries would be significantly more attractive to fuel suppliers.** Based on information generated by energy efficiency audits for California refineries' past and currently proposed projects, the LCFS credit value could more than double the operating savings at the facilities.[5] In addition to garnering operational savings associated with energy efficiency investments, refineries would be further incented under the LCFS to reduce the carbon-intensity of fuel products. Such improvements also allow fuel producers to forgo purchasing pollution permits under the state's cap-and-trade regulation.

- **Use of biomethane at refineries and crude oil facilities to displace fossil natural gas is a potentially attractive option to the reduce carbon-intensity of gasoline and diesel. Such uses are in addition to the use of biomethane in natural gas vehicles.** At the end of the Fall 2014, the LCFS incentive had resulted in an increase in the use of biomethane for natural gas vehicles to 40% of the mix, primarily from biogas capture at landfills.[6] However, a much greater volume of natural gas in California is currently consumed by refineries and crude oil facilities. Full substitution of this end-use with biomethane going forward would represent a potential of 12 MMT of reductions of carbon annually, such that even partial substitution could meet a significant portion of the LCFS.

- **Future capital and operating costs for cellulosic ethanol will decrease over time.** While it is possible for California entities to import hundreds of millions of gallons of ultra-low CI cellulosic ethanol at some point in the future, it is difficult to predict exactly when those gallons will be available. However, cellulosic technology providers have successfully reached commercial scale at some plants and the first wave build out is well underway. Future validation of the first wave of cellulosic production facilities will pave the way for financing of the second and third wave of cellulosic plants. It is widely

[5] Air Resources Board (2013), *Energy Efficiency and Co-Benefits Assessment of Large Industrial Sources Refinery Sector Public Report*, Issued June 6, 2013. http://www.arb.ca.gov/cc/energyaudits/eeareports/refinery.pdf
[6] Air Resources Board (2014), *Low Carbon Fuel Standard Reporting Tool Quarterly Summaries*, http://www.arb.ca.gov/fuels/lcfs/lrtqsummaries.htm.

expected, based on industry experience and learning, that the second wave and later facilities will have lower capital costs and improved efficiency.

- **Even remaining conservative on the timing and volumes for cellulosic ethanol in 2020, given the uncertainty of the second wave of production plants, other low-carbon fuels and technologies can provide sufficient credits under the scenarios evaluated.** Since the LCFS is technology-neutral performance based, and also includes an ability for parties to "bank" or save credits, regulated entities have enormous flexibility to comply. No single technology is required to generate the reductions needed.

- **Over-compliance over the 2015 to 2018 period will allow for compliance in later years through 2020**. The so-called "banking" provisions of the LCFS allow companies to flexibly utilize credits generated in earlier years to comply with future years. As of the end of 2014, parties registered within the LCFS have registered an over-compliance of approximately six million metric tons, with those credits banked for use in future years.[7]

Potential Barriers Moving Forward

- **The LCFS needs underlying regulatory stability to achieve a 10% reduction requirement by 2020 and a theoretical 15% requirement by 2025.** As a result of lawsuits brought against the state by oil and corn ethanol industry groups, the current LCFS reduction mandate has remained at a one percent (1%) CI reduction level since 2013, resulting in significant over-compliance with the standard. As the same time, LCFS credit prices have dropped from nearly $80 per ton in December of 2013 to $26 per credit in December of 2014.[8] Under a scenario where LCFS credit prices remain under $50/ton for 2016 and beyond, the sustained low credit price causes an insufficient market signal, with the overall LCFS market generating annual deficits beginning in 2018 and regulated industries fully using all banked credits by 2020. In 2020 and beyond, the LCFS would experience net cumulative deficits. Accordingly, for the LCFS to achieve full compliance, sufficient regulatory certainty must exist to provide a sufficient market signal to spur additional alternative fuel supplies.

- **Reductions in the carbon-intensity on the gasoline side will be slower than on the diesel side unless greater expansion of E15 and E85 occurs.** While credit values at $100/ton will be sufficient for production of low CI ethanol, further capital investments are needed to develop the next wave of cellulosic ethanol facilities. Furthermore, additional infrastructure investments will be needed to expand the use of low CI ethanol

[7] Air Resources Board (2014), *Low Carbon Fuel Standard Regulation: Initial Statement of Reasons*. December 31, 2014. http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs2015.htm
[8] Information based on reporting of the credit values by ARB. http://www.arb.ca.gov/fuels/lcfs/lrtqsummaries.htm.

beyond E10 (e.g. E15 or E85) and allow the industry to achieve a larger reduction. This includes ethanol producers overcoming limitations due to lack of upgraded ethanol infrastructure including tankage and blender pumps.

- **Long-term regulatory stability and firm commitment with both the Low Carbon Fuel Standard and the federal Renewable Fuels Standard is necessary for financing of new facilities**. Major investors are sensitive to regulatory instability and require long-term time horizons before financing major capital projects. Ensuring forward momentum will, at minimum, require the LCFS credit value to be sufficiently robust to achieve compliance.

4. Methodology

Promotum developed spreadsheets for each fuel technology. Where available we developed supply inputs based on prior studies and on discussions with industry experts and stakeholders. The modeling evaluated a Reference Case and Low Case, with calculations and accounting following ARB's methodology as presented in its regulatory analysis.[9]

For consistency we adopted ARB's baselines for gasoline and diesel CIs; forecasts for gasoline and diesel consumption; the proposed compliance curve from 2015 to 2020; and the banked LCFS credits estimated for 2014. For assumptions on CI, we used the CI look up table from ARB's *Initial Statement of Reasons* (ISOR) Appendix B "average annual CI assumptions." Using the CI values and forecasts, we calculated the overall compliance credits and deficits annually to evaluate compliance each year. Where available we utilized obligated party reporting (2013 and 2014) to ground the model, information that ARB makes publicly available.[10]

The fuel volume tables for the 2015 to 2025 period of study assume that refiners and fuel importers must reduce the lifecycle GHGs produced from gasoline and diesel. This includes crude oil production, transportation, refining, distribution, and combustion. LCFS deficits can be offset by blending lower CI gasoline and diesel substitutes, purchasing credits, utilizing banked credits, or generating credits directly from refinery investment projects or applying innovative technologies at crude oil production facilities. In cases where producers use blending as a compliance strategy, they will largely use ethanol and biodiesel. Additional credits accrue from electric vehicles, both fossil-based and bio-based natural gas (or biomethane), and hydrogen used for fuel cell vehicles. These categories are currently small but growing in their contributions to meeting the standard.

For each case we developed biofuel supply curves for 2015 to 2025. There are many pathways and approved biofuels, but the major substitutes include:

Major Gasoline Substitutes and Technologies	Major Diesel Substitutes and Technologies
Ethanol (Corn, Sorghum/Wheat, Sugar, Cellulosic)	Biodiesel (Soy, Corn Oil, Waste Grease/Used Cooking Oil, Animal Tallow)
Electricity	Renewable Diesel (similar feedstocks)
Petroleum Improvements	Compressed Natural Gas or Liquefied Natural Gas, (Fossil and biomethane)
Renewable Gasoline	Petroleum Improvements

[9] http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs2015.htm
[10] http://www.arb.ca.gov/fuels/lcfs/lrtqsummaries.htm

This report also examined potential GHG reductions in the petroleum value chain. Promotum believes there is significant opportunity to reduce the overall CI of traditional gasoline and diesel, principally by utilizing steam derived from biogas or solar thermal energy sources for Enhanced Oil Recovery (EOR) operations at the well head, substituting biomethane for fossil natural gas at refineries, and utilizing off-the-shelf energy efficiency technology and improved operations at refineries. Promotum did not evaluate use of carbon capture and sequestration (CCS) at petroleum facilities.

5. Scenarios

Promotum created two hypothetical cases to evaluate the effects of credit prices on potential achievement of LCFS targets. For each case, we calculated the LCFS deficits (MT CO_2e generated) produced by the petroleum value chain and the combustion of traditional gasoline and diesel. To this obligation, we added back the LCFS credits produced (MT CO_2e reduced) by substituting in biofuels and through reductions in emissions from the petroleum value chain. We then added previously banked credits before comparing the annual and cumulative total against ARB's compliance curve.

For purposes of the study, we assumed steady state average pricing for Low Carbon Fuel Standard credits. Based on these prices, we evaluated how much low carbon fuel could be produced or imported to California for each fuel type.

As a starting point for the biofuels portion of the scenario assessment, we started with the basic strategy of assuming the penetration of as much low CI substitute biofuel into the California fuels market as was available. This assessment took into account limitations in available supply or potential new capacity. We then backfilled needed fuel volumes with the best available corn ethanol and soy-based biodiesel - using compliance data filed quarterly with ARB to set starting levels of blended ethanol and biodiesel. The starting blend rate for ethanol was 10.6% (by volume) and about 2% for biodiesel.

To calculate the GHG reductions currently required by the LCFS, we used the currently proposed compliance schedule for 2016 through 2020 in ARB Staff's *Initial Statement of Reasons.* According to the analysis, by 2020 the LCFS requirements would effectively require enough credits to reach a 10% reduction in carbon-intensity for gasoline and diesel.

To calculate the GHG reductions required under an LCFS that extended to 2025, we extended the LCFS requirements to a 15% CI reduction, increasing at an additional rate of 1% per annum. Figure 1 shows the compliance requirements used for both scenarios.

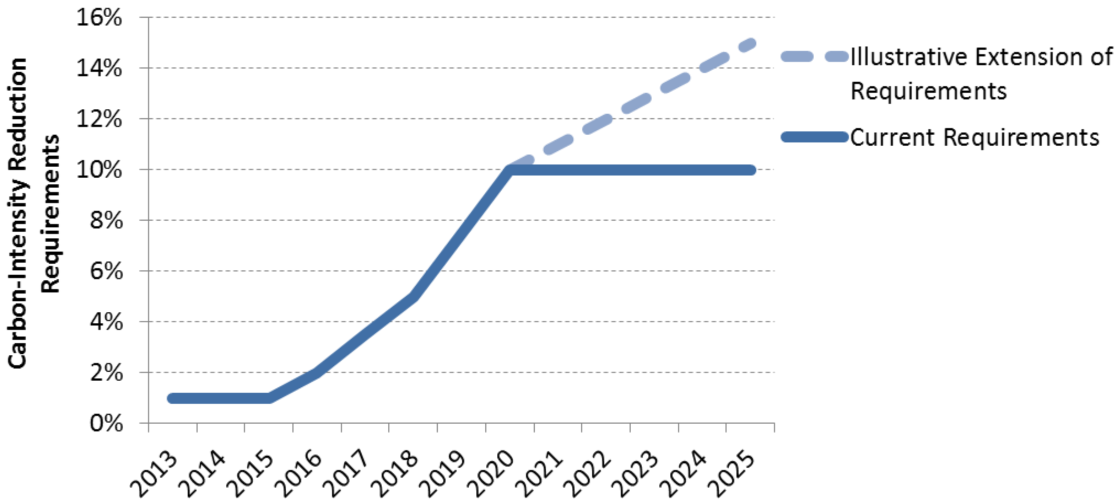

Figure 1: Current proposed requirements achieving 10% by 2020 and extension of requirements to 15% by 2025.

6. Issues and Considerations

Assessing the feasibility of LCFS reductions and differential credit values and the effect of those credit values on biofuel supplies is a considerable and complicated subject. We describe some of the complexities in the following section.

A. Internal LCFS Market Conditions

Since the program's inception, the credit values have experienced market fluctuations. Commodity market experts, such as at Argus, suggest the reasons for volatility encompass a number of factors[11]:

- Regulatory and legal uncertainty in the initial three years,
- Over-compliance occurring due to the low standard — one percent — maintained since 2013,
- A short spot market due to producers banking surplus credits in expectation of future shortfalls, and
- A thin LCFS credit market due to a limited numbers of buyers, sellers, and volumes of credits able to be bought and sold.

[11] *Argus White Paper: California Environmental Markets: Factors that Affect LCFS and GHG Trading,* Argusmedia.com

B. Combined Effects of the LCFS and the Renewable Fuel Standard

In addition, understanding the implications of the California GHG reduction measures must account for the federally mandated Renewable Fuel Standard (RFS) managed by the U.S. Environmental Protection Agency (EPA). The RFS requires increasing volumes of biomass-based fuels, with specific volumetric requirements for different categories of fuels meeting GHG reduction thresholds. Fuels that qualify are eligible to generate Renewable Identification Numbers (RINs), a serial number that both allows for tracking of fuel and allows for trading among parties. Like LCFS credits, RINs have a market value for those that own them. In addition, RINs become separable after biofuels are blended - meaning producers can choose to buy and retire RINs instead of blending biofuels themselves.

As a result, if the LCFS credit value plus RIN value exceeds transportation cost to California for a given gallon of biofuel, this should provide enough incentive for producers to make more biofuels and sell them into the California market. Figure 2 demonstrates how RINs and LCFS credit work in tandem to increase supplies of the biofuel.[12]

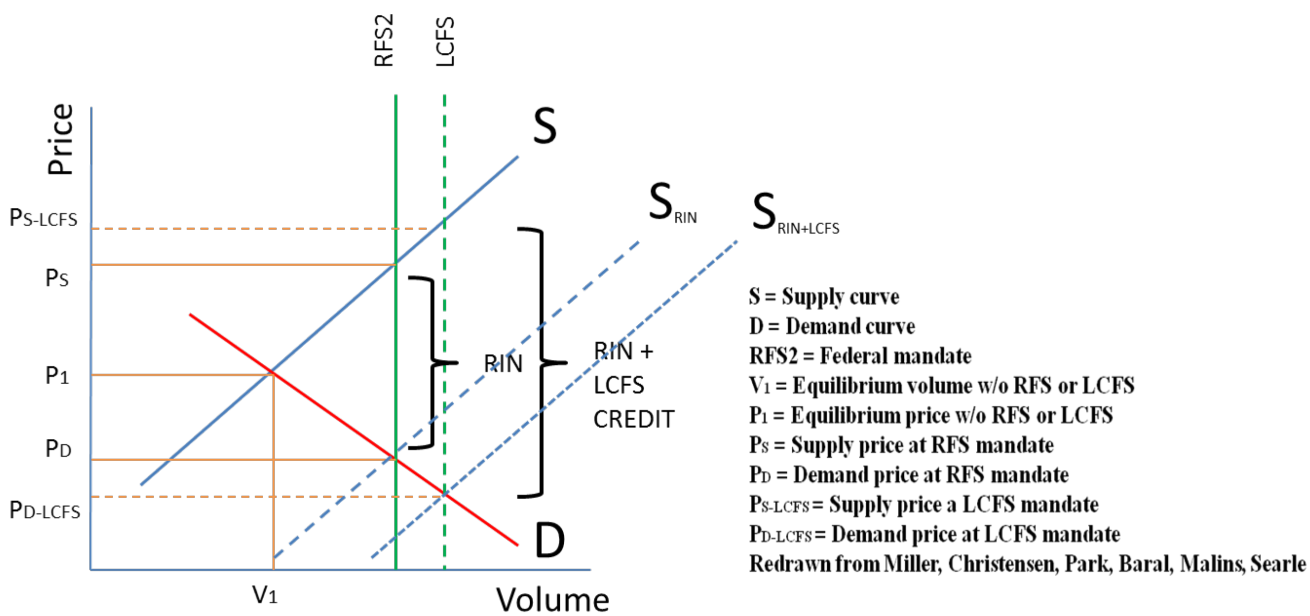

Figure 2: Biofuel economics of LCFS credits and RFS RINs.

[12]N. Miller et al (2013), *Measuring and addressing the investment risk in second-generation biofuels* industry, International Council on Clean Transportation, 2013. http://www.theicct.org/addressing-investment-risk-biofuels

C. Technology and infrastructure development

Notwithstanding the impact of overlapping LCFS and RIN credit prices, the market signal for Low-CI fuel development gets more complicated when considering the stages of technology development and production capacity for many low CI fuels (i.e. advanced biofuels). Based on present market conditions, it remains evident that much of the nation's prospective supply of low-CI fuels is still maturing. Significant infrastructure issues need to be addressed for many biofuels before the market is truly efficient with high price elasticity.

Under these circumstances technology developers are making investments in technology and capacity based on market expectations, including the future of the RFS and the LCFS programs in terms of regulatory certainty and the RIN and LCFS credit markets. The diagram below based on biofuel supply curves generated by Nathan Parker at UC Davis describes the situation graphically.[13] For our purposes we assumed that LCFS credit values will signal prospective suppliers in anticipation of a future efficient market.

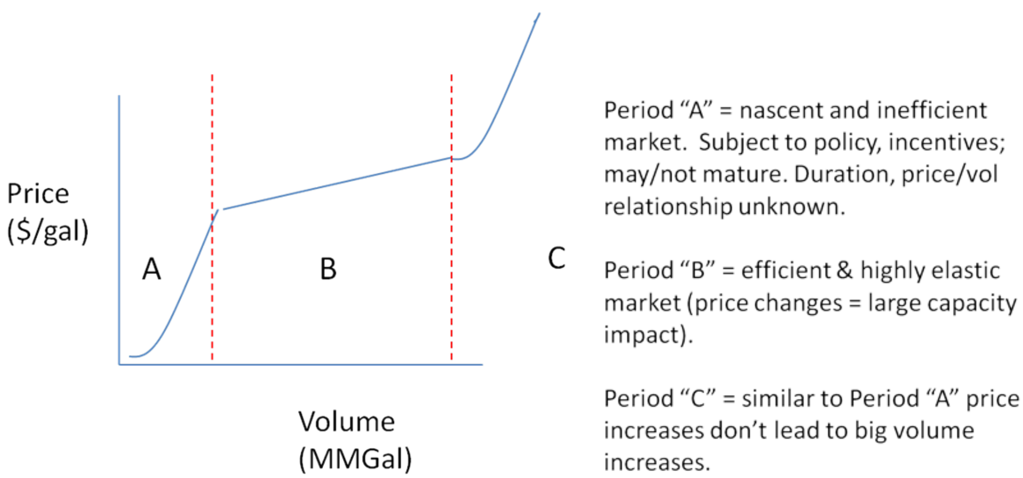

Figure 3: Biofuel supply at varying price points.

For each of our cases we estimated the biofuels volumes, which after analysis we believed would be available in California based on the LCFS credit value, constrained by our understanding of the current state of technology, infrastructure and U.S. or global forecast capacity. To understand the value of each biofuel to California we calculated how much each fuel resulted in reduced carbon dioxide emissions and then what additional value was associated with the fuel, on a dollar per gallon gasoline or diesel equivalent energy basis ($/gge or $/dge), depending on which fuel they substituted for.

[13] N. Parker (2011), *Modeling Future Biofuel Supply Chains Using Spatially Explicit Infrastructure Optimization*, Dissertation, Univeristy of California, Davis. http://www.its.ucdavis.edu/research/publications/publication-detail/?pub_id=1471

D. LCFS incentive value for alternative fuels

Figure 4 translates LCFS credit value for gasoline and diesel substitutes to a dollar per gallon gasoline equivalent basis. The credit value range shown represents a low of $50/MT CO_2e to a high of $150/MT.

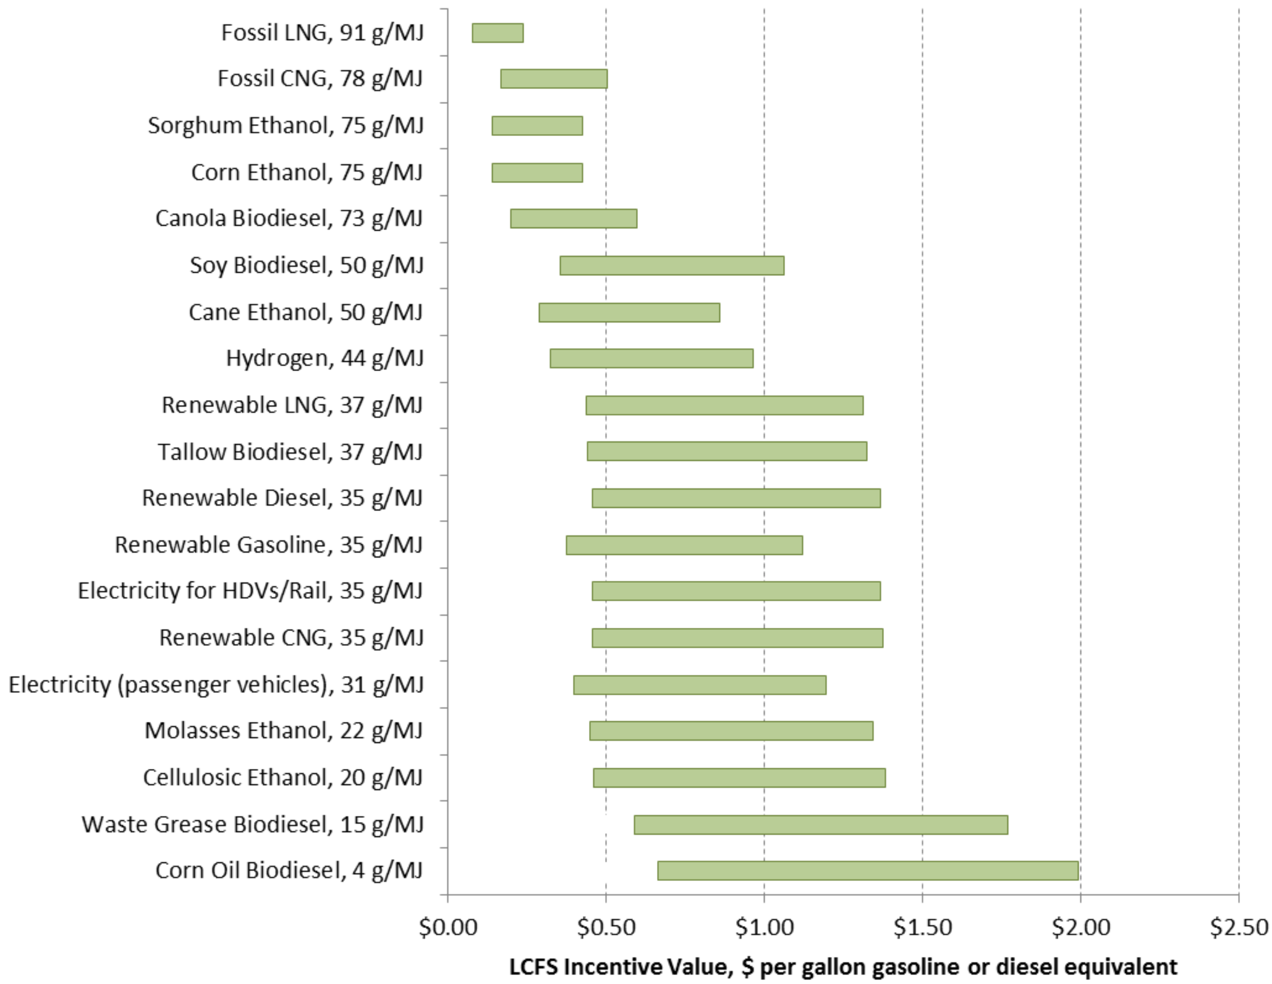

Figure 4: Incentive value provided by the LCFS. Range represents $50 to $150 per MT CO2e reduction.

As shown in Figure 4, the Reference Case of $100 per MT reduced of CO_2e translates into an additional value of $0.92/gallon for cellulosic ethanol. Theoretically, as long as the LCFS credit value together with the associated cellulosic RIN prices exceed transportation costs, we should see producers ramping up capacity and selling into California as well as California producers expanding and increasing production.

In the Low Case ($50/MT reduction), the value for cellulosic ethanol translates to $0.46/gallon in addition to the RIN value. Higher LCFS credit values, of course, are possible and would theoretically provide greater incentive for domestic production or greater importation. However, other factors, such as the state of technology development and availability for financing of new facilities, may be more critical in establishing necessary volumes than the incentive value of RINs and LCFS credits.

E. LCFS incentive value to reduce petroleum sector emissions

The LCFS also provides incentives and returns credit value to petroleum companies that choose to reduce lifecycle oil and gas emissions directly. These companies may generate credits by reducing the CI of crude oil production and refineries through greater use of energy efficiency, innovative technologies, or renewable inputs. Like other fuels, these investments can yield LCFS credits which have higher or lower value based on the overall credit price.

One example of the value of the LCFS for petroleum company investments can be extrapolated from self-reported data on energy efficiency investments by California petroleum refineries to the ARB. [14] As reported, there are over four hundred past and planned energy efficiency and co-generation projects at refineries in California, with a total capital cost of approximately $2,600 million - resulting in annual energy savings of about $200 million for refineries and 2.8 million metric tons of reduced GHGs.

Using past projects identified to ARB as an illustration, if refineries were to invest in future energy efficiency improvements that resulted in an additional 2.8 million metric tons of reductions and achieved the same annual operating savings, the additional LCFS credit value generated could be between $140 to $280 million dollars annually (at a $50 to $100/ton credit price respectively). In addition California refineries would avoid having to purchase permits, or allowances, within the state's cap-and-trade regulation to cover their remaining CO_2 emissions, yielding an additional cost saving of about $35 million annually, assuming current permit prices of just over $12 per ton. These savings, in theory, would increase the overall annual savings from $200 million (energy savings) to $375 to $515 million annually at refineries with the additional LCFS credit value and avoided need to purchase cap and trade pollution permits. While further analysis in this area is warranted to provide finer resolution on a project-specific basis, initial calculations suggest that the LCFS could more than halve the payback period for investments in energy efficiency projects in some cases, making these projects significantly more attractive for petroleum companies.

7. Key Outputs

Promotum's analysis incorporates three major mechanisms that drive reductions in the carbon intensity of transportation fuels. The first is to increase the volume of renewable fuels we

[14] http://www.arb.ca.gov/cc/energyaudits/eeareports/refinery.pdf

currently use (grow the market); the second is to improve the carbon-intensity (CI) of the fuel (improve the fuel in the market); and the third is reduce emissions directly at refineries and crude oil production facilities using energy efficiency, renewable energy, and innovative technologies. To achieve the greatest reductions, California will likely need to spur all three mechanisms to varying degrees.

In our estimate, compliance with the LCFS will result in the alternative fuels market growing to 14% of the transportation energy mix by 2020 and 20% by 2025. Constraints on growth include the E10 blend-wall as well as the rate at which biodiesel can expand and be utilized in California. More volumes of ethanol and biodiesel will be needed to achieve compliance. This means California will need to accelerate E15 and E85 deployment as well as biodiesel blends above B5 levels post 2017 based on the Reference Case scenario.

In terms of improving the carbon-intensity of fuels, achieving the LCFS will require migration toward lower-carbon feedstocks; improvements at the biofuel plant and at the agricultural level. The LCFS is already sending a market signal, but regulatory certainty is necessary to ensure sufficient value for technology improvements to continue.

Improvements along the petroleum value chain remains, to date, one of the largest untapped areas of potential for CI reductions across the existing fuel pool. While alternative fuels will increase in market share, the large majority of transportation fuels will remain petroleum-based over the timeframe. Even small changes in CI, when spread across large fuel volumes, will lead to significant reductions.

The analysis of the effects of credit prices demonstrates three findings. First, the LCFS credit value is an important factor in increasing low-carbon fuel supply and reductions in GHG emissions we can achieve. Second, ARB's regulatory analysis, showing credit prices around $100/ton, would be sufficient to allow for a 10% requirement to be met by 2020 while extending the standard to a 15% level by 2025. Third, if credit values remain low – as we saw in the past year, due to regulatory uncertainty– then sufficient incentive will not exist for low-carbon fuel production, and compliance beyond 2020 will be unlikely to occur.

Beyond the recent decreases in oil prices, the most significant barrier to the supply of low CI fuels in California remains uncertainty with the regulatory environment. Oil companies, alternative fuel companies, and other energy investors make large capital commitments and require enough time to achieve acceptable returns.

LCFS Reference Case:

Figure 5 demonstrates annual and cumulative credit balance over time for the Reference Case.

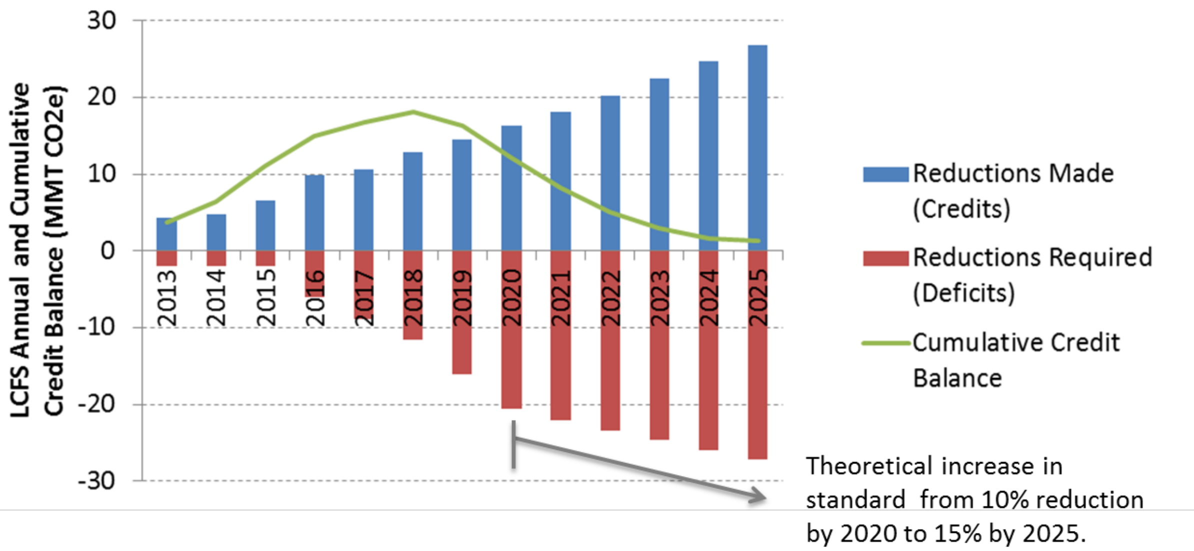

Figure 5: LCFS Annual Credit and Deficits, with the Cumulative Credit Balance (LCFS Reference Case).

The LCFS Reference Case is comprised of the following scenario:

- An LCFS credit value of $100/MT
- Assumes that the current requirement of 10% CI reductions by 2020 is increased to 15% CI reductions by 2025
- Biomass-based diesel, including biodiesel and renewable diesel, become a principal tool of compliance, taking advantage of underutilized production capacity and RIN and LCFS credit values to utilize waste greases, animal tallow, corn oil, and soy oil among other feedstocks.
- Blend rates of biodiesel grow to a 7% by volume mix in diesel (B7) by 2020 taking into account existing infrastructure constraints and restrictions on increased NOx. Blend rates increase to B12 in 2025 as the new NO_x control technologies on trucks are phased in by 2023.
- Direct emission reduction from the petroleum value chain make significant contributions to LCFS compliance
- Electricity used in passenger vehicles, as well as for off-road mobile and truck applications, also make significant contributions.
- Credit value is sufficient to incent the production and import of low CI cellulosic and sugarcane ethanol from existing facilities, but other factors related to investment and financing of new facilities, distribution infrastructure, and other issues limit availability.

The LCFS Low Case:

Figure 6 demonstrates annual and cumulative credit balance over time for the Low Case.

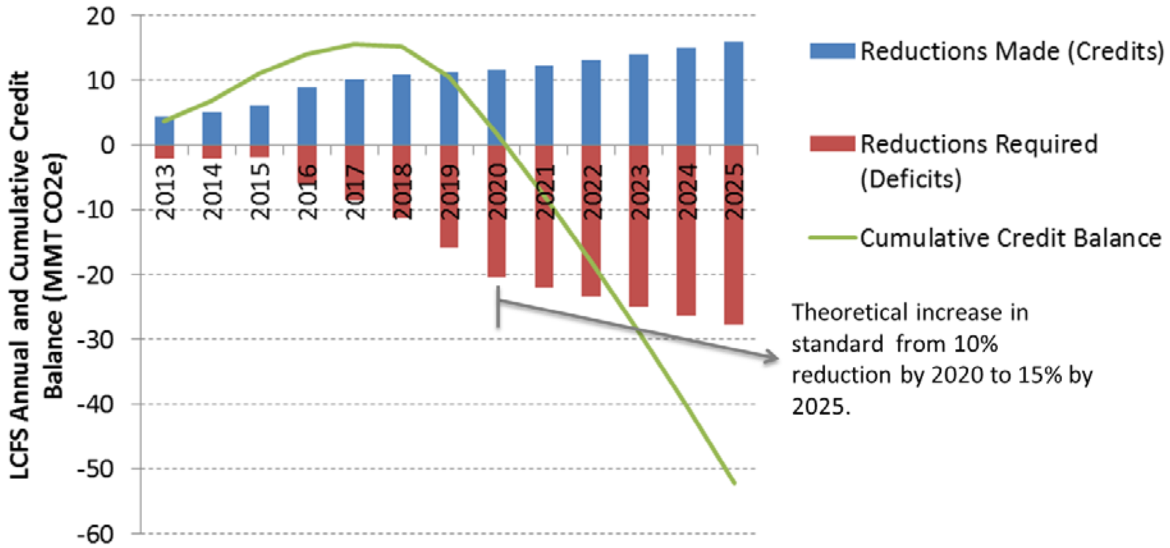

Figure 6: LCFS Annual Credit and Deficits, with the Cumulative Credit Balance (LCFS Low Case).

The LCFS Low Case is comprised of the following scenario:

- LCFS credit value below $50/MT
- Assumes that the current requirement of 10% CI reductions by 2020 is increased to 15% CI reductions by 2025
- Inexpensive and local waste based fuels come to the fore, which is positive, but under this scenario the incentive amount is not sufficient to persuade waste based biodiesel and renewable diesel producers to sell much more than the 2013/2014 volumes currently utilized in the state.
- California's LCFS market may achieve the Low Case scenario in the near term, but soy biodiesel (and other existing seed or vegetable oils) are not sufficiently incented to drive compliance.
- Absent large amounts of credits generated from diesel substitutes as in the Reference Case, greater ethanol demand occurs. In this scenario, a blend rate of 19% ethanol, including 2.5 billion gallons of mid-CI ethanol (e.g. corn, sorghum, wheat-based) would be required to achieve compliance in 2020.
- While there is enough ethanol production capacity, under a Low Case, significant investments in ethanol infrastructure to support E15 or E85 distribution are needed, including investments in storage tankage and retail blend pumps.
- In the Low Case, the LCFS incentives would be insufficient to allow for compliance beyond 2020.

Tables and additional descriptions of the compliance pathways are provided in the Appendices.

Appendix A: Description of compliance pathways

Reference Case ($100 per ton credit value)

Ethanol - Prior to the LCFS, requirements for reformulated gasoline to reduce smog – together with the federal RFS volume requirement – have effectively led to the growth in the use of ethanol to E10 levels. Corn-based ethanol has been the primary biofuel utilized in California. The LCFS has driven improvements in the carbon-intensity of the ethanol mix over the past three years. ARB has approved many ethanol pathways and the CIs of ethanol produced as well as imported into California continue to drop significantly. In our Reference Case we see a tapering of corn ethanol consumption starting in 2015, dropping steadily to 650 MMG in 2025 as other lower CI ethanol feedstocks and fuels become available.

Traditionally the US receives 50% to 60% of Brazil's cane ethanol exports and despite current challenges in the Brazilian marketplace, we expect imports of this low CI fuel to continue. These challenges, including sugar versus corn pricing and Brazil's domestic policies, will likely temper California's imports. Ultimately, we see consumption growing to 300 million gallons per year (MMGY) by 2020.

While it is easy to envision the importation of hundreds of million gallons of ultra-low CI cellulosic ethanol into California, it is difficult to predict exactly when those quantities will be available. Cellulosic ethanol (c-etoh) volumes remain highly uncertain.

Cellulosic technology providers have successfully reached commercial scale and the first wave build out is well underway. Based on separate estimates from Bloomberg New Energy Finance (2014) and Environmental Entrepreneurs (2015), about 220 million gallons per year of capacity of cellulosic ethanol is already built or forecasted to be completed by end of 2015, with about 100 million gallons of this capacity located in the U.S.[15] We expect availability of c-etoh to emerge in 2015 with the launch of the Abengoa, POET and DuPont facilities in the U.S. However, capacity utilization will likely be modest for the early years. Based on a healthy LCFS credit value and discussions with c-etoh technology providers, we expect a significant fraction of the available pool to make its way to California.

Coming validation will pave the way for financing of the second and third wave of cellulosic plants. At this time the facilities are more expensive and smaller than first generation ethanol plants. However, both capital and operating expenditures will decrease significantly over time as technology and operations improve. Cost of production estimates for cellulosic ethanol abound. Promotum reviewed publically available studies and analysis by academics as well as government agencies that incorporate theoretical cost models. In addition, Promotum spoke directly to several technology providers. We incorporated available data into our supply curves

[15] Bloomberg New Energy Finance data (http://about.bnef.com/). Environmental Entrepreneurs (2015), *Advanced Biofuel Market Report 2014*.

for the Reference Case and Low Case and this informed our thinking. We believe the estimates are conservative but reasonable.

US c-etoh facilities will largely be green field construction, scaling in modular fashion from 25 million gallons per year capacity followed by 50 and 75 MMGY plant capacities. Given issues around herbaceous feedstock transportation, achieving 100 MMGY capacity in any one plant is doubtful. Based on conversations with cellulosic ethanol technology providers we believe the price of cellulosic ethanol will fall on a fully loaded basis from $2.75/gallon today to about $1.70/gallon in 2030, including the cost of capital.

Electricity and Hydrogen –While internal combustion engine vehicles remain the current predominant technology on the road, automakers are rapidly investing in fuel efficient technologies, including various combinations of electric-drive vehicles, from plug-in hybrids to full battery electrics, even offering initial hydrogen fuel cell vehicles. As electric-drive vehicle sales continue to displace gasoline powered vehicles, demand for low CI electricity will increase and credits will be generated. We see electricity consumption almost quadrupling from 0.44GWhr in 2015 to 1.6GWhr in 2020 and nearly 4.4GWhr in 2025. For hydrogen, we believe the opportunities for fuel cell vehicles are good, but we have conservatively kept consumption at modest levels in the study, given potential hydrogen infrastructure constraints. We also note that improvements in the CI of electricity and hydrogen are expected, particularly if California meets targets to reach 50% renewable by 2030 in addition to the existing 33% Renewable Portfolio Standard requirements by 2020. To be conservative, however, we kept CI constant, as assumed in ARB Staff's *Initial Statement of Reasons*.

Petroleum Supply Chain Improvements – This study estimates GHG emission reductions in the petroleum value chain, including at the well head and refinery level will make up a significant percentage of overall compliance in the Reference Case.

Three technologies were included in this assessment using a study by TetraTech/NRDC (2014) as a starting point. These include use of solar thermal for steam generation in enhanced oil recovery, broader use of energy efficiency at refineries, and use of biomethane by the petroleum industry. These estimates may be conservative given the wider array of technologies available as well as industry experience with some of these technologies already.

For solar thermal, it is assumed that approximately 10% of the fossil natural gas used for steam injection projects is displaced in California by 2025. These estimates do not include an assessment of the potential for crude oil imported into the state, which currently represent 63% of the mix used in California, to utilize this technology. We estimate that by 2025, just over 0.7 MMT of reductions annually can be generated.

For refinery energy efficiency (EE) investments, it is assumed that at $100/ton, the incentive is sufficient to more than double the payback of EE, such that a reduction of 1.5% per year improvement in GHG emissions at refineries across the industry. We estimate that reductions from EE investments grow linearly from 2017 to 2025, reaching 4.3 MMT in annual reductions by 2025.

In terms of renewable energy inputs, we consider the use of biomethane to replace fossil natural gas at crude oil facilities, a fuel consumed at refineries, and a feedstock for hydrogen production utilized by refineries. We assume that 15% of the natural gas used by California crude oil and refining facilities could be displaced via biomethane purchases by 2020, growing to nearly 40% by 2025. The reductions would grow to 1.1 MMT annually by 2020 and 2.8 MMT annually by 2025. Significant volumes of biogas, which can be cleaned and processed into biomethane, are currently emitted, flared, or captured from landfills, dairy digesters, and waste-treatment facilities throughout the U.S.[16]

The study projects CI reductions, applied as credits for crude oil producers or refineries respectively, would be approximately 1.5% by 2020 and 3% by 2025 over the entire lifecycle of petroleum gasoline and diesel. This CI reduction level corresponds to 16% and 32% of the standard in 2020 and 2025 respectively being met in those years from direct petroleum supply measures. We believe the current environment of relatively low oil prices also lends itself to implementation of downstream projects, including refinery energy efficiency and GHG reduction projects, as other capital investments in the upstream and midstream are reduced in the U.S.

When combined, we see opportunities for 4.2MM MT of GHG reduction in 2020 reaching 8.8MM MT in 2025 from these three categories of technologies.

Renewable Diesel – We see opportunities for renewable diesel (R-Diesel) to play an important role in California's biofuel portfolio, based on existing domestic and international plant capacity, reaching 400 MMGY in 2020. This represents almost 50% of the ~850 million gallon global capacity, but is consistent with the estimates by the Air Resources Board staff in their regulatory analysis.[17] To some extent we have concerns with regard to the sustained availability of international supplies (~650 million gallons per year) and the high cost of new capacity. We do believe domestic capacity for hydrotreating waste oils will be constrained. We also believe there will be considerable competition for this capacity with military aviation fuel. Continued uncertainty around the US production tax credit will also inhibit financing capacity expansion.

Biodiesel – Biodiesel is a primary driver of compliance in the Reference Case. In California and the United States there are hundreds of millions of gallons of underutilized biodiesel production capacity. The technology is simple and mature, utilizes low carbon feedstocks and produces a low CI diesel substitute. We see an important opportunity to grow the blend rate beyond the currently anemic 2% levels by volume. Waste grease (used cooking oil),increasing volumes of corn oil biodiesel and soy biodiesel will contribute. We see total biodiesel consumption reaching 265 MMGY in 2020 and more than 500 MMGY in 2025.

[16] NREL (2013), *Biogas Potential in the United States*, NREL/FS-6A20-60178, October 2013, National Renewable Energy Laboratory, Energy Analysis, Golden, CO. Also see EPA Landfill Gas candidate project lists: http://www.epa.gov/lmop/projects-candidates/index.html.
[17] http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs2015.htm

Availability of corn oil depends primarily on the penetration of necessary unit operations within corn wet mills. Starting from approximately 59% in 2015 we see penetration increasing to ~90% by 2025. We forecast 68 million gallons of inedible corn oil biodiesel reaching California in 2020 out of an estimated US pool of 475 million gallons and greater than 100 million gallons in 2025.

Biodiesel from used cooking oil (waste grease) will continue to make an important contribution to the BD pool. We estimate 51 million gallons will be available to California in 2020 and 77 million gallons in 2025. While the very low CI makes it particularly attractive, community collection by its nature will remain a constraint.

Swing biodiesel feedstock will come in the form of soy oil. While often spurned because of its nominal association with food, soy oil is separated, from soy protein prior to utilization. A healthy LCFS credit value overcomes traditional soy pricing problems, which have mothballed many biodiesel facilities and left many others operating below capacity. With an improving CI profile we predict 51 million gallons of soy biodiesel in the California market in 2020 and 77 million gallons in 2025. We do not see a big role for canola based biodiesel in the US or California.

Natural Gas – We expect natural gas usage in fleets to increase and used to comply with the LCFS. We also assume that an increasing share will come from biomethane captured from landfills and other sources, including anaerobic digestion and waste-treatment facilities. We find approximately 170 million diesel gallon equivalents of liquefied natural gas will be utilized by 2025 and 306 million diesel gallon equivalents of compressed natural gas being utilized. We assume approximately 80% of these volumes will be derived from biomethane sources by 2025, given the increased value for biomethane producers and current levels in California approaching 40%.

Low Case (less than $50 per ton credit value)

Ethanol – In a Low Case scenario, inexpensive corn, wheat, or sorghum based ethanol becomes the primary tool of compliance. Instead of the tapering we saw in the Reference Case, a dramatic increase in these feedstocks occurs, reaching blending level of 2.5 BGY in 2020, together with an additional 140 MMGY of low-CI ethanol. This represents an effective blend rate of 19%-21% in the years 2020-2025.

Electricity and Hydrogen – We find that similar levels of electricity and hydrogen consumption for the transportation sector will occur between the LCFS Reference and Low Case. However, we have not analyzed the use of electricity credits by utilities and the effects on the market, given the lack of current data.

Petroleum Supply Chain Improvements – Lower credit values decrease the incentive for refinery and well head improvements. Significant reductions still occur, reaching 2.1MMT in 2020 and 5 MMT in 2025, but the pace of implementation is slower.

Renewable Diesel – R-Diesel remains relatively expensive from 2015 to 2025 and lower LCFS credit values mean blending remains stuck at circa 2015 levels, approximately 100MMGY.

Natural Gas – While we find that NGV usage and natural gas demand for transportation to remain at similar levels to the Reference Case, we see a significant drop in biomethane use to only double from current levels, growing to only 30 MMGY (diesel equivalent).

8. About Promotum

Promotum is a technology based management consulting firm working at the convergence of fuels, chemicals and biologics. We are a team of standout engineers, scientists and accomplished MBAs, who are as passionate about science and technology as we are about business. By focusing on the convergence of energy, materials, and biology we deal daily with complex issues and disciplines. Promotum is growth focused helping clients enter new markets, evaluate or create them. Our expertise allows us to maximize results for our clients around the world. Promotum is headquartered in Cambridge, Massachusetts.

Functional Practices

Subject: Tetratech/NRDC Study on Five Technologies to Reduce GHGs from Petro Supply Chain
Comment:
Please find attached a joint study by Tetratech and NRDC on several opportunities to reduce GHG emissions and carbon-intensity directly at refineries and crude oil production facilities.

Five approaches to reducing carbon pollution directly from the petroleum supply chain were analyzed. The study's results point to a significant portion of LCFS compliance and credit generation being possible through these technologies. LCFS 23-1

Cleaning Up California's Fuels: Technologies To Reduce The Oil Industry's Carbon Footprint And Meet The Low Carbon Fuel Standard

Since the adoption of the first-in-the-nation Low Carbon Fuel Standard (LCFS) in 2009, California continues to successfully reduce the carbon pollution of transportation fuels. The production and use of petroleum-based fuels are responsible for approximately half of the state's entire carbon emissions.[1] While the substitution of cleaner energy sources for crude oil, like advanced biofuels made from agricultural waste, is a key strategy to reduce carbon pollution, it is also important to employ technologies that can directly reduce the pollution generated from crude oil extraction and refining. A new report from Tetra Tech and NRDC, Carbon Reduction Opportunities in the California Petroleum Industry, looks at significant, concrete steps that the California oil industry can adopt today to curb its carbon emissions. These ready-to-deploy technologies could also go a long way to meeting the industry's responsibility under the LCFS.

The LCFS is a major component of California's Global Warming Solutions Act of 2006, known as A.B. 32, and requires the oil industry and other fuel providers to reduce the carbon footprint of transportation fuels by 10 percent by 2020. As a performance-based standard, the LCFS allows industry flexibility to invest in the most cost-effective technologies to reduce carbon pollution from fuels.

Solar thermal facility developed by BrightSource, Coalinga, California.

Source: tech.fortune.cnn.com/2012/04/17/yergin-gas-solar-wind

EVEN MORE OPPORTUNITIES TO REDUCE CARBON POLLUTION

Five approaches to reducing carbon pollution directly from the petroleum supply chain include:

- Renewable steam generation: using solar power to generate steam for enhanced oil recovery, rather than combusting fossil fuels for that purpose.
- Steam generation with carbon capture and sequestration (CCS): capturing and storing the flue gas emissions from once-through steam generators used in enhanced oil recovery.
- Refinery energy efficiency: enabling refineries to use less energy in their operations.
- Refinery CCS: capturing and storing carbon emissions resulting from the energy-intensive hydrogen processes needed for refining crude oil.
- Renewable refinery feedstocks: displacing part of the refinery's crude oil with renewable-based oils and waste oils.

The new report shows that modest adoption of the five carbon reduction technologies identified above could reduce emissions by nearly 3 million to 6.6 million metric tons annually in 2020. For a reference point, the full potential of these technologies—if adopted across the board—would result in 20 million metric tons of reduction annually, equivalent to the removal of nearly 5 million passenger vehicles from the road. Additional opportunities—such as

www.twitter.com/nrdc

renewable electricity and hydrogen use at refineries, use of other cleaner technologies at oil production operations, and efficiency improvements at crude oil production facilities—could help reduce emissions even further.

MEETING THE LOW CARBON FUEL STANDARD

Even moderate adoption of these technologies could help refiners meet the goals of California's LCFS. The standard requires oil companies to reduce their carbon intensity by 10 percent, or approximately 17 million metric tons, by 2020. Overall, the potential of the oil industry to directly reduce carbon emissions is sizable, and the technologies to do so are available and viable. Moreover, in addition to reducing carbon pollution, many of these technologies can reduce other air pollutants, providing further benefits to public health.

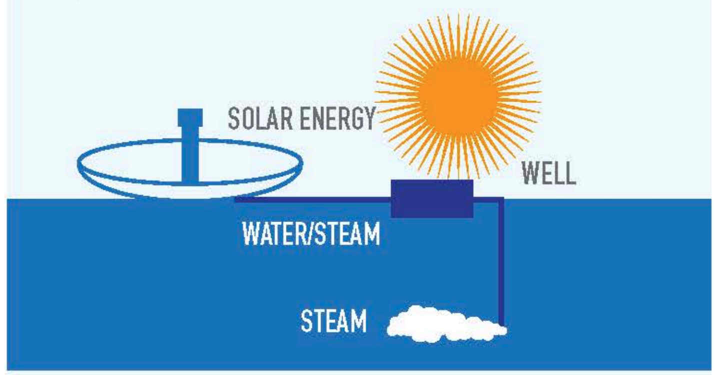
CLEANING UP EXISTING FUEL SUPPLIES

Despite claims to the contrary, there is no shortage of opportunities for the fuel industry to shrink the carbon footprint of transportation fuels. While the use of low carbon, advanced biofuels and the use of cleaner electricity remain key strategies to reduce emissions overall, cutting emissions from the production of petroleum, by far the largest portion of the market, is also important. Ninety five percent of California's transportation fuel supply is derived from crude oil. The oil industry operates more than 50,000 active oil wells and 18 refineries in the state, and the combined carbon emissions from these facilities account for more than 10 percent of the state's emissions, or an estimated 48 million metric tons of carbon dioxide annually.

Fortunately, the LCFS can provide a strong investment signal for existing petroleum facilities to deploy carbon reduction technologies. Meeting the state's air pollution and carbon reduction goals will ultimately require not only that we turn to new, cleaner fuels, but also that our current fuel supplies get cleaner over time. Fortunately, there exist hundreds of ways to accomplish both.

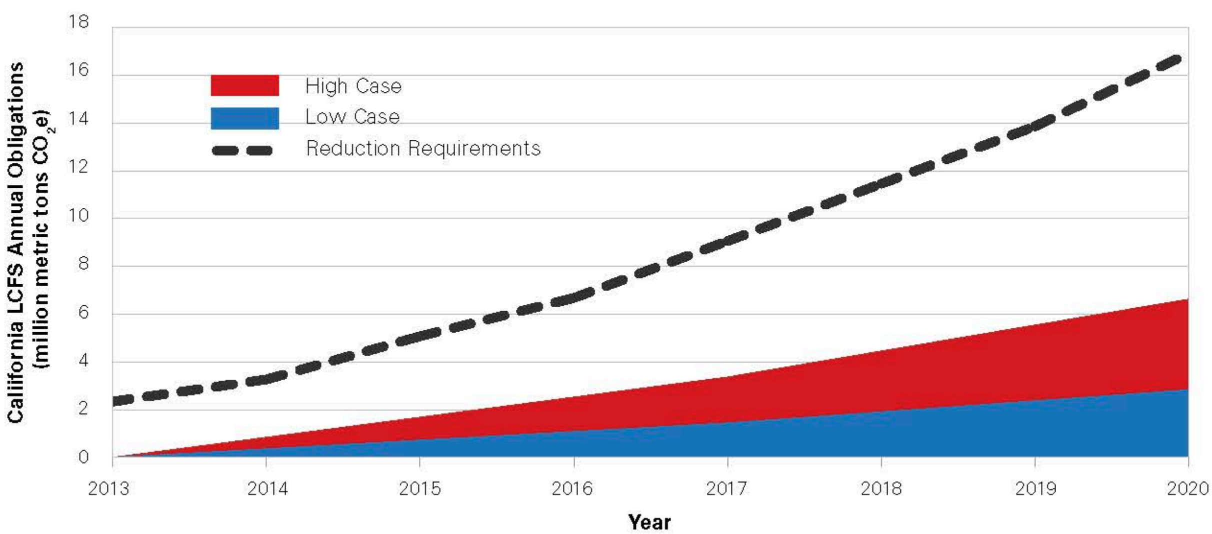
Using Solar Energy to Generate Steam

To generate steam renewably, mirrors and reflective surfaces are arranged to concentrate sunlight. The solar energy is directed at a central tube or tower containing water, which is heated and turned into steam. The steam is injected into oil wells to improve recovery rates



This renewable steam generation technology is currently being deployed commercially by BrightSource in Coalinga, California, and by GlassPoint in McKittrick, California, and Amal, Oman.

By adopting existing carbon reduction technologies and other cost-effective reduction strategies, refiners can meet a significant portion of their LCFS compliance obligations.



1 Estimates based on California's 2011 Greenhouse Gas (GHG) emissions inventory by the California Air Resources Board. Direct combustion emissions in the transportation sector account for approximately 38% of statewide emissions. The inclusion of GHG emissions from upstream crude oil production, refining, and transport increases the total carbon footprint to roughly half of statewide emissions. (www.arb.ca.gov/cc/inventory/inventory.htm)

SUMMARY

As industry leaders and policymakers seek to reduce the carbon pollution impacts caused by human activity, the petroleum supply chain and the use of petroleum products present numerous and significant opportunities for emission reductions. From crude oil production and refining to gasoline and diesel use in vehicles, each portion of the supply chain contributes to the oil industry's carbon footprint. While substitution of cleaner energy sources for oil is a key strategy to reduce carbon pollution, it is also important to take advantage of the technologies currently available that can directly reduce the carbon footprint of petroleum from production to final use. Opportunities to shrink this footprint include, but are not limited to:

- Renewable steam generation: generating steam for enhanced oil recovery using solar power, rather than combusting fossil fuels in once-through steam generators.
- Steam generation with carbon capture and sequestration (CCS): capturing and storing the flue gas emissions from once-through steam generators used in enhanced oil recovery.
- Refinery energy efficiency: enabling refineries to use less energy in their operations, thereby reducing their carbon emissions.
- Refinery CCS: capturing and storing carbon emissions resulting from the energy-intensive hydrogen processes needed for refining crude oil.
- Renewable refinery feedstocks: displacing part of the refinery's crude oil with natural oils, such as animal fats and waste oils, thereby reducing the full-fuel-cycle carbon intensity of the final refinery products.

The five technologies analyzed here do not encompass the full suite of opportunities to reduce greenhouse gas emissions (GHG, or herein "carbon") in the petroleum supply chain; such an extensive analysis is beyond the scope of this brief. Some of these additional technologies or practices include use of renewable electricity at refineries, use of biomass as an energy input, use of clean distributed generation technologies at oil production operations, renewable hydrogen inputs at refineries, avoidance of lower-quality crude oils that require greater extraction and refining energy, lower-carbon technologies for enhanced oil recovery that utilize gas or chemical injection, and efficiency improvements at crude oil production facilities.[1,2] In addition to these limitations, this brief does not evaluate the costs or cost-effectiveness of the various technologies or the potential reductions in criteria air pollutants.

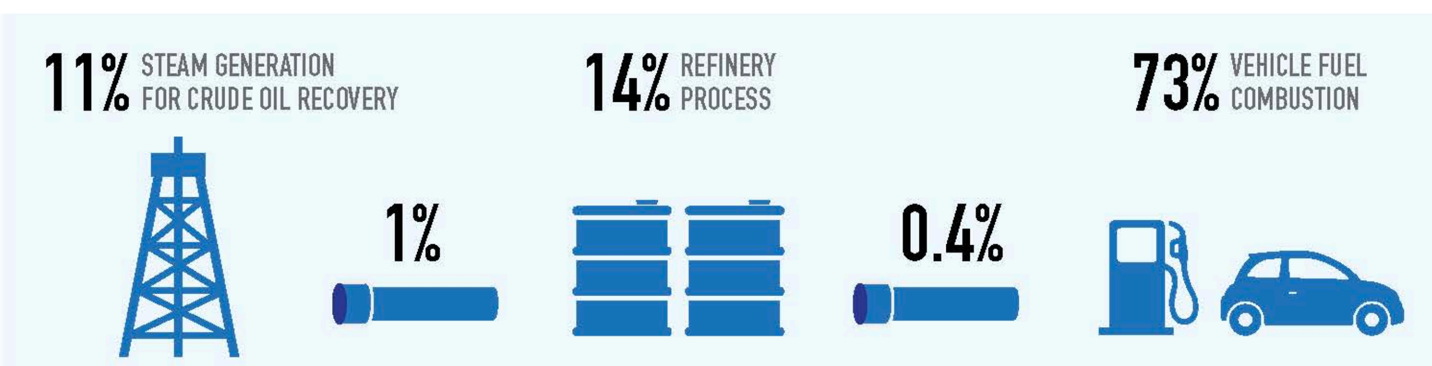
This brief analyzes a low and a high market adoption scenario for the 2014 to 2020 period to illustrate the potential impact of implementing the five carbon reduction technologies identified above. The low case represents a conservative scenario in which the technologies are adopted to a limited degree, whereas the high case represents a scenario in which the technologies are adopted more broadly, though still to a reasonable and achievable degree as discussed further in this brief. These cases are applied to California, which accounts for 11 percent of total U.S. petroleum refining capacity and 8 percent of total U.S. crude oil production.[3] GHG emissions from California petroleum refining and crude oil production are currently estimated to be approximately 31 million metric tons of CO_2e and 17 MMT, respectively, for a total of 48 MMT.[4]

In the low case, the combined GHG emission reductions may be 2.8 million metric tons annually in 2020. In the high case, the combined reductions may be approximately 6.6 million metric tons annually in 2020. As a reference point, the full potential of these technologies—if adopted across the board—would be more than 20 million metric tons of reduction annually.

These carbon reduction technologies can make major contributions to the petroleum industry's obligations under California's Global Warming Solutions Act of 2006 (known as AB32). In addition to carbon pollution reduction, many of these technologies can significantly reduce other air pollutants, providing further benefits to public health. If these technologies were all eligible reduction pathways under California's Low Carbon Fuel Standard (LCFS), part of AB32, even moderate adoption could meet a substantial portion of obligations for refiners under the standard, which requires a reduction of 17 million metric tons in 2020.[5] Overall, the potential to reduce carbon emissions from the petroleum industry is sizeable, and the technologies to achieve these reductions are available and viable. Additional opportunities, such as CCS at the refinery beyond hydrogen applications, and higher levels of renewable refinery feedstock content and inputs can further reduce the carbon footprint of the petroleum industry.

TECHNOLOGIES TO REDUCE CARBON EMISSIONS

The petroleum supply chain consists of multiple stages that, together with vehicle fuel combustion, are responsible for the full-fuel-cycle carbon emissions of the final products, such as gasoline and diesel. From crude oil production through refining to fuel combustion in vehicles, each portion of the supply chain contributes to the total carbon footprint of the petroleum industry. Furthermore, each offers opportunities to reduce this footprint. Three key stages where carbon reduction technologies can significantly impact total emissions are crude oil recovery, refinery processes, and vehicle fuel combustion.



The petroleum supply chain offers at least three key areas where promising technologies can enable significant reductions in carbon emissions. The percentages shown represent the contribution of each stage to total life-cycle emissions. Crude oil transport and finished product transport represent less than 2% of emissions. The totals are less than 100% due to rounding.

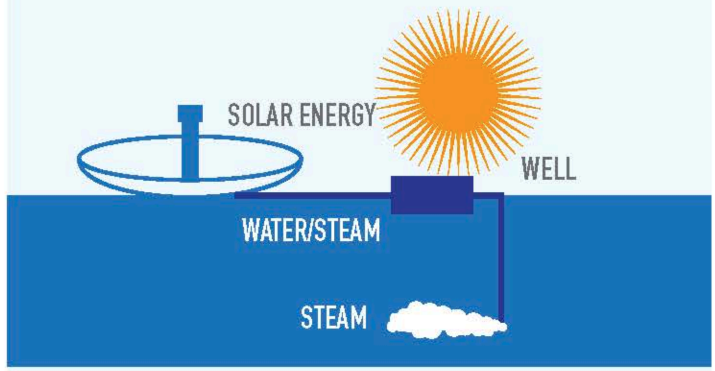
Crude Oil Recovery

The recovery (or extraction) stage may include the use of artificial lift or enhanced recovery methods to push crude oil from underground reservoirs to the surface after the natural reservoir pressure falls to a point where the well cannot produce on its own. In some cases, this process is accomplished by the injection of gas, water, or chemical agents to facilitate recovery. The major greenhouse gas emission sources at this stage are tied to energy use to lift or pump crude oil from the subsurface, production of steam in thermal enhanced oil recovery operations, and potential gas venting, flaring, and fugitive (VFF) emissions.[6]

For some oil fields, steam injection is used to enhance crude oil recovery by decreasing viscosity, causing the oil to swell, and helping sweep the oil out of the reservoir rock.[7],[8] In California, modern steam injection has been utilized since 1960. Today, steam injection is used to produce approximately 70 percent of the 630,000 barrels per day of oil produced in California.[9] Conventionally, fossil fuels such as natural gas are combusted to generate the steam, which is then pumped into injection wells.[10] The process is energy intensive, and the combustion of fossil fuel releases carbon into the atmosphere.[11] Two technologies that can eliminate this carbon release include:

Using Solar Energy to Generate Steam

To generate steam renewably, mirrors and reflective surfaces are arranged to concentrate sunlight. The solar energy is directed at a central tube or tower containing water, which is heated and turned into steam. The steam is injected into oil wells to improve recovery rates



This renewable steam generation technology is currently being deployed commercially by BrightSource in Coalinga, California, and by GlassPoint in McKittrick, California, and Amal, Oman.

- Renewable steam generation. Solar-thermal facilities that concentrate sunlight with mirrors to convert water into steam have been operating since the 1980s, including a pilot project by ARCO Solar utilizing the steam for enhanced oil recovery.[12] Over the past several years, a number of technology companies have been active in commercializing this technology. Because solar energy drives this process, the carbon impact of generating steam using this technology is near zero compared with utilizing natural gas.[13] [see sidebar "Using Solar Energy to Generate Steam"].

- Steam generation with carbon capture and sequestration (CCS). Fossils fuels are still combusted to generate steam, but the carbon from the flue gas emissions is captured and stored. Retrofits using post-combustion capture, which separates CO_2 from the flue gas, can be suitable for existing facilities such as natural gas– based steam generation units.[14] In addition, post-combustion capture can also be used for upgrading facilities, such as those that utilize steam methane reforming units to produce hydrogen.[15] Various subsurface locations exist for permanent disposal of the captured carbon, including deep saline formations, oil fields, and gas fields. Technology to capture, transport, and inject the carbon emissions is commercially available, and there is broad scientific consensus that, provided it is adequately regulated, CCS can be carried out safety and effectively and result in permanent storage in these reservoirs.[16]

Additional recovery-stage reduction opportunities not analyzed in this issue brief include measures to reduce VFF emissions and to improve energy efficiency. Flaring involves intentional burning of the associated gases dissolved in crude oil, which releases CO_2 and potentially other pollutants, depending on combustion efficiency. Venting refers to intentionally releasing the gases, including methane, a gas with a global warming potential 25 times that of CO_2. Fugitive emissions are unintentional or irregular releases of those gases, such as through leaks in valves and seals[17] In general, these emissions can be reduced through industry best practices such as systems to reduce methane loss during the completion of a well (i.e. green completions), better pipeline maintenance and repair, and proactive leakage monitoring and repair.[18] Similarly, improved efficiency through equipment modernization, improved maintenance and repair, and integrated energy management approaches can also lead to reduced emissions.[19]

Refinery Processes

Refineries are a collection of complex chemical process systems that convert crude oil to valuable petroleum products like gasoline, diesel, kerosene, and jet fuel. These typically include distillation, cracking, treating, and reforming. Carbon emissions result from the series of steps required to upgrade the crude oil into its final products. Two technologies that can reduce these emissions are:

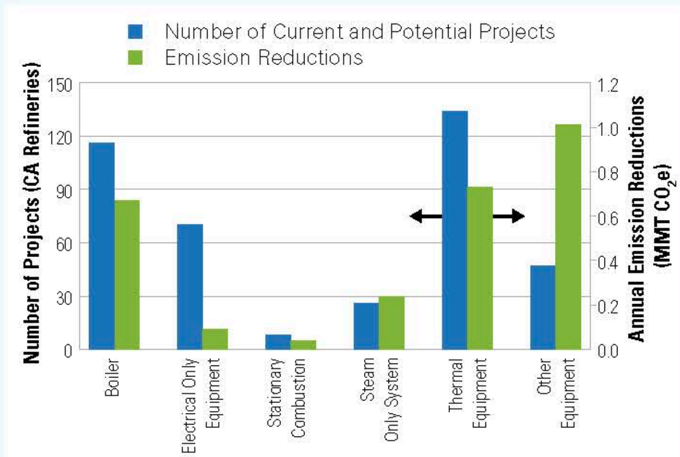
- Refinery energy efficiency. Continual improvements in the efficiency of the refinery enable it to use less energy in its operations, thereby reducing its carbon impact. Measures that increase the energy efficiency of a refinery include improved controls, improved heat recovery, hydrogen and fuel gas management, utilities optimization, and advanced process technologies. McKinsey & Company (2011) found that the U.S. refining industry could reduce its energy use by 13 percent by 2020 through commercially available technologies at an internal rate of return of at least 10 percent; others, such as Energetics Incorporated (2006), found that the technical potential was as high as 26 percent if best practices and state-of-the-art technologies were used.[20]

- Refinery CCS. As with carbon capture and sequestration for steam generation, emissions are not vented into the atmosphere but are instead stored over geological timescales with active measurement, monitoring, and verification protocols. There are many point sources of CO_2 emissions from refinery operations, including hydrogen production, the fluid catalytic cracking (FCC) unit, steam generation, and localized heat requirements. One particular carbon reduction opportunity among refinery processes is hydrogen-related CCS. The production of hydrogen by reforming or gasifying fossil fuels and its use in the refinery both emit carbon dioxide. Hydrogen production usually represents the best capture and sequestration opportunity at the facility, capable of appreciably reducing overall refinery emissions.[21],[22] Other potential CO_2 sources within a refinery are not included in this assessment. [See sidebar on "Opportunities for Refinery Energy Efficiency"]

While not analyzed here, the use of lower-quality crude oils and/or heavier crude oils —including but not limited to tar sands or other extra-heavy crude oils— can also result in greater production and refining emissions due to the additional energy necessary to extract, upgrade, and refine these feedstocks. California refineries utilize a significant mix of heavy crude oils, which is one reason why average refining emissions in California are higher than those in other major U.S. refining regions.[23] Reduced reliance on lower-quality or heavier crude oil feedstocks, through a switch to lighter, higher-quality crude oils and renewable crude oils, can help reduce carbon emissions and yield additional benefits in terms of reduced air pollutants, so long as the switch reduces overall production and refining of lower-quality, heavier crude oil and does not result in shifting those crude oils elsewhere.[24]

Opportunities for Refinery Energy Efficiency

The California Air Resources Board reports that the largest refineries in the state have implemented or are currently implementing efficiency improvement projects whose impact will be equivalent to approximately an 8 percent reduction in refining emissions. These projects involve boilers (cogeneration, steam, and combined cycle plants), electric motors, stationary combustion (gas turbines), steam motors, thermal equipment (furnaces and heat exchangers), and other equipment (including refinery-wide projects and flare systems).



Source: www.arb.ca.gov/cc/energyaudits/publicreports.htm.

Vehicle Fuel Combustion

At the end of the petroleum supply and processing chain, petroleum fuels like diesel are combusted to provide motive power. Examining only the fuel portion of the carbon footprint, most of the carbon content of the feedstocks used to create the fuel is released during vehicle operation and represents 73 percent of the total life cycle, or well-to-wheels, emissions for gasoline.[25] On a full-fuel-cycle basis, combusting fuel from petroleum directly increases atmospheric carbon concentration, whereas renewable feedstocks like biomass are grown using carbon dioxide from the atmosphere and can result in lower net emissions if regrown. The petroleum industry can reduce the direct emissions of fuel use in vehicles by reducing the carbon intensity of the fuel itself through many types of renewable feedstocks.

- Renewable refinery feedstocks. By displacing part of the crude oil with feedstocks from renewable sources, the carbon intensity of the ultimate fuel can be reduced. The use of natural oils, including animal fats, waste grease, and vegetable oils, does not completely eliminate the fuel's carbon impact, as the processing of renewable feedstocks and direct and indirect land conversion also generate emissions, but the full-fuel-cycle carbon intensity of diesel from renewable feedstocks can be 16 to 60 percent less than that of diesel made from crude oil alone. While supply and availability limitations will prevent renewable biomass from entirely replacing crude oil feedstocks, other opportunities, such as renewable electricity use, can also reduce carbon intensity but were not evaluated here.

POTENTIAL TO REDUCE CARBON EMISSIONS

The technologies described above can offer significant reductions in carbon emissions associated with the production of transportation fuels, as shown below. For comparison, the carbon intensities—on a full-life-cycle basis—of petroleum-based gasoline and diesel in California today are 99.18 and 98.03 gCO_2e/MJ, respectively.[26]

The implementation of carbon reduction technologies where applicable can appreciably decrease the overall carbon intensity of petroleum products. The potential carbon reductions are summarized below in the table with assumptions explained in this section.

Technology	Carbon Reduction Potential (gCO_2e/MJ finished product)*	Applicable to:	Estimated Annual Carbon Reduction Potential in California with Full Implementation (million metric tons CO_2e)**
Renewable steam generation	4.8	Finished products of crude oil derived from steam-enhanced oil recovery	7.3
Steam generation with CCS	4.2	Finished products of crude oil derived from steam-enhanced oil recovery	6.4
Refinery energy efficiency	0.5–1.0	Improvements in total refinery efficiency by 5 to 10%	7.3
Refinery CCS***	2.0	Hydrogen-related refinery processes	5.9
Renewable feedstocks	11	Finished products of natural oil	0.8

*See Technical Appendix for calculations of carbon reduction potential.

**Full implementation assumes 100% adoption of renewable steam generation or steam generation with CCS where applicable, 25% efficiency improvement at 100% of refineries, 100% adoption of refinery CCS on hydrogen production units where applicable, and 4% displacement of crude oil with co-processing of mixed renewable or waste/by-product feedstocks at 100% of refineries.

***CCS applied to refinery emissions associated with hydrogen production only. Some hydrogen is produced outside the refinery.

HIGH AND LOW ADOPTION CASES

To illustrate the potential impact of implementing the various carbon reduction technologies within the petroleum industry, two adoption cases between 2013 and 2020 were explored by Tetra Tech, Inc., using assumptions about potential adoption rates and quantitative estimates of emission reductions. The low case represents a conservative market scenario in which the oil producers and refineries adopt technologies to a limited degree, whereas the high case represents a scenario in which adoption is broader, though still to a reasonable and achievable degree. Assumptions for each technology in the low and high cases are described below.

Renewable Steam Generation

Steam generation by concentrating solar energy can replace combusting natural gas expressly for the purpose of generating steam to enhance oil recovery. GlassPoint, a manufacturer of solar steam generators for the oil and gas industry, estimates that as much as 80 percent of natural gas use can be displaced by solar energy, and simulations show that, despite the diurnal and seasonal nature of solar energy, oil recovery from renewable steam generation may be essentially the same as that of combusting natural gas.[27,28]

In the low adoption case, we assume that up to 5 percent of natural gas currently used in once-through steam generators is displaced by renewable steam generation or uses CCS, as described below, by 2020. In the high case, up to 20 percent of the natural gas used in once-through steam generators in California is displaced by renewable steam generation or uses CCS. Other crude oil production facilities globally may also employ this technology, such as the GlassPoint project currently underway in Oman. This study considers only California crude oil sources, making up about 37 percent of the petroleum used in the state.[29] Inclusion of reduction opportunities for foreign sources would increase the emission reduction potential.

Steam Generation with CCS

As an alternative to renewable steam generation, carbon from natural gas steam generation can be generally captured via post-combustion methods and stored. Retrofits using post-combustion capture, which separates CO_2 from the flue gas, can be suitable for existing facilities such as natural gas–based steam generation units.[30] Post-combustion capture can also be utilized for upgrading facilities, such as those that use steam methane units to produce hydrogen.[31] In the low case, we assume that up to 5 percent of carbon emissions from once-through steam generators used in enhanced oil recovery are captured and sequestered or reduced using renewable steam generation, as described above, by 2020. In the high case, up to 20 percent of these carbon emissions from California fields using natural gas steam generation are captured and sequestered or reduce using renewable steam generation. Other out-of-state crude oil production facilities that supply California refineries may also be able to employ this technology, thereby increasing the potential emission reductions. However, this issue paper focuses just on opportunities at California production facilities.

As with refinery CCS, combustion products are sequestered rather than emitted into the atmosphere. CCS is a particularly interesting option for this portion of the petroleum supply chain, as carbon dioxide injection is currently used widely for enhanced oil recovery as well, thereby aligning closely with the original purpose of steam generation. However, additional regulations are necessary for enhanced oil recovery projects to ensure that CO_2 injections into oil fields are sequestered. In fact, in some cases, fields that are amenable to steam recovery may also produce higher yields through the injection of carbon dioxide.[32]

Refinery Energy Efficiency

The opportunities for efficiency improvements in refinery energy consumption are substantial. Technology providers such as Honeywell UOP estimate the potential to be 12 to 25 percent in the United States, attainable through improved operation and control, improved heat recovery, advanced process technology, utilities optimization, and hydrogen and fuel gas management.[33] Lawrence Berkeley National Laboratory suggests that the potential improvement may be greater than 23 percent from energy efficiency measures for refinery boilers and more than 31 percent from energy efficiency measures for steam distribution systems in the United States.[34] Figures from McKinsey & Company indicate that a 13 percent improvement in refinery energy efficiency in the United States can be achieved using only commercially available technologies that offer a positive internal rate of return.[35] The refinery sector public report from the California Air Resources Board, based on self-audits by refineries, indicates that approximately 2.8 million metric tons of CO_2e can be avoided with refinery efficiency improvements, with just over 60 percent of the reductions coming from projects that were completed or were implemented prior to 2010.[36] The avoidance of 2.8 million metric tons is equivalent to an 8 percent reduction in refining emissions. We note that these estimates are likely conservative, given that (1) the information is based on self-audits and (2) the estimates do not include the off-site production of electricity, steam, or hydrogen, which is a potential major source of emissions and would be included in a life-cycle assessment.

The authors evaluate a low and higher case, considering the aforementioned studies that cite up to a 20 to 30 percent energy efficiency improvement while recognizing that some refineries may have already deployed some level of energy efficiency improvements. The cases also account for some conservatism with respect to timescale for planning, permitting, and installation. The low case applies a ramp-up to a very conservative 5 percent improvement in refinery efficiency by 2020 relative to 2010 levels. A 5 percent improvement can be attained, for example, by using advanced process technology, such as new catalysts. The high case applies a ramp-up to a still conservative 10 percent improvement in refinery efficiency by 2020. This level can be attained, for example, using improved heat recovery within and across process units.

Refinery Carbon Capture and Storage (CCS)

In the low case, we assume that 15 percent of the refining capacity in California utilizes CCS by 2020. This adoption rate is roughly equivalent to having just one of the largest refineries in California utilize CCS.[37] We assume that CCS is used to capture and store emissions from the hydrogen production unit. In the high case, up to 30 percent of the refining capacity in California utilizes CCS by 2020. This percentage is equivalent to the two largest refineries in California adopting CCS on hydrogen production.

Because CCS requires significant capital and is technologically intensive, implementation will likely take the form of maximum capture and sequestration at a small fraction of refineries, rather than partial capture and sequestration at all refineries. In addition, CCS is not limited to emissions associated with hydrogen production and may be further applied to other carbon emissions from the refinery. However, we consider only hydrogen-related CCS here since it is generally thought to be a lower-cost option that is comparatively easy to implement.

Renewable Feedstocks

Renewable feedstocks can include first-generation natural oils from vegetable seeds, animal fats, and greases, or second-generation feedstocks including camelina, lignocellulosic biomass, and algal oils.[38] Natural oil from renewable feedstocks is either directly co-processed with the incoming crude oil stream using existing refining equipment or processed in new, stand-alone units. For example, the Paramount Refinery in Paramount, California is currently being retrofitted to produce renewable diesel and jet fuel using Honeywell UOP technology consisting of stand-alone units, while the Valero Refinery in St. Charles, Louisiana, also has a stand-alone unit co-located with the existing refinery. For direct co-processing, there is no technical guidance yet on the maximum allowable renewable fraction that still ensures refinery performance. The level of renewable feedstock acceptable for co-processing in existing refineries depends on the level of contaminants (e.g., nitrogen, sulfur, chlorine, alkali metals), which can negatively affect catalyst performance, as well as the risk tolerance of individual refiners. To date, tests have generally incorporated less than 5 percent renewable feedstocks through co-processing, although up to 30 percent has been proposed.[39] Stand-alone units to produce renewable finished products allow for potentially higher blend levels with petroleum finished products. As more refineries adopt the use of renewables, growing industry experience with this technology will provide greater understanding and better characterization of its carbon reduction potential.

In the low case, we assume that up to 30 percent of refining capacity in California uses 2 percent renewable feedstocks in its refining operations by 2020. In a higher case, up to 60 percent of refineries use 4 percent renewable feedstocks in their refining operations.

Other opportunities to use renewable feedstocks (not analyzed here) include:

- Use of renewable fuels (e.g., biofuels) for refinery process heaters that could partially or fully replace fossil fuels.
- Greater use of renewable-based electricity as an energy input to refineries. Refineries are currently among the largest users of electricity in California.
- Use of renewable hydrogen sources, such as biomass to hydrogen, to displace fossil-based hydrogen sources.

The low and high cases represent modest levels of adoption of carbon reduction technologies by 2020.

Carbon Reduction Opportunity	Low Adoption Case	High Adoption Case
Renewable steam generation or steam generation from natural gas with CCS for oil extraction*	5% of once-through steam generators in CA adopt either solar thermal or CCS	20% of once-through steam generators in CA adopt either solar thermal or CCS
Refinery energy efficiency	Average 5% improvement across all refineries	Average 10% improvement across all refineries
Refinery CCS for hydrogen production**	15% of refining capacity	30% of refining capacity
Renewable feedstocks	30% of refineries using 2% renewable feedstocks in crude oil stream	60% of refineries use 4% renewable feedstocks in crude oil stream

*Renewable steam generation and steam generation from natural gas with CCS are generally mutually exclusive opportunities.

**CCS applied to the entirety of refinery emissions associated with hydrogen production and use as a process fuel.

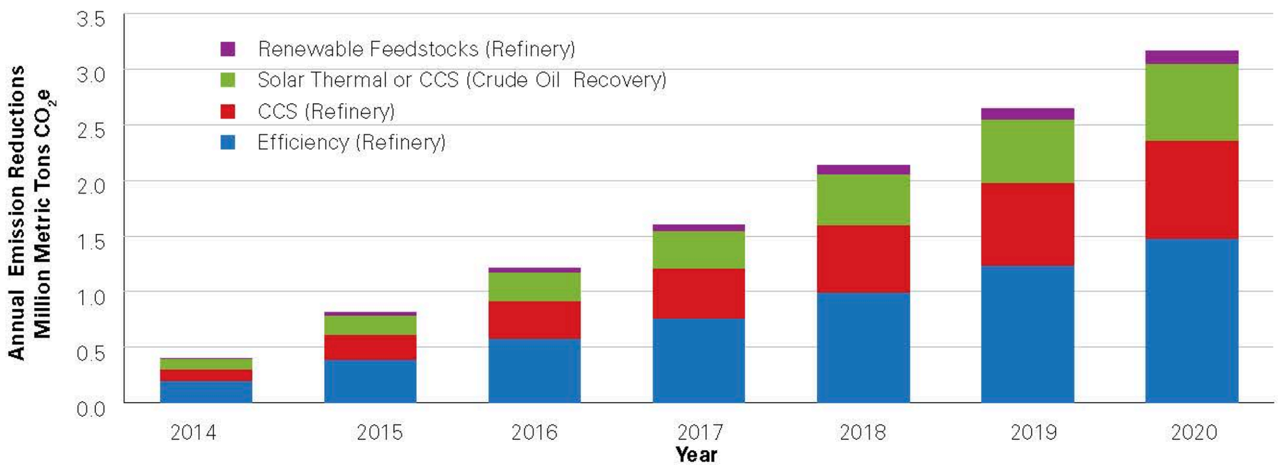
COMBINED CARBON REDUCTION POTENTIAL

The magnitude of potential carbon reductions in the low and high adoption cases is illustrated (in the two figures below) for California between 2014 and 2020. Refining in California represents 15 percent of total U.S. capacity. GHG emissions from California petroleum refining and crude oil production are currently estimated to be approximately 31 million metric tons of CO_2e and 17 MMT, respectively, for a total of 48 MMT.[40]

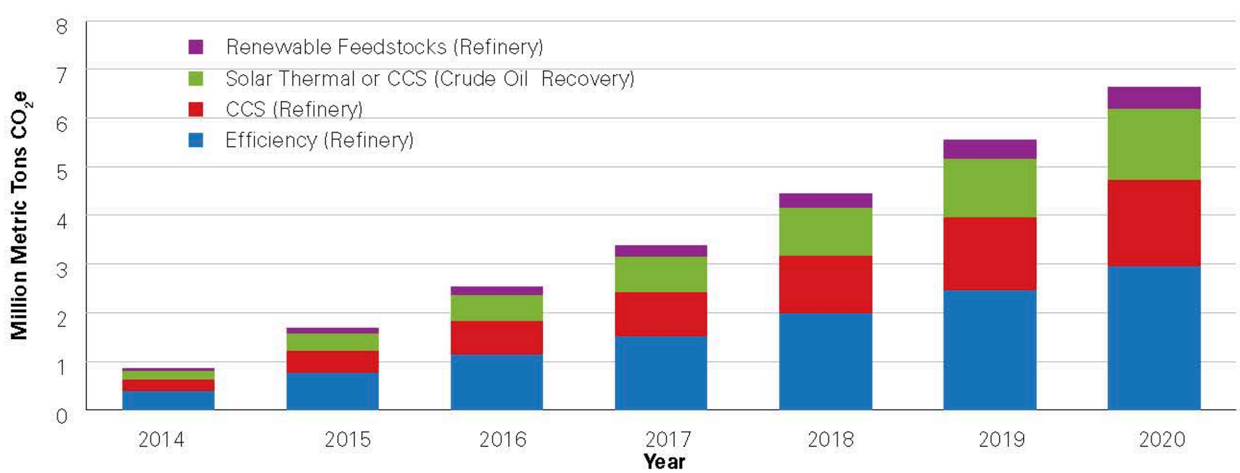
If carbon reduction opportunities for the petroleum industry were adopted to a limited degree (low case), the combined emissions reductions could be 2.8 million metric tons annually by 2020.

If carbon reduction opportunities for the petroleum industry were adopted more broadly to a reasonable and achievable degree (high case), the combined emissions reductions could be approximately 6.6 million metric tons annually by 2020. As a reference, full adoption of these opportunities could reduce carbon emissions by approximately 20 million metric tons annually but would be unlikely to occur by 2020.

Carbon Reduction Potential under a Low Adoption Case: The adoption of carbon reduction technologies to a limited degree is equivalent to reducing total California refining and oil production emissions by 6% by 2020.



Carbon Reduction Potential under a High Adoption Case: The adoption of carbon reduction technologies to a reasonable and achievable degree is equivalent to reducing total California refining and oil production emissions by 14% by 2020.



For oil recovery, renewable steam generation and steam generation utilizing CCS both show similar carbon benefits. Both the low and high cases evaluated here reflect conservative assumptions regarding the adoption of carbon reduction technologies by the petroleum industry. As discussed above, there are numerous technologies and applications not evaluated in this brief that may offer additional reductions. Because many of these technologies, particularly refinery efficiency improvements, also positively impact the economics of the petroleum industry, even higher levels of technology adoption may be feasible.

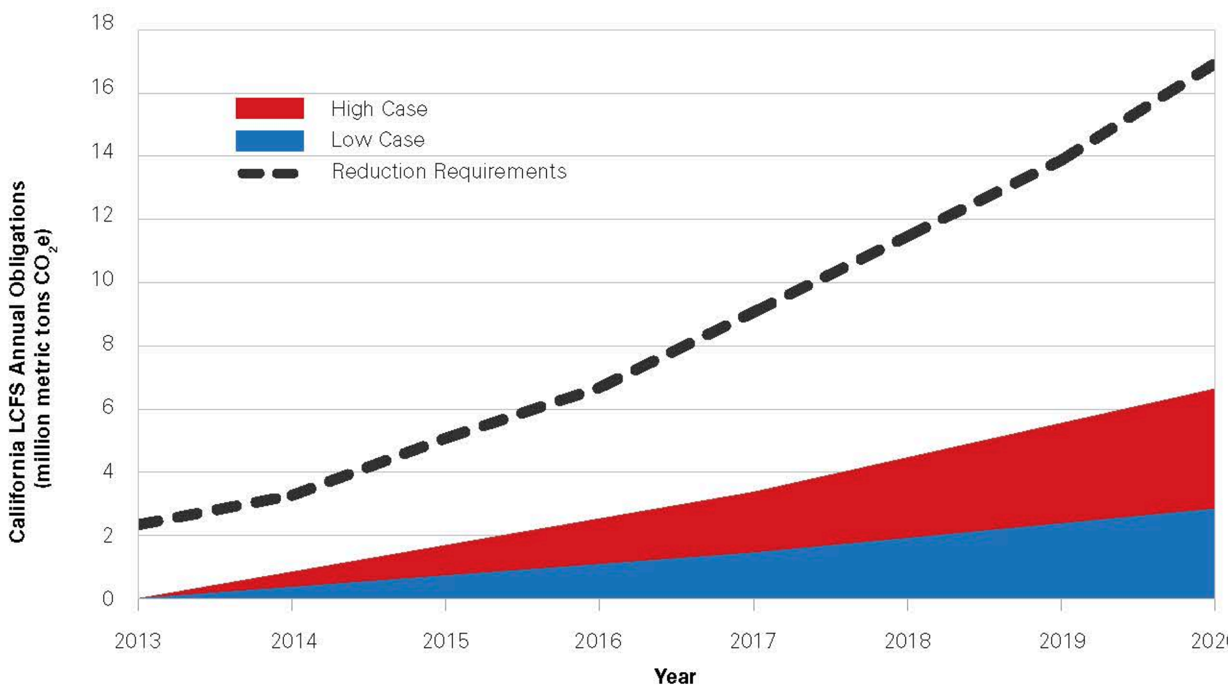
CONTRIBUTING TO CALIFORNIA'S LOW CARBON FUEL STANDARD

These carbon reduction technologies can make major contributions to the petroleum industry's obligations under California's LCFS. Under the standard, refineries must reduce the carbon intensity of their fuels by 10 percent by 2020, relative to 2010 levels. This level of reduction, applied to the projected California gasoline and diesel demand over the next decade, translates to obligations for refiners that reach nearly 17 million metric tons annually in carbon reductions in 2020.[41]

Currently, California's LCFS includes crediting opportunities for innovative technologies to reduce emissions from crude oil recovery, including CCS and solar steam generation. The state's Air Resources Board is currently evaluating refinery-specific measures to require or encourage refining energy efficiency improvements. The LCFS standard currently does not account for reduction opportunities that occur directly at petroleum refineries. Crediting for reductions that go above and beyond requirements could help create additional incentive for refineries to undertake these projects. Many of these technologies can significantly reduce air pollution, resulting in co-benefits in addition to carbon reductions.[42]

The low and high cases described above suggest that approximately 2.8 million to 6.6 million metric tons annually of these obligations can be met in 2020 under conservative assumptions regarding the adoption of the highlighted carbon reduction technologies. Even greater adoption of these technologies, along with other cost-effective reduction strategies, can greatly help refiners to achieve their LCFS obligations if the highlighted carbon reduction technologies are eligible under the program.

California LCFS Annual Compliance Obligations: Adoption of existing carbon reduction technologies and other cost-effective reduction strategies can allow refiners to comply with a significant portion of California's LCFS program.



CONCLUSION

The potential to reduce carbon emissions from the petroleum industry is sizable, and many of the technologies to achieve these reductions are available and viable. Along the supply chain, major opportunities exist in crude oil recovery, refining, and refinery feedstocks to shrink the carbon footprint of petroleum. In California alone, modest adoption of renewable steam generation or steam generation with CCS, refinery efficiency improvements, CCS of hydrogen-related refinery processes, and renewable refinery feedstocks can enable carbon reductions of nearly 3 million to 6.6 million metric tons of reductions annually by 2020. Full adoption of these technologies would result in 20 million metric tons of reduction. If all of these technologies were credited under the LCFS, they could contribute to meeting a significant portion of refiners' annual obligations. Additional opportunities, such as CCS at the refinery beyond hydrogen and additional use of renewable feedstocks and energy inputs, can further reduce the carbon impact of the petroleum industry.

7 According to the National Energy Technology Laboratory, "[i]n steamflooding, high-temperature steam is injected into a reservoir to heat the oil. The oil expands, becomes less viscous and partially vaporizes, making it easier to move to the production wells. Steamflooding is generally used in heavy oil recovery to overcome the high viscosity that inhibits movement of the oil." *See*: www.netl.doe.gov/technologies/oil-gas/publications/eordrawings/Color/coltr.pdf and www.netl.doe.gov/technologies/oil-gas/publications/eordrawings/Color/colsf.pdf.

8 We note that in addition to the thermal (or steam) enhanced oil recovery (EOR) technology evaluated here, gas (including natural gas) and chemical injection are the two other main methods for EOR. In some cases, natural gas injection and repressurization could lead to lower GHG emissions, but only if methane is not vented or leaked and if that natural gas is not later recovered as a primary energy source. Currently, repressurization of oil wells using inert or noncombustible gases like CO_2 and N_2 may be a more economical and stable option than using potentially valuable natural gas feedstocks.

24 While in general, reduced demand for these higher-carbon feedstocks can reduce overall production and use, we note that estimating the actual reduction in emissions is nontrivial and requires a market analysis of the reduced overall demand in heavy crude oil as well as accounting for potential feedstock substitution. We note that, in part because of these crediting challenges, the LCFS has remained focused on innovative technologies that require clear additional investments and result in direct, verifiable emission reductions.

25 Omitting carbon reduction technologies on the vehicle itself, e.g., fuel economy improvements and alternative fuels.

42 For example, the California Air Resources Board's 2013 public report, Energy Efficiency and Co-Benefits Assessment of Large Industrial Sources Refinery Sector Public Report, shows reductions in particulate matter (PM) and nitrous oxide (NOx) through adoption of energy efficiency technologies. While the report did not include the potential reduction estimates for toxic air pollutants (TACs), co-benefits of TAC reductions would be expected as well. www.arb.ca.gov/cc/energyaudits/energyaudits.htm.

TECHNICAL APPENDIX

This appendix details the methodology, references, assumptions, and calculations used to evaluate carbon reduction opportunities in the petroleum industry.

METHODOLOGY

Tetra Tech Inc. evaluated potential carbon reductions from each technology on the basis of engineering experience and expertise, review of the technical and scientific literature, and discussions with experts. Engineering estimates were made by considering the displaced or avoided energy consumption for the specific energy technology, with baseline energy consumption or emissions data obtained from a number of sources such as the U.S. Department of Energy's Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model, developed by the Argonne National Laboratory, as well as publically available data from the California Energy Commission and California Air Resources Board.

Low and High Adoption Cases

Overall technology adoption cases were estimated on the basis of reasonable, conservative what-if scenarios, including consideration of timescales for planning, permitting, and installation. The low and high cases apply linear adoption curves, assuming no technology implementation in 2013, half of scenario implementation by 2017, and full scenario implementation by 2020. The specific adoption percentages for each technology in the two cases are detailed in the issue brief.

Crude Oil Production Emissions

Emissions of direct and indirect GHG emissions from producing crude oil in California were estimated on the basis of field-level carbon-intensity and production data from the California Air Resources Board (2013).[1] We note that ARB estimates are for fields producing more than 10,000 barrels in 2011. Lower heating values were assigned to barrels based on API and utilizing factors in the Oil Production Greenhouse Gas Emission Estimator (OPGEEE), version 1.0.[2] Based on ARB's estimates, total production volume for 2011 was 213,630,418 barrels for fields producing more than 10,000 barrels with a weighted average carbon intensity of 12.4 grams per megajoule (g/MJ). Total emissions were estimated to be 16.8 MMT for California oil production and 0.8 MMT for California Outer Continental Shelf lands.

Steam Generation Emissions

The potential for carbon reductions from steam generation in enhanced oil recovery is assessed on the basis of natural gas consumption in steam flooding and cyclic steam injection for California onshore wells. Based on data from the California Department of Conservation, between January 2011 and June 2012, average natural gas consumption for steam injection was 522,103 million BTU (MMBtu) per day.[3] Of this amount, steam for oil recovery that is not generated through cogeneration is assumed to be generated via once-through steam generators (OTSGs), estimated to be responsible for 58 percent of California steam generation, or 301,330 MMBtu per day. The emissions associated with combustion of natural gas in OTSGs have two components: the emissions of the fuel itself (including natural gas recovery, transportation and distribution, and storage), and the emissions of burning the fuel in a boiler. The emissions profiles from the California version of the GREET model (Table 1) are used to estimate OTSG steam generation emissions.[4] The carbon reduction potential of renewable steam generation is calculated on the basis of the displacement of both natural gas fuel and combustion emissions, while the carbon reduction potential of carbon capture and sequestration (CCS) is based on the displacement of natural gas combustion emissions only. (Upstream emissions associated with the natural gas fuel itself would not be displaced in steam generation with CCS.) Carbon dioxide equivalents are calculated on the basis of the carbon content of the emissions and their global warming potentials utilized in GREET, with the GWP_{CH4} of 25 and a GWP_{N2O} of 298 utilized.

Table 1. Steam Generation Emissions

	Emissions (g/MMBtu)	
	Fuel	**Combustion**
VOC	6.3	1.6
CO	11	16
CH_4	130	1.1
N_20	0.066	0.32
CO_2	5,000	58,000

Refinery Emissions

California refinery greenhouse gas (GHG) emissions are derived from facility reports to the California Air Resources Board for calendar year 2010.[5] The relevant subset of these data, reflecting only the facilities whose primary purpose is petroleum refining, is reproduced in Table 2 below.

Table 2. California Refinery GHG Emissions

Facility ID #	Facility Name	Total Reported CO_2 Equivalent Emissions (metric tons/yr, 2010)
101384	Chevron Products Company—Richmond Refinery, 94802	4,511,882
100914	Shell Oil Products US	4,446,565
101246	BP West Coast Products LLC, Refinery	4,432,662

101320	Edgington Oil Company	20,378
		TOTAL: 31,731,977

Source: CARB

Projections to 2020 of California refinery emissions are based on gasoline and diesel forecasts from the "Low Petroleum Demand Scenario" of the California Energy Commission's 2011 *Integrated Energy Policy Report (IEPR) Transportation Forecasting Report*.[6] Volumes of gasoline and diesel demanded annually are linearly interpolated from IEPR estimates for 2009, 2015, and 2020 (Table 3), and crude oil volume and associated refinery emissions are projected by scaling the demand estimates using 2009 data (Table 4). In 2009, refinery GHG emissions were reported at 31,204,903 metric tons, and 597,132,000 barrels of crude oil were used to produce gasoline and diesel in California.[7]

Table 3. California Gasoline and Diesel Projections

Year	Gasoline (gallons)	Diesel (gallons)
2009	14,804,119,733	3,200,244,414
2010	14,685,955,128	3,265,236,366
2011	14,567,790,522	3,330,228,318
2012	14,449,625,917	3,395,220,270
2013	14,331,461,312	3,460,212,221
2014	14,213,296,706	3,525,204,173
2015	14,095,132,101	3,590,196,125
2016	13,898,190,554	3,641,464,547
2017	13,701,249,006	3,692,732,969
2018	13,504,307,459	3,744,001,392
2019	13,307,365,911	3,795,269,814
2020	13,110,424,364	3,846,538,236

Table 4. Projected California Refinery Volume and Emissions

Year	Total Crude Volume (thousands of barrels)	Total Refinery GHG Emissions (metric tons)
2013	591,388	30,904,714
2014	588,969	30,778,334
2015	586,551	30,651,955
2016	581,719	30,399,476
2017	576,888	30,146,998
2018	572,057	29,894,519
2019	567,225	29,642,041
2020	562,394	29,389,562

Note that refinery emissions were calculated by using crude volume projections to scale current emissions, so the decline in GHG emissions in this table is entirely due to a decline in crude volume. The crude volume decline is projected by the CEC IEPR, presumably accounting for fuel economy improvements and reduced travel demand due to policies that reduce vehicle-miles traveled.

Hydrogen processes make up part of total refinery emissions. As with natural gas used in steam generation, emissions for hydrogen also have two components: those generated during the reforming of natural gas (feed) to produce the hydrogen, and those generated from combustion of natural gas for the energy requirement (process energy) to produce hydrogen, such as a furnace. A more detailed description can be found in NREL (2003).[8]

Utilizing the LBNL "Profile of the Petroleum Refining Industry in California," TetraTech Inc. was able to estimate that 576 standard cubic feet (scf) of hydrogen, or 1.47 kg, is used on average to produce one barrel in California.[9] Utilizing the hydrogen production assumptions embedded in the California GREET model, there is an estimated 10.5 kg CO_2 of emissions per barrel of crude oil (kg/bbl) from H_2 production, with 8.0 kg CO_2 per barrel emitted from steam methane reforming to H_2 and the remaining 2.4 kg CO_2 per barrel from the natural gas utilized as process energy for the H_2 production. The assumptions in the California GREET model are that 0.238 MMBtu of natural gas is used as process energy for each MMBtu of H_2 produced. According to Collodi (2010), CO_2 removal efficiencies for specific streams can be about 90 percent (for tail gas and flue gas) to more than 99 percent (from raw H_2). For simplicity, it is assumed in the calculations that all the CO_2 is removed.[10]

RENEWABLE FEEDSTOCK EMISSIONS

The carbon reduction potential of using renewable feedstocks to displace crude oil is calculated on the basis of the full-fuel-cycle carbon intensity of diesel fuel compared with that of renewable diesel. Carbon intensity values are derived from the California Air Resources Board Low Carbon Fuel Standard (LCFS) regulation.[11] The carbon intensity of renewable diesel is assumed to be the average of fuel produced from soy oil and fuel produced from tallow (Table 5). From these carbon intensity values, the carbon reduction potential is calculated using the California diesel volume projections.

Table 5. Fuel Carbon Intensity Values

Fuel	Carbon Intensity (gCO_2e/MJ)
Diesel	98.03
Renewable diesel:	
From soy oil	82.16
From tallow	39.33
Average	**60.75**

Source: CARB

ANNUAL OBLIGATIONS FOR REFINERS

The annual obligations for refiners imposed by California's LCFS (Table 6) are derived from the California Air Resources Board's illustrative scenarios.[12] Gasoline Scenario 8 and Diesel Scenario 6 were selected as reasonable representations of the future fuel mix, and the carbon intensity values in these illustrative scenarios were modified using updated values from the LCFS final regulation order.[13]

Table 6. California LCFS Annual Obligations for Refiners

Year	LCFS Compliance Schedule for Average Carbon Intensity (gCO_2e/MJ)		Annual Credits Required (million metric tons)		
	Gasoline	Diesel	Gasoline	Diesel	Total
Baseline	99.18	98.03	–	–	–
2013	97.96	97.05	1.9	0.4	2.3
2014	97.47	96.56	2.6	0.6	3.3
2015	96.48	95.58	4.0	1.1	5.1
2016	95.49	94.6	5.3	1.4	6.7
2017	94.00	93.13	7.1	2.0	9.1
2018	92.52	91.66	8.9	2.6	11.5
2019	91.03	90.19	10.6	3.3	13.9
2020	89.06	88.23	12.8	4.2	16.9

Report: Pump Primed for Three-Fold Growth in Clean, Alternative Fuels by 2025

California's Low Carbon Fuel Standard Targets are Achievable and Will Drive Growth

SAN FRANCISCO (February 2, 2015) – California is capable of tripling its use of alternative fuels over the next 10 years, according to a new report by the fuels and energy consulting firm Promotum. The study examined the growth potential for cleaner fuels under California's Low Carbon Fuel Standard (LCFS), a program requiring the oil industry to reduce the carbon intensity of fuels through the production and use of cleaner fuels.

"It's time for the oil industry to send the lobbyists and lawyers home and put their engineers to work," said Dr. Simon Mui, director of NRDC's work on clean vehicles and fuels in California. "Despite their protests, this shows once and for all that industry can meet and exceed the standard by diversifying to cleaner fuels like advanced biofuels, renewable natural gas, and clean electricity. A range of cleaner options is there for the taking."

The report's findings show that the oil industry can meet the LCFS reduction target – a 10 percent decrease in carbon emissions by 2020 – through known, existing fuels and refinery technologies. This includes expanding the use of lower-carbon biodiesel and renewable diesel, biomethane, electricity, and ethanol, as well as improving the carbon-intensity of existing alternative fuels. It also found that existing oil refineries and crude oil production facilities could dramatically cut their carbon footprint by integrating renewable energy, utilizing innovative technologies, and investing in greater energy efficiency.

The study analyzed different scenarios in which the program would encourage cleaner fuels by rewarding producers based on their environmental performance, measured in tons of carbon pollution reduced. The strong, performance-based incentive provided by the LCFS – worth potentially more than a dollar per gallon for ultra-low carbon fuel producers of fuels such as ethanol made from agricultural waste or biodiesel made from recycled oils – will enable the market to expand and diversify.

"A growing body of evidence shows that the LCFS will be a critical tool toward achieving Gov. Brown's new goal of cutting petroleum use in cars and trucks in half by 2030 to help California meet its climate goals," said Dr. Jeremy Martin, Senior Scientist and Fuels Lead at the Union of Concerned Scientists.

"By providing a steadily growing market for clean fuels, the LCFS supports investments that will energize clean transportation for decades to come."

At its February 19 hearing, the California Air Resources Board will consider its staff's proposal for re-adoption of the LCFS together with a series of enhancements to the program. Together with other clean transportation policies, the standard will enable California to continue reducing carbon emissions that contribute to global warming and poor air quality

“The LCFS is working to diversify California’s energy mix. Innovation and investments in clean fuels is growing,” said Tim O’Connor, Director of EDF’s California Climate Initiative. “As part of a suite of smart policies under our clean energy law, AB32, we’re seeing more efficient vehicles, more clean fuel options, and better access to transit. Californians will breathe easier, save money at the pump, and reduce their dependence on oil.”

Over the next six years, 70 million tons of carbon pollution will be avoided and 280 million barrels oil will be saved. That’s equivalent to avoiding the pollution from nearly 15 million cars and trucks in one year.

As California considers more ambitious future targets, this report – along with a growing body of research over the last several years – demonstrates that the state can reduce the carbon intensity of fuels beyond its current 10 percent reduction target by 2020 to 15 percent by 2025. Long-term regulatory stability is key and will help enable the alternative fuels market to steadily grow to supply 20 percent of California’s transportation energy, up three-fold by 2025 compared to when the program began in 2011.

The report was commissioned by the Natural Resources Defense Council (NRDC), the Union of Concerned Scientists (UCS), and the Environmental Defense Fund (EDF).

###

The Natural Resources Defense Council (NRDC) is an international nonprofit environmental organization with more than 1.4 million members and online activists. Since 1970, our lawyers, scientists, and other environmental specialists have worked to protect the world's natural resources, public health, and the environment. NRDC has offices in New York City, Washington, D.C., Los Angeles, San Francisco, Chicago, Bozeman, MT, and Beijing. Visit us at www.nrdc.org and follow us on Twitter @NRDC.

The Union of Concerned Scientists puts rigorous, independent science to work to solve our planet's most pressing problems. Joining with citizens across the country, we combine technical analysis and effective advocacy to create innovative, practical solutions for a healthy, safe, and sustainable future. For more information, visit us at www.ucsusa.org and follow us on Twitter @UCSUSA

Environmental Defense Fund (edf.org), a leading international nonprofit organization, creates transformational solutions to the most serious environmental problems. EDF links science, economics, law and innovative private-sector partnerships. Connect with us on our California Dream 2.0 blog, Twitter and Facebook.

23_OP_LCFS_Tetra Responses

101. Comment: **LCFS 23-1**

The comment lists five potential approaches to reducing carbon pollution directly from the petroleum supply chain.

Agency Response: ARB staff appreciates the analysis included in this comment of potential GHG benefits provided by the innovative crude and refinery investment provisions. Staff agrees that if these technologies are widely adopted by crude oil producers and refiners, they will reduce emissions in the petroleum supply chain and generate significant quantities of credits for LCFS compliance and have been incorporated into the provisions.

Biotechnology Industry Organization

Biotechnology Industry Organization
Comments to the California Air Resources Board
On the Low Carbon Fuel Standard
Readoption Plan
February 17, 2014

The Biotechnology Industry Organization (BIO) appreciates the opportunity to submit comments to the California Air Resources Board (CARB) on the Low Carbon Fuel Standard (LCFS) readoption plan (the readoption plan, or the plan).

BIO is the world's largest biotechnology organization with more than 1,000 members worldwide. Among its membership, BIO represents over 85 leading technology companies in the production of conventional and advanced biofuels and other sustainable solutions to energy and climate change challenges. BIO also represents the leaders in developing new crop technologies for food, feed, fiber, and fuel. BIO member companies represent many of the low carbon fuel producers that will supply the State of California with the fuels for LCFS compliance.

BIO and its member companies commend CARB for its openness, inclusiveness and transparency throughout the LCFS rulemaking process. In light of its representation on the LCFS advisory panel, BIO has appreciated the opportunity to guide and comment on CARB staff review of the LCFS regulation. BIO and its member companies have reviewed the recent LCFS plan and wish to provide comments. LCFS 24-1

BIO supports California's efforts to reduce the carbon intensity of transportation fuels and believes that biofuels can and must contribute significantly to this important objective. LCFS 24-2 While we are generally supportive of the readoption plan, we do have concerns about certain aspects of it and its potential impact on the production, distribution and availability of low carbon fuels in the State of California. Please see below for our brief comments on these areas of concern.

<u>Compliance Curve</u>

Under the new compliance schedule, the majority of the reductions are set to occur in the last two years, between 2018 and 2020. This new schedule will thus reduce the amount of credits needed between now and 2018. Instead of having a deficit in credits in 2015, which would have likely occurred under the former plan, it now appears that it is not likely that there will be a credit deficit until 2018. Given current and expected low carbon credit prices, BIO is concerned that, despite CARB's apparent projections, the credit price now and over the next four years would not attract fuels generating significant credits. In fact, the new compliance LCFS 24-3

1201 Maryland Avenue SW
Suite 900
Washington DC 20024

202.962.9200 P
202.488.6301 F
bio.org

schedule under the readoption plan may slow down investment in new facilities that would produce the very low carbon fuels that CARB is expecting and which are needed for full LCFS compliance. LCFS 24-3 cont.

Reporting Requirements

BIO and its members are concerned that the intensified reporting requirements under the readoption plan could be particularly burdensome in time and cost to small and new low carbon fuel producers. BIO urges CARB take this concern into account as it works to finalize the readoption plan. CARB should make every effort to ensure that the new reporting (and other) requirements under the plan do not inadvertently discourage small producers or innovation. One way to accomplish this goal could be for the LCFS reporting requirements to be harmonized with other existing programs, including the Quality Assurance Plan under the federal Renewable Fuel Standard. LCFS 24-4

GREET Model

BIO recommends that CARB ensure that the final version of the plan provides for periodic updates to the GREET model to ensure that new feedstocks are added and accounted for in a timely manner. This will help to encourage new and innovative low carbon fuel producers under the program. LCFS 24-5

Denaturant Calculation

BIO opposes the change to the denaturant calculation under the readoption plan and urges CARB to reconsider it as it works toward adopting a final readoption plan. Under the previous LCFS plan, the denaturant calculation was a standard 0.8 in carbon intensity (CI) added. As such, it did not appear to have a significant impact on the overall CI. The new denaturant calculation under the readoption plan would have a significant impact on the overall CI, and it would place a greater disadvantage the lower the CI. For instance, as the CI of an ethanol pathway decreases, the denaturant effect would increase. For ethanol with a CI above that of the CARBOB CI, the effect is such that the denatured ethanol has a lower CI than the anhydrous ethanol. BIO is concerned about the percentage used for ethanol, and the assumption that the non-ethanol components are CARBOB and not already accounted for in the anhydrous ethanol CI. Under the new denaturant calculation, the effect could be as little as <1 or close to 4 CI points, with the greater impact on the lower carbon fuels. LCFS 24-6

Conclusion

BIO is generally supportive of the readoption plan, but has concerns as outlined in this letter with respect to the compliance curve, reporting requirements, GREET model, and denaturant calculation. We respectfully request that CARB consider BIO's comments and recommendations as it works to finalize the readoption plan.

Sincerely,

Brent Erickson
Executive Vice President
Industrial and Environmental Section

24_OP_LCFS_BIO Responses

102. Comment: **LCFS 24-1**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support of our public process.

103. Comment: **LCFS 24-2**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support of the re-adoption of the LCFS regulation.

104. Comment: **LCFS 24-3**

The commenter is concerned that given the new compliance schedule, credit price will not be sufficient to attract fuels generating significant credits.

Agency Response: The adopted compliance curve ramps up the percent reduction more slowly in the 2016 to 2018 period than the original adopted LCFS due to several factors. The first is a lower supply of some low carbon-intensity (CI) biofuels in the 2011 to 2018 period due to much less than originally expected production capacities for cellulosic fuels. The second is the uncertainty created by court suits and the decision of a State court to freeze the compliance level at one percent pending reconsideration of the LCFS. That may have impacted investments and delayed the deployment of production facilities for low CI fuels. Due to these factors, ARB staff's analysis in the Initial Statement of Reasons (ISOR) indicated a substantial possibility of insufficient credit production for full program compliance if the original reduction schedule were to be maintained.

In light of this information, ARB staff concluded that a more gradual implementation schedule was appropriate. Further, staff believes that retention of the ten percent reduction target in 2020 will both increase investment in cleaner fuels and create credit prices high enough to attract the needed fuels to California.

105. Comment: **LCFS 24-4**

The commenter is concerned that reporting requirements are burdensome.

Agency Response: ARB staff has carefully considered the parameters listed in the recordkeeping section. It is a list of what is needed to substantiate each fuel volume claimed within the LCFS Program. Staff has also worked with regulated parties that are currently reporting and workshopped the recordkeeping provision a number of times. We do not believe that the program's reporting requirements are overly burdensome.

ARB staff is aware of the voluntary quality assurance plan provision that the Environmental Protection Agency (U.S. EPA) has adopted in the Renewable Fuel Standard Program. Staff is working with U.S. EPA to better understand how this provision is being implemented at the federal level and to consider adding additional third-party checks to the LCFS system in future rulemakings.

106. Comment: **LCFS 24-5**

The comment recommends that ARB plan for periodic updates to the GREET model.

Agency Response: ARB staff plans to update the analytical models underlying the carbon intensity calculations in the program at regular intervals – possibly every three years. For example, the next update would occur as part of the program review rulemaking concluding prior to January 1st, 2019. Additionally, in the California-modified Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (CA-GREET)-2.0 model, Tier 2 calculator, staff has included a user-defined fuel option for new types of feedstock and fuel.

107. Comment: **LCFS 24-6**

The comment requests validation of the change to the denaturant calculation under the re-adoption plan.

Agency Response: The existing method of accounting for denaturant added to ethanol does not account for the fact that in each unit (MJ) of denatured ethanol, a portion of the ethanol is displaced by gasoline blendstock (denaturant). The impact of denaturant on carbon intensity (CI) was previously estimated as 0.8 gCO_2e/MJ by assuming an "average" anhydrous ethanol CI of approximately 90 gCO_2e/MJ. Given the development of improved ethanol pathways with reduced carbon intensities, ARB staff finds it necessary to account for the ethanol which is displaced when denaturant is added; thus, a lower CI ethanol results in a higher impact of denaturant CI. Denaturant CIs are now calculated on an ethanol pathway-specific basis, rather than as a constant adder. The formula for denaturant CI is given in CA-GREET 2.0 and a separate stand-alone spreadsheet calculator (http://www.arb.ca.gov/fuels/lcfs/ca-greet/ca-greet.htm) was released to more clearly demonstrate how the calculation works.

Transmitted via LCFS Comment Portal

Mary D. Nichols
Chairman
California Air Resources Board
P.O Box 2815
Sacramento, CA 95812

Re: Comments on Proposed LCFS Readoption

Dear Ms. Nichols,

Airlines for America (A4A) appreciates the opportunity to comment on the Air Resources Board's (ARB) proposed readoption of the Low Carbon Fuel Standard (LCFS).[1] We write to request that ARB include sustainable alternative jet fuel as an eligible credit-generating fuel under the LCFS. The U.S. airline industry has a strong record of fuel efficiency improvements and greenhouse gas (GHG) emissions reductions, and A4A and its members seek to build further on that record through the development and deployment of sustainable alternative jet fuel. There is particularly great interest among A4A members and biofuel producers in producing and utilizing such jet fuel in the California market. Sustainable alternative jet fuel (hereinafter referred to as "bio-jet fuel") is a "drop-in ready" fuel product – fully compatible with and capable of replacing petroleum jet fuels – that can be sustainably produced through the processing of waste oils and other biomass-based feedstocks, thereby resulting in reduced lifecycle GHG emissions relative to petroleum-based jet fuel. Unfortunately, the production of bio-jet fuel is currently *disincentivized* in California because biofuel producers can only generate LCFS credits for biofuel that displaces conventional ground transportation fuels. A4A urges ARB to allow for all low carbon transportation fuels to generate credits under the Clean Fuels Program. Such an approach would eliminate unnecessary distortions in the biofuels market, support the developing California advanced biofuels industry, and provide an additional pool of available credits to contain the costs of the LCFS. LCFS 25-1

For the past several decades, the U.S. airlines have dramatically improved fuel and GHG efficiency by investing billions in fuel-saving aircraft and engines, innovative technologies like winglets (which improve aerodynamics) and cutting-edge route-optimization software. As a result, between 1978 and 2013, the U.S. airline industry improved its fuel efficiency by 120 percent, resulting in 3.6 billion metric tons of CO_2 savings – equivalent to taking 22 million cars off the road on average in each of those years. Further, data from the Bureau of Transportation Statistics confirms that U.S. airlines burned 8 percent less fuel in 2013 than they did in 2000, resulting in an 8 percent reduction in CO_2 emissions, even though they carried 17 percent more passengers and cargo on a revenue-ton-mile basis.

But our airlines are not stopping there. A4A and our members are part of a global aviation coalition that has committed to a 1.5% annual average fuel efficiency improvement through 2020 and carbon neutral

[1] A4A is the principal trade and service organization of the U.S. scheduled airline industry. A4A members and affiliates transport more than 90% of U.S. airline passenger and cargo traffic. The members of the association are: Alaska Airlines, Inc.; American Airlines Group (American Airlines and US Airways); Atlas Air, Inc.; Delta Air Lines, Inc.; Federal Express Corporation.; Hawaiian Airlines; JetBlue Airways Corp.; Southwest Airlines Co.; United Continental Holdings, Inc.; and United Parcel Service Co. Air Canada is an associate member.

1301 Pennsylvania Ave, NW, Suite 1100, Washington, DC 20004-1707 T: 202.626.4000 E: a4a@airlines.org W: airlines.org

growth from 2020, subject to critical aviation infrastructure and technology advances achieved by government and industry. The initiatives our airlines are undertaking to further address GHG emissions are designed to responsibly and effectively limit their fuel consumption, GHG contribution and potential climate change impacts, while allowing commercial aviation to continue to serve as a key contributor to the U.S. economy.

The availability of bio-jet fuel in significant quantities is one key pillar to the achievement of the industry goals, and A4A and its members are working to lay the groundwork for the establishment of a sustainable aviation biofuels industry. A4A is a founding member of the Commercial Aviation Alternative Fuel Initiative® (CAAFI), a public-private partnership with the Federal Aviation Administration (FAA) and other stakeholders that is working to hasten the development and deployment of such fuels. Among other accomplishments, CAAFI helped lead the effort for specifications certifying three alternative jet fuels.

In California, United Airlines has executed an agreement with AltAir Fuels for the purchase of up to 15 million gallons of renewable jet fuel over a three-year period to begin in 2015. AltAir has created 100+ jobs in the Paramount area and added to the tax base considerably by taking over an idled refinery that had no active plans to restart. With appropriate treatment of bio-jet fuel under the LCFS, other facilities would likely follow, making California the undisputed hub of bio-jet fuel production.

Allowing bio-jet fuel producers to generate LCFS credits would significantly improve the economics of new and existing facilities by allowing them to generate credits from all transportation fuels produced, while also creating additional compliance flexibility for regulated parties. The AltAir facility, as well as other potential plants utilizing a similar conversion technology, can necessarily produce both diesel and bio-jet fuel. Given that the LCFS is intended to spur investment in facilities producing low carbon fuels that will enable the standard to be met, ARB should not dilute the investment signal for these facilities by not allowing significant portions of their fuel production to generate credits. Further, it would be inappropriate for ARB to create market distortions by crediting diesel and not bio-jet fuel, thereby creating a financial disincentive for the production of bio-jet fuel even though both fuels deliver similar GHG reductions. Indeed, as a result of the LCFS not crediting bio-jet fuel, AltAir is reducing the total available production of renewable jet fuel for United and others to purchase. Unnecessarily creating such disincentives for producers like AltAir (and thereby suppressing demand from airlines like United) is not only contrary to the GHG reduction goals of the LCFS, but it is particularly inappropriate in light of the critical role the airline industry can play in helping to obtain financing for facilities through dedicated off-take agreements, a role that the airline industry is uniquely situated to fill.

LCFS 25-1 cont.

The proposal's discussion of the future availability of renewable diesel for LCFS compliance cites several facilities that have already contractually committed to producing substantial volumes of bio-jet fuel for the airline industry. These include the above-mentioned AltAir facility, as well as planned facilities from Red Rock Biofuels in Oregon and Fulcrum Bioenergy in Nevada.[2] Instead of relying on the LCFS to incentivize these facilities to devote their production only to renewable diesel, ARB should allow for credit from either renewable diesel or bio-jet fuel and allow the market to determine where the fuel is ultimately allocated. Such an approach would lend more certainty to ARB's fuel availability projections, eliminate concerns that the LCFS may inhibit bio-jet fuel production, and lower compliance costs for regulated parties.

Crediting bio-jet fuel as a cost-containment mechanism is consistent with the direction in ARB Resolution 11-39 to explore "expansion of the LCFS credit trading market" and "incorporation of a flexible compliance

[2] http://www.prnewswire.com/news-releases/united-airlines-and-altair-fuels-to-bring-commercial-scale-cost-competitive-biofuels-to-aviation-industry-210073841.html; http://www.swamedia.com/releases/southwest-airlines-announces-purchase-agreement-with-red-rock-biofuels?l=en-US; http://www.cathaypacific.com/cx/en_HK/about-us/press-room/press-release/2014/Cathay-Pacific-invests-in-sustainable-biojet-fuel-developer.html

mechanism…"[3] While ARB has included several new forms of cost containment in the proposal, the simplest form of cost containment—enlarging the pool of available credits by allowing all low carbon transportation fuels used in California to generate credits—is unnecessarily absent from the proposal. In addition, crediting of bio-jet fuel could contribute to cost containment by providing an additional avenue for low carbon fuel use that is unaffected by ground transportation blending constraints.

We agree with ARB's general exemption of aircraft fuels from California's LCFS mandates.[4] Subjecting aircraft fuels to annual "carbon intensity" standards would raise serious federal preemption issues and would not be appropriate given the rigorous jet fuel specifications that make producing jet fuels a "higher hurdle" than producing ground-based fuels. However, ARB does have the authority to amend the LCFS regulations to create *incentives* to promote the use of low carbon, bio-jet fuels in aircraft by allowing credit for such fuels. By promoting the voluntary production and use of bio-jet fuel, ARB would not, in our view, cross the line into impermissibly regulating aircraft fuels, but rather would simply be creating opportunities for airlines to better support California's GHG objectives.

LCFS 25-1 cont.

Notably, allowing bio-jet fuel to generate LCFS credits would be a measure fully in line with the U.S. Environmental Protection Agency's approach under the Renewable Fuel Standard (RFS) regulations. The RFS explicitly allows for the generation of Renewable Identification Numbers (RINs) for the production of bio-jet fuel, although the RFS appropriately does not mandate the production or use of any volume of aviation biofuel.

A4A strongly urges ARB to adopt a similar approach to expand opportunities for new biofuel production facilities and create additional compliance flexibility for regulated parties. Several stakeholders have previously suggested allowing such a credit for bio-jet fuel under the LCFS. Although ARB declined to include such a provision in the original regulations, it committed to revisiting the issue during the mandatory program review in 2011.[5] While ARB did not address the issue in the 2011 program review, we urge ARB to do so now. Given the strong interest in bio-jet fuel in California, we believe the time is ripe for ARB to include a provision crediting the production of such fuel.

Sincerely yours,

Nancy N Young

108. Comment: **LCFS 25-1**

The comment requests that ARB staff include sustainable alternative jet fuel as an eligible credit-generating fuel under the LCFS.

Agency Response: Aircraft fuels are exempt because many flights occurring in California airspace originate and terminate at a wide variety of national and international locations. ARB staff has not yet attempted to develop a methodology by which aircraft fuel used by aircraft using California airspace can be allocated to the California transportation fuels market.

AEMETIS

February 17, 2015

Hon. Mary Nichols
Chairman, California Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Chairman Nichols,

Aemetis, Inc., a California-based company, owns and operates California's largest ethanol production facility located in Keyes. We believe grain sorghum has an essential role to play in helping California meet the greenhouse gas reduction goals set by the LCFS, and to reduce water usage on water-stressed farm acres in California.

To date, Aemetis has processed approximately 50,000 tons of lower-carbon grain sorghum into liquid transportation fuel, and going forward, we intend to continue processing sorghum. As you know, along with the other California ethanol producers, Aemetis has been awarded a CEC matching grant (#ARV-14-027) to develop the California In-State Sorghum (CISS) program that combines research, market development, and education to support the development of sorghum as a reliable and robust feedstock for the state's low carbon ethanol industry. Under the grant, each of the three California ethanol companies will process approximately 82,000 tons of grain sorghum (~7.9 million gallons of ethanol), eliminating over 15,500 MT of CO2. In short, we are committed to the development and use of grain sorghum as a lower-carbon feedstock as we work to support the LCFS.

As a larger part of our sorghum initiative, we maintain close contact with National Sorghum Producers (NSP) and understand they are submitting comments as well. Along with NSP, we applaud the California Air Resources Board for its update of the LCFS and appreciate special attention given to sorghum ILUC, sorghum fertilizer requirements, and N_2O emissions from sorghum stover. We also recommend that the ARB focus attention on information related to sorghum root-shoot ratios, and as it becomes available, incorporate this information into future versions of CA-GREET. LCFS 26-1

Thank you for the opportunity to comment, and for your strong leadership at the ARB.

Sincerely,

Andrew B. Foster
President

RE: 2015 LCFS Readoption

Dear Chairman Nichols,

As stated in prior comments, White Energy is an ethanol producer that has three facilities located in Kansas and Texas. We support the re-adoption of the Low Carbon Fuel Standard (LCFS) and commend California ARB for moving the program forward. We appreciate all of staff's hard work and the openness of the workshops leading up to the issuance of the proposed regulation order, allowing stakeholders to better understand the re-adoption process and development of the proposed regulation order. LCFS 27-1

We would suggest that fuel pathways voluntarily registered under the Biofuel Producer Registration system prior to the effective date of the new proposed regulation order all have the same deactivation schedule under Section 95488(a) regardless of the certification date or application date. Due to the decreased iLUC factor alone, it will be beneficial as an ethanol producer to immediately apply for a new certified pathway under the readopted regulation. However, considering the sheer volume of all new certifications that will need to occur across the program, the uncertainty of being able to obtain the new certifications prior to the effective date is a concern. LCFS 27-2

As stated in prior comments, we feel sorghum plays an important role in helping California meet the greenhouse gas reduction goals set by the LCFS and reducing water usage on irrigated acres. We support the comments of the National Sorghum Producers applauding the ARB for its special attention to sorghum iLUC, sorghum fertilizer requirements and N_2O emissions from sorghum stover. We also recommend that the ARB focus attention on information related to sorghum root:shoot ratios, and as it becomes available, incorporate this information into future versions of CA-GREET. LCFS 27-3

White Energy desires to part of the solution by providing low carbon fuels to help ARB meet its goals to reduce greenhouse gas emissions through the LCFS program.

Thank you for the opportunity to comment.

Sincerely,

Carol Tjiong
Vice President

27_OP_LCFS_WE Responses

110. Comment: **LCFS 27-1**

The comment expresses appreciation for staffs' openness in the workshops leading up to the proposed regulation.

Agency Response: ARB staff appreciates the support of the re-adoption of the LCFS regulation.

111. Comment: **LCFS 27-2**

The comment suggests that fuels pathways voluntarily registered under the Biofuel Producer Registration system prior to the effective date of the new proposed regulation order all have the same deactivation schedule.

Agency Response: Various holders of fuel pathways under the current regulation have voiced concern that recertifying those pathways under the proposed regulation on a first-in-first-out basis will create inequities in the form of market advantages and disadvantages. Holders with recertified carbon intensities (CIs) that are lower than their existing CIs would have a competitive advantage over their competitors if their pathways are processed first in the recertification queue. In order to minimize this inequity, the ARB Executive Officer will group all similar recertified CIs for activation in the LRT-CBTS system at the same time. All recertified landfill-gas-to-biomethane CIs, for example, will be activated in the LRT-CBTS system at the same time.

112. Comment: **LCFS 27-3**

The comment recommends that ARB staff stay up to date on any new information regarding root-shoot ratios, incorporating the information into future versions of CA-GREET.

Agency Response: See response to comment **LCFS 9-2.**

Re: Notice of Public Hearing to Consider a Low Carbon Fuel Standard (LCFS)

GlassPoint Solar Inc. (GlassPoint) appreciates and supports ARB's efforts to readopt the Low Carbon Fuel Standard (LCFS) to create a workable regulatory framework. We are pleased to provide these comments on the December 30, 2014 LCFS regulatory adoption package. LCFS 28-1

The proposed regulation is the result of a cooperative rulemaking process that GlassPoint believes has made the regulation better, and specifically the Innovative Crude Provisions. We look forward to the conclusion of the rulemaking in an expeditious manner as possible. GlassPoint is ready to build new low-carbon projects once regulatory standards are set.

GlassPoint is a California company that manufactures solar steam generators for thermal enhanced oil recovery (EOR). Our renewable energy technology has proven reliable, safe and economical in field operations in California and the Middle East. We were pleased to be selected by the U.S. State Department as one of nine finalists for the Secretary of State's prestigious 2014 Award for Corporate Excellence (ACE) for our technology and corporate behavior.

Thermal EOR, or steam injection, extends the value and the life of California's oilfields. Today, thermal EOR accounts for more than 40% of California's oil production and consumes more than 200 MM MMBTU per year of fuel for steam generation. Solar energy can replace a substantial fraction of that existing fuel use, reducing emissions resulting from upstream production.

GlassPoint appreciates ARB's understanding of the potential value of innovative crude production methods. Of the potential innovative methods, the use of solar energy is the lowest-cost, lowest-risk, and largest-scale opportunity to reduce the CI of petroleum fuels produced and used in California. Solar powered oil production technologies can contribute to California's economy while reducing emissions, costs and risks associated with achieving the LCFS targets.[1]

[1] ICF International: The Impact of Solar Powered Oil Production on California's Economy, An economic analysis of Innovative Crude Production Methods under the LCFS. January 2015. Attachment A

ICF has recently completed a study of the economic impact of solar innovative crude production. The study finds that solar EOR in California could deliver over 4.2 million credits per year into the LCFS market while creating up to 44,900 cumulative jobs in California's economy through 2020. In-state solar energy projects can deliver permanent emissions reductions, reduce production costs, and reduce dependence on imported fuels. The results further show that for every job created building and operating solar powered oil production facilities, about 2.5–2.7 jobs are created in supporting industries (indirect) and via spending by employees that are directly or indirectly supported by the industry (induced).[2]

GlassPoint strongly supports the Innovative Crude mechanisms and procedures as provided in the proposed regulation, and believes additional changes are not needed to those specific provisions. We appreciate the staff work that has greatly simplified and clarified the processes associated with project approval and credit monetization. LCFS 27-2

One final reminder on regulatory timing must be noted. This regulatory adoption schedule has been delayed several times and now creates challenges for customers and project developers to harvest the benefits of the Federal solar tax incentives, which expire at the end of 2016. An effective 20% price increase will occur for projects which come online after that date. LCFS 27-3

GlassPoint hopes to establish certainty in the investment community as soon as possible about the longevity of, and the benefits of, this program. That is the easiest way to start in-state investments in lower CI fuel production. We look forward to working with ARB so that projects can capture the Federal benefits and minimize total costs.

Thank you for the opportunity to comment and we look forward to the conclusion of this lengthy rulemaking, and to working on building a lower carbon infrastructure for California.

Sincerely,

John O'Donnell
Vice President, Business Development

Executive Summary

The California Air Resources Board (CARB) staff as proposed to re-adopt the Low Carbon Fuel Standard (LCFS), reaffirming its original target of a 10% reduction in the carbon intensity (CI) of transportation fuels used in California by 2020 and subsequent years. While most of the expected CI reductions will be derived from imported low-CI fuels, the regulation and the re-adoption proposal include provisions to promote innovations in crude oil production methods that reduce the CI of petroleum.

Of the potential innovative methods, the use of solar energy is the lowest-cost, lowest-risk, and largest-scale opportunity to reduce the CI of petroleum fuels produced and used in California. Solar powered oil production technologies—solar steam generation and solar electric power generation—have the potential to contribute to California's economy signifi antly while reducing costs and risks associated with meeting the LCFS. Solar steam generation used in thermal enhanced oil recovery (EOR) displaces imported natural gas that that would have otherwise been combusted. Solar electricity generated on-site at production facilities displaces electricity that would have otherwise been purchased from a utility provider. These solar technologies have the potential to reduce the carbon intensity of California's crude oil, thereby boosting investment in California-based industries, and helping shift LCFS compliance from importing low carbon fuels from out-of-state towards in-state investments and operations of low carbon infrastructure. Investment in these technologies can lead to job growth, increased industry activity, and increased state and local tax revenues. Furthermore, by reducing the carbon intensity of California crude oil, these solar technologies have the potential to preserve California refinery operations while fully meeting the emissions reductions goals of the LCFS.

ICF employed IMPLAN, an input-output model, to calculate the economic impacts of deploying solar steam generation and solar electric power generation technologies. ICF developed *steady* and *accelerated* deployment scenarios for each technology, capturing 5% and 30% of their respective markets (as measured by volume of steam or electricity consumption). ICF also considered the economic impacts of keeping LCFS credits generated by solar steam and solar power in California, rather than having the value of those credits transferred to low carbon fuel providers in other regions. Furthermore, we considered the impacts on refiners as a result of being able to maintain margins that would have otherwise been impacted by reduce crude runs or reduced margins from having to export the refined products.

Exhibit 1. Economic Contributions of Solar Oil Production in California

Cumulative Solar Impact 2015-2020	*Steady*	*Accelerated*
	$25/ton	$150/ton
Total Jobs	**11,000**	**44,900**
Income per Worker	$72,000	$77,900
GSP ($M)	**$1,160**	**$5,090**
Industry Activity ($M)	$2,910	$11,350

In the *accelerated* deployment scenario, where solar energy provides 30% of the state's EOR steam needs or onsite production electricity, ICF concluded:

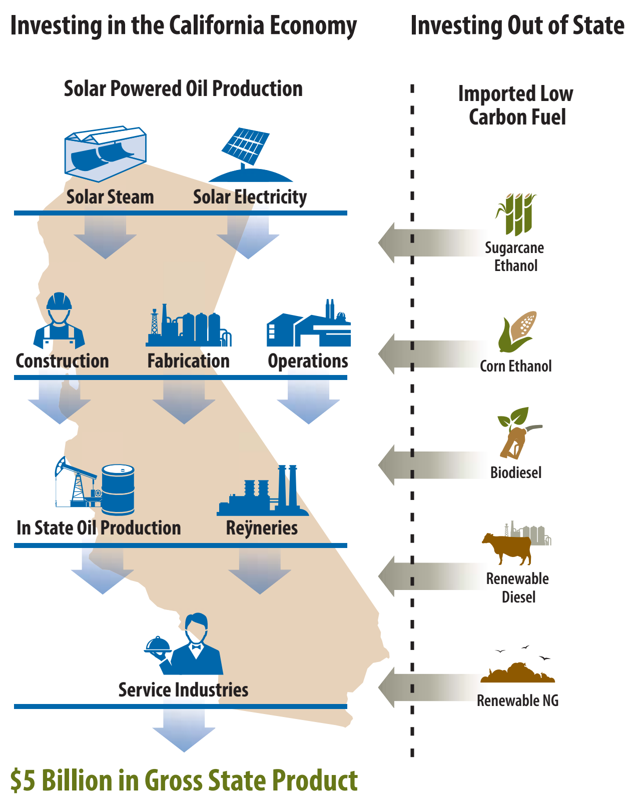
- Innovative crude oil production using solar energy adds 32,100–44,900 cumulative jobs to California's economy from 2015 through 2020, depending on LCFS market conditions.
- These are high value jobs, with labor income per job created in the range of $75,000 per job. Many of the jobs were created in sectors tied to upstream oil production, as well as construction, engineering related services, and fabrication/manufacturing.

- For every job created through investment in solar powered oil production, about 2.5–2.7 jobs are created in supporting industries (indirect) and via spending by employees that are directly or indirectly supported by the industry (induced).
- The deployment of these technologies leads to increased state and local tax revenues in the range of $117–575 million.

Solar steam has greater potential than solar electricity to deliver LCFS credits because 90% of the energy used in California oil production is in the form of steam. In the *accelerated* deployment scenario, solar steam generation has the potential to generate as many credits as some of the most promising low carbon fuel pathways by 2020, including renewable diesel, renewable natural gas, and low carbon intensity biodiesel (e.g., from corn oil). Solar electricity has the potential to generate LCFS credits in line with contributors like electricity and natural gas.

ICF also finds that solar powered oil production technologies may help stabilize the LCFS market in several ways. Firstly, these LCFS credits may help stabilize credit prices by offering a lower cost solution than importing low carbon fuels for compliance. Secondly, we find that these credits may hedge California's exposure to uncertainty in the federal Renewable Fuel Standard market. With the potential for RIN prices to be depressed because of uncertainty in that market, biofuel providers may seek higher LCFS credit prices to pick up the slack in market pricing. However, the deployment of solar powered oil production technologies will provide some buffer against credit price increases. Thirdly, solar powered oil production technologies will provide regulated parties, particularly integrated energy firms with oil production and refining investments, an opportunity to limit their exposure to the LCFS credit market.

Solar powered oil production technologies are commercially available today with low development risk, and unlike some low carbon fuel options, innovative crude methods tap into the existing petroleum supply chain without delay for infrastructure modifi ations or rollouts. The emissions reduction potential of the technologies will deliver credits to the oil producer and reduce the CI of petroleum fuels. Therefore, innovative crude offers the unique advantage of fully complying with the LCFS and achieving the state's GHG reduction goals without hindering the petroleum supply chain. These emissions reductions are available as a "drop in" option using today's fuel production, distribution, and vehicle infrastructure, with minimal infrastructure costs, development risk, and deployment timelines.



ICF's analysis demonstrates that investments in solar powered oil production will yield benefits up to $5 billion in Gross State Product, with jobs created in sectors such as construction, fabrication, oil field operations, and the service industry, while retaining jobs in the refining industry. This contrasts sharply with some of the alternative LCFS compliance pathways, whereby dollars (via commodity pricing and LCFS credits) are exported out of California to pay for low carbon fuels produced elsewhere.

1 Innovative Crude Oil Production

The California Air Resources Board (CARB) staff as proposed to re-adopt the Low Carbon Fuel Standard (LCFS) program in 2015, and to include updates and revisions to the regulation.[1] The regulation and the re-adoption proposal include provisions to promote innovations in crude oil production methods that reduce greenhouse gas (GHG) emissions. In this section, we briefly summarize California's Oil and Gas Sector, its outlook in the near- to mid-term as a result of carbon constraining regulations in the state, and review the relevant innovative crude oil production technologies.

1.1 California's Oil and Gas Sector

Excluding federal offshore areas, California ranks third in the United States in crude oil production. As recently as 2012, nearly 4,700 new wells were drilled in California, bringing the statewide total to 88,500 active wells, operated by 570 companies.[2] A recent report by the Los Angeles Economic Development Corporation (LAEDC) highlights some of the critical parameters characterizing the impact of the Oil and Gas Sector on California's economy, including:[3]

- About 70,000 direct jobs in California are tied to oil and gas production
- Oil and gas production contribute about 0.5% of total California labor income
- The average wage of the component industries in the oil and gas production sectors are considerably higher than the median private industry wage in California

Exhibit 2. Crude Oil Production in California, 2005-2014[4]

3 Oil and Gas in California: The Industry and Its Economic Contribution in 2012, LAEDC, April 2014, http://laedc.org/wp-content/uploads/2014/04/OG_Contribution_20140418.pdf

4 Based on data from EIA and DOGGR. The crude oil production for 2014 is an estimate made by ICF based on data reported through September. Note that production data via TEOR are not yet available past 2009. The shaded range is an estimate based on ICF analysis.

California's Low Carbon Fuel Standard

The LCFS requires a 10 percent reduction in the carbon intensity (CI) of transportation fuels used in California. Carbon intensity is a measure of the lifecycle GHGs of transportation fuels, and includes emissions over the entire fuel supply chain. The LCFS is implemented using a system of credits and defi its: Defi its are generated by fuels that have a carbon intensity greater than the standard and credits are generated by fuels that have a carbon intensity lower than the standard. At the end of each year, defi it-generating parties (generally refiners and fuel importers) must balance their defi its with credits.

Despite several years of reductions in overall crude production since 2005, crude produced from thermal enhanced oil recovery (EOR)[5] or steam injection has been increasing since 2006, as shown in Exhibit 2. Crude Oil Production in California, 2005-2014 above. Steam injection, which reduces the viscosity of oil and increases mobility, has been used commercially in California since the 1960s. Today, more than 40% of California's crude is produced with thermal EOR and is expected to account for half of production in the next few years. As an emitter of GHGs, the oil and gas production industry is impacted by CARB's implementation of the Global Warming Solutions Act of 2006, commonly known as AB 32. The LCFS and light-duty tailpipe GHG standards (originally referred to as Pavley standards) are both part of California's suite of GHG reduction policies under AB 32, and will both lead to reductions in demand for petroleum-based transportation fuels. Although the refinery sector is commonly identifi d and analyzed as one of the primary industry sectors to be impacted by AB 32, upstream oil and gas production sectors will likely experience the effects of the regulation as well.

This report focuses on a potential opportunity included in the proposed re-adoption of the LCFS: "Innovative Crude Production Methods". Operators who produce crude for California's refineries and employ a GHG-reducing "innovative method" in the recovery or extraction process can generate LCFS credits corresponding to the avoided GHG emissions.

1.2 Introduction to Innovative Crude Production Methods

The current proposed LCFS re-adoption regulation identifi s the following technologies as innovative methods for crude production:[6]

Technology	Image	Description	Technology Maturation	LCFS Considerations
Solar steam generation		Uses solar arrays to concentrate the sun's energy to heat water and generate steam for thermal EOR.	Deployed in multiple locations; several vendors.	Steam must be used onsite at the crude oil production facilities.
Carbon capture and storage		Captures CO_2 emissions produced from processing; prevents the CO_2 from entering the atmosphere.	Limited commercial deployment; no commercial deployment at oil field .	Carbon capture must take place onsite at the crude oil production facilities.
Solar or wind electricity generation		Electricity generation from solar technology or wind turbines. Electricity to be used on-site for production-related activities.	Solar PV technology is ubiquitous for non-residential installations. Wind technology is mature, but generally deployed in larger rather than on a smaller scale.	Qualifying electricity must be produced and consumed onsite or be provided directly to the crude oil production facilities from a third-party generator and not through a utility owned transmission or distribution network.
Solar heat generation		Uses solar arrays to concentrate the sun's energy for heat generation.	Concentrating solar technology that can produce process heat (similar to steam generation).	Heat must be used onsite at the crude oil production facilities.

The language also includes provisions regarding year of implementation (no earlier than 2010 for solar steam or CCS; no earlier than 2015 for electricity and heat generation projects), project registration, and minimum GHG reduction thresholds (a carbon intensity reduction of at least 0.10 gCO_2e/MJ or a reduction of at least 5,000 metric tons CO_2e per year).

[5] Thermal EOR is a process whereby heat is introduced to the reservoir in order to reduce the viscosity of the crude, and increase its permeability.

[6] Initial Statement of Reasons, II-17ff. Available online at: http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15isor.pdf

"Solar powered oil production technologies—solar steam generation and solar electric power generation—have the potential to contribute to California's economy significantly while reducing costs and risks associated with meeting the LCFS."

Technologies Selected For Further Analysis

For the purposes of this report, ICF narrowed our consideration of innovative crude methods to *solar steam generation* and *solar electricity generation* based on factors such as commercial availability of the technology, consideration of California oil fi ld characteristics, and industry interest. Other qualifying innovative technologies, including carbon capture and storage (CCS), wind electricity generation, and solar heat generation, were not considered due to limitations or uncertainty in market demand.

- **Solar steam generation.** The technology is commercially available and has been demonstrated by both GlassPoint Solar and BrightSource Energy. These companies have demonstration projects in Kern County and Fresno County, California, respectively. GlassPoint Solar also has deployed its technology in Oman at the Amal West oilfield (in partnership with the national oil company, Petroleum Development Oman, PDO). With about 492 million barrels of steam injected for thermal EOR in California in 2012, there is significant potential for solar steam generation in California. For such thermal EOR projects, steam is the primary energy requirement, with 185 million MMBtu of natural gas required to produce the 492 million barrels of steam injected for thermal EOR. This natural gas is the primary source of GHG emissions associated with oil production. The potential for the technology is limited by factors such as geography and the deployment of efficient combined heat and power (CHP) units at oilfields, which may be difficult to displace depending on when the units were installed and the operators' willingness to displace the technology given the investment. However, ICF anticipates sufficient demand for solar steam generation deployment as part of LCFS compliance.
- **Solar electricity generation.** Solar electric power generation is ubiquitous in California, with more than 8,500 MW of solar energy currently installed, and about 2,750 MW of that installed in 2013. Multiple photovoltaic (PV) technologies have experienced significant declines in installed cost over the last several years, with the average installed system price reported at about \$2.27/W for a non-residential system.[7] The location and electricity demands at oilfields will likely be a good match for solar PV deployment. The regulation restricts credits from potential solar electricity deployment to electricity which is produced and consumed onsite or is directly provided to the facility via third-party generator, not through the utility grid. As oil production operations are generally continuous, there are limits for the fraction of total energy provided by solar PV deployment without concomitant investments in energy storage. Despite these limitations, ICF anticipates that solar PV installations at oil fields will increase substantially between now and 2020 as part of a LCFS compliance strategy based on the cost competitiveness of the technology and the desirable onsite characteristics of oil production fields (e.g., sufficient solar radiation).

[7] US Solar Market Insight: Q3 2014, GTM Research and SEIA, available online: http://www.seia.org/sites/default/files/ esources/iV39f8059N.pdf; assumes a 200-300 kW rooftop installation at a non-residential facility.

2 Economic Impacts of Solar Powered Innovative Crude Production

ICF employed an input-output (I-O) economic model to calculate the economic benefi s of deploying solar steam generation and solar electricity generation in California. We considered several elements associated with the deployment of these technologies, including the following:

- **Capital expenditures.** ICF considered the capital expenditures associated with deploying the technologies in two scenarios (*steady* deployment and *accelerated* deployment). The capital expenditures include the labor and materials associated with building the solar steam installations and solar PV installations.
- **LCFS credit generation.** ICF also considered the value of LCFS credits generated via the deployment of these technologies in California. ICF assumed that the generation of credits would have otherwise been completed outside of California. This is a reasonable assumption given the structure of the LCFS program and a review of CARB's proposed LCFS compliance scenario, which relies heavily on biofuels (e.g., biodiesel, renewable diesel, and renewable natural gas). Given the limited in-state production of low carbon fuels, ICF made the reasonable assumption these innovative crude production technologies will create credits in-state from investments made in-state, versus credit revenues being exported out-of-state for imported low carbon fuels. We valued the credits in two scenarios: a low price of $25/ton and a high price of $150/ton.[8]
- **Refi ery margins.** Depending on the strategy employed, LCFS compliance may lead to significant demand destruction for gasoline and diesel. For instance, CARB's proposed compliance scenario includes about 900 million gallons of diesel replacements being consumed in 2020, representing about 20% of the projected diesel demand. Conversely, CARB's illustrative compliance scenario only projects about 110 million gallons of gasoline replacements being consumed in 2020, in a fuel market with projected demand of about 13.5 billion gallons. Regardless of the compliance strategy, it is highly likely that there will be reduced refinery margins as a result of the LCFS. ICF broadly categorizes these losses into two areas: 1) lost refinery margin and 2) reduced refinery margins as a result from having to export product.

Depending on the chosen means of LCFS compliance, varying levels of decreases occur in gasoline and diesel consumption in California. Although the reduction of petroleum consumption has positive impacts via improved energy security and increased fuel diversity, the decreased consumption of petroleum will also have direct negative impacts on the refining industry—in the same way that the investments in alternative fuels and advanced vehicles will yield positive impacts in the corresponding industries. ICF treated the reduction in gasoline and diesel consumption in the modeling as follows:

- **ICF assumed that there were lost margins on 50% of those crude runs that are assumed to be displaced entirely as a result of the LCFS.** These margins were estimated based on an ICF analysis of the 3-2-1 crack spread for California-based refiners (estimated at about $15/bbl).
- **ICF assumed that the remaining 50% of crude runs representing the reduction in gasoline and diesel consumption in California are exported, rather than displaced entirely.** For these exports, ICF assumed a corresponding decrease in revenue in the export markets because of increased freight costs and competitiveness on pricing (estimated at a combined $5/bbl).

Using CARB's illustrative compliance scenario, each credit generated in 2020 leads to a demand destruction of about 120-130 diesel gallons equivalents.[9]

[8] LCFS credit values traded around $25/ton for all of 2014, and likely are below forward credit prices considering the uncertainty associated with the LCFS program throughout 2014 and rising compliance obligations. The high value of $150/ton was selected for illustrative purposes; the program is capped at $200/ton via a cost compliance mechanism.

[9] The demand destruction is presented as a range because it ultimately depends on the carbon intensity of the low carbon fuels deployed in CARB's illustrative compliance scenario. Available online at http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15appb.pdf

Exhibit 3. Overview of Solar Powered Oil Production Scenarios

Technology Penetration	Solar Steam		Solar Electricity	
	Steady	*Accelerated*	*Steady*	*Accelerated*
Capital Expenditures ($ millions)	$1,900	$5,600	$390	$1,200
LCFS Credits / GHG Emission Reductions	1.4 million	4.3 million	160,000	490,000
LCFS Credit Value ($ millions)	$35–210	$108–645	$4–24	$12–74

Technology penetration notes:

- Solar Steam: About 492 million barrels of steam were injected at California oilfields for thermal EOR in 2012. ICF assumed that solar steam technology providers could capture 5% of the market for steam generation in a *steady* deployment scenario and 30% in an *accelerated* deployment scenario,[10] in accordance with CARB estimates. Note that ICF held the volume of steam injected constant throughout the analysis (2015-2020), despite the very likely possibility that the amount of steam injected into California oilfields will continue to increase over time. The *steady* and *accelerated* levels of solar steam technology deployment amount to about 16 million MMBtu and 49 million MMBtu of steam, respectively, in 2020.
- Solar Electricity: California oil producers purchased about 3.2 terawatt hours (TWh) of electricity as recently as 2012.[11] ICF made the same assumptions for solar PV as were made for solar steam regarding technology penetration: We assumed that solar PV could capture 5% and 30% of the market for electricity purchased by California oil producers by 2020 in *steady* and *accelerated* deployment scenarios, respectively. ICF estimated the deployment of solar PV that would be required to achieve this level using a capacity factor of 20%. In other words, to capture 30% of the market in 2020, ICF assumed that an installed capacity of about 550 MW would be able to provide 0.96 TWh operating at a 20% capacity factor.[12]

Capital expenditure notes:

- Solar Steam: ICF developed estimates for capital expenditures to achieve this level of deployment using data provided by GlassPoint and previous economic assessment of solar steam by Ernst & Young.[13]
- Solar Electricity: We assumed a starting price of $2.33/W[14] with modest decreases over time.[15]

The economic contribution of solar steam and solar electricity deployment are characterized by employment, labor income, value added, and value output.

- **Employment** is reported in terms of annualized job-years. The employment numbers are broken down by direct, indirect, and induced. We also present an employment metric referred to as a **jobs multiplier**, which is the sum of job-years (included direct, indirect, and induced) divided by the direct job-years. This is an indicator of the type of employment activity statewide that is generated by investment in a technology. We also present **labor income** and **labor income per worker**. The latter is a coarse estimate of the value of jobs created by the corresponding investment.
- **Statewide impacts.** We present several metrics measuring the impacts on California's economy, including Gross State Product (GSP), industry activity, output, and taxes.
    - ***Industry activity*** measures the value of goods and services.
    - The ***output multiplier*** mirrors the ***jobs multiplier*** and represents the total industry activity (including direct, indirect, and induced) divided by the direct industry activity. This is an indicator of the type of industry activity statewide that is generated by investment in a technology.
    - The values for ***taxes*** are based on the sum of taxes calculated by IMPLAN, including those associated with employee compensation, proprietor income, tax on production and imports, households, and corporations.

Exhibit 4 below summarizes the results for the *steady* deployment scenarios, with each technology capturing 5% of its respective market (as measured by volume of steam or electricity consumption). Note that for both solar steam and solar electricity, LCFS credits were modeled at values of $25/ton and $150/ton—the results from both LCFS credit pricing scenarios are shown in the table below.

10 Industry discussions and ISOR, II-19 Available online at: http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15isor.pdf

11 Personal communication with CARB staff who que ied the California Energy Consumption Database by county and NAICS code associated with crude petroleum extraction (211111).

12 There are some limitations to these assumptions, considering that crude oil producers are base loading operations. Further, there are no net metering provisions in the proposed language from CARB, and is effectively prohibited because the electricity cannot be purchased from a utility-owned transmission or distribution network. In reality, to capture 30% of the market for electricity consumption by crude oil producers, solar PV technology would have to be deployed in parallel with complementary technologies like solar trackers and energy storage (e.g., batteries) to level out the energy supply with the base loaded demand. To simplify our analysis and the comparison between solar PV and solar steam as innovative crude production technologies, however, we have not considered the expenditures that would likely be required to achieve this level of electricity consumption using solar PV. Rather, we simply quantified the xpenditures that would be required to deploy a given megawatt target of PV.

Exhibit 4. Modeling Results for Steady Deployment Scenarios, Cumulative 2015-2020

Economic Parameter	Solar Steam		Solar PV Electricity	
	$25/ton	$150/ton	$25/ton	$150/ton
Employment				
Direct	3,300	4,900	1,100	1,300
Indirect	2,300	2,900	800	800
Induced	2,600	4,200	900	1,100
Total	**8,200**	**12,000**	**2,800**	**3,200**
Jobs Multiplier	2.72	2.56	2.61	2.56
Labor Income ($M)	$590	$930	$200	$240
Income per Worker	$72,000	$77,500	$71,400	$75,000
Statewide Activity ($ millions)				
GSP	$860	$1,360	$300	$350
Industry Activity	$2,260	$3,070	$650	$740
Output Multiplier	1.53	1.59	1.73	1.74
Taxes	$89	$158	$27	$35

The values are shown as cumulative over the analysis period (2015-2020).

ICF notes that by reporting these numbers cumulatively, we may be double-counting jobs i.e., a single person could conceivably account for six job-years assuming that s/he is employed in each year as a result of a particular technology's deployment.

Summary of Economic Contributions

Direct: Impacts of capital expenditures to deploy innovative crude production technologies and the employees hired by the industry itself.

Indirect: Impacts that stem from the employment and business revenues motivated by the purchases made by the industry and any of its suppliers.

Induced: Impacts generated by the spending of employees whose wages are sustained by both direct and indirect spending.

Exhibit 5 summarizes the results for the *accelerated* deployment scenarios, with each technology capturing a 30% of its respective market (as measured by volume of steam or electricity consumption).

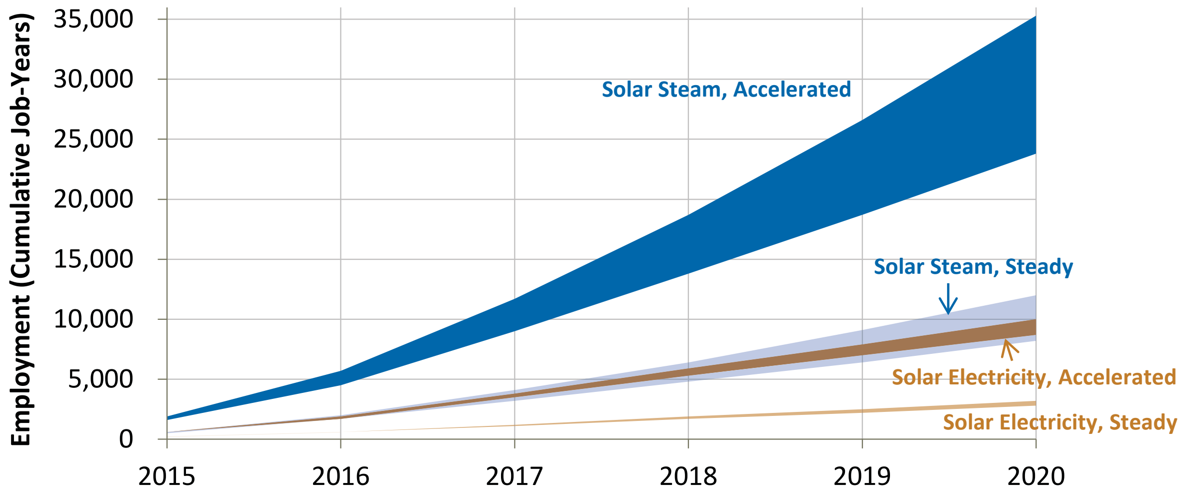
Exhibit 5. Modeling Results for Accelerated Deployment Scenarios, Cumulative 2015-2020

Economic Parameter	Solar Steam		Solar Electricity	
	$25/ton	$150/ton	$25/ton	$150/ton
Employment				
Direct	9,500	14,400	3,300	3,900
Indirect	6,600	8,600	2,300	2,500
Induced	7,700	12,300	2,700	3,200
Total	**23,800**	**35,300**	**8,300**	**9,600**
Jobs Multiplier	2.73	2.56	2.61	2.56
Labor Income ($M)	$1,720	$2,750	$610	$730
Income per Worker	$72,300	$77,900	$73,500	$76,000
Statewide Activity ($ millions)				
GSP	$2,520	$4,030	$890	$1,060
Industry Activity	$6,660	$9,120	$1,950	$2,230
Output Multiplier	1.53	1.59	1.73	1.74
Taxes	$263	$470	$81	$105

The solar steam technology deployment leads to signifi antly higher employment and statewide economic activity, largely as a result of higher capital expenditures associated with capturing the same market share (5% or 30%). The technologies yield similar results in terms of the multipliers for jobs and industry activity / output. In other words, the higher values for solar steam deployment are more of a reflection of the higher overall market opportunity for solar steam rather than something unique about deploying the technology. Solar PV technology has a slightly higher output multiplier, in part because a significant portion (upwards of 55%) of the expenditures associated with solar steam deployment occur outside of California, mainly as imported materials.

Exhibit 6 below shows how the cumulative employment impacts over time for both solar PV and solar steam technologies in the *steady* and *accelerated* scenarios. The range of impacts represents the low and high LCFS credit pricing.

Exhibit 6. Cumulative Employment Impacts in California of Solar Powered Oil Production



The IMPLAN Model

The IMPLAN model is a static input-output framework used to analyze the effects of an economic stimulus on a pre-specifi d economic region; in this study, the State of California. The IMPLAN model tracks economic activity across more than 500 industrial sectors using region-specific ultipliers to trace and calculate the fl w of dollars from the industries that originate the impact to supplier industries. The industrial sectors are based on the North American Industry Classifi ation System (NAICS). The IMPLAN model is one of the most widely used input-output impact models in the United States. For instance, IMPLAN was recently used to estimate the economic contribution of the oil and gas industry in California.

Oil and Gas in California: The Industry and Its Economic Contribution in 2012, LAEDC, April 2014

The IMPLAN model includes more than 500 industry sectors; the table below highlights the sectors that experienced the highest employment impacts. These sectors have been grouped broadly into three categories: oil and gas production industries, solar powered oil production technologies, and indirect and induced sectors. As noted previously, the indirect and induced sectors are those that are impacted by direct investments in the solar powered oil production technologies oil and gas production industries via linkages and increased household incomes. Across both solar steam and solar electricity technology penetration scenarios that were modeled, the construction sector and the drilling oil and gas wells sector captured the highest percentages of employment, accounting for as much as 15-20% of the total employment.

With a larger market penetration, solar steam also has more potential for LCFS credit generation—generating a cumulative 4.4 million and 13.3 million LCFS credits in the *steady* and *accelerated* deployment scenarios compared to just 0.5 million and 1.5 million LCFS credits generated in the *steady* and *accelerated* solar electricity deployment scenarios, respectively.

Exhibit 7. Most Impacted Industry Sectors via Solar Powered Oil Production Technology Deployment

Industry	IMPLAN Sector
Oil and Gas Production Industries	*Drilling oil and gas wells*
	Extraction of natural *gas* and crude petroleum
	Support activities for oil and gas operations
	Wholesale trade
Solar Powered Oil Production Technologies	*Construction of other new nonresidential structures*
	Architectural, engineering, and related services
	Fabricated pipe and pipe fitting manufa turing
	Semiconductor and related device manufacturing
	All other miscellaneous electrical equipment and component manufacturing
Indirect & Induced Sectors	Real estate
	Full-service restaurants
	Limited-service restaurants
	Employment services
	Employment and payroll of state govt, non-education

The higher market potential for solar steam also leads to higher retention of refinery margins attributed to increased refi ery runs and reduced exports of refined products. The retention of these refinery margins manifests itself in the modeling results primarily as increased output and industry activity, and to some extent labor income, rather than employment. Despite not having a significant impact on employment, this is due in part to the nature of the modeling exercise.

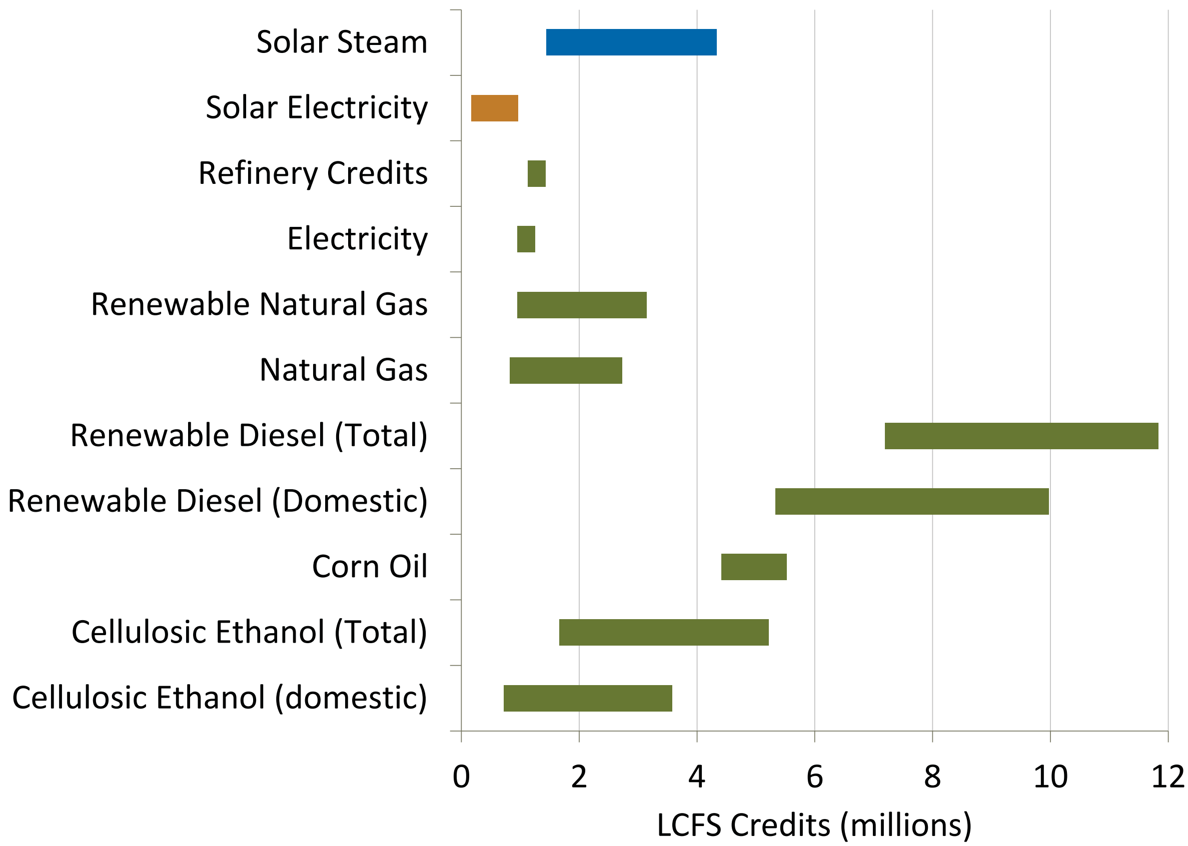
To some extent, the I-O model assumes “full” employment at refineries in the baseline case. In other words, the baseline case—against which the impacts of solar powered oil production technologies are measures—is not assuming that there will be refinery closures as a result of programs like the LCFS or the cap-and-trade program. Furthermore, an increased allocation of expenditures to the refinery sector in the modeling is not going to lead spontaneously to the opening or expansion of an existing refinery in California, thereby generating signifi ant new employment in the sector. Rather, it will lead to enhanced labor income, industry activity, and industry output.

“Solar steam [deployment] leads to higher retention of refinery margins attributed to increased refinery runs and reduced exports of refined products.”

3 Solar Powered Innovative Crude in Context

As part of the re-adoption package, CARB staff eveloped alternative transportation fuel production capacity estimates in various cases (e.g., low, medium, and high).[16] These estimates were used to develop an illustrative LCFS compliance scenario. Exhibit 8 below captures the technical potential for various alternative transportation fuels compared to solar powered oil production technologies in 2020. Note that these values represent the number of LCFS credits that would be generated using the low and high projected estimates published by CARB staff or total fuel volumes available in 2020, not the values assumed for a specific compliance scenario.

Exhibit 8. Total LCFS Credit Potential from Various Compliance Pathways



[16] Available online at http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15appb.pdf

Solar steam has the potential to generate credits comparable with the technical potential of significant pathways that CARB staff se to illustrate compliance, such as domestic cellulosic ethanol. Solar electricity has more limited potential, but is comparable to other contributors to compliance like electricity (used in plug-in electric vehicles) and potential credits generated by energy efficiency improvements at refineries.

While Exhibit 8 focuses on the overall technical potential of various pathways, Exhibit 9 shows the specific deployment potential of solar steam and solar electricity compared to CARB's illustrative compliance scenario for the years 2016-2020.

The potential for innovative crude production technologies is significant: In the *accelerated* deployment scenario, solar steam and solar electricity have the potential to generate 25% and 2%, respectively, of the total cumulative credits required in CARB's illustrative compliance scenario. This puts solar steam on par with pathways such as renewable diesel and renewable natural gas; solar electricity would make a contribution comparable to conventional natural gas. Even in the *steady* deployment scenarios, the LCFS credits generated by solar steam and solar electricity are on par with low carbon fuels like corn oil biodiesel and tallow biodiesel, respectively. Regardless of the deployment scenario, both solar steam and solar electricity have the potential to make material contributions towards LCFS compliance in the 2020 timeframe.

As highlighted in the table above, CARB's illustrative compliance scenario is largely dependent on importing low carbon fuels to California, including corn ethanol (15% of credits), cane-based ethanol (15%), and renewable diesel (22%). To date, nearly all of the renewable natural gas supplied to California for LCFS compliance has been from out-of-state. ICF anticipates that a significant portion of the renewable natural gas will continue to be imported to California from other parts of the United States in the near- to mid-term future (at least through 2018).[17]

Exhibit 9. Estimated LCFS Credit Generation, 2016-2020[18]

Pathway		LCFS Credits (millions) 2016-2020	
Gasoline Substitutes CARB Illustrative Compliance Scenario[17]	Corn Ethanol	9.03	
	Cane Ethanol	7.28	
	Sorghum/Corn Ethanol	1.02	
	Sorghum/Corn/Wheat Slurry Ethanol	0.88	
	Cellulosic Ethanol	1.42	
	Molasses Ethanol	1.49	
	Renewable Gasoline	0.30	
	Hydrogen	0.29	
	Electricity	3.96	
Diesel Substitutes CARB Illustrative Compliance Scenario	Soy Biodiesel	0.43	
	Waste Grease Biodiesel	3.11	
	Corn Oil Biodiesel	5.04	
	Tallow Biodiesel	0.43	
	Canola Biodiesel	0.11	
	Renewable Diesel	13.02	
	Natural Gas	1.39	
	Renewable Natural Gas	7.07	
	Electricity for HDVs and Rail	1.01	
	Refine y Credits	3.16	
	Total	**60.43**	
Solar Powered Oil Production Technologies *Steady* and *Accelerated* Deployment	Solar Steam	4.42	13.28
	Solar Electricity	0.50	1.50

Many of these compliance options are likely to command a significant premium in the market, especially liquid biofuels, thereby pushing credit prices up. California's regulated entities, absent other options, are largely price takers in the low carbon fuel market. In principle, LCFS credit prices will be determined by the marginal abatement cost (assuming a liquid market, and other indicators of a robust market). ICF estimates that the marginal abatement cost associated with the fuel pathways in CARB's illustrative scenario is greater than the abatement cost of the innovative crude production technologies considered here—solar steam and solar PV.

[17] CARB staff estim tes about 50 million diesel gallon equivalents (dge) of RNG consumption in 2014, and used 240 million dge of RNG in 2020 for the illustrative compliance scenario.

[18] Note that these values are calculated by ICF based on our assessment of information presented by CARB, available online at http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15appb.pdf

In other words, ICF believes that in either the *steady* or *accelerated* technology deployment scenarios, innovative crude production technologies have the potential to:

- reduce the marginal abatement cost in the LCFS program in 2020,
- decrease credit prices, and
- reduce California regulated parties' status as a price taker.

ICF estimates that in the *accelerated* deployment case for solar steam, for instance, the credits generated may reduce credit prices by as much as $20-$25/ton in 2020.[19]

Credits from innovative crude production offer a potential hedge against uncertainty in the federal Renewable Fuel Standard (RFS2) market. The RFS2 market has experienced significant volatility. The US Environmental Protection Agency (EPA) sets targets (renewable volume obligations, or RVOs) for the blending of renewable fuels on an annual basis. In November 2014, the EPA announced that they would postpone setting the 2014 RVO targets until 2015, extending a period of regulatory uncertainty in the marketplace. The RFS2 market has also experienced other volatility, such as the availability of federal tax credits. The role of biodiesel, for instance, in the market fluctuates significantly without certainty regarding the availability of a $1.00 per gallon blender's tax credit. This credit has expired and been re-instated retroactively several times in the last five years, creating a difficult investment atmosphere for producers and regulated parties. The uncertainty in the RFS2 market has led to and may continue to lead to volatility of Renewable Identification Numbers (RINs) pricing, the currency of the RFS2 market. For instance, if the RFS2 market is scaled back significantly (via reduced RVOs), it may decrease the price of RINs, and liquid biofuel providers may look to the LCFS program to pick up some of the slack in market pricing. This could lead to an increase in LCFS credit prices.

The credit streams arising from solar powered oil production may provide regulated parties in the LCFS market a buffer against such price volatility. This is dependent, however, on timely deployment of innovative crude production technologies as a compliance diversifi ation strategy.

ICF believes that innovative crude production technologies may provide regulated parties an opportunity to limit their exposure to the LCFS credit market via an integrated investment-based approach. Today, for instance, the majority of LCFS credits are purchased at the point of blending ethanol into gasoline and blending biodiesel or renewable diesel into conventional diesel. In some cases, the LCFS credit value paid is transparent. By and large, however, the LCFS credit market lacks liquidity and transparency in part because some transactions bundle the LCFS credit price paid with fuel price, or refl ct longer-term arrangements. Some market participants have various investments in both refining and low carbon fuels and transfer credits internally. CARB reports, for instance, that one-in-five LCFS credit transactions have $0 credits being transacted.[20] ICF regards this activity as an ordinary part of market participants seeking competitive advantage, and a means to limit their exposure to a potentially volatile LCFS credit market.

The innovative crude provisions of the LCFS allow regulated parties to co-invest in or otherwise source credits from production facilities that reduce the carbon intensity of crude oil, which will durably reduce emissions from upstream crude oil production. These investments will reduce forward uncertainty for all market participants and create economic growth in California, shifting a portion of investment in low-carbon energy facilities from out-of-state to in-state.

"Solar steam has the potential to generate credits comparable with the technical potential of significant pathways that CARB staff use to illustrate compliance, such as domestic cellulosic ethanol."

[19] Note that the economic contributions of such price reductions were not considered under this study's methodology.

Appendix

LCFS Credit Calculations

Solar Steam

The LCFS credits that could be generated for solar steam were calculated using the methodology outlined by CARB in the proposed language:

$$Credits_{innov\_SolarSteam} = 29{,}360 \times V_{steam} \times f_{solar} \times V_{crude\_produced} \times V_{innov\_crude} \times C$$

where $Credits_{innov\_SolarSteam}$ is the amount of LCFS credits generated in metric tons by the volume of crude oil produced and delivered to California refineries for processing; V_{steam} is the volume in barrels of cold water equivalent of steam injected, f_{solar} is the fraction of steam injected that was produced using solar energy; $V_{crude\_produced}$ is the volume (in barrels) of crude oil produced using the innovative method; V_{innov_crude} is the volume (in barrels) of crude oil produced using the innovative method and delivered to California refineries for processing; and C is the constant to convert from metric tons to grams (where 1 MT=106 gCO_2e). The constant at the outset of the equation, 29,360, is the emissions factor associated with the natural gas that would have otherwise been consumed in once through steam generators (OTSGs).21

Solar PV

The LCFS credits that could be generated by solar PV deployment were calculated using the methodology outlined by CARB in the draft language:

$$Credits_{innov\_SolarSteam} = 511 \times \frac{E_{electricity} \times f_{renew}}{V_{crude\_produced}} \times V_{innov\_crude} \times C$$

where $Credits_{innov\_SolarSteam}$ is the amount of LCFS credits generated in metric tons by the solar PV used to produce crude oil and delivered to California refineries for processing; $E_{electricity}$ is the electricity consumption to produce the crude (in units of kWh), and f_{renew} is the fraction of renewable electricity that was produced using solar or wind energy.

Model Description

In this analysis, the economic impacts were calculated using the IMPLAN[22] (IMpact analysis for PLANning), Version 3.0 input-output model. IMPLAN is developed and maintained by the Minnesota IMPLAN Group (MIG). The IMPLAN model is a static input-output framework used to analyze the effects of an economic stimulus on a pre-specified economic region; in this case, the State of California. IMPLAN is considered static because the impacts calculated by any scenario by the model estimate the indirect and induced impacts for one time period (typically on an annual basis).

The modeling framework in IMPLAN consists of two components—the descriptive model and the predictive model.

- The **descriptive model** defines the local economy in the specifi d modeling region, and includes accounting tables that trace the "flow of dollars from purchasers to producers within the region".[23] It also includes the trade flows that describe the movement of goods and services, both within, and outside of the modeling region (i.e., regional exports and imports with the outside world). In addition, it includes the Social Accounting Matrices (SAM) that trace the flow of money between institutions, such as transfer payments from governments to businesses and households, and taxes paid by households and businesses to governments.

---

21 ICF notes that the emissions factor for natural gas is derived from a draft version of the CA-GREET model and is subject to modific tion upon further CARB review.

22 IMPLAN was developed by the Minnesota IMPLAN Group (MIG). There are over 1,500 active users of MIG databases and software in the United State as well as internationally. They have clients in federal and state government, universities, as well as private sector consultants. More information is available at http://www.implan.com.

23 IMPLAN Pro Version 2.0 User Guide.

- The **predictive model** consists of a set of "local-level multipliers" that can then be used to analyze the changes in final demand and their ripple effects throughout the local economy. IMPLAN Version 3.0 uses 2008 data and improves on previous versions of model by implementing a new method for estimating regional imports and exports - a trade model. This new method of estimating imports looks at annual trade fl w information between economic regions; thereby allowing more sophisticated estimation of imports and exports than the traditional econometric RPC estimate used by the previous, Version 2. Additionally, this new modeling method allows for multi-regional modeling functions, in which IMPLAN tracks imports and exports between selected models allowing the users to assess how the impact in one region can impact additional regional economies.

The IMPLAN model is based on the input-output data from the U.S. National Income and Product Accounts (NIPA) from the Bureau of Economic Analysis. The model includes 440 sectors based on the North American Industry Classification System (NAICS). The model uses region-specific multipliers to trace and calculate the flow of dollars from the industries that originate the impact to supplier industries. These multipliers are thus coefficients that "describe the response of the economy to a stimulus (a change in demand or production)."[24] Three types of multipliers are used in IMPLAN:

- Direct—represents the impacts (e.g., employment or output changes) due to the investments that result in final demand changes, such as investments needed for cleanup and/or redevelopment efforts.
- Indirect—represents the impacts due to the industry inter-linkages caused by the iteration of industries purchasing from industries, brought about by the changes in final demands.

Induced—represents the impacts on all local industries due to consumers' consumption expenditures arising from the new household incomes that are generated by the direct and indirect effects of the final demand changes.

[24] Ibid.

The total impact is simply the sum of the multiple rounds of secondary indirect and induced impacts that remain in California (as opposed to "leaking out" to other areas). IMPLAN then uses this total impact to calculate subsequent impacts such as total jobs created and tax impacts. This methodology, and the software used, is consistent with similar studies conducted across the nation.

Inputs and Model Parameters

The direct economic impacts presented in the report are based on: a) investments required to deploy solar steam and solar PV technologies at oilfields in California, b) the value of LCFS credits being generated in-state, rather than exported to low carbon fuel producers outside of California, and c) the value of increased refinery runs and decreased exports that would have otherwise occurred as a result of LCFS compliance. ICF modeled the impacts of the investments for each individual year of the time period (2015-2020).

Output

Whenever new industry activity or income is injected into an economy, it starts a ripple effect that creates a total economic impact that is much larger than the initial input. This is because the recipients of the new income spend some percentage of it and the recipients of that share, in turn, spend some of it, and so on. The total spending impact of the new activity/income is the sum of these progressively smaller rounds of spending within the economy. This total economic impact creates a certain level of value added (GSP), jobs, called the total employment impact, and also tax revenue for state and local governments.

Due to the static nature of the IMPLAN model, the employment impacts must be presented in terms of annual job-years as the model calculates the annual impact of an annual investment. It is likely that once the job is created, it will be sustained, however to ensure that the impact is not overstated; it is conservatively assumed that the job impact is annual. The annualized GSP and tax impacts can be accrued over the program's duration to identify the total impact of the EB-5 program. These dollar values represent the investments that were placed into the economy each year aggregated over time.

Detailed Modeling Results

As noted previously, ICF used the IMPLAN model to calculate the economic impacts of solar powered oil production in California. The data provided in the body of this report have been aggregated into cumulative numbers. The tables below include selected outputs from IMPLAN—employment (in job-years), labor income, industry activity, and GSP—on an annual basis.

28_OP_LCFS_GPS Responses

113. Comment: **LCFS 28-1**

The comment expresses appreciation and support for ARB staffs' efforts to readopt the LCFS to create a workable regulatory framework.

Agency Response: ARB staff appreciates the support of the re-adoption of the LCFS regulation.

114. Comment: **LCFS 28-2**

The comment expresses strong support for the Innovative Crude provisions in the LCFS regulation.

Agency Response: ARB staff appreciates the support of the innovative crude oil provision.

115. Comment: **LCFS 28-3**

The commenter expresses concern about regulatory timing.

Agency Response: ARB staff appreciates the commenter's observation regarding regulatory timing and federal solar tax incentives that will expire at the end of 2016. Upon adoption of the regulation during 2015, ARB expects the regulation will be in place at the beginning of 2016.

Comments to the California Air Resources Board by the Clean Air Task Force

CLEANAIR TASK FORCE

On the Proposed Re-Adoption of the Low Carbon Fuel Standard

February 17, 2015

SUMMARY

The Clean Air Task Force (CATF) appreciates this opportunity to comment to the California Air Resources Board on the Low Carbon Fuel Standard (LCFS). CATF is a nonprofit organization that works to help safeguard against the worst impacts of climate change by catalyzing the rapid global development and deployment of low carbon energy and other climate-protecting technologies through research and analysis, public advocacy leadership, and partnership with the private sector.

Our comments focus on the following points:

- ARB should readopt the LCFS through 2020. Achieving compliance with the 2020 target will be difficult, but the LCFS remains the most promising policy tool available for reducing the climate impacts of the transportation sector. LCFS 29-1
- The LCFS's promise is undermined by the proposed adjustment to the lifecycle emissions for corn ethanol, and by the likelihood that regulated entities will increase their reliance on corn ethanol to meet LCFS targets. LCFS 29-2
- The proposed adjustment to corn ethanol's lifecycle emissions score rewards corn for its negative impact on global food security. ARB must acknowledge and address this issue before it erodes the legitimacy of the LCFS program. LCFS 29-3
- The prospects for deep reductions in transportation sector GHG emissions are likely to improve significantly after 2020, particularly if liquid ammonia's potential as an affordable low-carbon fuel is proven out. LCFS 29-4

READOPTION OF THE LCFS

Consistent with an order issued by the California Court of Appeals in *POET, LLC v. California Air Resources Board*, 218 Cal.App.4th 681 (2013), ARB staff has reviewed and revised the LCFS, and is now

> proposing that the Board re-adopt the LCFS, replacing the current LCFS regulation in its entirety. The proposed LCFS regulation will maintain the basic framework of the current LCFS regulation, including: declining carbon intensity targets; use of life cycle analyses; inclusion of indirect land use change effects;

quarterly and annual reporting requirements; and credit generation and trading.[1]

CATF urges the Board to readopt the LCFS. California's LCFS is the country's most promising public policy for bringing low-C fuels into the transportation market. It has several key attributes, all of which positively differentiate it from the federal Renewable Fuel Standard (RFS):

- Dynamic requirements: Increasingly stringent annual reduction requirements dissuade regulated entities from investing in marginally effective compliance strategies.
- Dynamic analyses: There are important ongoing debates about the performance of lifecycle GHG analyses—both with respect to specific technologies and their overall effectiveness. Regular reanalysis of compliance strategies prevents "lock-in" of outdated analyses and ineffectual technologies.
- No grandfathering: Under the LCFS, compliance options are measured according to their performance. Under the RFS, corn ethanol—which is largely exempt from the program's GHG reduction requirements—accounted for 83% of the overall volume mandate finalized by the Environmental Protection Agency (EPA) in 2013, the most recent year in which final renewable volume obligations were issued by EPA.
- Not limited to biofuels: Climate change mitigation depends on strategies that are scalable. That poses a problem for biofuels: the climate benefits of conventional biofuels typically diminish as production scales up, and advanced biofuels tend to be difficult (or impossible) to produce at a large scale.
- Clear focus on GHG reductions: The LCFS cannot blind itself to critically important non-climate impacts, especially the effect that increased consumption of biofuels can have on food prices and global food security. With appropriate safeguards in place, however, ARB can pursue the program's singular goal of GHG reductions without having to accommodate related-but-different objectives like price support for the agricultural sector or energy security.

LCFS 29-2 cont.

A strong, stringent, flexible, intellectually honest LCFS creates a forum in which to consider new, truly low-carbon fuels, and a key market in which to commercialize them. It needs to succeed. However, that success must be achieved in terms of real GHG reductions, not merely on paper. CATF is concerned that a short-term reliance on conventional biofuels—especially corn ethanol—could pull the LCFS in the wrong direction, and imperil its prospects for long term success.

LCFS 29-1 cont.

NET GHG EMISSIONS FROM CORN ETHANOL

When assessing a biofuel's net GHG emissions in the context of a given policy, an important—and complicated—component is the carbon release associated with land use changes. Of particular concern is indirect land use change (ILUC), or the amount of land use change that occurs as agricultural markets accommodate new policy-driven demand for biofuel feedstocks, and the amount of soil and plant-carbon that is released into the atmosphere as a consequence of those changes.

[1] California ARB, *Staff Report-Initial Statement of Reasons* (December 30, 2014) at ES-3.

As supply margins for corn and other crops tighten in the face of competition from policy-driven demand for biofuels, the price of foodstuffs increases. The increase in food prices encourages farmers around the world to cultivate previously unfarmed land—a process that results in substantial losses of soil- and plant-carbon to the atmosphere. Accordingly, a biofuel must "pay back" this "carbon debt" (via CO_2 sequestration by subsequent energy crop growth) before it can be credited with any net climate benefits as compared to petroleum-based fuels (which have comparatively insignificant land use-related carbon impacts).

ARB staff have proposed that the ILUC score for corn ethanol should be reduced from the current score of 30 gCO_2/MJ. Adopting the proposed reduction would be wrong, both as a matter of emissions accounting and as a matter of climate mitigation policy. The proposed reduction would make corn ethanol a more viable LCFS compliance strategy. Heavier reliance on corn ethanol would limit the near- and long-term GHG reductions that can be achieved by the LCFS and would undermine the program's innovation-forcing objective—despite corn ethanol's status as an outmoded technology, the significant uncertainty about whether corn delivers any climate benefits, and the concerns about the non-climate environmental damage associated with its production. LCFS 29-3 cont.

Reducing the ILUC score for corn would be wrong from an emissions accounting perspective because it ignores a host of relevant factors that ARB has not yet been able to effectively quantify in CA GTAP-BIO, but which it knows will raise the ILUC score if/when the factors are correctly incorporated into the model. These factors have been identified by ARB staff[2] and in comments submitted by CATF and other stakeholders.[3] They include:

- The effect of water scarcity constraints on projected crop expansion. Researchers from Purdue University who used GTAP to examine the likely role of water scarcity on crop expansion found that earlier ILUC analyses "likely underestimated induced land use emissions due to ethanol production by more than one quarter."[4] As discussed below, ARB has not yet succeeded in sensitizing CA GTAP-BIO to water constraints, so the effect that such constraints have on LUC patterns and resulting emissions are not fully accounted for. LCFS 29-5
- GTAP's inability to differentiate commercial forest from non-commercial forests, which means that the model wrongly assumes that markets respond to the conversion of both land types in the same way. LCFS 29-6
- The yield improvement assumptions in GTAP overlook important differences among crops and growing regions, they fail to incorporate new research on future corn yields in the Midwest United States, and they do not adequately address the climate impact associated with the increased use of nitrogen-based fertilizers to sustain yield growth. LCFS 29-7

3 CATF, Comments on ARB Proposed ILUC Analysis (May 2014) (http://www.catf.us/resources/filings/biofuels/20140519-CATF%20Comments%20on%20ARB%20Proposed%20ILUC%20Analysis.pdf)
4 Farzad Taheripour, Thomas W. Hertel and Jing Liu. 2013. The Role of Irrigation in Determining the Global Land Use Impacts of Biofuels. ENERGY, SUSTAINABILITY AND SOCIETY.

These issues are described more fully in the appended comments that CATF submitted to ARB in May 2014.

Even if the fundamental concerns described above are put aside for a moment, the proposed ILUC reduction for corn ethanol is problematic because the materials prepared by ARB staff appear to consider two different reduced scores. The first—19.8 gCO_2/MJ—is the unweighted average of the thirty different production scenarios run on CA GTAP-BIO.[5] ARB's potential reliance on this value implies that it believes all thirty scenarios are equally plausible—a position that ARB has not, and cannot, justify. The second score—21.8 gCO_2/MJ—was derived by performing a Monte Carlo simulation (MCS). ARB's Expert Working Group has urged the use of MCS because of its "ability to represent arbitrary input and output distributions, … perform global sensitivity analysis (e.g., contribution to variance) to identify which input parameters contribute most to the variance in the output, and … represent parameter correlations."[6] As between the two scores, the value that was derived from the Monte Carlo simulation—*i.e.*, 21.8 gCO_2/MJ—is superior. LCFS 29-8

A recent paper by Bruce Babcock and Zabid Iqbal of Iowa State University asserts that ILUC models utilized by ARB and EPA have overestimated land use changes by "attribut[ing] all supply response[s] not captured by increased crop yields to land use conversion on the extensive margin."[7] The paper argues for the use of lower ILUC scores by attempting to prove that "the primary land use change response of the world's farmers from 2004 to 2012 has been to use available land resources more efficiently rather than to expand the amount of land brought into production."[8] The paper has several shortcomings, however:

- Babcock and Iqbal only consider intensification techniques such as double cropping rather than analyzing yield increases over this time period.
- The paper dismisses data on extensive land use changes in Africa on the grounds that the linkage between global food prices and those in rural Africa is weak (implying that biofuel policies in the US and EU have little effect on African food prices and land use change)—even though the authors note a correlation between global food prices and food prices in urban Africa.
- The paper makes overly generous assumptions about the extensiveness of double cropping. As Jeremy Martin of the Union of Concerned Scientists wrote in recent comments to ARB, double cropping is not widely used in Southeast Asia where palm oil plantations have moved into formerly uncultivated areas. Nor is double cropping widely adopted in parts of the Midwest where most U.S. biofuels feedstocks—primarily corn and soybeans—are grown. The Babcock and Iqbal paper also fails to account for increased GHG emissions from increased fertilizer usage where it does assume the use of additional double cropping in response to higher crop prices.

8 *Id*.

- Finally, the authors assume the "only net contributor to US cropland from 2007 to 2010 was a reduction in [Conservation Reserve Program (CRP)] land," but this too is an inappropriate assumption, because several studies (from South Dakota State University and even U.S. Department of Agriculture Economic Research Service, Farm Service Agency, and Natural Resources Conservation Service data) show that cropland conversions exceeded acres exiting CRP, with huge impacts on GHG emissions.[9]

Reducing the ILUC score for corn ethanol would also be a mistake in terms of climate mitigation policy. The use of highly complex models like CA GTAP-BIO to determine the net emissions associated with biofuels produces values that have the veneer of objective validity. But the modeling outputs are enormously dependent on the data that are fed into the system and on the system's assumptions about how those data affect physical and economic processes.

LCFS 29-9

A recently published paper examines the extent to which subjective decisions about incorporating different assumptions and data into a lifecycle model can affect the outcome.[10] Plevin *et al*. used a Monte Carlo simulation to characterize the parametric uncertainty associated with the two components of the lifecycle analysis that California used to evaluate biofuels: "an economic modeling component that propagates market-mediated changes in commodity production and land use induced by increased demand for biofuel globally, and a carbon accounting component that calculates the GHG emissions associated with (some) of these induced changes."[11]

The authors found that three parameters have particularly strong influences on the uncertainty importance for ILUC emissions intensity:

- Elasticity of crop yield with respect to price (YDEL) (in the economic model);
- Relative productivity of newly converted cropland (in the economic model); and
- Ratio of emissions from cropland-pasture to cropland, as compared to the ratio from converting standard pasture (in the emissions factor model).[12]

Among these factors, "[b]y far, the greatest contributor to variance in the estimate of ILUC LCFS 29-10

[12] *Id*.

emissions was YDEL, the elasticity of crop yield to price;" in fact, in ILUC analyses for corn ethanol, YDEL accounts for "nearly 50%"of the variance among possible modeling results.[13] ARB currently uses a YDEL value of 0.25 in GTAP-BIO—a subjective decision that is increasingly difficult to justify in light of separate analyses conducted for ARB by Steven Berry and David Locke. Berry reviewed a collection of studies on yield price elasticity (YPE) and, according to an ARB staff report, "concluded that YPE was mostly zero and the largest value that could be used was 0.1."[14] Locke ran a statistical analysis of a similar set of studies and found "that based on methodologically sound analyses, yield price elasticities are generally small to zero."[15] ARB has nonetheless chosen to include YPE values up 0.35 in its ILUC analyses.[16] [[Id. at Attachment 1-6]]

Developing the relevant data and determining which datasets to use (and which to exclude) are highly subjective exercises, as are the processes of choosing and programming the relational assumptions that drive the model. Viewed in this context, the proposal to reduce the corn ethanol ILUC score can be more appropriately understood as the product of a subjective process—one that reflects the current availability of certain data and analyses that would contribute to a lower ILUC score, but fails to account for a host of countervailing factors that ARB does not yet understand how to model.

LCFS 29-10 cont.

The Board should recognize these limitations, as well as the necessary role that it and ARB staff play in interpreting and acting upon modeling results. The Board should exercise its best judgment in light of the overarching policy objective of the LCFS, which CATF understands to be a meaningful reduction in GHG emissions from the transportation sector. Because corn ethanol's lifecycle GHG emissions are—at best—only slightly lower than those from gasoline, and because increased reliance on corn ethanol would frustrate the development of more innovative and effective compliance options, the proposal to reduce the ILUC score for corn ethanol undermines the objectives of the LCFS. Accordingly, CATF urges the Board to table the proposal.

CORN ETHANOL'S IMPACT ON FOOD SECURITY

Another critically important way in which ILUC estimates are the product of subjective decisions (and not just objective calculations) relates to the treatment of food price increases associated with policy-induced demand for biofuels. As Plevin *et al*. (2015) write, "ILUC emission estimates depend on various modeling choices, such as whether a reduction of food consumption resulting from biofuel expansion is treated as a climate benefit."[17] ARB currently chooses to count GHG reductions that result from reduced food consumption when analyzing the lifecycle emissions of biofuels, but that—again—is a subjective decision. (Moreover, doing

LCFS 29-11

[16] *Id*. at Attachment 1-6.
[17] Plevin *et al*. (2015), *supra*.

so implies that ARB assumes that national governments would not subsidize food consumption in the face of rising food prices.)

If instead ARB chose to assume that society would limit the extent to which food consumption would decline (especially taking into consideration a growing world population demanding significantly more calories and protein), its ILUC analysis would produce different results. For example, Thomas Hertel *et al.* (2010) found that if food consumption were held constant in GTAP, the estimated emissions from biofuel expansion would increase by 41%.[18]

LCFS 29-11 cont.

As with the other factors discussed above, the problematic and highly subjective treatment of reduced food consumption reinforces the point that ARB is not obligated to reduce the ILUC score for corn ethanol on the basis of the most recent—but highly incomplete—modeling results.

More generally, CATF urges ARB to reconsider how it accounts for reduced food consumption within the LCFS context, before the issues erodes the legitimacy of the LCFS program.

EMISSION REDUCTION OPPORTUNITIES POST-2020

ARB is appropriately interested in using the LCFS to achieve deep, long-term reductions.

> Although post-2020 goals for the LCFS are not part of this proposed rulemaking, continuing these policies beyond 2020 will ensure that fuel carbon intensity continues to decline and that low-carbon alternatives to petroleum are available in sufficient quantities in the long term. Achieving California's mid and long-term greenhouse gas and air quality goals will require a renewable portfolio of transportation fuels—including electricity and hydrogen—well beyond the current policy trajectories. Accordingly, ARB, in a future rulemaking, will consider extending the LCFS with more aggressive targets for 2030.[19]

LCFS 29-12

An unwarranted reduction to the corn ethanol ILUC score would do more than undermine the actual climate benefits that the LCFS can achieve through 2020; it would lower the ceiling on the long-term effectiveness of the program by extending the period in which marginally beneficial technologies can compete with the far better options that will be available to California after 2020. Chief among these better options may be ammonia, a hydrogen-based energy carrier that CATF has previously discussed with ARB management and staff.

The potential benefits associated with ammonia fuel ammonia are enormous, both for the environment and for the prospects of the LCFS:

LCFS 29-4 cont.

[18] TW Hertel, *et al.* 2010. *Effects of US Maize Ethanol on Global Land Use and Greenhouse Gas Emissions: Estimating Market-Mediated Responses*. BIOSCIENCE. 60:223-231(doi: 10.1525/bio.2010.60.3.8).
[19] California ARB, *Staff Report-Initial Statement of Reasons* (December 30, 2014) at ES-1.

- Zero-carbon ammonia can be produced using air, water, and electricity generated by renewable or nuclear power plants, or by fossil fuel-based generating stations equipped with carbon capture and storage systems.
- A wide range of engines and fuel cells can use ammonia to generate electricity or to power vehicles, and can do so without emitting CO_2.
- Substantial global ammonia production and transport infrastructure is already in place. At 150 million metric tons per year, it is the third largest chemical produced globally.
- At $3.27 per gallon (on an energy equivalent basis to gasoline, at current prices) and $1.78 per gallon (when compared against gasoline's 10-year average price), ammonia is affordable. And as a liquid, it can be more easily transported and stored than hydrogen and natural gas.

The steps that need to be taken before a widespread transition to ammonia fuel can occur are significant—but not insurmountable. These include:

- Building awareness among industry, regulators, and other stakeholders about the economic and environmental advantages of using ammonia fuel for power generation and transportation (especially, at the outset, rail and long-haul truck fleets).
- Helping innovators and investors identify small volume/high profit projects to jumpstart the ammonia energy industry.
- Highlighting opportunities to shift ammonia production to zero-carbon processes (*e.g.*, using stranded or otherwise underutilized wind power assets for ammonia synthesis).
- Detailing ammonia's toxicity risk (which is similar to that of LPG), describing how that risk is managed by farmers globally, and outlining protocols for how it can be managed in the power and transportation sectors.
- Developing a long-term roadmap for building up ammonia production and distribution capacity to the scale of a global energy commodity.

LCFS 29-4 cont.

Since CATF briefed ARB on ammonia in July 2014, research in Texas (on ammonia-gasoline blending in internal combustion engines), Toronto (on the use of ammonia to fuel locomotives), and California have continued to validate the concept and develop demonstration projects.

The California project—which involves the University of California at Los Angeles (UCLA), California Energy Commission, and South Coast Air Quality Management District (SCAQMD)—is among the most interesting efforts to date. UCLA is spearheading a comprehensive program to utilize advanced engines from Sturman Industries for a multifuel (gas and ammonia), low NO_x combined-heat-and-power system. The system will be designed, installed, and optimized at a metals foundry in Los Angeles called California Metal-X (CMX). The project goal is to provide power at $0.097/kwh compared to a current base load cost of $0.18/kwh and peak power costs ranging from $0.20-$0.50/kwh from the grid. These cost savings come along with the potential to prove out an ammonia-based, scalable power source that meets the stringent air quality requirements implemented by SCAQMD.

The system will be designed to run in a wide range of modes including pure ammonia as a peak fuel and a variety of combined heat/power modes depending on power pricing, air quality standards, process efficiency, and power export profitability. UCLA, Sturman Industries, and other project partners will instrument the system to test and optimize ammonia engines, emissions, costs, maintenance, safety and other aspects of these types of operations in the real world. This project is being designed to provide a robust prototype for low cost, clean electricity across the California economy. If successful, the project will provide a technology and engineering basis for installing ammonia power in various markets around the world.

LCFS 29-4 cont.

CONCLUSION

CATF urges ARB to readopt the LCFS through 2020. Although significant challenges remain, the LCFS is the most promising policy tool available for reducing the climate impacts of the transportation sector.

However, that promise is undermined by the proposed adjustment to the lifecycle emissions for corn ethanol, and by the likelihood that regulated entities will increase their reliance on corn ethanol to meet LCFS targets. The proposed adjustment to corn ethanol's lifecycle emissions score rewards corn for its negative impact on global food security. ARB must acknowledge and address this issue before it erodes the legitimacy of the LCFS program.

LCFS 29-3 cont.

An unwarranted reduction to the corn ethanol ILUC score would also lower the ceiling on the long-term effectiveness of the program by extending the period in which marginally beneficial technologies can compete with the far better options that will be available to California after 2020. The prospects for deep reductions in transportation sector GHG emissions are likely to improve significantly after 2020, particularly if liquid ammonia's potential as an affordable low-carbon fuel is proven out.

29_OP_LCFS_CATF Responses

116. Comment: **LCFS 29-3, LCFS 29-5 through LCFS 29-7, and LCFS 29-11**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

117. Comment: **LCFS 29-1**

The comment expresses support for re-adoption of the LCFS.

Agency Response: ARB staff appreciates the support for the compliance targets.

118. Comment: **LCFS 29-2**

The comment suggests that the benefits of the LCFS regulation are undermined by the adjustment to the lifecycle emission of corn ethanol.

Agency Response: The use of ethanol as part of the compliance strategy does not undermine the LCFS targets. The ARB staff-proposed carbon intensity (CI) targets and standards for biofuels are designed to be fuel neutral. In other words, all biofuels including corn ethanol, sugarcane ethanol, sorghum ethanol, soy oil biodiesel, canola biodiesel, and palm oil biodiesel have the opportunity to contribute to LCFS and their CI is estimated using the same methodology. In addition to corn ethanol, other biofuels that have made improvements have also received lower CI values than previously estimated. The goal of the LCFS regulation is to evaluate fuels based on their CI scores. As the standard gets stricter, the reliance on lower CI fuels will increase and reliance on higher CI fuels will be limited. The proposed structure of the LCFS regulation is flexible to allow all biofuels to participate, it encourages innovation and recognizes improvements, and by progressively requiring stringent standards provides incentives for low CI fuels to be developed for and used in the California transportation sector.

119. Comment: **LCFS 29-4**

The comment states that prospects for deep reductions in transportation sector GHG emissions are likely to improve significantly after 2020.

Agency Response: ARB staff agrees that further reductions are feasible beyond 2020, and the Board directed the staff to determine what additional reductions can be obtained in the 2020 to 2030 timeframe and to return to the Board with a proposal to further strengthen the LCFS for that time period.

120. Comment: **LCFS 29-8**

The comment states that the proposed iLUC reduction for corn ethanol is problematic.

Agency Response: ARB disagrees with the criticism; we used the unweighted mean in the absence of sufficient information that would have allowed a weighted mean. No evidence clearly suggested that any value deserved more or less weight. Our approach was consistent with the 2009 approach. It should be noted that the mean estimated from the uncertainty analysis is similar to the average calculated from the scenario runs for all of the six biofuels.

121. Comment: **LCFS 29-9**

The comment questions the reduction of the ILUC score for corn ethanol. The comment goes on to add that the assumptions put into the model can have enormous effects on the modeling outputs.

Agency Response: See Response to **LCFS 29-2**.

ARB staff understands that Yield Price Elasticity (YPE)[2], relative productivity of newly converted cropland, and ratio of emissions for land conversion are important elements and have strong influence in the modeling outcome. All of these parameters have been fully accounted for in ARB's modeling approach. Furthermore, ARB staff agrees on the importance of YPE. However, data for YPE are not conclusive to allow assigning a single value for YPE. Since different studies give a range of possible values for YPE, staff used multiple values within this range and created an average of the results. Staff believes that this approach captures the variability in values of YPE from different studies. See also response to **LCFS 8-9**.

[2] YPE is sometimes used interchangeably with YDEL.

122. Comment: **LCFS 29-10**

The comment states that the greatest contributor to variance in the estimate of iLUC emissions was the YDEL.

Agency Response: See Response to **LCFS 8-9**.

123. Comment: **LCFS 29-12**

The comment argues that the reduction to the corn ethanol iLUC score would extend the period in which marginally beneficial technologies can compete with long-term options, including ammonia fuels.

Agency Response: ARB staff disagrees because we believe the revisions to the corn ethanol iLUC value are technically warranted and substantiated. Additionally, the LCFS imposes no barriers to the establishment of fuel pathways for ammonia fuels. Fuel specifications and multimedia analyses must be prepared for all new fuels, but these can be pursued independently from the LCFS fuel pathways.

Producers of ammonia fuel can apply any time for an LCFS pathway. As with any other pathway, the certified carbon intensity (CI) of an ammonia pathway will be based on the results of an ARB staff evaluation of the application submitted.

Subject: CI Calculations re Fuel Ethanol
Comment:
As with the sorghum issue, Calgren Renewable Fuels applauds the ARB for its handling of the re-authorization of the LCFS. Perhaps the re-authorization was prompted by the lawsuit brought by others in the ethanol industry. If so, we applaud the ARB for its measured and appropriate response. While Calgren did not and does not support the lawsuit, it does support the ARB's attempts to strengthen the LCFS. LCFS 30-1

To be stronger, the LCFS must be based upon good science. Calculation of life-cycle carbon intensities is inherently complicated and a few anomalies are to be expected. We believe our consultant has discovered one such anomaly regarding the CI impact of denaturant. Please review his comments as reflected in the attached summary. Correcting what appear to be inconsistencies and errors regarding the CI impact of denaturant on fuel ethanol will help strengthen the LCFS. LCFS 30-2

On a somewhat related subject, we applaud the ARB for correcting the erroneous 1:1 distillers grain-to-corn displacement ratio that appears in GREET 1.8. But we firmly believe and have previously submitted data showing that the displacement ratio varies somewhat depending upon whether distillers grain is fed to hogs, poultry, feedlot cattle or dairy cows. We urge the ARB to take note of relevant research in this area and apply it where applicable. LCFS 30-3

Thank you for the opportunity to comment.

Board Comments Home

Denaturant Composition and Denatured ethanol Content Changes

Instead of the assumption of 2.5% volume denaturant used by ARB to determine the energy density of ethanol (81.51 MJ/gal), ARB has effectively increased it to 5.4% by assuming the minimum ethanol content, under the ASTM denatured ethanol standard, of 94.6% ethanol and assuming all the other compounds that could be in ethanol are the equivalent of CARBOB in terms of physical properties.

We understand ARB attempts to explain this inconsistency thus: "Denaturant includes CARBOB and "other." According to the California EPA GHG Report, denatured ethanol must contain 94.6% v/v pure ethanol, allowing for up to 2.5% denaturant, 1 percent water, 0.5 percent methanol and 1.4 percent other. Consistent with California's Greenhouse Gas Inventory, the substances potentially contained in the denaturant-ethanol blend are assumed to have the same characteristics as CARBOB for the purpose of estimating emissions."

LCFS 30-2 cont.

<u>ARB's Total "Denaturant Materials" it considers as CARBOB in terms of properties:</u>

Denaturant:	2.5%vol
Water:	1.0% (Note: odd that water is considered to have the energy of CARBOB)
Methanol:	0.5% (Note: at 59.94 MJ/gal is 50% of CARBOB energy density)
<u>Other:</u>	<u>1.4% (Note: often these are the fusel oils produced with the ethanol)</u>
Total:	5.4%vol

Using the energy densities of pure anhydrous ethanol (80.53 MJ/gal) and CARBOB (119.53 MJ/gal) and the assumption that all the non-ethanol compounds have CARBOB properties (and that this is the typical composition of denatured ethanol), the energy density of denatured ethanol would be 82.64 MJ/gal, 1.4% more than the energy density for denatured ethanol (81.51 MJ/gal) codified in the regulations and used by ARB for many other things including carbon credit calculations and in the calculation of the ethanol pathway CI with the revised assumptions on denatured ethanol composition.

From this 5.4%vol CARBOB content of denatured ethanol, using the CARBOB CI of 100.58 gCO2e/MJ, and using ARB's assumption that the energy density of denatured ethanol is 81.51 MJ/gal (note inconsistency, since this is based on 2.5%vol denaturant), the CI of the 5.4% volume non-ethanol portion in a gallon of denatured ethanol, on a gCO2e/MJ of denatured ethanol basis is 7.92 gCO2e/MJ of denatured ethanol. Using the consistent 82.64 MJ/gal basis for denatured ethanol, the denaturant portion of the CI would be only slightly different, 7.86 gCO2e/MJ. This is constant regardless of the pure anhydrous ethanol CI.

Denaturant Displacement of Anhydrous Ethanol

With the current regulations and ethanol pathway CI calculations, a factor of 0.8 gCO2e/MJ is added to the CI calculated with the CA-GREET model to account for denaturant, just as the ILUC factor is added to determine the total pathway CI. Now, ARB is proposing to revise the calculations based on the denaturant displacing anhydrous ethanol such that the CI of the denatured ethanol would be based on the CI of CARBOB and anhydrous ethanol weighted by the energy fraction of each in the resulting denatured ethanol blend. As an example, starting with anhydrous ethanol with a CI of 70 gCO2e/MJ, after multiplying by the anhydrous energy fraction of 92.08%, the CI contribution to the finished blend would be 64.46 gCO2e/MJ. Then the non-ethanol portion of 7.92% of the finished blend energy is multiplied by the CARBOB CI to arrive at 7.97 gCO2e/MJ (which is the same for any E10 blend using ARB's assumptions). The CI of the denatured ethanol is the sum of the two fractions, and is 72.42 gCO2e/MJ. The effect of this method is that the CI is 2.42 gCO2e/MJ higher than the CI of the anhydrous ethanol. LCFS 30-2 cont.

As the CI of the anhydrous ethanol changes, the impact of the denaturant displacement varies as well, with the impact being greater for low CI ethanol and less for higher CI ethanol. For ethanol with a CI above that of the CARBOB CI, the effect is such that the denatured ethanol has a lower CI than the anhydrous ethanol.

There are several issues with this method: the percentage used, and the assumptions that the non-ethanol components are CARBOB and not already accounted for in the anhydrous ethanol CI. Since the CA-GREET model is calculating the direct CI of anhydrous ethanol being produced, and the non-ethanol components before denaturant is added have been produced in the ethanol production process (residual water, methanol as a by-product, and other compounds which are mainly fusel oil also by-products), it seems inconsistent not to assign the same CI to these compounds as the CI of the rest of the anhydrous ethanol. ARB's assumption appears to be that all of the non-ethanol compounds were added to the anhydrous ethanol downstream of the production facility. While this may be true of a portion of the water in the ethanol, since when did water have a CI? The answer is that water has a CI when it is assumed to be CARBOB as CARB has done.

Instead, if denatured ethanol were assumed to be 2.5% denaturant and the remainder anhydrous ethanol without any other compounds, the denaturant would be 3.67% of the energy in denatured ethanol (rather than the 7.92% using the 5.4% CARBOB basis). With this basis, the denaturant portion of the CI would be 3.69 gCO2e/MJ (constant for all ethanol CIs), and the anhydrous ethanol portion of a 70 gCO2e/MJ would be 67.43 gCO2e/MJ (70 x (100% - 3.67%)). The CI of the denatured ethanol would be 71.12 gCO2e/MJ, which is still more than with the old method using 0.8 gCO2e/MJ as the denaturant factor, but is 1.3 gCO2e/MJ less than the 2.42 gCO2e/MJ using the assumption of 5.4% CARBOB in denatured ethanol as proposed by CARB.

LCFS 30-2 cont.

30_OP_LCFS_CRF Responses

124. Comment: **LCFS 30-1**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

125. Comment: **LCFS 30-2**

The comment calls into question the method that is used to calculate the CI impact of denaturant.

Agency Response: Please see response to **LCFS 8-12** and **LCFS 24-6**.

126. Comment: **LCFS 30-3**

The comment requests that ARB staff take note of relevant research that affects the DGS displacement ratio and apply it where applicable.

Agency Response: ARB staff agrees with the commenter that there are studies in the scientific literature that show varying distillers grain with solubles (DGS) credits for specific animals and possibly for specific types of DGS (e.g., wet distillers grain with solubles [WDGS]). But ARB disagrees to the extent the commenter is suggesting that ARB attempt to calculate different credits based on where DGS is sent, and what animal it is fed to – factors that change day to day in commerce. It is not currently possible for staff to know how DGS producers adapt to various market forces over the long-term for selling their DGS. Agricultural products and prices for feed tend to vary over time. It is particularly important to be able to verify the DGS markets for a specific LCFS-approved pathway if a specific credit is to be given for feeding certain animals. Similarly, it is not currently possible for staff to know that individual farmers use a certain amount of agricultural inputs for producing their feedstock over the lifetime of the LCFS fuel pathway. In these and similar cases, staff recommends average values for such inputs until updates are made to the LCA model (CA-GREET 2.0), verification is available, and the science or rigorous multiple-feed market analyses justifies a more specific credit for the duration of specific LCFS fuel pathways.

Similar uncertainty is associated with granting credits for enteric emission reductions from DGS-fed animals. Please see **LCFS 8-13** for further explanation regarding enteric emissions analysis and further discussion on the DGS credit calculation, and LCA boundary not extending to the animals.

ARB staff reviewed the values for DGS credits used in GREET1 2013 and associated peer-reviewed studies, in addition to Argonne National Laboratory technical memorandums. Staff recommends that dry-mill corn (and grain sorghum) ethanol plants use the aggregated displacement ratio for U.S. and export markets proposed in Appendix C of the LCFS Initial Statement of Reasons (ISOR).

ARB staff appreciates the desire of stakeholders to improve the LCA of their fuel through credits or process improvements specific to their fuel pathway. In future iterations of the LCFS, staff hopes to develop a method that considers multiple parameters in the fuel lifecycle to enable applicants to verify the net effects of actual improvements over average default values.

RE: Proposed Adoption of a Regulation Governing the Commercialization of Motor Vehicle Alternative Diesel Fuels; Proposed Re-Adoption of an Updated Low Carbon Fuel Standard

Dear Ms. Nichols,

Imperial Western Products (IWP) is a biodiesel producer located in Coachella, California. We have been producing biodiesel continuously since 2001, and have made over 54 million gallons of biodiesel. Almost all of the biodiesel we make is made from used cooking oil collected throughout California, and the fuel we sell is sold back into the same areas. In the early years of our biodiesel production, we had to rely on specialty markets, where people who wanted to use biodiesel were willing to go to great lengths to buy it. This resulted in uneven demand, and our business had many wild swings in profitability. We would increase production, then slow production. We would hire and then lay off workers.

Upon the introduction of the federal Renewable Fuel Standard (RFS), and California's Low Carbon Fuel Standard (LCFS), we began to see more and more interest from larger, established fuel providers. These programs, especially the LCFS, resulted in more widespread blending of biodiesel into diesel at the fuel terminals in California, which resulted in steady demand for our biodiesel. Of the 54 million gallons of biodiesel we have made, 30 million gallons have been made since 2011. This demand has allowed us to hire more workers, and keep production steady throughout the year. We currently employ 30 workers directly in the biodiesel production plant. These jobs are good paying manufacturing jobs located in an area where these jobs are scarce. Many of our employees worked in temporary agriculture jobs, or in service jobs in the Coachella valley prior to coming to IWP. In addition to the workers who are employed directly in the biodiesel production plant, we have dozens of employees who work in our used cooking oil collection business. These workers are located throughout the state.

LCFS 31-1

I would like to point out three back stories of some of our employees. Lee Munoz grew up in Coachella, and was working for a television satellite dish installer when we hired

P.O. Box 1110
Coachella, CA 92236
(760) 398-0815
(760) 398-3515

him to work in the biodiesel plant in 2002. Lee began to learn about biodiesel production, became a shift supervisor, and is now Production Manager overseeing 22 plant operators.

Danny Chiang was also raised in the Coachella valley. A mechanical engineer and graduate of UC Berkeley, he was working in a clothing store in Rancho Mirage when we hired him in 2011. Danny quickly learned about biodiesel production, and oversaw installation of a plant-wide control system. Danny programmed all of the plant control system, and not only supervised installation, but actually did a lot of the wiring himself. Danny is now lead plant engineer and supervises another engineer.

Eduardo Zepeda grew up in Coachella and attended the University of California Riverside and studied mechanical engineering. One of his professors, Dr. Wayne Miller, would bring his chemical engineering class to our plant every year on a field trip. I called Dr. Miller in the spring of 2012 and asked him if he had any students who would be interested in a summer internship. He allowed me to post a message to his students, and Eddie responded and was hired. After graduating, we hired him full time. He is now learning the biodiesel production process and has successfully completed several projects, including a water treatment and disposal system.

These are just three of the success stories in our biodiesel plant, and all are possible because of steady demand for biodiesel in California. The LCFS has added value to blending biodiesel in California, and when it gets back on track it will provide additional stability to the market which will allow our company to plan for the future, and continue to provide good paying jobs.

LCFS 31-2

With LCFS back on track, the Alternative Diesel Fuel (ADF) regulations will provide a framework for biodiesel to be blended and prevent any adverse emission impacts until the fleet turnover of new technology diesel engines is achieved. It is important to us that the ADF regulations have a clearly defined sunset, when 90% of the miles travelled are done by new technology diesel engines, and that this end point is reviewed annually so that as soon as this milestone is reached, limits on biodiesel blending are removed. With this provision, hopefully LCFS reductions won't be hindered. We feel strongly that biodiesel, California's advanced biofuel, will be important in helping reach LCFS goals.

ADF 11-1

IWP has been making biodiesel in the Coachella valley since 2001, and with re-adoption of LCFS and implementation of ADF we are confident we can continue to increase biodiesel production to displace petroleum, lower greenhouse gasses, lower criteria air pollutants, and provide jobs in California.

Sincerely,

Curtis Wright

Re: BP America Comments on the Proposed Re-Adoption of the LCFS

Dear Sam:

BP appreciates the opportunity to submit comments on the proposed re-adoption of the Low Carbon Fuel Standard (LCFS). As the Board is considering a full re-adoption of the LCFS, we believe it is worthwhile to review why BP continues to have deep concerns about a program that we believe is overly complex, potentially costly and likely infeasible. We also provide comments on specific elements of the revised regulation.

In summary, we believe the LCFS is not a fuel neutral approach, that it picks winners and losers, that it puts a price on carbon emissions from conventional fuels beyond that introduced by a cap and trade system, that it misaligns incentives, rewards and regulated parties, that it shields some pathways from exposure to competition and the market, and that it suffers from a lack of a focused objective. Perhaps most importantly, a LCFS results in <u>no incremental GHG reductions</u> and is not necessary in order to meet the state's GHG reduction goal. LCFS 32-1

The State Should Focus on the Most Cost Effective Approaches

BP continues to believe that a market-based approach (either a well-designed cap and trade or carbon tax) to addressing climate change is not only the most efficient and cost effective – but also the only approach that incorporates a scalable solution recognizing the global nature of the issue of climate change. A market-based approach, such as a cap and trade system, is also the only policy alternative that provides the assurance of meeting a specific emissions reduction target - and does so while delivering this outcome at the lowest cost – ultimately allowing more emission reductions to be achieved. A market-based approach to addressing climate change recognizes that the most efficient emission reduction strategies LCFS 32-2 will change over time as markets and technologies evolve and develop. A market-based approach, such as a cap and trade system, can react quickly to evolving technologies and new approaches in a way that direct measures, or command and control regulatory approaches, simply cannot.

A primary objective of a market-based, GHG-reduction program should be to establish a broad, consistent price for carbon across the widest segment of the economy as is practicable. A broad, consistent carbon price will result in the fairest, most effective and most efficient reduction of GHGs and will best distribute the economic burden and increasing opportunities for low-cost abatement measures. A broader market, including one designed to easily integrate into an eventual regional or federal system, will reduce the impact of leakage and will increase the incentive and marketplace for innovation. That's why the aspiration of such a system should be an economy-wide, market-based program, while recognizing that it may take some time to achieve a fully economy-wide approach.

LCFS 32-2 cont.

BP understands that in certain situations well-designed complementary policies may accelerate commercialization of certain low carbon technologies deemed by regulators to be worthy of support. However, the LCFS is not well designed and in fact may actually discourage investments because of its propensity for picking winners and because of the great uncertainty around feasibility of the targets. While some amount of direct regulation, or command and control regulation, can be justified on a limited basis, going forward the state should acknowledge the transitional nature and shortcomings of the current approach that relies heavily on command and control. A command and control system is not scalable – regionally, nationally or internationally. Because climate change is a global problem that requires a global solution, we need a program that has the potential to be scaled into a large program that will create a common carbon currency.

LCFS 32-3

The LCFS is <u>Not</u> a Market-Based Program

The LCFS is not a market-based approach. It is a direct measure – a command and control regulation with a minor market element. And because the LCFS is a direct measure that regulates GHG emissions on a source (i.e. transportation fuel) that is already covered by the cap and trade program – it is important to acknowledge that the LCFS results in <u>no incremental GHG emission reductions</u>. Every emission reduction that results from the LCFS simply displaces an emission reduction that would otherwise have had to occur in the cap and trade program. In that way, the LCFS doesn't result in any additional or incremental GHG reductions – it simply shifts the reductions from the cap and trade program – to a method prescribed by CARB – in this case to the LCFS. And in doing so, the LCFS forces and shifts emission reductions from an efficient, low cost program where the market chooses how and where the emission reduction is achieved – to a high cost program where the emission reductions occur at multiple times the cost that could be achieved in the cap and trade program.

LCFS 32-1

LCFS 32-4

The LCFS Only Raises Costs – and Does Not Produce Incremental GHG Reductions

How does this work in the real world? Under the California cap and trade program, refiners remain responsible for purchasing allowances to cover emissions from the fuel they refine or import – whether or not a LCFS is in place. The effect of direct regulations

LCFS 32-5

such as the LCFS is that they can lower fuel emissions by either reducing fuel demand or carbon intensity. In the absence of these reductions by the LCFS, the burden on refiners under a cap and trade program is not removed or shifted. Refiners would simply be required to reduce emissions elsewhere, purchase additional allowances (or pay other sectors to make reductions) to cover the emissions that would have been otherwise reduced by these direct measures. The market is able to seek out the lowest cost method of achieving these reductions – rather than being subject to a prescribed (and much more expensive) method of GHG reduction. So when a LCFS is in place, it means refiners simply have fewer obligations in the cap and trade program.

So what is the impact on cost? Given that the demand for cap and trade allowances will be somewhat lower when GHG reductions on sources covered by the cap and trade happen outside of the cap and trade program as the result of a direct regulation such as the LCFS, the price of allowances will likely be reduced some small amount. However, the overall societal cost of the AB32 program will be *much* higher – because in the presence of a direct measure such as a LCFS, GHG reductions are not allowed to occur in the most cost effective manner – but rather in a manner prescribed by policymakers. This might seem paradoxical in a way – but is actually logical. The existence of what most acknowledge is a very expensive regulatory measure in terms of $/tonne CO2e reduced (i.e. the LCFS) will slightly lower the cost of allowances in the cap and trade program – but significantly increase overall societal costs of achieving the GHG reduction target. This is because a direct measure removes the reductions from occurring and being transparently and efficiently priced in the cap and trade system, and masks the costs by imposing them directly and non-transparently on regulated parties.

LCFS 32-5 cont.

Therefore it is incomplete, at best, for the regulation to claim, as it does, that the LCFS will "reduce compliance costs under California's Cap-and-Trade program for regulated entities that are subject to both regulations". The full story is that while the LCFS may result in a minor reduction in the cost of allowances, the overall cost to regulated entities and the overall societal costs of achieving AB32's goals will be <u>much higher</u> in the presence of a LCFS – with no additional, incremental emission reductions occurring from this increased cost and complexity.

Actual Benefits of the LCFS are Unclear

The LCFS was conceived and adopted with a very optimistic view that a robust market for low carbon alternative fuels would exist early in the LCFS program – stimulating supply of large volumes of low cost, low carbon fuels – such as cellulosic ethanol. In fact, the original economic analysis produced by CARB to support the initial adoption of the LCFS estimated that the program would save the state "as much as $11 billion from 2011-2020."

LCFS 32-6

BP believes there will be breakthroughs in alternative fuel technology, including biofuels (driven largely by the federal RFS), and that use of advanced, low carbon biofuels in more efficient conventional engines will provide the bulk of GHG emission reductions in the transportation sector in the mid-term. However, it is clear that this robust, low-cost, alternative fuels industry has not materialized – and may not for many more years. Thus, the LFCS has been premised and designed on fundamentally flawed assumptions that we believe necessitates a complete re-thinking of the program.

Similarly, it is also not clear what role the LCFS is playing in driving innovation in alternative fuels. We believe the federal RFS is the clear and primary driver for innovation in biofuels. With respect to other alternative fuels, we believe that the current price advantage in natural gas (and not the LCFS) is driving renewed consideration of natural gas as a transport fuel, and that a LCFS does not address in any material manner the primary hurdle for use of electricity as a transport fuel – i.e. the cost of electric vehicles. We do believe it is possible to make the case that the LCFS is a driver for bringing biogas, biodiesel, and renewable diesel to California for use in the transportation sector. However, we believe it is difficult to make the case that a LCFS with its expense and complexity, is the appropriate policy choice to drive these outcomes – as opposed to more targeted, less complex and less costly incentives. LCFS 32-6 cont.

A LCFS is Not the Right Long Term Policy for the State

Some have opined that complementary polices, such as a LCFS, are necessary or should be *the* enduring policy for transportation fuels because the price of carbon in a cap and trade system may not rise quickly enough or ever reach the level necessary to bring about material emission reductions in the transport sector. We believe this view demonstrates a misunderstanding of the dynamics of a properly designed cap and trade system. If the cap is properly set, and includes a broad set of emissions sources (including transportation emissions), the carbon price will necessarily rise to deliver the required emission reductions. Furthermore, if it is believed that the public will not accept a carbon price that is necessary for a cap and trade system to deliver emission reductions from the transportation sector, then there is little reason to believe the public would accept the same (or much higher) carbon price imposed on the transportation sector as a result of a complementary policy such as a LCFS. LCFS 32-7

As California looks toward setting longer term climate policy goals, it is more important than ever that the focus be on the most efficient and cost effective means of reducing GHG emissions. Going forward much is at stake in the state's consideration of how to proceed with climate policy post 2020. Reaching post 2020 targets will require nothing less than a fundamental transformation in the way that California produces and uses energy - with significant uncertainty as to the cost and availability of the technology necessary for that transformation to occur.

According to the Scoping Plan Update, achieving post 2020 emission reduction targets that put the state on a path to achieving 2050 goals "will require that the pace of GHG emission reductions in California accelerate significantly. Emissions from 2020 to 2050 will need to decline several times faster than the rate needed to reach the 2020 emissions limit."[1] It has been estimated that the pace of post 2020 emission reductions will need to be <u>five times</u> that of the current program. Governor Brown has said that these future programs will be "far more stringent" and "far more difficult" than current programs. Moreover, these

[1] Proposed First Update to the Climate Change Scoping Plan: Building on the Framework, February, 2014. Page 37 and Figure 6, page 38.

future, much deeper emission cuts will likely (and hopefully) occur during a period of economic growth in the state rather than during the period of economic contraction the state has experienced during much of the current program.

The stakes are therefore much higher, and the potential for significant impact to consumers and the state's economy much more pronounced in a post 2020 GHG reduction program – with the deep emission cuts envisioned. At this important time, with the challenges of deeper, long term emission reductions, and the eyes of the world on California, it is more important than ever that the state focus on the most efficient and cost effective means of reducing GHG emissions. By 2020, California's GHG reduction program- whether it be the program to maintain the 2020 goal or an expanded program - should be far along the way toward relying on a market as the primary mechanism for GHG emission reductions. It is simply not reasonable to expect that current policymakers are equipped today to design a series of command and control policies that determine the exact "recipe" of emission reductions that will meet this century-scale challenge. That should be left to the market. The LCFS is complex, uncertain, expensive and unnecessary to meet the state's long term climate policy goals – and need not be a part of state's climate change policy going forward.

LCFS 32-8 cont.

Cost Containment Proposal

In the development of a cost containment proposal, we appreciate that staff have acknowledged that "some amount of uncertainty will always exist regarding the future supplies of low-CI fuels and the availability and price of LCFS credits". In response, the proposed regulation puts in place a LCFS credit price cap of $200 (with escalation) and a so-called annual credit clearance process.

While we believe the proposed cost containment proposal is not wise or appropriate for a range of reasons, we do believe it represents an important acknowledgement that a) it is very likely that the fuels or vehicles necessary for LCFS compliance won't materialize in required volumes within the timeframe of the regulation and likely for some time after that, b) the original LCFS cost estimates were wildly inaccurate – and rather than saving billions of dollars for fuel consumers, LCFS compliance costs are likely to run into the billions of dollars, and c) emission reductions in the LCFS come at a cost per tonne that are multiple times that of emission reductions in the cap and trade program.

LCFS 32-9

Our internal review of various alternatives to address changes to the LCFS, should the program prove to be infeasible or not cost effective, came to the conclusion that there is no simple, pain-free way to alter the LCFS once it has begun. In fact, the only way to avoid having to make difficult choices about whether or how to alter the program in the future is to set targets from the outset that are demonstrably feasible and cost effective. Credible targets send a consistent market signal to obligated parties and to investors in low carbon fuels. As difficult as these decisions will be around how to alter a LCFS that proves to be infeasible – even more difficult and painful would be to avoid these discussions and later be forced to make last minute, abrupt, arbitrary decisions on how to alter the program.

Cost control, flexible compliance or alternative compliance mechanisms can be useful design features for fundamentally sound programs that have perhaps hit a snag in their implementation. We do not believe the LCFS meets these criteria as it was based on overly optimistic projections about the cost, timing and availability of alternative, low carbon fuels. If, as the evidence suggests, the LCFS is infeasible within its current timeframe, it is the regulation that needs to be changed – or completely reconsidered. If policymakers have miscalculated, then they should go back to the drawing board.

If a LCFS program is to be continued in the short term, we believe CARB should expand its thinking on addressing shortfalls in fuel availability and other LCFS program flaws. The focus should be on solutions that directly address the cause of the problem – not merely reacting to a symptom. Excessive compliance costs that result from the unavailability of alternative fuels is a symptom of a larger problem. Designing cost control measures is a classic example of treating the symptom rather than the disease.

Regarding the specific proposal for a $200/ton price cap on LCFS credits, there are several areas of concern we hope the Board and staff will consider before moving forward. First, it is important to acknowledge that this price cap of $200/ton represents a significant departure from the LCFS compliance cost estimates contained in the 3/5/09 staff report - and which were used to support and adopt the original LCFS.

Conclusions from the 3/5/09 Staff Report include:

LCFS 32-9 cont.

> *"Staff estimated that the displacement of petroleum-based fuels with lower-carbon intensity fuels will result in an overall savings in the State, as much as $11 billion from 2010 -2020" (p.239).*
>
> *"For the five gasoline analyses, the cumulative net cost effectiveness ranged from ($121) to ($142)/MT CO2E reduced, which, for the period of 2010 – 2020, is a cumulative savings of $8 to $9 billion" (p.272).*

If reached, this cost cap would represent billions of dollars per year in additional costs of supplying fuel in the state. In Table ES-4 of the LCFS ISOR, the annual compliance cost in 2020 is estimated at $2.1 billion using a LCFS credit price of $100. The updated regulation contains no analysis as to compliance costs or impact on fuel prices if the $200 cost cap level is achieved. The regulation should model and estimate the cost of the program – and the potential impact on fuel prices should the cost cap level be achieved. The regulation should also analyze the potential market impacts of setting such a price cap. For instance, how could buyers and sellers react to such a price cap and how will this price cap impact the market?

A $200/tonne C02e price cap acknowledges the much higher cost of reducing emissions under the LCFS than could be achieved using a well-designed cap and trade program. This large difference can be seen by investigating both the price cap in the current cap and trade program vs the proposed price cap in the LCFS – and in the current market prices for credits in each of the respective programs. First, regarding current market prices (both which represent the cost of a tonne of C02e), LCFS credits are trading at approximately twice the cost of a cap and trade allowance. Second, comparing the level of the price cap for the respective programs, the LCFS price cap of $200/tonne is approximately 5 times the level of the lowest "price cap" of the state's cap and trade program. These large differences acknowledge the much higher cost of reducing GHG emissions in the LCFS when compared to the cap and trade program. This means the state, and its consumers, are paying a high price in order to allow policymakers to exercise their preference as to how and where GHG emission reductions will occur in meeting the state's GHG goals. California consumers would be much better served by having policymakers set targets and allow the market to choose how the state's GHG targets are met.

Furthermore, the LCFS regulation contains no discussion or analysis about how the cost cap of $200/tonne was arrived at. The regulation could benefit from a discussion as to why the LCFS price cap needs to be set at a level so much higher than cost containment provisions in the cap and trade program. On the other hand, some investors in alternative fuels might argue that $200/tonne cost cap is not sufficient to drive the necessary innovation in alternative fuels. In fact, Board members Dan Sperling and Mary Nichols wrote in a 2012 piece in "Issues in Science and Technology", that a price signal of $.70 per gallon is "not enough to motivate oil companies to switch to alternative fuels". A $0.70 per gallon cost suggests a cost cap much higher than $200/tonne. So while it is clear that GHG reductions under a LCFS will be much more expensive than equivalent reductions under the cap and trade program - it is not clear that the proposed cost cap will allow the LCFS to achieve its intended purpose – that is, innovation in the transport sector. LCFS 32-9 cont.

Moreover, it is not clear that the proposed cost containment mechanism, or the LCFS in general, meets the requirements of AB32 for cost-effectiveness. The language of AB32 requires that GHG reductions in the program are "cost-effective". It is difficult to understand how a LCFS can be considered cost effective when, as shown in previous paragraphs, the cost of a reduction of one tonne of CO2e from the LCFS costs the state multiple times that of equivalent GHG reductions that could be obtained from the cap and trade program. Staff has offered in response to this point that the LCFS is a "transformational" policy, however there appears to be no language in AB32 that provides exemptions from cost effectiveness for transformational policies.

The proposed cost containment mechanism does not facilitate more emission reductions or innovation or change the supply/demand balance of credits - it simply caps costs and allows regulated parties to carry forward unmet compliance obligations. Since this proposal does not result in equivalent emission reductions in the same timeframe (emphasis added) as the regulation, we believe this violates Section 38505 (b) of AB32 which requires:

> *"Alternative compliance mechanism" means an action undertaken by a greenhouse gas emission source that achieves the equivalent reduction of greenhouse gas emissions over the same time period as a direct emission reduction, and that is approved by the state board. "Alternative compliance*

mechanism" includes but is not limited to, a flexible compliance schedule, alternative control technology, a process change, or a product substitution.

For all these reasons, we recommend that the proposed cost containment mechanism, and the LCFS itself, are completely re-evaluated – both for the short and long term. If past assessments of cost and feasibility prove to be so far off from actual costs, what is needed is not an ill-advised cost cap, but rather a re-assessment of the targets, timelines and advisability of the program. If there is a wide-spread inability to comply with the LCFS, what is needed is an acknowledgement of a miscalculation by policymakers.

LCFS 32-9 cont.

We recognize the need for policymakers to address climate change and believe the transportation fuel sector should play a role. However, we don't believe it is reasonable or productive to be wedded to a particular strategy to reach that goal - especially in the face of clear evidence that the program is costly, unachievable, overly complex, unnecessary or otherwise problematic. All options for alternatives should be on the table – both for the current program and post 2020.

Treatment of Crude Oil

It has been and continues to be BP's position that the LCFS should not differentiate between crude oils. We believe strongly that a reasonable evaluation of the effect and impact of differentiating crudes will conclude that there is <u>no environmental benefit</u> from differentiation – only severe unintended consequences to California refiners and fuel suppliers and to the market for transportation fuels. Importantly, a LCFS that does not differentiate crude oils and therefore treats all crudes as equal will maintain the same incentive for innovation and investment in lower carbon fuels.

Before a decision is made to consider differentiation of crudes, we believe it is incumbent on the proponents of differentiation – that they are able to demonstrate, definitively, that there will be material environmental benefits to differentiation of crudes in the California LCFS – and that these benefits will outweigh the consequences of differentiation. We believe the potential unintended consequences are too great to ignore, and that any potential benefits cannot be simply assumed. This important policy decision cannot be justified by the hope that there will be benefits – or by the desire to send a symbolic signal to producers of crude oil. There must be a definitive demonstration of benefits that outweigh risks and consequences. We strongly suggest an evaluation including but not limited to analyzing the following questions:

LCFS 32-10

- Does the differentiation of crude oil in the California LCFS result in a meaningful increase in the volumes of low carbon fuel used in the state?
- Does the differentiation of crude oil in the California LCFS result in meaningful incremental incentive for innovation in low carbon fuels?
- Will the differentiation of crude oil in the California LCFS result in net global GHG reduction?
- Will the differentiation of crude oil in the California LCFS effect what crude is produced globally?

We believe it can be demonstrated that the answer to all of these questions is – no. Further, we believe it can be demonstrated that the likelihood is that differentiation of crude oil in the California LCFS will result in *higher* global GHG emissions. LCFS 32-10 cont.

Electricity Provisions
With regard to the electricity provisions of the draft regulatory changes, we are most troubled by the proposal to remove the requirement that direct metering of electricity usage in electric vehicle charging is necessary to generate credits by 2015. Staff provided little rationale for this proposed change other than that "many EV drivers have elected not to install dedicated EV meters at their residences". In our view, this is precisely why a requirement for metering is necessary. A primary driver of the LCFS is to drive innovation and investment in alternative fuels.

The proposal to eliminate metering brings up many issues including:

1) Verifiability of emission reductions.
An overriding and oft-stated criterion for emission reductions under AB32 is that reductions are real and verifiable. Policymakers, the public and regulated parties who purchase these credits must be able to rely on the fact that these emission reductions are real, that the credits generated are actual and that a ton is a ton. We can think of no other example within the AB32 program where direct generation of a currency within the system is directly and solely generated based on an estimation process – especially where a clear and more reliable method of direct measurement exists.

2) Innovation LCFS 32-11
The LCFS is meant to drive innovation and investment in alternative fuels. It is clear that for electricity in transport, innovation is required for determining and optimizing how, when and why customers recharge their vehicles. This innovation is necessary in order to inform consumer choice, plan for generation needs and load servicing, and to better determine the carbon intensity of actual electricity usage. Because electricity is already ubiquitous as an energy source and the primary hurdle to electrification is in the cost of the vehicle, it is unclear what innovation in electrification would be driven by a LCFS short of that which would come from metering and the information derived from metering. Because of this, it is hard to understand why CARB would backtrack on the requirement that metering be required for electricity generation in the electricity sector.

3) Fairness/Consistency
For most fuels, the LCFS requires considerable investment and innovation in the development and deployment of alternative fuels in order to both generate credits and comply with the CI reductions. Obligated parties, particularly those dealing in liquid fuels, are required to undergo extensive documentation to show the carbon intensity and pathway for their fuel. Metering is required to determine the volume of fuel sold and regulated parties are subject to enforcement and fines if problems with meters arise.

Absent a requirement for metering, it is unclear what investment is required by utilities in order to generate a LCFS credit. Utilities already enjoy a market closed to competition for retail sale of this form of transportation fuel, benefit from an assumption that electricity used is the marginal megawatt – rather than the "conservative default" CI that other fuels have to utilize in the absence of specific data, and now apparently may not even have to actually measure the amount of power that is used by electric vehicles.

4) Taxation
The state of California is already massively underfunded when it comes to funding transportation infrastructure. There are multiple efforts underway by policymakers and stakeholders to find additional sources of revenue. As alternative fuels such as electricity displace petroleum, the transportation funding deficit will only grow. It is likely only a matter of time before transportation fuel taxes are applied to alternative fuels such as electricity. The state Board of Equalization is unlikely to rely on an estimation method to determine tax payment when metering is possible and clearly more accurate.

Researchers who have investigated the role of electricity in a LCFS also agree that metering should be required. UC Davis concluded that: LCFS 32-11 cont.

> *The market for PEV chargers is emerging, so there will be a great deal of innovation in the arena of metering and billing for PEVs in the coming decades…LCFS requirements for metering and reporting for the purposes of credit generation may accelerate these changes".*
>
> *Since PEV chargers are now being built with utility grade meters, it makes sense to tie the generation of LCFS credits to requirements on electricity providers to supply regulators with verifiable, metered data and detailed charging timing profiles that can be used for utility planning and CI calculations.*
>
> *In order to obtain LCFS credits, electricity providers should be required to provide detailed data on charging load, timing and location by a verifiable, utility-grade meter. This information will be used for grid planning and CI calculations and also ensure that PEV charging does not cause or exacerbate grid issues.*[2]

For all these reasons, we urge CARB not to backtrack on the requirement for metering in order to generate LCFS credits from electricity.

GREET Revisions
The proposed regulation contains significant revisions to the carbon intensity values for many alternative fuels pathways as well as for baseline fuels. In some cases, the revisions would increase carbon intensities (CI) by nearly 200%. These contemplated LCFS 32-12

[2] Fuel Electricity and Plug-in Electric Vehicles in a Low Carbon Fuel Standard, Christopher Yang, May 2013

revisions would have significant impacts not only on investments that have been made in good faith reliance on the regulation, but on compliance plans that have incorporated these fuels and pathways, and on the general confidence of the market to rely on the LCFS regulation. We request that CARB adopt a much more deliberative approach to consideration of these changes. This approach would include public workshops held well in advance of any formal rulemaking that review in detail the data upon which the contemplated changes are based, the impact on investments and compliance, the wisdom of making such significant changes to the rules of this regulation at this point and the unintended consequences of these contemplated changes. LCFS 32-12 cont.

Full Data Transparency
At a previous workshop where these CI revisions were discussed, staff did not make available the data or analysis to support the contemplated CI changes. Without seeing the data, it is difficult to provide comment on the validity of the new values. The science of lifecycle analysis as well as understanding of related issues such as methane leakage rates continue to evolve – and are not without controversy.

CARB has a responsibility to ensure that the proposed CA-GREET 2.0 model is based on the most up-to-date, accurate methodologies and data available. Given that the newly proposed CI values are based on evolving science and, if adopted, <u>will</u> have significant impact on investors and compliance entities, it is vital that consideration of any CI revisions – especially changes as significant as these – <u>start</u> with a full and transparent discussion of the data and analysis upon which the changes are based. LCFS 32-13 BP concurs with the following examples of where this transparency and discussion is particularly warranted, as provided by the California Natural Gas Vehicle Coalition and the Coalition for Renewable Natural Gas in their letter of 1/21/15 (summarized here):

1. Tailpipe methane slip factors – concerns have been raised as to the quality and accuracy of the data used to adjust the model's methodology and calculate methane tailpipe emissions factors. Peer reviewed sources of the most up-to-date tailpipe methodology and emissions factors based on actual NGV emissions data, such as the soon-to-be released Argonne National Lab (ANL) Heavy Duty Vehicles Report, calculates methane slip values <u>four to six times lower</u> than those currently being used by CARB staff. LCFS 32-14

2. Methane leakage from RNG production facilities - the current proposed leakage rates are not consistent with New Source Performance Standards which US landfills are subject to for operational and control systems. Concern must be raised as to CARB's reliance on European studies for anaerobic digestion facilities that are not applicable to the US RNG production from landfills. LCFS 32-15

3. Methane leakage from conventional natural gas processes and transport – assumptions currently in CA-GREET 2.0 are based on a national-level EPA methodology, which may not be representative of California's natural gas distribution systems or the primary gas-producing basis supplying natural gas to California. Finalizing these GREET revisions should be delayed to incorporate LCFS 32-16

the release of more up-to-date studies on system leakage which CARB's ISOR (Appendix D) acknowledges is due soon. LCFS 32-16 cont.

We therefore strongly suggest that this portion of the regulatory process is put on hold until the data and analysis upon which the changes are based is presented to the stakeholders and that stakeholders are given ample opportunity to comment on the data and analysis. LCFS 32-17

Impact on Feasibility and Investments
Significantly raising CI values for alternative fuels will have an impact on investments made in reliance on the current LCFS regulation and on the feasibility of what is already a very challenging, possibly infeasible, regulation. For instance, contemplated increases to natural gas and biogas pathways include CI increases ranging from 15% to nearly 200%. For sugar cane ethanol pathways, CI increases are as much as 88%. Companies have made significant, long-term investments in these pathways – and are currently considering future investments. Even at the low end, these changes will impact current investments, significantly altering the economics of these investments - and will put a chill on investments that are being currently considered. At the high end, they make projects uneconomic.

With regard to impact on compliance, to date, natural gas and biogas pathways have contributed a significant amount to compliance. According to the latest UC Davis LCFS Status Review, natural gas and biogas together have accounted for approximately 11% of total LCFS credits – and approximately 90% of non-biofuel LCFS credits[3]. These fuels have provided, and are required to continue to provide, an important compliance bridge while other low carbon fuels such as cellulosic ethanol continue to develop. The contemplated CI increases for these fuels would therefore have a profound effect on regulated entities whose plans have, in good faith, incorporated these pathways into their compliance plans. LCFS 32-18

Grandfathering/Transition
As both the science of lifecycle analysis and related data on fuel pathways – such as methane leakage - continue to evolve - investors and compliance entities cannot and should not be subjected to constant tinkering of CI values – let alone significant, game-changing shifts in carbon intensities during the current timeframe of the regulation.

Even if, after appropriate vetting through a robust public process, the data and analysis support CI changes to existing fuel pathways, there are real public policy questions about whether or how such game-changing revisions are implemented. Staff should consider what will likely be important and unfortunate unintended consequences of increases to the CI of pathways that capture methane that would otherwise be emitted to the atmosphere under business as usual scenarios. By levying a heavy penalty on these pathways, the revised regulation greatly reduces the incentive for projects designed to capture these emissions. LCFS 32-13 cont.

[3] Status Review of California's Low Carbon Fuel Standard, Yeh and Witcover, July, 2014

Moreover, in the recently released pamphlet on Reducing Short-Lived Climate Pollutants in California, CARB states that "The Low Carbon Fuel Standard provides strong financial incentives to use captured methane from landfills and anaerobic digestion facilities as transportation fuels" – and makes similar statements for capture of methane from dairies. If CI revisions on the order of what was presented at the 8/22/14 workshop are adopted, going forward, significantly less incentive will be in place to address methane emissions from both the LCFS and from any market-oriented regulations that may be focused on short-lived climate pollutants.

Any changes that may be justified, after a full vetting of the appropriate data input and assumptions, should go into effect only after a lengthy, well-noticed transition period. Investors and compliance entities must be able to rely on the regulation over an appropriate time period.

LCFS 32-13 cont.

BP Method 2a Pathway Application, Use of GREET and ILUC Revisions
Though BP has concerns with the LCFS, we continue to invest in good faith, both to comply with the regulation and as part of our commitment and contribution toward to a lower carbon transportation sector. These investments include a material business in Brazil to produce efficient, low carbon sugar cane ethanol. Our three sugarcane ethanol mills in Brazil have combined crushing capacity of 10 million tonnes of sugarcane and we are working towards expanding this business further (we recently completed a project to double the capacity of our Tropical mill). Since acquisition, BP has implemented a number of technologies and measures that reduced steam use within the process and improved electricity efficiency of cogeneration. We have also implemented a number of upgrades and installed new-cogeneration capacity at one of the mills. BP supports a sustainable approach to biofuels. We are an active member of Bonsucro – the Better Sugarcane Initiative, and our Tropical mill is already certified under the Bonsucro standard as well as the SA8000 standard for social accountability. We are working to extend certification across our other mills.

BP submitted an LCFS method 2a pathway application for these Brazilian sugar cane ethanol plants in May 2014. Staff has obviously been busy working on the large number of LCFS revisions but has been generous with their time in helping us to work through the many issues around the application. As you might imagine, we are anxious to have our pathway application approved in a timely manner so that the higher efficiency of these plants can be recognized.

In addition to the normal complexities of the 2a process, the approval process has been slowed by the pending adoption of CA-GREET 2.0 and the revisions in ILUC factors. We understand that the science of lifecycle analysis continues to evolve and we want to incorporate the latest science into our application. However, in our most recent discussions with staff, we have been made aware of what we see as troubling inconsistencies in the planned timing of the application of various parts of the pending regulatory revisions. In short, it appears to be CARB's position that the GREET 2.0 revised CIs (which are generally higher for Brazilian cane ethanol) should be modeled into all new pathway applications immediately, while the pending ILUC revisions (which

LCFS 32-19

are generally lower) cannot be used until the effective date of the regulation (approximately 1/1/16).

It is also our understanding, based on a presentation at a 12/17/14 workshop, that because our application was submitted prior to 12/1/14, another option would be for us to utilize GREET 1.8, with certain revisions already implemented in GREET 2.0, for our pending application until one year after the adoption of the revised regulation – at which time we would also adopt the new ILUC factors. This option is sub-optimal for us not only because it will require us to have our application submitted and approved twice, but also because it will put us at a disadvantage with applicants who were allowed to use GREET 1.8 without revisions. This option also increases staff workload by having to evaluate 2a applications multiple times.

LCFS 32-19 cont.

As staff seem willing to allow regulated parties to adopt the most recent science in method 2a application immediately (i.e. GREET 2.0), it seems only fair and consistent to also allow use of the newest ILUC values at the same time – i.e. immediately. This not only makes the application of the regulatory revisions fair and consistent, but also reduces the potential for a large increase in staff workload as applications are submitted now – and then revised after the regulation becomes effective.

Traceability of LCFS Credits
Regulated parties and others have long voiced concerned over CARB's general approach to 'Buyer Liability' within the AB32 program. Buyer Liability provisions increase transaction costs by requiring buyers who have asymmetric access to information and little reasonable capacity to complete their own due diligence, to verify the likely validity of a given credit. The responsibility for ensuring credit validity should sit with those who are in the best position to manage the risk – i.e. credit generators.

Several of the LCFS fuels pathways would require that regulated entities participate in the LCFS credit market in order to attain compliance. Further, in the event of an inability to comply, regulated entities must purchase LCFS credits on the market. The expectation that regulated entities can or will participate in the LCFS credit market, either via a normal compliance approach or via the credit clearance market necessitates a program that allows them to be able to rely on the validity of these credits. In fact, we believe the following language of the current statute requires that CARB ensure the validity of these credits:

LCFS 32-20

> Cal. Health & Safety Code § 38562(d)(1)
> *Any regulation adopted by the state board pursuant to this part or Part 5 [market-based compliance mechanisms] shall ensure all of the following: (1) The greenhouse gas emission reductions achieved are real, permanent, quantifiable,* ***verifiable****, and enforceable by the state board …*

BP urges CARB to act to reduce the risk of invalidation born by market participants by:

1. Limiting the basis for invalidation under proposed section 95495(b)(1) and adding a statute of limitations on the right to commence invalidation procedures, and;

2. Allowing buyers to better access and manage the inherent risk by providing for traceability of LCFS credits. By giving LCFS Credits a unique serial number similar to that applied to offsets generated under the Cap and Trade program or RINs, a buyer would be able to implement their own quality assurance and risk management programs to better evaluate and ensure the integrity of the credits they are purchasing, and in doing so better support the integrity of the program.

LCFS 32-20 cont.

32_OP_LCFS_BP Responses

130. Comment: **LCFS 32-1**

This comment is a summary of the commenter's more detailed comments that follow, and responses to those subsequent comments will likewise go into more detail.

Agency Response: In general, the LCFS regulation is fuel neutral in the sense it neither requires nor prohibits the use of any specific transportation fuels in California. Neither does it set volume limitations or goals for any fuels. Instead, it establishes science-based carbon intensity values for all fuels and it requires that the statewide average carbon intensity of transportation fuels be reduced each year through 2020. The reduced-carbon standard can be met through proportionally greater use of lower-carbon fuels, reduction in the carbon intensities of specific fuels sold in California, or, most likely, a combination of the two. While the use of some fuels are expected to grow in California and the use of other fuels is expected to decline as a result of LCFS, these changes are the result of each fuel's ability to contribute to the carbon reduction objectives of the LCFS rather than ARB's desires to designate "winners" and "losers" in the regulation.

While compliance with the LCFS will add to costs that transportation fuel producers would face from compliance with the Cap-and-Trade Program alone, the LCFS regulation will help achieve important California objectives beyond what the Cap-and-Trade Program alone could achieve and is therefore an important part of the state's overall effort to reduce GHG emissions. The LCFS will guarantee that GHG reductions occur in the transportation sector, which the Cap-and-Trade Program alone would not, and will help to achieve greater diversification of the state's fuel portfolio, help reduce dependence on petroleum, and spur greater innovation and development of cleaner fuels.

See responses to **LCFS 32-2** to **LCFS 32-8**.

131. Comment: **LCFS 32-2**

The comment states that only market-based approaches succeed for reducing GHG emissions. The comment adds that the LCFS regulation is a command and control regulatory approach and will be ineffective.

Agency Response: The LCFS is a market-based approach designed to reduce the carbon intensity of transportation fuels by 10 percent by 2020, from a 2010 baseline. It is important to note that the Cap-and-Trade Program and the LCFS program have complementary, but not identical programmatic goals: Cap-and-Trade is designed to reduce greenhouse gasses from multiple sources by setting a firm limit on GHGs; the LCFS is designed to reduce the carbon intensity of transportation fuels. As a market-based, fuel-neutral program, the LCFS provides regulated parties with flexibility to achieve the most cost-effective approach for reducing transportation fuels' carbon intensity.

132. Comment: **LCFS 32-3**

The comment states that the LCFS regulation is not well designed and may discourage investments.

Agency Response: The existing LCFS regulation, in combination with the federal Renewable Fuels Standard and other programs, already has a track record of encouraging investments in lower-carbon fuels, and ARB staff anticipates the proposed regulation will send an even stronger signal to investors in these technologies since it will introduce a revised carbon standard that will require accelerating reductions in transportation fuels' average carbon intensity moving toward 2020. ARB staff disagrees that the proposed LCFS is poorly designed because it picks "winners." As explained in response to **LCFS 32-1**, above, the proposed regulation merely requires that regulated parties find ways to reduce the average carbon content of transportation fuels in succeeding years. To the extent that requirement incentivizes development and greater use of alternative fuels, such development and use will achieve program objectives of reducing GHG emissions from the transportation sector and diversification of the state's transportation fuel pool.

ARB staff does not agree that the proposed LCFS regulation is primarily a "command and control" system; it leaves decisions about how to achieve required fuel carbon intensity reductions up to the transportation fuel market and individual transportation fuel producers and providers. While the proposal is undeniably a complex, technical regulation, this does not mean it cannot be successfully implemented elsewhere. The State of Oregon and the Canadian Province of British Columbia are both implementing low carbon fuel programs. ARB's proposed regulation will include periodic reviews to ensure the program is working as planned and to make adjustments that might be needed.

133. Comment: **LCFS 32-4**

The comment states that the LCFS regulation is a command and control regulatory approach with a minor market element.

Agency Response: ARB staff disagrees that the LCFS is fundamentally a command-and-control system. The LCFS is a fuel-neutral, market-based program that does not give preference to specific transportation fuels and instead bases compliance on a system of credits and deficits based on each fuel's carbon intensity. Carbon intensity (CI) is a measure of the GHG emissions associated with the various production, distribution, and consumption steps in the "life cycle" of a transportation fuel.

It is difficult to respond with depth to this assertion because the commenter provides no specifics to support the claim that the LCFS is not market-based. Notably, the commenter does not describe what components of the program could be considered command-and-control.

134. Comment: **LCFS 32-5**

The comment states that the LCFS regulation raises costs and does not produce incremental GHG reductions.

Agency Response: It is important to note that the primary goal of the LCFS proposal is to achieve a 10 percent reduction in the carbon intensity of California transportation fuels by 2020, from a 2010 baseline. In addition, the LCFS is designed to diversify California's transportation fuel portfolio and to create a durable regulatory framework that can be adopted by other jurisdictions. From these goals flow two important ancillary benefits: long-term reductions in transportation-sector GHG emissions and diversification of the fuel supply by providing consumers with more clean fuel choices.

The LCFS and Cap-and-Trade programs are designed to complement one another – providing a multi-pronged approach to meet the goals of AB 32 for the transportation sector. Fuel suppliers have a compliance obligation under the Cap-and-Trade Program for the GHG emissions that result from the production and use of fuels. This provides an incentive to reduce emissions and sell cleaner fuels in the market, but it does not require cleaner fuels, as fuel suppliers can purchase allowances to cover their emissions if they so choose. The LCFS requires that fuel providers supply cleaner fuels in California. As the LCFS reduces the carbon intensity of fuels, it changes the composition of the state's transportation fuel mix and dependence on traditional petroleum-based fuels. In addition, investments made to comply with one of the programs will generally result in reduced compliance requirements for the other program.

135. Comment: **LCFS 32-6**

The comment states that the original LCFS regulation has not delivered low cost, low carbon fuels or innovation in alternative fuels.

Agency Response: The LCFS is working as designed and intended. Even with the standards frozen at one percent, and continuing legal challenge increasing regulatory risk for producers of low carbon fuels planning investments, tangible results can been seen. For example, as reported in the publicly available LCFS LRT system data, the amount of renewable natural gas used in vehicles in California has increased by over 700 percent since the program started; the amount of biodiesel quadrupled; renewable diesel has grown dramatically to become more than three percent of the total diesel market in California in 2013; and the average crude CI used by California refiners have remained below the 2010 baseline, meaning that the carbon footprint of the crude slate has not increased. Additionally, fuel producers are innovating and achieving material reductions in their fuel pathways' CI, an effect the LCFS regulation is expressly designed to encourage. Credits have been generated from ethanol (60 percent), renewable diesel (15 percent), biodiesel (13 percent), natural gas (ten percent), and electricity (two percent).

136. Comment: **LCFS 32-7**

The comment asserts that the California Air Resources Board (ARB) should not have any regulatory programs, but instead should only rely on the Cap-and-Trade program to achieve GHG reductions and the goals of AB32.

Agency Response: The comment asserts that ARB should not have any regulatory programs, but instead should only rely on the Cap and Trade program to achieve GHG reductions and the goals of AB32. Instead, ARB has chosen to rely on a combination of policies, planning, direct regulations, market approaches, incentives and voluntary efforts. The LCFS is one of the core regulatory foundations.

The Cap and Trade and the LCFS are two complementary programs. While both programs impact transportation fuels, they have different objectives and approaches to emission reductions. These programs work synergistically to achieve the objectives of AB 32 and Executive Order S-01-07. Most importantly, while the focus of the Cap and Trade program is on the reduction of GHG emissions, the objective of the LCFS program is to lower the carbon intensity of transportation fuels – thereby achieving GHG reductions as well as helping transform and diversify transportation fuel in California.

Regarding the cost of the LCFS, the market-based core of the LCFS program along with features such as the cost containment will allow the objectives of the LCFS program to be achieved at the lowest possible cost.

137. Comment: **LCFS 32-8**

The comment states that the LCFS regulation is too prescriptive and expensive to meet the long term climate policy goals of the State of California.

Agency Response: ARB staff disagrees that using the LCFS to drive further reductions beyond 2020 would be inappropriate and therefore should not be studied further. Clearly additional reductions in global warming emissions are needed post 2020 if the State is to continue progress toward its 2050 goals – to such an extent that transportation will need to be revolutionized. The LCFS holds promise for changing the energy and emissions associated with transportation. In recognition of this need the Board directed staff to determine what additional reductions can be obtained in the 2020 to 2030 timeframe and to return to the Board with a proposal to further strengthen the LCFS in that period. The cost and feasibility of additional reductions will be fully considered at that time.

138. Comment: **LCFS 32-9**

The comment questions the use of a cost containment proposal and expands upon a series of concerns related to it.

Agency Response: ARB staff analysis regarding the availability of low carbon intensity (low-CI) fuels indicates that there will be sufficient credit producing fuels available to meet the programs goals through 2020 from existing low-CI fuel technologies and promising low-CI fuels on the horizon. Please see response to **LCFS 40-8.**

Although the overall supply of credits is expected to be adequate to meet the total demand, there may be periods of low market liquidity. For example, parties that possess more credits than they need for near term compliance but have chosen to bank credits for use in future years rather than make them available to others. The cost containment provision was developed to address this possibility. The provision allows regulated parties to achieve compliance with their annual obligations if, for whatever reason, one or more parties is unable to obtain the credits needed for annual compliance due to a lack of liquidity in the ongoing LCFS credit market.

In the event that the demands on the credit market prove to be more than the market can deliver in a given year, the cost containment provision will allow orderly compliance without extreme measures or unacceptable price spikes. The Clearance Market greatly reduces the potential for chaos or extreme volatility in the market should a short term demand for credits exceed supply. The price cap mechanism curbs volatility allowing regulated parties to achieve compliance using a pre-determined mechanism and at a maximum price per credit.

ARB staff proposes the creation of a year-end “credit clearance” process to provide additional compliance options if the LCFS credit market gets tight; to increase market certainty regarding maximum compliance costs; to strengthen incentives to invest in and produce low-CI fuels; and to reduce the probability of credit shortfalls and price spikes. Under this process, regulated parties would be allowed to carry over deficits to the next compliance period, provided that they purchase their pro-rata share of all credits made available for sale during a year-end credit clearance market. This ensures that regulated parties can achieve compliance under all possible credit supply outcomes.

The Clearance Market is not designed as a method of dealing with the situation sometimes describes as “systematic credit shortages”. ARB staff does not believe systematic credit shortages will occur however, as part of the overall LCFS program the ARB will conduct periodic evaluations that would allow for stringency adjustments if they prove to be necessary.

The cost containment provision also significantly increases certainty over how issues related to market liquidity would affect the overall LCFS and thus serves to increase the willingness of investors to pursue low CI fuel technologies and projects. Investment decisions in new fuel supplies will depend on having clarity regarding how the program will manage price volatility or temporary shortfalls in credits from low-CI fuel. Implementing a clear, predictable provision to handle any credit shortage and to limit price spikes without lowering the overall demand for credits reduces the risk of both short-run supply shortages and fuel price spikes. Thus the cost containment provision increases the likelihood of meeting the standard by providing regulatory certainty for investors that the LCFS will continue to provide the needed price premium for low-CI fuels in the future.

The price cap provides an upper bound on the potential cost of credits, and should not be construed as a projection of future credit prices or as a projection of cost of compliance or cost-effectiveness of the regulation. The price cap is set at $200 per credit in 2016 and increase at the rate of inflation in subsequent years. ARB staff's expert judgement indicates that $200 per ton is high enough to provide a sufficient value added to stimulate the investments in and production of low-CI fuels, and sufficiently high to attract these fuels to California if they are produced elsewhere. The price cap at $200 is anticipated to result in multiple, ancillary market benefits, including reduced price uncertainty, and reduced regulatory uncertainty. Reducing both these sources of uncertainty is anticipated to increase the incentives for investment. Potential investors might otherwise be hesitant to invest in low-CI fuel production facilities given conditions of undue uncertainty, particularly because production facilities for low-CI fuels are typically capital-intensive projects with relatively long payback periods.

With respect to the portion of the comment pertaining to the economic impacts of the proposed regulation, see responses to **LCFS 40-13.**

With respect to the portion of the comment pertaining overlap between the Cap-and-Trade Program and the LCFS program, please see response to **LCFS 32-1, 32-2, 32-5 and 32-7.**

139. Comment: **LCFS 32-10**

The commenter recommends that the LCFS not differentiate between crude oils based on carbon intensity and argues that crude differentiation provides no environmental benefit but rather may result in unintended consequences.

Agency Response: There are real, quantifiable, and significant differences between the lifecycle GHG emissions of crude oils. In evaluating the various alternatives for crude oil emissions accounting under the LCFS, ARB staff has used several guiding principles (see page 81 of 2011 ISOR at http://www.arb.ca.gov/regact/2011/lcfs2011/lcfsisor.pdf):

1) *Accurate accounting for emissions from production and transport of crude oil:*

   Since the LCFS regulation takes into account full lifecycle GHG emissions for fuel pathways, including all stages of feedstock production and distribution, the upstream emissions from energy-intensive crude recovery methods need to be accounted for to provide consistent treatment versus other regulated fuels. Establishing an accurate performance-based accounting system will ensure that additional emissions in the carbon intensity of gasoline and diesel fuels from the baseline are captured.

2) *Discouraging potential increases in emissions and ensuring that increases that do occur are mitigated:*

   An incremental deficit for backsliding with respect to the baseline will ensure that the GHG emission contributions from petroleum fuels do not increase over time without being mitigated.

3) *Promoting innovation for emission reduction activities:*

   Providing credits for purchase of crude from production facilities that have implemented innovative methods, such as carbon capture and storage (CCS), to reduce emissions for crude recovery is consistent with the goal of promoting innovation, at the same time accurately accounting for the reduction in upstream emissions. Apart from providing a market signal for cleaner production, credits generated through such activities can provide extra flexibility for meeting LCFS GHG reduction targets.

4) *Avoiding or limiting incentives to use crude shuffling to generate credits, avoid deficits, or transfer GHG emissions to other jurisdictions to avoid regulation under the LCFS:*

   Additionally, a program design that can be exported to other jurisdictions will result in minimizing such GHG emission transfers if other jurisdictions adopt consistent programs.

In addition to meeting the above-mentioned key guiding principles to achieve the intended GHG benefits, the crude oil provision should be designed so as to avoid, as much as possible, adverse environmental and economic impacts. Additionally, considerations for a successful implementation, such as simplicity of methodology, availability of data, and administrative burden, as well as other issues such as fuel supply impacts, etc., should reflect on the decision-making process. Various alternatives for crude oil emissions accounting fall under two broad categories:

1) *Crude Differentiation accounting*:

   Under refinery-specific and California Average approaches, all crudes are differentiated by carbon intensity. Average crude emissions and potential incremental deficits are assessed and assigned annually on a refinery or industry-wide basis. Technologies that reduce emissions from crude production are acknowledged through reduced carbon intensity for crudes and potentially through the innovative crude provision.

2) *No Crude Differentiation accounting*:

   Under the "No Crude Differentiation" or "Crude is Crude" approach, average crude emissions are only determined for the 2010 Baseline and potential increases or decreases in crude production emissions are not evaluated.

Although the No Crude Differentiation approach advocated by the commenter eliminates any incentive for crude shuffling in response to the LCFS, it fails to provide accurate accounting of emissions, to discourage potential increases in emissions, and to promote innovation for emission reduction activities. As discussed on page 84 of the 2011 ISOR, the No Crude Differentiation approach does not account for, track, or mitigate increases in upstream emissions from crudes used by California refineries. This is inconsistent with the life cycle analysis basis of the LCFS and undermines the program's goal to achieve a ten percent emission reduction from the 2010 baseline for transportation. The No Crude Differentiation approach provides no incentive for producers of crude oil that supply California refineries to reduce emissions (e.g., by reducing flaring) since these reductions will have no benefit relative to the compliance with the LCFS. Because the approach provides complete flexibility to purchase worldwide crude supplies irrespective of the emissions associated with producing and transporting the crude, no mitigation would be required if crudes with higher CIs were to be used. Moreover, this approach could result in significantly greater amounts of harder to refine crude oil being used at California refineries because there is no incentive to avoid their use. Consequently, the No Crude Differentiation approach could have adverse environmental impacts for the communities located in the vicinity of the refineries. On the basis of this evaluation, we determined the No Crude Differentiation approach to be inadequate and inconsistent with the key guiding principles for crude oil treatment under the LCFS.

The LCFS is designed to account for all emissions over the lifecycle of a fuel. Although driving innovation in new, low carbon fuels such as biofuels, electricity, hydrogen and natural gas is a priority under the LCFS, the goal of the regulation is to reduce the average carbon intensity of transportation fuels sold in California by ten percent in the year 2020. Ensuring this goal is met is not possible without accurately accounting for emissions associated with the production and transport of crude oil and requiring that increases that do occur are mitigated.

140. Comment: **LCFS 32-11**

The comment questions the reasoning behind the removal of the direct metering of electricity usage requirement in electric vehicle charging to generate credits.

Agency Response: Electricity, unlike almost all other transportation fuels, is primarily distributed directly to residential and commercial users over a shared electrical distribution grid. The transportation electricity shares the existing electrical distribution network with electricity destined for other end-use appliances and applications. The shared electrical distribution network is fundamentally different than other transportation fuel distribution infrastructures. It is technically difficult to segregate the transportation electricity. Due to the unique distribution structure, staff proposed different schemes to calculate the transportation electricity use in different settings.

Installing a separately dedicated meter for residential EV charging was initially viewed to be feasible. However, because separate meters remain costly for EV customers, the majority of EV owners have elected not to install dedicated EV meters at their residences. The percentage of directly metered EV charging residences varies from 5% to 10% in the major California electric utility service territories. Rather than adding a cost barrier to EV adoption by requiring direct metering, staff intends to continuously improve the calculation for retail charging based on the best sources of information about how EVs are charged and driven.

1. *Verifiability of emission reductions*

   ARB staff believes credits for residential EV charging can continue to be real and verifiable even in the absence of direct metering at the residence for all customers. Just as liquid fuels volumes are not measured at individual retail fuel pumps, the amount of electricity used as a vehicle fuel does not need to be monitored at the individual home to be an accurate source of credit in the program.

   In a 15-day change of the regulation, staff added the calculation method for unmetered residential charging, including the determination of the number of non-directly metered residential PEVs, into the LCFS regulation language. In a 15-day change, the proposal was modified to have ARB (rather than the utilities) calculate the generated credits for electricity use from residential charging.

   The EV populations in each service territory are accurately known based on the California Vehicle Rebate Project (CVRP)[3] database, and California Department of Motor Vehicles registration data and other relevant sources. The daily electricity use of PEVs without direct metering will be represented by the best available data regarding daily electricity use of residential PEV in a given compliance period.

   Currently, the best available representative data for unmetered residential charging are likely to continue to be the directly metered data in the same utility service territory. However, this may change with the progress of studies (some external and some directly funded by ARB) focused on evaluating how plug-in electric vehicles are driven, or through potential advances in smart grid technologies coupled with EV on-vehicle technology.

[3] https://energycenter.org/clean-vehicle-rebate-project/rebate-statistics

Currently available data from select, early model year plug-in electric vehicles shows similar electricity consumption across technology type. However, per the direction in Board Resolution 12-11, ARB staff is conducting an evaluation of the charging behavior of both battery electric vehicles (BEV) and plug-in hybrid electric vehicles (PHEV) with an assortment of battery capacities and will report to the Board by 2016 as part of the midterm review for the Advanced Clean Cars program. Additional findings from this assessment will be incorporated into the calculation method per the 15-day changes that provide flexibility to adjust for any future observable differences if future data demonstrates a shift in this area.

The current data collected by California utilities for directly metered customers shows electricity use of about 8kWh per day from home charging. The value is consistent with national level data from U.S. DOE's EV Project, which has been collecting data on Nissan Leaf and Chevrolet Volt vehicles since late 2010.[4] The EV Project shows that the kW hours of daily charging of each major California utility service areas (Los Angeles, San Francisco, and San Diego) are consistent, with values ranging from 8 kWh to 9kWh per day. The data from EV Project consisted of both directly metered charging activities and non-metered charging obtained through on-board data collection system. The EV Project data did not show much variation between metered and non-metered charging activities. Staff will continue to monitor other sources of data for updated information on daily electricity usage of EVs and incorporate those into the calculation method.

Moving forward ARB staff will calculate the generated credits for each utility (after receiving data that are relevant to the calculations submitted by each utility).

2. *Innovation*

Staff agrees that one of the objectives of the proposed Low Carbon Fuel Standard is to foster innovations and investments in the production of the low carbon intensity (CI) fuels. This is one reason that ARB plans to adjust this calculation to account for the progress of technology innovation delivering better data. We note, however, that incentivizing development and use of alternative fuels such as electricity takes precedence over

[4] http://avt.inel.gov/evproject.shtml#ReportsAndMaps

incentivizing innovation in metering. Where a metering requirement could specifically dis-incent use of electricity as a vehicle fuel, such a requirement is inappropriate.

3. *Fairness/Consistency*

   In the proposed regulation, the requirements for application, reporting, and recordkeeping are consistent across all alternative fuel providers. The parameters for credit calculation, however, may differ from one alternative fuel to another, due to the fuel-specific manufacturing, blending, distributing, and marketing processes.

   The credits generated through residential EV charging will be calculated by ARB staff and documented in the Electrical Distribution Utility's LRT-CBTS account. This would reduce burdens on electricity providers, and reduce the probability of miscalculations and subsequent credit invalidation.

4. *Taxation*

   As stated above, the calculation method is sufficiently accurate in calculating the actual electricity use of non-metered residential EV charging for the purpose of the LCFS rule. Staff cannot speak to what methods would or would not be acceptable to other state agencies including State Board of Equalization, should that agency ever be mandated to impose a fuel tax on residential EV charging.

141. Comment: **LCFS 32-12**

The comment questions ARB staffs' revisions to the carbon intensity values for many alternative fuel pathways and baseline fuels.

Agency Response: Based on stakeholder feedback received over last several years and advances in lifecycle analysis, it is imperative that we update our California-modified Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (CA-GREET) model at this time. These updates were thoroughly vetted through a full and open public process, including workshops and numerous individual meetings with stakeholders.

ARB staff is very sensitive to market stability. In order to preserve stability, staff is attempting to establish a predictable update cycle for these analytical models. The next update is expected in the program review that will conclude prior to January 1, 2019.

Changes will be vetted through the same complete and open public process that ARB employs for all rulemakings.

142. Comment: **LCFS 32-13**

The comment requests that any proposed CI value changes should include a transparent public discussion prior to the change.

Agency Response: The LCFS re-adoption public process, including discussion of CI model changes, was complete and extensive. ARB staff believes that the identification and adoption of new, accurate estimates of GHG emissions from methane are more likely to result in actions to reduce emissions than to suppress the fuel source. For more information about this process please see the response to comment **LCFS 1-12**. With respect to the timing of changes and the impact on investments see response to **LCFS 32-18**.

143. Comment: **LCFS 32-14**

The comment questions the values used in CA-GREET for tailpipe methane slip factors.

Agency Response: See response to comment **LCFS 1-4**.

144. Comment: **LCFS 32-15**

The comment questions the values used in CA-GREET for methane leakage from RNG production facilities.

Agency Response: See response to comment **LCFS 1-5**.

145. Comment: **LCFS 32-16**

The comment questions the values used in CA-GREET for methane leakage from conventional natural gas processes and transport.

Agency Response: See response to comment **LCFS 1-6**.

146. Comment: **LCFS 32-17**

The commenter suggests delaying changes in CI values.

Agency Response: The commenter had made the suggestion to put changes to CI values on hold based on three areas – tailpipe methane slip emissions, methane leakage from RNG production facilities, and methane leakage from natural gas processes and transport. Staff addresses tailpipe emissions in response to

LCFS 1-4, methane leakage from RNG in response to **LCFS 1-5** and **LCFS 32-15**, and methane leakage from natural gas in response to **LCFS 1-6**.

ARB staff is constantly evaluating new data and attempting to strike a balance between accuracy and predictability by transitioning to a regular review and update cycle under the new regulation.

147. Comment: **LCFS 32-18**

The comment questions changes in CI values for specific fuel pathways due to investor expectations based on prior values.

Agency Response: Staff employed the best available science to update the CI value of each fuel in order to be as accurate as possible and encourage the appropriate actions to reduce CI. We understand that changing the CI value for fuels shifts the investment incentives and may impact the economics of existing projects or pathways that were financed assuming a certain value under the prior CI regime. Therefore, we will continue to endeavor to shift CI values in a methodical and transparent way that correctly balances the need to update to the latest science and to provide a stable investment framework. In this iteration, the new 'recertified' CI values will not be applicable until 2016, meaning that the CI incentives in LCFS have remained essentially constant for a five-year period (from 2011-2015). The next scheduled update to the CI calculation models will occur during the program review that will conclude prior to January 1, 2019.

148. Comment: **LCFS 32-19**

The comment expresses concern for the amount of time being taken to approve 2A pathways. The comment also states that revised CIs should be modeled into all new pathway applications immediately while the pending ILUC revisions cannot be used until the effective date of the regulation.

Agency Response: ARB staff acknowledges that the Method 2A LCFS pathway applications submitted by the commenter remain uncertified. With the limited staffing resources available to process pathway applications, a backlog of LCFS pathway applications exists waiting to be processed for certification. To some extent, staff resources were being re-directed to issues related to the re-adoption of the LCFS regulation and to the development of an updated life cycle analysis model for GHG impacts assessments of transportation fuel pathways. Staff sympathizes with the commenter and will process the applications as soon as reasonably possible.

The proposed LCFS regulation will not be used to process applications until January 2016. Thus, the CA-GREET 2.0 model and 2016 LCFS iLUC values cannot be used to evaluate lifecycle GHG emissions of fuel pathways until January 2016. Fuel pathway applications submitted prior to January 2016 for certification must be modeled using the current regulation and the presently-approved CA-GREETv1.8b model, along with iLUC carbon intensity values (land use or other effect) adopted by the Board pursuant to the Final Regulation Order for the Low Carbon Fuel Standard.[5].

149. Comment: **LCFS 32-20**

The comment suggests allowing buyers to better manage their risk by providing traceability of LCFS credits.

Agency Response: ARB staff agrees that monitoring, auditing and enforcement of the LCFS Program are critical to ensure the emission benefits of the program are realized. The ARB's Cap-and-Trade Program currently employs use of third party verifiers and the LCFS staff is interested in adopting such a program for LCFS.

ARB staff is aware of the voluntary quality assurance plan provisions that the U.S. Environmental Protection Agency (U.S. EPA) has adopted in the Renewable Fuel Standard (RFS) Program. The RFS Program requires that all retired credits which are found to be invalid must be offset by honorable credits with real emission benefits. Staff has had discussions with U.S. EPA staff regarding their implementation experience with this recently-adopted provision, as their program uses a similar "buyer-beware" approach.

The ARB staff believes that it would be valuable to add unique serial numbers to the credits generated in the LCFS. Staff is currently exploring the costs and timeframes associated with implementing this change in the LRT-CBTS while efforts are increased to focus resources on the overall quality assurance of LCFS credits.

[5] Title 17, California Code of Regulations (CCR), Subchapter 10. Climate Change, Article 4, Regulations to Achieve Greenhouse Gas Emission Reductions, Subarticle 7. Low Carbon Fuel Standard, § 95486, Determination of Carbon Intensity Values, (b) Method 1 – ARB Lookup Table, Table 6. Carbon Intensity Lookup Table for Gasoline and Fuels that Substitute for Gasoline.

ARB staff does not support limiting the basis for invalidation under proposed section 95495(b)(1); such a limit could diminish the program's ability to accomplish its goals.

Comments of the California Independent Petroleum Association on the Readoption of the Low Carbon Fuel Standard

Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814

February 17, 2015

Via electronic submittal to: http://www.arb.ca.gov/lispub/comm/bcsubform.php?listname=lcfs2015&comm_period=A

The California Independent Petroleum Association (CIPA) appreciates the opportunity to submit the following comments to the California Air Resources Board (CARB) for its consideration.

The mission of CIPA is to promote greater understanding and awareness of the unique nature of California's independent oil and natural gas producer and the market place in which he or she operates; highlight the economic contributions made by California independents to local, state and national economies; foster the efficient utilization of California's petroleum resources; promote a balanced approach to resource development and environmental protection and improve business conditions for members of our industry.

The members of CIPA believe that domestic petroleum production already plays a meaningful role in helping the state meet its policy goals for reducing greenhouse gas emissions in California. Staff's proposed Innovative Crude Method Provisions enable our members the opportunity to create additional carbon intensity reductions within the program.

CIPA appreciates the staff proposal on Innovative Crude Methods and believes these changes could provide a substantial impetus for California's in-state producers to include more renewable energy in the production of crude. CIPA looks forward to working with CARB on implementing these provisions and lowering the carbon intensity of in-state crude.

CARB's understanding of the potential impact of solar EOR was critical to revising the regulation. To more fully quantify the economic benefits of the proposal, we partnered on a study whose results show that solar EOR in California could deliver over 4.2 million LCFS credits per year while creating between 32,100–44,900 cumulative jobs to California's economy from 2015 through 2020, depending on the LCFS market. Our analysis shows further benefits in that for every job created through investment in solar powered oil production, about 2.5–2.7 jobs are created in supporting industries (indirect) and via

LCFS 33-1

spending by employees that are directly or indirectly supported by the industry (induced).[1] LCFS 33-1 cont.

Thank you for your attention to this important matter. Any questions or follow-up comments can be directed to myself at rock@cipa.org.

Sincerely,

Rock Zierman
CEO

About ICF International

ICF International (NASDAQ:ICFI) provides professional services and technology solutions that deliver beneficial impact in areas critical to the world's future. ICF is fluent in the language of change, whether driven by markets, technology, or policy. Since 1969, we have combined a passion for our work with deep industry expertise to tackle our clients' most important challenges. We partner with clients around the globe—advising, executing, innovating—to help them define and achieve success. Our more than 4,500 employees serve government and commercial clients from more than 70 offices worldwide. ICF's website is www.icfi.com.

Executive Summary

The California Air Resources Board (CARB) staff has proposed to re-adopt the Low Carbon Fuel Standard (LCFS), reaffirming its original target of a 10% reduction in the carbon intensity (CI) of transportation fuels used in California by 2020 and subsequent years. While most of the expected CI reductions will be derived from imported low-CI fuels, the regulation and the re-adoption proposal include provisions to promote innovations in crude oil production methods that reduce the CI of petroleum.

Of the potential innovative methods, the use of solar energy is the lowest-cost, lowest-risk, and largest-scale opportunity to reduce the CI of petroleum fuels produced and used in California. Solar powered oil production technologies—solar steam generation and solar electric power generation—have the potential to contribute to California's economy significantly while reducing costs and risks associated with meeting the LCFS. Solar steam generation used in thermal enhanced oil recovery (EOR) displaces imported natural gas that that would have otherwise been combusted. Solar electricity generated on-site at production facilities displaces electricity that would have otherwise been purchased from a utility provider. These solar technologies have the potential to reduce the carbon intensity of California's crude oil, thereby boosting investment in California-based industries, and helping shift LCFS compliance from importing low carbon fuels from out-of-state towards in-state investments and operations of low carbon infrastructure. Investment in these technologies can lead to job growth, increased industry activity, and increased state and local tax revenues. Furthermore, by reducing the carbon intensity of California crude oil, these solar technologies have the potential to preserve California refinery operations while fully meeting the emissions reductions goals of the LCFS.

ICF employed IMPLAN, an input-output model, to calculate the economic impacts of deploying solar steam generation and solar electric power generation technologies. ICF developed *steady* and *accelerated* deployment scenarios for each technology, capturing 5% and 30% of their respective markets (as measured by volume of steam or electricity consumption). ICF also considered the economic impacts of keeping LCFS credits generated by solar steam and solar power in California, rather than having the value of those credits transferred to low carbon fuel providers in other regions. Furthermore, we considered the impacts on refiners as a result of being able to maintain margins that would have otherwise been impacted by reduce crude runs or reduced margins from having to export the refined products.

Exhibit 1. Economic Contributions of Solar Oil Production in California

Cumulative Solar Impact 2015-2020	*Steady*	*Accelerated*
	$25/ton	$150/ton
Total Jobs	**11,000**	**44,900**
Income per Worker	$72,000	$77,900
GSP ($M)	**$1,160**	**$5,090**
Industry Activity ($M)	$2,910	$11,350

In the *accelerated* deployment scenario, where solar energy provides 30% of the state's EOR steam needs or onsite production electricity, ICF concluded:

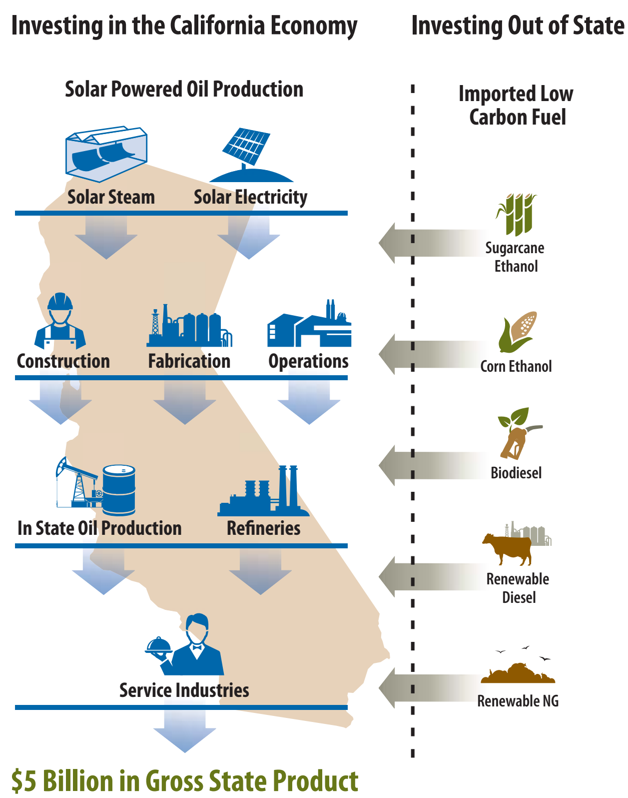
- Innovative crude oil production using solar energy adds 32,100–44,900 cumulative jobs to California's economy from 2015 through 2020, depending on LCFS market conditions.
- These are high value jobs, with labor income per job created in the range of $75,000 per job. Many of the jobs were created in sectors tied to upstream oil production, as well as construction, engineering related services, and fabrication/manufacturing.

- For every job created through investment in solar powered oil production, about 2.5–2.7 jobs are created in supporting industries (indirect) and via spending by employees that are directly or indirectly supported by the industry (induced).
- The deployment of these technologies leads to increased state and local tax revenues in the range of $117–575 million.

Solar steam has greater potential than solar electricity to deliver LCFS credits because 90% of the energy used in California oil production is in the form of steam. In the *accelerated* deployment scenario, solar steam generation has the potential to generate as many credits as some of the most promising low carbon fuel pathways by 2020, including renewable diesel, renewable natural gas, and low carbon intensity biodiesel (e.g., from corn oil). Solar electricity has the potential to generate LCFS credits in line with contributors like electricity and natural gas.

ICF also finds that solar powered oil production technologies may help stabilize the LCFS market in several ways. Firstly, these LCFS credits may help stabilize credit prices by offering a lower cost solution than importing low carbon fuels for compliance. Secondly, we find that these credits may hedge California's exposure to uncertainty in the federal Renewable Fuel Standard market. With the potential for RIN prices to be depressed because of uncertainty in that market, biofuel providers may seek higher LCFS credit prices to pick up the slack in market pricing. However, the deployment of solar powered oil production technologies will provide some buffer against credit price increases. Thirdly, solar powered oil production technologies will provide regulated parties, particularly integrated energy firms with oil production and refining investments, an opportunity to limit their exposure to the LCFS credit market.

Solar powered oil production technologies are commercially available today with low development risk, and unlike some low carbon fuel options, innovative crude methods tap into the existing petroleum supply chain without delay for infrastructure modifications or rollouts. The emissions reduction potential of the technologies will deliver credits to the oil producer and reduce the CI of petroleum fuels. Therefore, innovative crude offers the unique advantage of fully complying with the LCFS and achieving the state's GHG reduction goals without hindering the petroleum supply chain. These emissions reductions are available as a "drop in" option using today's fuel production, distribution, and vehicle infrastructure, with minimal infrastructure costs, development risk, and deployment timelines.



ICF's analysis demonstrates that investments in solar powered oil production will yield benefits up to $5 billion in Gross State Product, with jobs created in sectors such as construction, fabrication, oil field operations, and the service industry, while retaining jobs in the refining industry. This contrasts sharply with some of the alternative LCFS compliance pathways, whereby dollars (via commodity pricing and LCFS credits) are exported out of California to pay for low carbon fuels produced elsewhere.

1 Innovative Crude Oil Production

The California Air Resources Board (CARB) staff has proposed to re-adopt the Low Carbon Fuel Standard (LCFS) program in 2015, and to include updates and revisions to the regulation.[1] The regulation and the re-adoption proposal include provisions to promote innovations in crude oil production methods that reduce greenhouse gas (GHG) emissions. In this section, we briefly summarize California's Oil and Gas Sector, its outlook in the near- to mid-term as a result of carbon constraining regulations in the state, and review the relevant innovative crude oil production technologies.

1.1 California's Oil and Gas Sector

Excluding federal offshore areas, California ranks third in the United States in crude oil production. As recently as 2012, nearly 4,700 new wells were drilled in California, bringing the statewide total to 88,500 active wells, operated by 570 companies.[2] A recent report by the Los Angeles Economic Development Corporation (LAEDC) highlights some of the critical parameters characterizing the impact of the Oil and Gas Sector on California's economy, including:[3]

- About 70,000 direct jobs in California are tied to oil and gas production
- Oil and gas production contribute about 0.5% of total California labor income
- The average wage of the component industries in the oil and gas production sectors are considerably higher than the median private industry wage in California

Exhibit 2. Crude Oil Production in California, 2005-2014[4]

[4] Based on data from EIA and DOGGR. The crude oil production for 2014 is an estimate made by ICF based on data reported through September. Note that production data via TEOR are not yet available past 2009. The shaded range is an estimate based on ICF analysis.

California's Low Carbon Fuel Standard

The LCFS requires a 10 percent reduction in the carbon intensity (CI) of transportation fuels used in California. Carbon intensity is a measure of the lifecycle GHGs of transportation fuels, and includes emissions over the entire fuel supply chain. The LCFS is implemented using a system of credits and deficits: Deficits are generated by fuels that have a carbon intensity greater than the standard and credits are generated by fuels that have a carbon intensity lower than the standard. At the end of each year, deficit-generating parties (generally refiners and fuel importers) must balance their deficits with credits.

Despite several years of reductions in overall crude production since 2005, crude produced from thermal enhanced oil recovery (EOR)[5] or steam injection has been increasing since 2006, as shown in Exhibit 2. Crude Oil Production in California, 2005-2014 above. Steam injection, which reduces the viscosity of oil and increases mobility, has been used commercially in California since the 1960s. Today, more than 40% of California's crude is produced with thermal EOR and is expected to account for half of production in the next few years. As an emitter of GHGs, the oil and gas production industry is impacted by CARB's implementation of the Global Warming Solutions Act of 2006, commonly known as AB 32. The LCFS and light-duty tailpipe GHG standards (originally referred to as Pavley standards) are both part of California's suite of GHG reduction policies under AB 32, and will both lead to reductions in demand for petroleum-based transportation fuels. Although the refinery sector is commonly identified and analyzed as one of the primary industry sectors to be impacted by AB 32, upstream oil and gas production sectors will likely experience the effects of the regulation as well.

This report focuses on a potential opportunity included in the proposed re-adoption of the LCFS: "Innovative Crude Production Methods". Operators who produce crude for California's refineries and employ a GHG-reducing "innovative method" in the recovery or extraction process can generate LCFS credits corresponding to the avoided GHG emissions.

1.2 Introduction to Innovative Crude Production Methods

The current proposed LCFS re-adoption regulation identifies the following technologies as innovative methods for crude production:[6]

Technology	Image	Description	Technology Maturation	LCFS Considerations
Solar steam generation		Uses solar arrays to concentrate the sun's energy to heat water and generate steam for thermal EOR.	Deployed in multiple locations; several vendors.	Steam must be used onsite at the crude oil production facilities.
Carbon capture and storage		Captures CO_2 emissions produced from processing; prevents the CO_2 from entering the atmosphere.	Limited commercial deployment; no commercial deployment at oil fields.	Carbon capture must take place onsite at the crude oil production facilities.
Solar or wind electricity generation		Electricity generation from solar technology or wind turbines. Electricity to be used on-site for production-related activities.	Solar PV technology is ubiquitous for non-residential installations. Wind technology is mature, but generally deployed in larger rather than on a smaller scale.	Qualifying electricity must be produced and consumed onsite or be provided directly to the crude oil production facilities from a third-party generator and not through a utility owned transmission or distribution network.
Solar heat generation		Uses solar arrays to concentrate the sun's energy for heat generation.	Concentrating solar technology that can produce process heat (similar to steam generation).	Heat must be used onsite at the crude oil production facilities.

The language also includes provisions regarding year of implementation (no earlier than 2010 for solar steam or CCS; no earlier than 2015 for electricity and heat generation projects), project registration, and minimum GHG reduction thresholds (a carbon intensity reduction of at least 0.10 gCO_2e/MJ or a reduction of at least 5,000 metric tons CO_2e per year).

[5] Thermal EOR is a process whereby heat is introduced to the reservoir in order to reduce the viscosity of the crude, and increase its permeability.

[6] Initial Statement of Reasons, II-17ff. Available online at: http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15isor.pdf

"Solar powered oil production technologies—solar steam generation and solar electric power generation—have the potential to contribute to California's economy significantly while reducing costs and risks associated with meeting the LCFS."

Technologies Selected For Further Analysis

For the purposes of this report, ICF narrowed our consideration of innovative crude methods to *solar steam generation* and *solar electricity generation* based on factors such as commercial availability of the technology, consideration of California oil field characteristics, and industry interest. Other qualifying innovative technologies, including carbon capture and storage (CCS), wind electricity generation, and solar heat generation, were not considered due to limitations or uncertainty in market demand.

- **Solar steam generation.** The technology is commercially available and has been demonstrated by both GlassPoint Solar and BrightSource Energy. These companies have demonstration projects in Kern County and Fresno County, California, respectively. GlassPoint Solar also has deployed its technology in Oman at the Amal West oilfield (in partnership with the national oil company, Petroleum Development Oman, PDO). With about 492 million barrels of steam injected for thermal EOR in California in 2012, there is significant potential for solar steam generation in California. For such thermal EOR projects, steam is the primary energy requirement, with 185 million MMBtu of natural gas required to produce the 492 million barrels of steam injected for thermal EOR. This natural gas is the primary source of GHG emissions associated with oil production. The potential for the technology is limited by factors such as geography and the deployment of efficient combined heat and power (CHP) units at oilfields, which may be difficult to displace depending on when the units were installed and the operators' willingness to displace the technology given the investment. However, ICF anticipates sufficient demand for solar steam generation deployment as part of LCFS compliance.
- **Solar electricity generation.** Solar electric power generation is ubiquitous in California, with more than 8,500 MW of solar energy currently installed, and about 2,750 MW of that installed in 2013. Multiple photovoltaic (PV) technologies have experienced significant declines in installed cost over the last several years, with the average installed system price reported at about \$2.27/W for a non-residential system.[7] The location and electricity demands at oilfields will likely be a good match for solar PV deployment. The regulation restricts credits from potential solar electricity deployment to electricity which is produced and consumed onsite or is directly provided to the facility via third-party generator, not through the utility grid. As oil production operations are generally continuous, there are limits for the fraction of total energy provided by solar PV deployment without concomitant investments in energy storage. Despite these limitations, ICF anticipates that solar PV installations at oil fields will increase substantially between now and 2020 as part of a LCFS compliance strategy based on the cost competitiveness of the technology and the desirable onsite characteristics of oil production fields (e.g., sufficient solar radiation).

[7] US Solar Market Insight: Q3 2014, GTM Research and SEIA, available online: http://www.seia.org/sites/default/files/resources/iV39f8059N.pdf; assumes a 200-300 kW rooftop installation at a non-residential facility.

2 Economic Impacts of Solar Powered Innovative Crude Production

ICF employed an input-output (I-O) economic model to calculate the economic benefits of deploying solar steam generation and solar electricity generation in California. We considered several elements associated with the deployment of these technologies, including the following:

- **Capital expenditures.** ICF considered the capital expenditures associated with deploying the technologies in two scenarios (*steady* deployment and *accelerated* deployment). The capital expenditures include the labor and materials associated with building the solar steam installations and solar PV installations.
- **LCFS credit generation.** ICF also considered the value of LCFS credits generated via the deployment of these technologies in California. ICF assumed that the generation of credits would have otherwise been completed outside of California. This is a reasonable assumption given the structure of the LCFS program and a review of CARB's proposed LCFS compliance scenario, which relies heavily on biofuels (e.g., biodiesel, renewable diesel, and renewable natural gas). Given the limited in-state production of low carbon fuels, ICF made the reasonable assumption these innovative crude production technologies will create credits in-state from investments made in-state, versus credit revenues being exported out-of-state for imported low carbon fuels. We valued the credits in two scenarios: a low price of $25/ton and a high price of $150/ton.[8]
- **Refinery margins.** Depending on the strategy employed, LCFS compliance may lead to significant demand destruction for gasoline and diesel. For instance, CARB's proposed compliance scenario includes about 900 million gallons of diesel replacements being consumed in 2020, representing about 20% of the projected diesel demand. Conversely, CARB's illustrative compliance scenario only projects about 110 million gallons of gasoline replacements being consumed in 2020, in a fuel market with projected demand of about 13.5 billion gallons. Regardless of the compliance strategy, it is highly likely that there will be reduced refinery margins as a result of the LCFS. ICF broadly categorizes these losses into two areas: 1) lost refinery margin and 2) reduced refinery margins as a result from having to export product.

Depending on the chosen means of LCFS compliance, varying levels of decreases occur in gasoline and diesel consumption in California. Although the reduction of petroleum consumption has positive impacts via improved energy security and increased fuel diversity, the decreased consumption of petroleum will also have direct negative impacts on the refining industry—in the same way that the investments in alternative fuels and advanced vehicles will yield positive impacts in the corresponding industries. ICF treated the reduction in gasoline and diesel consumption in the modeling as follows:

- **ICF assumed that there were lost margins on 50% of those crude runs that are assumed to be displaced entirely as a result of the LCFS.** These margins were estimated based on an ICF analysis of the 3-2-1 crack spread for California-based refiners (estimated at about $15/bbl).
- **ICF assumed that the remaining 50% of crude runs representing the reduction in gasoline and diesel consumption in California are exported, rather than displaced entirely.** For these exports, ICF assumed a corresponding decrease in revenue in the export markets because of increased freight costs and competitiveness on pricing (estimated at a combined $5/bbl).

Using CARB's illustrative compliance scenario, each credit generated in 2020 leads to a demand destruction of about 120-130 diesel gallons equivalents.[9]

8 LCFS credit values traded around $25/ton for all of 2014, and likely are below forward credit prices considering the uncertainty associated with the LCFS program throughout 2014 and rising compliance obligations. The high value of $150/ton was selected for illustrative purposes; the program is capped at $200/ton via a cost compliance mechanism.

9 The demand destruction is presented as a range because it ultimately depends on the carbon intensity of the low carbon fuels deployed in CARB's illustrative compliance scenario. Available online at http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15appb.pdf

Exhibit 3. Overview of Solar Powered Oil Production Scenarios

Technology Penetration	Solar Steam		Solar Electricity	
	Steady	*Accelerated*	*Steady*	*Accelerated*
Capital Expenditures ($ millions)	$1,900	$5,600	$390	$1,200
LCFS Credits / GHG Emission Reductions	1.4 million	4.3 million	160,000	490,000
LCFS Credit Value ($ millions)	$35–210	$108–645	$4–24	$12–74

Technology penetration notes:

- Solar Steam: About 492 million barrels of steam were injected at California oilfields for thermal EOR in 2012. ICF assumed that solar steam technology providers could capture 5% of the market for steam generation in a *steady* deployment scenario and 30% in an *accelerated* deployment scenario,[10] in accordance with CARB estimates. Note that ICF held the volume of steam injected constant throughout the analysis (2015-2020), despite the very likely possibility that the amount of steam injected into California oilfields will continue to increase over time. The *steady* and *accelerated* levels of solar steam technology deployment amount to about 16 million MMBtu and 49 million MMBtu of steam, respectively, in 2020.
- Solar Electricity: California oil producers purchased about 3.2 terawatt hours (TWh) of electricity as recently as 2012.[11] ICF made the same assumptions for solar PV as were made for solar steam regarding technology penetration: We assumed that solar PV could capture 5% and 30% of the market for electricity purchased by California oil producers by 2020 in *steady* and *accelerated* deployment scenarios, respectively. ICF estimated the deployment of solar PV that would be required to achieve this level using a capacity factor of 20%. In other words, to capture 30% of the market in 2020, ICF assumed that an installed capacity of about 550 MW would be able to provide 0.96 TWh operating at a 20% capacity factor.[12]

Capital expenditure notes:

- Solar Steam: ICF developed estimates for capital expenditures to achieve this level of deployment using data provided by GlassPoint and previous economic assessment of solar steam by Ernst & Young.[13]
- Solar Electricity: We assumed a starting price of $2.33/W[14] with modest decreases over time.[15]

The economic contribution of solar steam and solar electricity deployment are characterized by employment, labor income, value added, and value output.

- **Employment** is reported in terms of annualized job-years. The employment numbers are broken down by direct, indirect, and induced. We also present an employment metric referred to as a **jobs multiplier**, which is the sum of job-years (included direct, indirect, and induced) divided by the direct job-years. This is an indicator of the type of employment activity statewide that is generated by investment in a technology. We also present **labor income** and **labor income per worker**. The latter is a coarse estimate of the value of jobs created by the corresponding investment.
- **Statewide impacts.** We present several metrics measuring the impacts on California's economy, including Gross State Product (GSP), industry activity, output, and taxes.
    - ***Industry activity*** measures the value of goods and services.
    - The ***output multiplier*** mirrors the ***jobs multiplier*** and represents the total industry activity (including direct, indirect, and induced) divided by the direct industry activity. This is an indicator of the type of industry activity statewide that is generated by investment in a technology.
    - The values for ***taxes*** are based on the sum of taxes calculated by IMPLAN, including those associated with employee compensation, proprietor income, tax on production and imports, households, and corporations.

Exhibit 4 below summarizes the results for the *steady* deployment scenarios, with each technology capturing 5% of its respective market (as measured by volume of steam or electricity consumption). Note that for both solar steam and solar electricity, LCFS credits were modeled at values of $25/ton and $150/ton—the results from both LCFS credit pricing scenarios are shown in the table below.

10 Industry discussions and ISOR, II-19 Available online at: http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15isor.pdf

11 Personal communication with CARB staff who queried the California Energy Consumption Database by county and NAICS code associated with crude petroleum extraction (211111).

12 There are some limitations to these assumptions, considering that crude oil producers are base loading operations. Further, there are no net metering provisions in the proposed language from CARB, and is effectively prohibited because the electricity cannot be purchased from a utility-owned transmission or distribution network. In reality, to capture 30% of the market for electricity consumption by crude oil producers, solar PV technology would have to be deployed in parallel with complementary technologies like solar trackers and energy storage (e.g., batteries) to level out the energy supply with the base loaded demand. To simplify our analysis and the comparison between solar PV and solar steam as innovative crude production technologies, however, we have not considered the expenditures that would likely be required to achieve this level of electricity consumption using solar PV. Rather, we simply quantified the expenditures that would be required to deploy a given megawatt target of PV.

Exhibit 4. Modeling Results for Steady Deployment Scenarios, Cumulative 2015-2020

Economic Parameter	Solar Steam		Solar PV Electricity	
	$25/ton	$150/ton	$25/ton	$150/ton
Employment				
Direct	3,300	4,900	1,100	1,300
Indirect	2,300	2,900	800	800
Induced	2,600	4,200	900	1,100
Total	**8,200**	**12,000**	**2,800**	**3,200**
Jobs Multiplier	2.72	2.56	2.61	2.56
Labor Income ($M)	$590	$930	$200	$240
Income per Worker	$72,000	$77,500	$71,400	$75,000
Statewide Activity ($ millions)				
GSP	$860	$1,360	$300	$350
Industry Activity	$2,260	$3,070	$650	$740
Output Multiplier	1.53	1.59	1.73	1.74
Taxes	$89	$158	$27	$35

The values are shown as cumulative over the analysis period (2015-2020).

ICF notes that by reporting these numbers cumulatively, we may be double-counting jobs i.e., a single person could conceivably account for six job-years assuming that s/he is employed in each year as a result of a particular technology's deployment.

Summary of Economic Contributions

Direct: Impacts of capital expenditures to deploy innovative crude production technologies and the employees hired by the industry itself.

Indirect: Impacts that stem from the employment and business revenues motivated by the purchases made by the industry and any of its suppliers.

Induced: Impacts generated by the spending of employees whose wages are sustained by both direct and indirect spending.

Exhibit 5 summarizes the results for the *accelerated* deployment scenarios, with each technology capturing a 30% of its respective market (as measured by volume of steam or electricity consumption).

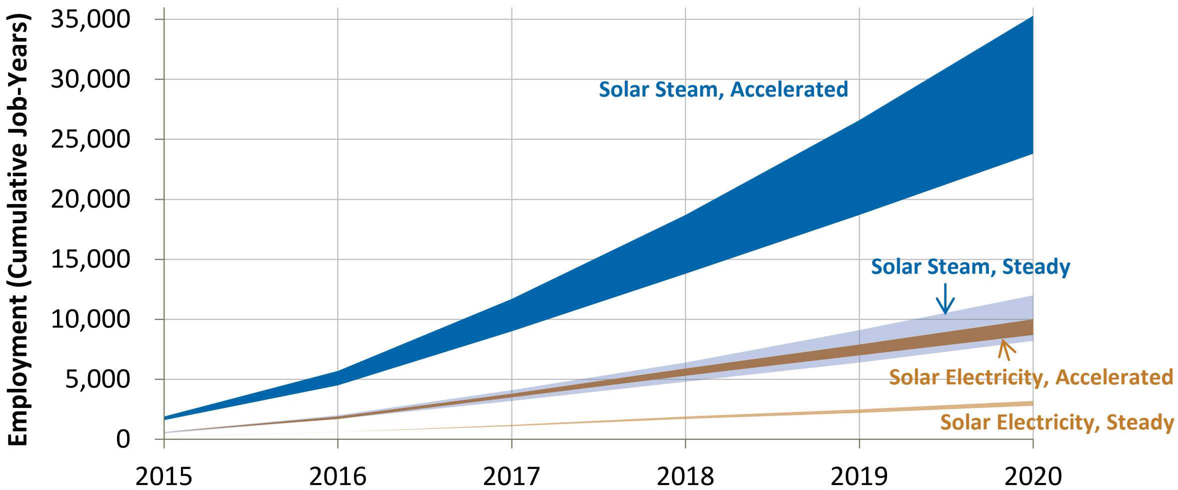
Exhibit 5. Modeling Results for Accelerated Deployment Scenarios, Cumulative 2015-2020

Economic Parameter	Solar Steam		Solar Electricity	
	$25/ton	$150/ton	$25/ton	$150/ton
Employment				
Direct	9,500	14,400	3,300	3,900
Indirect	6,600	8,600	2,300	2,500
Induced	7,700	12,300	2,700	3,200
Total	**23,800**	**35,300**	**8,300**	**9,600**
Jobs Multiplier	2.73	2.56	2.61	2.56
Labor Income ($M)	$1,720	$2,750	$610	$730
Income per Worker	$72,300	$77,900	$73,500	$76,000
Statewide Activity ($ millions)				
GSP	$2,520	$4,030	$890	$1,060
Industry Activity	$6,660	$9,120	$1,950	$2,230
Output Multiplier	1.53	1.59	1.73	1.74
Taxes	$263	$470	$81	$105

The solar steam technology deployment leads to significantly higher employment and statewide economic activity, largely as a result of higher capital expenditures associated with capturing the same market share (5% or 30%). The technologies yield similar results in terms of the multipliers for jobs and industry activity / output. In other words, the higher values for solar steam deployment are more of a reflection of the higher overall market opportunity for solar steam rather than something unique about deploying the technology. Solar PV technology has a slightly higher output multiplier, in part because a significant portion (upwards of 55%) of the expenditures associated with solar steam deployment occur outside of California, mainly as imported materials.

Exhibit 6 below shows how the cumulative employment impacts over time for both solar PV and solar steam technologies in the *steady* and *accelerated* scenarios. The range of impacts represents the low and high LCFS credit pricing.

Exhibit 6. Cumulative Employment Impacts in California of Solar Powered Oil Production



The IMPLAN Model

The IMPLAN model is a static input-output framework used to analyze the effects of an economic stimulus on a pre-specified economic region; in this study, the State of California. The IMPLAN model tracks economic activity across more than 500 industrial sectors using region-specific multipliers to trace and calculate the flow of dollars from the industries that originate the impact to supplier industries. The industrial sectors are based on the North American Industry Classification System (NAICS). The IMPLAN model is one of the most widely used input-output impact models in the United States. For instance, IMPLAN was recently used to estimate the economic contribution of the oil and gas industry in California.

Oil and Gas in California: The Industry and Its Economic Contribution in 2012, LAEDC, April 2014

The IMPLAN model includes more than 500 industry sectors; the table below highlights the sectors that experienced the highest employment impacts. These sectors have been grouped broadly into three categories: oil and gas production industries, solar powered oil production technologies, and indirect and induced sectors. As noted previously, the indirect and induced sectors are those that are impacted by direct investments in the solar powered oil production technologies oil and gas production industries via linkages and increased household incomes. Across both solar steam and solar electricity technology penetration scenarios that were modeled, the construction sector and the drilling oil and gas wells sector captured the highest percentages of employment, accounting for as much as 15-20% of the total employment.

With a larger market penetration, solar steam also has more potential for LCFS credit generation—generating a cumulative 4.4 million and 13.3 million LCFS credits in the *steady* and *accelerated* deployment scenarios compared to just 0.5 million and 1.5 million LCFS credits generated in the *steady* and *accelerated* solar electricity deployment scenarios, respectively.

Exhibit 7. Most Impacted Industry Sectors via Solar Powered Oil Production Technology Deployment

Industry	IMPLAN Sector
Oil and Gas Production Industries	*Drilling oil and gas wells*
	Extraction of natural gas and crude petroleum
	Support activities for oil and gas operations
	Wholesale trade
Solar Powered Oil Production Technologies	*Construction of other new nonresidential structures*
	Architectural, engineering, and related services
	Fabricated pipe and pipe fitting manufacturing
	Semiconductor and related device manufacturing
	All other miscellaneous electrical equipment and component manufacturing
Indirect & Induced Sectors	Real estate
	Full-service restaurants
	Limited-service restaurants
	Employment services
	Employment and payroll of state govt, non-education

The higher market potential for solar steam also leads to higher retention of refinery margins attributed to increased refinery runs and reduced exports of refined products. The retention of these refinery margins manifests itself in the modeling results primarily as increased output and industry activity, and to some extent labor income, rather than employment. Despite not having a significant impact on employment, this is due in part to the nature of the modeling exercise.

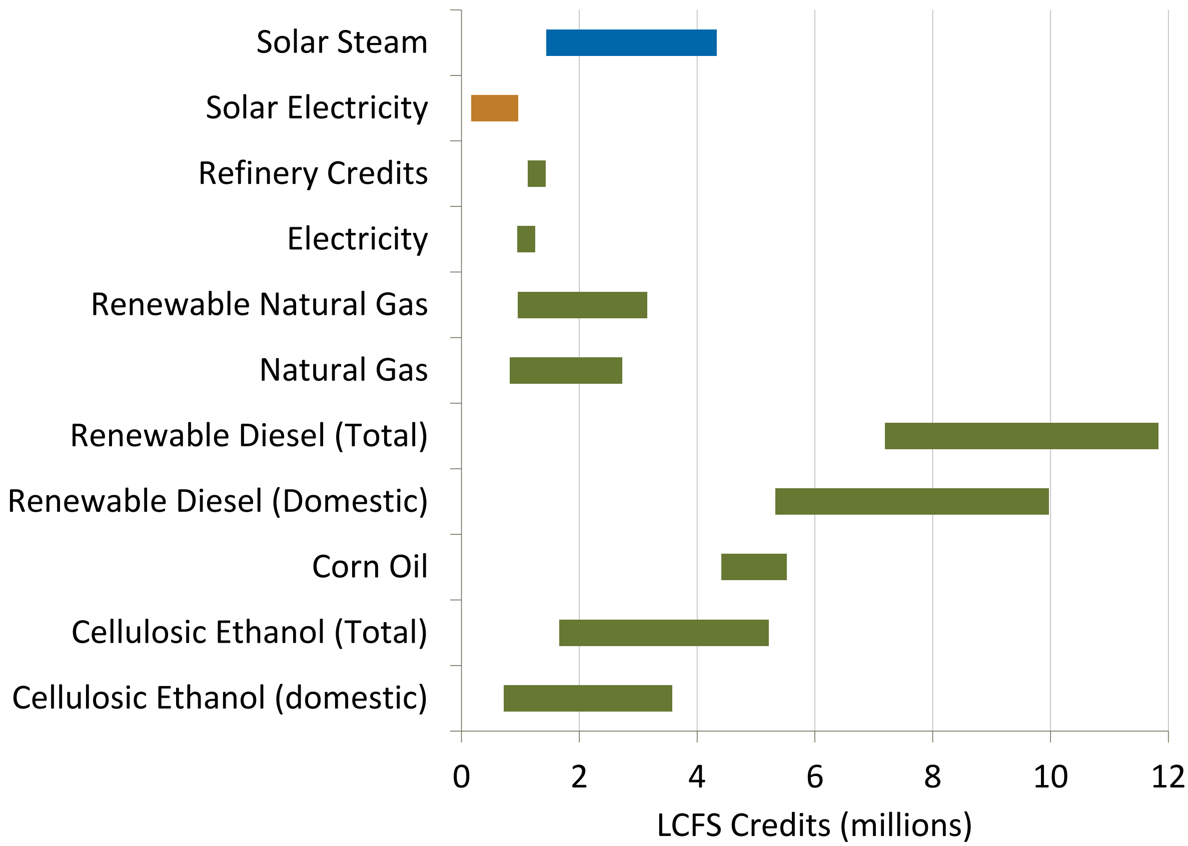
To some extent, the I-O model assumes "full" employment at refineries in the baseline case. In other words, the baseline case—against which the impacts of solar powered oil production technologies are measures—is not assuming that there will be refinery closures as a result of programs like the LCFS or the cap-and-trade program. Furthermore, an increased allocation of expenditures to the refinery sector in the modeling is not going to lead spontaneously to the opening or expansion of an existing refinery in California, thereby generating significant new employment in the sector. Rather, it will lead to enhanced labor income, industry activity, and industry output.

"Solar steam [deployment] leads to higher retention of refinery margins attributed to increased refinery runs and reduced exports of refined products."

3 Solar Powered Innovative Crude in Context

As part of the re-adoption package, CARB staff developed alternative transportation fuel production capacity estimates in various cases (e.g., low, medium, and high).[16] These estimates were used to develop an illustrative LCFS compliance scenario. Exhibit 8 below captures the technical potential for various alternative transportation fuels compared to solar powered oil production technologies in 2020. Note that these values represent the number of LCFS credits that would be generated using the low and high projected estimates published by CARB staff for total fuel volumes available in 2020, not the values assumed for a specific compliance scenario.

Exhibit 8. Total LCFS Credit Potential from Various Compliance Pathways



[16] Available online at http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15appb.pdf

Solar steam has the potential to generate credits comparable with the technical potential of significant pathways that CARB staff use to illustrate compliance, such as domestic cellulosic ethanol. Solar electricity has more limited potential, but is comparable to other contributors to compliance like electricity (used in plug-in electric vehicles) and potential credits generated by energy efficiency improvements at refineries.

While Exhibit 8 focuses on the overall technical potential of various pathways, Exhibit 9 shows the specific deployment potential of solar steam and solar electricity compared to CARB's illustrative compliance scenario for the years 2016-2020.

The potential for innovative crude production technologies is significant: In the *accelerated* deployment scenario, solar steam and solar electricity have the potential to generate 25% and 2%, respectively, of the total cumulative credits required in CARB's illustrative compliance scenario. This puts solar steam on par with pathways such as renewable diesel and renewable natural gas; solar electricity would make a contribution comparable to conventional natural gas. Even in the *steady* deployment scenarios, the LCFS credits generated by solar steam and solar electricity are on par with low carbon fuels like corn oil biodiesel and tallow biodiesel, respectively. Regardless of the deployment scenario, both solar steam and solar electricity have the potential to make material contributions towards LCFS compliance in the 2020 timeframe.

As highlighted in the table above, CARB's illustrative compliance scenario is largely dependent on importing low carbon fuels to California, including corn ethanol (15% of credits), cane-based ethanol (15%), and renewable diesel (22%). To date, nearly all of the renewable natural gas supplied to California for LCFS compliance has been from out-of-state. ICF anticipates that a significant portion of the renewable natural gas will continue to be imported to California from other parts of the United States in the near- to mid-term future (at least through 2018).[17]

Exhibit 9. Estimated LCFS Credit Generation, 2016-2020[18]

Pathway		LCFS Credits (millions) 2016-2020	
Gasoline Substitutes CARB Illustrative Compliance Scenario[17]	Corn Ethanol	9.03	
	Cane Ethanol	7.28	
	Sorghum/Corn Ethanol	1.02	
	Sorghum/Corn/Wheat Slurry Ethanol	0.88	
	Cellulosic Ethanol	1.42	
	Molasses Ethanol	1.49	
	Renewable Gasoline	0.30	
	Hydrogen	0.29	
	Electricity	3.96	
Diesel Substitutes CARB Illustrative Compliance Scenario	Soy Biodiesel	0.43	
	Waste Grease Biodiesel	3.11	
	Corn Oil Biodiesel	5.04	
	Tallow Biodiesel	0.43	
	Canola Biodiesel	0.11	
	Renewable Diesel	13.02	
	Natural Gas	1.39	
	Renewable Natural Gas	7.07	
	Electricity for HDVs and Rail	1.01	
	Refinery Credits	3.16	
	Total	**60.43**	
Solar Powered Oil Production Technologies *Steady* and *Accelerated* Deployment	Solar Steam	4.42	13.28
	Solar Electricity	0.50	1.50

Many of these compliance options are likely to command a significant premium in the market, especially liquid biofuels, thereby pushing credit prices up. California's regulated entities, absent other options, are largely price takers in the low carbon fuel market. In principle, LCFS credit prices will be determined by the marginal abatement cost (assuming a liquid market, and other indicators of a robust market). ICF estimates that the marginal abatement cost associated with the fuel pathways in CARB's illustrative scenario is greater than the abatement cost of the innovative crude production technologies considered here—solar steam and solar PV.

[17] CARB staff estimates about 50 million diesel gallon equivalents (dge) of RNG consumption in 2014, and used 240 million dge of RNG in 2020 for the illustrative compliance scenario.

[18] Note that these values are calculated by ICF based on our assessment of information presented by CARB, available online at http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs15appb.pdf

In other words, ICF believes that in either the *steady* or *accelerated* technology deployment scenarios, innovative crude production technologies have the potential to:

- reduce the marginal abatement cost in the LCFS program in 2020,
- decrease credit prices, and
- reduce California regulated parties' status as a price taker.

ICF estimates that in the *accelerated* deployment case for solar steam, for instance, the credits generated may reduce credit prices by as much as $20-$25/ton in 2020.[19]

Credits from innovative crude production offer a potential hedge against uncertainty in the federal Renewable Fuel Standard (RFS2) market. The RFS2 market has experienced significant volatility. The US Environmental Protection Agency (EPA) sets targets (renewable volume obligations, or RVOs) for the blending of renewable fuels on an annual basis. In November 2014, the EPA announced that they would postpone setting the 2014 RVO targets until 2015, extending a period of regulatory uncertainty in the marketplace. The RFS2 market has also experienced other volatility, such as the availability of federal tax credits. The role of biodiesel, for instance, in the market fluctuates significantly without certainty regarding the availability of a $1.00 per gallon blender's tax credit. This credit has expired and been re-instated retroactively several times in the last five years, creating a difficult investment atmosphere for producers and regulated parties. The uncertainty in the RFS2 market has led to and may continue to lead to volatility of Renewable Identification Numbers (RINs) pricing, the currency of the RFS2 market. For instance, if the RFS2 market is scaled back significantly (via reduced RVOs), it may decrease the price of RINs, and liquid biofuel providers may look to the LCFS program to pick up some of the slack in market pricing. This could lead to an increase in LCFS credit prices.

The credit streams arising from solar powered oil production may provide regulated parties in the LCFS market a buffer against such price volatility. This is dependent, however, on timely deployment of innovative crude production technologies as a compliance diversification strategy.

ICF believes that innovative crude production technologies may provide regulated parties an opportunity to limit their exposure to the LCFS credit market via an integrated investment-based approach. Today, for instance, the majority of LCFS credits are purchased at the point of blending ethanol into gasoline and blending biodiesel or renewable diesel into conventional diesel. In some cases, the LCFS credit value paid is transparent. By and large, however, the LCFS credit market lacks liquidity and transparency in part because some transactions bundle the LCFS credit price paid with fuel price, or reflect longer-term arrangements. Some market participants have various investments in both refining and low carbon fuels and transfer credits internally. CARB reports, for instance, that one-in-five LCFS credit transactions have $0 credits being transacted.[20] ICF regards this activity as an ordinary part of market participants seeking competitive advantage, and a means to limit their exposure to a potentially volatile LCFS credit market.

The innovative crude provisions of the LCFS allow regulated parties to co-invest in or otherwise source credits from production facilities that reduce the carbon intensity of crude oil, which will durably reduce emissions from upstream crude oil production. These investments will reduce forward uncertainty for all market participants and create economic growth in California, shifting a portion of investment in low-carbon energy facilities from out-of-state to in-state.

"Solar steam has the potential to generate credits comparable with the technical potential of significant pathways that CARB staff use to illustrate compliance, such as domestic cellulosic ethanol."

[19] Note that the economic contributions of such price reductions were not considered under this study's methodology.

[20] CARB, October 27, 2014 LCFS Workshop on Proposed Compliance Curves and Cost Compliance Provision.

Appendix

LCFS Credit Calculations

Solar Steam

The LCFS credits that could be generated for solar steam were calculated using the methodology outlined by CARB in the proposed language:

$$Credits_{innov\_SolarSteam} = 29{,}360 \times V_{steam} \times f_{solar} \times V_{crude\_produced} \times V_{innov\_crude} \times C$$

where $Credits_{innov\_SolarSteam}$ is the amount of LCFS credits generated in metric tons by the volume of crude oil produced and delivered to California refineries for processing; V_{steam} is the volume in barrels of cold water equivalent of steam injected, f_{solar} is the fraction of steam injected that was produced using solar energy; $V_{crude\_produced}$ is the volume (in barrels) of crude oil produced using the innovative method; V_{innov_crude} is the volume (in barrels) of crude oil produced using the innovative method and delivered to California refineries for processing; and C is the constant to convert from metric tons to grams (where 1 MT=106 gCO_2e). The constant at the outset of the equation, 29,360, is the emissions factor associated with the natural gas that would have otherwise been consumed in once through steam generators (OTSGs).21

Solar PV

The LCFS credits that could be generated by solar PV deployment were calculated using the methodology outlined by CARB in the draft language:

$$Credits_{innov\_SolarSteam} = 511 \times \frac{E_{electricity} \times f_{renew}}{V_{crude\_produced}} \times V_{innov\_crude} \times C$$

where $Credits_{innov\_SolarSteam}$ is the amount of LCFS credits generated in metric tons by the solar PV used to produce crude oil and delivered to California refineries for processing; $E_{electricity}$ is the electricity consumption to produce the crude (in units of kWh), and f_{renew} is the fraction of renewable electricity that was produced using solar or wind energy.

[21] ICF notes that the emissions factor for natural gas is derived from a draft version of the CA-GREET model and is subject to modification upon further CARB review.

Model Description

In this analysis, the economic impacts were calculated using the IMPLAN[22] (IMpact analysis for PLANning), Version 3.0 input-output model. IMPLAN is developed and maintained by the Minnesota IMPLAN Group (MIG). The IMPLAN model is a static input-output framework used to analyze the effects of an economic stimulus on a pre-specified economic region; in this case, the State of California. IMPLAN is considered static because the impacts calculated by any scenario by the model estimate the indirect and induced impacts for one time period (typically on an annual basis).

The modeling framework in IMPLAN consists of two components—the descriptive model and the predictive model.

- The **descriptive model** defines the local economy in the specified modeling region, and includes accounting tables that trace the "flow of dollars from purchasers to producers within the region".[23] It also includes the trade flows that describe the movement of goods and services, both within, and outside of the modeling region (i.e., regional exports and imports with the outside world). In addition, it includes the Social Accounting Matrices (SAM) that trace the flow of money between institutions, such as transfer payments from governments to businesses and households, and taxes paid by households and businesses to governments.

[22] IMPLAN was developed by the Minnesota IMPLAN Group (MIG). There are over 1,500 active users of MIG databases and software in the United State as well as internationally. They have clients in federal and state government, universities, as well as private sector consultants. More information is available at http://www.implan.com.

[23] IMPLAN Pro Version 2.0 User Guide.

- The **predictive model** consists of a set of "local-level multipliers" that can then be used to analyze the changes in final demand and their ripple effects throughout the local economy. IMPLAN Version 3.0 uses 2008 data and improves on previous versions of model by implementing a new method for estimating regional imports and exports - a trade model. This new method of estimating imports looks at annual trade flow information between economic regions; thereby allowing more sophisticated estimation of imports and exports than the traditional econometric RPC estimate used by the previous, Version 2. Additionally, this new modeling method allows for multi-regional modeling functions, in which IMPLAN tracks imports and exports between selected models allowing the users to assess how the impact in one region can impact additional regional economies.

The IMPLAN model is based on the input-output data from the U.S. National Income and Product Accounts (NIPA) from the Bureau of Economic Analysis. The model includes 440 sectors based on the North American Industry Classification System (NAICS). The model uses region-specific multipliers to trace and calculate the flow of dollars from the industries that originate the impact to supplier industries. These multipliers are thus coefficients that "describe the response of the economy to a stimulus (a change in demand or production)."[24] Three types of multipliers are used in IMPLAN:

- Direct—represents the impacts (e.g., employment or output changes) due to the investments that result in final demand changes, such as investments needed for cleanup and/or redevelopment efforts.
- Indirect—represents the impacts due to the industry inter-linkages caused by the iteration of industries purchasing from industries, brought about by the changes in final demands.

Induced—represents the impacts on all local industries due to consumers' consumption expenditures arising from the new household incomes that are generated by the direct and indirect effects of the final demand changes.

[24] Ibid.

The total impact is simply the sum of the multiple rounds of secondary indirect and induced impacts that remain in California (as opposed to "leaking out" to other areas). IMPLAN then uses this total impact to calculate subsequent impacts such as total jobs created and tax impacts. This methodology, and the software used, is consistent with similar studies conducted across the nation.

Inputs and Model Parameters

The direct economic impacts presented in the report are based on: a) investments required to deploy solar steam and solar PV technologies at oilfields in California, b) the value of LCFS credits being generated in-state, rather than exported to low carbon fuel producers outside of California, and c) the value of increased refinery runs and decreased exports that would have otherwise occurred as a result of LCFS compliance. ICF modeled the impacts of the investments for each individual year of the time period (2015-2020).

Output

Whenever new industry activity or income is injected into an economy, it starts a ripple effect that creates a total economic impact that is much larger than the initial input. This is because the recipients of the new income spend some percentage of it and the recipients of that share, in turn, spend some of it, and so on. The total spending impact of the new activity/income is the sum of these progressively smaller rounds of spending within the economy. This total economic impact creates a certain level of value added (GSP), jobs, called the total employment impact, and also tax revenue for state and local governments.

Due to the static nature of the IMPLAN model, the employment impacts must be presented in terms of annual job-years as the model calculates the annual impact of an annual investment. It is likely that once the job is created, it will be sustained, however to ensure that the impact is not overstated; it is conservatively assumed that the job impact is annual. The annualized GSP and tax impacts can be accrued over the program's duration to identify the total impact of the EB-5 program. These dollar values represent the investments that were placed into the economy each year aggregated over time.

Detailed Modeling Results

As noted previously, ICF used the IMPLAN model to calculate the economic impacts of solar powered oil production in California. The data provided in the body of this report have been aggregated into cumulative numbers. The tables below include selected outputs from IMPLAN—employment (in job-years), labor income, industry activity, and GSP—on an annual basis.

Exhibit 10. Changes in Employment, All Scenarios

Solar Technology	Deployment	LCFS	2015	2016	2017	2018	2019	2020
Solar Steam	*Steady*	Low	500	1,100	1,500	1,600	1,700	1,700
		High	600	1,400	2,100	2,400	2,600	2,900
	Accelerated	Low	1,600	3,000	4,500	4,700	4,900	5,100
		High	1,900	3,800	6,100	7,000	7,900	8,700

RE: **SUPPORT FOR LCFS READOPTION AND ADF REGULATION ADOPTION** at February 19-20, California Air Resources Board Hearing

Dear Chair Nichols:

Please accept these brief comments from the California Biodiesel Alliance (CBA) in support of both the readoption of the Low Carbon Fuel Standard (LCFS) and the adoption of the Alternative Diesel Fuel (ADF) regulation. CBA is California's not-for-profit biodiesel industry trade association, representing over 50 businesses and stakeholders, including all of the state's biodiesel producers. CBA strives to increase awareness about biodiesel as California's leading and widely available advanced biofuel that delivers significant economic, environmental, and energy diversity benefits throughout the state.

We submit these comments as part of a unified statement from the biodiesel industry, and specifically support the comments of the National Biodiesel Board (NBB) on both program areas, including the technical issues related to ARB's updating of the carbon intensities for biofuels.

First, we wish to thank your California Air Resources Board (ARB) staff for their diligent and inclusive process of seeking and incorporating public comments and specifically for working with our industry over many years as we have endeavored to assure accuracy for biodiesel pathways under LCFS and to finally achieve full legal acceptance for biodiesel. We very much appreciate staff's extraordinary investment of resources and expertise in implementing state law, including California's notable progress in reaching its goals under AB 32, while working to provide the critically needed stable regulatory environment required by the investor community.

In our previous comments on the LCFS, CBA has supported key ARB proposals, including for the Compliance Curve and the Price Cap, and have weighed in on the details of the abundant supply of biodiesel available to help reach program targets. Our industry is happy to have generated a steadily increasing percentage of LCFS credits, up to 13% in Q3 2014. We value our ability to make this contribution to the success of LCFS as the world looks to California for solutions to the dire realities of climate change.

CALIFORNIA BIODIESEL ALLIANCE

34_OP_ADF _CBA

In urging your adoption of the ADF regulation, we wish to express our appreciation for the framework that allows biodiesel to move forward with some time to develop a new NOx mitigation additive and for the exemptions for light and medium duty fleets and for those with 90% NTDEs. We support the 2019 review that will provide for data on actual vehicle miles traveled as fleets turnover to the use of NTDEs. CBA looks forward to continued discussions with ARB staff on ways to address the concerns of some of our member companies, as expressed in their written comments, and to the adoption of the best possible final ADF regulation. ADF 34-1

We appreciated Richard Corey's recent reference to the state's reliance on biodiesel for "future reductions of toxic diesel particulate matter" in his presentation at the California Biodiesel Conference on February 4th in Sacramento. Our industry will continue to bring that and other of biodiesel's many benefits to California, especially to communities that are economically disadvantaged and suffer disproportionately from diesel emissions-related diseases.

Thank you again for your leadership. We applaud your success and look forward to working with you going forward.

Sincerely,

Curtis Wright
Chairman
California Biodiesel Alliance

Re: Low Carbon Fuel Standard

Dear Chairman Nichols and CARB Board Members:
ActionAid USA, a nonprofit organization working with millions of people around the world and the US to fight the causes of poverty and injustice, applauds the California Air Resources Board's (CARB) proactive approach to climate change mitigation. However, as the Board considers re-adoption of the Low Carbon Fuel Standard (LCFS), we strongly urge it not to lower the indirect land use change (ILUC) score for corn ethanol. Summary

Attached you will find a working paper by Timothy A. Wise and Emily Cole of the Global Development and Environment Institute at Tufts University, "Mandating Food Insecurity: The Global Impacts of Rising Biofuel Mandates and Targets." This paper studies the impact of government biofuel mandates and estimates that mandates will drive a 43% growth in demand for biofuels over the next decade. This level of growth has extremely concerning implications for food security, as well as land and water use. Further incentivizing the use of corn ethanol, which undermines food security and has questionable environmental benefits, would be step in the wrong direction. LCFS 35-1

Crop-based biofuels, particularly corn ethanol, undermine food security around the world by driving up food prices and increasing price volatility.
This not only true for corn products people consume directly; corn is one of the most popular feeds for animals, so an increase in the LCFS 35-2

price of corn also increases the price of meat and dairy products. A 2012 study published by ActionAid estimated that US ethanol expansion cost net corn importing countries $11.6 billion between 2006 and 2011. $6.8 billion of this additional cost was born by developing countries. In fact, during fiscal year 2011, the U.S. spent as much on food aid to Guatemala as the additional money Guatemala paid to import corn at the increased prices.

LCFS 35-2 cont.

Corn ethanol also presents environmental concerns.
In addition to the emissions from direct and indirect land use change, corn ethanol undermines water quality. The nitrogen, phosphorous and other chemicals applied to corn crops are washed from those crops into drainage, local water supplies, rivers and eventually oceans. This poisons the water, and in the case of nitrogen, creates algae blooms that reduce the oxygen levels in the water. The resulting dead zones kill fish and aquatic life or force them to move elsewhere. In 2014, the dead zone in the Gulf of Mexico was 5,052 square miles. The impact of biofuel expansion on water quantity should not be ignored. Corn uses more irrigated water than any other crop in the US, even though the overwhelming majority of corn is currently rain-fed. In recent years, irrigated corn crops increased with the growth in corn production. Perhaps not surprisingly, 87% of irrigated corn crops are grown in areas already showing extremely high water stress. Considering the water demands of growing corn and the strain current corn production is placing on water levels, policy makers should be cautious about policies that encourage further demand.

LCFS 35-3

One other lesson to take from "Mandating Food Insecurity," is that government policies continue to profoundly shape the biofuels industry. Government mandates have and will continue to drive demand growth for first-generation biofuels, such as corn ethanol, that undermine food security and hurt the environment. I strongly urge the Board to ensure that the LCFS does not further incentivize corn ethanol expansion.

LCFS 35-4

Thank you for your consideration and please do not hesitate to contact us should you need additional information.
Sincerely,

WORKING PAPER NO. 15-01

Mandating Food Insecurity:

The Global Impacts of Rising Biofuel Mandates and Targets

Timothy A. Wise and Emily Cole
February 2015

Tufts University
Medford MA 02155, USA
http://ase.tufts.edu/gdae

Abstract

Expanding demand for biofuels, fed significantly by government policies mandating rising levels of consumption in transportation fuel, has been strongly implicated in food price increases and food price volatility most recently seen in 2008 and 2011-2012. First-generation biofuels, made from agricultural crops, divert food directly to fuel markets and divert land, water and other food-producing resources from their current or potential uses for production of feed for animals and food for human consumption. A key policy driver of biofuel consumption is government mandates to increase or maintain rates or levels of biofuel blends in transportation fuel, the U.S. Renewable Fuel Standard and the E.U. Renewable Energy Directive being the most prominent cases. In this paper we assess the spread of such mandates and targets, finding that at least 64 countries now have such policies. We estimate the consumption increases implied by full implementation of such mandates in the seven countries/regions with the highest biofuel consumption, suggesting a 43% increase in first-generation biofuel consumption in 2025 over current levels. We compare this to even higher estimates from international agencies. We assess the likelihood of implementation in key countries and regions, which suggests that with reform, particularly in OECD countries, consumption growth could be slowed. We conclude with policy recommendations to reduce the mandate-driven expansion of first-generation biofuels and mitigate their negative social and environmental impacts.

Keywords: biofuels, agriculture, food policy, hunger, land use.

Mandating Food Insecurity:
The Global Impacts of Rising Biofuel Mandates and Targets

Timothy A. Wise and Emily Cole*

Executive Summary

Expanding demand for biofuels, fed significantly by government policies mandating rising levels of consumption in transportation fuel, has been strongly implicated in food price increases and food price volatility most recently seen in 2008 and 2011-2012. First-generation biofuels, made from agricultural crops, divert food directly to fuel markets and divert land, water and other food-producing resources from their current or potential uses for production of feed for animals and food for human consumption.

A wide range of international bodies, including the World Bank, the United Nation's Committee on World Food Security, and a landmark report prepared by G20 countries, has called for reforms to government policies that encourage the continued expansion of first-generation biofuel production. Unlike second-generation biofuels, which are less likely to compete with food crops for land and other resources, first-generation biofuels such as corn ethanol, soy and palm biodiesel, and sugarcane ethanol dominate the current global biofuels market.

In this paper, we document the global spread of the most widespread government support policies for biofuels: consumption mandates, with a particular focus on first-generation biofuels. These policies generally mandate the incorporation over time of a rising share or volume of biofuel into a country's transportation fuel. The U.S. Renewable Fuel Standard (RFS) is one such example, as is the European Union's (EU) Renewable Energy Directive (RED). Sixty-four countries now have biofuel mandates that reflect a wide range of ambition but that all encourage the use and usually the expansion of biofuel use.[1]

We show the current national and regional mandates (focusing on first-generation biofuels mandates) in place at this writing, assess the extent of their implementation based on available data, and estimate to the extent possible the implications of likely implementation. Using a range of projections from international agencies for comparison, we gauge the extent to which current mandates will expand future levels of biofuel consumption and production by 2025.

We find that the projected expansion of biofuels, and the resulting demands on food, land, and water, is indeed worrisome. Today we live in a world where two[2] to three[3] percent of transportation fuel is accounted for by biofuels (depending on the source one uses). Biofuels in the largest biofuel-producing countries, such as the United States and Brazil, comprise approximately 9% and 22% of gasoline and diesel blends consumed in each country, respectively, while most other countries' fuel supplies contain smaller percentages of ethanol and biodiesel.

* Timothy A. Wise is the Director of Policy Research and Emily Cole is a Researcher with the Global Development and Environment Institute at Tufts University. They would like to thank Sheila Karpf for her invaluable editorial assistance. The paper benefited from review by several experts, who remain nameless here. All errors are, of course, the responsibility of the authors.

The most commonly cited scenario from the International Energy Agency (IEA) projects a 150% increase in first-generation biofuel use by 2035. The agency estimates that 8% of transportation fuel (by volume) would come from biofuels,[4] with four-fifths of this expected to come from first-generation sources and just one-fifth from the assumed development of cellulosic ethanol and other second-generation biofuels produced from feedstocks that result in less competition for food and land.[5] IEA thus estimates that roughly 6% of transportation fuel would come from first-generation biofuels in 2035.[6]

Other international agencies estimate lower rates of expansion, and those are more consistent with our estimates based on current mandates and targets. The Organization for Economic Cooperation and Development and the UN Food and Agriculture Organization (OECD/FAO), for example, suggest a 50-60% increase in ethanol and biodiesel consumption over the next ten years.[7]

According to our estimates of global mandates for seven major biofuel-consuming countries (the United States, EU, Brazil, Argentina, China, India, and Indonesia), first-generation biofuel consumption could be expected to grow 43% over its current levels if existing mandates are fully implemented. This means the world would be blending 3-5% of first-generation biofuels into domestic fuel supplies by 2025.

These estimates are indeed worrisome, though they fall well short of the IEA estimates of a world with 8% of transportation fuel being derived from biofuels. This should bring little comfort to those concerned with the food, feed, land, and water demands of continued first-generation biofuel development. A 43% increase over current levels would likely require 13-17 million hectares more land than we are currently already devoting to biofuel production and approximately 145 billion more liters of water (assuming biofuels production requires roughly the same amount as current U.S. corn ethanol production).[8] A more detailed quantitative assessment of these impacts is much-needed to evaluate the specific impacts in different regions and countries under different scenarios.

What's more, the policies (and data) remain uncertain in several large developing countries, most notably China and India. We have good reason to believe that both will experience relatively limited expansion of first-generation biofuel use, but any large-scale commitment to first-generation biofuel development in these countries would have a dramatic and devastating impact, whether the feedstocks or fuel are sourced domestically or imported.

In addition, we find:

Mandates Are Key Drivers

- The number of countries with consumption mandates has risen to 64 and is continuing to grow.
- OECD mandates will continue to be the real drivers of biofuels demand, with the United States and the European Union projected to account for roughly 60% of global biofuel consumption in 2025, and nearly 50% of projected new biofuel consumption.
- Most mandates are based on percentage shares of consumption, rather than volumes as in the United States. The mere growth in demand for transportation fuels, due to economic growth

and the rise in the prevalence of private automobiles, particularly in large, fast-growing developing countries, can be expected to account for a 16% rise in biofuel consumption over current levels.
- An oversupply of palm oil production in supplier countries like Indonesia, partially caused by EU mandates, has contributed to more ambitious consumption mandates in Indonesia.[9] Indonesia shows the most ambitious targets and the most dramatic growth in first-generation biofuel consumption among developing countries, contributing to an already-serious deforestation problem.
- Full implementation of mandates is by no means certain. In India, for example, ethanol targets were recently scaled back from 20% to 5% because the country has lagged in sugar production to provide the necessary feedstock. India is now blending only about 2% ethanol into its transportation fuel supply. India also has a 20% biodiesel target, but there is good reason to doubt it will meet such a goal.[10]

Trade is a Major Driver
- Brazil is a major producer and consumer. Economic growth will drive rises in domestic consumption, but ethanol exports are also expected to increase depending on market and trade conditions. The United States is also seeking to expand its ethanol exports.
- Mandates are driving growing ethanol trade, in perverse ways. Brazilian sugar ethanol is imported by the United States to fulfill its mandates for advanced biofuels, while the United States has sometimes exported corn ethanol to Brazil to make up for losses to the Brazilian domestic market.
- Prior to Dec. 2011 when the U.S. ethanol tax credit and tariff were eliminated, Caribbean Basin Initiative (CBI) countries received preferential treatment in the U.S. ethanol market. The Central American Free Trade Agreement allowed Brazilian ethanol to be dehydrated in CBI countries and then exported to the United States.[11]

Significant Technological and Policy Uncertainty
- China is the biggest wild card in these projections. With a mandate that covers just nine provinces now, China is blending only 1.1% biofuel into its transportation fuels, and that is not expected to grow appreciably. The government has been sensitive to the food-fuel competition in its policies to date, but the country’s demand for transportation fuel is projected to grow dramatically, creating strong incentives for the government to promote consumption. Any expansion of China’s biofuel consumption would have global repercussions, particularly if China relies on imported feedstock or fuel to meet such mandates.
- The emergence of potentially more sustainable non-food-based, second-generation biofuels and implementation of sustainability standards could alter these estimates considerably if the technology and commercial applications proceed more quickly than currently projected. Public research and incentives for second-generation biofuels may help jumpstart the industry beyond its current small scale, but much is still unknown.
- Second-generation biofuels could be no better than first-generation fuels if they displace land or other resources from other productive uses.

Recommendations

Our analysis suggests the need for governments to cease the implementation and expansion of current food-based biofuels consumption mandates and to forgo the creation of new mandates. Mandates prop up demand for biofuels, particularly at times when oil prices are relatively low. Governments and international bodies should also eliminate perverse incentives such as biofuels subsidies for first-generation biofuels that impact the food supply.

Proposed reforms to U.S. and EU mandates are welcome and needed. The EU proposal to limit first-generation biofuels to 7%, within the EU's 10% mandate, would reduce the EU's contribution to global biofuel expansion by 50%.

The United States would do well to consider similar reforms. The United States is expected to remain by far the largest global consumer of first-generation biofuels in 2025, contribute the most to global consumption, and do so using the feedstock – corn – that provides the fewest environmental benefits and most directly competes with food and feed markets. Even a modest reform, such as that proposed by the Environmental Protection Agency in 2013 to scale back the mandate, would reduce projected consumption growth in 2022 by one-third.

Mandates must be scaled back further, and strict sustainability criteria must be applied to mandates for both first and second-generation biofuels. Otherwise, governments are mandating not just biofuel consumption but hunger and unsustainable resource use.

The full paper is available at:
http://www.ase.tufts.edu/gdae/policy_research/BiofuelMandates.html

I. Introduction

Expanded demand for biofuels, fed significantly by government policies mandating rising levels of consumption in transportation fuel, has been strongly implicated in the recent rise and volatility in global food and feed prices.[12] First-generation biofuels, made from agricultural crops, divert food directly to fuel markets and divert land, water and other food-producing resources from their current or potential uses for production of feed for animals and food for human consumption. First-generation biofuels produced from input-intensive and food-based crops have been tied to food and feed price increases, increased greenhouse gas (GHG) emissions for certain fuels, land rights disputes in developing countries, conversion of native grasslands and wetlands to biofuels crops, and other unintended consequences.[13]

Unlike some second-generation biofuels, which are less likely to compete with food crops for land and other resources, first-generation biofuels such as corn ethanol, soy and palm biodiesel, and sugarcane ethanol dominate the current global biofuels market. When the biofuels industry was in its infancy, its proponents promised that second-generation biofuels would come on line in a few years and food versus fuel concerns would wane as perennial grasses, agricultural residues (such as corn stalks or cobs), and wood residues would be used for cellulosic ethanol production.[14] However, cellulosic ethanol production is failing to reach large-scale commercial production, and hence, biofuels produced around the world are failing to meet high levels of GHG emissions reductions that were once promised. New estimates suggest, for instance, that corn ethanol production in the United States may actually contribute to greater carbon emissions than gasoline.[15]

The biofuels industry seeks additional expansion of both first- and second-generation biofuels production. Agribusinesses and biofuels lobbying organizations have pushed for biofuels expansion in countries that currently have large biofuels mandates – most notably Brazil, the European Union (EU), and the United States – and in others where biofuels mandates have yet to be filled or greatly scaled up such as in India and China.[16]

In this paper, we document the global spread of the most widespread government support policies for biofuels, consumption mandates. Sixty-four countries now have biofuel mandates that reflect a wide range of ambition but that all encourage the use and usually the expansion of biofuels.[17] These generally mandate the incorporation over time of a rising share or volume of biofuel into a country's transportation fuel.

The three largest mandates include the U.S. RFS, Brazil's ethanol and biodiesel mandates, and the EU's RED. U.S. demand for ethanol has expanded drastically since 2007, partially a result of subsidies and the RFS mandate but also its use as an oxygenate additive as a replacement for lead. The mandate rose from 11BL a decade ago to nearly 53BL today. Brazil, a country with the oldest global ethanol mandate of 25% ethanol (E25), consumed 24BL of ethanol in 2014.[18] Responding to recent concerns about food vs. fuel, the EU proposed a cap on the amount of biofuels that can be derived from food crops at 7%, out of its 10% biofuels mandate, by 2020. The EU currently consumes about 19BL of biofuels, and most member states will expand consumption further to meet both the 7% proposed food-based biofuels cap and the 10% overall mandate.

We show these and other national and regional mandates in place at this writing, assess the extent of their implementation and likelihood of fulfillment based on available data, and estimate to the extent possible the implications of implementation on global land availability and water use. Using a range of projections from international agencies for comparison, we gauge the extent to which current mandates will expand future levels of biofuel consumption and production by 2025.

Today we live in a world where two[19] to three[20] percent of transportation fuel (depending on the source one uses) is comprised of biofuels. Biofuels in the largest biofuel-producing countries, such as the United States and Brazil, comprise approximately 9% and 22% of gasoline and diesel blends consumed in each country, respectively, while most other countries' fuel supplies contain a smaller percentage of ethanol and biodiesel.

The most widely cited scenario from the International Energy Agency (IEA) suggests a 150% increase in first-generation biofuel use by 2035, with 80% derived from non-cellulosic fuel.[21] This demand increase would mean that the world's transportation fuel supply would be comprised of 8% biofuels in 2035, with 6% from first-generation biofuels.[22]

Other international agencies estimate lower rates of expansion, which are in line with our estimates of demand growth. The Organization for Economic Cooperation and Development and the United Nation's (UN) Food and Agriculture Organization (OECD/FAO), for example, suggest a 50-60% increase in ethanol and biodiesel consumption over the next ten years.[23] Considering current levels of implementation of existing mandates and projections from these and other institutions, it is clear, even with the most conservative estimates, that first-generation biofuels production and consumption will grow significantly over the next one to two decades with significant implications for the environment, food prices, and the livelihoods of people around the world.

II. Background

Biofuels include all fuels made from organic matter. In this paper, we focus on biofuels that can be used for transport, specifically ethanol and biodiesel, and more specifically so-called first-generation biofuels, which are made from food or feed crops. While many of the concerns presented in this paper are equally true of biomass used for electricity production, biomass has not been explicitly included in our estimates and analysis.

A biofuels feedstock is the organic material that is used to make the ethanol or biodiesel. Different countries produce and consume biofuels from different feedstocks with different environmental and social impacts. The principal feedstock in the United States is corn for ethanol. In the EU it is biodiesel made from vegetable oils such as palm oil. Brazil relies on sugar for ethanol. While every feedstock may have an appropriate use, at high volumes they all can have unintended consequences, especially those that are in limited supply. For example, used cooking oil is a feedstock for European biodiesel, which would otherwise go to waste. But heavy demand for used cooking oil is increasing demand for virgin cooking oil such as from African palm, in effect feeding a competition between fuel and food.

Biofuels: Defining Terms

The terms "first- and second-generation biofuels," "conventional ethanol," "advanced biofuels," and "cellulosic ethanol" are used throughout this paper. Below is a definition of each as it is used here:

First-generation biofuels: ethanol and biodiesel produced from crops such as corn and sugarcane (for ethanol) and palm oil, soybean oil, rapeseed oil, used cooking oil, and other vegetable oils (for biodiesel), which are largely also used as food and feed crops. These biofuels have been produced for decades, especially in the case of Brazil with sugarcane ethanol and the United States with corn ethanol.

Second-generation biofuels: ethanol or biodiesel produced from largely non-food feedstocks such as perennial grasses, wood and agricultural residues, algae, etc. While these could potentially result in less competition with the food supply, second-generation biofuels have yet to be produced at large commercial scales so their effects on land use, water supplies, food security, and GHG emissions are still little known.

U.S. Renewable Fuel Standard categories: The U.S. RFS, enacted in 2005 but expanded in 2007, mandates that the U.S. fuel supply contain 138 billion liters (BL) of biofuels from three different biofuels categories by 2022. Note that these categories differ from those of first- and second-generation biofuels listed above, meaning that even though our analysis focuses on first-generation biofuels, the United States considers some first-generation biofuels such as sugarcane ethanol to qualify as an "advanced" biofuel. Terms used in the U.S. case include the following:

- **Conventional ethanol:** the "renewable fuel/conventional ethanol" category in the RFS requires ethanol to meet a 20% GHG reduction threshold although most facilities were grandfathered into this category, meaning they may actually *increase* GHG emissions; conventional ethanol is mostly comprised of corn ethanol.
- **Advanced biofuels:** biofuels that meet a 50% GHG reduction threshold; types of approved advanced biofuels include soy biodiesel, biodiesel from other vegetable oils and animal fats, cellulosic ethanol (see below), and sugarcane ethanol.
- **Cellulosic ethanol:** cellulosic biofuels that meet a 60% GHG reduction threshold and are derived from cellulosic feedstocks such as perennial grasses and wood or agricultural residues.

In 2011, the global biofuels market was worth $83 billion—roughly the size of the world coffee market.[24] The global biofuels market tripled between 2000 and 2007.[25] More recently, between 2009 and 2011 the market doubled again.[26] Today 2-3% of global transportation fuel is from biofuels.[27] A global commodity, biofuels is heavily traded across the globe with some countries both exporting and importing biofuels.

Social and Environmental Costs

Sizeable percentages of food crops are diverted to biofuels production now and will continue to be diverted in the future, with implications for food security. According to FAO-OECD projections, by 2023, 12% of maize and other coarse grains will go to biofuel production, while 14% of global vegetable oils will be used to produce biodiesel; for sugar, 28% will go into the production of transportation fuels.[28] During the recent 2008 food price crisis, 20-40% of the food price increases were attributed to biofuels.[29]

An October 2012 GDAE/ActionAid report found that corn-importing countries paid $11.6 billion in higher corn prices due to U.S. ethanol expansion from 2006 until 2011, $6.6 billion of which was borne by developing nations where much of the population already spends 60-80% of their income on food.[30] A May 2012 GDAE/ActionAid report estimated additional import costs to Mexico in particular, in the form of higher corn prices due to U.S. ethanol expansion, of at least $1.5 billion since 2004. Increased corn prices reduce purchasing power for consumers and can offset international aid dollars sent to developing countries for food and agricultural programs.[31]

Many international agencies have called for reforms to government policies that encourage the continued expansion of first-generation biofuel production. In 2008, the former head of the World Bank, Robert Zoellick, called on countries to reform biofuels mandates due to negative impacts on food security.[32] In 2011, a report commissioned by G20 agricultural ministers, recommended that countries "remove provisions of current national policies that subsidize (or mandate) biofuels production or consumption," acknowledging that biofuels production was a significant factor in increased food prices and food price volatility.[33] And in 2013, the UN Committee on World Food Security's (CFS) High Level Panel of Experts report on biofuels noted that "biofuels and more generally bioenergy compete for land and water with food production"; it recommended an additional set of guidelines be created to evaluate the viability of national biofuels policies based on the impact of said policies on access to land and on international food security.[34]

The environmental benefits of biofuels have also been called into question. Land used to grow biofuels crops is often converted from non-food uses, such as forests, adding to the environmental issues associated with deforestation. In Indonesia, for example, overall forest losses (due partly to palm oil expansion) have been projected as high as 6 million hectares from 2000 to 2012.[35] A recent study from the journal *Nature Climate Change*, estimated that by 2012 Indonesia was losing primary forests at a rate of 840,000 hectares per year, higher than losses in Brazil. (The Indonesian government, however, has reported significantly lower rates of deforestation to the UN – approximately 400,000 hectares annually between 2009 and 2011.)[36] As the World Resources Institute notes, "although the evidence of destruction is mounting, the picture has been muddied by conflicting data, disinformation, claim and counterclaim."[37] The Rainforest Action Network reports that Indonesia is the "third largest emitter of global warming emissions after China and the United States, with 85% of its emissions profile coming from deforestation and drainage of peatlands [of which palm oil is a major driver]."[38]

Two of the original goals for biofuel development in the EU and United States in particular were to increase energy independence and to reduce GHG emissions in the transportation sector. The case for each has gotten weaker over time. As one IEA study puts it, "It is increasingly understood that 1st–generation biofuels (produced primarily from food crops such as grains, sugar beet and oil seeds) are limited in their ability to achieve targets for oil-product substitution, climate change mitigation, and economic growth."[39] In 2011, the National Academies of Science concluded that first-generation biofuels such as corn ethanol are failing to significantly reduce GHG emissions in part due to indirect land use change, and that cellulosic ethanol production in the United States is unlikely to reach a large commercial scale due to technological and economic challenges.[40]

Other first-generation biofuels may result in GHG emission reductions, but figures vary primarily due to different calculations of emissions from indirect land use change. For instance, when corn in the United States is diverted from the feed supply to biofuel production, for instance, additional feed crops must be produced elsewhere which can lead to farmers tearing up native grassland and draining wetlands to create more arable farmland. Cropland dedicated to other food and feed crops (oats, barley, alfalfa, etc.) has decreased in countries such as the United States, Guatemala, and Brazil as demand for corn, sugar, and soybean cropland rose over the past several years.[41]

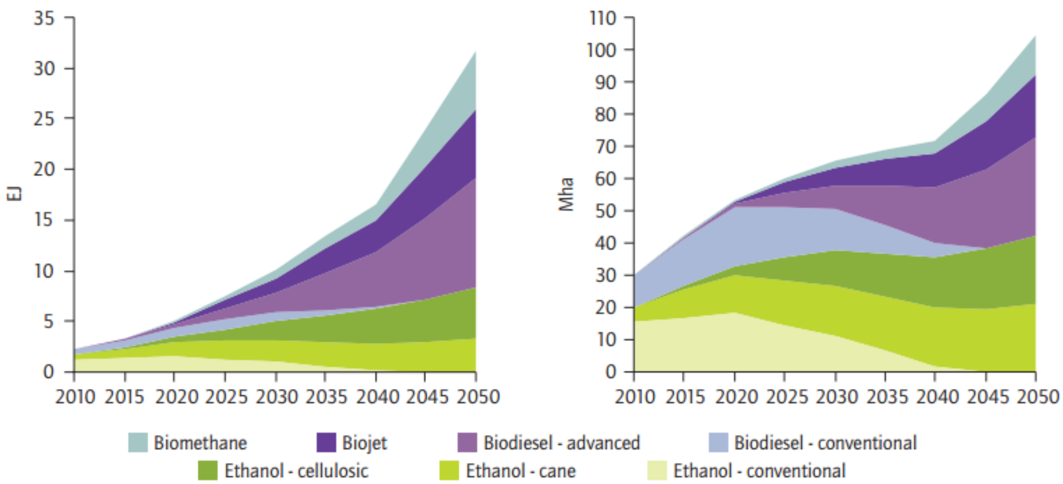
Cellulosic biofuels, a specific type of second generation biofuel, may offer significant GHG benefits and could have more limited impact on land use. Cellulosic biofuels are also expected to lead to fewer food-versus-fuel impacts associated with first-generation biofuels. However, some next-generation biofuels recently proposed in the United States, such as corn biobutanol, would still be produced from food-based crops. Second-generation technologies are under development, and they are not expected to be commercially viable in a significant way by 2025.[42]

Even organizations that are bullish on the use of biofuels, such as the IEA, recognize the land demands for their future biofuels scenarios. Each exajoule (EJ, 10^{18} joules, a unit of energy used at the industrial production level) of energy created requires about 10 million hectares of land. (See Figure 1)[43] It is worth noting that the land-intensity estimates even for second-generation biofuels remains significant (about 3 million ha/EJ), raising questions about their sustainability.

Estimates vary, but according to the FAO, an estimated 2-3% of arable land is devoted to biofuels production.[44] FAO estimates "an equivalent of 20.4 million [hectares (ha)] of sugar cane, or 38.5 million ha of corn, or, if it were biodiesel, 58.8 million ha of rapeseed" are now used in biofuels production worldwide.[45] In the developed world and emerging economies, the energy and land use investments in biofuels vary dramatically. For example, in the United States, 37% of the corn crop is diverted to ethanol production (but one-third of this corn ends up as livestock feed via a by-product called distiller's grain).[46] In the UK in 2011, 1.8% of all farmland was dedicated to growing crops for ethanol,[47] but it also relied upon imported biofuels and biofuel feedstocks from other countries to meet its mandate.

Figure 1[48]

Figure 11: Demand for biofuels (left) and resulting land demand (right) in this roadmap



Note: This is gross land demand excluding land-use reduction potential of biofuel co-products. This assumes 50% of advanced biofuels and biomethane are produced from wastes and residues, requiring 1 Gt of residue biomass. If more residues were used, land demand could be reduced significantly.

Source: IEA analysis based on IEA, 2010c and Table 2 below.

In developed countries and in emerging economies, biofuels production may cause relatively little social disruption, environmental and land use implications aside. In the developing world, however, the demands of biofuels production are much more likely to disrupt the local population and economy.[49] In some countries, such as India and Thailand, there is already great pressure on cropland. Expanding biofuels production in these countries, from any feedstock, would have additional impacts on land use. Countries such as Brazil have systems in place to reduce direct and indirect land use change.[50] However, these systems have not necessarily been effective since soybeans have instead been planted in areas with restrictions on new sugar plantations.

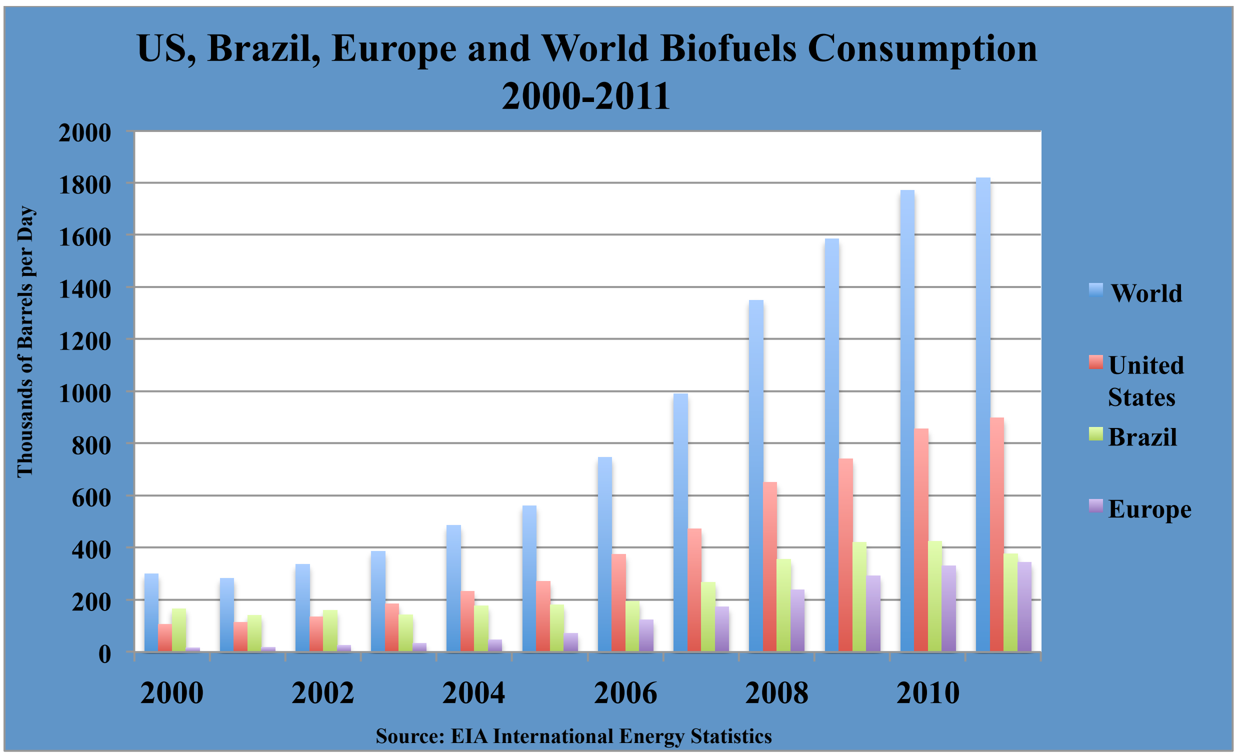
In other countries such as Ethiopia where there are already large-scale land acquisitions and significant displacements of people due to foreign investments in land projects and "villagization," large-scale biofuels projects are yet another threat to rural communities' livelihoods, food security, and human rights. (See Appendix C for list of existing and planned biofuels projects in Ethiopia). In other African countries such as Tanzania, the land rush for biofuels and other agricultural production has resulted in vast tracts of land being sold or leased to commercial interests, many of which are large multinational biofuels companies or agribusinesses aiming to export biofuels to the EU and other countries with large biofuels mandates. Local communities lose land previously used for farming, animal grazing, fishing and gathering wild foods, as well as for wood and water collection, when land deals prioritize investors and outside interests over local livelihoods.

Key Players

While 64 countries have biofuels mandates or targets, global production and consumption of biofuels is driven principally by a few countries. The United States is responsible for 43% of global production of biofuels.[51] Brazil, the second largest producer, provides 26% of global production.[52] Germany (4.9%), France (3.9%), and Spain (2%) round out the top five biofuel producers.[53]

OECD countries are the largest consumers of biofuels and drive biofuels production within their own borders and across the world.[54] As Figure 2 shows, biofuels consumption has increased dramatically since 2000. By 2011, world use had increased 500% with the largest increases coming in the United States.

Figure 2[55]



Focus on Mandates

While subsidies have also played a large part in the development of biofuels industries, the primary focus of this paper is biofuels mandates, as they are the primary government support across countries. Mandates provide security for investors knowing a market for their goods will continue over their investment period, and they drive the development of fuel distribution networks, such as the blending of ethanol into gasoline and its storage and dispensing at fueling stations.

Mandates can take one of two forms. The first, a consumption mandate, requires a certain volume of biofuels to be blended with gasoline and diesel each year. This is the type of mandate that exists in the U.S. RFS.[56] The more common form of mandate requires that a certain percentage of transport fuel consist of ethanol or biodiesel. This is the form of mandate used in the EU[57] and most other countries.

Countries have pursued biofuels policies for many seemingly worthwhile goals:

- Promoting energy security
- Reducing dependence on fossil fuels
- Supporting rural communities, smallholder farmers and rural development
- Reducing GHG emissions and accessing a low-carbon transportation fuel (particularly the EU)
- Improving the nation's trade balance or balance of payments by reducing oil imports
- Promoting national self-sufficiency

In the OECD, these policies were mainly crafted in the early 2000s. In hindsight, mandates were overly optimistic with respect to technical, infrastructure, and market challenges. It is now apparent that biofuels mandates failed to predict future negative impacts on land use, GHG emissions, food security, and rural communities. GHG emissions reductions have been found to be more limited than first thought, indirect land use changes are now understood to be significant, and with high crop prices in 2011-2012 farmers and consumers alike have dealt with higher and more volatile crop and food prices. In the EU and United States in particular, these changes have led to recent proposed policy reforms and ongoing debate over the value of biofuels use.

In other countries, the motivating factors above remain strong. For some countries, such as South Korea, the world's fifth largest oil importer, the pressure to diversify its energy mix for security and economic reasons may outweigh the higher cost and social and environmental impacts of biofuels consumption.[58] Indonesia is a similar story.

Many developing countries have followed the OECD's lead in instituting biofuels mandates. These countries have pursued biofuels policies to show their commitment to fighting climate change and advancing energy security, but also to spur rural development, support the agricultural sector, and move up the agricultural value chain. In addition these policies provide subsidies for particular industries (sugar in India, for example). In Southeast Asia, Malaysia and Indonesia have recently increased domestic biofuels mandates to counteract deteriorating export opportunities as a result of anti-deforestation policies taken by buyers such as the EU. Utilizing more palm oil for biofuels increases demand for the feedstock, increases farm-gate prices, and reduces the amount of diesel that must be imported for consumers. Countries have looked to biofuels both to reduce their dependence on expensive foreign oil but also to create an export industry that could help provide a source of foreign exchange.

The notable exception to this typology is Brazil, the country with the oldest and most fully developed biofuels sector. In the 1970s, Brazil invested heavily in producing ethanol from sugar cane in response to high international oil prices, leading to its position as a leader in the biofuels market, particularly for ethanol.[59]

From biofuels producers to large landholders, every country producing biofuels has much at stake if biofuels mandates are reduced or eliminated, although some biofuels would still be blended (for use as an oxygenate, for instance). This is widely seen as one of the reasons biofuels policies have been so slow to respond to high crop prices and social and environmental concerns.

Government Supports for Biofuels

Major biofuel-producing countries – including Brazil and the United States - have relied on mandates and subsidies to build their biofuels industries. These incentives span the supply chain, from feedstock production to final blending of biofuels with gasoline or diesel. European biodiesel is also subsidized, and cost-competitive because of the significantly higher cost of gasoline in the EU. In France, the estimated cost of biofuels subsidies for 2011 only was between €170 million and €210 million for ethanol and almost three times that amount for biodiesel—between €612 million and €800 million.[60] But it is also the case that in other markets like Indonesia, the drain on national budgets from fossil fuel subsidies makes the mobilization of homegrown feedstocks – in this case, palm oil – a more attractive proposition. Fossil fuel subsidies themselves distort markets, and layering biofuels subsidies on top of them creates large national expenditures and several unintended consequences as certain fuels are prioritized over others.

As the IEA has noted about the rise of biofuels, "The rapid growth of the biofuels industry would not have been possible without government subsidies because many biofuel producers, especially in developed countries, are not cost competitive."[61] The story of biofuels expansion is, therefore, a story of subsidies and mandates. Using the United States as an example, its ethanol and biodiesel industries were propelled by decades of subsidies for production and blending with gasoline and diesel, import tariffs, and the RFS mandate which was enacted in 2005 but greatly expanded in 2007. While the largest tax credits for ethanol and biodiesel have expired, the biodiesel and cellulosic tax credits and other credits such as those for biofuel infrastructure investments are routinely extended, and other smaller supports in various government agency programs continue to prop up the industry.

III. International Biofuels Production and Consumption Estimates

Before presenting our assessment of current mandates and what they would mean for global biofuel demand, we present some of the most important projections from international organizations. They vary in their assumptions, methodologies, and time horizons, but all confirm that we are likely to see significant expansion in biofuel consumption for at least the next ten years. The estimates range from a low of 50-60% growth in demand by 2023, to a high of 150% by 2035. Below, we examine estimates from the International Energy Agency (IEA), the OECD/FAO's Agricultural Outlook, and the U.S. Energy Information Agency (EIA).

Each agency makes assumptions about the key drivers of biofuel demand, both in terms of government policies and market-based factors. All attempt to incorporate announced government policies, though it is difficult to keep up with the ever-changing policy environment. Any projections of 10-20 years into the future will be sensitive to assumed growth rates in key drivers, and such differences in assumptions explain the variation in these estimates.

Transportation fuel demand will be a primary driver of biofuels consumption, especially in fast-growing developing countries such as China and India, but also in areas with mandates for biofuels blending by percentage of transportation fuel. (The blending percentage can stay the same but the effective demand increases with the growth in the market unless fuel efficiency increases, thus reducing the level of fuel demand.) This consumption will be driven by:

- *Population Growth*: with economic growth and economic growth, population growth, especially in emerging markets, will be a key driver of transportation fuel demand.

- *Economic Growth (world, nation, per capita)*: as countries become more affluent, they drive more, demanding more transportation fuel.

- *Number of Miles Driven*: While the United States does not serve as a good model for the rest of the world, recent reductions in number of miles driven show the uncertainty in predicting future patterns of consumption.

- *Fuel Efficiency Standards and Vehicle Technological Change*: changes in transportation technology such as hybrid cars, electric cars, E15- and E85-ready cars and increased fuel efficiency standards will also affect demand. Radical, global change in fuel efficiency could temper demand growth. Consumer uptake of E15, E85, and other higher ethanol blends, stations offering higher blends of ethanol, and availability of flex fuel vehicles also affects consumption, particularly in the United States

- *Broader Energy Markets:* decisions made about broader transportation planning affect demand, including reliance on electrification, commitments to mass transit, and alternative forms of transport.

Other key drivers of biofuels demand include:

- *Oil Prices*: when deciding whether or not to substitute some petroleum consumption with biofuels, the relative prices of these goods is paramount. As petroleum prices are notoriously difficult to predict, oil prices in particular may pose a problem for complex modelers looking several years in the future. In addition, petroleum is an input for first generation biofuel feedstock that is grown with petroleum-based fertilizers. As an input, as oil prices increase, the price of biofuels may also rise. The effect on their relative prices will be a key biofuels demand driver, factoring in subsidies and mandates, which affect prices.

- *Food and Fiber Prices*: like oil prices, the prices of food and fiber will determine whether or not biofuels consumption is economically viable. First generation biofuels are not only competing with food and fiber for land, fertilizer and water, but are produced from food and feed products themselves.

- *GHG Emissions Pricing Schemes*: in the estimates cited here from the IEA, EIA and OECD/FAO, carbon markets and the assumption of a carbon savings from biofuels are key to their continued expansion.

- *Speed of Technological Change in Biofuels*: technological changes and commercial adoption of these technologies are built into IEA and other models projecting increased demand. For years, the biofuels industry promised cellulosic fuels would be commercially viable, but they have been slow to develop due to technological and economic challenges. In the U.S. 2007 energy bill, for instance, policymakers mandated 6.65BL of cellulosic ethanol to be blended with gasoline in 2014, but only 65 million liters (barely 1% of the mandate) are expected to be produced. Whether and how quickly such industries develop will determine a great deal about first-generation biofuel growth.

International Energy Agency Projections

The International Energy Agency (IEA) makes several energy consumption estimates in its *World Energy Outlook* each year. The estimates below are drawn from its 2013 report. The IEA uses three policy scenarios to make its projections.

1. *New Policies Scenario*: this is the most commonly cited set of global projected-demand numbers in research and policy circles. It models "cautious implementation of existing policies," meaning it accounts for policies that are currently in place and assumes the implementation of announced policies. [62] It is the scenario IEA believes reflects the most likely future.

2. *Current Policies Scenario*: this very conservative scenario considers only policies that were in place by mid-2013.

3. *450 Scenario*: the 450 Scenario considers "an energy pathway compatible with a 50% chance of limiting the long-term increase in average global temperature to 2 degrees Celsius."[63]

Biofuels consumption is assumed to increase based on economic and population growth, reductions in fossil fuels subsidies, and a modest increase in petroleum prices. In addition, all three scenarios assume a GHG benefit from biofuels use, although the importance given to GHG reductions as a demand parameter is different in each scenario. In these models, biofuels would have an added economic benefit in carbon trading schemes or with the enactment of a carbon tax making them significantly more price competitive with fossil fuels, although actual GHG emission reductions seen on the ground may differ from projections.

New Policies Scenario

The New Policies Scenario assumes an average rate of GDP growth of 3.6% per year until 2035.[64] It also assumes non-OECD GDP will surpass OECD GDP as early as next year,[65] with strong growth rates for China (5.7%)[66] and India (6.3%)[67] through 2035. Moreover, IEA assumes world population will reach 8.7 billion by 2035 and that 62% of the population will live in urban areas.[68] At the same time, this scenario assumes only modest increases in oil prices from \$110/barrel in 2011, \$113/barrel in 2020 and \$128/barrel in 2035.[69] More than 175 countries currently have fossil fuel subsidies, which the IEA sees declining in the next 20 years, making biofuels more economically competitive.[70] IEA also assumes that China will stick to its goal of reducing its dependence on coal and that India will meet its current 5% ethanol mandate and continue to blend 5% ethanol even as gasoline demand increases.

In line with industry and other academic and governmental predictions, IEA finds "the U.S., Brazil, EU and China make up more than 80% of biofuels demand."[71] By 2035, OECD countries will make up a little under half of biofuels consumption.[72] IEA predicts China will drive growth in biofuels until 2020 when consumption will be driven by India, whose population will be surpassing China and Southeast Asian countries.

The New Policies Scenario assumes an initial increase in energy demand of 1.6% per year, which slows after 2020 to an average of 1%.[73] In this scenario, therefore, there will be a 33% increase in total energy demand by 2035.[74] Energy demanded for "transport grows at an average rate of 1.3% per year over the projection period," with the majority of growth coming from non-OECD countries.[75]

Bioenergy investments are expected to outpace energy demand in aggregate and are thus expected to represent a larger share of total transport-sector demand by 2035. Specifically, IEA predicts a 1.5% annual increase in investments in bioenergy—both biofuels and biomass.[76] This growth is small compared to other renewables (7.3%),[77] but represents a dramatic and persistent increase in production. IEA expects biofuels production to account for only 5% of the increased investment in renewables.[78] However, projections on investment as opposed to production are highly speculative.

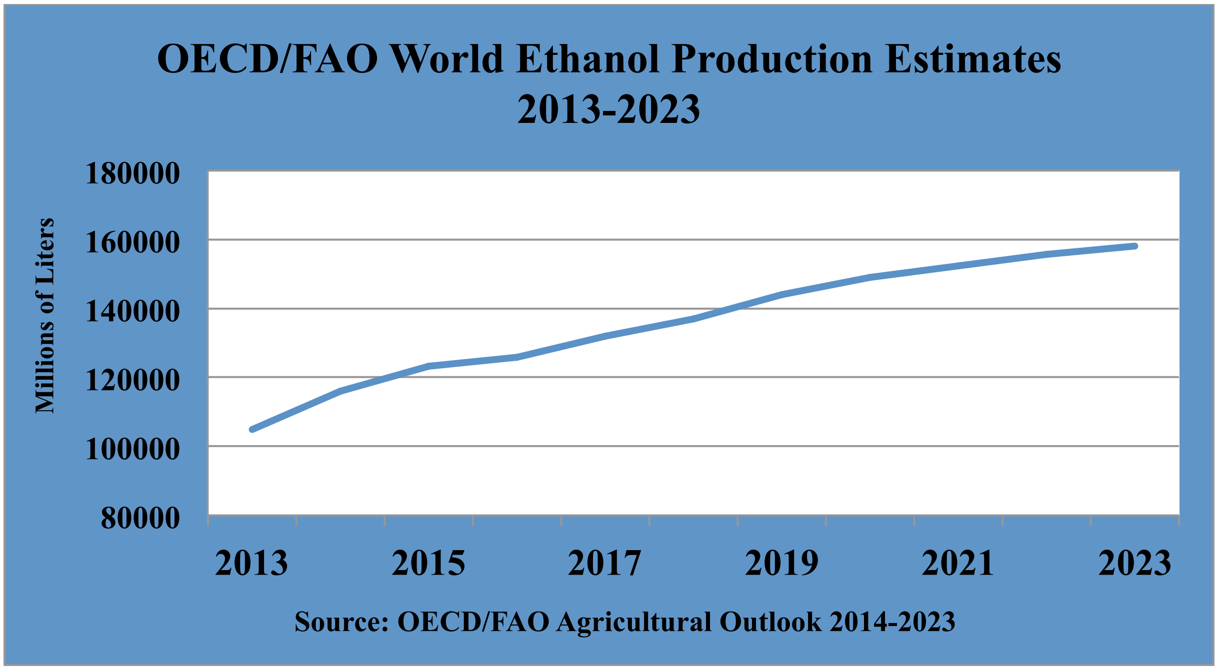
In terms of volumes, IEA predicts consumption of biofuels will increase from 1.3mboe/d in 2011 to 4.1mboe/d in 2035.[79] This aggressive projection predicts 8% of road-transport fuel demand in 2035 will come from biofuels.[80] Yet, they predict that*, even in 2035,* 80% of that fuel will still come from first-generation biofuels, with just 20% coming from cellulosic or other advanced fuels.[81] (Note that the IEA definition of "advanced" may not align with the RFS definition as IEA does not consider sugar ethanol to be advanced).

OECD/FAO Projections

The OECD, established in 1961 to "promote policies that will improve the economic and social well-being of people around the world," predicts an overall increase in global biofuels production but a smaller share in percentage terms represented by demand in OECD countries.[82] OECD countries include the world's richest and the top two biofuels producers in the world – the United States and EU – but also emerging countries like Mexico, Chile and Turkey. The OECD also works closely with emerging economies such as Brazil and those that may greatly influence biofuels markets in the future – China and India.[83]

The OECD, in its annual *Agricultural Outlook* report with the FAO, projects a 50% increase in world ethanol production between 2013 and 2023 with production jumping from 105BL to 158BL.[84] It also finds biodiesel consumption will rise from 26BL in 2013 to 40BL in 2023—a 54% increase over 2013 consumption.[85] The projected expansion in world ethanol production is shown below.

Figure 3[86]



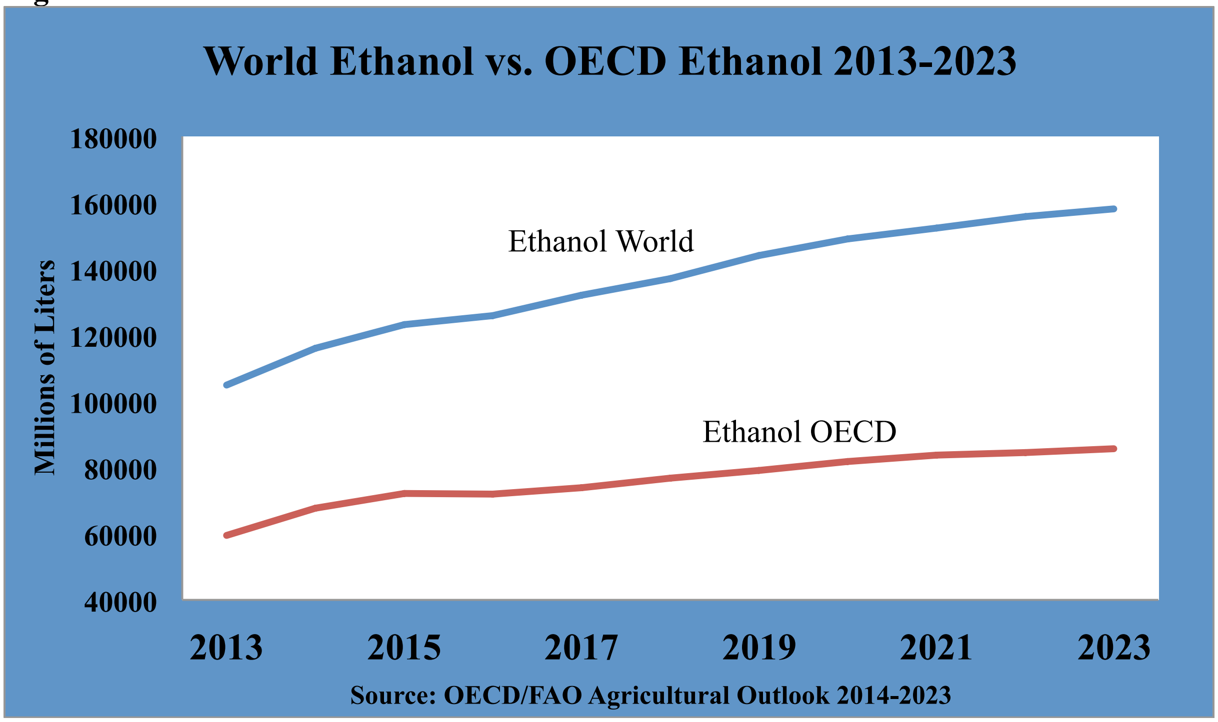
In addition, OECD/FAO predicts, "By 2023, 12%, 28% and 14% of world coarse grains, sugar cane, and vegetable oil production, respectively, are expected to be used to produce biofuels."[87]

While OECD countries dominate biofuels consumption today, the OECD/FAO report finds member states will play a less dominant role in the world biofuels market, as illustrated in the graph below. Brazil currently accounts for most consumption in Latin America, but it is Asia where OECD/FAO predicts biofuels will see the greatest growth, particularly in China and India.[88] Overall, OECD/FAO predicts that growth in ethanol production among developing countries from 45BL in 2013 to 71BL in 2023, will be mostly be driven by Brazil and its 25% ethanol mandate.[89]

OECD/FAO predicts U.S. ethanol use will be significantly restricted by the blend wall and will grow only marginally in terms of percentage consumption.[90] They assume only 12% of the U.S. cellulosic mandate will be implemented by 2023.[91] In addition, OECD/FAO considered political factors in its estimates, including the assumption that the biodiesel blender tax credit will not be renewed.[92] This political analysis is important in bringing predictions in line with political changes instead of assuming a continuation of current policy, although the biodiesel tax credit has typically been renewed.[93]

OECD/FAO's analysis of European demand assumes that current mandates will be fulfilled and carried forward at least through 2023. OECD/FAO finds further that the EU RED fulfillment percentage will be 8.5% accounting for allowable double-counting of GHG-reducing fuels (out of its mandate for 10% of transportation fuels coming from biofuels by 2020).[94]

Figure 4[95]



U.S. Energy Information Agency Projections

The U.S. Energy Information Administration (EIA) has arrived at very different projections from those of the OECD/FAO and IEA. EIA finds that world biofuels production will increase from 1.5 million barrels of oil equivalent per day (Mboe/d) in 2011 to 1.7Mboe/d in 2020, 2.7Mboe/d in 2035 and 3Mboe/d in 2040.[96] Similar to the other models, EIA sees OECD countries dominating production in the short term and non-OECD countries overtaking OECD output in the long term. The timeline for this change is much slower than the other models, however. In 2011 EIA has OECD countries producing 1.0Mboe/d and non-OECD countries producing only 0.5Mboe/d.[97] In this model, OECD and non-OECD countries do not produce equivalent amounts of biofuel (1.2Mboe/d) until 2030, and by 2040 non-OECD countries only lead OECD countries by 1.6Mboe/d to 1.3Mboe/d.[98]

Unlike the other two models, EIA does not see rapid growth in either China or India. While it predicts an annual percent change of 7.8% in India—a significant year over year increase—they find that India will not even produce 0.1Mboe/d by 2040.[99] EIA finds China will produce only 0.1Mboe/d by 2020, 0.3Mboe/d in 2035 and 0.4Mboe/d in 2040, but this growth still translates to a 300% growth rate from 2020 to 2040.[100]

IV. Country Mandates and Main Findings

Sixty-four countries now have biofuels mandates or targets.[101] The level of implementation varies dramatically among these countries, from fully implemented to just announced. Some countries have only begun to create a legal framework for biofuels blending (Mozambique), while others have been producing and consuming biofuels for decades (Brazil). While the background information underlying our analysis is static, our findings show a great deal of movement within biofuels targets and mandates with many countries recently readjusting their mandates or targets both up and down based on price and availability of ethanol and biodiesel in their markets as well as in response to other political, social, and economic objectives.

Mandates and targets range from a high of 25% ethanol blend in Brazil and Paraguay to a low of a 1% biodiesel mandate in Taiwan. The EU's RED has a 10% blending mandate by 2020, but if reforms are approved only 7% is expected to be derived from food-based feedstocks due to recent proposals in the EU to cap the use of crop-based biofuels. The United States has a volume-based mandate that is effectively 10% currently because only up to 10% ethanol can currently be blended into the existing vehicle fleet; the U.S. Environmental Protection Agency (EPA) has approved a 15% ethanol blend (E15) for newer vehicles, but consumers are unlikely to use E15 soon due to due to its incompatibility with older vehicles and small engines, in addition to engine warranty and liability concerns.

In Latin America and East Asia, mandates are much more likely to be tied to levels of production, while mandates in Sub-Saharan Africa and South Asia are largely aspirational. For example, India recently scaled back its 20% ethanol target to 5% and is likely to be at just 2.5% in 2015. India initially hoped to support local sugar production, but faced several hurdles in implementing its plan. An outlier is Zimbabwe, which has invested heavily in biofuels and has a 15% ethanol mandate because it faces economic and trade sanctions, leading to ethanol being more economical than regular gasoline.

With the notable exception of Brazil, countries such as the United States and members of the EU were some of the first countries to implement biofuels mandates. Today, many countries in the developing world, especially biofuels producers, also have biofuels mandates. Our research finds that countries in the developed world are much more likely to have implemented their biofuels mandates or have come close to meeting biofuels targets/mandates (United States, Canada, and Germany) than countries in the developing world (India, Nigeria, and Ethiopia). This reflects both the time countries have had to meet these mandates and secure supply, but also the difficulties of starting a biofuels blending program.

This developed-developing world divide masks, however, the important differences between countries with established and functioning biofuels production and those without. Even in the developing world—especially emerging-market countries—countries where biofuels production has already taken root are consistently meeting their current mandates (Colombia and Ecuador). For countries without the buying power of the OECD, the driving factor behind the implementation of their mandates is the success or failure of domestic production (Panama and Zimbabwe).

In many cases mandates attempt to track biofuels availability and domestic consumption. Indonesia's palm oil biofuels industry is the best example of this trend. It currently has a 5% biofuels mandate, with a target of 15% ethanol and 20% biodiesel by 2025, not only to support domestic production, but also to absorb local demand in part due to the EU proposing to cap food-based biofuels at 7% of volume.[102] In Colombia, the ethanol mandate is explicitly reliant on ethanol stocks and is either 8% or 10% depending on availability. This would also be true from a different angle in the United States if the EPA elected to waive the RFS mandate downward to reflect lower production of cellulosic ethanol.

Overall, there is great variety in mandates, with producers with excess capacity looking to expand their mandates and export biofuels, and importing and OECD countries leveling off their mandates either in terms of volumes or as a percentage of their total consumption due to various food-price, land-use, or environmental concerns.

Methodology

In the summary table below and in the more expansive tables in the appendices, we strive to present the most up-to-date information on whether biofuels volume mandates have been met and the primary feedstock being produced and/or consumed in these countries. As discussed later, there is very good data on biofuels production and consumption in OECD countries, but data are less complete in parts of the developing world and in countries that have recently adopted mandates.

Information has been compiled from industry, international and country reports, and U.S. Department of Agriculture (USDA) country reports. We have privileged the most up-to-date information in our search, but some of this information is a few years old. We have included information we were able to access through regular desk research methods. All of the information below and in the appendices is publically available.

The full list of countries and regions with biofuels mandates can be found in Appendix B. For purposes of analysis we divided the countries in the appendix into several categories, each of which has large consumers in the summary table:

- **OECD**, or developed countries such as the United States and EU, which mostly have 10% ethanol mandates and which mostly are moving toward those goals.

- **High-production countries meeting high mandates**, most notably Brazil and Argentina but also several other countries, such as Colombia and the Philippines.

- **High-production countries failing to meet high mandates or targets,** such as China, India, and Indonesia but also several other Asian countries such as Malaysia, Thailand, and Vietnam.

- Other **countries with aspirational mandates** or targets, with varying degrees of likelihood that they will meet them, such as Chile, Nigeria, and South Africa.

The majority of countries in the world do not have biofuel mandates or targets, and these include several large consumers. Most notable are large petroleum-producing countries such as Russia, Venezuela and the Persian and Arabian Gulf countries, although some of them import biofuels from countries such as Brazil and the United States. The United Arab Emirates is one of the largest importers of U.S. ethanol, for instance.[103] They see little need or value in developing domestic biofuel industries.

As the summary table of selected biofuels consumption mandates shows (Table 1), full implementation of existing mandates and targets would represent a 43% expansion of first-generation biofuels demand over current levels. We present the seven most important biofuels consumers, their mandates and/or targets, their current consumption levels as both volume and as a share of transportation fuel, the additional volume and share implied by full implementation, and the total volume adding in anticipated demand growth for transportation fuels. Added transportation demand contributes significantly (20% of the overall increase in demand) to the total projected biofuels volumes in the countries in which the mandates/targets are a percentage of fuel, but the United States is the notable exception here. (A version of the summary table, with additional notes on sources, can be found in Appendix A.)

Growth pathways could increase further if full mandates/targets are fulfilled, not just those for first-generation biofuels. For instance, we assume: (1) India fails to meet its 20% biodiesel target, which is unlikely in the short-run; and (2) the United States meets mandates for first-generation biofuels but not for cellulosic biofuels, meaning just over half of the mandate is included in this analysis. We assume the United States uses 76BL of first-generation biofuels (such as corn ethanol, soy biodiesel, and sugarcane ethanol) in its fuel supply by 2025, out of a total of 137BL required by the RFS in 2022.[†]

Other assumptions in the summary table analysis include the following:

- EU estimate includes double-counting for advanced fuels, so the effective demand increase from its 10% mandate is 8.6%.[104]
- Consumption numbers for Brazil are calculated based on its 25% ethanol mandate, the latest figures available.
- Argentina's transportation demand is calculated differently because USDA estimates a change in ratio of gasoline to diesel. Separate demand increases were calculated for gasoline and diesel, which have implications for ethanol and biodiesel use.
- China has both a 10% mandate and a 15% target, but only for nine provinces. We assumed China would meet its 15% target because past targets have systematically been met. China's transportation fuel demand growth rate in affected provinces is assumed to be the same as China's overall growth rate. Where uncertainty in current implementation of mandates exists, the midpoint of the range was used for calculations (e.g. China 8-12% current ethanol blend was calculated at 10%).

[†] We assume the U.S. meets its 57BL mandate for corn starch ethanol, 3.8BL mandate for biodiesel (which could be increased by the U.S. EPA), and that the remaining 15BL are met by imported sugarcane ethanol (total of 76BL). We assume the remaining 61BL, mandated to be filled with cellulosic ethanol, a second-generation biofuel, are not produced due to technological and economic challenges, and that EPA waives down this mandate, leaving just 76BL of the mandate to be fulfilled. However, this volume could increase further if the U.S. Congress or EPA alters biofuels mandates to allow more food-based biofuels (such as corn biobutanol and corn oil biodiesel) to count toward its "advanced biofuels" mandate since cellulosic ethanol production has failed to materialize as policymakers projected in 2007.

- We only considered India's 5% ethanol mandate to be binding, so we did not assume the country's 20% ethanol and 20% biodiesel targets would be filled.
- Indonesia currently has a 5% mandate for biofuels, but also has more aggressive targets of 15% ethanol and 20% biodiesel by 2025. The higher targets are used in this analysis.
- All transportation growth is annualized on a linear basis from IEA and USDA growth rates.

Table 1: Selected Biofuel-Consuming Country Mandates through 2025

(in billions of liters)

Country	Mandate/target			Current Consumption		Mandated Increase	Transport Fuel Demand Growth through 2025	Added Volume, Full Mandate+ Demand Growth	Projected Demand 2025

All current volumes are taken from the most recent US Department of Agriculture (USDA) GAIN reports unless otherwise noted.
Transport fuel demand growth rates are calculated from IEA's New Policies Scenario except for Indonesia and Argentina.
Ethanol and diesel demand estimates for Argentina, for 2015-2024, are taken from USDA's GAIN Report for Argentina, 2014.
Ethanol and diesel demand estimates for Indonesia, for 2015-2024, are taken from USDA's GAIN Report for Indonesia, 2014.
Diesel consumption for India is derived from USDA's GAIN Report for India, 2013.
Current volumes for the US are the Environmental Protection Agency's (EPA) 2013 mandated biofuels volumes.
*China's mandate is for nine provinces only, representing just 1.1% of current fuel use and a projected 1.3% in 2025.

Full Implementation of Existing Mandates

As the table shows, most large consuming countries with mandates or targets have only partially implemented them, Brazil being the most notable exception. The United States is close to fulfilling its mandate for first-generation ethanol (13BL away from its 76BL mandate of first-generation biofuels). The EU is about 12BL away from its overall 10% mandate, though there is wide variation among member countries in their progress.

OECD countries drive current consumption and account for about half of the growth in projected biofuels demand by 2025. This would be considerably lower if the United States and the EU reformed their mandates. As noted earlier, the EU is currently considering capping the use of crop-based biofuels at 7%. (Here we estimate implementation based on the full 10% mandate, adjusting for double-counting.)

Mandates and targets in key large emerging economies have important implications for future growth in biofuel consumption and production. Information is less reliable, and policy goals are under revision. Still, we present the likely mandates/targets of major biofuel-producing countries and their implications.

Brazil is a large producer and consumer, with high mandates that have been filled. The projected 36% increase in its consumption comes solely from fast-growing demand for transportation fuels, a high percentage of which are biofuels. While the pie may be getting bigger, biofuels' share of the transportation fuel supply is expected to stay relatively flat. Argentina is a much smaller consumer with lower mandates, but increased transportation demand, in addition to increased mandates, are expected to lead to a 64% increase in consumption by 2025.

Two of the least certain mandates include those in China and India. China currently has a 10% mandate in nine provinces only, which it has reached, with a target of 15%, suggesting 50% growth in demand from the target alone. Given anticipated high growth rates in demand for transportation fuels in addition to increased biofuels targets, the projected growth rate is 109% through 2025. This represents an increase of only 3.9BL despite the high percentage increase because the mandate is limited to nine provinces. Future Chinese biofuels policies are expected to continue to be mindful of food vs. fuel concerns (which began after food price spikes in 2008) and future analyses of demand for agricultural commodities. Nationally, biofuels now account for just 1.1% of transportation fuels and that share would grow to just 1.3% in 2025.

India is only halfway to meeting its 5% ethanol mandate, recently scaled back from 20%. Its 20% biodiesel target has not been reduced, but we do not include it here as it is not a binding mandate and, as we explain below, there is good reason to believe India will have to reduce it. Still, even without added biodiesel, we expect India's biofuel production to increase 89% to 4.3BL by 2025.

Indonesia presents the largest planned growth on a percentage basis (860%) as it moves from its current 5% biofuel mandates to aggressive 15% and 20% targets for ethanol and biodiesel, respectively. With high anticipated transportation fuel demand growth, such targets would make Indonesia one of the most significant sources of new demand for biofuels between now and 2025 – 8.0BL – with the bulk of the feedstock expected to come from palm oil.

Overall, these countries account for the large majority of current biofuel production. Assuming they continue to account for such a proportion, the impact of full implementation of their mandates and targets would have huge impacts on land use, water quality and quantity, food prices, and GHG emissions. Our figures suggest a 43% increase in first-generation biofuels consumption over current levels. This world in which 3-5% of the global fuel supply is comprised of first-generation biofuels is close to projections offered by the OECD/FAO scenario. However, growth rates could increase to 115% if second-generation biofuels mandates are met and if other countries such as India meet their lofty biofuels targets. This would result in a world in which 4-7% of the world fuel supply is comprised of biofuels, which is closer to IEA estimates.

For a full list of country mandates please see Appendix B.

Limits to Full Implementation

There is good reason to believe that many countries will be unable to fulfill their current mandates. For some, such as countries in the EU, a likely future 7% cap on food-based biofuels (out of a 10% mandate) leaves a 3% gap to be filled with non-food-based biofuels that have been slow to come to full commercialization. Many countries have yet to meet even the proposed 7% cap. For the United States, the blend wall currently prevents the full implementation of the RFS, and since cellulosic biofuels are required to meet nearly half of the 137BL mandate, policy reforms will be required to bring the mandate more in line with realistic production volumes. For others, such as India, access to feedstock (sugar) is proving difficult to secure.

There are, of course, risks that additional mandates in key countries could add to biofuel demand in ways not anticipated here. As is often the case, China and India are the two most important wild cards for such estimates.

Below we analyze the likelihood of implementation, recent calls for reform, and present the key factors guiding the development of biofuels policies, consumption, and production in selected countries and regions. We find that if recently-proposed policy reforms are implemented (such as in the United States and EU), we can expect lower first-generation biofuel growth, but overall global demand is still expected to increase significantly.

United States

The United States is the world's largest biofuels producer and consumer.[105] The twin pillars of U.S. biofuels policy have included a mandate as well as an intertwined set of subsidies focused at the dominant feedstock (corn), as well as refining and blending facilities (some of which have expired). While the largest tax credit for ethanol production, the Volumetric Ethanol Excise Tax Credit (VEETC), ended in 2011, the biodiesel blenders and cellulosic ethanol production tax credits are routinely extended. State incentives and other federal government programs have also contributed to establishing the required infrastructure to make biofuels production economically viable.

The RFS mandates 137BL of conventional ethanol (mainly corn ethanol), advanced biofuels, and cellulosic biofuels to be blended into the U.S. fuel supply by 2022. In the U.S. mandate, definitions of these different types of biofuels are based primarily on their contributions to reducing life-cycle GHG emissions, as estimated by EPA. In our analysis, we assume the corn ethanol, biodiesel (biomass-based diesel), and a portion of the advanced biofuels mandates will be met (totaling 80BL of the full 137BL mandate), but importantly, we do not assume the 61BL cellulosic ethanol mandate is met since production is just beginning to come on line and experts estimate the mandate will not be filled by 2022. The gap that exists between the advanced biofuels and cellulosic ethanol mandates creates an incentive for additional production/importation of food-based biofuels such as imports of sugarcane ethanol from Brazil and production of other food-based biofuels such as soy biodiesel and corn biobutanol.

U.S. Renewable Fuel Standard Definitions

The RFS mandates increasing levels of the following types of biofuels by 2022:

- **Corn starch ethanol:** the mandate for corn starch ethanol is 57BL by 2015, and this mandated level continues throughout the life of the full RFS. This category is required to meet a 20% GHG reduction threshold (as compared to U.S. gasoline), although several corn ethanol facilities were grandfathered into the law, meaning they were not required to reduce GHG emissions.

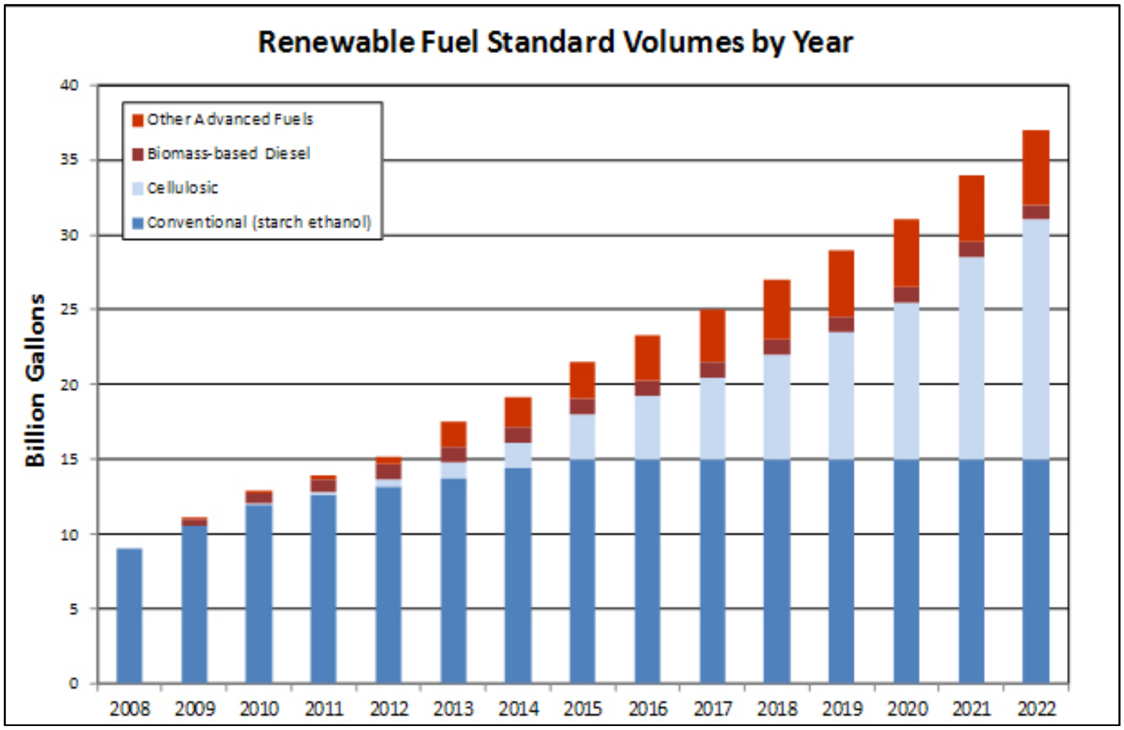
- **Advanced biofuels:** Rising to 80BL by 2022, the advanced biofuel mandate may include biofuels such as sugarcane ethanol, biomass-based diesel (such as biodiesel derived from animal fats, soy, or other vegetable oils), cellulosic ethanol (see below), and other advanced biofuels. These are required to meet a 50% GHG reduction threshold set by the U.S. EPA. The EPA is currently considering whether to treat corn biobutanol, a fuel that does not face the same fueling infrastructure challenges as corn ethanol, as an advanced biofuel, meaning that food-based biofuels may still be considered advanced biofuels in the United States

- **Cellulosic ethanol:** Rising to 61BL by 2022, the cellulosic ethanol mandate may include ethanol derived from cellulosic sources such as perennial grasses and wood and agricultural residues. This category is required to meet a 60% GHG reduction threshold. However, cellulosic ethanol is not produced at a large commercial scale yet, so in our analysis, we do not assume the United States meets its 61BL cellulosic mandate by 2022 (or 2025), leaving a gap of 19BL of advanced biofuels to be filled with fuels such as sugarcane ethanol and soy biodiesel (identified as "other advanced biofuels" in Figure 8).

Figure 5 details the scheduled increase in RFS mandated biofuels volumes, with corn ethanol leveling off at 57BL in 2015 and years thereafter, and cellulosic biofuels mandated to grow steadily after 2010.

Approximately 10% of U.S. gasoline supply currently comes from ethanol—primarily corn ethanol, while biodiesel blends are much lower. Growth projections are relatively flat though, given the issue of the E10 blend wall. The most recent EIA estimates project that biofuels will account for only 11% of U.S. transportation fuel in 2040, although its previous energy projections have estimated significantly higher volumes of biofuels.[106] As a comparison, the RFS mandate requires approximately 25% of the United States fuel supply be comprised of biofuels by 2022, the majority from cellulosic or advanced feedstocks.

Figure 5 [107]



Three key issues have led to the U.S. biofuels market expanding at a significantly slower rate than initially thought. First, Americans are driving less. The Great Recession led to large reductions in driving and this behavior change has not rebounded at the same rate as the economy. The EIA also projects that there will be fewer drivers per capita in the future.[108]

Second, Americans are driving more fuel-efficient cars. Higher Corporate Average Fuel Economy (CAFE) standards are lowering fuel demand. So are American preferences for cars with better fuel economy. Trading large vehicles for smaller cars and hybrids is leading to demand far lower than the EIA anticipated 10 years ago.

Third, the United States has hit the blend wall, or the maximum amount of ethanol deemed safe to blend into the U.S. fuel supply. Gasoline blended with 15% ethanol (E15) is now allowed in cars manufactured after 2001, but it is not available in most areas and issues with engine warranties and negative effects on older vehicles and small engines have prevented its widespread adoption. In addition, for the reasons cited earlier, unlike Brazil there is little indication the United States will significantly increase adoption of flex-fuel vehicles in the near future. If either of those occurred, the U.S. fuel supply could accommodate significantly higher levels of biofuels.

Each year, the Environmental Protection Agency (EPA) is able to revise RFS mandates based on the commercial availability of cellulosic biofuels. In recent years, the EPA has reduced cellulosic ethanol mandates by more than 95% because each year less cellulosic fuel is available than the RFS originally mandated. In 2015, EPA will consider waiving the *entire* RFS downward for calendar year 2014, for the first time in history, due to these lower cellulosic volumes and the ethanol blend wall.[109]

Such reforms can make a large difference in global biofuel demand. If EPA finalized 2014 biofuel volumes in line with those proposed in late 2013 (one way to reform the RFS) and maintained these lower mandates throughout the rest of the RFS, the United States would contribute 4.6BL less to global first-generation biofuel demand, leading to a 14% demand increase instead of a 21% increase by 2022.

EPA is also able to waive RFS mandates downward based on petitions tying biofuels mandates to “severe economic harm.” While several petitions have been submitted to EPA in recent years by U.S. states negatively affected by high crop and food prices, EPA rejected these citing other demand factors playing a larger role in higher food prices. In addition to administrative action, several legislative proposals have been introduced in the U.S. Congress to either eliminate or significantly reform biofuels mandates due to their impacts on food and feed prices and negative effects on the environment. If implemented, reform proposals would bring biofuels mandates more in line with current production volumes.

The arrival of the blend wall and the failure of cellulosic ethanol to come to large commercial production have resulted in numerous unintended consequences of the RFS. Combined with low feedstock (corn) prices, ethanol production in the United States is beginning to exceed the amount of ethanol that can be used in the current domestic vehicle fleet. Hence, U.S. ethanol exports are expected to increase to record levels in 2015 due to this confluence of factors. The RFS has also created a particular market for Brazilian sugarcane ethanol in the United States since cellulosic ethanol has failed to meet advanced biofuels mandates. Hence, in addition to soy biodiesel, sugarcane ethanol from Brazil is a major source of advanced biofuels, with imports of 7.7BL in 2013.[110] OECD projects that by 2023 Brazil could supply up to 38BL to the United States while the United States ships 19BL of corn-based ethanol to Brazil.[111] Others consider this level of bilateral ethanol trade unlikely.

Because Brazil has no restrictions in its own mandates or laws on GHG impacts, corn ethanol can substitute freely in the Brazilian market for some of the sugarcane ethanol exported to the United States The net effect leads to expansion of less beneficial corn-based ethanol fuel beyond its RFS mandate, while the mandate for advanced biofuels is met with additional food-based biofuel. However, these trade flows are highly dependent on volumes that the U.S. EPA finalizes, since the agency can lower advanced and cellulosic biofuels mandates if production is insufficient. Furthermore, the advanced biofuels gap at most is 19BL, with some of this likely being filled with soy biodiesel, so these projections are highly speculative.

The RFS provides a prime example of how domestic mandates interact with existing trade flows and lead to unexpected outcomes, and ones that frequently undermine the political purposes for which a domestic biofuel mandate was originally passed. And since the RFS has primarily been filled with corn ethanol, the RFS has failed to significantly reduce GHG emissions.[112]

European Union

In 2009, the European Commission (EC) established a minimum target of deriving 10% of transportation fuels from biofuels in each member state by 2020. Countries submitted their energy action plans to the Commission by June 2010.[113] During that time, civil society became concerned about both the environmental and social ramifications of this decision. As more evidence became available about indirect land use change due to biofuels, biofuels' effect on food prices, and the human and land rights issues associated with the production of biofuels in some countries around the world, advocates mobilized to change the law. In part, advocates were able to point to the sustainability criteria laid out in Articles 17, 18, and 19 of Directive 2009/28/EC.[114] These GHG and land use sustainability criteria have been in effect since December 2010.

As a result of these intense educational efforts, in October 2012, the EC proposed limiting food-based biofuels to 7% of the 10% renewable energy target in the RED.[115] While it does not go far enough, three-percentage points less in first-generation biofuel represents 11BL in avoided production (assuming the remaining 3% would be difficult to meet with non-food-based feedstocks). This reform would reduce the EU's projected growth rate in first-generation biofuel volume from 64% to 33%, (which also factors in a drop in transportation demand growth through 2025). Because this reform has not yet been implemented, the higher 10% biofuels mandate has been used in our analysis.

OECD/FAO reports 65% of European vegetable oil is being used for biodiesel.[116] In addition, several companies based in EU countries have acquired land in African countries to produce biofuel feedstocks, some of these resulting in land grabs which deprive local communities of land once used for food production, housing, burial grounds, forestry, etc.

The following table shows the origin of biofuels consumed in the EU.

Figure 6[117]

Origin of final biofuels consumed in the EU in 2010[17]

	Biodiesel		Bioethanol		
	Volume (ktoe)	Share		Volume (ktoe)	Share
EU	8,270	83.2%	EU	2,243	80.1%
Argentina	1,003	10.1%	Brazil	234	8.4%
Indonesia	285	2.9%	U.S.	121	4.3%
Malaysia	123	1.2%	Peru	26	0.9%
China	67	0.7%	Kazakhstan	24	0.8%
U.S.	61	0.6%	Bolivia	20	0.7%
Other countries	129	1.3%	Egypt	15	0.5%
			S.Korea	16	0.6%
			Other countries	101	3.6%
Total	9938			2800	

Source: EUROSTAT, COMTRADE.

Figure 7 shows the origin of the feedstocks of biofuels consumed in the EU, showing the EU's dependence on imports of feedstocks.

Figure 7[118]

Origin of all biofuel feedstock consumed in the EU in 2010

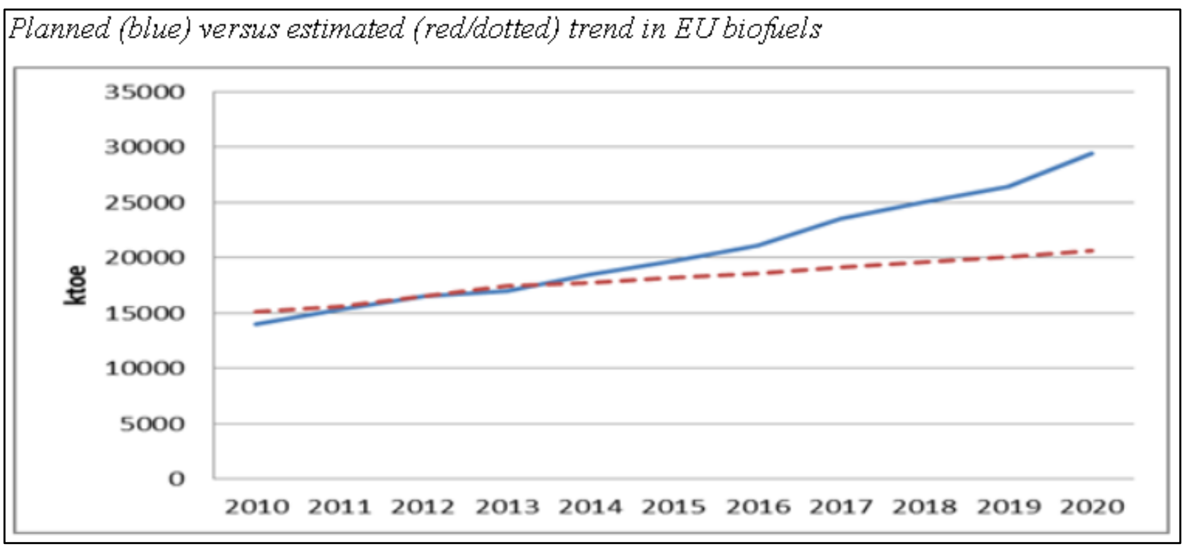
EU	Argentina	Indonesia	Brazil	U.S.	Canada	Ukraine	Malaysia	Paraguay	Other
63.9%	9.7%	6.6%	5.3%	3.0%	2.4%	2.3%	1.7%	1.5%	1.3%

Russia	China	Switzerland	Peru	Bolivia	Peru	Egypt	Guatemala
1.0%	0.5%	0.2%	0.2%	0.2%	0.2%	0.1%	0.1%

Overall, progress toward the 10% mandate has been uneven, leaving the EU as a whole unlikely to reach that goal, although added consumption is still projected to be an important driver of global biofuels demand. According to the EC, biofuel use in 2020, the end of the mandate period, is expected to be just two-thirds of the planned total.[119] (See Figure 8.)

Some European countries are already well on their way to meeting the 10% target, with Sweden already blending 10% biofuel into its transportation fuel. However, other countries such as the UK and Spain have yet to meet the newly proposed 7% cap on food-based biofuels, meaning there is still room to expand current blending levels. And since production of non-food-based biofuels has been slow due to technological and economic challenges, meeting the overall 10% targets will be difficult. Despite these constraints, recently proposed reforms, and concerns about biofuels' environmental and social impacts, the EU biofuel market is expected to continue to grow.

Figure 8[120]



Brazil

A dominant force in biofuels markets, Brazil has the longest running biofuels mandates in the world, a large flex-fuel vehicle fleet (which can operate on Brazil's 25% ethanol blend mandate) as well as tax incentives for biofuels production. Brazil's production and consumption of biofuels continue to increase. Ethanol production in 2015 is projected to be up 5% over 2014 at 26.9BL.[121] The Brazilian Senate passed a measure to increase the ethanol mandate to 27.5% from 25% and to cap biodiesel blending at 6%, but the proposal has yet to be approved by the

President.[122] In any case, the mandates in Brazil are seen more as a reflection of the market than a driver, in part because it affects only a small share of ethanol used in the country's vehicle fleet.

In addition to its domestic consumption, Brazil was also the world's largest ethanol exporter in 2013, although exports were down significantly in 2014.[123] In this interconnected market, Brazil exports sugarcane ethanol to the United States while the United States sometimes exports corn ethanol to Brazil to make up for losses. The United States is also its largest importer and accounts for 70% of Brazil's exports of ethanol.[124] Brazil's exports are projected to drop 46% in 2014 to 1.5BL as the United States considers scaling back its mandates for advanced biofuels, although previous estimates from the OECD/FAO projected increased ethanol trade over the next ten years.[125]

Even outside of the U.S.-Brazil relationship, Brazil has been a significant supply-side driver of the global biofuels market. It has used its technical expertise in ethanol as a source of soft power toward other emerging and developing countries to increase biofuels use, although this has leveled off in recent years.[126] For example, Brazil has invested in land, entered into "cooperative agreements," and provided biofuels technology to other countries, including many in Africa and countries in the Western Hemisphere.[127] Brazil and the U.S. signed a Memorandum of Understanding (MOU) in 2007 aimed at increasing agricultural and biofuels investments in developing countries such as Honduras, Nicaragua, Costa Rica, Panama, the Dominican Republic and Haiti, which the governments termed "ethanol diplomacy" at the time.[128] As a Committee on Foreign Relations (CFR) brief wrote in 2007, "Ethanol ha[d] become Lula's [Luiz Inacio Lula da Silva, the former President of Brazil] best diplomatic lever in Latin America…"[129]

Despite its influence, the domestic Brazilian ethanol industry has recently seen setbacks, including a reduction of gasoline taxes resulting in relatively cheaper gasoline and the country's discovery of new oil deposits, which may decrease domestic oil prices – the opposite reason biofuels mandates were first enacted in Brazil.

Argentina

Behind only Brazil in biofuels production and consumption in Latin America, Argentina has invested heavily in both ethanol and biodiesel production. A 10% biodiesel mandate and an ethanol blend rate of 7.6%--even higher than its 5% mandate—are driving Argentina's consumption of biofuels.

Argentina's biofuels production and consumption have expanded rapidly over the last few years. In 2010, Argentina's ethanol blend rate was only 2% but it is expected to rise to 7.5% in 2014.[130] As ethanol demand rises, Argentina is adding additional refining capacity, creating the infrastructure for future production. In the past year a new ethanol plant has brought annual production capacity up to 840 million liters.[131]

Its biodiesel blend rate is expected to double to 8% in 2014, from 4% in 2010. [132] In 2014, its biodiesel consumption and production were projected to be 1.4BL and 2.6BL, respectively, leaving room for biodiesel exports.[133] [134]

Peoples Republic of China

China initially embarked on a biofuels policy to absorb excess grain stores in the early 2000s. It switched course when the 2008 food price spikes led to concerns about shortages if this food was converted to fuel. Since then, China has invested in so-called advanced biofuels that can be grown on marginal land.[135] It has also involved its national oil companies in some biofuels production, showing its interest in developing biofuels for national energy security.[136]

When China makes investments, an entire market can move. The second largest economy in the world and home to one-sixth of the world's people, China has included biofuels in its current five-year energy plan. The U.S. EIA reports China produced 2.6BL of ethanol and 966 million liters of biodiesel in 2013.[137] Compared to the production of the United States or Brazil, these volumes are small. China has mandated 10% ethanol blends in gasoline in nine of its provinces, but this mandate is set to increase to a 15% target in 2020.[138] China is such a large market that these mandates and other infrastructure investments are worth particular attention.

China's investments in biofuels reflect their general approach to energy investing, ensuring the country is investing in all industries and that they are prepared for technological gain in any particular one. If, for example, cellulosic biofuel were to become commercially viable, it is likely China would be an early investor and adopter of this fuel. China is a large net importer of transportation fuel and depends on fuel for its continued economic growth. Considering China's investments in overseas oil fields, its investment in biofuels is modest indeed.

The quick reversal of policy in 2008 demonstrates that China is not wedded to biofuels production for ideological reasons and is likely to be sensitive to biofuels' competition with food crops to the extent that it affects food prices. Without powerful interest groups promoting biofuels, it is better able to adjust quickly to changes in the market either expanding or contracting its production. China has also recently announced it will remove or dial back other policy supports for ethanol. In 2015, it will remove the 17% value-added tax rebate at the same time it is adding a 5% tax on food-based biofuels.[139]

Based on China's stated intentions and recent actions on biofuels, it seems unlikely the government will increase its 15% biofuels target in the near future. Nor is it likely to extend the target to other parts of the country. As demand rises, of course, its consumption of biofuels will rise even with the same target in place. But its limited mandate means that presently only 1.1% of China's transportation fuel comes from biofuels, and even with anticipated growth that percentage would rise to just 1.3%.

If China were to choose to increase dramatically its biofuels production or consumption, it could dwarf production and consumption of many OECD countries. Any move to take the nine-province mandates national would have dramatic impacts, as would policies to import large quantities of biofuels. The environmental and human impacts could be overwhelming. In all models of future biofuels production and consumption, China, and to a lesser extent India, are wild cards, although China has a history of being an innovator in biogas and other homegrown bioenergy sectors.

India

The world's largest democracy embarked on a national biofuels policy in 2009.[140] Like China, India is a major transportation fuel importer and is hoping to improve its trade balance, support local agriculture and agricultural processing, and insulate itself from international oil markets by making non-petroleum energy investments. With a declared non-binding target of a 20% biofuel and biodiesel blend in transport fuels by 2017, India has publicly committed to scaling up biofuels production, but in practice it has done far less.[141]

In 2012, India's Cabinet Committee of Economic Affairs recommended its ethanol *target* be scaled back and changed to a 5% blending *mandate*. The country is currently blending only 2.1% ethanol into its transportation supply.[142] This is mainly due to limited supplies of sugarcane, especially after poor harvests in the past few years. Even with this dramatic reduction in its blending goals, India is projected to produce 2BL of ethanol in 2014.[143]

India's biodiesel target of 20% remains in place, but it is non-binding and it has not been replaced with a binding mandate (as was done with ethanol). The biodiesel industry has also failed to develop, with production in 2013 of just 115 million liters. The primary feedstock was intended to be jatropha, but the government and other countries are now searching for alternatives given its potential to become an invasive feedstock and its high water usage. Meeting the 20% biodiesel target would raise the country's biofuel use to more than 20BL, making it one of the world's largest biofuel consumers.

The Indian government set these initial targets in response to the country's impressive economic growth rate, fluctuating international oil prices, and a desire to be more energy secure.[144] In its own biofuels policy document it makes clear that its policy, unlike those of other countries, will not come into conflict with its food security goals and that biofuels will be derived from non-food feedstocks.[145] India is, however, unlikely to take food security concerns of other countries into consideration in its own biofuels import policies. Moreover, if a fully functioning, large-scale biofuels industry comes online, it is unclear if and how the Indian government would reverse its policy decisions to protect food security.

Despite significant targets and the outsized power of large sugar producers in India, it is unlikely that India will end up blending nearly as much ethanol and/or biodiesel by percentage into its transportation supply as Brazil. India's commitment to food security and its stated goal of prioritizing food security over biofuels development also makes it likely that its program will not grow significantly in the future. These qualifications aside, India's continued economic growth and increased energy demand coupled with its growing population could drive very high biofuels consumption even with its current blend rate. In terms of volume, India's demand could expand dramatically in the coming decade without changing its percentage mandate.

Indonesia

In 2011, Indonesia was the sixth largest producer of biodiesel.[146] Over the past several years, Indonesia has cleared huge tracks of land for its main biodiesel feedstock - palm oil – intended both for export and domestic consumption. Since the EU's adoption of a biofuels mandate, Europe has become a significant consumer of Indonesian palm oil. A new proposal to limit biofuels from food-based feedstocks to 7% in the EU RED, in addition to broader concerns about unsustainable production of palm oil, has slowed exports to Europe.[147]

Indonesia is now using domestic mandates to drive local consumption as it continues to support production for both domestic and export markets through production subsidies and tax incentives.[148] It is too early to say if Indonesia's aggressive 2025 targets—15% for ethanol and 20% for biodiesel—will be met.[149] It currently has a 5% biofuel mandate, but is blending only 4.5% biodiesel and a marginal volume of ethanol.[150] Nevertheless, such dramatic growth in mandates and targets, especially as the country experiences economic growth and increased energy demand, would have huge environmental and social implications unless the government adopts smallholder-led palm oil development strategies and works to close the "productivity gap" with Malaysia.

Indonesia's biofuels expansion and other palm oil demand drivers have resulted in numerous negative impacts, including deforestation, large GHG emissions, and land and human rights issues. Groups such as the Rainforest Alliance, World Wildlife Fund, and Girl Scouts U.S.A. have raised issues of negative consequences of increased palm oil production in Indonesia such as "land-grabbing," forced displacement of communities, poor labor standards, large GHG emissions, and destruction of wildlife habitat. [151]

African Nations

Several African countries have enacted ethanol mandates or targets. Many of these mandates are new and were created in anticipation of domestic biofuels industries. It is too early to tell whether these mandates and targets will drive demand and help support these nascent industries.

South Africa, the most developed of the Sub-Saharan nations, has only begun its biofuels mandate, which is relatively low in any case – 2% ethanol and 5% biodiesel starting in 2015. Significant restrictions on water and land availability in the country make the development of a large domestic biofuels sector unlikely.[152] Moreover, South Africa has excluded maize use for biofuels because of food security concerns, and has also excluded jatropha for fears of it becoming invasive.[153] Despite these restrictions, there were four bioenergy projects operating in 2010 with four more in the pipeline,[154] and South Africa has begun to export ethanol to the EU.[155]

Countries from Senegal in West Africa to Tanzania in East Africa have been the sites of biofuels related land-grabs and failed biofuels projects as international companies seek new land to produce feedstocks in developing countries. Developed country biofuels mandates drive investment in not only biofuel feedstock production (such as sugar) but also biofuel refining facilities. Business setbacks as well as local unrest over forced displacement and other human rights abuses have been raised as reasons why governments should reconsider biofuels mandates, targets, and other incentives and investments in biofuels. Malawi and Zimbabwe are exceptions, being two of the only major producers of ethanol in Southern Africa. Zimbabwe, for instance, is currently blending 15% ethanol.[156]

It is unclear how African countries will approach biofuels moving forward. This is particularly true of countries and regions with recent discoveries of oil and gas. While countries like Angola and Nigeria have put biofuels mandates on the books, it seems unlikely that these large oil producers will follow through on these mandates. The lower domestic price of oil, especially with oil subsidies, makes biofuels particularly uncompetitive in these countries. Like oil producers in Northern Africa where no biofuels mandates exist, Sub-Saharan producers are unlikely sources of high biofuels consumption irrespective of the biofuels mandates they have on the books.

If OECD countries continue to demand biofuels, African production of biofuels is likely to expand in the coming years to meet at least part of this expanded demand. This is especially true in countries such as Ethiopia and Tanzania, which have prioritized large-scale commercial agriculture and foreign direct investment in the sector.

V. Conclusions

Our review of government biofuels mandates suggests consumption of first-generation biofuels in selected major biofuel-producing countries would increase about 43% by 2025 if most of these countries' mandates and targets were fully implemented. This analysis does not include mandates and targets that have little chance of implementation such as India's biodiesel target. The figure would be somewhat lower if existing mandates prove too difficult to achieve, and in some countries that is likely to be the case. First-generation biofuels consumption could be much higher by 2025 if the 64 current governments with mandates/targets continue expanding mandates/targets or if additional countries enact and actively pursue implementation of domestic biofuels mandates or targets.

Over the next ten years, OECD countries will continue to account for nearly two-thirds of first-generation biofuel consumption, and the fulfillment of their mandates would contribute to 50% of added first-generation biofuel use between now and 2025. The United States would be the largest contributor of new biofuels demand, adding 13BL, while the EU would add 12BL by 2025 to meet first-generation biofuel mandates. The United States would remain by far the largest consumer in 2025, with 76BL of first-generation biofuel consumption, which is projected to increase 21% in the coming years barring major policy reforms.

However, if recently proposed EU reforms (to cap food-based biofuels at 7% of the fuel supply) and U.S. EPA reforms (to limit the growth of biofuels expansion) were implemented, the EU and United States would contribute 11BL less to global first-generation biofuels demand in 2025; this would reduce mandate-driven global expansion from 43% to 38%. While these reforms do not go far enough, this demonstrates the impact that short-term policy reforms can have on global biofuels expansion.

Brazil will continue to be a major producer and consumer of biofuels, remaining the second largest consumer in 2025 after the United States with 41BL of consumption. Its consumption is projected to expand 36% if biofuel blending levels are maintained due to increasing demand for transportation fuel as a result of economic growth. The country is expected to continue to be a net exporter, helping other countries fulfill their mandates. This has historically included the export of first-generation biofuel (sugarcane ethanol) to the United States for its advanced biofuel mandate in exchange for the import of another (corn ethanol). However, the economics of fuel blending could change if Brazil expands its oil industry, with the recent discovery of offshore oil, which is expected to increase its proven reserves and double its production capacity by 2020.[157]

China and India present the biggest sources of uncertainty. Any significant moves toward expanded biofuel consumption, over today's comparatively low levels, would have huge impacts for the environment, food prices, and agricultural markets. Based on current mandates and policies, however, the two are projected to contribute an additional 6BL to global consumption, barely half the consumption added by the United States. China's projected blend rate in 2025 is just 1.3%, moderation which keeps the country's large transportation sector from driving biofuel demand to even more unsustainable levels.

Indonesia, on the other hand, has the most aggressive targets, which it is moving to implement. Full implementation would add 7BL to global biofuel demand. This would only deepen the negative environmental and social impacts caused by the country's expanded production. In part, the EU biofuels mandate was responsible for Indonesia's large-scale planting of palm oil, in addition to other demand factors for palm oil and the government's intent to prop up domestic palm oil prices. The government's current mandates have responded to reduced demand by increasing domestic biofuel demand to absorb the excess feedstocks.

Given this increased demand for biofuels, the implications for land and water use and food security are huge. A 43% increase in biofuel production by 2025 would continue to divert food and feed crops into fuel markets. At current land-use rates, it would divert an additional 13-17 million hectares more land than we are currently already devoting to biofuel production and approximately 145 billion more liters of water at rates currently used in corn ethanol production. This is an important area for further research, with the implications depending significantly on the feedstocks used.

If the IEA's projections, which predict full implementation of global biofuels mandates, are accurate, however, our findings would represent only a portion of increased biofuels demand over the next two decades. Importantly, IEA includes second-generation biofuels mandates in addition to those for first-generation biofuels, suggesting that by 2035, the world fuel supply would be comprised of 8% biofuels by volume, with 80% of the biofuels still derived from food crop sources instead of second-generation, non-food feedstocks such as agricultural residues or perennial grasses. Meeting first-generation biofuels estimates would result in consistent growth rates to reach a world with 6% of transportation fuel comprised of biofuels by 2035, in line with our projections if full (first- and second-generation) mandates are met.

Policy Implications

This analysis suggests the need for governments to cease the implementation, expansion, and creation of new food-based biofuels consumption mandates. While recently proposed reforms to U.S. and EU mandates are welcome, even if they are implemented these OECD countries will still account for about one-third of new biofuel demand over the next ten years. Percentage-based mandates, which prevail in most countries, will require additional demand for biofuels as demand for transportation fuels is expected to grow about 16% by 2025; many countries that maintain and enforce such mandates will contribute added demand for biofuels even if they don't increase their mandates.

Governments need to scale back their mandates further, enforce strict sustainability criteria, and ensure that so-called "advanced" biofuel mandates are not feeding further first-generation production or continued production of food-based and land-intensive biofuels.

Other policy recommendations that flow from this analysis include:

- *Remove Food-Based Mandates.* The United States should eliminate food-based biofuels mandates and ensure that future biofuels don't compete heavily with land used for food production.
- *Stop and Do Not Adopt New Food-Based Mandates.* Other countries should eliminate and forgo adoption of food-based and land-intensive biofuels mandates and other incentives working at cross-purposes with food security, biodiversity preservation, land tenure rights, and GHG reduction goals. Governments should work toward international cooperation on these issues in international policymaking venues such as the G7, G20, UN Framework Convention on Climate Change (UNFCCC), UN Committee on Food Security, UN Convention on Biological Diversity, post-2015 development agenda, etc.
- *Continue Research with a Focus on Sustainability.* Research and development of second-generation biofuels should increase but with strong attention to sustainability criteria that can be widely and consistently implemented. Given the volumes required to meet global biofuel demand, even seemingly benign feedstocks can prove unsustainable at large scale.
- *Feedstocks Matter*.[158] As policymakers rethink their biofuels mandates, it is important to pay particular attention to feedstocks and to volumes. If countries are able to produce commercially competitive biofuels from non-food feedstocks in the next ten years, this would transform the current biofuels market; however, as many experts have pointed out, there is a low likelihood of second-generation biofuels being produced in significant quantities soon. Current biofuels production has resulted in large social and environmental externalities, and these will only worsen if first-generation biofuels production continues to increase as expected or if second-generation biofuels result in the same food vs. fuel and other negative impacts as first-generation biofuels. Biofuels are not created equal, and they should not be treated the same.
- *Volumes Are Key*. The United States producing a few billion liters to replace lead in gasoline as an oxygenate may have been warranted, but decades of subsidies and aggressive mandates for approximately 76BL of food-based biofuels continuing on auto-pilot regardless of food or crop prices has led to numerous unintended consequences.

Policymakers now have a choice. Given all we have learned over the past decade about the impacts of biofuels use, it is time to rethink mandates, targets and other subsidies for biofuels, especially those made from crop-based feedstocks or from other sources with large land-use impacts.

Appendix A: Summary Table with Notes

Table 1: Selected Biofuel-Consuming Country Mandates through 2025

(in billions of liters)

Country	Mandate/target			Current Consumption		Mandated Increase	Transport Fuel Demand Growth through 2025	Added Volume, Full Mandate+ Demand Growth	Projected Demand 2025	
	Timeframe	Ethanol	Diesel	vol	% fuel supply	%	%	vol	vol	% increase
United States	2022	72 BL	3.8 BL	62.9		21%	N/A	13.1	**76.0**	**21%**
European Union	2020	10.0%		18.7	5.0%	72%	-8%	12.1	**30.8**	**64%**
Brazil	2014	25.0%	7%	29.0	27.5%	0%	36%	12.2	**41.2**	**36%**
Argentina	2014	5%	10%	2.0	7.6%	25%	57%	1.3	**3.2**	**64%**

Sources:

All current volumes are taken from the most recent US Department of Agriculture (USDA) GAIN reports unless otherwise noted.
Transport fuel demand growth rates are calculated from IEA's New Policies Scenario except for Indonesia and Argentina.
Ethanol and diesel demand estimates for Argentina, for 2015-2024, are taken from USDA's GAIN Report for Argentina, 2014.
Ethanol and diesel demand estimates for Indonesia, for 2015-2024, are taken from USDA's GAIN Report for Indonesia, 2014.
Diesel consumption for India is derived from USDA's GAIN Report for India, 2013.
Current volumes for the US are the Environmental Protection Agency's (EPA) 2013 mandated biofuels volumes.
*China's mandate is for nine provinces only, representing just 1.1% of current fuel use and a projected 1.3% in 2025.

Notes/Assumptions:

(1) The US is assumed to meet slightly over half (20 billion gallons) of its 36 billion gallon Renewable Fuel Standard (RFS) mandate by 2022 (and 2025 for this analysis). We assume the US meets its 15 billion gallon mandate for corn starch ethanol, 1 billion gallon mandate for biodiesel (which could be increased by US EPA), and that the remaining 4 billion gallons are met by imported sugarcane ethanol (total of 20 billion gallons). Again, the biodiesel target could be increased by EPA, leading to less imported sugarcane ethanol, but both are considered first-generation biofuels in this analysis. We assume the remaining 16 billion gallons, mandated to be filled with cellulosic ethanol, a second-generation biofuel, are not produced due to technological and economic challenges, and that EPA waives down this mandate, leaving just 20 billion gallons of the mandate to be fulfilled.

(2) EU estimate for "mandated increase" assumes that adjusting for double-counting for advanced fuels the effective mandate would be 8.6%. At this writing,, the proposed reform to 7% from crop-based sources had not been approved.

(3) Consumption numbers for Brazil are calculated based on the 25% ethanol mandate, the latest figures available. Mandate applies to only a small portion of ethanol market, but we estimate total projected demand for all biofuels driven not by mandate but by demand growth including all biofuel types.

(4) Calculated Argentina's transportation demand differently because USDA estimates a change in ratios of gasoline to diesel. Calculated separate demand increases for gasoline and diesel, which has implications for ethanol and biodiesel use.

(5) China has a 10% mandate and a 15% target but for only nine provinces. We assumed China would not expand beyond the nine provinces and would meet its 15% target (and used this as its mandate) because past targets have systematically been met. China's transportation fuel demand growth rate in affected provinces is assumed to be the same as China's overall growth rate. Where uncertainty in current implementation of mandates exists, the midpoint of the range was used for calculations (e.g. China 8-12% current ethanol blend was calculated at 10%).

(6) Only considered India's 5% bioethanol mandate to be binding, so we did not assume the country's 20% bioethanol and 20% biodiesel targets would be filled.

(7) Indonesia currently has a 5% mandate for biofuels, but also has more aggressive targets of E15 and B20 by 2025. The higher targets are used in this analysis.

(8) All transportation growth is annualized on a linear basis from IEA and USDA growth rates.

(9) The growth rate for Chinese transportation fuel demand is for the entire country though the mandate covers only nine provinces.

Appendix B: Global Biofuel Mandates

OECD

Country/ Region	Mandate/Target	Level of Implementation	Anticipated Growth to Reach Mandate (%)	Primary Feedstock
OECD	**Various**	**Implemented, or on track to be fully implemented by target dates.**	**Various**	**Various. Both domestically produced and imported.**
United States	137BL of biofuels by 2022 divided into requirements for first generation, advanced and cellulosic fuels.[159]		21% growth to meet non-cellulosic mandate by 2022. Current production of 58BL of ethanol (corn and sugar) and 5BL of biodiesel.	Corn, soy, animal fat, sugar cane (imported).
Canada	5% national bioethanol mandate; 2% national biodiesel mandate; up to 8.5% bioethanol mandates in four provinces.	Fully implemented.	None.	Corn, wheat, canola oil.[160]
European Union	10% of transportation fuels from renewables by 2020 but proposal for only 7% from food-based feedstocks. Projected volumes for full implementation would be around 30,000ktoe.[161]	In 2012, most countries were on track to meet the 2020 targets. Projections show the EU will fall short of its 2020 goal by approximately 1/3 using around 20,000ktoe in 2020.[162]	92% increase required to meet 10% mandate, which accounts for a drop in transportation demand.	Varies from country to country.
Germany		7-8% of transportation fuel from bioethanol in 2009.[163] 2.6 billion tonnes of biodiesel in 2010; insolvency in companies is leading to lower numbers in recent years.[164]	2-3% from EU 2020 target.	Vegetable oil.[165]
United Kingdom		3.45% of transport fuel from bioethanol.[166]	6.55% from EU 2020 target.	Wheat and sugar beets.[167]

Country/ Region	Mandate/Target	Level of Implementation	Anticipated Growth to Reach Mandate (%)	Primary Feedstock
Spain	Revised targets down to 4.1% for all bioenergy and 3/9% for bioethanol in 2013.[168]	Biodiesel blending has not been enforced since 2010. Revised targets were met in 2013.[169]	6.1% from EU 2020 target.	Domestic oil seeds, imported palm, and animal fat.[170]
France	Current target of 7%.[171]	5.78% from bioethanol and 7.07% from biodiesel.[172]	4.28% from EU 2020 target.	Corn and sugar beets.[173]
Italy		4% of transport fuel from bioethanol in 2009.[174]	6% from EU 2020 target.	Rapeseed, soy, palm, cereal and wine byproducts.[175]
Sweden		Reached target of 10% biofuels in transport fuels.[176]	Met EU 2020 target.	Rapeseed and wood pellets.[177]
Australia	New South Wales 5% ethanol mandate and 2% biodiesel mandate.[178]	Implemented. 6% ethanol mandate adjusted down to 5% until more local supplies are available.[179]	None.	
New Zealand	Biofuel mandate allowed to expire.[180]	The bioethanol excise exemption remains, but other subsidies have been allowed to expire.[181]	N/A.	
South Korea	2% biodiesel mandate.[182]	Since 2010, held production at 400,00kL/year.[183]	None.	
Mexico	2% ethanol mandates in two provinces.	Not fully implemented.	Unclear.	
Chile	5% ethanol and biodiesel target.	Target not met.	Unclear.	Import dependent. No significant domestic production.
Turkey	6% ethanol mandate and 1% biodiesel mandate.[184]	Implemented. Biodiesel blend rate exceeded.[185]	Ethanol usage must double.[186]	Waste cooking oil and sugar beets.[187]

Producers Meeting High Mandates

Country/ Region	Mandate/Target	Level of Implementation	Anticipated Growth to Reach Mandate (%)	Primary Feedstock
	Greater than or equal to 10% ethanol or biodiesel.	**Fully implemented or close to full implementation.**	**Various.**	**Various.**
Argentina	10% biodiesel mandate, 5% ethanol mandate.[188]	Implemented, average national ethanol blend of 7.6% in 2013 (600 million liters).[189]	64% increase to meet current mandates in 2025, which includes increased transport demand.	Soy, sugarcane.[190]
Brazil	25% ethanol blend mandate, 7% biodiesel mandate.[191]	Fully implemented.	36% increase required to maintain current blend level with increased transport demand by 2025.	Sugarcane and soy.
Colombia	8% or 10% ethanol mandate depending on stocks.	Fully implemented.	None.	Sugar cane and palm.[192]
Ecuador	5% biodiesel mandate to increase to 10%; 10% ethanol mandate.[193]	Mandates were being filled as of 2012.[194]	None.	Palm, sugar cane, jatropha.[195]
Paraguay	25% ethanol mandate, but the Senate has passed an increase to 27.5%; 1% biodiesel mandate.[196]	Fully implemented.	None.	Sugarcane.
Peru	7.8% ethanol mandate; 5% biodiesel mandate.[197]	Implemented.	None.	Primarily importing Argentine biodiesel.[198]
Philippines	10% ethanol mandate; 2% biodiesel mandate.[199]	Implemented, but difficulty reaching the 10% ethanol mandate,[200] planned expansion to 5% biodiesel is not yet implemented.	None. 3% for proposed biodiesel expansion.	Palm and coconut oil.
Zimbabwe	15% ethanol mandate (recently up from 5%).[201]	Forced to scale back 20% mandate due to lower production.[202]	None for adjusted mandate.	

Producers Proposing High Mandates

Country/ Region	Mandate/Target	Level of Implementation	Anticipated Growth to Reach Mandate (%)	Primary Feedstock
	Mandates over 5%.	**Not yet fully implemented or level of future implementation is unclear.**	**Various.**	**Various.**
Costa Rica	7% ethanol mandate; 20% biodiesel mandate.[203]	Unclear: seemingly not fully implemented.[204]	Unclear.	Jatropha,[205] palm, sugar cane.[206]
Panama	Currently 5% ethanol mandate to rise to 10% by 2016.	Unlikely to reach 10% by 2016 due to lack of capacity.[207]	5%.	Sugarcane.
China (PRC)	10% biofuels mandate by 2020; 15% biofuels target by 2020.[208]	E10 required and implemented in 9 provinces.[209] Actual blend rate reported between 8 and 12%.[210]	109% increase required to meet 15% biofuels target, which includes expected increased transport demand.	Grain, waste cooking oil, investing in sorghum, cassava and other food crops that can be grown on marginal land.[211]
India	5% ethanol mandate (reduced from 20% target); 20% biodiesel target.[212]	Projected at 2.1% in 2014 and 2.5% in 2015.[213]	89% increase to meet 5% ethanol mandate only by 2025, which includes expected increased transport demand.	Sugarcane, multiple feedstocks for biodiesel moving from jatropha to tree nuts.[214]
Indonesia	5% biofuel mandate; 15% ethanol target and 20% biodiesel target by 2025[215]	4.5% of biodiesel mandate met, but 0% for ethanol.	945% increase to meet full targets and future projected demand for transport fuel.	Palm.
Malaysia	5% biodiesel mandate[216]	Not yet fully implemented throughout the country. Target of this year for implementation in all locations.[217]	Unclear. None if goal is met this year.	Palm.
Thailand	10% biodiesel target by 2019.[218]	Level of implementation depends on palm oil supplies.	Unclear.	Palm.
Vietnam	5% ethanol mandate to go into effect at the end of 2014.[219]	Has not yet begun.	N/A	

Country/ Region	Mandate/Target	Level of Implementation	Anticipated Growth to Reach Mandate (%)	Primary Feedstock
Malawi	10% ethanol mandate.[220]	Only major producer of ethanol in Southern Africa. No readily available data on steps it has taken to meet the mandate.	Unclear.	Jatropha[221] and sugarcane.

All Other Mandates

Country/ Region	Mandate/Target	Level of Implementation	Anticipated Growth to Reach Mandate (%)	Primary Feedstock
Jamaica	10% ethanol mandate[222]	Unclear.	Unclear.	
Uruguay	2% biodiesel mandate from domestic biodiesel; thought will move to 5% ethanol mandate.[223]	Unclear.	Unclear.	Soy, tallow, sugarcane.[224]
Fiji	Voluntary 10% ethanol blend, 5% biodiesel blend.[225]	Unclear.	Unclear.	Unclear.
Taiwan	1% biodiesel mandate.[226]		None.	
Angola	10% ethanol mandate.[227]		Unclear.	Sugar.[228]
Ethiopia	5% ethanol mandate.[229]	Some biofuels plants online, the majority are pre-implementation.[230]	Unclear.	Sugar and jatropha.[231]
Kenya	Kisumu has a 10% ethanol mandate.[232]	Not implemented. Mandate remains a target.	Unclear (close to 10%)	Jatropha.[233]
Mozambique	10% ethanol mandate.[234]	Have created a legal framework, but not fully implemented.[235] 36MnL/year average 2010-2012.[236]	Unclear (close to 10%)	
Nigeria	10% ethanol target.[237]	Not implemented.[238]	Unclear (close to 10%)	
South Africa	Planned 2% ethanol targets and 5% biodiesel targets to begin in 2015.[239]	367MnL/year ethanol production average 2010-2012.[240]	N/A	Sugar cane, sugar beet, sweet sorghum, soybeans, sunflower seed, canola oil and vegetable oil.[241]
Sudan	5% ethanol mandate.[242]	Plans for expanded production. No indication have reached 5%.	Unclear.	Jatropha.

Appendix C: Biofuels Projects in Ethiopia[243]

Table 2: List of biofuel projects in Ethiopia as of December 2012

Feedstock	Project	Investment Type (Public, domestic private, foreign private)	Area (ha)	Location	Current Status of implementation
Sugar cane [3]	Fincha Sugar Factory	Public	21,000	Oromiya	Operational
	Metahara Sugar Factory	Public		Oromiya	Operational
	WONJI / SHOA SUGAR FACTORY	Public	16,000	Oromiya	Operational
	Tendaho Sugar Development Project	Public	50,000	Afar	Implementation
	Wolkaiyt Sugar Development Project	Public	45,000	Tigray	Implementation
	Kuraz Sugar Development Project	Public	175,000	SNNPR	Implementation
	Kessem Sugar Development Project	Public	20,000	Oromiya	Implementation
	Belles Sugar Development Project	Public	75,000	Amhara	Implementation

35_OP_LCFS_AAUSA Responses

152. Comment: **LCFS 35-2 through LCFS 35-3**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

153. Comment: **LCFS 35-1**

The comment states that lowering the iLUC score for corn ethanol will incentivize greater use of corn ethanol which undermines food security and has questionable environmental benefits.

Agency Response: See response to **LCFS 35-2**.

154. Comment: **LCFS 35-4**

The comment states that government mandates will drive demand growth for biofuels, such as corn ethanol.

Agency Response: The adjustments to the carbon intensity (CI) of corn ethanol as well as the adjustments for other biofuels are based on the latest science and improved modeling. The model as currently structured does not allow a detailed evaluation of the impacts of biofuels on global food security. To evaluate such effects ARB staff would need to collect data for calorific content of food and feed production, and the modeling structure would need to be modified accordingly. When these data become available and are collected, future revisions of the model could allow the evaluation of global food security effects and the effect could be incorporated into the indirect Land Use Change (iLUC) analysis.

February 17, 2015

Mary D. Nichols, Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95812

RE: **SUPPORT FOR LCFS READOPTION AND ADF REGULATION ADOPTION** at February 19-20, California Air Resources Board Hearing

Dear Chair Nichols:

I am writing to express our support of both the re-adoption of the Low Carbon Fuel Standard ("LCFS") and the adoption of the Alternative Diesel Fuel ("ADF") regulation. We want to thank the leadership and staff at the Air Resources Board (ARB) for all of the hard work on these very important issues to Californians, and applaud you on implementing a program that has served as a blueprint for other carbon reduction plans all over the country. LCFS 36-1

My friends and family started New Leaf Biofuel in San Diego in 2006. Our mission was, and is, to convert used cooking oil into biodiesel, which we then sell back to the community in order to create local jobs at our plant and to reduce greenhouse gas emissions caused by the burning of fossil fuels. We chose to locate our production facility in Barrio Logan because we wanted to contribute to an economically disadvantaged community. Our mission has always focused on serving as a model for economic, environmental, and social sustainability.

Over the years, New Leaf, and the biodiesel industry in general, has faced enormous challenges. These include lack of infrastructure, unstable federal policy, and opposition from fossil fuel interests—just to name a few. The Low Carbon Fuel Standard is a critical policy that demonstrates California's commitment to the environment, and provides stability that will spur investment and innovation to further our carbon reduction goals. We, therefore, fully support the re-adoption of the Low Carbon Fuel Standard. LCFS 36-2

I recognize that the process to craft the ADF regulation has been challenging, and I appreciate your efforts to keep the interests of all stakeholders in mind. Importantly for New Leaf and other community-sized businesses that serve smaller diesel markets, we are particularly supportive of the implementation timeline that is designed to allow our industry to certify an ADF 14-1 additive “solution,” improve infrastructure, or otherwise adjust business plans to comply with the ADF regulation. ADF 14-1 cont.

We also look forward to continuing to work with the ARB on the evaluation of options that would allow limited, district-specific exemptions for some fleets to continue use of biodiesel blends up to and including 20 percent (B20). ADF 14-2 We are optimistic that by continuing to work together, we can strike a balance that will address the air quality and public health concerns particular to each part of the state, while achieving the objectives of the Low Carbon Fuel Standard. LCFS 36-2

Again, thank you for your work on this important issue and for your interest in understanding New Leaf’s perspective.

Sincerely,

New Leaf Biofuel, LLC

a California limited liability company

Jennifer Case, President

36_OP_LCFS_NLB Responses

155. Comment: **ADF14-1 and ADF 14-2**

Agency Response: The responses to these comments are in the Alternative Diesel Regulation Final Statement of Reasons under Comment Letter **14_OP_ADF_NLB**.

156. Comment: **LCFS 36-1**

The comment expresses support for the re-adoption of the LCFS regulation and adoption of the ADF regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

157. Comment: **LCFS 36-2**

The comment expresses appreciation for ARB staff's commitment to both the environment and to providing stability that will spur investment and innovation to further carbon reduction goals.

Agency Response: Staff appreciates New Leaf Biodiesel's support of proposed LCFS regulation. Staff agrees with New Leaf Biodiesel that the objectives of the LCFS are achievable, and the air quality and public health concerns can be addressed simultaneously.

February 17, 2015

Ms. Tracy Jansen
Clerk of the Board
California Air Resources Board
1001 I Street
PO Box 2815
Sacramento, California 95812
USA

Dear Ms. Jansen:

On behalf of the Government of Alberta, I would like to provide you with comments on the re-adoption of the updated Low Carbon Fuel Standard (LCFS) being implemented by the California Air Resources Board (CARB).

Albertans, like Californians, understand the importance of carbon management and the need to gradually transition to alternative, less carbon intensive forms of energy. Nevertheless, North America will continue to require secure supplies of oil and gas for decades to come. As Alberta develops its natural resources, environmental stewardship and social responsibility will continue to remain of great importance.

Alberta has a strong desire to collaborate with other jurisdictions to strengthen North America's integrated energy and economic systems as we continue to focus on technology and innovation to address climate change. Alberta has been a strong supporter of long-term efforts to reduce greenhouse gas emissions and continues to support the intent of the LCFS. The Government of Alberta encourages California to consider Alberta's mandatory upstream oil greenhouse gas emissions reduction policies in the development of Alberta's crude oil carbon intensity (CI) values. Under Alberta's greenhouse gas emissions regulatory framework, oil that comes from a regulated facility has a reduction obligation.

In 2007, Alberta passed the Specified Gas Emitters Regulation (SGER), a regulatory framework to reduce greenhouse gas emissions intensity from large industrial emitters and to set up a carbon trading market. Since July 1, 2007, the regulatory framework requires large emitters (facilities releasing 100,000 tonnes or more of greenhouse gas emissions annually) to reduce emissions intensity by 12 per cent.

.../2

There are four choices to comply with reduction targets:

1) make facility improvements to reduce greenhouse gas emissions intensity;
2) use emission performance credits (exceeding 12 per cent target) created in previous years or at other facilities;
3) purchase Alberta-based carbon offset credits; and/or
4) pay $15 per tonne into the Climate Change and Emissions Management Fund (CCEMF).

To date, nearly 51 megatonnes of reductions have been realized relative to business-as-usual projections, and over $503 million has been contributed to the CCEMF, with $249 million invested into clean energy projects.

In the re-proposed LCFS, there does not appear to be recognition of emissions reductions achieved through flexible compliance options, such as Alberta-based carbon offsets, in the development of CI values. A robust analysis of various international crudes should recognize all emissions reductions driven by a jurisdiction's climate change policies. This should include direct emission reductions, as well as greenhouse gas emission reductions that occur through carbon offsets. LCFS 37-1

It would also be of interest to Alberta to understand how marketable crude oils (MCOs) derived from SGER facilities may be incentivized under the re-adopted LCFS. We are pleased to see that the proposed and updated *Crude Oil Carbon Intensity Lookup Table* values now reference a single, non-discriminatory baseline default CI value for all MCOs that comprise the California crude basket, regardless of production method. However, as previously outlined to the CARB in our 2012 submission, updating the LCFS to address issues regarding crude production data quality will be paramount to LCFS's ability to meet regulatory goals. LCFS 37-2

Assumptions made on crude oil production in absence of transparent data may have significant impact on the overall carbon-intensity value of a particular crude oil pathway and how it is categorized. LCFS 37-3

.../3

As drafted, accuracy for LCFS crude estimates is ultimately limited by the data quality reported by an operator. Data quality within North America, and even more significantly from overseas sources, varies considerably from region to region, with key crude production data often remaining undisclosed, such as flaring and venting and produced fluids. As such, data variability and information gaps between jurisdictions have a considerable impact on the uncertainty associated with the estimated carbon-intensity value of their respective crude oils. Relative to Alberta, the availability and reliability of crude production data input into the Oil Production Greenhouse Gas Emissions Estimator (OPGEE) model provided to California by other jurisdictions remains an outstanding concern. LCFS 37-3 cont.

During a February 20, 2014 workshop[1] in Brussels, Belgium, Professor Adam Brandt discussed details for current work in areas of model calibration and data uncertainty, and also planned Phase II activities for the OPGEE, including oil sands modelling, tight oil, hydraulic fracturing, CO_2 enhanced oil recovery and solar-thermal technology. Updates for such modules may have considerable impacts on the carbon intensities for current MCOs comprising the California feedstock and warrant regular updates to the re-adopted *Crude Oil CI Lookup Table*. The Alberta government welcomes the opportunity to work with the CARB in its modelling efforts for such Phase II activities, particularly in areas related to oil sands. LCFS 37-4

Alberta continues to make efforts in reducing its environmental footprint and in effectively managing its carbon emissions, illustrated by the use of innovative crude production technologies in existing reserves and improved environmental monitoring technologies that encourage responsible development of Alberta-based crude oils.

It is clear that Alberta and California are both working toward reducing the overall environmental footprint of our energy production and use. We are working toward a clean energy future that includes de-carbonized fossil fuels. Alberta has stringent legislation and measures in place to protect air, land and water during oil and gas development, and we are committed to ongoing environmental improvements that will ensure we remain among the most environmentally responsible energy producers in the world.

Alberta welcomes the opportunity to continue to work with California, and I would like to offer our province's key learnings and experiences in crude oil data collection and management. Attached are additional technical comments for your consideration, and we would be happy to further discuss these with you.

Thank you again for providing the opportunity for Alberta to further discuss the LCFS with you.

Best regards,

Gitane De Silva

Alberta Government

State of California's Low Carbon Fuel Standards' (LCFS) Rulemaking Proposal

GOVERNMENT OF ALBERTA TECHNICAL SUBMISSION

- Current activities for the Oil Production Greenhouse Gas Emissions Estimator (OPGEE) model have been stated to include:
    i. calibration; and
    ii. an uncertainty analysis and examination of models such as PRELIM.
  - Could the California Air Resource Board (CARB) please provide further modelling details and elaborate on the timelines for such activities (i.e. planned, underway, or finalized) for these respective area/modules? LCFS 37-5

- Planned Phase II activities for the OPGEE model have been stated in various CARB workshops to include:
    i. oil sands modelling;
    ii. tight oil; and
    iii. hydraulic fracturing , CO_2 enhanced oil recovery and finally solar-thermal technology.
  - Could CARB please provide further details on potential changes to the OPGEE and elaborate on the timelines for such activities (i.e. planned, underway, or finalized) for these respective area/modules listed, including potential dates? LCFS 37-6
  - Is it foreseen that select Marketable Crude Oils (MCOs) listed in the *Carbon Intensity Values for the Crude Lookup Table* would be subject to regular (i.e. bi-annual or annual) amendments based on future developments for the respective areas/modules? If so, will an impact assessment be conducted annually, or every three years, for the California baseline default value? LCFS 37-7

- Given the OPGEE 1.1 model uses a separate module based on GHGenius, will cited[1] differences be accounted for in overall crude production carbon intensities under the re-adopted LCFS? Could the CARB comment on carbon intensity differences for mining based MCOs? Specifically, are values higher or lower when MCOs are input into the OPGEE, compared to GHGenius? LCFS 37-8

- Some uncertainty exists as to whether OPGEE updates will occur every three years, as outlined in the LCFS rulemaking proposal, or every one to two years, as outlined in the OPGEE 1.1 user's manual. LCFS 37-9

- The preferred compliance curves presented on III-13 (Option 3's 'gradual compliance curve') call for a 50 per cent reduction in fuel carbon intensity in two years. The possibility exists that credit supplies will be exhausted in these more intensive years (or perhaps even beforehand), thereby negating their envisioned use in the 2020-2025 period. LCFS 37-10

[1] O'Connor, D. (2013) OPGEE analysis and comparison to GHGenius. Prepared for Natural Resources Canada, August 19, 2013.

- The LCFS rulemaking proposal outlines that credit prices are not expected to exceed $100/credit. What then is the need for placing a cap on the credit price and can such a control de-incentivize program participants? LCFS 37-11

- Though only presented as being under staff consideration, the rationale behind limiting LCFS eligibility to on-site carbon capture and storage production facilities is not made entirely clear and this proposal's relation to California's Cap and Trade program needs to be more fully clarified. LCFS 37-12

- Proper Tier 2 carbon-pathway validation (third party engineering reports, submissions for Environmental Protection Agency approval, etc.) may require more than 30 days to fulfill. LCFS 37-13 Likewise, submission of evidence for out of state fuel transport modes (or related updates) may also require more than 30 days. LCFS 37-14

37_OP_LCFS_Alberta Responses

158. Comment: **LCFS 37-1**

The commenter recommends that ARB include emission reductions associated with carbon offsets purchased through Alberta's Specified Gas Emitters Regulation in assessing carbon intensities for Alberta crude.

Agency Response: The LCFS is based on the principle that each fuel has "life cycle" GHG emissions that include CO_2, N_2O, and other GHG contributors. This life cycle assessment (LCA) examines the GHG emissions associated with the production, transportation, and use of a given fuel. Therefore, only those activities that directly affect the emissions associated with production, transportation, and use of the fuel will be reflected in the fuel's carbon intensity. Offset credits purchased through climate change programs such as the California Cap and Trade or Alberta's Specified Gas Emitters Regulation (SGER) do not directly affect the life cycle emissions of the fuel and therefore are not acknowledged under the LCFS.

159. Comment: **LCFS 37-2**

The commenter is interested in understanding how crude oil produced in Alberta under the SGER may be incentivized under the re-adopted LCFS.

Agency Response: ARB staff welcomes the opportunity to work with crude oil producers who are willing to provide data to more accurately model the carbon intensity of crudes they produce. Facility improvements designed to lower emissions under Alberta's SGER will lead to lower carbon intensity for the crude under the LCFS. Moreover, crude oil producers may earn LCFS credit on crude sold to California refineries that is produced using innovative production methods.

160. Comment: **LCFS 37-3**

The commenter expresses concern about carbon intensity estimates made for crude oil produced in regions with poor availability of crude production data.

Agency Response: While very good data is available for California, Alaska, western U.S., Alberta oil sands, and some foreign crudes, ARB staff agrees that the lack of accurate data on production parameters for many imported crudes, including conventional light, medium, and cold heavy production from Alberta, is a problem. This lack of data takes two forms: lack of field production data and lack of data that maps field production to marketable crude blends. We have explored options for obtaining this data from several data collection sources and have asked refiners and oil producers to supply this data with very little success. Oil producers are also encouraged to supply data to ARB in order to help maintain a robust database. If crude-specific data cannot be obtained and are not provided by producers, the Oil Production Greenhouse Gas Emissions Estimator (OPGEE) assigns default parameters when estimating the carbon intensity for these crudes. OPGEE defaults are based on available information for a parameter and within the range observed worldwide. Moreover, for some input parameters, OPGEE makes use of "smart defaults." Smart defaults are used by OPGEE for those parameters that can be correlated to other parameters that are often known. For instance, the produced water-to-oil ratio is often unknown, but this parameter can be correlated to field age which is almost always known. We believe that these default parameters generally result in conservatively high carbon intensity (CI) estimates for crudes that are lacking in quality data. Producers who do not believe that these defaults accurately represent their crude production are encouraged to provide ARB with complete and accurate data.

161. Comment: **LCFS 37-4**

The commenter discusses current and future work related to the Oil Production Greenhouse gas Emissions Estimator (OPGEE) and CI values in the crude lookup table.

Agency Response: See responses to **LCFS 37-5**, **LCFS 37-6**, and **LCFS 37-7**.

162. Comment: **LCFS 37-5**

The commenter requests ARB to elaborate on activities involving calibration and uncertainty analysis for the OPGEE model.

Agency Response: ARB staff has not engaged in either calibration or uncertainty analysis for the OPGEE model. However, Adam Brandt at Stanford University has published several papers on the topics of model uncertainty and comparison of OPGEE model results to other LCA models. Citations for these papers include:

1. Vafi, K and A.R. Brandt (2014), Uncertainty of Oil Field GHG Emissions Resulting from Information Gaps: A Monte Carlo

Approach, *Environmental Science and Technology*, 48, 10511-10518, dx.doi.org/10.1021/es502107s.

2. Vafi, K., A.R. Brandt, (2014). Reproducibility of LCA models of crude oil production. *Environmental Science & Technology*. DOI: 10.1021/es501847p

3. Brandt, A.R., Y. Sun, K. Vafi (2014). Uncertainty in regional-average petroleum GHG intensities: Countering information gaps with targeted data gathering. *Environmental Science & Technology*. DOI: 10.1021/es505376t

163. Comment: **LCFS 37-6**

The commenter asks ARB to elaborate on "Phase II" activities involving updates to the OPGEE model.

Agency Response: In mid-2014, ARB staff issued a contact to Adam Brandt of Stanford University. The project scope includes revisions to the treatment of oil sands mining, thermal recovery, and bitumen upgrading and new pathways for tight oil and gas production using hydraulic fracturing and carbon capture with CO_2 enhanced oil recovery. The project is expected to be completed in 2016, at which time the draft model will be posted for public review and one or more workshops will be held to discuss the model changes.

164. Comment: **LCFS 37-7**

The commenter asks ARB to elaborate on the timing of future revisions to the OPGEE model, the crude lookup table CI values, and the 2010 Baseline Crude Average CI.

Agency Response: The regulation language states that "Revisions to the OPGEE model, addition of crudes to Table 8, and updates to all carbon intensity values listed in Table 8 will be considered on a three-year cycle through proposed amendments of the Low Carbon Fuel Standard regulation." If OPGEE model revisions or availability of new oil production data result in changes to the carbon intensity values for 2010 baseline crudes, the 2010 Baseline Crude Average carbon intensity (CI) will be updated as well.

165. Comment: **LCFS 37-8**

The commenter asks ARB to elaborate on differences between the treatment of mined oil sands in the OPGEE and GHGenius models.

Agency Response: The carbon intensity value for "mined and upgraded" synthetic crude oil is slightly higher in OPGEE than in GHGenius. The major differences between the two models are for emissions related to land use change (OPGEE is higher) and transport (GHGenius is higher). OPGEE also includes a small, 0.5 g/MJ assessment for small sources. Emissions estimates for feedstock recovery; upgrading; and venting, flaring, and fugitives are very similar between the two models. Overall, the carbon intensity value for light synthetic crude as estimated by OPGEE is less than 5 percent greater than the value estimated by GHGenius.

166. Comment: **LCFS 37-9**

The commenter asks ARB to clarify the update cycle for the OPGEE model.

Agency Response: See response to **LCFS 37-7**.

167. Comment: **LCFS 37-10**

The comment states that there is a risk that credit supplies will be exhausted in two years.

Agency Response: ARB staff agrees that there will likely be a significant drawdown of banked credits in the 2018 to 2020 period. However, staff's analysis show that there should be a sufficient carry-over of banked credits to maintain a surplus through the post-2020 timeframe when annual credit production, as shown in the illustrative compliance scenario, is expected to begin to exceed the annual rate of deficit incurrence at the 10 percent carbon intensity reduction level. Additionally, given the strong incentives to maintain compliance with the LCFS, ARB staff believes that most, if not all, regulated parties will take steps to ensure they acquire sufficient credits to maintain compliance with the regulation.

168. Comment: **LCFS 37-11**

The comment questions the need for a cap on the credit price. It goes on to add that such a cap may de-incentivize program participants.

Agency Response: The price cap provides an upper bound on the potential cost of credits, and should not be construed as a projection of future credit prices or as a projection of future cost of compliance. Likewise, the $100 illustrative credit price referenced in staff's economic analysis should not be construed as a forecast of future credit prices; ARB does not project future credit prices.

A cost containment mechanism is an essential component of the market rules governing the LCFS fuel market. Investment decisions in new fuel supplies will depend on having clarity regarding how the program will manage price volatility or shortfalls in low CI fuel. Implementing a clear, predictable provision to handle any credit shortage or price spike reduces the risk of supply shortages or price spikes. This means that cost containment actually *increases* the likelihood of meeting the standard by providing regulatory certainty for investors that the LCFS will continue to provide a predictable price premium for low-CI fuels in the future, under all possible outcomes.

See response to **LCFS 32-9**.

169. Comment: **LCFS 37-12**

The commenter asks ARB to clarify the treatment of CCS for credit under the LCFS and particularly the innovative crude provision.

Agency Response: As discussed on pages III-47 and 48 of the Initial Statement of Reasons, ARB staff is proposing to include two revisions restricting the use of carbon capture and storage (CCS) as an innovative crude oil production method. These revisions will help align the treatment of CCS under the innovative crude provision with the treatment under the Cap-and-Trade (C&T) Program. Under the C&T Program, the emission reduction credit for CCS projects is effectively allocated to the facility where carbon capture occurs. In order to be consistent with this allocation methodology, ARB staff is proposing that CCS projects will only qualify for innovative crude provision credit if the carbon capture occurs onsite at the oil production facility. The C&T Program has also delayed credit generation for CCS projects until after ARB has in place an approved quantification methodology for monitoring, reporting, verification, and permanence requirements associated with the carbon storage method. Staff proposes to adopt the same restriction for CCS credit generation under the LCFS.

The most common method of sequestration being considered for carbon capture projects in the United States is through carbon dioxide enhanced oil recovery (CO_2 EOR). Sources of anthropogenic carbon include natural gas, ethanol, synthesis gas, and electrical power production. Therefore, carbon capture with CO_2 EOR projects often involve the production of two fuels, the fuel produced at the capture facility and the crude oil produced using CO_2 EOR. Under the LCFS, the GHG emissions benefits of capture and sequestration for these projects can either be allocated to the fuel produced at the capture facility (i.e., Method 2 pathway application), the oil produced using CO_2 EOR (i.e., innovative crude method provision), or partially allocated to both. ARB staff has decided that emissions benefits of CCS projects are best allocated to the capture facility as this allocation is consistent with:

- Treatment of CCS under the Cap-and-Trade Program and the proposed LCFS refinery investment provision, as well as the U.S. Environmental Protection Agency's (U.S. EPA's) GHG regulations on new power plants. Under all of these programs, credit for emissions reduction due to CCS is allocated to the capture facility.
- The goals of the LCFS, which include reducing the CI of fuels in the transportation sector and promoting the development and use of alternative fuels. By allocating to the capture facility, the capture and sequestration of CO_2 emitted during the production of alternative fuels such as ethanol and hydrogen is promoted as these alternative fuels may be eligible for a much lower CI through the LCFS Method 2 application process.
- The fact that CO_2 EOR is not innovative, as it has been used for decades. However, capturing CO_2 from a steam generator at the oil production facility or from a methane reformer at a bitumen upgrader is considered to be innovative.

Therefore, under the innovative crude provision, ARB staff is proposing that carbon capture must occur onsite at the crude production facility in order for the oil producer to receive innovative crude method credit. Oil producers that simply inject CO2 that has been captured elsewhere are not eligible for innovative method credit.

While ARB staff acknowledges that limiting CCS as an innovative method to only those instances where capture occurs onsite will reduce the potential for generating LCFS credit, staff continues to believe significant credit potential exists for onsite carbon capture and that these proposed changes are appropriate.

170. Comment: **LCFS 37-13**

The comment states that the time allowed to submit evidence for validation of Tier 2 pathways may not be sufficient.

Agency Response: ARB staff believes the deadlines proposed are adequate for processing of Tier 2 applications. Section 95488(e) of the proposed LCFS regulation includes a 90-day period, not the 30-days as the commenter states, for regulated parties to submit the demonstration of a fuel transport mode as follows:

> "*Evidence of Fuel Transport Mode.* A regulated party may not generate credits pursuant to section 95486 unless it has demonstrated to the Executive Officer that a fuel transport mode exists, for each of the transportation fuels for which it is responsible under the LCFS regulation, and that each fuel transport mode has been approved by the Executive Officer pursuant to this section. Transactions associated with fuels for which a fuel transport mode has not yet been approved must be reported using a fuel transport mode code PHY10 in the LRT-CBTS. Electricity used as a transportation fuel is exempt from this requirement. For purposes of this provision, "demonstrated" and "demonstration" includes any combination of either (i) a showing by the regulated party using its own documentation; or (ii) a showing by the regulated party that incorporates by reference documentation voluntarily submitted by another regulated party or a non-regulated party fuel producer that accurately represents the regulated party's transportation fuel.
>
> A regulated party must submit the demonstration of a fuel transport mode to the **Executive Officer within 90 days of** providing a fuel in California unless an initial demonstration of fuel transport mode was previously submitted and approved under the provisions of the previous LCFS regulation order. The Executive Officer shall not approve a fuel transport mode demonstration unless it meets the following requirements:"

If the applicant has previously submitted the physical transport mode information and there are no changes to the fuel transport mode, there is no need for resubmittal. In addition, ARB staff provides flexibility on the submission of out-of-state fuel transport modes by offering two application options: 1) CA-GREET user default, and 2) use of alternative bill of lading for new fuel pathways. Staff will continue to work with the public on a case-by-case basis, upon request, during the application evaluation process.

171. Comment: **LCFS 37-14**

The comment states that the time allowed to submit evidence for out of state fuel transport modes may not be sufficient.

Agency Response: See response to **LCFS 37-13**.

Re: Low Carbon Fuel Standard Re-Adoption

Dear Madam or Sir:

Chevron appreciates the opportunity to review and comment on the referenced re-adoption proposal.

Chevron is a major refiner and marketer of petroleum products in the state of California and a regulated party under the Low Carbon Fuel Standard (LCFS). We are a member of the Western States Petroleum Association (WSPA) and we support the comments submitted by WSPA in response to this proposed rulemaking. We are providing our separate comments below that highlight the issues of greatest importance to Chevron.

If you have any questions regarding our comments, please contact Nick Economides (925-842-5054) or Rick Powell (832-854-6541).

Thank you for providing this opportunity for Chevron to comment on the re-adoption.

Kind Regards,

Rick Powell
General Manager
Fuels & Product Strategy

Comments of Chevron

Re-Adoption of the California Low Carbon Fuel Standard:
Initial Statement of Reasons

February 17, 2015

Chevron appreciates the opportunity to submit written comments for the record on the above proposed rulemaking. Chevron is a California-based company engaged in oil and gas exploration, petroleum refining and petroleum product marketing. We are a regulated party under the Low Carbon Fuel Standard (LCFS). We are a member of the Western States Petroleum Association (WSPA) and we support the comments submitted by WSPA in response to this proposed rulemaking.

We understand that at the February 19-20 Air Resources Board (ARB) hearing, the Board will consider re-adoption of the Low Carbon Fuel Standard (LCFS) Regulation as well as adoption of the Alternative Diesel Fuel (ADF) regulation. Staff has jointly progressed these two rulemakings and considers them intimately connected as a joint regulatory action “package” to address requirements emanating from the July 15, 2013 State of California Court of Appeal, Fifth Appellate District (Court) opinion in POET LLC *v*. California Air Resources Board (2013) 218 Cal.App.4th 661. The judge’s opinion was that ARB did not adequately address biodiesel NOx emissions that could potentially result from LCFS implementation. The ADF regulation represents staff’s proposed solution to address California Environmental Quality Act deficiencies associated with biodiesel NOx impacts. Chevron’s comments on the ADF proposed rule have been incorporated in those submitted by the Western States Petroleum Association (WSPA), of which Chevron is a member. Our comments below are exclusively devoted to the LCFS rulemaking.

Chevron has worked with ARB over the past few months on the proposed LCFS re-adoption and participated in the series of workshops held by staff on individual segments of the proposed regulations. Chevron was also a member of ARB’s LCFS Advisory Panel and participated in that group’s meetings in 2014. Chevron has provided feedback to ARB through WSPA throughout the rule development process. Finally, Chevron has met with staff individually before and after the issuance of staff’s Statement of Reasons document to outline our concerns regarding the proposed revisions to the program. We appreciate staff’s openness in receiving our input on the large number of issues and considerations involved in this rulemaking and look forward to working with staff on additional refinement of the details of the proposed regulation in the coming months. We are prepared to discuss our comments further with ARB staff, if needed.

Summary

Halfway through the compliance decade (2010-2020), the LCFS program is falling short of meeting its originally envisioned targets and should be adjusted to more accurately reflect the real-world rate of development and market penetration of advanced low carbon intensity fuels. The primary reason is that technology in the cellulosic biofuel space has not emerged as ARB had anticipated. Chevron has first-hand knowledge of this; we embarked on an aggressive program to evaluate and develop promising new technologies and have been largely unsuccessful in this costly endeavor.

Staff implicitly recognizes that the original program targets are overly aggressive; they propose to revise the interim year (2016-2019) CI reduction targets downward in the proposed rule re-adoption. However, staff maintains that the 10% reduction target remains achievable and that "the program is working as intended." Staff's adjustment of the interim year targets, while welcomed, does not go far enough toward establishing the sustainability of the program moving forward. Moreover, claiming that the program's original CI reduction target can be met through the use of massive quantities of accumulated credits in the early years (when over-compliance may be possible), masks the true nature of the challenge the program faces as we head to 2020.

LCFS 38-1

In doing so, staff is not informing California policy makers of the need for immediate adjustment of the program's targets, choosing instead to delay action that will only yield a more severe crisis that must be addressed the next time program progress is reviewed. This decision further propagates the climate of uncertainty that this program has been shrouded in since its inception. It denies all stakeholders the opportunity to formulate concrete compliance strategies and turn their attention to their execution. Instead, affected stakeholders recognize that the program targets will need to be revised once again at some time in the near future. Thus, they remain "on hold" awaiting such revisions, with the delay further casting the program's 2020 goals in doubt. Chevron strongly recommends that staff adopt reasonable, achievable and sustainable CI reduction targets for all years up to and including 2020 as part of the LCFS' re-adoption and has provided staff with its estimates of what such a compliance schedule entails.

Chevron defines program "success" as the achievement of sustainable CI reductions, i.e., targets that can be met largely by the CI reductions generated during the individual compliance year with minimal reliance on an accumulated credit bank to accommodate the expected normal market fluctuations during the year. In that context, Chevron believes that the program's success depends on a dual-pronged strategy involving the setting of reasonable CI reduction targets (the "compliance curve") and maintaining close oversight of the program as it moves forward to ensure it is meeting its forecasted targets. To this end, Chevron recommends that ARB build mandatory biennial comprehensive LCFS program reviews into the re-adoption proposal, with the first one to be completed no later than 1/1/2017.

LCFS 38-2

While we recognize that the actions emanating from such interim LCFS program reviews cannot be predetermined, we expect ARB to consider concrete and specific key indicators (e.g., predicted vs. actual low-CI fuel penetration, predicted vs. actual LCFS credit balances, predicted vs. actual credit prices, overall credit market liquidity, differential of CA gasoline and diesel market prices versus the rest of the nation) as part of these reviews. Chevron also expects staff to include adjustment of the program's outer year targets in the scope of the interim reviews, should evidence of significant and systemic over- or underperformance versus the program targets be established. LCFS 38-2

Chevron is opposed to the Credit Clearance Market (CCM) proposed by staff as a cost control mechanism in the LCFS re-adoption rule. While we appreciate staff's intent in controlling costs to the consumer during short-lived periods when compliance obligations cannot be met and credit availability declines, Chevron believes that the proposed CCM mechanism has serious flaws and could very well result in unintended negative consequences. More specifically, CCM:

- Does not stipulate a mechanism for retiring deficits, if multi-year market shortages persist leaving the regulated community with the prospect of ever-increasing deficit accruals.
- May drive credit costs up, if credits are withheld from the regular market to get a higher CCM price at the end of the year.
- Provides no liability protection against invalid credits secured through the year-end CCM. LCFS 38-3
- Offers no connection between CCM outcome, program off-ramps, and future CI reduction targets.
- Offers refiners no flexibility to voluntarily participate and eliminates their ability to carry-over credits if they do not.

For these reasons, Chevron believes that staff should abandon the proposed CCM and rely instead on the combination of setting achievable targets and frequent interim program reviews outlined earlier. If staff insists on including a cost containment mechanism in the LCFS, Chevron recommends adoption of a simpler program analogous to that employed by EPA in the Renewable Fuels Standard. LCFS 38-4

Chevron believes that staff's forecast of potential CI reductions (and associated targets) in the 2018-2020 time frame are ambitious and unsustainable. Staff's own estimates show that only 7% of the 10% 2020 CI reduction target is sustainable, with the balance (3% CI reduction) attributable to using 7 million metric tons of CO_2e ($MMTCO_2e$) from the forecasted credit bank. Chevron notes that:

- Staff's assumptions on the potential LCFS credit buildup (through 2016) and drawdown (in 2017-2020) are unrealistic. The credit bank, since program inception, stood at slightly under 4 MMT at the end of the 3rd quarter of 2014 (the most recent available actual data). Staff assumes that it will rise to approximately 9MMT by the end of 2015 but offers little in terms of factual support for this aspirational view other than program re-adoption will provide the necessary program certainty for credit generation to begin in earnest. LCFS 38-5

Chevron's view is that the credit bank will likely build at a much slower pace and be exhausted by 2020, as individual year deficits materialize as early as 2017. LCFS 38-5 cont.

- Chevron's projections of relative contributions from most low-CI reduction fuels (e.g., ethanol, biodiesel) and other credit sources (e.g., electric vehicles) over the 2015 to 2020 period are approximately consistent with staff's. However, Chevron disagrees with key staff assumptions of the rate of growth (and associated contribution to meeting LCFS targets) of renewable diesel (RD) and renewable natural gas/biogas (RNG):

    - While renewable diesel is one of the more promising available low carbon intensity fuels for LCFS compliance, ARB's supply projections are optimistic and overly reliant on announced projects and nameplate capacities and downplay inherent feedstock availability concerns that will limit the longer term "upside" of RD. Furthermore, logistical hurdles in the short term (through 2016) involving Federal Trade Commission dispenser pump labeling regulations, superimposed on the fungible nature of the common carrier pipeline system, will be more difficult to overcome than staff assumes in projecting that RD will represent 12% of CARB diesel by 2020. LCFS 38-6

    - Staff's degree of reliance on large-scale production of RNG and diversion to motor fuel applications to generate LCFS credits is questionable. Without RFS and LCFS credit subsidies, RNG for transportation is uneconomic and, in our experience, investors are loath to take on projects where the entire rate of return is based on valuation of regulatory compliance credits. While biogas production is growing steadily, the economics are driving most new production to electricity. RNG projects typically cost twice as much as electricity projects yet offer no additional GHG emission benefits nor do they offer higher non-subsidy revenue to the producer. Furthermore, pipeline injection remains a major barrier due to its high cost, gas quality concerns, and surplus capacity availability.

- Chevron recognizes ARB's efforts to allow credit for refinery investments as an element of LCFS GHG reductions. Chevron is opposed to the concept of stationary source credits being applied to LCFS; we believe that these are covered under ARB's cap and trade program. However, since staff appears to be moving in this direction regardless of our input, we have turned our attention to ensuring the program's efficacy. We recognize that, before considering specific project applications, staff will need to establish the relative efficiency of the applicant refinery versus its peers. Staff's proposed choice of method and tools for efficiency ranking refiners in the state is inappropriate and inequitable toward larger, more efficient refiners. Moreover, the proposed thresholds and restrictions proposed by staff risk eliminating most potential projects. Chevron has conveyed its views of necessary modifications to staff; highlights of our proposed changes in the Refinery Investment Credit segment of the rule are included below: LCFS 38-7

    - The metric used to establish relative refinery efficiency should be the Complexity Weighted Barrel (CWB) as described in the detailed section of our comments. LCFS 38-8

- o Refiners should be allowed to offer offsets of criteria and air toxic pollutants if their efficiency improvement projects indicate a potentially adverse impact in such emissions. LCFS 38-9
- o The 0.1 gCO2e/MJ threshold is too stringent and should be revised consistent with staff's proposed minimum for Innovative Crude Production Technologies. LCFS 38-10
- o Investments should not be limited to capital projects; oftentimes sizeable energy efficiency improvements are funded out of operating expense per established IRS accounting regulations**.** LCFS 38-11
- o The project eligibility cutoff date should be changed to the project's startup date for any project commissioning post 1/1/2015; regardless of when initial project permit applications were filed, the project has not delivered GHG reductions until it starts up. LCFS 38-12
- o The bio-feedstock 10% threshold is too restrictive, even if defined as "percent of total process unit feed." Staff should convert this threshold to a minimum absolute GHG reduction impact. LCFS 38-13

Chevron recognizes that staff is recommending no changes to the crude handling provisions in LCFS as part of the re-adoption rulemaking. Notwithstanding Chevron's concerns with crude differentiation within the LCFS, <u>Chevron supports staff's decision not to recommend conversion from the current three-year CA average crude intensity tracking system to individual refinery baseline crude CI values and agrees with the rationale offered by staff for this decision</u>. Chevron also recognizes ARB's desire to continually improve the accuracy of LCFS data inputs, and recognizes that staff's approach in the re-adoption rulemaking is consistent with that principle. However, <u>we also believe that the degree of crude differentiation built into LCFS, unfairly penalizes indigenous CA crude production and remains unnecessarily excessive and should be reduced</u>. Our reasoning is as follows: LCFS 38-14

LCFS 38-15

- The fundamental reason for these provisions in the rule was to ensure that the average carbon intensity of crudes processed by California refiners did not increase over time. The available crude breakdown data for recent years (2012-1H2014) suggests that this threat has never materialized and that the CA crude average CI has remained relatively stable.
- The revised average indigenous California crude CI values included in the re-adoption package are overwhelmingly higher than corresponding values in the existing rule. Based on first half of 2014 crude volumes, the CI has increased by approximately 19% (comparing "old" vs. "new" Table 8 crude values). Our industry is effectively penalized for its attempts to maintain and increase in-state crude production even though the mix of crudes processed by CA refineries is not changing.
- The worst case scenario these provisions could potentially drive (i.e., exporting heavy California crude to maintain a constant annual average crude CI) yields no tangible greenhouse gas reduction benefits from a global standpoint.

- The ongoing staff effort to maintain and improve crude differentiation inputs and modeling tools in the LCFS is resource-intensive for ARB and equally burdensome for our industry.

In the absence of a valid GHG justification for engaging in such a complex crude differentiation and tracking scheme and in view of the potential adverse impact on indigenous California crude, we believe staff should be moving in the opposite direction than they have been following, i.e., one of simplification and streamlining. We look forward to working with staff on potential improvements to the LCFS crude differentiation provisions following the February Board Hearing. LCFS 38-15 cont.

Chevron does not view the Innovative Crude Production provisions proposed for inclusion in the LFCS re-adoption as yielding meaningful contributions for compliance by 2020 and notes that staff's illustrative compliance scenario does not include contributions from this sector. As mentioned in the Refinery Investment Credit provision discussion above, Chevron does not favor inclusion of credits from stationary sources in LCFS. Should staff choose to proceed, Chevron objects to limiting the application of carbon sequestration (CCS) to those instances where the carbon capture occurs onsite at the crude oil production facilities. CCS has the potential to generate a substantial number of credits under this provision, but many projects (and proposed projects) involve capturing carbon not at the same physical site where the crude is extracted. This restriction could seriously limit the potential for CCS to generate LCFS credits. While the capture of CO_2 from a steam generator or other equipment used in the oil production process may be desirable, the overall cost of doing so is prohibitive compared to capture from other large CO_2 emission sources. LCFS 38-16

Detailed Comments

Following is a series of comments on the various components of ARB's LCFS re-adoption proposal. For each of the topics below, we are providing detailed comments in the subsequent sections.

- **Program Status and Proposed Compliance Targets:** Staff has adjusted the interim year CI reduction compliance targets (2016-2019) lower in the proposed re-adoption rule but has retained the original regulation's 10% reduction target for 2020. The proposed LCFS targets appear to be unsustainable, even by ARB's own analyses.
- **Low-CI Fuel Availability:** Staff's projections of Renewable Diesel use and Biogas market penetration are substantially higher than Chevron's.
- **Cost Containment Mechanism**: Staff proposes a credit clearance market that is overly complicated and predicated on the false premise that any failure to meet the LCFS CI reduction targets will be the result of a lack of credit buyers rather than a lack of credit sellers.
- **Refinery Investment Credit:** ARB proposes to allow refiners to generate credits for GHG reduction projects, but has established restrictions that are likely to prevent many potential projects from qualifying.
- **Electricity Provisions:** The proposals to allow credit generation for electric transportation usage that predates the LCFS and for estimated home vehicle charging

are inappropriate. These artificial credits would have no tie to real GHG reduction, and are inconsistent with proposed rules related to refinery credits.

- **OPGEE:** ARB's continued insistence on crude differentiation serves only to lead to inefficiency, competitive disadvantage for California crude production, and potential "crude shuffling."
- **Indirect Land Use Change:** ARB has refined the ILUC values contained in the proposed regulation based on updated data sources, as well as input from academia and the regulated community. We encourage ARB to keep this process open and transparent.
- **Low Complexity / Low Energy Use Refineries:** ARB is adding unnecessary complication by allowing those refineries who have not invested in the scale needed to meet the high demands of the California fuel market to generate credits and opt out of the state average CI calculations.
- **Innovative Crude Production:** The proposed additions and enhancements to the innovative crude technology options are encouraging, but there is room for improvement.
- **Reporting and Recordkeeping:** We appreciate ARB's efforts to improve accuracy in reporting and the added time for reconciliation with counterparties. We do not, however, agree with some of the other proposed changes.
- **Enforcement:** The proposed per-day violations for reporting errors have the potential to be unduly punitive. We recommend reducing the applicable time period to cover only the time beginning with discovery of the error. Further, there should be an affirmative defense for invalid credits analogous to the RFS.
- **Economic Impact Analysis:** While acknowledging that the LCFS will likely put upward pressure on the cost of fuel in California, ARB understates the expected economic impact by relying on an upper limit of $100/MT for credit prices.

Current Program Status and Proposed Compliance Targets

Since its inception, the LCFS program has aspired to deliver a 10% reduction in California motor fuel carbon intensity (CI) by 2020 versus the 2010 baseline year.
As a result, Chevron engaged in an extensive program to aggressively evaluate promising emerging technologies in this space and invested considerable resources in pursuing those that we believed held the highest potential for success. Unfortunately, five years into the LCFS program, the progress envisioned in cellulosic biofuel development has not materialized, rendering the achievement of the LCFS program's original goals and targets questionable at best. Nevertheless, In the LCFS re-adoption proposal, staff holds on steadfastly to the 10% CI reduction target by 2020. In associated statements, both in California and other jurisdictions considering LCFS programs (e.g., Washington, Oregon), staff holds that "the program is working as intended,"

LCFS 38-1 cont.

Half-way through the 2010-2020 compliance decade, the program is delivering approximately 2% CI reduction (versus an annual target of 1% for 2014 and 2015). Despite a nearly year-long re-examination of the program's components and targets leading up to the re-adoption Board hearing, staff is reluctant to admit that the program faces considerable challenges, even as it proposes to scale back some of the program's targets (e.g., interim-year CI reduction targets – "the compliance schedule") while leaving others (e.g., the 10% 2020 target) in place despite clear evidence that they cannot be met.

ARB's own estimates indicate that the LCFS program as proposed in the re-adoption proposal is not sustainable. Approximately 3% of 10% CI reduction shown for staff's illustrative scenario in 2020 is derived from accumulated credits (from "over-compliance" during previous years) and only 7% is actual, sustainable CI reduction obtained during the year. Annual targets remain unsustainable; staff forecasts a credit bank build up to 9 MMT at the end of 2015 to help satisfy the inherently un-sustainable reductions that the program calls for as we head toward 2020. The reality is that the credit bank stood at just under 4 MMT at the end of the third quarter of 2014 (since program inception) and the expectation it will reach 9MMT over the next 15 months is largely aspirational. ARB's view is that there will be an extraordinary increase in the rate of credit generation over this period as industry will have the benefit of "certainty" following the regulation's re-adoption.

Setting aside the issue of ARB's reliance on an unrealistic initial credit bank starting point at the start of 2016 (to meet the 10% 2020 target), Chevron does not agree that staff's projection of a 7% sustainable reduction in 2020 is accurate. The primary reasons are: staff is using overly aggressive projections in estimating the degree of market penetration of renewable biogas for motor fuel applications and the volumes of renewable diesel that will be incorporated in the CARB diesel pool. Questionable LCFS credit contributions are also forecasted from the Refinery Investment Credit segment of the re-adoption program. The reasons for Chevron's reservations in these areas are outlined further in the detailed comments on these topics.

LCFS 38-1 cont.

Chevron notes the "redirection" of ARBs reliance on different sector contributions to achieve the program's CI reduction goals. There is no significant contribution expectation from advanced cellulosic biofuels that lay at the core of the original program's aggressive goals. This is not surprising given that staff's expectations for growth in that area have not materialized. Going forward, the relative contribution of such low-CI fuels is but a very small fraction of the overall program CI reduction needs. Faced with a substantial reduction in the contribution expected from advanced biofuels, ARB should have reduced LCFS program targets accordingly. We are disappointed that ARB has largely held on to the original program targets (at least for 2020) and looked to fill the cellulosic fuel CI reduction "gap" through aspirational increases in renewable biogas and renewable diesel, as well as arbitrary inclusion of LCFS credits from stationary source segments such the "Refinery Investment Credit" and "Innovative Technologies for Crude Oil Production." In Chevron's view, this "redirection," aspirational CI reduction projections, and over-reliance on banked credits in the 2016-2020 timeframe reflect the magnitude of the challenges that the program is currently facing.

Chevron continues to maintain that there is no certainty in the setting of unrealistic goals and targets that the entire regulated community views as mere placeholders that will have to be ultimately revised. In fact, this approach only serves to prolong the very climate of uncertainty, and sustain deferred action on compliance plans, investments, etc. that ARB should be seeking to promote. In the case of the re-adopted LCFS, once the credit bank status for 2015 is confirmed to be substantially lower than staff's expectations (i.e., roughly within a year's time from re-adoption), the infeasibility of the 2020 CI reduction target will be difficult to dispute and the need for revision will be even more urgent since 2020 will be only four years away at that point.

ARB's ISOR documentation is lacking in terms of detailed data to clearly support the contention that the program is still feasible. A full analysis of the available supply of low-CI fuels; the projected cost of the available fuels; the supply logistics (marine, rail, etc.) which are available to accommodate these alternative fuels; the infrastructure needed to blend, transport and dispense these fuels; the incentives which are needed for consumer acceptance; and other regulatory impediments should all be delineated.

Chevron has developed its own estimates of low-CI fuel volumes which might be available through 2020. We have shared our estimates with ARB, which has also received corresponding input from WSPA based on the work of the Boston Consulting Group (BCG). We have analyzed ARB's assumptions relating to the LCFS compliance curves and are pleased that staff's estimates have been gradually adjusted through this process to more closely reflect our own. In most areas, essential alignment has been reached between our respective viewpoints/estimates with only minor differences remaining. However, key differences remain in:

- The definition of what constitutes a sustainable program. Chevron believes that targets are sustainable if they can be met through the CI reductions accomplished during a particular compliance year with minimum reliance on credit to cover short-term shortfalls.

- The size of the credit bank on 1/1/2016 that will be available to cover future program shortfalls. Chevron's view is that the credit buildup forecasted by ARB is unsubstantiated and is unlikely to materialize.

- Chevron also forecasts that individual credit deficit years will be seen as early as 2017, requiring earlier withdrawals from the credit bank.

- As a combined result of the two previous items (lower credit bank "build" and earlier withdrawals), Chevron expects the credit bank to be essentially exhausted in the 2018 timeframe, leaving no reserves for the large credit drawn necessary to meet the 2020 10% reduction target.

- Chevron's realistic market based outlook indicates substantial differences in our projections of RNG and RD market penetration versus staff's. We also believe that, unless the proposed Refinery Investment Credit provisions are adjusted, there will be no meaningful contributions from that segment in meeting the LCFS targets.

As mentioned earlier, we have met several times with ARB during the re-adoption rule development period and after the ISOR was released, and continue to urge ARB to reset the 2020 target CI reduction level to a more realistic and sustainable level of approximately 4.5%, as

LCFS 38-1 cont.

indicated by our internal projections and those of BCG's most recent study that WSPA has been shared with staff. LCFS 38-1 cont.

Low-CI Fuel Availability

Supply and Blending Limits for Renewable Diesel

Chevron believes that renewable diesel is one of the more promising available low carbon intensity fuels for LCFS compliance. However, ARB's supply projections are optimistic and overly reliant on announced projects and nameplate capacities.

The critical barriers to the market penetration of renewable diesel, however, are not production levels but blending infrastructure and regulatory hurdles. ARB has projected that renewable diesel will make up 12% of the California diesel pool by 2020, but we anticipate it will reach roughly half that level. Logistical hurdles on pump labeling (FTC regulations), superimposed on the fungible nature of the common carrier pipeline system will be difficult to overcome in the 2016-2020 timeframe. We project that the vast majority of diesel in the state will contain 5% renewable diesel by 2020 with higher percentages seen in select centrally-fueled fleet applications, resulting in an overall pool average at 6% renewable diesel.

ARB staff has speculated that regulated parties may pursue several options for getting around the 5% blending limit imposed by FTC labeling rules.

- Segregated grades of diesel at terminals – Staff contends that selling two blend levels (0-5% and 6-20% renewable diesel) would enable higher blend levels. LCFS 38-6 cont.

  This option is problematic as terminals face multiple logistical constraints when it comes to any attempts at additional product segregation (e.g. plot space for additional tankage). Even where it could be considered, it is highly unlikely to occur until LCFS implementation establishes RD supply stability and justifies the investment in expansion of diesel grade infrastructure.

- Moving entire pipeline/terminal systems to higher blend levels – Some terminal position holders could move to 6-20% blends, causing the retailer community served by those terminals to label accordingly.

  Voluntarily industry adoption of an RD6-RD20 specification is equally problematic. The existing fungible pipeline system dictates that industry must move in "lockstep" for any geographic move to higher blends. Such a change would have to be implemented through common carrier pipeline specification change, which would be difficult to achieve short term for competitive reasons. While unlikely before 2020, this is the most likely path forward longer term. It will just take time for the dynamics of the market to make such a dramatic change.

- Large-scale fleet blending – Bypassing the traditional supply system to blend high renewable diesel levels for fleet applications.

  This is a very real possibility. Centrally-fueled fleet blending at higher renewable diesel percentages will likely occur but its impact is small and it has already been comprehended in our estimates.

- Relying on an FTC re-interpretation of the underlying law (2007 EISA) – The FTC may revisit their understanding of Congress' intent and remove the regulatory barriers.

  This is the least likely solution. Several unsuccessful inquiries have already taken place by both fuel providers and renewable diesel producers as expanded blending has been pursued for Renewable Fuel Standard and other blending mandate compliance. The FTC has been unmoved on this point. Congress providing the necessary authority (by reopening EISA) is even more unlikely near term; strong opposition is expected by the biodiesel lobby to any revision attempt.

Given all of this, terminal blending above 5% before 2020 is highly unlikely and fleet blending will have only a marginal impact on the overall market balance, bringing the statewide average to approximately 6% vs. ARB's forecast of 12%.

Biogas Projections

LCFS 38-6 cont.

Reliance on large-scale production of renewable natural gas as a supply of LCFS credits is questionable. Investors will weigh high regulatory risk as they consider such projects. Without RFS and LCFS credit subsidies, renewable natural gas for transportation is uneconomic. Cellulosic RINs are estimated to add three times the commodity value of natural gas and the LCFS may add another one to two times the value. While this may seem like a significant motivator for investment, the possibility that these programs may be modified at any time (based on political and/or regulatory reassessment) represents a significant issue for investors as they consider projects whose returns are based solely on the RFS and/or LCFS credit premiums that they generate.

Typical economics (capital investment, absence of need for gas "cleanup", access to gas pipeline, etc.) of biogas utilization drive the application of such gas to power generation and not motor fuel use. We have cautioned ARB that the GHG reduction benefits associated with "re-purposing" biogas from power generation to CNG/LNG production are not appropriately accounted for in staff's estimates. ARB's carbon intensity assessment of these products ignores this very real possibility, taking full credit for any renewable CNG/LNG production as though it represents green-field landfill gas production. Should it be found that a significant portion of the landfill gas supply used for CNG/LNG production was redirected from electricity production, much of the compliance value of those biogas products will have been lost.

The current version of CA-GREET2.0 estimates the lifecycle CI of CNG from landfill gas to be 17 gCO2e/MJ. If this landfill gas was re-purposed from on-site electricity generation, the amount of electricity displaced from the grid would need to be accounted for as average grid electricity, which has a much higher CI than electricity from landfill gas. CA-GREET2.0 estimates the US-average electricity CI to be 183 gCO2e/MJ, while EPA has estimated the CI of electricity from landfill gas to be 11.4 gCO2e/MJ. EPA also estimated that 3.4 MJ of landfill gas energy is required to produce 1 MJ of electricity[1]. The increase in the landfill gas CNG/LNG CI from displacing landfill gas (LFG) electricity would therefore be:

(1 MJ Elec. / 3.4 MJ LFG) * (183 - 11.4 gCO2e/MJ Elec.) = 50 gCO2e/MJ LFG

For the example above (Landfill Gas CNG), the CI would increase from 17 gCO2e/MJ to 67 gCO2e/MJ if re-purposed from on-site electricity generation, or about the same as fossil natural gas.

Cellulosic Biofuels

ARB staff continues to strongly assert that the LCFS program (and more particularly LCFS credit prices) will drive advanced biofuels production. Evidence that the RFS2 program is struggling in meeting its advanced biofuel objectives does not appear to be materially impacting staff's estimates. Chevron notes that almost all of the advanced biofuel production facilities ARB and others mention are not in California – challenging the notion that the state is really driving the advanced biofuel market and attracting investments. As previously commented by WSPA in its Wood Mackenzie and BCG contractor work in 2012, the LCFS will draw any limited quantities of these fuels that may be available to California via shuffling resulting in sub-optimal costs and often increased emissions.

LCFS 38-6 cont.

When calculating/projecting future biofuels supply, ARB should not rely on press announcements as credible evidence of actual facilities/volumes, since many projects are cancelled after initial press announcements but prior to construction, based on engineering studies that are completed and a more definitive cost estimate becoming available. ARB should count facilities that have started construction for potential facility/volume availability in the next 2 – 3 years. If construction has not started, then a discount factor of at least 50% should be used in projecting future capacity. When using past growth rates and projecting them into the future, ARB should take into account the period of two or so years of essentially no growth.

The ARB documentation is lacking in terms of detailed data to clearly support the contention that the program is still feasible. A full analysis of what supply of low-CI fuels is truly available to California and at what projected cost; what the supply logistics (marine, rail, etc.) are available to accommodate these alternative fuels; what infrastructure is needed to blend, transport and

[1] "Support for Classification of Biofuel Produced from Waste Derived Biogas as Cellulosic Biofuel and Summary of Lifecycle Analysis Assumptions and Calculations for Biofuel Produced from Waste Derived Biofuel," U.S. EPA Office of Transportation and Air Quality Memorandum to Docket EPA-HQ-OAR-2012-0401, July 1, 2014.
Table 6: CI of Electricity from Landfills that Flared Biogas = 12 kg CO2e/mmBTU (= 11.4 gCO2e/MJ)
Table 5: Efficiency of Electricity Generation from Biogas = 11,700 BTU biogas/kWh (= 3.4 MJ biogas/MJ electricity)

dispense these fuels; what incentives are needed for consumer acceptance; and other regulatory impediments should all be delineated. LCFS 38-6 cont.

Cost Containment Mechanism

Staff maintains that sufficient low-CI fuels and credits will be available and, thus, the cost containment mechanism will be seldom (if ever) needed. Staff's stated expectation is that the cost containment mechanism will only be invoked when necessary to respond to some short-lived market "blip" or disturbance that will quickly give way to reestablishment of equilibrium. Staff acknowledges that this tool is not designed to accommodate systemic and prolonged LCFS credit shortages. They consider the ability to carry deficits forward (albeit with interest) for up to five years an "insurance policy" and they see no particular negative aspects to the end-of-year credit clearance market they are proposing (where regulated parties must buy their pro-rata share of pledged credits at a price as high as $200/MT).

We are opposed to the inclusion of such a cost containment mechanism in the LCFS because we believe that it will not accomplish its stated objective (contain prices) and will instead have a number of undesirable (and unintended) consequences. More specifically, the Credit Clearance Market (CCM):

Does not stipulate a mechanism for retiring deficits, if multi-year market shortages persist. If there are inadequate credits available in the year-end auction of credits pledged by suppliers at prices as high as the pre-determined "cap" price, then regulated parties will have to carry a deficit into the following year. As presently designed, carrying over a deficit is an involuntary act by the regulated party – it is not caused by its own failure but by the failure of the market to meet the demand with sufficient supply. Consequently, imposing a 5% deficit interest subjects the regulated party to an unfair and inequitable penalty that only increases the deficit. Our analysis projects that the market will in fact be consistently short credits year after year, and if the annual obligation is not corrected to match actual credit supply, then the regulated community will be facing ever-increasing and interest bearing deficits. LCFS 38-3 cont.

May drive credit costs up (if credits are withheld from the regular market for CCM price). During periods of rising prices (i.e., credit shortages in the open market), the CCM will not keep credit prices in check. In fact, in a credit short year, the CCM is meaningless as there will not be any remaining credits to be brought to the table by sellers. The compounding of "interest" on the carryover/deferred balances will ensure credit buyers soak up the available pool of real LCFS credits in the market during the year and not wait for the CCM. The pool of real LCFS credits available is fixed – it is only their price that remains in question. Staff's setting of the price at $200/MT will serve as the benchmark for credit prices in that environment.

During periods of stable or declining prices (i.e., credit surplus in the open market), the CCM cap price creates an artificial "floor" value below which sellers will be hesitant to offer real LCFS credits for sale to the regulated community at substantially lower prices. This would artificially increase compliance costs – as credit prices will be artificially raised to (or near) the ARB cap and very few transactions will take place before the end-of-year sale. Credit trading would be seriously impaired as the open market would not be allowed to function as it should.

Provides no liability protection against invalid credits secured through the CCM.
Later we identify, in general terms, how the lack of a liability defense available to obligated parties from fraudulent credit sellers is inequitable. However, in the specific context of the CCM provisions, not only is there no liability defense for fraudulent or otherwise invalid credits, there is also no opportunity to conduct due diligence of the sellers. Moreover, ARB's time-table to organize and complete the CCM, suggests that the agency will not be doing any screening of the pledged credits.

Offers no connection between CCM outcome, program off-ramps, future CI reduction targets
The liquidity of the LCFS credit market is not only essential to the program's success. The absence of such liquidity is a clear signal that the program's CI reduction targets are overly aggressive and will render the program infeasible. There is presently no provision in the CCM to conduct a comprehensive program review in the event of repeated credit shortages.

Does not adequately define mechanics of deficit carryover (recordkeeping, reporting, etc.)
Even if all of the above issues were somehow resolved satisfactorily, the CCM proposal in the ISOR and draft regulatory language is sorely lacking in the execution/implementation details that would allow us to understand exactly how it would work. For example: What is the "order" of applying generated credits (through blending or purchases) to the various potential uses for a regulated party on any given year (e.g., meet the current year's obligation, retire previous years' obligations)?

LCFS 38-3 cont.

Finally, the proposal to make public the long and short credit positions of regulated parties undermines the competitiveness of the credit market by disclosing confidential business information. The release of such information would allow competitors and sellers insight into a regulated party's confidential compliance strategy. Using this information and average market pricing, one could estimate the financial impact of LCFS compliance on a regulated party.

Recommended Alternative to the CCM
In lieu of the CCM, Chevron favors a dual approach of setting reasonable, practically achievable CI reduction targets and holding frequent (biennial) program reviews to ensure that the program remains on track and the LCFS credit market is healthy. More specifically, we would like to see staff eliminate the proposed CCM and:

- Provide for biennial mandatory program reviews with the first one completed by 1/1/2017. The initial review should include LCFS credit history including actual credit generation, obligation, and a comparison of actual current credit bank versus staff's projections in the ISOR. As part of the review, staff should include a projection of where the credit bank is expected to be two years later when the next review is due. If overall credit generation is above or below staff's projections (plus/minus a modest estimate allowance/tolerance), CI reduction targets should be adjusted up or down to re-establish an aggressive yet achievable program.

- Establish triggers that would require early program reviews prior to the planned dates outlined above. Specific, measurable thresholds and triggers should be established as part of this process. Some example of such triggers for an early review of subsequent year CI targets include:
  - Monthly credit price exceeds $150
  - Industry credit bank falls below 5 million metric tons (MMT)
  - CA fuel price >70cpg above national average

- Incorporate a simple carryover rule for one-off company imbalances. We would recommend tailoring the provisions of this segment along the lines established for RINs by EPA in the RFS program, with additional enhancements. Key features include:
  - A regulated party may carry over a deficit balance for one year, without penalty
  - Carryover credits must be retired in the following year to completely settle the deficit balance
  - A deficit balance cannot be carried over two years in a row
  - Retirement of any credit shortfall that an obligated party still has at the end of the carryover year, if it is determined that sufficient credits are not available in the market to satisfy the deficit balance (as well as deficits carried over by others). Once again, this situation would force an automatic program review.

LCFS 38-3 cont.

This simple-to-execute approach would satisfy staff's stated goal of addressing short-term tightness in the credit market, while avoiding the market-manipulating aspects of the proposed CCM. Neither this solution nor the CCM can address the very real possibility of a long-term credit shortage. This must be met with the program reviews and schedule adjustments recommended above.

Refinery Investment Credits

It is unlikely that the refinery credits of 1.13 MM MTCO2e in 2020 projected in ARB's compliance curve will be possible. According to the Initial Statement of Reasons, 80% of the 400 refinery efficiency projects identified in the referenced ARB Energy Audit study are now in place, resulting in 2.2 MMT CO2e reductions. Only 0.6 MMT CO2e identified projects remain, just half the amount in ARB's compliance curve. It is not clear that these remaining 20% will proceed given the fact that they have not been pursued already.

LCFS 38-7 cont.

As described below, restrictions on qualifying projects will significantly limit available credits. The proposed 0.1 CI threshold implies that a relatively large emissions reduction of more than 1% of a refinery's emissions per project is required for a project to qualify. Because most, if not all, of the large energy efficiency projects have already been completed ("low-hanging fruit"), a majority of the remaining opportunities are relatively small. However, the cumulative potential of several small projects should not be ignored. Past investments in energy efficiency will limit potential for additional reductions, especially for more efficient refineries, thus remaining improvements are lower than ARB's projections.

The proposed thresholds and restrictions included in the proposed refinery investment credit mechanism risk arbitrarily eliminating most potential emission reduction projects. Changes are necessary to make the proposal viable and equitable. Chevron in particular has a long history of investing in energy efficiency projects and operating with industry-leading efficiency. Due to our prior investments, the proposed limitations and restrictions create arbitrary inequities. We suggest the following modifications to the refinery credits section to address these issues: LCFS 38-7 cont.

- Ensure equity for more efficient refineries by using methodologies that do not discriminate against complex refineries or penalize prior investments.
- Avoid arbitrary restrictions and thresholds, including 0.1 gCO2e/MJ CI and 10% biofeedstock limits, to encourage innovative GHG reductions.
- Eliminate the prohibition on criteria pollutants, as they are adequately regulated by multiple other programs.
- Clarify definitions and language in the rule, for specificity and to increase equity.
- Reduce projections for credit generation to a more realistic level.
- Review refinery carbon intensity gap between GREET and ARB calculations.

Define an equitable industry benchmark

The proposal to handle differences in refinery efficiency (credit varies depending on whether a refinery is above or below the California average carbon intensity for each fuel) is a step in the right direction to ensuring equity. However, emissions per barrel of gasoline and diesel (carbon intensity) are not an appropriate method for comparison due to structural differences in refinery complexity and product mix. The 50% credit for higher-than-average carbon intensity refineries could adversely affect more efficient, but larger and more complex, refineries that produce a range of products.

We propose a Complexity Weighted Barrel (CWB) benchmark, consistent with AB32 cap and trade. Solomon's Complexity Weighted Barrel (CWB), has been implemented for the AB32 cap and trade emissions benchmark to ensure that more complex or diverse product slate refineries are not unfairly penalized. For consistency, we recommend ARB adopt the California average emissions per complexity weighted barrel (4.32 Tonnes Co2(e)/CWB) as the determining threshold for which less efficient refineries qualify for partial (50%) credits. This threshold is consistent with the refinery benchmark of 3.89 allowances/CWB, or 90% of California refinery average. For LCFS, if a refinery has more than 4.32 tons of greenhouse gas per CWB, it should only receive partial credit under the LCFS program, while refineries that have less than the average CWB intensity should receive full credit. LCFS 38-8 cont.

Allow credit for projects implemented since LCFS adoption

The proposed January 1, 2015 permit date limitation for eligibility penalizes early actors contrary to AB 32 provisions 38560.5(b)(1) and (2). We propose that the deadline for project eligibility be the start of the LCFS in 2010, for fairness and consistency. The major investments identified by LCFS 38-12 cont.

the Energy Audit have already implemented over 2.2 MMT CO2e/yr reductions and these projects should be eligible to apply for LCFS credits on a go-forward basis. Should ARB retain the proposed January 1, 2015 cutoff date, Chevron believes ARB should allow refinery greenhouse gas emissions reduction projects to be eligible if implemented (i.e., started up) after that date, regardless of when permits for the project were initially filed. Since permitting can be a multi-year process this will avoid penalizing refineries that are already proceeding with such projects. Moreover, since some projects may not necessitate permit applications this approach would apply a consistent threshold to all projects. LCFS 38-12 cont.

Remove impractical restrictions and thresholds

Several revisions are recommended that may increase success of this new LCFS channel. As it is written the program will not incentivize reductions because it is fatally flawed by the following restrictions and thresholds that could be extremely difficult to achieve:

- Biofeedstock 10% threshold
- 0.1 gCO2e/MJ threshold
- Allow non-capital or offsite investments
- Criteria air pollutants and toxics should remain outside the scope of the LCFS

Biofeedstock percentage of 10% is technically impractical for larger refineries

We recommend ARB reconsider and eliminate the 10% biofeedstock threshold. The threshold is inequitable; the quantity of biofeedstock supply necessary to meet this threshold for larger facilities becomes impractical. A 200,000 BPD refinery would require 20,000 BPD of bio-feedstock, nearly 10 times more than a typical 2000 BPD (i.e., 30 MGY) biodiesel plant. Furthermore, co-processing biofeedstocks is generally technically possible only below 10% due to unsolved process technology constraints. Eliminating this threshold could allow innovation to occur. LCFS 38-13 cont.

CI reduction threshold of 0.1 gCO2e/MJ eliminates many legitimate projects

The threshold of 0.1 gCO2e/MJ is overly restrictive and inequitable; we recommend eliminating it. Especially for larger refineries, which may be 100 times larger than a typical biofuel plant, the absolute quantity of CO2 emissions required to cross this threshold is larger by a similar ratio. Also, with an industry average refinery carbon intensity (excluding tailpipe CO2) of only 7.61 gCO2e/MJ for gasoline and 8.95 gCO2e/MJ for diesel, 0.1 gCO2e/MJ is a relatively large reduction. This threshold is even more challenging for larger, more complex facilities, and for those that are already more efficient than industry average. LCFS 38-10 cont.

If thresholds are included, use absolute rather than percentage emissions impact

Percentage throughput limits are unfair to larger refineries, since the absolute reductions must be larger as facility size increases. This is a perverse outcome, since the larger refineries may be more efficient at the start and therefore should not be precluded from further improvements. Similarly, if CI is calculated based on volume percent of each fuel produced, a refinery's fuel slate will affect its ability to receive LCFS credits for energy efficiency projects. If two refineries have total emissions of 4,000,000 tonnes each, but one produces 10% diesel, while the other produces only 5%, the number of tonnes of emissions reductions necessary to meet the diesel CI target will be different for each refinery (40,000 or 20,000). If thresholds must be included, we LCFS 38-13 cont.

recommend an absolute emission reduction threshold (e.g. 1000 MT/year), rather than a per-unit measure. LCFS 38-13 cont.

Consider including non-capital projects, bundled projects, and offsite portions of projects

Non-capital but sustained improvements should be included since many energy efficiency upgrades are considered non-capital. Also to simplify accounting and increase the success of this pathway, in the same application package ARB could allow bundling of smaller projects. Offsite portions of projects, such as hydrogen plants, could also be made eligible. LCFS 38-11 cont.

Allow de minimis criteria pollutants and overall site offsets

The LCFS should focus on the reduction of GHGs and avoid the additional and unnecessary complexity of regulating emissions that are covered by strict stationary source regulations and CEQA. This is supported by ARB's analysis that concluded that emissions increases at the statewide, regional, or local level are unlikely based on current law and policies that control industrial sources.[2] Furthermore, this provision is inequitable as other credit-generating activities in the LCFS (e.g. alternative fuel pathways, electricity credits, etc.) do not include similar provisions. LCFS 38-9 cont.

At a minimum, Chevron recommends that ARB allow refiners to offset any criteria pollutant and/or toxics health risk impact associated with their submitted efficiency improvement projects. The LCFS should provide refiners the opportunity to offset any criteria pollutant increases related to GHG reduction projects and only require that when de minimis levels are exceeded, using similar thresholds as the Air Pollution Control Districts for criteria pollutants. Adding flexibility to meet such a de minimis criteria pollutant threshold with other offsetting reductions is more practical than the implications of attempting to track second-order criteria pollutant cascading impacts of GHG reduction projects throughout the refinery's operations.

Clarify definitions and language in the rule

Chevron requests that ARB clearly define the following to enable effective implementation of the rule:

- Percent bio-feedstock calculation
- Total volume and energy calculations included in the allocation formula
- Quantification of baseline and reductions
- Harmonization with AB32

Percent bio-feedstock calculation

If the percent biofeedstock restriction is not removed, ARB should clarify whether percent is relative to crude oil feed, intermediate feeds such as VGO or hydrogen, or gasoline and diesel individually, and how this is to be calculated. We also propose that ARB specifically define that these biofeedstock credits apply to both coprocessing bio-oils and coprocessing bio-gas biofeedstocks. LCFS 38-13 cont.

---

[2] *CARB, October 28, 2010, Cap-and -Trade Regulation, Volume VI, Appendix P: Co-Pollutant Emissions Assessment*

Total volume and energy calculations included in the allocation formula

The formula for calculating the total volume and energy of the refinery appears ambiguous. In particular, the basis of the product volumes is not defined. Use of life cycle assessments and other studies to calculate total volume and energy as proposed in this formula is not a technically sound method for allocating energy and emissions to products which fall outside the LCFS. For example, emission allocations between products based on volumes are not representative for refineries that make lubricants or other products besides gasoline and diesel. In order to avoid an arbitrary allocation while still incentivizing projects, a simplified formula could simply allocate the total emission reductions from any given project to that refinery's gasoline and diesel production. LCFS 38-17

Quantification of baseline and reductions

For calculating baselines and reductions, please define type of measurement needed, for instance CEMS, Parametrics, EFs, etc. The LCFS is generally based on a 2010 baseline year but this program seems to be using a 2011-2013 average baseline, the expected baseline year should be clarified. Also the regulatory text is not clear as to how unrelated changes in refinery carbon intensity over time would affect previous refinery credits (such as changes in throughput rates or operational changes such as new units). LCFS 38-18

Harmonization with AB32

For ease of implementation, the proposed definitions of the LCFS should be harmonized with the AB32 requirements such as MRR reporting. LCFS 38-19

Explain apparent inconsistency on petroleum refining Carbon Intensity

According to staff's reported values, there exists a 5 to 7 gCO2e/MJ gap between GREET and ARB calculated industry carbon intensity values for gasoline and diesel. ARB's calculated refinery carbon intensity shown in Initial Statement of Reasons Table III-9 below is 5 gCO2e/MJ below the GREET model for California gasoline, and 7 gCO2e/MJ for diesel. This relatively large difference implies that on average, California refineries have lower actual carbon intensity than modeled by GREET's baseline. These data may indicate a gap in the accuracy of the GREET model, or in the proposed refinery carbon intensity formula. California refineries have been aggressive in implementation of energy efficiency improvements, and petroleum fuels should receive full and fair credit for improved carbon intensity in the LCFS program. LCFS 38-20

Staff investigated the actual carbon intensity of the gasoline and diesel produced by refineries using data from 2011 to 2013 and Equations 14 through 16, above.

Table III-9. Gasoline and Diesel Refinery Carbon Intensities

	CA-GREET (gCO_2e/MJ)	*Industry Average (gCO_2e/MJ)*
Gasoline	13.94	8.95
Diesel	15.33	7.61

Table III-9 lists the average carbon intensity for gasoline and diesel for all refineries. The average gasoline carbon intensity is 8.95 gCO_2e/MJ. Figure III-8 shows the average CI for gasoline for all refineries.

Electricity Provisions

Electricity Credits for Fixed Guideway Transit and Electric Forklifts

Chevron opposes the allowance of LCFS credits for fixed guideway transit and electric forklifts for the following reasons:

- Allowing these credits does nothing to encourage the development of new, low-carbon transportation fuels. Instead, the rule change simply allows the generation of funds from credits sold back to transportation fuel providers and does nothing to further reduce GHG emissions. The value of these credits is estimated by ARB staff to amount to $40 to $100 million for fixed guideway systems and $10 to $25 million for forklifts in the 2015-2020 timeframe.

- Much of the equipment that could generate credits has been in existence for many years – in some cases for decades. As such, only the incremental increase in electricity usage relative to the 2010 baseline should be allowed for credit generation. Staff partly acknowledges this inconsistency by not allowing the use of an Energy Economy Ratio (EER) when calculating the amount of fuel energy displaced for forklifts and only allowing its use for fixed guideway system expansion beyond 2010. LCFS 38-21

- Chevron believes that any credits generated for electric forklifts should be based on metered usage and not calculated based on estimates and assumptions. Staff proposes that electrical distribution utilities (EDUs) would be the regulated party for forklifts and that electricity usage would be estimated based on national shipment data, battery size, assumed annual operating hours, and load factor. Statewide data would be allocated to each service area on the basis of each utility's share of business/commercial accounts. Chevron is strongly opposed to this approach as there is no way to verify that the estimated electricity usage is real. Notwithstanding our opposition on the basis that much of the equipment receiving credits has been in service for many years, if ARB were to go forward with this credit generation scheme, it should be based on metered data that can be directly tied to the vehicles in which the electricity is used.

- Staff has assumed that electric forklift charging will displace diesel fuel in calculating credits. Considering many forklifts are powered by LPG, this is a questionable assumption. ARB has not provided data or information to validate this approach. Therefore, it is not possible to verify that the credits will be accurately generated. LCFS 38-21 cont.

Elimination of Metering Requirement for Residential EV Recharging

The current regulation allows the use of an estimation procedure to approximate residential electric vehicle (EV) recharging electricity usage. However, that provision was to sunset at the end of 2014, and instead electricity used for EV recharging was to be based on direct metering. ARB staff is now proposing to eliminate the requirement for direct metering of electric vehicle (EV) recharging at residences in the post-2014 timeframe. Chevron strongly opposes this proposal for the following reasons:

- All parties participating in the LCFS, both opt-in and required, must be held to the same set of standards with respect to reporting, recordkeeping, validation, etc. Allowing a simple estimation procedure for some fuels and rigorous reporting and recordkeeping for others establishes an uneven playing field among fuel providers.

- Basing credits on an estimation procedure increases the risk of invalid credits. At the very least, credits generated via an estimation procedure are more likely to be open to challenges and invalidation.

Notwithstanding Chevron's opposition to this proposal as noted above, if ARB does go forward with an estimation procedure for determining the amount of electricity used for EV recharging, it needs to be much more rigorous than the current method approved by ARB (see http://www.arb.ca.gov/fuels/lcfs/workgroups/elect/04122013-caletc-letter.pdf). Based on the limited information available in this approval letter, it appears that the method would assume that vehicles within a service area without direct metering would be used in the same fashion as those that do have direct metering. We have a number of concerns and questions about this approach: LCFS 38-22

- Vehicle owners who go to the trouble of installing a separate meter are likely to plug-in more faithfully than those who do not and are therefore not representative of the entire fleet. This is particularly important for PHEV estimates. To justify the estimation methodology, data must be presented to confirm that the results from the metered fleet can be extrapolated to the unmetered fleet.

- The data collected on vehicles with direct metering cannot be applied to the entire fleet of BEVs and PHEVs in an area without also confirming that the distribution of vehicles (by BEV/PHEV and by all-electric range) is the same between those with meters and those without. It is highly unlikely that this distribution would be the same. For example, a PHEV with a 10-mile electric range that was purchased primarily for carpool lane access would likely be under-represented in the sub-set of vehicles with at-home meters.

- A method for avoiding double-counting of electricity usage must be included. If at-home charging for those vehicles without a separate EV meter is accounted for with this method, the method must account for a vehicle owner who only charges at public or work-based charging stations and rarely charges at home. Estimating home usage but then giving full credit to public charging stations has significant potential for double counting.

- At the May 30, 2014, workshop, ARB had proposed to exclude some supplemental information now required in annual reporting. It is unclear from the ISOR whether this change will be implemented. However, if so, Chevron disagrees with this, particularly the exclusion of the number of EVs operating in a service territory. Without this basic piece of information, it will not be possible to cross-check reported electricity usage by EVs for reasonableness. In fact, we suggest that the reporting requirements be enhanced to include not only the number of EVs in a service territory, but also the number of plug-in vehicles in various categories (i.e., pure electric vs. plug-in hybrids by range).

- It is important to distinguish between pure battery electric vehicles (BEV) and plug-in hybrid electric vehicles (PHEV), and within each of those categories, identify the distribution of vehicles by electric range. For example, data collected by the Idaho National Laboratory on in-use driving patterns for the Chevrolet Volt and Nissan Leaf can be found at: http://avt.inl.gov/evproject.shtml#. Dividing the all-electric miles by the number of vehicles reported at that website gives quarterly VMT per vehicle for Oct-Dec 2013. The BEV Leaf (~6000 miles per year if 4Q2013 numbers are forecast to a full year) is accumulating fewer miles on electricity than the PHEV Volt (~8000 miles per year). Clearly, the limited range of the Leaf is resulting in much lower VMT than a typical new car, while the broader utility of the Volt results in greater overall usage and higher VMT on electricity. However, PHEVs with lower range would have fewer miles on electricity, while BEVs with greater range would likely have more miles on electricity. These results reinforce the importance of understanding the make-up of the plug-in fleet in a particular area to generate an accurate estimate of on-road electricity usage. In addition, it is important to continue monitoring recharging and electricity usage of these vehicles as the patterns of usage may change as the vehicles expand beyond "first-adopters."

LCFS 38-22 cont.

Elimination of Public Reporting of Electricity Credit Information

Chevron does not support removal of this requirement from the regulation. The current regulation requires regulated parties for residential and public EV charging to include a public accounting of the number of credits generated, sold, and banked in annual compliance reports. In the ISOR, ARB argues that because public credit accounting is not required of regulated parties of other fuels it is not necessary for electricity. Chevron supports the principle that all fuels and fuel providers should be subject to the same requirements – ARB should not pick "winners and losers." Our positions outlined above with respect to electricity credits for fixed guideway transit/electric forklifts and elimination of metering requirement for residential EV recharging are consistent with that principle. However, if electricity credits are based on estimated

LCFS 38-23

electricity usage rather than direct metering, the public has a right to know precisely how those estimates were prepared and the number of credits generated as a result. LCFS 38-23 cont.

Updates to the OPGEE Model

General Treatment of Crude Oil in the LCFS

Chevron continues to disagree with the crude differentiation approach that ARB has adopted for the LCFS. As several studies have shown, such an approach leads to inefficiencies in the crude market and could potentially lead to "shuffling," with an increase in GHG emissions associated with increased transportation distances. Ultimately, if crudes are valued based on their carbon intensity (CI), there is no evidence to suggest that they will not be produced. In addition, if crudes are valued based on their CI, many crudes produced in California will be at a competitive disadvantage relative to other crudes imported into the state. We encourage ARB to re-think the efficacy of the differentiated crude approach.

"Ground-Truthing" OPGEE

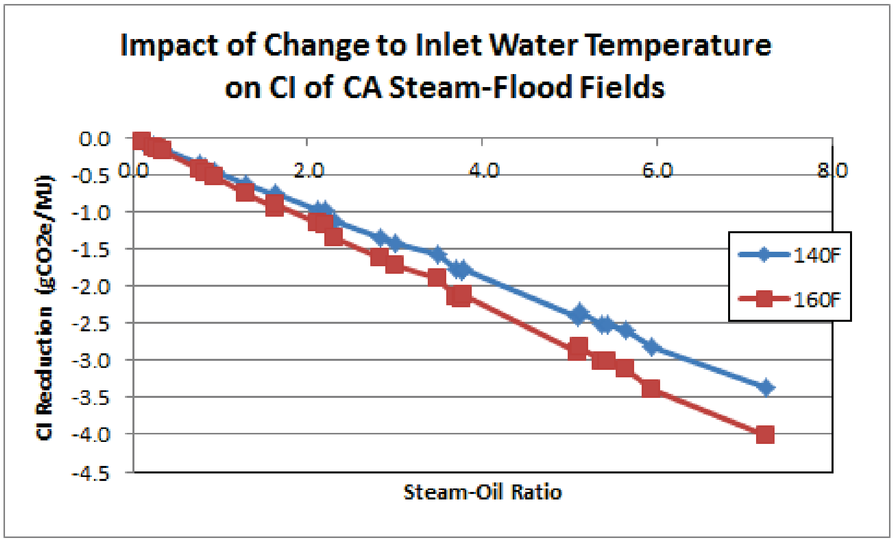
ARB staff, in conjunction with researchers at Stanford University, has continued to make revisions to the OPGEE model over the past several years. The OPGEE model relies on numerous inputs and assumptions about oil field attributes and operational parameters such as field depth, reservoir pressure, number of production wells, number of injection wells, water-oil ratio, gas-oil ratio, steam-oil ratio, API gravity, etc. For many oil fields, little data are available for the input parameters and the model populates the entries with "smart defaults." The CI estimates from OPGEE must be validated against actual data for a given field in California, the U.S., or elsewhere. Given the importance of the crude CI estimates in terms of establishing the 2010 Baseline crude CI and the California-average crude CI for each calendar year, this "ground-truthing" is an important test of the validity of the model approach that should be undertaken. LCFS 38-24

OPGEE Inputs

As noted above, many inputs are required to run the OPGEE model for a particular oil field. For California fields, a number of important parameters, such as water-oil ratio, steam-oil ratio, and production volumes are available or can be calculated from data published by the California Department of Conservation, Division of Oil, Gas, and Geothermal Resources. One such input parameter, the steam-oil ratio (SOR), has a significant influence on the CI calculated by OPGEE for an individual field. The amount of energy required (and therefore the GHG emissions associated) with a given SOR is calculated using a heat balance over the steam generator. A critical input to that calculation is the temperature of the input water to the steam generator. The OPGEE model assumes a default water input temperature of 40°F and provides no rationale for this assumption.

Based on Chevron's experience with steam-flood fields in the San Joaquin Valley, a value of 40°F for inlet water temperature to steam generators is much too low. Because water that is input to steam generators is typically recycled from water produced in the field, its temperature is well above 40°F. For our fields in the San Joaquin Valley, the inlet water temperature typically ranges from 140°F to 160°F, and in some cases is even higher.

The figure below shows the impact on the CI of California steam-flood fields if the inlet water temperature to the steam generators was 140°F and 160°F instead of the assumed default of 40°F. As expected, the influence is greater on fields with the higher SOR values. For SORs in the 5 to 6 range, the CI of the crude would drop by 2.5 to 3.5 gCO2e/MJ by using more realistic estimates of the inlet water temperature. This reflects a CI reduction of 8% to 11% for those fields.



LCFS 38-24 cont.

We encourage ARB staff to revise the OPGEE modeling to reflect a realistic input value for the steam generator feed water temperature, and we will work with ARB staff to provide more specific data on this and other model inputs. As these values will be static for several years once finalized in the regulation, it is important to get them right.

California Crudes are Disadvantaged Under the LCFS

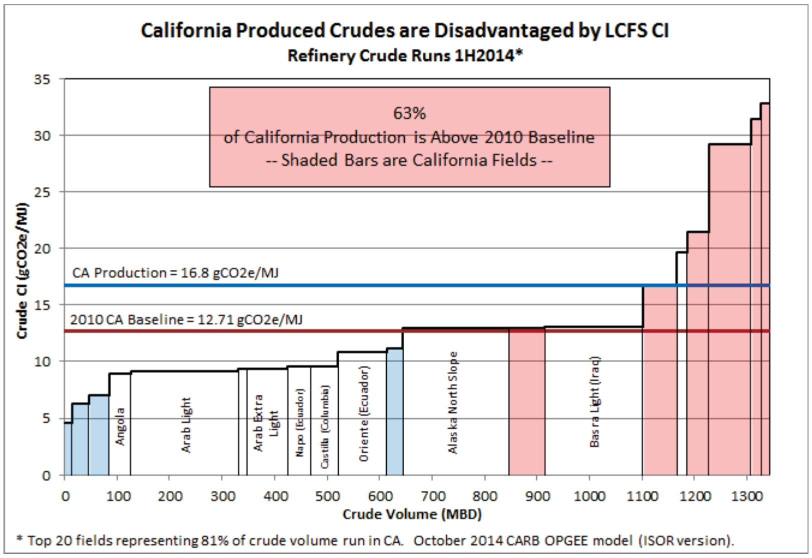
In the 2009 regulation, crudes produced in California were not subject to the high carbon intensity crude oil (HCICO) requirements of the standard as they constituted more than two percent of the 2006 baseline crude mix run in California refineries. The trigger level of two percent was put in place to ensure that ***new crudes*** introduced into the California market with high CI values would have their increased GHG emissions mitigated. This was not intended to punish California producers as their GHG emissions are already regulated under the broader AB32 program.

LCFS 38-25

The current construct of the regulation puts California crudes at a distinct disadvantage. As observed in the figure below, California production averaged 16.8 gCO2e/MJ based on field volumes for the first half of 2014 (see http://www.arb.ca.gov/fuels/lcfs/crude-oil/mid-2014-crude-ave-ci.pdf) and the CI values in Table 8 of the proposed regulation. In addition, 63% of California production has a carbon intensity greater than the 2010 baseline value of 12.71 gCO2e/MJ.

We encourage ARB staff to develop a more equitable treatment of California crudes in the LCFS that recognizes that GHG emissions from the production of those crudes are controlled via AB32. ARB should develop a single CI value for all California crudes without differentiating among the ~150 fields included in the current crude CI lookup table. Changes to that CI value should only be made in the event of a significant change to the average CI of California fields, e.g., +/- 1 to 2 gCO2e/MJ.

LCFS 38-25 cont.



Operator-Specific CI Values

ARB currently evaluates the CI of California oil fields as a single value, although there may be multiple operators within each field with much different operating parameters. If crudes are ultimately valued based on their CI, there should be the ability for individual operators to obtain a separate CI specific to their operation. This would award operators for more efficient operations, similar to what has occurred in the biofuels industry (e.g., there are scores of different CI values for corn ethanol).

LCFS 38-26

De Minimis Level Incremental Crude Deficits

As currently written, incremental deficits are incurred if the California-average crude CI for a particular year is greater than the 2010 Baseline crude CI. In order to avoid increased regulatory and reporting burden for small changes in crude CI, the difference between the California-average crude CI and the Baseline crude CI should exceed a de minimis level (e.g., 0.1 gCO2e/MJ) before an incremental deficit is incurred.

LCFS 38-27

Regulatory Language

Pages 95-96 of the Proposed Regulation Order contains the regulatory language for calculating the incremental deficit if the California-average crude CI for a given year exceeds the 2010 Baseline crude CI. We have the following comments on the proposed regulatory language:

LCFS 38-28

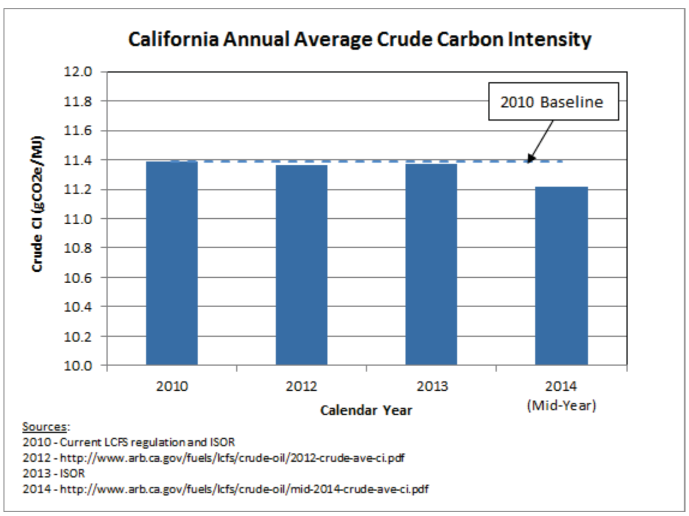
- The language needs to be clear that the parameter E^{XD} (fuel energy, in MJ, for either CARBOB or diesel) is for the calendar year for which the deficit is calculated.
- The language needs to be clear that the parameter E^{XD} is for fuel **supplied** to the California market; the current language refers to fuel "produced in California or imported into California." Fuels produced for export should not be subject to this regulatory requirement.
- The current language appears to calculate debits based on the amount of fuel supplied in the year in which the debits become effective, which is two years after the debits are incurred. Instead, this should be based on the amount of fuel supplied during the year that the debits are incurred.

LCFS 38-28 cont.

Annual Crude CI Calculation

Chevron appreciates ARB's desire to continually improve the accuracy of LCFS data inputs, and recognizes the approach taken by staff in attempting to refine the crude handling provisions as part of the re-adoption rulemaking is consistent with that principle. However, we also believe that the degree of crude differentiation built into LCFS, to comprehend concerns over CA crude CI increasing over time, remains unnecessarily excessive and should be reduced. Our reasoning is as follows:

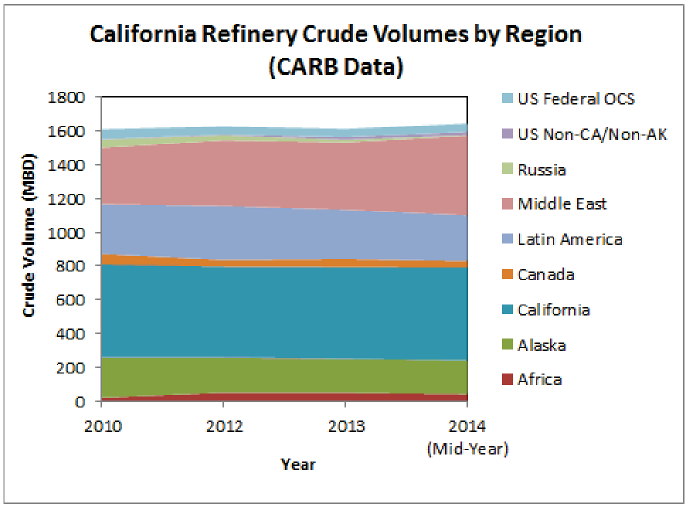
- The fundamental reason for these provisions in the rule was to ensure that the Average carbon intensity of the California crude slate did not increase over time. The available crude breakdown data for recent years (2012-1H2014) suggests that this threat has never materialized and that the CA crude average CI has remained relatively stable.

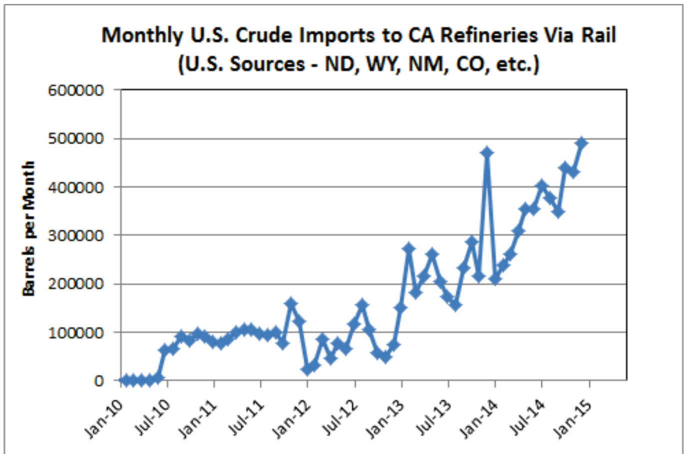


- Moreover, ARB data on crude volumes run in California refineries show a decreasing trend in heavier Canadian crudes, while light Middle Eastern and U.S. mid-continent crudes ("US Non-CA/Non-AK" in the figure below) have trended upwards. Furthermore,

LCFS 38-15 cont.

CEC data on U.S. mid-continent crude imports by rail show strong growth over the past three years that has continued through the second half of 2014. LCFS 38-15 cont.





Source: California Energy Commission
http://energyalmanac.ca.gov/petroleum/statistics/2010_crude_by_rail.html
http://energyalmanac.ca.gov/petroleum/statistics/2011_crude_by_rail.html, etc.

- As a result, we believe that the justification drivers for installing, maintaining and expanding the current LCFS crude differentiation provisions have been greatly diminished since these provisions were implemented.

- Even if ongoing monitoring is necessary to ensure that staff's concerns that a heavier crude CI outlook does not materialize, the worst case scenario (i.e., exporting heavy California crude to maintain a constant annual average crude CI) yields no tangible greenhouse gas reduction benefits from a global standpoint. California's average crude CI may well remain constant, but global GHG emissions are likely to increase as the GHG emissions associated with transporting the crude exported from California (to non-optimal refining centers for processing) will be higher.

- The ongoing staff effort to maintain and improve crude differentiation inputs and modeling tools in LCFS is resource-intensive for the Agency and equally burdensome for our industry in terms of the recordkeeping and reporting requirements it entails. In the absence of a valid GHG justification for engaging in such a complex crude differentiation and tracking scheme, we believe staff should be moving in the opposite direction than they have been following, i.e., one of simplification and streamlining.

We understand that staff does not propose a fundamental change in the California Crude Average approach as part of this re-adoption package. We support staff's decision not to proceed with refinery-specific crude accounting for large, complex refineries and understand the rationale offered for doing so. We agree that there is no practical alternative to facilitate detailed individual crude breakdown in the pipeline crude blends that comprise a large part of refinery crude inputs in the state. We look forward to working with staff in the near future to examine potential options to modify the crude differentiation requirements in LCFS (post re-adoption), toward a less complex alternative that can hopefully satisfy staff's desire to track crude CI trends over time while reducing the compliance burden on our industry.

We note the proposed changes in the methodology for calculating the CA crude average to rely on CA on-shore crude production data (supplied by The Department of Conservation- DOC) and off-shore data (supplied by The Bureau of Safety and Environmental Enforcement- BSEE). This is in lieu of refinery-reported crude volumes that have been used for this purpose heretofore. Staff's rationale is simply that this is essential to improve the accuracy of the crude volumes used in the calculation of the CA Annual Crude Average. There is no backup support or analysis of the impact of the proposed changed in calculation methodology. More specifically, staff does not:

LCFS 38-15 cont.

- Present data to determine how this change will impact the calculated annual volume averages to date. Staff merely indicates that total refinery-reported volumes for 2012 and 2013 closely match the volumes reported by CA field operators. We would recommend a more rigorous side-by-side comparison for 2011-2013 using the CA crude volumes estimated/reported by refineries versus the newly proposed utilization of DOC and BSEE data.

- Elaborate on the methodology that will be used to combine the in-state crude data with out-of-state crude volumes imported into California (both U.S. and foreign) to develop the overall annual CA crude average. Furthermore there is no indication that any potential discrepancies with the refinery-reported volumes will be investigated and reconciled.

- Recognize the difficulty that increased CA exports will entail should this methodology be adopted, dismissing such concerns by simply indicating that production volumes will be adjusted for exported crude volumes (should the need arise). Staff believes their proposal will work as long as all CA-produced crude is processed in CA, which is currently the case. However, staff's proposal appears to be short-sighted and inconsistent with the overall crude handling approach in LCFS which, despite WSPA's input, is designed to drive increased crude exports to prevent CA crude average CI increases. Moreover, the same issues staff outlines in breaking down reported volumes of typical CA pipeline crude blends currently will be in play if/when staff tries to back out exported crude volumes out of the calculated CA annual average. LCFS 38-15 cont.

Indirect Land Use Change

General Comments

Indirect land use change (ILUC) estimates continue to be a source of uncertainty in the overall lifecycle GHG footprint of biofuels, and significant efforts to refine those estimates have continued since ARB initially included ILUC in the LCFS. Although uncertainty in the estimates remains, Chevron agrees that ILUC effects need to be addressed in the context of the LCFS regulation. In principle, the scientific basis for addressing ILUC in the LCFS remains sound, and improvements to methods and models for estimating ILUC values continue to be made.

During the 2009 rulemaking, the Board directed staff to convene a Work Group with experts on both sides of the debate to ensure a balanced and transparent approach to further work on the issue. We applaud ARB for facilitating that effort, as well as the work group participants who devoted considerable time and energy to better define the issues around indirect effects. Although disagreements remained among experts about some key elements of the ILUC calculations (e.g., time accounting), there were other areas of agreement and recommended GTAP model improvements that have been incorporated by Purdue University and ARB (e.g., improved treatment of co-products for corn ethanol and soy biodiesel). LCFS 38-29

Specific Comments on the ILUC Analysis Presented in Appendix I of the ISOR

The detailed analysis of revised ILUC values is summarized in Appendix I of the ISOR. While we believe the inclusion of ILUC is relevant and necessary to a valid assessment of lifecycle impacts, the process for establishing and updating ILUC values should be open and transparent. To that end, we have the following comments and questions on the analysis and the ensuing results. We request that ARB address these questions as they proceed to finalize the modeling updates and rulemaking.

A comparison of the current regulatory ILUC values and the proposed ILUC values is shown in the table below. Also shown are values presented at the November 20, 2014, workshop.

Comparison of Current and Proposed ILUC Values (gCO2e/MJ)			
Fuel Pathway	Current Value (2009 Regulation)	Proposed Value (December 2014 ISOR)	November 2014 Workshop[3]
Corn Ethanol	30	19.8	20.0
Sugarcane Ethanol	46	11.8	19.6
Soy Biodiesel	62	29.1	27.0
Canola Biodiesel	n/a	14.5	14.5
Sorghum Ethanol	n/a	19.4	12.7
Palm Biodiesel	n/a	71.4	46.4

Given the significant changes to both the GTAP model, which estimates the location and amount of land use change for a particular biofuel pathway and a given volume "shock," as well as the emission factors applied to the land use change (via the AEZ-EF model), it would be useful for ARB staff to identify how much of the ILUC changes in the table above are associated with GTAP model revisions versus emission factor revisions. Additionally, what is the basis for the changes between the November 2014 workshop and the December 2014 release of the ISOR?

LCFS 38-30

Table I-1 of Appendix I summarizes the "shocks" used in GTAP to model ILUC emissions. For sugarcane ethanol, the table appears to indicate that 3 billion gallons of Brazilian production and 1 billion gallons of U.S. production were assumed. Is this a correct interpretation of the table, or do those volumes reflect the volumes consumed in Brazil and the U.S.? If the former interpretation is correct, what is the basis for these estimates, as we are not aware of large volumes of sugarcane ethanol being produced in the U.S.? What is the sensitivity of the model to changes in the split between Brazilian production and U.S. production?

LCFS 38-31

The proposed ILUC values are based on an average of 30 model runs which used 5 different values for the yield-price elasticity, 2 sets of values for a yield adjustment for the cropland pasture land category, and 3 sets of values for the elasticity of crop yields with respect to area expansion (5 X 2 X 3 = 30 runs). ARB also prepared a Monte Carlo uncertainty analysis that consisted of up to 1,000 model runs for some pathways. Why were the means of the 30 discrete scenarios used to establish the ILUC values rather than the means of the Monte Carlo simulations?

LCFS 38-32

As noted above, one of the parameters that was varied to establish the 30 model runs for the ILUC analysis was a yield adjustment for the cropland pasture land category, which is a new land category in the GTAP model relative to the 2009 analysis. This yield adjustment is intended to account for potential investments to increase the productivity of this land as it is brought into crop production. The discussion on page I-12 of Appendix I indicates:

LCFS 38-33

[3] See http://www.arb.ca.gov/fuels/lcfs/lcfs_meetings/112014presentation.pdf

> *However, Purdue researchers acknowledge that although they believe the effect is real, there is no empirical basis for the elasticity parameter proposed for this endogenous yield adjustment.*

In the absence of empirical evidence to estimate this parameter, staff used two sets of values for the runs employed for each biofuel analyzed here. Given the lack of empirical data with which to estimate this parameter, Chevron requests that staff clarify the basis it used for the elasticities in this analysis. LCFS 38-33 cont.

Land use change effects for cellulosic ethanol are discussed beginning on page I-18 of Appendix I. The discussion indicates that a value of 18 gCO2e/MJ is proposed for cellulosic feedstocks, and that staff is continuing to work on model inputs for cellulosic ethanol from non-food crops and waste. The discussion further indicates that results will be published when the analysis is complete. Will an updated ILUC value be proposed for cellulosic ethanol via a 15-day change notice as part of the current rulemaking, or does staff envision another avenue to formalize this value? In what timeframe does staff expect to have an updated ILUC value for cellulosic feedstocks? Is the 18 gCO2e/MJ value only for farmed trees, miscanthus, and other purpose-grown cellulosic feedstocks, i.e., would waste products used for cellulosic ethanol feedstock be assigned a land use change value of zero? LCFS 38-34

Low Complexity/Low Energy Use Refinery Provisions

Chevron is opposed to ARB's proposal to allow low complexity / low energy use refineries to generate credits equivalent to 5 gCO2e/MJ for their CARBOB and CARB diesel production. The criteria proposed for identifying these refineries is questionable as it ignores energy used per barrel of production in favor of total energy used by the facility. This unfairly penalizes those refiners who have invested in the complex facilities required to meet the demand of the California market at the state's unique specifications. We also oppose this proposal as it adds additional complexity to an already extremely complex program. LCFS 38-35

Refinery-specific crude provisions

The proposal to allow low complexity / low energy use refineries to opt out of the California crude average is also inappropriate. As we and others have stated repeatedly, crude differentiation under the LCFS does not benefit the environment, consumers, or regulated parties and may increase GHG emissions as crude shuffling increasing transportation impacts. Any move to make that differentiation more complicated only serves to compound the problem. There is little benefit to this change to the program or regulated parties and, as ARB states in the ISOR, tracking field-level crude use is extremely complicated. While it may be somewhat easier at the small refinery level, the added complexity of tracking multiple class-level crude CI baselines and usage is not worth the questionable benefit to those choosing to opt out. LCFS 38-36

Innovative crude production

ARB's proposed revisions to the LCFS innovative crude provision, Section 95489(d) are creative and perceptive and address several issues identified as inhibiting the use of innovative crude LCFS 38-37 production methods to reduce GHG emissions. As staff noted in the Initial Statement of Reasons (ISOR) no application has been submitted to date under the current provision. The supported changes include 1) allowing the crude producer to opt in and earn LCFS credit based on the volume of crude supplied to California refineries, 2) reducing the minimum threshold for CI reduction from 1.0 g/MJ to 0.1 g/MJ and allowing projects not meeting the 0.1 g/MJ threshold to be certified if they reduce annual emissions by 5,000 MTCO2e or more, 3) adding solar and wind electrical power generation and solar heat generation to the allowable innovative methods, and 4) the use of simplified, default credit calculations for solar-based steam generation and solar-or wind-based power generation.

However, in keeping with the intent of the innovative crude provision as stated in the ISOR, to promote the development and implementation of innovative crude production methods, additional adjustments to the provision and Staff proposed revisions should also be considered. First, the source and sink of the CO2 used for Carbon Capture and Sequestration (CCS) should not be restricted. LCFS credits should be provided regardless of where capture and storage occurs, not if both are solely onsite at the crude production facilities. This added restriction is contrary to the 2014 First Update to the Climate Change Scoping Plan which promotes innovative strategies such as CCS use to reduce GHG emissions from electricity generation and industrial emitters. Such geographic limitation would further dis-incentivize CCS in California as the overall economics for a third party's carbon capture project would be diminished as most amenable, readily capture volume, carbon capture opportunities are not onsite at the oil production facilities. While the capture of CO2 from a steam generator at the oil production facility may be an admirable objective, the overall cost of actual capture, sufficient volume, gathering and clean-up to a CO2 purity to allow for miscible injection and recovery at a reasonable economic scale is prohibitive as compared to capture from power generation or other industrial emission streams.

LCFS 38-37 cont.

Also, this same limitation requiring onsite generation for solar heat generation and solar or wind electricity generation should be removed. There are no less GHG emission reductions if the oil field operator generates or purchases his power onsite. Greater benefit would be achieved by focusing on regulating emission sources and not emissions footprint. Chevron's solar to steam test project in the Coalinga Field would not qualify for innovative crude consideration under the current definition, although having met the revised emissions reduction threshold, as the mirror field was on adjacent property to the oil operations.

Reducing minimum acceptable steam quality from 65% to 55% for solar steam generation would also be appropriate as several existing oil fields generate steam at a steam quality lower than 65%. This change and increasing the assumed inlet water temperature from 40 F to 140 F and reducing the steam generator pressure from 2000 psi to 700 -1000psi in the crude credit quantity calculation would be more accurate in representing typical oil field operations. Hot produced water is primarily used for steam generation.

While ARB is commended for expanding the list of allowable innovative methods, any new oil recovery method that reduces GHG emissions beyond the required threshold should be allowed to submit their project for Executive Officer consideration as approved innovative technology crude. As an example, the use of polymer flooding in the Wabasca Field in Canada instead of steamflooding for enhanced oil recovery would not qualify for consideration under the current proposed revisions. LCFS 38-37 cont.

Reporting and Recordkeeping

Quarterly Reporting & Reconciliation

Chevron supports and appreciates ARB's proposal to change the quarterly reporting process from a simple 60-day reporting deadline to include a 45-day deadline for reporting, followed by a 45-day reconciliation period. Given the extremely large volume of transactional data involved in compiling these quarterly reports, this structured approach to business partner reconciliation should help to alleviate reporting discrepancies.

Even then, discrepancies are never completely avoidable as billing errors, volume adjustments, and other corrections can occur well after the reporting deadlines. Chevron appreciates that ARB has retained a provision in the regulations for regulated parties to request the reopening of prior quarterly reports for corrections. We support the use of the LRT-CBTS as the vehicle for submitting these requests, as indicated in the proposed regulations. We do not, however, see the need for the accompanying letter on letterhead described in the ISOR. This is an unnecessary manual step that adds no discernable value to the process. LCFS 38-38

Product Transfer Documents

The revised definition of Product Transfer Document (PTD) is problematic. The new definition describes the PTD as a single document that contains "information collective supplied by other fuel transaction documents, including bills of lading, invoices, contracts, meter tickets, rail inventory sheets, Renewable Fuels [sic] Standard (RFS2) product transfer documents, etc." This is in direct contrast with the traditional definition of "product transfer document" under this and other regulatory programs, including the Renewable Fuel Standard and other EPA and state programs. The term is specifically generalized so that required information and messaging can be included on any of the types of documents indicated, without requiring the expense and process burden of generating a new document for every new regulatory program. This definition should be corrected to refer to a document or "collection of documents" that transmits the required information for the LCFS program. LCFS 38-39

Reporting Exports

In the ISOR, ARB proposes to require that a party who sells fuel without obligation report any subsequent export of that fuel by the buyer or any subsequent buyer. This is impractical as there is no way for one party to monitor the movement of fuel owned by another party, particularly in California's fungible supply system and especially if the fuel changes hands again after the initial sale. While ARB proposes to require PTD language stating that any subsequent export of fuel sold without obligation must be reported, this PTD language does not create a legal obligation for the buyer to notify the seller of the export. More importantly, it is inappropriate and unreasonable for ARB to assign the compliance burden related to an export of fuel to anyone other than the actual exporter. The fact that another party at one time held title to that fuel is not sufficient justification for assigning the CI obligation for that fuel to that party for an export LCFS 38-40 decision made by another. It is understandable that ARB wants to track the export of fuels in order to keep the LCFS program whole, but they must assign any associated compliance burden to the actual exporter. This concept has been successfully incorporated into the Renewable Fuel Standard, where an export of renewable fuels results in a renewable volume obligation for the exporter, and there is no reason why the same approach cannot work here. LCFS 38-40 cont.

Enforcement

Violations/Civil Penalties

The LCFS, similar to the federal RFS, imposes liability for the validity of the submitted credit on the submitter. Essentially, this is a "buyer beware" program, where the buyer is expected to conduct due diligence of the credit to establish that it was not fraudulently created and the CI valuation is accurate. The LCFS, as presently drafted, would require the party that submits a credit that was subsequently invalidated to replace those credits, and be potentially subject to civil penalties. As we have seen with the RFS, however, such a system did not prevent extensive fraud which undermined market confidence in small producers. We propose that the LCFS adopt an affirmative defense from civil penalty and credit replacement upon a showing that the invalidity of the credit was caused by a third party and the regulated party neither knew nor should have known of the cause of the invalidity at the time it was submitted for compliance.

Though responsible parties are obligated to exercise diligence and make good faith efforts (and include attestations of accuracy), the volumes of data and the complexity of the reports creates a potential for errors that cannot be eliminated. Since an error may go undetected for months or years, assessing a per day violation for incomplete or inaccurate reports from the date of submittal as proposed in § 95494(b) will produce penalties that are grossly disproportionate to the harm. Therefore, if the error is discovered by the regulated party, it should be afforded an opportunity to cure within 5 business days of discovery without penalty. If the error is discovered by ARB, then penalty should accrue upon the date of notice that the report is incomplete or inaccurate. For un-submitted, incomplete or inaccurate reports, the per-day maximum penalty amount should not exceed $1000 per day. LCFS 38-41

In instances where a civil penalty is to be assessed for an invalid credit, we support ARB's proposal that penalties be assessed on a per credit basis (a maximum of $1000/MT), rather than on a per-day basis. Time- based penalties are often magnified by variables unrelated to the alleged violating act such as by the time required to investigate a suspected violation and obtain the necessary facts to make a determination. Consequently, time based penalties are often disproportionate to the violating conduct.

Authority to Suspend, Revoke, or Modify

ARB should establish an administrative hearing process to allow regulated parties an opportunity to appeal a ARB decision to suspend, revoke or modify a credit or CI valuation. LCFS 38-42

Severability

ARB proposes added a section to the regulations stating that any declaration of one part of the program as invalid would not invalidate the remainder of the program. A general assertion of severability is inappropriate and ignores the interdependence of the LCFS provisions. There are many provisions in the LCFS that significantly impact other provisions, and if declared invalid would render the regulation unworkable. For instance, if the CI values for out-of-state producers were nullified, compliance with LCFS would become impossible in the near term, if not immediately. LCFS 38-43

Economic Impact Analysis

The economic impact analysis presented in the ISOR is based on a number of projections and assertions that we find troubling.

Cost of Credits

ARB applies an upper limit of $100/MT in its economic analysis. This limit naturally has an effect on ARB's assessment of the cost of the program to regulated parties, other business, individuals, and state and local economies. Given ARB's proposal for a Credit Clearance Market with a $200/MT price cap, we believe that $200/MT should be the upper limit used in the economic analysis. Should the market fall short of meeting ARB's credit supply projections, there is a very real possibility that the $200/MT price cap will become a price floor for a significant portion of the available credits. LCFS 38-44

Production Volumes and Price of Low-CI Fuels

We disagree with the assertion that "Since 2010, the production of low-CI fuels has increased in response to the financial incentives provided by the existing LCFS regulation." (p. VII-4) While there has been some incremental reduction in the average CI of corn ethanol supplied to California, sugarcane ethanol imports were at lower levels last year and there still today is no cellulosic biofuel available in large quantities. Also, while biomass-based diesel production levels are up, this could be attributed to the federal blender's tax credit and the federal Renewable Fuel Standard (RFS) rather than the LCFS. LCFS 38-45

Revision of Program Goals

We are surprised with the new *stated* goals of the program (p VII-11) – "To create a durable regulatory framework that can be adopted by other jurisdictions". This is not one of the goals described in Governor Schwarzenegger's executive order establishing the program. LCFS 38-46

Flawed Macroeconomic Analysis

The macroeconomic analysis is flawed based on some faulty assumptions. As stated, the scenario should be run at a maximum credit price of $200, adjusted for inflation, from 2016 through 2020. LCFS 38-47

The macroeconomic analysis assumes that production of conventional fuels in CA remains static due to increasing exports (VII-14). Thus, GHG emissions are not lowered but exported.

Additionally, no impact of lost margin has been taken into account for increased exports, nor have capital effects of exporting been addressed. LCFS 38-47 cont.

Additional Sensitivity Cases Are Needed

ARB needs to include an analysis on the impact to the program if the low-CI products are not available as projected. Also, existing fuel trends which show a decreasing demand in California do not account for low crude oil prices. A scenario should be modeled reflecting a $50/barrel crude oil environment.

Table VII-7 of the ISOR shows ARB's projections related to fuel consumption in 2016 and 2020 under a baseline scenario (no LCFS) and an illustrative compliance scenario (with LCFS). While the table indicates expected growth in renewable diesel and biodiesel, it indicates no growth whatsoever caused by the LCFS in the use of ethanol, electricity or natural gas for transportation. This contrasts directly with ARB's assertion in part VII-E of the ISOR that the LCFS is a necessary complement to the federal RFS because "the potential value of electricity, hydrogen, and natural gas are not considered in an overall program to reduce the carbon intensity of transportation fuels." Yet ARB projects no effect on the consumption of these fuels because of the LCFS. Given the complexity and projected cost of the program and the significant uncertainty regarding ARB's projections regarding the availability of these fuels, it is highly questionable whether the LCFS is worth re-adopting. LCFS 38-48

This page intentionally left blank.

38_OP_LCFS_Chevron Responses

172. Comment: **LCFS 38-1**

The comment questions whether the timetable of reductions is feasible with the current standards of the LCFS program.

Agency Response: ARB staff agrees that the LCFS should be periodically reviewed, and the Board has directed that this be accomplished in 2017 and 2018. However, staff disagrees that, after accounting for these adjustments, there will likely be insufficient credits to achieve the required 10 percent reduction in 2020 and at least maintain that level beyond 2020.

The LCFS compliance curve has been designed to take advantage of the court-mandated slowdown in the program while re-adoption was being considered. As structured, the LCFS compliance curve allows a steady build-up of banked credits through 2018 to facilitate compliance and lower costs through 2020. The combination of banked credits and production of credits in the 2018 to 2020 period was designed to provide sufficient credits for overall compliance with the annual requirements for 2019 and 2020. The staff's analyses indicated that sufficient low carbon intensity (CI) fuels to meet a 10 percent reduction in CI without using banked credits is expected shortly after 2020. Finally, staff recognizes that a number of parties backed off from their previous level of use of low CI fuels in 2014, and that overall credit generation was less than anticipated in the illustrative compliance scenario used in the Initial Statement of Reasons (ISOR). Staff has adjusted the estimates of 2014 credit generation accordingly, and the revised assessment continues to show that there will be sufficient credits to meet the rule's 10 percent requirement in 2020. Given these circumstances, the regulation maintains the 10 percent requirement for 2020.

ARB staff provided extensive information in the ISOR on the potential volumes of low CI fuels that are expected to be available over the next ten years. These included both an upper and lower range of supplies, information on the type of fuels and raw materials needed, and the location of production facilities. The illustrative compliance scenario assumes California would attract relatively minor percent volumes of several low CI fuels (for example in 2020 between 10 to 20 percent of the medium case volumes of cellulosic ethanol and biodiesel) and significantly higher, yet still moderate, percentages of several other low CI fuels (for example in 2020 about one-third of the medium case volumes of renewable diesel and cane ethanol). These somewhat higher percentages are consistent with the history of the LCFS to date. For example, in 2014 virtually all of the renewable diesel (RD) imports into the U.S. came to California for use in the LCFS. Additionally, in 2013, when significant imports of cane ethanol were received in the U.S., California's share was on the order of 35 percent.

The LCFS is a very flexible program that allows regulated parties wide discretion in their choice of compliance paths and fuel choices. The ISOR identifies a wide variety of sources of low-CI fuels that are expected to be available to fuel suppliers in California and which, collectively if they all were to be used in California, have the potential to create far more credits that needed for LCFS compliance in 2020 and beyond.

Finally, staff feels that progress relative to the LCFS targets should be periodically reviewed, and has committed to do so publicly with both a progress report to the Board in mid-2017 and a full program review prior to January 1, 2019.

173. Comment: **LCFS 38-2**

The comment states that there should be a mandatory biennial comprehensive LCFS program review, built into the proposal.

Agency Response: Staff agrees with Chevron that it is important to build a LCFS program review mechanism into the proposed regulation although staff believes a biennial review would create unnecessary market uncertainty and staff workload. Section 95496: Regulation Review addresses the need for program review and allows the Executive Officer and the Board to review the implementation of the LCFS program.

Staff considered Chevron and other stakeholders' recommendations, and incorporated a 15-day change to Section 95496 to further address the timing and minimum scope of the review, and to allow stakeholders to provide input to ARB regarding the implementation of the LCFS program.

174. Comment: **LCFS 38-3**

The commenter is opposed to the Credit Clearance Market and identifies five flaws that they believe will result in unintended negative consequences.

Agency Response: With respect to the general thrust of the comment pertaining to the need for and design of the Credit

Clearance Market, see response to **LCFS 32-9.** With respect to the liability protection portion of the comment see response to **LCFS 40-17**. Relative to the other concerns expressed:

During periods of sufficient credit supply, the price cap is unlikely to act as a floor because competition between low-CI fuel producers to sell their credits will ensure that the credit price is set by the market forces of supply and demand. Implementing a price cap doesn't change the fundamental forces of supply and demand. In the LCFS credit market, low-CI fuel producers compete to sell their credits to regulated parties with compliance obligations; in periods of a credit surplus, competition among credit sellers will prevent the cap price from acting as a floor, and will instead drive down the price of credits to the efficient price based on supply and demand. The California Cap-and-Trade carbon market provides real-world evidence that supports this fundamental economic theory: while the cap-and-trade market has a price cap, allowance prices have historically traded well below the cap.

Moreover, ARB staff has analyzed the potential for the cost containment provision to cause low-CI fuel producers to withhold offering credits for sale in order to manipulate the price of credits upward. Staff's assessment of the market shows that a hoarding situation such as Chevron describes is unlikely because the large number and small size of low-CI fuel producers limits their ability to manipulate the market by hoarding credits. Additionally, the incentive structure of the price cap is designed to address concerns that sellers might hesitate to offer LCFS credits for sale. The cap price increases annually to match the rate of inflation. When the price ceiling is held constant in real terms across all years, low-CI fuel producers have little if any incentive to withhold offering credits for sale, as the maximum credit prices can only decrease in future years, when adjusted for inflation.

The Cost Containment Provision (CCP) is designed to enhance the market signals to encourage investment in low-CI fuels and to provide regulated parties with increased certainty regarding the maximum cost of compliance. Staff analysis and feedback from LCFS market participants has underscored the importance of regulatory consistency in order to facilitate business planning, particularly regarding the stringency of the program's CI reduction targets. Chevron proposes eliminating the CCP and potentially changing the compliance targets annually. Rather than strengthening the market signal provided by the LCFS, Chevron's suggestion of setting CI reduction targets only one year in advance would reduce the incentive for innovation and investments in low-CI fuels, increase administrative burden, weaken the market signal provided by the LCFS, and increase uncertainty for regulated parties. As it can take two to three years to build a new low-CI biofuel facility, for example, investment decisions require greater confidence in the future demand for low-CI fuels than could be provided by CI reduction targets that are known only one year in advance.

ARB staff's analysis indicates that a voluntary cost cap is unlikely to be as effective at containing the cost of compliance and providing certainty on the upward bound for credit prices as a cost cap that applies to all credits in the LCFS market.

Chevron requests that the deficit carry-over provision be reinstated. Regulated parties may still carry deficits from one year to the next if the clearance market is triggered, although any accumulated deficits carried over to subsequent years will be assessed the five percent interest rate. Accumulated deficits are subject to the requirements of Section 95485(c).

175. Comment: **LCFS 38-4**

The comment recommends adoption of a simpler program, analogous to that employed by EPA in the Renewable Fuels Standard.

Agency Response: ARB considered the adoption of a simpler cost containment mechanism but selected the proposed mechanism design for the reasons outlined on pages II-5 through II-9 of the Initial Statement of Reasons. See also the responses to **LCFS 32-9** and **LCFS 38-3**.

176. Comment: **LCFS 38-5**

The comment states that the potential LCFS credit buildup and drawdown are unrealistic.

Agency Response: See response to **LCFS 38-1.**

177. Comment: **LCFS 38-6**

The comment asserts that the issues identified relative to the availability of either Renewable Diesel (RD) or Renewable Natural gas (RNG) will significantly reduce the ability to use these fuels to produce LCFS credits.

Agency Response: ARB staff disagrees that the issues identified relative to the availability of either RD or RNG will significantly reduce the ability to use these fuels to produce LCFS credits. Relative to RD, there are sufficient current and projected production capacities to provide the volumes modeled in the illustrative compliance scenario by California, obtaining between roughly 25 to 45 percent of the 2020 volumes anticipated to be available for use in the U.S. Accommodating this amount of RD in the California fuel distribution system can occur without changes in federal law or regulations. It will require cooperation among the five major refiners that produce virtually all of the State's entire diesel fuel to establish appropriate pipeline specifications and labeling conventions. While not trivial, these steps are well within the abilities of the affected parties, which have accomplished similarly difficult transitions in the efforts to phase out methyl tertiary butyl ether (MTBE) and to modify pipeline specifications to accommodate other changes in California's rules for Cleaner Burning Gasoline. By the commenters own statement, the only thing that would prevent pipeline blending of blends above R5 would be lack of industry support for common carrier pipeline specification changes. Staff therefore believes that the illustrative compliance scenario volumes are reasonable.

Relative to RNG, there has already been significant growth in the displacement of conventional natural gas (NG) with RNG by major suppliers of vehicular NG in California. The development of supplies of RNG has occurred in response to the current LCFS, with supplies increasing by more than 100 percent in both 2013 and 2014, respectively. These producers have indicated their intention to strive to provide 100 percent RNG as a means of maximizing LCFS credit generation and increasing the value of their fuel. It is reasonable to anticipate that these trends will continue as the stringency of the LCFS increases and credit values rise.

Regarding increases in advanced biofuel supply, the LCFS and other incentives, including the federal 2014 Renewable Fuel Standards for the Renewable Fuel Standard Program (RFS2) and tax credits, are expected to increase advanced biofuel supply. ARB staff's experience with the advanced biofuel industry is that some plants have made statements that they were built primarily to supply the California market because of LCFS and some others have made changes to their plant operations specifically to get a lower carbon intensity score in the LCFS program. This experience leads staff to believe that the commenter is incorrect, and that the LCFS, in combination with the other incentives, can lead to supply increases of advanced biofuels.

Regarding discounting certain project or plants when projecting future biofuel supply, staff's methodology is sufficient to yield a conservative range of projected supply potential as described in Appendix B to the Initial Statement of reasons and the responses to comments **LCFS 38-1**, **LCFS 40-8** and **LCFS 40-9**.

178. Comment: **LCFS 38-7**

The commenter is opposed to the concept of stationary source credits being applied to LCFS because they are covered under ARB's cap and trade program. The commenter believes the proposed credit has a number of shortcomings.

Agency Response: ARB staff believes crediting for actions at refiners is a reasonable additional compliance option in LCFS. Staff's analysis has indicated that there are a significant number of projects that could be available for use under the Refinery Investment Credit Provision with the 0.1 gCO_2e/MJ carbon intensity reduction threshold. Specific recommendations proposed by the commenter regarding the method and tools for efficiency ranking of refiners are addressed in **LCFS 38-8** to **LCFS 38-13**.

179. Comment: **LCFS 38-8**

The commenter suggests that the metric used to establish relative refinery efficiency should be the Complexity Weighted Barrel.

Agency Response: The LCFS is based on carbon intensities of transportation fuels. The Refinery Investment Credit Provision was also developed using carbon intensity as the basis for credit generation. By contrast, the Complexity Weighted Barrel (CWB) method evaluates a refinery's efficiency by comparing carbon dioxide emissions for each process unit to a worldwide standard. While there are merits to both methods, the current method of evaluating refineries in the Refinery Investment Credit Provision is more consistent with the design of the LCFS.

180. Comment: **LCFS 38-9**

The comment asserts that refiners should be allowed to offer offsets of criteria and air toxic pollutants if their efficiency improvement projects indicate a potentially adverse impact in such emissions.

Agency Response: ARB staff made a 15-day change to remove the prior language referring to 'no increases in criteria pollutants and toxic emissions' and replaced it with more specific language stating that the project applicant must demonstrate that any net increases in criteria air pollutant or toxic air contaminant emissions from the project must be mitigated in accordance with all local, state and national environmental and health and safety regulations. Some of the applicable regulations do allow offsets.

181. Comment: **LCFS 38-10**

The comment asserts that the 0.1 gCO_2e/MJ threshold is too stringent and should be revised consistent with staff's proposed minimum for Innovative Crude Production Technologies.

Agency Response: Staff's analysis has indicated that there are a significant number of projects that could be available for use under the Refinery Investment Credit Provision with the 0.1 gCO2e/MJ carbon intensity reduction threshold. Further, this threshold is used in other provisions within the program including pathway applications. ARB staff believes this threshold creates an appropriate balance between greenhouse gas reductions and efficient use of current staff resources, but will continue to analyze this threshold for possible modification as projects are submitted and analyzed.

182. Comment: **LCFS 38-11**

The comment suggests that investments should not be limited to capital projects; oftentimes sizeable energy efficiency improvements are funded out of operating expense per established IRS accounting regulations**.**

Agency Response: ARB staff made a 15-day change to allow non-capital energy efficiency projects to be eligible in the Refinery Investment Credit Provision as long as they meet the 0.1 gCO_2e/MJ threshold. Staff included specific exclusions to prevent non-efficiency-related shutdowns and regularly scheduled maintenance from qualifying for this provision.

183. Comment: **LCFS 38-12**

The comment suggests that the project eligibility cutoff date should be changed to the project's startup date for any project commissioning post 1/1/2015.

Agency Response: ARB staff made a 15-day change to make projects eligible that have their authority-to-construct permits approved after January 1, 2016. The purpose of the Refinery

Investment Credit Provision is to incentivize marginal projects that might not have otherwise been economical without the provision. Projects that have undergone permitting to the point of permit approval prior to the existence of this credit have likely already been deemed economical and are not the target of this provision.

184. Comment: **LCFS 38-13**

The comment asserts that the bio-feedstock 10% threshold is too restrictive, even if defined as "percent of total process unit feed."

Agency Response: ARB staff made a 15-day change to the 10 percent renewable feedstock threshold. The renewable feedstock portion of the Refinery Investment Credit Provision is being made into a separate provision, called the Renewable Hydrogen Refinery Credit, and the renewable feedstock threshold is being removed in favor of a threshold based on fossil hydrogen displaced.

185. Comment: **LCFS 38-14**

Agency Response: ARB staff acknowledges the commenter's support of our decision not to recommend refinery-specific incremental deficit accounting for large, complex refineries.

186. Comment: **LCFS 38-15**

In the first part of this comment, the commenter advocates for reducing the extent of crude differentiation within the regulation. The second part of this comment is in regard to ARB staff's proposal to clarify the methodology for calculating the Annual Crude Average CI by specifying that production data from the California Department of Conservation and Bureau of Safety and Environmental Enforcement is to be used in lieu of volumes reported by refineries for California State and Federal Offshore crude.

Agency Response: As the commenter has stated, the Annual Crude Average CI has not exceeded the 2010 Baseline and crude imports by rail from western U.S are increasing. However, the policy decision to differentiate crude based on carbon intensity is still valid going forward, as described in the response to **LCFS 32-10**.

The change in regulation language to clarify the methodology for the Annual Crude Average CI is meant simply to clearly match the regulation language to the calculation methodology already being used for estimating the Annual Crude Average CI (e.g., see 2013 Crude Average CI calculation at http://www.arb.ca.gov/fuels/lcfs/crude-oil/2013-crude-ave-ci.pdf). Staff's justification for this change is further described in the ISOR on pages II-16 and II-17. As stated in the ISOR, the total volume of California crude reported by refineries in 2012 and 2013 very closely matches the total volume of California production reported by oil field operators. During 2012 and 2013, refineries reported a total volume of 432 million barrels while oil field operators reported a total volume of 431 million barrels. Also as stated in the ISOR, staff will continue to validate the assumption that all crude produced in California is refined in California by checking the total California crude volume reported by refineries against the total production volume reported by producers. Exports of California-produced crude can also be checked by consulting with the California Energy Commission, which requires reporting of crude exports as part of the Petroleum Industry Information Reporting Act. If it becomes clearly evident that California crude is being exported, ARB staff will use the best available information to determine the field source(s) of exported crude and reduce the appropriate production volumes used in the Annual Crude Average CI calculation to account for the exported crude.

187. Comment: **LCFS 38-16**

The commenter objects to limiting the application of CCS under the innovative crude provision to only those instances where the carbon capture occurs onsite at the crude oil production facilities.

Agency Response: See response to **LCFS 37-12.**

188. Comment: **LCFS 38-17**

The comment states that the formula for calculating the total volume and energy of the refinery appears ambiguous. In particular, the basis of the product volumes is not defined.

Agency Response: ARB staff agrees and made 15 day changes to clarify. See response to **LCFS 40-115** and **LCFS 40-117.**

189. Comment: **LCFS 38-18**

The comment asks ARB staff to define type of measurement needed for calculating baselines and reductions, to clarify the expected baseline year, and to clarify the regulatory text regarding how unrelated changes in refinery carbon intensity over time would affect previous refinery credits (such as changes in throughput rates or operational changes such as new units).

Agency Response: Data from the Mandatory Reporting Regulation (MRR) was used for calculating baselines and reductions. The first year of complete data for this sector in MRR is 2011. Staff considered using 2011 as the data for the baseline year, but chose a three-year average (2011-2013) to establish a baseline that moderated any single year extreme variances. Amendments have been made in the 15-day package to address the fact that the credits will not be retroactively affected if there are unrelated changes in refinery carbon intensity. However, if the carbon intensity changes the credits going forward would change.

190. Comment: **LCFS 38-19**

The commenter suggests that the proposed definitions of the LCFS should be harmonized with the AB32 requirements such as MRR reporting.

Agency Response: ARB staff has attempted to harmonize definitions across programs where appropriate. The different programs under AB 32 have different purposes and LCFS definitions may necessarily differ from MRR definitions. Staff will continue to review definitions and specific suggestions would be considered in future rulemakings.

191. Comment: **LCFS 38-20**

The comments states that there exists a 5 to 7 gCO2e/MJ gap between GREET and ARB calculated industry carbon intensity values for gasoline and diesel according to staff's reported values.

Agency Response: The Greenhouse Gas, Regulated Emissions, and Energy Use in Transportation (GREET) model is based on Argonne National lab[6] data for refinery emissions, while the average carbon intensities in the Refinery Investment Credit Provision were calculated using MRR data. However, partially due to this discrepancy, ARB staff has decided to remove the portion of the Refinery Investment Credit Provisions in a 15-day change that makes reference to the average carbon intensities. Staff will continue to investigate this discrepancy.

[6] Forman, Grant Stephen, Vincent B. Divita, Jeongwoo Han, Hao Cai, Amgad Elgowainy, and Michael Q. Wang. "US Refinery Efficiency: Impacts Analysis and Implications for Fuel Carbon Policy Implementation." Environmental science & technology (2014).

192. Comment: **LCFS 38-21**

The commenter opposes the allowance of LCFS credits for fixed guideway transit and electric forklifts as well as using non-metered data for forklifts.

Agency Response: With respect to the fixed-guideway transit portions of this comment, the Board directed staff in Resolutions 09-31 and 11-39 to evaluate the feasibility of issuing credits for non-road, electricity-based transportation sources, including mass transit. These vehicles displace gasoline and diesel fuel transportation energy, and use significant and quantifiable electricity for transportation, therefore should be allowed to generate LCFS credits.

The credit calculation adjusts to account for the exclusion of the pre-LCFS off-road electricity applications in 2010 baseline. The LCFS credit formulas for all electric forklifts and existing electric fixed guideways do not include credits for fuel displacement, which substantially reduces the number of credits these electrical applications could generate. In contrast, the LCFS credit formula for new electric fixed guideway system does have the fuel displacement credits. This approach addresses the commenter's concerns related to allowing sources to generate credits without including them in the 2010 baseline.

Staff disagrees with the comment that the proposed electricity provisions create an un-level playing field. Early adopters of lower carbon intensity fuels, such as electricity, should not be penalized by excluding them from LCFS credit generating. Instead, they should be incented to continue and expand such applications.

With respect to metering of electric forklifts, many electric forklifts are charged without the use of a dedicated meter to measure electricity use. Forklift fleet operators often charge batteries used in multiple equipment types using the same charging equipment and meter. In addition, tracking metered data for thousands of forklifts would likely be cost-prohibitive. For these reasons, staff proposes to calculate the amount of electricity used to charge electric forklifts in each utility service area. The calculation method proposed for electric forklift charging is robust. In addition, staff commits to revisit the estimation method as more accurate charging information becomes available.

As indicated in the Initial Statement of Reasons, electric forklifts, including motorized hand trucks, have taken a larger market share nationwide than internal combustion engine (ICE) forklifts powered by gasoline, propane, CNG, or diesel fuel in recent years. An increase in electric forklift use coupled with a decrease in ICE forklift is expected to result in decreased GHG emissions and contribute to meeting the goals of the LCFS program. The commenter is incorrect, staff did not assume that the electric forklifts charging would displace diesel fuel in calculating credits. As stated in the ISOR, because the displacement of diesel fuel cannot be attributed entirely to the LCFS for the forklifts that were already operating in 2010, staff proposes to use a modified credit formula that does not give credit for diesel fuel displacement. For details please refer to III-10 of ISOR.

Staff proposes to estimate the amount of electricity used to charge electric forklifts in each utility service area. The number of forklifts used in California and the amount of electricity used by the fleet can be estimated using national shipment data, battery size, assumed annual operating hours and load factor. Further, each utility's share can be approximated based on their share of the state's non-residential (business/commercial) accounts.

In addition, in the Second 15-Day Modified Regulation Order released on June 23, 2015, staff proposed to allow electrical forklift fleet operators to opt-in to LCFS and generate credits, in order to better encourage technology innovations and foster capital investments to electrical forklifts. Under such a circumstance, the electric forklift fleet operators shall report the directly measured annual electricity use.

193. Comment: **LCFS 38-22**

The comment states objection to the removal of direct metering requirements on electric vehicle recharging at residences. It goes on to add that should staff go forward with an estimate procedure for electric vehicles in residences, then the estimate procedure should be more rigorous than the current method.

Agency Response: With respect to removal of direct metering requirements for residential charging, data on number of EVs in a utility's service territory, and credit invalidation concerns, see responses to **LCFS 32-11** and **LCFS 40-52**. With respect to overlap between public charging and residential charging, see the response to **LCFS 40-61**.

U.S. DOE's EV Project has been collecting extensive data on Nissan Leaf and Chevrolet Volt since late 2010. Although the total

VMTs might be different for BEVs and PHEVs, the EV Project shows that the kW hours of average daily charging for Nissan Leafs (BEVs) and Chevrolet Volts (PHEVs) are similar. Therefore, the daily use data of BEVs and PHEVs are not separated in the proposed calculation method.

194. Comment: **LCFS 38-23**

The comment states that the public reporting requirement of electricity credit information should not be removed from the proposed regulation.

Agency Response: The current LCFS regulation requires regulated parties for residential and public EV charging to include public reporting of certain information. However, public credit accounting is not required for regulated parties of other fuels. Staff revised the rule to make the reporting requirements more consistent among regulated parties. Further, ARB staff will now directly control the calculation of credits for residential charging and will make this calculation as transparent as possible without providing confidential business information.

195. Comment: **LCFS 38-24**

This comment includes three parts: 1) an objection to crude differentiation in the LCFS, 2) a recommendation for ground-truthing the Oil Production Greenhouse Gas Emission Estimator (OPGEE) model, and 3) a recommendation for changing the default value in OPGEE for feed water temperature to steam generators.

Agency Response: In response to part 1 of the comment, see the response to **LCFS 32-10**.

In response to part 2 of the comment, ARB staff agrees that “ground truthing” is an important test of the validity of the model approach that should be undertaken. Unfortunately, staff has yet to find an oil producer who will work closely with us and supply the necessary data to ground truth or calibrate the model against actual GHG emissions. Since the commenter produces about 25 to 30 percent of the oil in California, staff would welcome their participation in such an endeavor. However, Adam Brandt at Stanford University has published several papers on the topics of model uncertainty and comparison of OPGEE model results to other life cycle assessment (LCA) models as described in the response to **LCFS 37-5**

In response to part 3 of the comment, the OPGEE model default for feed water temperature to the steam generator of 40^{o} F was chosen as a very conservative default to be used in the absence of more specific field data. However, ARB staff agrees with the commenter that produced water is logically recycled and enters the steam generator at a higher temperature than the current OPGEE model default value. Therefore, staff has changed the default feed water temperature to 140^{o} F in OPGEEv1.1. This revision to OPGEE affects not only crude CI values in Tables 8 and 9, but also the 2010 Baseline Crude Average CI, the California Reformulated Gasoline Blendstock for Oxygenate Blending (CARBOB), ultra-low sulfur diesel (ULSD), and California Reformulated Gasoline (CARFG) CI values and the compliance schedule targets, which have also been revised as 15-day changes.

196. Comment: **LCFS 38-25**

The commenter suggests that ARB develop a single CI value for all California crude and not differentiate among the 150 California fields listed in the crude lookup table.

Agency Response: Using the actual specific values better tailors the program to encourage/discourage use of low/high CI crudes. To the extent possible, CI values for crudes are specific to each marketable crude name and the fields that contribute to that crude name. Aggregated CI values or CI values calculated with regional average data are only used when data is unavailable to allow for differentiation.

197. Comment: **LCFS 38-26**

The commenter recommends allowing individual operators within a California oil field to provide operator specific data in order to obtain a separate CI specific to their operation.

Agency Response: ARB staff notes that this comment contradicts the recommendation the commenter made in **LCFS 38-25** that ARB develop a single CI for all California crudes. Calculation of the California annual crude average CI will use California field CI values and volumes as specified in the proposed section 95489(c)(3)(A). When calculating a volume-weighted average CI value such as the California annual crude average CI, there will be little difference between using average field CIs and field volumes versus using individual operator CIs and operator volumes, as all crude produced in California is being refined in California. Therefore, staff does not intend to provide operator-specific CI values at the sub-field level unless the operator is directly supplying crude to a LC/LE refinery that has opted for refinery-specific incremental deficit accounting.

198. Comment: **LCFS 38-27**

The commenter proposes that ARB include a de minimis threshold that must be exceeded prior to assessing an incremental deficit.

Agency Response: ARB staff agrees that the use of a de minimis level that must be exceeded before an incremental deficit is incurred has merit and proposed this revision as a 15-day change for both the California Average incremental deficit determination and the LC/LEU refinery-specific incremental deficit determination. Under the revised language, an incremental deficit will only be triggered if the Three-year California Crude Average CI exceeds the 2010 Baseline Crude Average CI by 0.10 gCO_2e/MJ, but, if an incremental deficit is triggered, the resulting incremental deficit will still be calculated relative to the 2010 Baseline Crude Average CI.

199. Comment: **LCFS 38-28**

The commenter requests clarification on several issues regarding calculating and assessing an incremental deficit.

Agency Response: If the Three-year California Crude Average carbon intensity exceeds the 2010 Baseline Crude Average carbon intensity, incremental deficits for CARBOB and diesel will be added to each affected regulated party's compliance obligation in the year following the year in which the Three-year California Crude Average CI was calculated. For example, the Three-year California Crude Average carbon intensity for years 2013, 2014, and 2015 is calculated in May of 2016. If this value exceeds the 2010 Baseline Crude Average CI, then incremental deficits will be added in the year 2017. These incremental deficits will be based upon the amount of CARBOB and diesel supplied by the regulated party in the year 2017. ARB staff disagrees with the commenter's recommendation that the incremental deficit be based on and applied to the amount of CARBOB and diesel supplied in the year in which the debits are incurred for several reasons. First, the incremental deficit is calculated by comparing a three-year rolling average to the 2010 baseline, and therefore, there is not a single year in which the debits are incurred. Second, it would be extremely difficult and cumbersome to apply incremental deficits retroactively to a year in which the annual compliance reporting has already been completed. Third, applying the incremental deficits to the year following the year in which the deficits are established allows the regulated parties time to plan ahead and ensure that they will have sufficient credits to cover the additional deficits in the following year.

200. Comment: **LCFS 38-29**

The comment states that the scientific basis for addressing iLUC in the LCFS is sound and improvements to methods and models for estimating iLUC values continue to be made.

Agency Response: ARB staff appreciates the commenter's support.

201. Comment: **LCFS 38-30**

The comment requests that ARB staff identify the reasons for adjustments to iLUC values between the original 2009 proposed regulation values, through the 2014 ISOR.

Agency Response: The 2009 analysis used a single model, Global Trade Analysis Project (GTAP), to estimate indirect land use change (iLUC) emissions. Also, in the 2009 analysis, emission factors were embedded within the GTAP model. The current analysis uses two separate models to estimate iLUC emissions. It is not possible to attribute changes in current iLUC values (compared to 2009) specifically to revisions in either the GTAP or Agro-ecological Zone Emission Factor (AEZ-EF) models since the current modeling methodology is different compared to the one used for the 2009 analysis.

As for the changes from the November 2014 workshop results to the proposed values, ARB staff discovered an error in the AEZ-EF model which has been detailed in Appendix I of the ISOR. Fixing the error resulted in a new set of iLUC values for biofuels which were published in the ISOR released in December 2014 (different compared to November 2014). See also response to **LCFS SF8-1**.

202. Comment: **LCFS 38-31**

The comment requests clarification on the basis for sugarcane ethanol production levels in both the U.S. and Brazil.

Agency Response: Since there is no current production of sugarcane ethanol in the United States, ARB staff does not model the production of this biofuel in the United States. Instead, for the iLUC analysis, staff applies a shock of 3 billion gallons of sugarcane ethanol production in Brazil, of which 1 billion gallons is exported to the U.S. The sensitivity of the model to changes in the split between Brazilian production and U.S. production is therefore irrelevant.

203. Comment: **LCFS 38-32**

The comment questions the method used to select iLUC values.

Agency Response: For the Monte Carlo analysis, distributions for many of the parameters were not readily available from published literature. ARB staff therefore had to rely on expert opinion in the development of distributions for many of the parameters. See response to **LCFS 29-8**.

204. Comment: **LCFS 38-33**

The comment requests clarification of the elasticity values used for the yield-price elasticity analysis for the cropland pasture land category.

Agency Response: Cropland Pasture is a new land cover category that was included in the GTAP model in 2010 to enhance the land use analysis. Purdue, in the GTAP model, used a parameter termed cropland pasture elasticity to account for endogenous yield adjustments resulting from changes in crop prices. This is a parameter similar to the Yield Price Elasticity (YPE) parameter for cropland. In the absence of detailed empirical data, researchers at Purdue University developed a value of 0.4 for cropland pasture elasticity based on model calibration. Model calibration adjusts parameter values to produce realistic model outputs. However, when anomalous outputs were observed (i.e., significant reforestation in several regions of the world due to additional cropland change), additional calibration adjustments were made. Using values of 0.1 and 0.2 for cropland pasture elasticity parameter generated model responses without leading to anomalous behavior.

205. Comment: **LCFS 38-34**

The comment questions how future analysis of cellulosic feedstocks will be incorporated into iLUC values.

Agency Response: An updated iLUC value for cellulosic ethanol will require additional data and changes to the model that are not currently available for cellulosic ethanol analysis. Such changes may be included in a future rulemaking. An iLUC value of 18 gCO_2/MJ has been used in the current regulatory framework since the LCFS regulation was adopted in 2009. For the re-adoption, and to be consistent with previous rulemaking, ARB staff proposes to continue using this value for cellulosic feedstocks. Staff is currently working with the California Energy Commission (CEC), Purdue researchers, the U.S. Environmental Protection Agency, and others in determining appropriate inputs, values, etc., for cellulosic ethanol from non-food crops and waste. No timeframe has been established for the completion of this work and the results will be published when the analyses are completed. Staff has not yet determined an iLUC estimate for waste product feedstock.

206. Comment: **LCFS 38-35**

The commenter is opposed to ARB's proposal to allow low complexity / low energy use refineries to generate credits equivalent to 5 gCO_2e/MJ for their CARBOB and CARB diesel production.

Agency Response: The Board directed staff in Resolution 11-39 to consider provisions to the LCFS to address low-energy-use refining processes. This Resolution language was meant to address the lower energy inherently embedded into the transportation fuels from refineries that use simple processes to refine transportation fuel. ARB staff explained our rationale this credit in detail on pages II-14 through II-15 of the Initial Statement of Reasons.

207. Comment: **LCFS 38-36**

The commenter argues that the proposal to allow low complexity, low energy use refineries to opt out of the California Average provision is inappropriate.

Agency Response: See also the response to **LCFS 32-10**.

ARB staff disagrees with commenter's suggestion that the added complexity is not worth the benefit to those choosing refinery-specific accounting. Staff explained our rationale for allowing low complexity, low energy use refineries to opt for refinery-specific incremental deficit accounting in the ISOR on pages II-15 and II-16.

208. Comment: **LCFS 38-37**

The comment includes four recommendations for the innovative crude provision: 1) allow carbon capture to occur offsite of the crude oil production facilities, 2) remove the limitation for onsite solar heat generation and onsite solar and wind electricity generation, 3) reduce the minimum acceptable steam quality from 65 to 55 percent and revise some parameters in the calculation of the default credit value, and 4) allow crude producers to submit any new production method that reduces GHG emissions to the Executive Officer for approval

Agency Response:

1. *Allow carbon capture to occur offsite of the crude oil production facilities*.

   Please see response to Comment **LCFS 37-12**.

2. *Remove the limitation for onsite solar heat generation and onsite solar and wind electricity generation*.

   The commenter is mistaken as the regulation language does not require onsite generation of heat, steam, or electricity. The regulation only requires that the solar heat or steam and solar or wind electricity be consumed onsite. Additionally, offsite electricity must be provided directly to the crude producer from a third party generator and not through a utility owned transmission or distribution network.

3. *Reduce the minimum acceptable steam quality from 65 to 55 percent and revise some parameters in the calculation of the default credit value.*

   ARB staff agrees with this recommendation and has proposed an additional default credit for 55 to 65 percent quality steam. Staff also agrees with the recommendation to change the assumed feed water temperature and steam pressure in calculating the default credit for solar steam generation. Revised default credit values were proposed as a 15-day change.

4. *Allow crude producers to submit any new production method that reduces GHG emissions to the Executive Officer for approval*.

   ARB staff disagrees with this recommendation. While operators may submit data for any new production method that reduces GHG emissions and have these reductions accounted in estimating the CI value for the crude lookup table, staff believes that those categories of projects qualifying for innovative method credit, as well as any limitations specified for those projects, should be subject to a regulatory process in which the public can participate as a way to test the merits of various proposals. Staff encourages crude producers to submit types of projects that they believe should be considered for innovative method credit as part of future amendment cycles.

209. Comment: **LCFS 38-38**

The comment questions the usefulness of submitting an accompanying letter on letterhead in the event a regulated party requests correction of a quarterly report.

Agency Response: Regulated parties are strictly liable for misreporting data in the first instance and may be subject to penalties for each day a quarterly report remains incorrect. The required letter is meant to prevent unauthorized tampering with prior reported information, and to maintain a clear record of which reporting entities have violated the LCFS by misreporting transactions in the LRT-CBTS, as well as a summary of what information was later changed and why the change was needed. If ARB staff finds that enforcement action is necessary based on misreporting, the letter will eliminate confusion and disputes about what took place. The ARB does allow correction requests for multiple quarters to be addressed within a single letter to reduce the workload to regulated parties. Also, the additional time to be provided for report reconciliation is expected to dramatically reduce the number of correction requests.

210. Comment: **LCFS 38-39**

The commenter wishes to return to the earlier Product Transfer Document (PTD) definition.

Agency Response: There have been many cases involving LCFS fuel transactions in the first years of the program where the flexibility associated with a PTD as a "collection of documents" approach has not worked. ARB staff has received input from a number of regulated parties that the "PTD" related information that they receive from their business partners, and which they need for accurate LCFS reporting, is often incomplete, inconsistent, and late. There has been contention between regulated parties over which party has the compliance obligation and confusion regarding the fuel pathway code (CI) transferred. Also, a single PTD provides a simple means for passing alternative fuel production facility information with alternative fuel transactions.

Many of the regulated parties are already passing along the same information as a single record in a document in a consolidated form. It is expected that if a single PTD is transmitted in some format to the recipient of the fuel, there will be less need for reconciliation, and ARB will receive fewer LCFS report correction requests.

211. Comment: **LCFS 38-40**

The comment questions the provision requiring the seller of no-obligation fuel to track the export to any subsequent buyer.

Agency Response: Whenever an obligation is retained by the transferor they are required to notify the downstream transferee in the PTD using a prescribed notice provided in the proposed LCFS regulation. The commenter notes that adding language to the PTD may not impose a legal obligation on the recipient. At a minimum, the warning language puts the recipient on notice of the fuel's regulatory status, which in itself could facilitate enforcement by ARB against the recipient in the event of an unreported export. Moreover, the warning language would improve the transferor's legal position vis-à-vis the transferee in the event of a commercial dispute or indemnification claim based on a transferor's loss of credits caused by the fuel's export. When the fuel obligation is retained, the prescribed notice will be required on the PTD when the fuel is transferred to the recipient buyer.

212. Comment: **LCFS 38-41**

The comment questions making the buyer of credits responsible for verifying that the credits purchased were indeed generated from low carbon fuels.

Agency Response: As stated in this comment, the LCFS is a "buyer-beware" Program. The buyer needs to verify that the credits being purchased were generated from low carbon intensity fuels. Health and Safety Code section 43031 details that the prevention efforts taken by the defendant (i.e., the regulated party) will be taken into consideration when a penalty is assessed. See response to **LCFS 7-3**.

213. Comment: **LCFS 38-42**

The comment asserts that ARB should establish an administrative hearing process to allow regulated parties an opportunity to appeal an ARB decision to suspend, revoke, or modify a credit or CI valuation.

Agency Response: Staff does not agree with having an additional administrative hearing process to allow regulated parties an opportunity to appeal an ARB decision to suspend, revoke or modify a credit or CI valuation. Staff anticipates working with all affected parties after the initial notice is issued; parties can submit information that is considered before the Executive Officer makes his/her final determination. Additionally, the LCFS Program includes a Program Review Process for purposes of evaluating the implementation of the Program. If affected parties find the process detailed in section 95495 inadequate, this is a good public forum to raise these concerns. Staff can consider how best to move forward after having an open dialog with all stakeholders on this topic.

214. Comment: **LCFS 38-43**

The comment suggests deleting the severability provision of the LCFS regulation.

Agency Response: ARB staff recognizes that while some portions of the proposed regulation are interdependent, staff does not believe it is correct to say that every aspect of every provision is integral to the continued functioning of the regulation. In the event a court were to invalidate one provision, it may well be possible to continue implementing the program to the public's benefit. Because of that possibility, staff does not deem it appropriate to delete the severability provision proposed as section 95497.

215. Comment: **LCFS 38-44**

The comment states that ARB should use an upper limit of $200/MT in the economic analysis, like that used for the Credit Clearance Market, rather than $100/MT.

Agency Response: We agree that the $200 price cap provides an upper bound on the potential price of credits, but it should not be construed as a projection of future credit prices or as a projection of the likely future cost of compliance.

ARB staff completed an in-depth economic analysis of the economic impacts of the proposed regulation using what staff believed to be a reasonable range of credit prices (considering multiple potential credit prices but focusing on $100 dollars per credit in some portions of the analysis). The $100 credit price was illustrative and designed to reflect historic prices as indicated on page VII-1 of the ISOR. We note that historical credit prices have remained below the $100 value.

216. Comment: **LCFS 38-45**

The comment disagrees with ARB's assessment that "Since 2010, the production of low-CI fuels has increased in response to the financial incentives provided by the existing LCFS regulation."

Agency Response: Although it is always challenging to tease out the incremental impact of overlapping policy drivers for low-CI fuels, the LCFS unequivocally improves the economics of low carbon fuel production supplied to California, and thus has contributed to the financial incentive for increased production of low-CI fuels worldwide.

As described in the Initial Statement of Reasons, ARB staff has analyzed the historic production of low-CI fuels since the inception of the LCFS in 2010, as well as the potential growth trajectories for low-CI fuels in the Initial Statement of Reasons. This analysis indicates that many innovative, low-CI fuel technologies have moved past the demonstration stage, and have overcome techno-economic challenges that have in recent years limited their supplies.

It is also important to note that neither the federal RFS2 nor the Biodiesel Blenders' Tax Credit specifically incentivize reductions in carbon intensity, which supports the findings of ARB staff's analysis that the carbon intensity reduction goals of the LCFS will not be achieved in full without the LCFS program specifically requiring reductions in carbon intensity.

217. Comment: **LCFS 38-46**

The comment evinces surprise that the regulation's stated goals are not among those outlined by Governor Schwarzenegger in an executive order.

Agency Response: The same goal was mentioned in the 2009 ISOR. More importantly, ARB's authority is not limited to a single executive order; in AB 32 the Legislature stated that when developing measures to reduce emissions, ARB should design its measures to allow harmonizing with market-based measures in other states, regions, nationally, and internationally. It further indicates that this encouragement will "provide an opportunity for the state to take a global economic and technological leadership role in reducing emissions of greenhouse gases."

218. Comment: **LCFS 38-47**

The comment claims that the macroeconomic analysis is flawed and based on faulty assumptions; the commenter believes that continued production and export of petro fuels in California means that emissions will simply be exported.

Agency Response: ARB staff disagrees with both points. The $100 credit price was illustrative and designed to reflect historic prices as indicated on page VII-1 of the ISOR. In addition, the credit price represents the marginal cost of abatement - or the cost of the last ton of emission reductions to comply; most other reductions will be achieved at a lower price. Given the current price of $25, and the average for 2012-2013 was $57, this approach is conservative, as credits can be generated at a lower cost, and the credit price is not known with certainty.

The export assumption does not indicate that the emissions are exported but instead that increasing world demand[7] could be met with California petroleum fuels displaced by lower-carbon fuels used under the LCFS; accordingly there should be less new production (and associated emissions) elsewhere, resulting in a net emissions reduction with an LCFS in place compared to a no-LCFS scenario.[8]

ARB staff used the unadjusted Annual Energy Outlook (AEO) base price, which is lower than the California price to account for the lower value of finished fuels exported.

The increased excess capacity from California refiners is predominantly driven by existing trends that have led to reduced fuel consumption in California that is forecasted to persist in the future.[9] These trends are not exclusively driven by the LCFS; however, the historic trend of the inverse relationship between California demand and exports of finished fuels indicate that the capital effects of exporting are not a barrier. Additionally, the macroeconomic model used considers all aspects of exports including capital and labor costs and economies of scale.

219. Comment: **LCFS 38-48**

The comment states that the illustrative scenario does not account for the penetration of electric, hydrogen, and natural gas.

Agency Response: ARB staff provided one illustrative scenario of a plausible mix of fuels that would achieve compliance. Because the program is fuel neutral there is flexibility for industry to choose the most cost-effective fuel mix. Alternate scenarios with greater penetration of electric, hydrogen and natural gas use partially incented by the value of LCFS credits are conceivable, especially if the availability of low-cost low-carbon liquid biofuels is limited. See response to **LCFS 32-6**.

Sam Wade
Chief, Transportation Fuels Branch
California Air Resources Board
1001 "I" Street
Sacramento, CA 95814

Re: Pacific Gas and Electric Company's Comments on the February 19 Board Hearing on Re-Adoption of the Low Carbon Fuel Standard

Dear Mr. Wade,

Pacific Gas and Electric Company (PG&E) appreciates the opportunity to comment on the proposed re-adoption of the Low Carbon Fuel Standard (LCFS), which addresses the State of California Court of Appeals, Fifth Appellate District's (Court) opinion in *POET, LCC vs. California Air Resources Board*. Per the meeting notice, the Board will consider the proposed regulation and provide direction to ARB staff, with adoption occurring at a second hearing in 2015.[1]

Accordingly, PG&E expresses its strong support for the LCFS and asks the Board to instruct staff to move forward with re-adoption. The consumption of transportation fuels is the single largest source of greenhouse gas (GHG) emissions in California and the LCFS is an important program transitioning the state to lower carbon intensity transportation fuels. Re-adoption will provide the regulatory certainty necessary for continued development of alternative fuels. LCFS 39-1

In addition to addressing the Court's ruling, ARB Staff is revising critical technical information and programmatic requirements. Overall, PG&E believes ARB Staff's proposal enhances program integrity and effectiveness, and thanks ARB Staff for an open and collaborative stakeholder process.

LCFS 39-2

PG&E has participated extensively during the re-adoption process, especially with respect to ARB's update to the carbon intensity values for transportation fuels in the LCFS.[2] Given that the LCFS uses a crediting approach to incentivize the lowest carbon transportation fuels, the carbon intensity of each fuel pathway is crucial because it ultimately determines the

[2] Carbon intensity values are determined using the California Modified Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (CA-GREET2.0) in conjunction with the Indirect Land Use Change (iLUC) estimates from the GTAP model.

degree to which each fuel generates credits or deficits, and how transportation fuel providers comply. LCFS 39-2 cont.

PG&E, along with other natural gas and electricity fuel suppliers, provided extensive comments and technical information to ARB Staff during the development of the regulatory package, which is before the Board. While additional changes will be needed prior to re-adoption—like incorporating forthcoming studies on methane emissions—PG&E believes it can continue to work collaboratively with ARB Staff to arrive at carbon intensity values that are based on the best available science and technical information. PG&E looks forward to additional collaboration with ARB Staff on this and other technical issues prior to Board adoption later in 2015. LCFS 39-3

Sincerely,

/s/

Matthew Plummer

39_OP_LCFS_PGE Responses

220. Comment: **LCFS 39-1**

The comment expresses strong support for the LCFS re-adoption because it will reduce GHG emissions and provide certainty for development of alternative fuels.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

221. Comment: **LCFS 39-2**

The comment states that the LCFS proposal changes enhance program integrity and effectiveness and thanks ARB staff for an open and collaborative stakeholder process.

Agency Response: ARB staff concurs with the comment that the proposal enhances program integrity and effectiveness.

222. Comment: **LCFS 39-3**

The comment notes that additional changes may be necessary as new studies and analysis are completed.

Agency Response: ARB staff looks forward to continued collaboration with stakeholders on methane emission studies and other topics. Staff strives to maintain an open public process and will incorporate actionable information made available through that process.

Re: **Public Hearing to Consider a Low Carbon Fuel Standard (LCFS) – Board Agenda Item 15-2-4**

The Western States Petroleum Association (WSPA) appreciates the opportunity to submit written comments for the record on the above proposed rulemaking. WSPA is a non-profit trade association representing twenty-five companies that explore for, produce, refine, transport and market petroleum, petroleum products, natural gas and other energy supplies in California and four other western states.

WSPA members hold the compliance obligation under the LCFS and are responsible for the challenging job of producing the vast majority of the transportation fuels used daily in California. WSPA has been engaged in the rulemaking process to develop and implement the LCFS since 2007. We have continued to make technical comments on updated regulatory packages and changes to the program despite our concerns about the overall feasibility of the LCFS program.

LCFS 40-1

The fundamental problem with the LCFS remains that it is not good public policy and is incorrectly structured in its reliance on the emergence of a significant low carbon fuels market. We do not see anything in the regulatory package to change our assessment that the LCFS program and compliance schedule will remain infeasible when reauthorized.

A government agency such as ARB should not be setting goals that are aspirational and unrealistic, and then following up with band aid measures that make compliance easier while the market waits for low carbon intensity (CI) fuels to be produced at commercial volumes. The fact that a multitude of credit generation options and a cost containment provision are being proposed for inclusion in the program is a signal reflective of the program's fundamental problems.

In our view, the current 1% CI reduction freeze has given all stakeholders and ARB an opportunity to reflect on what has worked, and particularly what has not worked within the LCFS. As ARB has admitted frequently, the development of commercial–scale low CI fuels, such as cellulosic ethanol, has been much slower than originally envisioned. We must take this re-adoption effort as an opportunity to assess the true status of low CI fuel production, infrastructure, vehicle availability, and consumer acceptance (not aspirational projected or nameplate capacity estimates) and make the changes necessary for an effective program. Additional research and development needs to occur before we can transform to a low CI fuel system. LCFS 40-2

At its core we believe the LCFS, as envisioned by Governor Schwarzenegger in his original Executive Order and as currently designed, is infeasible. Although there will continue to be a slow shift in the transportation fuels market, staying the course with the current design of the program could result in disruptions in the transportation fuels market. There needs to be recognition that California consumers depend on and expect a reliable, useable, and scalable fuel source based on the vehicle population and fuels infrastructure in existence now. LCFS 40-3

A successful climate-oriented fuels policy must protect against fuel supply disruptions, severe job losses in the state's refining industry and unacceptable economic harm to California and its citizens. WSPA and its members are committed to engaging with you to find better, achievable ways of reducing carbon emissions from transportation fuels.

<u>WSPA Requests</u>

WSPA requests two main items of ARB relative to the effort to reauthorize the program. We also have a number of more specific recommendations and requests in our detailed comments that follow. In short:

- WSPA requests program reviews that culminate in staff reports to the Board on an annual basis. LCFS 40-4
- WSPA requests no further efforts to create post-2020 LCFS reduction targets until the pre-2020 program is a proven, feasible program. LCFS 40-5

Western States Petroleum Association Comments on CARB's Public Hearing to Consider a LCFS – February 19, 2015

General Comments

1. **Current Program Status and Proposed Compliance Targets**

Since its inception, the LCFS program has aspired to deliver a 10% reduction in California motor fuel carbon intensity by 2020 versus the 2010 baseline year. Over the same period, WSPA questioned the program's viability pointing out that ARB is relying on as-yet to be developed novel technologies to supply the low CI fuels necessary to meet this goal. WSPA also questioned whether the timetable for the emergence of such technologies (primarily cellulosic fuels) would coincide with ARB's projections. To date, ARB staff has maintained that the LCFS program is working as intended, but WSPA remains concerned about the viability of achieving the targets proposed in the LCFS reauthorization proposal, given the current status of low-CI fuel-producing technologies.

Halfway through the 2010-2020 "compliance" decade, the program is delivering approximately 2% CI reduction (versus an annual target of 1% for 2014 and 2015). ARB maintains the primary reason the program CI reduction targets have not been ratcheted up as originally intended is pending litigation (discussed later in our comments). WSPA is concerned that the program still faces considerable challenges, even as ARB proposes to scale back some of the program's targets, e.g., interim year CI reduction targets, while leaving others such as the 10% 2020 target in place, despite mounting evidence that it cannot be met.

LCFS 40-6

ARB's own estimates indicate the LCFS program as proposed in the reauthorization proposal is not sustainable. Approximately 3% of the 10% CI reduction shown for staff's illustrative scenario for 2020 is derived from accumulated credits (from "over-compliance" during previous years) and only 7% is actual, sustainable CI reductions obtained during the year. While ARB staff forecasts a credit bank build up to 9 MMT at the end of 2015 to help satisfy the otherwise un-sustainable reduction targets, in actuality the credit bank stood at just under 4 MMT at the end of the third quarter of 2014 (since program inception) and, given the rate of credit buildup to date, the assumption that banked credits will reach 9MMT over the next 15 months is aspirational. Even if credit generation sees an increase due to more regulatory certainty, as ARB posits it will, there is unlikely to be enough of a generation increase to meet ARB's projections.

Setting aside the issue of ARB's reliance on an unrealistic initial credit bank at the start of 2016 (to meet the 10% 2020 target), WSPA does not agree that staff's projection of a 7% sustainable reduction in 2020 is accurate. WSPA believes ARB's projections for estimating the degree of market penetration of renewable biogas for motor fuel applications and the volumes of renewable diesel that will be incorporated in the CARB diesel pool are too optimistic. Questionable LCFS credit contributions are also forecasted from the Refinery Investment Credit segment of the re-adoption program. The reasons for WSPA's reservations in these areas are outlined further in the detailed section of our comments.

WSPA notes the "redirection" of ARB's reliance on different sector contributions to achieve the program's CI reduction goals, in particular, the absence of a significant contribution expectation from advanced cellulosic biofuels – an expectation that once provided justification for the original program's ambitious goals. While this appropriately reflects the lack of growth in technologies for advanced cellulosic biofuels, the degree to which such low CI fuels are expected to contribute going forward is now but a fraction of the overall program CI reduction needs. Given ARB's tacit acknowledgment that this area has not grown as initially projected, resulting in a substantial decrease in its potential contribution to program CI reduction, WSPA is surprised that ARB has not reduced program targets accordingly.

Instead, ARB has largely held on to the original program targets (at least for 2020) and looked to fill the CI reduction "gap" created by the lack of development in cellulosic fuels through larger-than-justified increases in reliance on renewable biogas and renewable diesel, and the arbitrary decision to allow the generation of LCFS credits from stationary source segments such the "Refinery Investment Credit" and "Innovative Technologies for Crude Oil Production", and the inclusion of "Pre-LCFS electricity sources (e.g. fixed guideways and electric forklifts)". In WSPA's view, this "redirection" coupled with the overstated focus on credit reliance in the 2016-2020 timeframe without an acknowledgement of the magnitude of sustainable CI reductions, fails to accurately project the true challenges of meeting the program's targets. LCFS 40-6 cont.

WSPA is concerned that if unachievable targets are set at the outset, the regulated community will not receive the benefit of the certainty ARB is seeking to provide with the LCFS because the targets will be viewed as placeholders that will ultimately have to be revised. If overly ambitious targets are promulgated, they may have the unintended consequence of prolonging the climate of uncertainty, sustaining deferred action on compliance plans, investments, etc. that are necessary to the success of the program, and potentially undermining the program's goals. In the case of the readopted LCFS, if the credit bank status for 2015 is confirmed to be substantially lower than staff's expectations (roughly within a year's time from re-adoption), the 2020 CI reduction target will be infeasible and the need for revision will be even more urgent since 2020 will be only four years away at that point.

ARB's ISOR documentation lacks detailed data to clearly support the contention that the program is still feasible. A full analysis of the supply of low CI fuels actually available to California and the projected cost; the supply logistics (marine, rail, etc.) available to accommodate these alternative fuels; the infrastructure needed to blend, transport and dispense these fuels; incentives necessary for consumer acceptance; and other regulatory impediments should all be delineated.

Since the original LCFS adoption package, WSPA has worked with the Boston Consulting Group (BCG) to both analyze ARB's assumptions relating to the LCFS compliance curves but also to provide its own projections of what can sustainably be accomplished by certain timeframes. WSPA and BCG have met several times with ARB during the initial work on the re-authorization in 2014 to compare updated analyses relative to the program's feasibility. WSPA continues to urge ARB to reset the 2020 target CI reduction level to a more realistic and sustainable level of approximately 5%, as indicated in the projections of the Boston Consulting Group's most recent study that has been shared with staff. This WSPA recommendation of the 2020 target factors in staff's proposed lowering of the interim year targets and the associated credit bank impacts it will have.

The attached BCG report (Appendix 1) contains their most recent analysis that compares ARB's and BCG's forecasts and investigates the reasons for the differences. Some of the summary conclusions from the BCG report are:

- A 5.1% reduction in the total fuel pool is sustainable by 2020 based on credits available through blending low-CI fuels (e.g. renewable diesel, biodiesel) and purchasing credits (e.g. electric, natural gas).
- Using the same compliance schedule, BCG forecasts banked credits being exhausted earlier than ARB with annual deficits starting in 2018.
- BCG forecasts a 4.4MMT larger deficit in 2020 versus ARB's scenario
- ARB's near term growth is overestimated [ARB's "illustrative" compliance curves show significantly MORE banked credits in 2014 than are actually going to be available based on projections for the year-end report. While ARB has only published the credit numbers through 3Q2014 as 3.9MMT excess credits, it is highly unlikely this will balloon to 5.5MMT excess credits through 4Q2014.]
- Even ARB's forecast shows only a 6MMT credit bank remaining for 2020, so there is no sustainability anticipated beyond 2020.
- ARB's forecasts of volumes of several low CI fuels through the first three-quarters of 2014 remain excessively aggressive
- The program continues to depend heavily on CI reductions in the diesel/distillate pool.

LCFS 40-7

2. **<u>LCFS Program Feasibility – Low CI Fuel Availability</u>**

   - <u>WSPA requests credible assessment of projections of low CI fuel availability using WSPA criteria, fuel cost competitiveness, plus an assessment of infrastructure and vehicle availability to match with the fuels.</u>

Overall, WSPA's greatest concern continues to be the lack of a credible ARB assessment and forecast of the availability and costs of low carbon fuels and credits that ARB has assumed will be available. We note that multiple caveats are included in ARB's analyses indicating the illustrative scenarios are <u>not forecasts or predictions</u>.

LCFS 40-8

In addition, ARB staff must justify why assumptions that the bulk of the nationwide supply will be delivered to and used in California, are reasonable in light of current and proposed competing programs (i.e., RFS2 and LCFS initiatives in the Pacific Northwest states and B.C.). It is also imperative this analysis include the expected added costs for compliance, including those associated with fuel distribution and refueling infrastructure, and specialized vehicles (e.g., battery electric vehicles).

Although no one can say with any degree of certainty what fuel/credit combinations may be used to attempt to comply with the program, there are a number of assumptions ARB staff has used in the past that are not believable based on EIA projections, historical experience with timing and volumes of new fuel/vehicle introductions, and future market economics.

WSPA has requested several times now that ARB provide an updated analysis based on the technical criteria below, so staff can provide the Board with a realistic update. The technical criteria relate to the three interrelated transportation system components: fuel (availability and cost), infrastructure and vehicles:

Fuel Volumes

The volume analysis should include the following items to assess the capability of the low CI fuel production facilities (current and proposed):

1. Design capacity in gallons per day
2. Date of construction completion
3. Date that feedstock first introduced to process
4. Date that on-specification product first produced
5. Highest utilization demonstrated in a consecutive three month period (utilization is defined as production rate divided by design capacity, inclusive of downtime)
6. Percent of product that was produced on-specification without reprocessing or blending during the period in Question #5.
7. Duration in days of longest continuous period of plant operation
8. Utilization during last calendar year (production rate divided by design capacity, inclusive of downtime)
9. Percent of product that was produced on-specification without reprocessing or blending during the period in Question #8. Qualified biofuels have to be able to replace a certain meaningful percentage of the previous year’s demand for the on- ramp to be triggered.
10. Feedstock availability analysis including what percentage of available feedstock the actual production volume requires. Analysis of feedstock

LCFS 40-8
cont.

availability should be done separately for domestic and foreign supply sources.

Footnote: A definition of "success" could, for example, be once answers to questions #5 and #6 exceed 80%. Or, before a facility is deemed to be viable and included in a consideration of low CI fuels facilities to be in ARB's list of "available fuels" would be the answer to question #5 multiplied by the answer to question #1. Note that typical refinery process utilization ranges between 93 and 98 percent, on an annual basis.

Fuel Cost-competitiveness

Not only is the availability of low CI fuels important, but those fuels must also be cost competitive if the LCFS is to be feasible in a real world market. Accordingly, a cost-competitive analysis must be performed. This analysis should assess how much greater the low CI fuels are in average market costs than petroleum products on a per-gallon basis, and the analysis should also evaluate the role or continued need for subsidies in the cost of the fuels.

LCFS 40-8 cont.

Fuel Infrastructure

This analysis should also consider the capability of the distribution system infrastructure (including retail sites) to handle these volumes and types of fuels and what additional infrastructure would be needed, including costs, to support the assessed volumes.

Vehicle Availability

A mandate for further CI reduction should consider whether commercially produced vehicles are available in sufficient quantity to use the low CI fuels. Further, the compatibility of the existing vehicle fleet to use these higher volumes or types of fuels needs to be analyzed. Barriers like consumer acceptance should also be analyzed in an intellectually honest manner with sensitivity runs to bracket an appropriate range of consumer acceptance.

- <u>Low CI Fuel Availability - Three Fuel Examples</u>:

<u>Renewable Diesel</u>

Renewable diesel is one of the more promising available low carbon intensity fuels for LCFS compliance. However, ARB's supply projections are optimistic and overly reliant on announced projects and nameplate capacities. Announcements regarding new production facilities are frequently optimistic in their projected startup dates and facilities rarely reach nameplate capacities in the first months or even years following completion of construction as they face startup issues. Feedstock availability is of particular concern for a product like renewable diesel that will be competing with established food and industrial product markets for the same lipid feedstocks.

LCFS 40-9

The critical barriers to the market penetration of renewable diesel, however, are not production levels but blending infrastructure and regulatory hurdles. ARB has projected that renewable diesel will make up 12% of the California diesel pool by 2020, but we anticipate it will reach roughly half that level. Logistical hurdles on pump labeling (FTC regulations), superimposed on the fungible nature of the common carrier pipeline system will be difficult to overcome in the 2016-2020 timeframe. BCG projects that the vast majority of diesel in the state will contain 5% renewable diesel by 2020, with higher percentages seen in select centrally fueled fleet applications, resulting in an overall pool average slightly above 5% renewable diesel.

ARB has speculated that regulated parties may pursue several options for getting around the 5% blending limit imposed by FTC labeling rules.

- <u>Segregated grades of diesel at terminals</u> – Staff contends that selling two blend levels (0-5% and 6-20% renewable diesel) would enable higher blend levels.

  This option is problematic as terminals face multiple logistical constraints when it comes to any attempts at additional product segregation (e.g. plot space for additional tankage). Even where it could be considered, it is highly unlikely to occur until LCFS implementation establishes RD supply stability and justifies the investment in expansion of diesel grade infrastructure.

- <u>Moving entire pipeline/terminal systems to higher blend levels</u> – Some terminal position holders could move to 6-20% blends, causing the retailer community served by those terminals to label accordingly.

  Voluntarily industry adoption of an RD6-RD-20 specification is equally problematic. The existing fungible pipeline system dictates that industry must move in "lockstep" for any geographic move to higher blends. Such a change would have to be implemented through a common carrier pipeline specification change, which can take a lot longer than expected.

- <u>Large-scale fleet blending</u> – Bypassing the traditional supply system to blend high renewable diesel levels for fleet applications.

  This is a very real possibility. Centrally-fueled fleet blending at higher renewable diesel percentages will likely occur but its impact is small and it has already been comprehended in BCG's estimates.

- <u>Relying on an FTC re-interpretation of the underlying law (2007 EISA)</u> – The FTC may revisit their understanding of Congress' intent and remove the regulatory barriers.

  This is the least likely solution. Several unsuccessful inquiries have already taken place by both fuel providers and renewable diesel producers as expanded blending has been pursued for Renewable Fuel Standard and other blending mandate compliance. The FTC has been unmoved on this point. Congress providing the necessary authority (by reopening EISA) is even more unlikely near term.

LCFS 40-9 cont.

Furthermore, strong opposition should be expected by the biodiesel lobby to any revision attempt.

In view of the above, terminal blending above 5% (on average) before 2020 is highly unlikely and fleet blending will have only a marginal impact on the overall market balance.

LCFS 40-9 cont.

Renewable Biogas

Reliance on large-scale production of renewable natural gas as a supply of LCFS credits is questionable. Investors will weigh high regulatory risk as they consider such projects. Without RFS and LCFS credit subsidies, renewable natural gas for transportation is uneconomic. Cellulosic RINs are estimated to add three times the commodity value of natural gas, the LCFS may add another one to two times the value. While this may seem like a significant motivator for investment, the possibility that these programs may be modified at any time (based on political and/or regulatory reassessment) represents a significant issue for investors as the consider projects whose returns are based solely on the RFS and/or LCFS credit premiums that they generate.

Typical economics (capital investment, absence of need for gas "cleanup", access to gas pipeline, etc.) of biogas utilization drive the application of such gas to power generation and not motor fuel use. We have cautioned ARB that the GHG reduction benefits associated with "re-purposing" biogas from power generation CNG/LNG production are not appropriately accounted for in staff's estimates. ARB's carbon intensity assessment of these products ignores this very real possibility, taking full credit for any renewable CNG/LNG production as though it represents green-field landfill gas production. Should it be found that a significant portion of the landfill gas supply used for CNG/LNG production was redirected from electricity production, much of the compliance value of those biogas products will have been lost.

LCFS 40-10

The current version of CA-GREET2.0 estimates the lifecycle CI of CNG from landfill gas to be 17gCO2e/MJ. If this landfill gas was re-purposed from on-site electricity generation, the amount of electricity displaced from the grid would need to be accounted for as average grid electricity, which has a much higher CI than electricity from landfill gas. CA-GREET2.0 estimates the US-average electricity CI to be 183gCO2e/MJ, while EPA has estimated the CI of electricity from landfill gas to be 11.4gCO2e/MJ. EPA has also estimated that 3.4MJ of landfill gas energy is required to produce 1MJ of electricity*. The increase in the landfill gas CNG/LNG CI from displacing LFG electricity would therefore be:

(1 MJ Elec. / 3.4 MJ LFG) * (183 - 11.4gCO2e/MJ Elec.) = 50gCO2e/MJ LFG

For the example above (Landfill Gas CNG), the CI would increase from 17gCO2e/MJ to 67gCO2e/MJ if re-purposed from on-site electricity generation, or about the same as fossil natural gas.

*Note: *"Support for Classification of Biofuel Produced from Waste Derived Biogas as Cellulosic Biofuel and Summary of Lifecycle Analysis Assumptions and Calculations for Biofuel Produced from Waste Derived Biofuel," U.S. EPA Office of Transportation and Air Quality Memorandum to Docket EPA-HQ-OAR-2012-0401, July 1, 2014.*

Table 6: CI of Electricity from Landfills that Flared Biogas = 12 kg CO2e/mmBTU (= 11.4 gCO2e/MJ)
Table 5: Efficiency of Electricity Generation from Biogas = 11,700 BTU biogas/kWh (= 3.4 MJ biogas/MJ electricity)

Advanced Biofuels

ARB staff continues to strongly assert that the LCFS program (and more particularly LCFS credit prices) will drive advanced biofuels production. WSPA notes that almost all of the advanced biofuel production facilities ARB and others mention are not in California – challenging the notion that the state is really driving the advanced biofuel market and attracting investments. As previously commented by WSPA in our Wood Mackenzie and BCG contractor work in 2012, the LCFS will draw any limited quantities of these fuels that may be available to California via shuffling resulting in sub-optimal costs and often increased emissions.

LCFS 40-11

When calculating/projecting future biofuels supply, ARB should not rely on press announcements as credible evidence of actual facilities/volumes, since many projects are cancelled after initial press announcements but prior to construction, based on engineering studies that are completed and a more definitive cost estimate becoming available. ARB should count facilities that have started construction for potential facility/volume availability in the next 2 – 3 years. If construction has not started, then a discount factor of at least 50% should be used in projecting future capacity. When using past growth rates and projecting them into the future, ARB should take into account the period of two or so years of essentially no growth.

3. Assessment of LCFS Program – Major Milestone Review

Although ARB has conducted two formal Periodic Reviews of the LCFS program since its inception, WSPA believes ARB needs to conduct a Major Milestone review to inform transportation fuel consumers and state policymakers of the program's progress towards meeting its objectives over the first 5 years of its existence. We note that during the 2014 Advisory Panel meetings there was discussion of the need for a thorough review which provided more definitive data. We urge ARB to conduct such a review where the analysis is focused on quantifiable metrics that should include, at a minimum, the following considerations that are different in scope from the normal Periodic Reviews:

• Actual GHG reductions achieved through the program (in-state and out-of-state reductions quantified separately), and the avenues/means used to drive those reductions.

LCFS 40-12

• GHG reduction achieved solely by the LCFS, exclusive of other programs, (such as the federal RFS2 and CAFÉ standards, or the California ZEV mandate.) To objectively assess LCFS program progress, GHG reduction benefits should be viewed on an incremental basis, i.e. above and beyond what is delivered from these other programs.

• Costs associated with the LCFS program. These should include any subsidies or program expenditures (i.e., total cost for the California taxpayer), and any additional fuel costs.

• Cost-effectiveness of the LCFS program. The analyses should compare the cost-effectiveness of the incremental GHG reduction delivered by the LCFS program (in terms of dollars per ton CO2 reduction) to those of other GHG reduction programs such as the California Cap and Trade Program or and vehicular efficiency programs (CAFÉ).

• Prospects for future successes in terms of GHG reduction which may be attributed to the LCFS program [in the absence of other related regulatory policies], and a reasonable assessment as to their probability of success.

• Assessment of incremental incentives for innovation and in-state employment paid for by state or local dollars. We believe the California public should be apprised as to what their taxes have supported, their incremental fuel and vehicle costs, and be allowed to judge the effectiveness of the LCFS program versus other transportation-related GHG reduction approaches in a transparent, objective manner.

LCFS 40-12 cont.

Economic Impact Analysis Update

To add to the above note on a Major Milestone review, there appears to be a false sense of the degree of updates staff has provided – especially for the economic analysis. There has been minimal effort to update the 2009 economic impact analysis, and during the various 2014 Workshops staff indicated there would not be a comprehensive update to the five year old economic impact analysis.

During the 2011 program updates ARB stated that much of the 2009 analysis remains valid, but acknowledged the need for an entirely new analysis. It was also stated that staff was considering using a contractor to conduct a more comprehensive economic analysis of the LCFS. We were told such an analysis would not be completed until sometime in 2012 or early 2013, but this seems to not have materialized.

LCFS 40-13

4. Cost Containment Mechanism – Credit Clearance

WSPA is concerned that the cost containment mechanism proposed will also act as either a price floor or have the unintended effect of raising LCFS credit prices. Because LCFS credits do not expire, the proposed cost containment mechanism will provide an incentive for those parties that have excess credits to hold on to their credits if they believe that a Clearance Market will occur in the future or to hold out for an offer that is near the Clearance Market price. This negative impact of the cost containment mechanism could be partially mitigated if participation in the Clearance Market was voluntary and if staff re-inserts the deficit carry over provision that was in the previous LCFS reglulations (which WSPA is also suggesting).

In June 2014 WSPA commissioned a paper by Analysis Group, Inc. to review the cost containment mechanisms being proposed by ARB at that point in time.

The Analysis Group pointed out that there "*is a meaningful risk that LCFS compliance costs will increase significantly at some point in the near- to medium-term due to the*

LCFS 40-14

confluence of an increasingly stringent standard, and diminishing opportunities for low-CI fuel substitutions. By virtue of the rate at which the LCFS standard declines, the nature of the transportation systems regulated, and the LCFS design, there is a meaningful risk in the near- to medium-term that compliance with the LCFS could become increasingly difficult. Due to these factors, the cost of actions to generate LCFS credits could rise significantly. Despite the current large bank of surplus credits, the risk of either cumulative deficits or significantly elevated credit costs is high, although the timing and severity of these outcomes is uncertain."

ARB recognized the need for some mechanism to accommodate short-term market disruptions and prevent excessive LCFS cost of compliance during such periods from ultimately impacting fuel prices. WSPA's advice in that regard has been that the setting of realistic goals coupled with frequent program reviews to ensure ample credit availability in a liquid LCFS credit market would obviate the need for a cost containment mechanism such as the Credit Clearance Market that ARB is proposing as part of the re-adoption package.

WSPA agrees with the Analysis Group's finding that, "*While regulated parties are building up a cumulative credit surplus in the early program years, there is a definite risk that these credit surpluses will become exhausted as the standard becomes more stringent, which could lead to very high costs and/or a cumulative credit deficit, which would increase the risk that regulated parties could not achieve compliance. Current ARB proposals that might add limited credits to the market (e.g., Innovative Technologies for Crude Oil Production) would only shift out the date at which these barriers are hit. While there is much technological uncertainty about the timing and severity of these constraints, there is a clear risk that compliance with the LCFS could become increasingly costly and challenging to comply with. Thus, there is justified concern about cost containment*."

LCFS 40-14 cont.

ARB staff maintains that sufficient low CI fuels and credits will be available and, thus, the cost containment mechanism will be seldom (if ever) needed. Staff's vision is that, when it is necessary, it will be in response to some short-lived market "blip" or disturbance that will quickly give way to reestablishment of equilibrium. Staff acknowledges that this tool is not designed to accommodate systemic and prolonged LCFS credit shortages. Staff considers the ability to carry deficits forward (albeit with interest) for up to five years an "insurance policy" and sees no particular negative aspects to the end-of-year credit clearance auction they are proposing (where regulated parties can buy their pro-rata share of pledged credits at a price as high as $200/ton).

WSPA is opposed to the inclusion of such a cost containment mechanism in the LCFS because we believe that it will not accomplish its stated objective (contain costs) and will instead have a number of undesirable (and unintended) consequences. More specifically, the Credit Clearance Market (CCM):

<u>Does not stipulate a mechanism for retiring deficits, if multi-year market shortages persist</u>.
Obligated parties that participate in the year-end auction of credits pledged by suppliers at costs as high as the pre-determined "cap" Maximum Price, have no recourse but to

LCFS 40-15

carry over any remaining deficit into the following year with interest. There is no way to retire deficits if shortages persist year to year. Instead, obligated parties face the prospect of an ever-increasing accrued financial liability that is essentially outside their control. In a market that is consistently short credits year after year, the ability to defer unsatisfied obligation (with interest) offers little comfort to the regulated community staring down the specter of ever-increasing deficits and no method to retire part of the obligation generated by an infeasible standard.

LCFS 40-15 cont.

<u>May drive credit costs up (if credits are withheld from the regular market to get a higher CCM cost)</u>.
During periods of rising costs (i.e., credit shortages in the open market), the CCM will not keep credit costs in check. In fact, the CCM to clear the market at the end of the year is meaningless during a credit-short environment as there will not be any remaining credits to be brought to the table by sellers. The compounding of "interest" on the carryover/deferred balances will ensure credit buyers soak up the available pool of real LCFS credits in the market during the year rather than wait for the CCM. The pool of real LCFS credits available is fixed – it is only their cost that remains in question. Staff's setting of the Maximum Price at $200/ton will serve as the benchmark for credit costs in that environment.

During periods of stable or declining costs (i.e., credit surplus in the open market), the CCM cap Maximum Price creates an artificial "floor" value below which sellers will be hesitant to offer real LCFS credits for sale to the regulated community at substantially lower costs. This would artificially increase compliance costs – as credit costs will be artificially raised to (or near) the ARB cap and very few transactions will take place before the end-of-year sale. Credit trading would be seriously impaired as the open market would not be allowed to function as it should.

LCFS 40-16

<u>Provides no liability protection against invalid credits secured through the CCM.</u>
We reference the issue of lack of an acceptable liability defense provision or protocol in the LCFS to protect obligated parties from potentially fraudulent credit sellers elsewhere in our comments. For the purposes of discussing this topic within the CCM provisions, we emphasize that the only protection we have as buyers of credits is to perform our due diligence and carefully screen the parties we choose to engage as partners in LCFS credit-buying transactions. It appears to WSPA that we will not be afforded this ability with respect to the credits we are obligated to purchase (our pro-rata share) through the CCM. Moreover, the timetable set by ARB to organize and complete the CCM raises concerns that the agency will be undertaking minimal, if any, screening of the credits that are pledged by sellers for the CCM. WSPA objects to the fact that regulated entities may potentially wind up in a position of non-compliance through no fault of their own simply because there is a credit shortage and they are required to participate in a CCM that provides them no control over what credits they buy and from whom.

LCFS 40-17

Offers no connection between CCM outcome, program off-ramps, future CI reduction targets

It stands to reason that LCFS credit market liquidity (measurable potentially through a number of different indicators) is not only essential to the program's success but, also, that the absence of such liquidity should be viewed as a clear signal that the program's CI reduction targets are overly ambitious and that the regulated community is finding it difficult to meet its obligations and remain in compliance. There is no connection or tie-in in the current CCM proposal to initiate a comprehensive program review should the alarming trend of potential credit shortages materialize and become evident through the CCM. LCFS 40-18

Is incomplete in its definition of the mechanics (recordkeeping, reporting, etc.) of deficit carryover

Even if all of the above issues were resolved, the CCM proposal in the ISOR and draft regulatory language is sorely lacking in the execution/implementation details that would allow the regulated community to understand exactly how it would work. For example: What is the "order" of applying generated credits (through blending or purchases) to the various potential uses for a regulated party o on any given year (e.g., meet the current year's obligation, retire previous years' obligations)?

LCFS 40-19

Finally, the proposal to make public the long and short credit positions of regulated parties flies in the face of the principle of confidential business information. A regulated party's competitive position could be seriously compromised by the publication of this information. In addition, this information would give competitors both an understanding of a regulated party's compliance strategy and a view into the regulated party's fuel and credit acquisition activity for the year. Using this information and average market pricing, one could estimate the financial impact of LCFS compliance on a regulated party.

Alternative to the CCM

In lieu of the CCM, a dual approach of setting reasonable, practically achievable CI reduction targets and holding frequent (annual) program reviews to ensure that the program remains on track and the LCFS credit market is healthy should prevent the type of cost excursions that CCM is meant to accommodate. More specifically, staff could eliminate the proposed CCM and:

- Provide for annual mandatory program reviews with the first one due by 1/1/2017. The initial review should include LCFS credit history including actual credit generation, obligation, and a comparison of actual current credit bank versus staff's projections in the ISOR. As part of the review, staff should include a projection of where the credit bank is expected to be in the future. If overall credit generation is above or below staff's projections (plus/minus a modest estimate allowance/tolerance), CI reduction targets should be adjusted up or down to re-establish an aggressive yet achievable program. LCFS 40-20

- Establish triggers that would require early program reviews prior to the planned annual staff report. Specific, measurable thresholds and triggers should be

established as part of this process. Some examples of such triggers for an early review of subsequent year CI targets include:
  - Monthly credit cost exceeds $150
  - Industry credit bank falls below 5 million metric tons (MMT)
  - CA fuel price > "x"cpg above national average

- Incorporate a simple carryover rule for one-off company imbalances. The provisions of this segment could be tailored along the lines established for RINs by EPA in the RFS program, with potential additional enhancements. Key features could include:
  - A regulated party may carry over a deficit balance for one year, without penalty
  - Credits must be retired in the following year to completely settle the deficit balance
  - A deficit balance cannot be carried over two years in a row

LCFS 40-20 cont.

This simple-to-execute approach would satisfy staff's stated goal of addressing short-term tightness in the credit market, while avoiding the market-manipulating aspects of the proposed CCM. Neither this solution nor the CCM can address the very real possibility of a long-term credit shortage. This must be met with the program reviews and schedule adjustments recommended above.

If staff insists on moving forward with a CCM, WSPA recommends that, at a minimum, the following changes should be made:

- Participation in the CCM should be voluntary. In order for ARB to determine whether or not to hold a CCM for a particular year, ARB could issue a "Call For Deficits" similar to the "Call For Credits" already incorporated in staff's proposal.

- Regulated parties that have pledged credits to sell into the Clearance Market, and have not sold or contractually agreed to sell all their pledged credits, cannot reject an offer to purchase pledged credits at the Maximum Price.

- The LCFS credit balance and the individual entity names should be treated as highly confidential because the release of this information could adversely impact business operations. The release of the LCFS credit balance would provide competitors and other LCFS credit market participants with short or long position knowledge.

- The Deficit Carryover provisions should be reinstated. WSPA objects to the removal of the Deficit Carryover provisions in the proposed regulations and request that the current provisions be retained as there may be planning or operational reasons why a regulated party may wish to carry deficits from one year to the next.

LCFS 40-21

On many occasions, WSPA has raised concerns about the interactions between the LCFS and the GHG cap-and-trade program.[1] In general, "quantity-based" programs such as the

LCFS 40-22

LCFS (which relies on averaging across entities to meet a standard) that overlap with a cap-and-trade program do not generate additional emission reductions but do potentially raise costs. Because the LCFS affects sources both under and outside of the GHG cap-and-trade system, these interactions are somewhat more complex. However, this does not affect the conclusion that these interactions create significant concerns for the environmental and economic efficacy of the LCFS.

ARB's cost containment proposal in no way affects these conclusions. The cost containment proposals may mitigate the extent to which the LCFS raises the costs of meeting the AB 32 targets compared to a policy that relies solely on the GHG cap-and-trade program, but does not affect the conclusion that the LCFS raises overall costs.

LCFS 40-22 cont.

WSPA provides additional detailed comments later in this document regarding specific concerns about the cost containment provision as proposed by ARB.

[1.] *see* Schatzki, Todd and Robert Stavins, "Implications of Interactions for California's Climate Policy," Regulatory Policy Program, Mossavar-Rahmani Center for Business and Government, Harvard Kennedy School, August 27, 2012.

Legal Comments:

1. ***ARB has failed to comply with statutory requirements with respect to enacting a fuel specification, including inadequately analyzing fuels impacts through multimedia analysis.***

WSPA strongly disagrees with ARB's characterization of the LCFS as a fuel "standard" rather than a fuel "specification." ARB argues that because the LCFS governs the production process for fuels, rather than imposing "an ARB mandate on a vehicular fuel's particular composition," the LCFS is not a fuel "specification" subject to the Health & Safety Code's requirements for fuel control measures. Initial Statement of Reasons for Proposed Rulemaking, Proposed Re-Adoption of the Low Carbon Fuel Standard ("ISOR"), at III-58 – III-63. ARB argues that a fuel "specification" would be more like a recipe, with quantifiable measurements of components that would make up the fuel; because carbon intensity measurements rely more on how a fuel is made than what is in it, ARB says the LCFS is not a "specification." *See* ISOR at III-61.

LCFS 40-23

But contrary to ARB's assertion, carbon intensity is a criterion or "specification" to which motor vehicle fuels must comply. The Health & Safety Code nowhere requires that a "specification" relate only to the quantity of fuel components. Indeed, the Code recognizes a fuel specification for light-duty vehicle exhaust emission standards—standards that, like the LCFS, are based on overall emissions from fuels as opposed to quantification of their particular components. Cal. Health & Safety Code § 43018(d)(1).

Furthermore, the LCFS will change specifications of California reformulated gasoline and diesel and may require fuel additives to be added to or removed from fuels and new fuels to be used statewide. ARB Draft LCFS Regulation, § 95422

("[T]he transportation gasoline and diesel fuel for which a regulated party is responsible in each calendar year must meet the average carbon intensity standards set forth in this section . . . "). ARB is not permitted to avoid the statutory requirements associated with fuel control measures by simply labeling the LCFS a "standard" as opposed to a "specification."

Furthermore, the Ninth Circuit has already considered the LCFS to be a fuel control measure. *See Rocky Mountain Farmers Union v. Corey*, 730 F.3d 1070 (9th Cir. 2013) (recognizing that the LCFS is "a control respecting a fuel or fuel additive and was enacted for the purpose of emissions control"). In fact, ARB itself has argued that it should have the authority to enact the LCFS precisely because the LCFS is a control on motor vehicle fuels. *See* Defendants' Memorandum in Support of Cross-Motion for Summary Judgment, *Rocky Mountain Farmers Union v. Goldstene*, Case No. 09-CV-02234 (C.D. Cal. Dec. 17, 2010) at 2, 11-18. In its *Rocky Mountain Farmers Union* papers, ARB admitted that "[t]he LCFS controls the carbon intensity of fuels offered for sale in California. It does so by applying a lifecycle analysis." *Id*. at 15. ARB even pointed out that as fuel sources diversify, "differentiating among them on the basis of lifecycle carbon intensity becomes even more critical"— in other words, carbon intensity <u>is</u> a specification of fuels that is controlled by the LCFS with the goal of reducing emissions.

ARB cannot now change its tune in an effort to escape the statutory requirements applicable to fuel control measures. Under the California Health & Safety Code, ARB must assess not only the cost-effectiveness of such controls, but also the technological feasibility of the controls, including, but not limited to, the availability, effectiveness, reliability, and safety of the proposed technology. Cal. Health & Safety Code § 43013(e). ARB's documentation does not adequately assess any of these factors. In addition, as discussed in greater detail below, ARB has failed to undertake the requisite multimedia analysis for the LCFS, also mandated by the Health & Safety Code.

LCFS 40-23 cont.

<u>*Multimedia Analysis Under Health & Safety Code § 43830.8*</u>
One key requirement ARB has attempted to avoid by its improper characterization of the LCFS, is conducting multimedia analyses for fuels that will likely be used to comply with the LCFS, as required under the Health & Safety Code.

Under section 43830.8 of the Health & Safety Code, ARB may not adopt "any regulation that establishes a specification for motor vehicle fuel" unless the regulation, and a multimedia evaluation for the regulation, are reviewed by the California Environmental Policy Council ("Council"). Cal. Health & Safety Code § 43830.8(a). A multimedia evaluation requires ARB to identify and evaluate "any significant adverse impact on public health or the environment, including air, water, or soil, that may result from the production, use, or disposal of the motor vehicle fuel that may be used to meet the state board's motor vehicle fuel specifications." Cal. Health & Safety Code § 43830.8(b).

ARB staff promises they will perform a multimedia analysis later—either if and/or when ARB adopts a new fuel specification (such as the current specification for biodiesel) or if and/or when it amends an existing fuel specification (such as natural gas or E85). ISOR at III-64. Such an approach fails to address upfront any adverse environmental impacts that may be associated with producing fuels that can meet the carbon intensity requirements of the LCFS. Multimedia evaluations are necessary in order to obtain a full and independent assessment of the range of potential environmental impacts of any newly proposed fuel regulations across all media. This assessment should be completed as soon as feasible, not at later dates if and/or when ARB chooses to prepare it.

LCFS 40-23 cont.

In addition, delaying such an evaluation until a later time could hinder the development of the full range of LCFS-compliant fuels due to concerns about allocating any significant resources to the commercialization of a fuel that could ultimately fail a multimedia evaluation.

Nearly six years have passed since ARB stated, during the first LCFS rulemaking, that there was not enough information to conduct a multimedia evaluation for fuels designed to comply with the LCFS. ARB and fuel producers have much better information now regarding the types and blends of fuels that will likely be used under the LCFS. In fact, ARB completed a multimedia analysis for biodiesel in conjunction with the Alternative Diesel Fuel (ADF) rulemaking. ARB should now complete multimedia analyses for all fuels that will likely be used to comply with the LCFS in order to comply with its statutory duty under the Health & Safety Code.

2. ***Combining the ADF and LCFS processes into one CEQA "project" is not procedurally appropriate, and results in an insufficient environmental analysis.***

ARB should analyze the LCFS and the ADF as two separate projects. At the very least, ARB must acknowledge the possibility that the two regulations will not pass concurrently, and should rework the Draft EA to clarify the impacts from each of the regulations, and the specific mitigation measures applicable to each.

LCFS 40-24

The Draft EA published by ARB is the environmental document for both the LCFS and the ADF regulations. While these two rulemakings are being run concurrently, parallel to one another, they are also being run as two separate processes. Because the two regulations are subject to two separate rulemakings, there is the possibility that one regulation could pass but the other could not, or that one regulation could be challenged and its implementation delayed while the other continues to move forward.

ARB has cited CEQA Guidelines § 15378(a) in support of its approach to combine environmental review of the two regulations into one CEQA "project." However, section 15378(a) of the Guidelines simply states that a "project" is "the whole of an action, which has a potential for resulting in either a direct physical change in the environment, or a reasonably foreseeable indirect physical change in the environment…" While section 15378(c) of the Guidelines clarifies that a "project" can include an activity that requires more than one discretionary approval by one or multiple government agencies, the Guidelines nowhere provide for a "project" that encompasses two separate activities that happen to be related to one another, but are not interdependent. *See* CEQA Guidelines § 15378(c). LCFS 40-25

Interdependence, an element lacking here, is key to including separate actions under the umbrella of one CEQA "project" for purposes of environmental review. *Tuolumne County Citizens for Responsible Growth, Inc. v. City of Sonora* (2007) 155 Cal.App.4th 1214, 1230-1231 [finding a road realignment and construction of a shopping center were part of the same "project" because the shopping center's opening was legally dependent upon the road's realignment]. The LCFS and ADF regulations certainly pertain to related subject matter, but they are not legally dependent upon one another—the LCFS can (and has, in the past) exist without the ADF, and vice versa.

Both statute and regulation recognize the need to analyze separate "projects" in circumstances similar to these. For example, while a real estate developer may request a rezoning of property, as well as a tentative subdivision map, for purposes of effectuating development, those two related but separate actions are recognized as distinct "projects." *See El Dorado Union High School Dist. v. City of Placerville* (1983) 144 Cal.App.3d 123, 129-130; CEQA Guidelines § 15037. Just as with the two related but distinct rulemakings here, each of these two legal actions, which may very well impact the same development, nonetheless may occur without the other and in completely separate processes, and may produce significantly different impacts. LCFS 40-26

Simply put, CEQA does not allow ARB to take two different activities which each have different impacts and require different analyses and pass them off as one "project" to streamline its environmental review process. The process that ARB has adopted here makes it impossible to separate out which impacts stem from the LCFS regulations and which from the ADF regulations, <u>even though the two rules are being considered in separate rulemakings, have distinct impacts as a practical matter, and may not both be adopted, or may be adopted on different schedules</u>. LCFS 40-27

CEQA requires that environmental review documents be "written in a manner that will be meaningful and useful to decision-makers and to the public." Cal. Pub. Res. Code § 21003(b); *see Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 392. When neither decision- LCFS 40-28 LCFS 40-29 makers nor the public can meaningfully understand the impacts that will arise from each proposal and available mitigation, the usefulness of the Draft EA as a valuable decision-making tool for is significantly undermined, contravening the intent of CEQA. LCFS 40-29 cont.

3. ***The Draft EA does not sufficiently analyze alternatives.***

Under CEQA, an environmental review document "must consider a reasonable range of alternatives to the project" and must "make an in-depth discussion of those alternatives identified as at least potentially feasible." LCFS 40-30 *See Preservation Action Council v. City of San Jose* (2006) 141 Cal.App.4th 1336, 1350; *Sierra Club v. County of Napa* (2004) 121 Cal.App.4th 1490. The purpose of such an analysis is to allow informed decision-making, and the onus for analyzing a sufficient range of alternatives falls squarely on the agency. *Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 405. LCFS 40-31

But ARB's Draft EA falls far short of this requirement. The Draft EA only analyzes a "no project" alternative—LCFS regulations being set aside as a result of the *POET* decision and no adoption of the ADF; a second alternative—re-adopting the existing LCFS without any of the proposed updates and adopting the ADF regulation as proposed; and finally, a "Gasoline-Only Compliance Curve" alternative—an alternative that would remove the diesel standard from the LCFS so that the compliance curves apply only to gasoline and gasoline substitute fuels. LCFS 40-32 Despite the Draft EA's statement that it presents a fourth action alternative—the "No Trading Case Alternative" –ARB never includes a description of that alternative in the Draft EA. Draft EA at 130. LCFS 40-33

Additionally, ARB's description of the alternatives is somewhat misleading. The alternatives that ARB discusses are more accurately described as: (1) no LCFS and no ADF; (2) re-adoption of the existing LCFS and adoption of the proposed ADF as-is; and (3) the "Gasoline-Only Compliance Curve Alternative," which, like the first alternative, would not adopt the proposed ADF, or any rule on diesel fuels. There is no analysis of an alternative that would involve re-adoption of the proposed LCFS with a different ADF regulation, or of a different approach to the LCFS beyond simply dropping diesel fuels from the regulation. In contravention of CEQA, this analysis overlooks potentially less impactful options. *See Citizens of Goleta Valley v. Board of Supervisors* (1990) 53 Cal.3d 553, 566. LCFS 40-34

The mere three alternatives presented by the Draft EA insufficiently represent the broad scope of alternatives, and fail to take into account clearly feasible scenarios—such as an ADF regulation that is substantively different from the one proposed by ARB. In fact, the Draft EA analyzes no alternatives beyond a "no project" alternative for ADF: either the ADF is not adopted at all, or it is adopted exactly as is. ARB cannot limit the alternatives analysis on the ADF without explaining "in meaningful detail" the basis for its conclusion that there are no LCFS 40-35 feasible alternatives to the ADF as proposed. *Laurel Heights Improvement Assn.*, 47 Cal.3d at 405. LCFS 40-35 cont.

CEQA requires that the Draft EA explore more alternatives than the three presented here. ARB has provided an insufficient alternatives analysis in connection with these rulemakings, and therefore the Draft EA should be revised accordingly. LCFS 40-36

4. ***The Draft EA does not sufficiently analyze air quality impacts.***

CEQA requires that reasonably foreseeable impacts of a project must be adequately analyzed and, if necessary, mitigated by the agency. Cal. Pub. Res. Code § 21003(b); *see Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 392; *Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* (2007) 40 Cal.4th 412, 431 . But ARB has not adequately analyzed the potential impacts of the interplay between NOx and VOC emissions stemming from the implementation of the LCFS and ADF.

The Draft EA does not attempt to assess the impacts of the LCFS and ADF regulations on ambient ozone and PM concentrations. Instead, ARB staff simply analyzed the impacts of the LCFS in combination with the ADF on the emissions inventory. Table 4-1 of the Draft EA summarizes ARB staff estimates of the NOx emissions impacts of the LCFS and ADF regulations. That table reports a net reduction in NOx emissions of 1.0 tons per day in 2020, growing to 1.3 tons per day in 2023. The Draft EA then asserts that the "long-term impacts on air quality would be **beneficial**." (emphasis in original text) LCFS 40-37

Ozone formation chemistry is highly non-linear and so to assess whether the proposed NOx reduction would bring about discernible reductions in ambient ozone, photochemical modeling is necessary. Because the draft EA does not include the impact of LCFS and ADF on VOC emissions, it is impossible to even qualify the net ozone response due to the regulation.

Air quality impacts of the LCFS are addressed in a recent report prepared by ENVIRON International Corporation for the Coordinating Research Council.[1] Among the findings of that report were:

- The LCFS rule constitutes a potential regional control strategy that has not been specifically studied.
- Reductions in precursor emissions (i.e., NOx, VOC reductions) do not always provide air quality benefits, because ozone chemistry is highly non-linear.

[1] "Low Carbon Fuel Standard Program Air Emissions Effects," Prepared by ENVIRON International Corporation, CRC Project No. A-86, September 24, 2014. http://www.crcao.com/reports/recentstudies2014/A-86%20Low%20Carbon%20Fuel%20Standard%20Program%20Air%20Emissions%20Effects/CRC%20A86%20Final%20Report_%20Sep30_2014.pdf

- In the 2009 rulemaking ARB asserted that due to the relatively small magnitude of emission reductions associated with LCFS it was not practical to expect the air quality model to reasonably predict the cumulative potential benefit on ozone air quality. However, such modeling may be warranted. LCFS 40-37 cont.

5. ***Formulas have changed without the appropriate level of transparency.***

Key elements of the regulation depend on data that are used in calculations that compute indirect land use change and carbon intensity values relevant to the regulation's overall compliance scheme. Changes in the type of data used to compute these values can therefore have a significant effect on the thresholds regulated entities need to meet to come into compliance.

ARB has removed indirect land use change values from the look-up tables that were included in the prior version of the regulation, and now simply describes a credit calculation which requires the incorporation of a land use modifier. The values for such a modifier are not included in the regulation.

Additionally, the carbon intensity calculation process relies on CA-GREET. However, ARB has failed to provide a transparent process to outline bases for changes to the GREET model or allow input for future changes to the model is lacking. ARB acknowledges GREET is used "to provide many emission factors, life cycle inventory data, and fuel cycle emissions values." ARB, LCFS Reauthorization Initial Statement of Reasons, p. II-20. In fact, ARB admits that changes to the GREET model were the impetus for OPGEE revisions—but the GREET changes themselves lacked transparency; even ARB's comparison of the updated model to prior models offers conclusory statements of changes rather than explanations for them. *See, e.g.,* ARB, Comparison of CA-GREET 1.8B, GREET1 2013, and CA-GREET 2.0, pp. C-2-C-3, C-8-C-9. Nothing in the regulations suggests future changes to GREET will be more transparent. LCFS 40-38

Similarly, the sources for data to be used in calculating the Annual Crude Average carbon intensity value have changed, and that data is now to be provided by two different state agencies, with no apparent opportunity for verification or explanation of the data's bases.

Each of these actions opens the door to changes to key formulas outside of the rulemaking process and without opportunity for public comment. When regulations are amended, the California Administrative Procedure Act requires "basic minimum procedural requirements" for rulemaking, including giving interested parties an opportunity to comment on the rulemaking, and a response to public comments. *See Tidewater Marine Western, Inc. v. Bradshaw* (1996) 14 Cal.4th 557, 558; Cal. Gov. Code § 11346. But the proposed regulations attempt to avoid public discourse on potentially significant changes to the implementation of the LCFS by tying key values that are the rule's backbone to calculations and data that could change at any time, with no explanation—essentially a *de facto* amendment of the regulation with no public process.

ARB must explain the bases for relying on the data sources it has chosen, and must provide more certainty that key values and calculations will not change without public input.

LCFS 40-38 cont.

6. ***ARB does not have the authority to compel regulated parties to purchase credits without the capability of verifying those credits.***

The regulations penalize credit holders if they hold invalid credits, even if that is through no fault of their own. Because credits must be verifiable, ARB lacks power to require entities to participate in the credit scheme without providing some level of certainty that credits validly represent the reductions they purport to represent. *See* Cal. Health & Safety Code § 38562(d)(1) ["Any regulation adopted by the state board pursuant to this part or Part 5 [market-based compliance mechanisms] shall ensure all of the following: (1) The greenhouse gas emission reductions achieved are real, permanent, quantifiable, ***verifiable***, and enforceable by the state board …"] [emphasis added].

The statute and regulations do not address independent verification by purchasers of credits, and we have not located any comparable program with such provisions. However, even if buyers were provided the opportunity to verify credits prior to purchase, ARB's authority to suspend, revoke or modify credits under proposed section 95495 would not be limited and, as a result, there is still a risk credits could be invalidated by ARB.

LCFS 40-39

Such a scenario is not without precedent. In 2012, EPA invalidated over 60 million Renewable Identification Numbers (RINs), the tradable credits that are generated as part of the federal Renewable Fuels Standard program, due to criminal fraud perpetrated by certain RIN generators. Because the RFS was set up as a strict buyer liability system, unknowing, good faith obligated parties were left with worthless invalidated RINs and faced enforcement penalties from EPA. ARB should avoid the risk of creating a similar situation under the LCFS regulations.

However, the risk of invalidation could be reduced by limiting the bases for invalidation under proposed section 95495(b)(1) and adding a statute of limitations on ARB's right to commence invalidation procedures.

WSPA therefore requests the following changes be made to the regulations (bold, underlined type):

Section 95495(a)

<u>(1)</u> If the Executive Officer determines that any basis for invalidation set forth in subsection (b)(1) below occurred, in addition to taking any enforcement action, he or she may: suspend, restrict, modify, or revoke an LRT-CBTS account; modify or delete an Approved CI; restrict, suspend, or invalidate credits; or recalculate the deficits in a regulated party's LRT-CBTS account. For purposes of this section, "Approved CI" includes any determination relating to carbon intensity made pursuant to section 95488, or relating to a credit-generating activity approved under section 95489.

<u>**(2) The Executive Officer shall commence enforcement actions under subsections (b)(1)(A)-(F) as follows:**</u>

<u>**(A) The Executive Officer shall commence an action under subsections (b)(1)(A), (C), or (D) within one (1) year from either the date that the subject Approved CI or credit was generated in accordance with section 95486 or the date upon which disputed data was reported in accordance with section 95488, as applicable.**</u>

<u>**(B) The Executive Officer shall commence an action under subsection (b)(1)(B) arising from incorrect material information submitted in connection with an Approved CI or credit transaction within one (1) year from either the date of approval of the CI or the recordation date, as defined by section 95487, of the first transaction wherein incorrect material information was submitted, as applicable.**</u>

LCFS 40-39 cont.

<u>**(C) The Executive Officer shall commence an action arising from a transaction made in violation of applicable laws, statutes and regulations under subsection (b)(1)(E) within one (1) year from the recordation date, as defined by section 95487, of the disputed transaction or from the date the credit was generated in accordance with section 95486, as applicable.**</u>

<u>**(D) The Executive Officer shall commence an action under subsection (b)(1)(F) within six (6) months from the date that a party refused to provide records or failed to produce records within the required time.**</u>

Section 95495(b)(1)

Determination that a Credit, Deficit Calculation, or Approved CI is Invalid.
(1) *Basis for Invalidating.* The Executive Officer may modify or delete an Approved CI and invalidate credits or recalculate deficits based on any of the following:
(A) any of the information used to generate or support the Approved CI was incorrect **for reasons including** <u>**due to**</u> the omission of material information **or changes to the process following submission**;
(B) any material information submitted in connection with any Approved CI or credit transaction was incorrect;

(C) fuel reported under a given pathway was produced or transported in a manner that varies in any way from the methods set forth in any corresponding pathway application documents submitted pursuant to section 95488 (or former section 95486, effective January 1, 2010);
(D) fuel transaction or other data reported into LRT-CBTS and used in calculating credits and deficits was incorrect or omitted material information;
(E) credits or deficits were generated or transferred in violation of any provision of this subarticle or in violation of other laws, statutes or regulations **directly applicable to the credit generation or transfer**; and
(F) a party obligated to provide records under this subarticle refused to provide such records or failed to produce them within the required time.
For purposes of this subsection, "material" means information directly relevant to the generation and calculation of credits under section 95486 or the requirements for credit transactions under section 95487, as applicable.

LCFS 40-39 cont.

7. ***Enforcement provisions with respect to credits and carbon intensities are deficient.***

If invalidation of a credit or CI creates a deficit, the generator and/or holder of the credit will have 60 days to correct the compliance issue by purchasing new credits. *See* proposed section 95495(b)(4) ("If [the Executive Officer's] final determination invalidates credits or deficit calculations, the corresponding credits and deficits will be added to or subtracted from the appropriate LRT-CBTS accounts. Where such action creates a deficit in a past compliance period, the deficit holder has 60 days from the date of the final determination to purchase sufficient credits to eliminate the entire deficit. A return to compliance does not preclude further enforcement actions.").

The proposed regulations do not include an appeals mechanism for challenging the Executive Officer's final determination as to invalidated credits. Although appeals may be brought in Superior Court pursuant to Civil Procedure Code section 1085, it would be preferable for ARB to create a hearing and appeals procedure within its regulations. The 60-day period for correcting deficits should not commence until appeals are exhausted.

LCFS 40-40

WSPA therefore requests the following additions to the regulations (bold, underlined type):

Section 95495(b)(2)

Notice ***and Opportunity for Hearing***. Upon making an initial determination that a credit, deficit calculation, or Approved CI may be subject to modification, deletion, recalculation, or invalidation under subsection (b)(1), above, the Executive Officer will notify all potentially affected parties, including those who hold or generate credits or deficits based on an Approved CI that may be invalid, and may notify any linked program. The notice shall state the reason for the initial determination **<u>and the party's right to request a hearing</u>**, and may be distributed using the LRT-CBTS. Any party receiving such notice may submit, within 20 days, any information that it wants to the Executive Officer to consider **<u>and, if desired, its request for a hearing.</u>** The Executive Officer may request information or documentation from any party likely to have information or records relevant to the validity of a credit, deficit calculation, or Approved CI. Within 20 days of any such request, a regulated party shall make records and personnel available to assist the Executive Officer in determining the validity of the credit, deficit calculation, or Approved CI. **<u>If a party requests a hearing on the Executive Officer's initial determination, the Executive Officer must set a hearing date no later than 60 days from the date of the hearing request.</u>**

Section 95495(b)(4)

Final Determination.

<u>(A)</u> Within 50 days after making an initial determination under sections 95483.3(b)(1) and (2), above, **<u>or holding a hearing, whichever is later,</u>** the Executive Officer shall make a final determination based on available information whether, in his or her judgment, any of the bases listed in subsection (b)(1) exists, and notify affected parties and any linked program. **<u>Affected parties may appeal the Executive Officer's final determination to the Board within 30 days of receiving notice of the Executive Officer's final determination. Such appeals shall be placed on the agenda of the next regularly scheduled Board meeting.</u>**

<u>(B)</u> If the final determination invalidates credits or deficit calculations, the corresponding credits and deficits will be added to or subtracted from the appropriate LRT-CBTS accounts. Where such action creates a deficit in a past compliance period, the deficit holder has 60 days from the date of the final determination **<u>or the disposition of any appeal, whichever is later,</u>** to purchase sufficient credits to eliminate the entire deficit. A return to compliance does not preclude further enforcement actions.

LCFS 40-40 cont.

8. ***ARB's proposed per-day penalties for violations of the LCFS are unnecessary.***

Proposed section 95494 sets penalties for the failure to demonstrate compliance at the end of a compliance period or carry over all deficits; under the proposed regulations, such a failure would constitute a separate violation for each day of the compliance period or, alternatively, ARB could impose a penalty of $1000 per deficit.

LCFS 40-41

WSPA opposes a per day penalty, and proposes that ARB's suggested alternative penalty of $1000 per deficit be employed. While AB 32's enforcement provisions provide for per day penalties when a violation results in the emission of an air contaminant, where, as here, no actual emission of air contaminant is occurring on a per day basis, the imposition of such a penalty would be unnecessary. *See* Cal. Health & Safety Code §§ 42400.1, 42400.3. For example, even if a penalty drew the lowest strict liability level of $10,000 per violation, a failure to demonstrate compliance or carry over deficits could draw a penalty in the range of millions of dollars. Such a penalty is far too severe for an offense that does not signify actual emission of air contaminants beyond a statutory threshold.

Instead, penalties should be assessed on a per deficit basis, an approach which is authorized by the applicable penalty provisions of the Health & Safety Code and which ARB has already suggested. *See* Cal. Health & Safety Code § 38580(b)(3); proposed LCFS regulation § 95494(c). Unlike the extreme per day penalty provision, a per deficit penalty of $1000 is reasonable and more consistent with the nature of the violation.

LCFS 40-41 cont.

WSPA therefore proposes a revision to the text of section 95494(c) as follows:

"~~Failure to demonstrate compliance at the end of a compliance period or carry over all deficits pursuant to section 95485(c) constitutes a separate violation for each day within the compliance period. Alternatively,~~ **E**ach deficit that is not eliminated or carried over **at the end of a compliance period** as required by section 95485(c) constitutes a separate violation of this subarticle for purposes of determining penalties pursuant to Health and Safety Code section 38580(b)(3), subject to a penalty not to exceed $1000 per deficit."

9. ***The requirement that refinery investment credits only be approved for reductions from projects with no increase in criteria or toxic emissions should be eliminated.***

WSPA strongly opposes the additional complex provisions that ARB has added to the refinery investment credit provisions. This added complexity and ambiguity will limit or eliminate legitimate GHG reduction projects from receiving credits. In particular, we oppose the requirement to approve credits only from projects with no increase in criteria or toxic emissions. It is complex, unnecessary, and inequitable when compared to other parties that are participating in the LCFS.

LCFS 40-42

First, while seemingly simple in concept, there are volumes of regulations, guidance documents, and court cases related to air quality permitting where various methodologies are employed for determining what constitutes an increase.

For example, some of the questions that arise are: Is it only operational emissions or construction emissions? Is it only direct emissions from the source or indirect emissions? What if it adds personnel – will their driving trips be included? Should the increase be in terms of mass or concentration at sensitive receptors? What is the baseline for determining an increase? What years are picked for the baseline? What if there is an increase – but it is still within the permitted limit for that source or facility? How is it enforced after-the- fact – when other non-related changes at the refinery may occur that impact emissions year to year? The list can go on and on. This is a regulatory quagmire for ARB since any attempt to address or clarify these issues in the regulation could double the size of the regulation and create substantial litigation risk from various parties.

Second, this limitation is unnecessary because various regulations are in place to make sure emission increases either do not occur or are appropriately mitigated.

Under the California Health & Safety Code and Clean Air Act permitting requirements, there are already ample regulations that reduce the likelihood of an emission increase, and ensure that increases are within regulatory limits. Compliance with these programs is sufficient to ensure that no negative impact would arise from an increase in toxic or criteria air pollutants, should one occur, and thus limiting credits to GHG emission reduction modifications that do not result in <u>any</u> net increase of these pollutants is at best redundant and at worst unnecessarily restricts crediting when sufficient controls on increases are already in place.

For example, pursuant to California Health & Safety Code 39666, California has already adopted airborne toxic control measures to reduce toxic air contaminant emissions from non-vehicular sources such as refineries. Generally, refineries are also subject to Clean Air Act requirements, including permitting, which mandate that their emissions of criteria pollutants remain below a particular emission limitation. *See* 42 U.S.C. 7661c(a).

LCFS 40-42 cont.

Increases of toxic and criteria air pollutants are already sufficiently regulated. ARB's requirement that refinery investment credits only be given when there is no net increase of criteria or toxic air pollutants is unnecessary and should be removed from the regulations.

Finally, this limitation is inequitable. There is no effort by ARB to address contemporaneous criteria and toxic emission impacts for any of the other credit generating parties in the regulation. Is this being addressed for innovative crude projects or modifications at alternative fuel facilities for improving their fuel pathway CI? Is this addressed for the construction of natural gas fueling stations or for receptors near the power plants that generate the electricity for new charging stations?

WSPA therefore requests that, at a minimum, ARB strike proposed section 95489(f)(1)(D) from the proposed regulations. Moreover, we ask that ARB eliminate the capital project requirement, any distinction based on historic refinery efficiency, and the complexity of a CI based on metric and references to petroleum products consistent with prior WSPA comments.

It is WSPA's position that ARB should make this process simple, allowing the applicant to demonstrate that a project or initiative implemented since 2010 will have a decrease in greenhouse gas emissions after 2016. ARB should also work with the applicant on appropriate, on-going monitoring provisions to ensure that the decrease is real, verifiable, quantifiable and sustainable. Refinements can be made to this process based on the applications submitted, but the complexity of the current proposal presents huge barriers to legitimate, creditable projects.

LCFS 40-42 cont.

Policy/Technical Comments:

Section 95481- Definitions and Acronyms

The following terms are in the definition section, but not used in the rule. They should be removed.

- "Aggregation Indicator"
- "Biodiesel Blend"
- "Biofuel Production Facility"
- "Intermediate calculated value"
- "LRT-CBTS Reporting Deadlines"
- "Petroleum Intermediate"

The following terms are in the definition & acronym section, but not used in the rule. They should be removed.

- "AEZ-EF Model"
- "GTAP" or "GTAP Model"

WSPA recommends the following changes to section 95481 definitions (denoted in red):

"B100" – defined in "Biodiesel – does not need to be defined twice. Recommend either:

LCFS 40-43

- ~~(6) "B100" means biodiesel meeting ASTM D6751-14 (2014) (Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels), which is incorporated herein by reference.~~

OR

- (8) "Biodiesel" means a diesel fuel substitute produced from nonpetroleum renewable resources that meet the registration requirements for fuels and fuel additives established by the Environmental Protection Agency under section 211 of the Clean Air Act. It includes biodiesel meeting all the following:
  - (A) Registered as a motor vehicle fuel or fuel additive under 40 Code of Federal Regulations (CFR) part 79;
  - (B) A mono-alkyl ester;
  - (C) Meets ASTM D6751-08 (2014), ~~Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels, which is incorporated herein by reference~~;
  - (D) Intended for use in engines that are designed to run on conventional diesel fuel; and

(E) Derived from nonpetroleum renewable resources.

(11) "Biogas" means the raw methane and carbon dioxide derived from the anaerobic decomposition of organic matter in a landfill or ~~artificial~~ manufactured reactor (digester).

(12) "Bio-CNG" means biogas-derived biomethane which has been compressed to CNG. Bio-CNG has equivalent performance characteristics when compared to fossil CNG.

(13) "Bio-LNG" means biogas-derived biomethane which has been compressed and liquefied into LNG. Bio-LNG has equivalent performance characteristics when compared to fossil LNG.

(14) "Bio-L-CNG" means biogas-derived biomethane which has L-CNG. Bio-L-CNG has equivalent or better performance characteristics than fossil L-CNG.

(15) "Biomass" means …

(17) "Biomethane" is the refined end product when carbon dioxide and the impurities present in biogas are separated from the methane in the mixture, resulting in a product ~~about~~ containing approximately 99 percent methane content….

(69) "Producer" means, with respect to any fuel, the entity that made or prepared the fuel. This definition includes "out-of-state" where the production facility is out of the State of California and the entity has opted into the LCFS ~~production as long as~~ pursuant to section 95483.1.

LCFS 40-43 cont.

(70) "Product Transfer Document (PTD)" means a document or set of documents that authenticate(s) the transfer of ownership of fuel from a regulated party to the recipient of the fuel and convey(s) the specific information required by this regulation.

The above correction to the PTD definition is a typographical correction only. WSPA has additional comments regarding this PTD definition below.

(75) "Reporting Party" means any person who, pursuant to section 95483 or 95483.1 is the initial regulated party holding the compliance obligation, and any person to whom the compliance obligation has been transferred ~~directly or indirectly~~ from the initial upstream regulated party.

The following terms are in the Acronyms section, but not used in the rule. They should be removed.

- "FFV"
- "FOA"
- "FPCOA"
- "GREET" (defined in CA-GREET acronym – duplicative)
- "ILUC"
- "TOER"

Section 95481(a)(3)(B) – recommend the following changes *(denoted in red)*:

Transfer of Oxygenate or Biomass-Based Diesel and Retaining Compliance Obligation. Section 95483(a)(3)(A) notwithstanding, a regulated party transferring ownership of oxygenate or Biomass-Based Diesel may elect to remain the regulated party and retain the LCFS compliance obligation for the transferred oxygenate or Biomass-Based Diesel by providing the recipient at the time of transfer with a product transfer document that prominently states the information specified in 95491(c)(1). LCFS 40-44

Section 95481(a)(5) – incorrect reference *(denoted in red)*:

(5) *Effect of Transfer by a Regulated Party of Oxygenate to be Blended with Gasoline.* Where oxygenate is added to gasoline, the regulated party, with respect to the oxygenate, is initially the producer or importer of the oxygenate. Transfers of the oxygenate are subject to section 95483(a)(1)(C). LCFS 40-45

Section 95481(c)(2 & 3) – incorrect reference *(denoted in red)*:

(2) *Transfer of a Blend of Liquid Alternative Fuel and Gasoline or Diesel Fuel and Compliance Obligation.* Except as provided for in section 95483(a)(4)(C), on each occasion that a person transfers ownership of fuel that falls within section 95483(a)(4) ("alternative liquid fuel blend") … LCFS 40-46

(3) *Transfer of a Blend of Liquid Alternative Fuel and Gasoline or Diesel Fuel and Retaining Compliance Obligation.* Section 95483(a)(4)(B) notwithstanding, …

<u>Section 95482 – Fuels Subject to Regulation</u>
No comments.

<u>Section 95483 – Regulated Parties</u>
Section 95483.2 *Establishing a LCFS Reporting tool Account*

This section contains new regulations and establishes registration requirements, account management roles and duties, and an application submittal deadline. The proposed regulations allow for two Account Administrators (primary and secondary). The proposed regulations do not contain a definition for Account Administrator in the definition section but their responsibilities are defined in this section.

WSPA requests ARB include the definition of "Account Administrator" in the definition section (§95481). LCFS 40-47

<u>Q. Regulated Party Miscellaneous Updates</u>

Section 95483(a)(2)(A) - WSPA does not support inclusion of the requirement for the buyer to notify the seller as to whether a company is a producer or importer. The typical LCFS 40-48 transaction is completed entirely with the seller's paperwork and the only buyer response would be to reject a term. No response implies acceptance after a customary 10-day period. This would create a huge burden on a transaction-by-transaction basis. If ARB is presuming this communication is done verbally, then how is it documented in order to show compliance? If the seller's contract passes the obligation on to the buyer, by default, can it be assumed that the buyer communicated their status to them? Can ARB post entity status on the website and enable this to be the communication tool by directing sellers to the website?

LCFS 40-48 cont.

WSPA does not believe the requirement outlined in the first sentence above is necessary and opposes its addition to the regulation. The addition of the language makes a long, complicated regulation even longer and more complicated.

ARB is adding new language to an existing paragraph (§95483(a)(2)(E)) dealing with the transfer of diesel fuel and adding a new section (§95483(d)(3)) dealing with LNG that is re-gasified and then compressed. Here are WSPA's comments:

Section 95483(a)(2)(E) Regulated Parties for Gasoline and Diesel

ARB is proposing to add explicit and clarifying language to what is already allowed in the existing regulation. ARB has added a proposed definition for "Above the Rack" (§95481(a)(1)) and added new language to an existing paragraph dealing with the obligation transfer. The proposed language states:
"… A person, who is neither a producer nor an importer and who acquires ownership of Diesel Fuel or Diesel Fuel Blends from the regulated party above the rack, may become the regulated party for the Diesel Fuel or Diesel Fuel Blends if, by the time ownership is transferred, the two parties agree by written contract that the person acquiring ownership accepts the LCFS compliance obligation as the regulated party…".

LCFS 40-49

WSPA agrees with staff that any party who acquires ownership of Diesel Fuel or Diesel Fuel Blends above the rack may become the regulated party. However, WSPA does not believe the proposed change to the existing regulatory language is necessary.

Section 95483(e) Regulated Parties for Electricity [Note: WSPA has consolidated our comments on the electric portion of the regulation below]

As WSPA has stated numerous times in the past, we strongly oppose ARB's electricity provisions, and continue to propose that electricity NOT be part of the LCFS program. ARB should account for the GHGs from electricity separately and reduce the compliance obligation within the LCFS proportionally based on ARB's anticipated success of the roll-out of EVs.

LCFS 40-50

The electricity provisions should be eliminated from the LCFS since it is a readily available fuel – in fact ubiquitous. Based on ARB's experience, the innovative market signal hoped for from the LCFS is not needed for this fuel. In fact, ARB is proposing to reduce the incentive funding to EVs based on successful consumer acceptance to date.

The applications for incentive funds are chronically over-subscribed; and moreover, this has all been accomplished without any credit generation revenue from the LCFS. Utility reports to ARB in 2012 and 2013 indicate that no revenue has been derived from credit generation; and yet, ARB is touting the popularity of EVs amongst consumers. Clearly, the LCFS credits have not contributed to consumer acceptance to date and should not be needed in the future.

Barring removal from the regulation, there are key issues related to the electricity provisions that need to be addressed include the following:

LCFS 40-50 cont.

Credit Generation For Pre-LCFS Off-Road Electricity Applications: WSPA is opposed to this provision.

1) It is unclear whether ARB has the statutory authority to allow credit generations from sources that pre-date the LCFS.
   - The off-road sources that will generate credits under this provision were in existence prior to the development or implementation of the LCFS.
   - ARB's own projections in the ISOR Appendix B, Table B-19 show that Electricity usage for HDVs/Rail is expected to remain static between 2016 and 2020.
   - The generation of credits for pre-LCFS electric does not meet the intent of the LCFS. These credits do not:
     - o Reduce transportation fuel CI,
     - o Reduce dependence of petroleum,
     - o Reduce GHG emissions.
1) This proposal creates an un-level playing field.
   - "Rewards" status quo activities by allowing them to generate CI credits.
   - Sales of these credits results in a cross-sector subsidy (transportation fuel sector to the electricity sector)
   - Merely allows ARB to justify an infeasible LCFS reduction target.
     - o For example, the ARB estimates HDV/Rail credits will be range from approximately 35 – 59% of the total electricity credits between 2016 and 2020 (from ARB's illustrative mix of fuels, ISOR Appendix B tables B-18 and B-19).

LCFS 40-51

Removal Of Direct Metering Requirement: WSPA opposes the removal of the direct metering requirement.
1) Its removal creates concerns related to credit validity:
   - Due diligence of credits generated from residential charging of EVs is extremely difficult, if not impossible.
   - There is increased probability of credit invalidation.
   - Credit validity is further eroded by:
     - o The proposed CalETC calculation methodology and,
     - o The removal of supplemental reporting by electricity credit generators.

2) This proposal creates an un-level playing field**:**

LCFS 40-52

- ARB is picking "winners and losers" by allowing electricity providers to bypass the detailed application, reporting, and recordkeeping, and rigor required by providers of liquid fuels.

3) Does ARB have the authority to remove the direct metering requirements?
4) Does ARB have the authority to authorize the sale of credits from estimated fuel usage?
5) ARB should, at a minimum, guarantee the validity of such credits and hold transportation fuel providers harmless in the event the credits are invalidated, including not requiring regulated parties to replace invalidated credits used or purchased for compliance.

LCFS 40-52 cont.

Inclusion of new Heavy Duty EERs

1) WSPA does not support the proposal to allow these sources to generate credits without accurately including them in the 2010 baseline.

2) We do not support the proposed EER values for electric buses, and have provided specific comments below. We are concerned there is not sufficient information to establish EER values for electric buses as proposed.

3) If ARB continues to move forward with the proposed electric bus EER, the application should be limited specifically to new electric buses of the type tested and not be extended to existing electric buses (e.g. cantilever buses) in service prior to the implementation of the LCFS.

More detailed comments related to ARB's electricity provisions are outlined below:

LCFS 40-53

Credit Generation for Off-Road pre-LCFS electricity applications:

In ARB's ISOR for the re-adoption of the LCFS, ARB states:

" Providing an opportunity for credit generation for use of use of electricity as a transportation fuel supports the overall purpose of the LCFS to reduce the carbon intensity of the transportation fuel in California, reduce California's dependence on petroleum, create a lasting market for clean transportation technology, and simulate the production and use of alternative, low-carbon fuels."

WSPA argues that while this may be true for new off-road electricity applications, it is certainly not the case for pre-LCFS electrical installations. In addition, the majority (if not all) of the GHG reductions provided by these sources pre-date the LCFS and will not provide any of the opportunities identified above nor reduce GHGs in the road transport sector.

This provision does not reduce the carbon intensity of transportation fuels, but rather "rewards" status quo activities by allowing them to generate CI credits. In addition, the sale of any such credits results in a cross-sector subsidy from the transportation fuel sector to the electricity sector, with no GHG or transportation fuel CI reductions. The

LCFS 40-54

generation of credits by pre-LCFS electrical installation merely allows ARB to justify an infeasible LCFS reduction target.

Allowance of LCFS credits for electricity used in applications in place prior to 2010 will lead to a smaller reduction in transportation fuel CI and GHGs undermining the stated LCFS objectives. WSPA's position continues to be that we are against including credits for fixed guideway systems and electric forklifts unless they are also properly accounted for in the 2010 baseline. Under no circumstances is it appropriate to make credits available for systems and equipment, such as BART, that have been in operation for decades. If ARB insists on pursuing credits for these off-road sources, credits should only be generated for prospective alternative fuel projects that occurred after LCFS adoption. LCFS 40-54 cont.

Direct Metering: §95491(a)(3)(D)(1)(b):

The proposed rule eliminates the requirement that reporting of electricity dispensed to electric vehicles at residences must be based on direct metering. Instead, staff is proposing to allow the use of a "robust estimation method" developed by CalETC.

We continue to emphasize that credit generators should be held to the same set of standards as liquid fuel providers and not be allowed to estimate the fuel supplied for transportation purposes. Eliminating the direct metering requirements also increases the risk of generating invalid credits, which weakens the integrity of the entire LCFS program. In our opinion the credits obtained through the use of estimates are more suspect than credits generated from actual metered electricity usage.

There is also a fairness issue. Considering the minutia of OPGEE inputs, the level of detail required for liquid fuel reporting and the detail involved with obtaining a CI pathway (and the record-keeping requirements for some pathways) simply allowing estimates of electricity used for residential charging is inconsistent. ARB is picking "winners and losers" by not requiring similar degrees of rigor across the program. LCFS 40-55

Further, because credits must be verifiable, ARB lacks power to require entities to participate in the credit scheme without providing some level of certainty that credits validly represent the reductions they purport to represent. *See* Cal. Health & Safety Code § 38562(d)(1) ["Any regulation adopted by the state board pursuant to this part or Part 5 [market-based compliance mechanisms] shall ensure all of the following: (1) The greenhouse gas emission reductions achieved are real, permanent, quantifiable, ***verifiable***, and enforceable by the state board …"] [emphasis added]. ARB should not remove direct metering requirements, which erode the ability to verify and validate credits, and lacks authority to authorize the sale of credits from estimated fuel usage, which cannot be verifiable under California law.

As regulated parties, we are concerned that any credits generated via estimation techniques are more susceptible to challenges and invalidation. ARB should require measures to increase the validity of credits and not erode the validity. Only verified credits should be allowed in the program. WSPA believes the utilities ought to provide enough incentives through LCFS credit revenue or other incentive programs to maximize the amount of direct metering deployed for charging. We continue to oppose the proposal to allow electricity producers to generate credits from unmetered residential EV charging. LCFS 40-55 cont.

Calculation methodology:

Although staff has posted a letter on the ARB website approving this method (dated April 5, 2012), there are insufficient details for us to adequately review and comment upon the methodology. Based on the limited information available, it appears that the method would assume that vehicles within a service area without direct metering would be used in the same fashion as those that do have direct metering. Closer examination of this approval raises many questions/issues as follows:

- The proposal requires the utilities to report data quarterly for EV charging that is metered. The intention is to use this data as a proxy for unmetered EV charging. What is the extent of the metered data? Will this assessment be done only on a regional utility basis because the driving and utilization patterns might vary from region to region? What is the percentage of the metered data relative to unmetered data? What discussions have occurred about the extent necessary to be statistically relevant? For example – one metered customer should not represent hundreds of unmetered customers in the calculation. Is it ARB's intention to post this data in a de-identified or aggregated manner for public review? LCFS 40-56

- The proposal then allows a utility that does not have the ability to compile and report their direct metered data to use a statewide average of the direct metered data that is submitted. This means that a utility can use a statewide average value for direct metering as a proxy for its direct metering information that will be submitted to ARB, which will in turn be used as a proxy for statewide unmetered charging. An embedded approximation like this for use in a broader approximation is hardly robust. Moreover, will ARB report on which utilities have direct metering data and which do not and why? At a minimum, any utility that lacks any directly metered data should be excluded from the estimation technique and the ability to generate credits. There is no guarantee that the usage patterns in one utility's region will be representative of the usage patterns in another region. LCFS 40-57

- To determine numbers of PEV customers, CalETC will obtain 'zip+4' PEV registration data from a data management firm that accesses DMV data, or data from other sources. First, what are the zip+4 data and will this data be posted on the website? Second, who is the data management firm and what controls do they have to ensure the validity of the data? Are they subject to ARB audit and jurisdiction? If DMV data is not used, what are the other sources? How can the data from these other sources be assured? LCFS 40-58

- Is data separately available for PHEVs and BEVs? What is the average and range of the directly-metered data? It would be important to understand the variation potential that exists to understand the potential error band in the unmetered data. Perhaps some safety factor based on a statistically significant lower range should be incorporated into the credit calculation. LCFS 40-59

- Vehicle owners who go to the trouble of installing a separate meter are likely to plug in more faithfully than those who do not and are therefore not representative of the entire fleet. This is particularly important for PHEV estimates. Are there any data with which to confirm that the results from the metered fleet can be extrapolated to the unmetered fleet? LCFS 40-60

- Is ARB accounting for metering in public and work place setting and adjusting the residential estimates as appropriate? Will ARB review the total credits generated by all EV charging and compare it to the DMV records to ensure charging estimates are not "double counting"? LCFS 40-61

- The data collected on vehicles with direct metering cannot be applied to the entire fleet of BEVs and PHEVs in an area without also confirming that the distribution of vehicles (by BEV/PHEV and by all-electric range) is the same between those with meters and those without. It is highly unlikely that this distribution would be the same. For example, a PHEV with a 10-mile electric range that was purchased primarily for carpool lane access would likely be under-represented in the sub-set of vehicles with at-home meters. LCFS 40-62

- How is double-counting of electricity usage prevented? If at-home charging for those vehicles without a separate EV meter is accounted for with this method, is it assumed that all of the public charging stations get full credit for that electricity? What if a vehicle owner only charges at public or work-based charging stations and rarely charges at home? Is that vehicle assigned home-based charging at the same rate as those vehicles with at-home meters? LCFS 40-63

Excluding Supplemental Information:

ARB is proposing to exclude some supplemental information now required in annual reporting. WSPA disagrees with this, particularly the exclusion of the number of EVs operating in a service territory. Without this basic piece of information, ARB will not able to cross-check reported electricity usage by EVs for reasonableness.

In fact, we suggest that the reporting requirements be enhanced to include not only the number of EVs in a service territory, but also the number of plug-in vehicles in various categories (i.e., pure electric vs. plug-in hybrids by range). LCFS 40-64

It is important to distinguish between pure battery electric vehicles (BEV) and plug-in hybrid electric vehicles (PHEV); and within each of those categories, identifying the distribution of vehicles by electric range. For example, data collected by the Idaho

National Laboratory on in-use driving patterns for the Chevrolet Volt and Nissan Leaf can be found at: http://avt.inl.gov/evproject.shtml#.

Dividing the all-electric miles by the number of vehicles reported at that website gives quarterly VMT per vehicle for Oct-Dec 2013. The BEV Leaf (~6000 miles per year if 4Q2013 numbers are forecast to a full year) is accumulating fewer miles on electricity than the PHEV Volt (~8000 miles per year).[1] Clearly, the limited range of the Leaf is resulting in much lower VMT than a typical new car, while the broader utility of the Volt results in greater overall usage and higher VMT on electricity. However, PHEVs with lower range would have fewer miles on electricity, while BEVs with greater range would likely have more miles on electricity. These results reinforce the importance of understanding the make-up of the plug-in fleet in a particular area to generate an accurate estimate of on-road electricity usage. In addition, it is important to continue monitoring recharging and electricity usage of these vehicles as the patterns of usage may change as the vehicles expand beyond "first adopters." LCFS 40-64 cont.

WSPA opposes the proposal to remove the Supplemental Information from electricity providers reporting obligations, including accounting of credits generated, sold, and banked and accounting of number of EVs known to be operating in the service territory.

While WSPA recognizes the confidential nature of credit generation in the LCFS, if electricity credits are based on estimated electricity usage rather than direct metering, the public has a right to know precisely how those estimates were prepared and the number of credits generated as a result.

H.D. EERs: §95490 Table 5

Staff has proposed changes to the heavy-duty EV EER based on electric buses operating in California. Similarly, staff has proposed EERs for heavy rail, light rail and trolley buses, and electric forklifts. WSPA cannot comment on these values without reviewing the data upon which they were based. In general, however, we reiterate our concern about allowing these sources to generate credits without accurately including them in the 2010 baseline.

It is unclear whether ARB has adequate information to establish EER values for electric buses as proposed, and recommend that ARB evaluate whether additional testing or other information is needed prior to publication of EER values. We do not support the use of the proposed EER values. LCFS 40-65

Specific concerns that we would like to raise include the following:

1. There is insufficient evidence available to show that the proposed EERs represent actual in service fuel economies.
    a. The test procedure for electric buses is incomplete. Key information such as the measurement of energy consumption is not adequately described to independently repeat the test.

b. The Altoona Bus Test website does not have a published test procedure for electric buses and the test procedure posted on the website is dated 2006.
c. It is not illustrated that the posted 2006 diesel bus testing procedure is applicable to electric buses.
d. In the posted test results and on the Altoona website, there are caveats presented that indicate that the Fuel Economy tests "will not represent actual "in service" fuel economy but will provide comparative data" (see http://www.altoonabustest.com/bus-tests.htm).

LCFS 40-65 cont.

2. Modifications to the testing protocols have the potential to impact test results, making them non-representative of in-service conditions:
   a. Both an acceleration and deceleration profile should be followed during testing – there is the potential for a biased comparison between buses without a set profile.
   b. Modification of the maximum speed during the commuter cycle testing from 55 miles per hour (mph) to 40 mph may not be representative of real world conditions.
   c. A control vehicle should be used in the testing to account for external factors.

We continue to stress that ARB has not given regulated parties adequate time or information to truly evaluate this proposal. Given the concerns raised and the short comment timeframe, we urge ARB to not include the proposed EER values for electric buses. If ARB continues to move forward with this proposal, the application should be limited specifically to new electric buses of the type tested and not be extended to existing electric buses (e.g. cantilever buses) in service prior to the implementation of the LCFS.

LCFS 40-66

Section 95484 – Average CI Requirements

CaRFG Carbon Intensity
WSPA cannot find a reference to the carbon intensity for CaRFG in the regulation. This is important because it is the baseline against which the reductions are determined. In the existing regulation it is part of the look-up table. Neither can we find any documentation detailing how the CI was derived. WSPA requests that it be included in the regulation.

LCFS 40-67

Section 95485 - Demonstrating Compliance

Credit Clearance 95485(c)(1)(B)2 – we continue to have concerns with the credit clearance proposal as summarized below:

- This provision only serves to 'kick the can down the road' and adds additional complexity to an already complex regulation.
- We question whether any parties will pledge credits to the credit clearance market knowing that parties will have more obligation added the following year.
- The proposal to include a 5% interest rate on carried over credits only exacerbates the issues with infeasibility of LCFS targets in later years of the program.

LCFS 40-68

- This option does not address the infeasibility of the LCFS targets.
- It is not clear how ARB developed the $200 / credit price ceiling.
- We have concerns regarding the ability to perform any due diligence on the Credit Clearance Market credits. ARB should, at a minimum, guarantee the validity of such credits and hold transportation fuel providers harmless in the event the credits are invalidated; including not requiring regulated parties to replace invalidated Credit Clearance Market Credits.

Here are some suggested revisions:

WSPA proposes that participation in the CCM be voluntary. In order for ARB to determine whether or not to hold a CCM for a particular year, ARB could issue a "Call For Deficits" similar to the "Call For Credits" described in §95485(c)(3)(A) in order to inform their decision.

LCFS 40-68 cont.

Section §95485(c)(3)(E)(5) – recommend the following additions *(denoted in red)*:

Regulated parties that have pledged credits to sell into the Clearance Market, and have not sold or contractually agreed to sell all their pledged credits, cannot reject an offer to purchase pledged credits at the Maximum Price.

Deficit Carryover (formerly Section 95488(a)(4))
WSPA objects to the removal of the Deficit Carryover provisions in the proposed regulations. There may be planning or operational reasons why a regulated party may wish to carry deficits from one year to the next. We request that this section remain in the regulation as an option for entities not wishing to participate in the CCM.

This would be accomplished by changing Section 95485 Demonstrating Compliance, (c) *Credit Clearance Market*, (1) by adding the following:

"*(D) Deficit Carryover*. Non-withstanding the above, a regulated party may carry over the deficit to the next compliance period, without penalty and without participating in the Credit Clearance Market, if both of the following conditions are met:

(A) The regulated party fully met its annual compliance obligation or participated in the Credit Clearance Market in the previous compliance period; and
(B) The number of credits retired for the current annual compliance period is at least equal to 90 percent of the current annual compliance obligation."

LCFS 40-69

If this change is made the following changes would also be required to the proposed regulatory language:

Section 95485(c)(4) - Add the following to the first paragraph: "unless the party elected to exercise the Deficit Carryover provision.

And for <u>95485(c)(4) (A)</u> change the definition of "total Deficits" to: "total deficits" refers to the sum of all regulated parties' obligations for the compliance year that have not been met pursuant to section 95485(a) <u>or the Deficit Carryover provision</u>; and
Section 95485(c)(4)(B) The LCFS credit balance and the individual entity names should be treated as highly confidential because the release of this information could adversely impact business operations. The release of the LCFS credit balance would provide competitors and other LCFS credit market participants with short or long position knowledge. While that knowledge would enable the credit clearance market to perform as desired, it would allow for manipulation of the normal LCFS credit market. For example, if a party has to purchase a specified pro rata share of LCFS credits in the credit clearance market and is unable to, then the parties who have credits to sell after the credit clearance market is completed would have a financial incentive not to sell until the next credit clearance market and they would be aware of entities' shortfalls. Rather than have positions posted publicly as noted in 95485(c)(4)(B)1. and 2., regulated parties would prefer to have a designated overseer within the California Air Resources Board to bring buyers and sellers together and preserve confidentiality of individual parties positions.

LCFS 40-69 cont.

Section 95485(c)(5) – WSPA understands ARB is proposing to prohibit entities that have a roll-over deficit under the credit clearance approach from transferring/selling credits to another party until the deficit is "paid back." WSPA understands this prohibition is only intended to apply to "separated" credit transactions and not to the transfer of obligation with physical fuel. We are requesting that ARB confirm this in writing.

LCFS 40-70

Section 95486 – Generating & Calculating Deficits & Credits

Section 95486(a)(4)(A) – recommend the following change – to be consistent with existing regulation & §95486(a)(4)(B)(2) *(denoted in red):*

(A) *Extended Credit Acquisition Period.* A regulated party may acquire, via purchase or transfer, additional credits between January 1st and March 31st ("extended period") to be used for meeting the compliance obligation of the year immediately prior to the extended period. Credits acquired for this purpose are defined as "carryback" credits. All carryback credit transfers must be initiated in the LRT-CBTS by March 31st and completed by April ~~15~~30th to be valid for meeting the compliance obligation of the year immediately prior.

LCFS 40-71

Section 95486(a)(4)(B)(2) – recommend the following change – to be consistent with existing regulation *(denoted in red):*

The additional credit was generated in a compliance year prior to the extended period.

A regulated party electing to use carryback credits must identify the number and source of credits it desires to use as carryback credits in its annual compliance report submitted to the Executive Officer no later than April 30th of the year in which the additional credits were obtained.

LCFS 40-72

A regulated party electing to use carryback credits must acquire and retire a sufficient amount of carryback and other credits to meet 100 percent of its compliance obligation in the prior compliance year. If sufficient credits are not available, a regulated party must minimize its compliance shortfall by retiring all credits purchased during the extended periods that are eligible to be used as carry back credits. LCFS 40-72 cont.

Section 95486(c) - Credit Generation Frequency. Beginning 2011 and every year afterwards, a regulated party may generate credits quarterly after data are reconciled with its business partner.

WSPA believes that the new proposed language is unworkable in its current form. WSPA supports the goals of staff of accurate reporting, and we support the new reporting provisions requiring an initial report followed by a 45 day reconciliation period. Section 95491 Reporting and Recordkeeping (a)(1)(A) calls for reporting parties to "work in good faith with their counter parties to resolve and fuel transaction discrepancies between the parties". WSPA supports this but notes that this does not ensure that there will not be any discrepancies between reporting parties. To be consistent with section 95491, WSPA believes the language of 85486 (c) should be modified to state: LCFS 40-73

(c) Credit Generation Frequency. Beginning 2011 and every year afterwards, a regulated party may generate credits quarterly after its quarterly report has been filed and it has made a good faith effort to ~~after data are~~ reconcile~~d~~ its data with its business partner

Section 95487 – Enhancements to LCFS Credit Provisions

WSPA agrees with the required use of the LRT for initiating and completing all credit transfers. However, WSPA questions whether ARB has a contingency plan for any prolonged outages that the system may experience. It may be appropriate to include a provision empowering ARB to put a temporary manual transaction process in place under such circumstances. LCFS 40-74

Section 95488 - Obtaining and Using Fuel Pathways

(a*)* Applicability-(page 51 – 52 of Appendix A)
Item (1)
WSPA is concerned about the short timeframe for parties to register and obtain a fuel pathway certification for those pathways that do not meet the requirements of 95488 (a)(1) given the two step board adoption process and the possibility of one or more 15-day packages. WSPA suggests a sunset date of one year after the effective date of the LCFS Re-Adoption regulations for **all** fuel pathways. LCFS 40-75

This can be accomplished by deleting the last sentence of the first paragraph 95488 (a) and the following paragraphs (1), (1)(A), (1)(B), (1)(C); and the following to the first paragraph in 95488 (a):

A fuel pathway certification or a registered fuel provider's use of a fuel pathway that was approved under the provisions of the previous LCFS regulation order may remain valid for as long as one year after the effective date of this subsection, and then shall be automatically deactivated.
Item (2)
For clarification purposes, assuming staff makes the above change, WSPA suggests the following phrase "both with approved physical pathways and those with physical pathways pending" be inserted into the revised first sentence of 95488 (a) ~~(1)~~ so it reads as follows: LCFS 40-75 cont.

A fuel pathway certification or a registered fuel provider's use of a fuel pathway both with approved physical pathways and those with physical pathways pending, that was approved under the provisions of the previous LCFS regulation order may remain valid for as long as one year after the effective date of this subsection, and shall then be automatically deactivated.

WSPA believes the above proposed change is consistent with the language in this subsection which uses the terms "in effect", "registered", and "certified"; but does not specifically address the initial demonstration of physical pathway.

(c) Specific Requirements and Procedures.
Item (4)
For increased transparency and because it is used to calculate the CI of denatured ethanol and the CI of CARFG for the 2010 standard, WSPA believes the regulations should contain a specific reference to the California Reformulated Gasoline and Ethanol Denaturant Calculator spreadsheet. LCFS 40-76

This can be accomplished by adding a new paragraph (o) after paragraph 95488 (c) (1) (N) that reads as follows:

(N) A copy of the California Reformulated Gasoline and Ethanol Denaturant Calculator spreadsheet showing the anhydrous and denatured ethanol CI values if the pathway is for ethanol.

California Reformulated Gasoline and Ethanol Denaturant Calculator spreadsheet
Item (5)

WSPA recommends that several changes be made to the spreadsheet that staff has posted that is used to calculate the Carbon Intensity (CI) of CARFG and the incremental CI value that parties are directed to add to their CA-GREET 2.0 Pathway CI Result to account for the denaturant added to anhydrous ethanol. LCFS 40-77

Cell C13 (Line C) should be corrected to contain the correct updated ILUC value for corn ethanol. The proposed new value is 19.8g CO_2e/MJ. Cell C13 currently has a value of

20.00g CO_2e/MJ. The proposed CaRFG baseline number and the 2016+ standards in section 95484 should be updated to reflect this change. LCFS 40-77 cont.

WSPA believes staff is incorrectly characterizing the content of denatured ethanol based on the fuel specification rather than actual industry practice. The denatured ethanol standard allows up to 2.5 vol% denaturant, 1% water, 0.5% methanol and 1.4% other. Ethanol produced at ethanol plants does contain some water and methanol plus higher order alcohols. The reference cited in the spreadsheet only cites the current ethanol specification and gives no justification for treating the water, methanol, and other (which are higher order bio-alcohols) as CARBOB for the CI calculation.

Ethanol producers do not add more than 2.5% denaturant because exceeding this amount would result in having to assign less than 1 RIN per gallon of denatured ethanol (per EPA regulations) and ethanol buyers expect each gallon of ethanol to have 1 RIN attached to it. Thus WSPA agrees that 2.5 vol% should be used for the percent denaturant.

Ethanol producers also typically add water to ethanol up to the 1% standard. This water has no Carbon Intensity (CI) since it is not petroleum based. Theoretically, staff should divide the calculated ethanol vol% of anhydrous ethanol by .99 to account for this.

Ethanol producers do not add anything else to the ethanol. Any methanol contained should be treated as a biofuel (which it is) and not assigned a CI of CARBOB by subtracting the methanol content when calculating the ethanol content of denatured ethanol. The goal is to calculate the biofuel content. The “other” compounds are higher order alcohols which should also be treated as biofuels and not as CARBOB. Their energy content is greater than ethanol which makes up for the lower energy content of methanol. To not over calculate the CI of denatured ethanol staff should set the ethanol content at 96.5% (100% - 2.5% - 1%) or 97.47% (100% - 2.5% - 1%)/0.99 if staff elects to back out the water. Commercial denatured ethanol contains above 96% ethanol if not 97%. LCFS 40-78

To make the changes Cell C33 Line N should be changed to 9.698250% (10.05% times 96.5%). In addition, Cell C49 Line Y should be changed to 96.5% and Cell C50 Line Z should be changed to 3.5% (100% - 96.5%).

Making these changes including the iLUC correction will change the value of CaRFG from 98.18 to 98.14gCO_2e/MJ. More importantly, it will change the 2010 denatured minus anhydrous value Cell 55 to 1.15gCO_2e/MJ from the incorrect high value of 1.78.

Making these changes will also correct the calculated CI impact of denaturant in Cell C62 Line HH which ethanol producers have to use in calculating their new CI values per section 95488 or the regulations. For a 60 CI anhydrous ethanol the denaturant value to add would now be the correct value of 2.03gCO_2/MJ versus the high value (when treating the methanol and other higher order alcohols as CARBOB) of 3.15gCO_2/MJ. This is a decline of 1.12gCO_2/MJ which is significant. If fact, the proposed regulations in this section at 95488(c)(4)(G)(2) Substantiality Requirements, consider 1.0 gCO2e/MJ to be a significant threshold for applying for a new pathway. LCFS 40-78 cont.

Item (6)
WSPA believes that the inclusion of regulated parties reporting CI's in addition to fuel producers, in section 95488(c)(6) *Relationship of Pathway Carbon Intensities to Units of Fuel Sold in California,* is unworkable. Regulated parties that are not fuel producers cannot reasonably be held responsible for the producer's assignment of a CI value. Nor should they be required to determine that the actual CI of the fuel is equal to or less that the CI value reported. This paragraph should just refer to fuel producers. LCFS 40-79

This can be fixed by changing the two references of "regulated parties" to "fuel producers" in paragraph 95488(c)(6)(A).

Evidence of Fuel Transport Mode- (page 84 – 87 of Appendix A)
Item (7)
WSPA suggests that all existing and submitted demonstrations of fuel transport modes be grandfathered into the LCFS Re-Adoption regulations. This could be accomplished by adding a statement to this effect to the second paragraph of 95488(e) Evidence of Fuel Transport Mode so it reads as follows:

A regulated party must submit the demonstration of a fuel transport mode to the Executive Officer within 90 days of providing a fuel in California unless an initial demonstration of fuel transport mode was previously submitted and approved for that facility under the provisions of the previous LCFS regulation order. LCFS 40-80

WSPA cannot see any benefit of having alternative fuel providers re-submit their initial or updated demonstrations of fuel transport modes to ARB. The changes in the LCFS Re-Adoption regulations do not have any impact on the validity of previous initial demonstrations of physical pathways under the existing regulations.

Revised Indirect Land Use Change (iLUC) Values

Indirect land use change (iLUC) estimates continue to be a source of uncertainty in the overall lifecycle GHG footprint of biofuels, and significant efforts to refine those estimates[2] have continued since ARB initially included iLUC in the LCFS. Although uncertainty in the estimates remains, WSPA agrees that iLUC effects for biofuel production need to be addressed in the context of the LCFS regulation, consistent with our comments on the 2009 LCFS rulemaking. In principle, the scientific basis for addressing iLUC in the LCFS remains sound, and improvements to methods and models for estimating iLUC values continue to be made.

In our 2009 comments WSPA also supported convening a Work Group with experts on both sides of the debate to ensure a balanced and transparent approach to further work on

[2] See, for example, proceedings from Coordinating Research Council workshops on life cycle analysis of biofuels/ transportation fuels held in 2009, 2011, and 2013 at http://www.crcao.com/workshops/index.html.

the issue. We applaud ARB for facilitating that effort, as well as the work group participants who devoted considerable time and energy to better define the issues around indirect effects. Although disagreements remained among experts about some key elements of the iLUC calculations (e.g., time accounting), there were other areas of agreement and recommended GTAP model improvements that have been incorporated by Purdue University and ARB (e.g., improved treatment of co-products for corn ethanol and soy biodiesel).

The detailed analysis of revised iLUC values is summarized in Appendix I of the ISOR. We have the following comments and questions on that analysis and the ensuing results.

1. A comparison of the current regulatory iLUC values and the proposed iLUC values is shown in the table below. Also shown are values presented at the November 20, 2014, workshop.

Comparison of Current and Proposed iLUC Values (gCO2e/MJ)			
Fuel Pathway	**Current Value (2009 Regulation)**	**Proposed Value (December 2014 ISOR)**	**November 2014 Workshop[3]**
Corn Ethanol	30	19.8	20.0
Sugarcane Ethanol	46	11.8	19.6
Soy Biodiesel	62	29.1	27.0
Canola Biodiesel	n/a	14.5	14.5
Sorghum Ethanol	n/a	19.4	12.7
Palm Biodiesel	n/a	71.4	46.4

Given the significant changes to both the GTAP model, which estimates the location and amount of land use change for a particular biofuel pathway and a given volume "shock," as well as the emission factors applied to the land use change (via the AEZ-EF model), it would be useful for ARB staff to identify how much of the ILUC changes in the table above are associated with GTAP model revisions versus emission factor revisions. Additionally, what is the basis for the changes between the November 2014 workshop and the December 2014 release of the ISOR?

LCFS 40-81

2. It appears CARB is making a procedural change in how they plan to address iLUC. In the current regulation, iLUC values are part of the regulation (they are specified in the look-up tables). In the proposed regulation, the only mention of iLUC values is in §95486(b)(3)(B) which describes the credit calculation. The calculation requires incorporation of "a land use modifier (if applicable)" but those values are not found in the regulation.

LCFS 40-82

[3] See http://www.arb.ca.gov/fuels/lcfs/lcfs_meetings/112014presentation.pdf

This opens the door to changes to key formulas outside of the rulemaking process and without opportunity for public comment. When regulations are amended, the California Administrative Procedure Act requires "basic minimum procedural requirements" for rulemaking, including giving interested parties an opportunity to comment on the rulemaking, and a response to public comments. *See Tidewater Marine Western, Inc. v. Bradshaw* (1996) 14 Cal.4th 557, 558; Cal. Gov. Code § 11346. But the proposed regulations attempt to avoid public discourse on potentially significant changes to the implementation of the LCFS by tying key values that are the rule's backbone to calculations and data that could change at any time, with no explanation—essentially a *de facto* amendment of the regulation with no public process.

ARB must provide more certainty that key values and calculations will not change without public input. A possible remedy would be to add a table of iLUC values to the regulation.

LCFS 40-82 cont.

3. Table I-1 of Appendix I summarizes the "shocks" used in GTAP to model iLUC emissions. For sugarcane ethanol, the table appears to indicate that 3 billion gallons of Brazilian production and 1 billion gallons of U.S. production were assumed. Is this a correct interpretation of the table, or do those volumes reflect the volumes consumed in Brazil and the U.S.? If the former interpretation is correct, what is the basis for these estimates, as we are not aware of large volumes of sugarcane ethanol being produced in the U.S.? What is the sensitivity of the model to changes in the split between Brazilian production and U.S. production?

LCFS 40-83

4. The proposed iLUC values are based on an average of 30 model runs which used 5 different values for the yield-price elasticity, 2 sets of values for a yield adjustment for the cropland pasture land category, and 3 sets of values for the elasticity of crop yields with respect to area expansion (5 X 2 X 3 = 30 runs). ARB also prepared a Monte Carlo uncertainty analysis that consisted of up to 1,000 model runs for some pathways. Why were the means of the 30 discrete scenarios used to establish the iLUC values rather than the means of the Monte Carlo simulations?

LCFS 40-84

5. As noted above, one of the parameters that was varied to establish the 30 model runs for the iLUC analysis was a yield adjustment for the cropland pasture land category, which is a new land category in the GTAP model relative to the 2009 analysis. This yield adjustment is intended to account for potential investments to increase the productivity of this land as it is brought into crop production. The discussion on page I-12 of Appendix I indicates:

> "However, Purdue researchers acknowledge that although they believe the effect is real, there is no empirical basis for the elasticity parameter proposed for this endogenous yield adjustment. In the absence of

LCFS 40-85

> empirical evidence to estimate this parameter, staff used two sets of values for the runs employed for each biofuel analyzed here."

Given the lack of empirical data with which to estimate this parameter, what was the basis for the elasticities used in the analysis?

LCFS 40-85 cont.

6. Land use change effects for cellulosic ethanol are discussed beginning on page I-18 of Appendix I. The discussion indicates that a value of 18gCO2e/MJ is proposed for cellulosic feedstocks, and that staff is continuing to work on model inputs for cellulosic ethanol from non-food crops and waste. The discussion further indicates that results will be published when the analysis is complete. Will an updated iLUC value be proposed for cellulosic ethanol via a 15-day change notice as part of the current rulemaking, or does staff envision another avenue to formalize this value? In what timeframe does staff expect to have an updated iLUC value for cellulosic feedstocks? Is the 18 gCO2e/MJ value only for farmed trees, miscanthus, and other purpose-grown cellulosic feedstocks, i.e., would waste products used for cellulosic ethanol feedstocks be assigned a land use change value of zero?

LCFS 40-86

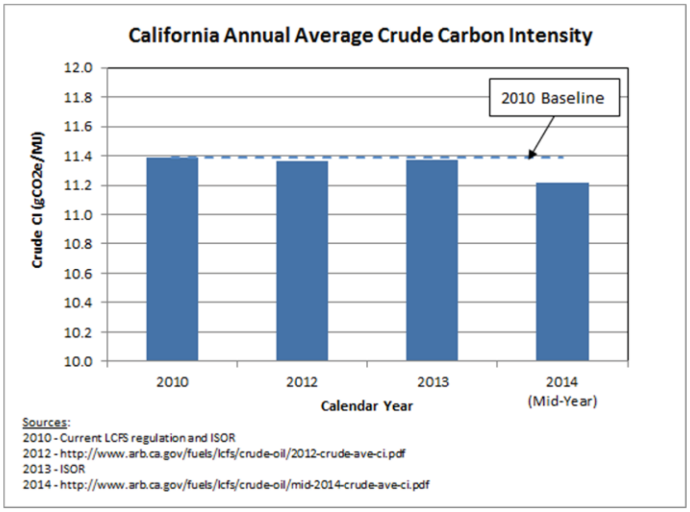
Section 95489- Provisions for Petroleum-Based Fuels

Section (a) – General - Annual Crude CI Calculation

WSPA comprehends ARB's desire to continually improve the accuracy of LCFS data inputs, and recognizes the approach taken by staff in attempting to refine the crude handling provisions as part of the re-adoption rulemaking is consistent with that principle. However, we also believe that the degree of crude differentiation built into LCFS, to comprehend concerns over CA crude CI increasing over time, remains unnecessarily excessive and should be reduced. Our reasoning is as follows:

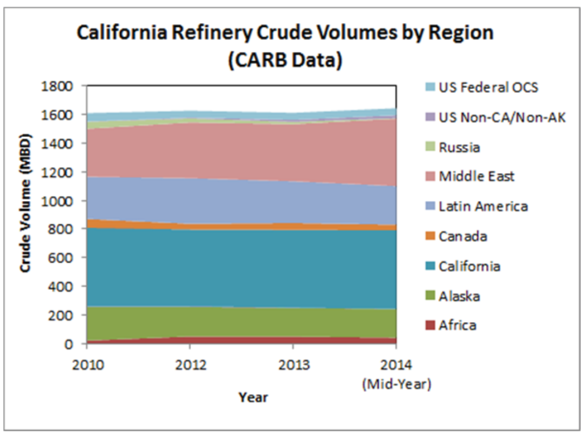
- The fundamental reason for these provisions in the rule was to ensure that the Average carbon intensity of the California crude slate did not increase over time. The available crude breakdown data for recent years (2011-2013) suggests that this threat has never materialized and that the CA crude average CI has remained relatively stable (see plot below).

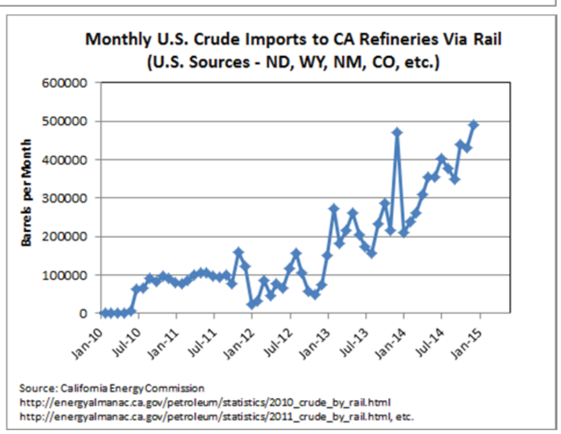
LCFS 40-87



Moreover, ARB data on crude volumes run in California Refineries show a decreasing trend in heavier Canadian crudes, while light Middle Eastern and U.S. mid-continent crudes ("U.S. Non-CA/Non-AK" in the figure below) have trended upwards. Furthermore, CEC data on U.S. mid-continent crude imports by rail show strong growth over the past three years that has continued through the second half of 2014.

LCFS 40-87 cont.





50

- As a result, we believe that the justification drivers for installing, maintaining and expanding the current LCFS crude differentiation provisions have been greatly diminished since these provisions were implemented.
- Even if ongoing monitoring is necessary to ensure that staff's concerns that a heavier crude CI outlook does not materialize, the worst case scenario (i.e., exporting heavy California crude to maintain a constant annual average crude CI) yields no tangible greenhouse gas reduction benefits from a global standpoint. California's average crude CI may well remain constant, but global GHG emissions are likely to increase as the GHG emissions associated with transporting the crude exported from California (to non-optimal refining centers for processing) will be higher.
- The ongoing staff effort to maintain and improve crude differentiation inputs and modeling tools in the LCFS is resource-intensive for the ARB and equally burdensome for our industry in terms of the recordkeeping and reporting requirements it entails. In the absence of a valid GHG justification for engaging in such a complex crude differentiation and tracking scheme, we believe staff should be moving in the opposite direction than they have been following, i.e., one of simplification and streamlining.

LCFS 40-87 cont.

WSPA understands staff does not propose a fundamental change in the California Crude Average approach as part of this re-adoption package. We support staff's decision not to proceed with Refinery-Specific Crude Accounting for large, complex refineries and understand the rationale offered for doing so. We agree that there is no practical alternative to facilitate detailed individual crude breakdown in the pipeline crude blends that comprise a large part of refinery crude inputs in the state. We look forward to working with staff in the near future to examine potential options to modify the crude differentiation requirements in LCFS (post re-adoption), toward a less complex alternative that can hopefully satisfy staff's desire to track crude CI trends over time while reducing the compliance burden on our industry.

LCFS 40-88

We note the proposed changes in the methodology for calculating the CA crude average to rely on CA on-shore crude production data (supplied by The Department of Conservation- DOC) and off-shore data (supplied by The Bureau of Safety and Environmental Enforcement- BSEE). This is in lieu of refinery-reported crude volumes that have been used for this purpose up to this point. Staff's rationale is simply that this is essential to improve the accuracy of the crude volumes used in the calculation of the CA Annual Crude Average. There is no backup support or analysis of the impact of the proposed changed in calculation methodology. More specifically, staff does not:

- Present data to determine how this change will impact the calculated annual volume averages to date. Staff merely indicates that total refinery-reported volumes for 2012 and 2013 closely match the volumes reported by CA field

LCFS 40-89

operators. We would recommend a more rigorous side-by-side comparison for 2011-2013 using the CA crude volumes estimated/reported by refineries versus the newly proposed utilization of DOC and BSEE data.

- Elaborate on the methodology that will be used to combine the in-state crude data with out-of-state crude volumes imported into California (both U.S. and foreign) to develop the overall annual CA crude average. Furthermore there is no indication that any potential discrepancies with the refinery-reported volumes will be investigated and reconciled.
- Recognize the difficulty that increased CA exports will entail should this methodology be adopted, dismissing such concerns by simply indicating that production volumes will be adjusted for exported crude volumes (should the need arise). Staff believes their proposal will work as long as all CA-produced crude is processed in CA, which is currently the case. However, staff's proposal appears to be short-sighted and inconsistent with the overall crude handling approach in the LCFS which, despite WSPA's input, is designed to drive increased crude exports to prevent CA crude average CI increases. Moreover, the same issues staff outlines in breaking down reported volumes of typical CA pipeline crude blends currently will be in play if/when staff tries to back out exported crude volumes out of the calculated CA annual average.

LCFS 40-89 cont.

Many inputs are required to run the OPGEE model for a specific oil field and in particular for California fields, a number of important parameters, such as water-oil ratio, steam-oil ratio, and production volumes are available or are calculated from data published by the California Department of Conservation, Division of Oil, Gas, and Geothermal Resources. We encourage ARB staff to revise the OPGEE modeling to reflect actual realistic input values, such as for the steam generator feed water temperature, and we will work with ARB staff to provide more specific data on this and other model inputs for California crudes. ARB should pursue collecting the same composition, quality, and environmental profile details for other domestic and worldwide crudes as transparency and comprehensive, reliable, comparable data is critical to making effective and sustainable decisions.

LCFS 40-90

Section (c) Addition of Incremental Deficits that Result from Increases in the Carbon Intensity of Crude Oil to a Regulated Party's Compliance Obligation (page 96 – 97 of Appendix A)

Item (1)
95489(c)(3)(B)
WSPA is concerned about the long lag time between the submittal of quarterly crude receipt data to ARB and the regulatory requirement of posting the prior year's Annual Crude Average carbon intensity calculation at the LCFS web site. WSPA requests that in order to facilitate obligated parties compliance planning and execution that ARB be required by the regulations to also post a quarterly Crude Average compliance calculation within 15 days of receiving the 1st, 2nd, and 3rd Quarter Compliance reports. This requirement should be added to paragraph (B) of 95489(c)(3).

LCFS 40-91

Item (2)

95489(c)(3)(C)
The LCFS Regulations have been in a constant state of change since they were adopted by the board. WSPA believes that this uncertainty has and could continue to result in increased LCFS credit prices, compliance issues and difficulty in meeting the goals of the LCFS program. WSPA believes that a three-year cycle for not just updating Table 8 but of the LCFS regulations will have little benefit and add uncertainty to the program. WSPA suggests all LCFS regulatory revisions occur no more frequent than once every 5 years. This should not preclude CARB from adding new crudes to Table 8 on an annual basis. However, overall revisions to Table 8 or the OPGEE model should occur no more frequent than once every 5 years. LCFS 40-92

Section (d) – Credits for Crudes Using Innovative Methods

WSPA notes the revisions to the innovative crude provision, which help resolve several issues with the original provision that rendered it unworkable and thereby inhibited the use of these low-carbon production methods.

Most importantly, reducing the minimum threshold for carbon intensity reduction from 1.0 g/MJ to 0.1 g/MJ, or alternatively achieving annual emissions reductions of 5,000 MTCO2e or more, removes an impossibly high hurdle and might allow for a number of projects to receive approval. Allowing the producer to opt in as a regulated party and generate the credits rather than the refiner generating the credits provides the producer with a stronger incentive than the current regulation to apply to the Executive Officer for approval of the method. WSPA supports replacing the complex formula for calculating credits with default calculations as it will also aid applicants. Finally, WSPA supports the addition of solar and wind electrical power generation and solar heat generation as allowable innovative methods, as this could result in more successful applicants and therefore more available credits for regulated parties. LCFS 40-93

However, WSPA takes issue with limiting CCS as an innovative method to those instances where the carbon capture occurs onsite at the crude oil production facilities. CCS has the potential to generate a substantial number of credits under this provision, but many projects (and proposed projects) involve capturing carbon such as from power generation or other industrial emission streams not at the same physical site where the crude is extracted. This could seriously limit the potential of CCS under this provision and in general and stem the flow of much-needed credits. The capture of CO2 from a steam generator or other equipment at the oil production is desirable, but the overall cost of actual capture, sufficient volume, gathering and clean-up to a CO2 purity to allow for miscible injection and recovery at a reasonable economic scale is prohibitive in/through CCS as compared to capture from other large CO2 emission sources. LCFS 40-94

WSPA also objects to Section 95489 (d)(1)(B), which proposes that credit generation for CCS projects will only be allowed through the use of a Board-approved quantification methodology including monitoring, reporting, verification, and permanence requirements associated with the carbon storage method being proposed for the innovative method." Since applicants are required to be approved by the Executive Officer, WSPA proposes LCFS 40-95 that quantification methodology for CCS projects should only require the approval of the Executive Officer, not the entire Board. WSPA would also encourage ARB to expedite the process for implementing the quantification methodology in order to incentivize applications under this provision. LCFS 40-96

Moreover, the proposal should include an option for Crude Production companies to apply for this credit for other GHG reduction projects above and beyond the four envisioned by ARB and included in the regulations:

- There are other technologies (e.g. solvent extraction) that may result in reduced energy usage and/or GHG from crude oil production.
- Limiting credits to solar and wind eliminates credits for other renewable energy, such as land fill gas, tidal power, etc.
- We feel the use of renewable electricity transmitted through an electricity grid should be eligible for this credit.
- We oppose the requirement that third parties providing either innovative steam or electricity must be co-applicants, especially given that co-applicants are not able to generate credits under the proposal.
    - Any recordkeeping or regulatory requirement would be more appropriately managed through contractual language between third party providers and crude producers.
    - Such a requirement may dis-incent applications for this credit and the use of the technologies ARB is trying promote. LCFS 41-90

LCFS 40-97

Section (e) - Low Complexity/Low Energy Use (LC/LE) Refinery Provisions.

WSPA opposes the LC/LE Refinery provisions. We continue to believe it is inappropriate for ARB to be picking "winners and losers" among the refiners in the state and to effectively place those who have made the investments necessary to generate the volumes of refined product demanded by the market at a competitive disadvantage as far as LCFS compliance is concerned. LCFS 40-98

We oppose the LC/LE Incremental Deficit proposal, as we have consistently opposed crude differentiation in the LCFS program. If crude slate changes are going to be accounted for, WSPA opposes the treatment of individual refinery carbon intensities and particularly when such treatment is separate from, but additive to the statewide average. LCFS 40-99

In general, WSPA has the following concerns about the LC/LE approach to incremental crude oil CI calculation:

- The options are already overly complex for refiners and importers.
- It continues to differentiate between crudes and disadvantage one over the other.
- It could reward a refinery for past high CI crude use while penalizing a refinery with historically low CI crudes. It is not sensitive to energy security concerns.
- Allowing some refiners to opt-out of the industry-wide average approach creates a bifurcated market and introduces the potential for fraud given the chain of custody for crude and feed stocks is immensely complex and there is no uniform,

LCFS 40-100

verifiable certification scheme. ARB's LCFS regulatory requirements should be fraud resistant. LCFS 40-100

If ARB moves forward with the LC/LE provision, we support the proposal to limit the LC/LE Refinery provisions only to transportation fuels produced from crude oil. However, the proposal as outlined raises some specific concerns:

- We believe the definition of "LE refineries" should be based on the lifecycle carbon intensity of the transportation fuels produced. The current proposed definition is based on total energy used at a refinery, and does not take into account life cycle energy use, e.g. whether the energy used per barrel of transportation fuels ***produced from crude oil*** for the LC/LE refiner is high or low compared to other refiners in the state. A LC/LE refiner that uses more energy per gallon of transportation fuel ***produced from crude oil*** should not be granted special treatment. LCFS 40-101
- In the ISOR ARB states that CARBOB and ULSD produced by LC/LE refiners have a CI that is approximately 5gCO2e/MJ less than the CI of other California refiners. However, it is not clear from the ISOR how ARB calculated the LC/LE refiners transportation fuel CI. LCFS 40-102
- Does the calculation of LC/LE overall CI include the transportation fuels produced from all feedstocks to the LC/LE refineries or the transportation fuels produced from crude oil? If the overall CI used to calculate the 5 gCO2e/MJ "adjustment" includes the processing of feedstocks other than crude oil, WSPA believes ARB should modify the adjustment to only take into account the transportation fuels produced from crude oil. LCFS 40-103
- With respect to Low Complexity-Low Energy Use Refineries seeking CI adjustments for the CARBOB and Diesel production from crude oil in 95489 (e), please explain how the volumes of CARBOB and diesel produced from crude oil versus transmix versus "intermediates" in 95489 (e)(2) are calculated? We request that ARB include a methodology for calculation of these different volumes in the regulation. LCFS 40-104
- In the ISOR, ARB staff stated these credits would only be used for compliance obligation by the LC/LE Refinery generating the credit, and would not be eligible to be sold or traded. However the draft regulation does not include any restrictions on how these credits are treated. The regulatory language should indicate that the sale and/or trade of any credits generated under the Low Complexity-Low Energy Use Refinery provisions is prohibited. LCFS 40-105

Section (e)(1) – incorrect reference *(denoted in red)*:

- To be eligible for the credit and deficit calculations in section 95489(e)(3) and the refinery-specific incremental deficit calculation in section 95489(e)(4), a Low-Complexity/Low-Energy-Use Refinery must meet the criteria in section 95481(a)(55~~7~~) using the following equations: LCFS 40-106

Section (e)(2)(C) – if ARB does not remove the definition of "Petroleum Intermediate" recommend the following *(denoted in red)*: LCFS 40-107

- The volume of CARBOB and diesel produced from Petroleum ~~i~~Intermediate feedstocks; and… LCFS 40-107 cont.

Formatting in the refinery-specific incremental deficit equations listed in 95489 (e)(4)(B) contains very little spacing between the individual portions of the "If" and "And" statements. It would be helpful for clarity if a line was inserted to increase the space between the "If" and "and" equations to avoid any confusion about subscripts in the upper equation versus potential superscripts in the lower equation. LCFS 40-108

Section (f) - Refinery Investment Credit

WSPA recognizes ARB's efforts to allow credit for refinery investments as an element of LCFS GHG reductions. However, the proposed thresholds and restrictions risk eliminating most potential projects for arbitrary reasons. California refineries have a long history of investing in energy efficiency and optimization projects. This history is documented in the ARB energy efficiency summary for the refinery sector (http://www.arb.ca.gov/cc/energyaudits/eeareports/refinery.pdf).

WSPA's consultant, PetroTech Consultants, reviewed a recently-released Promotum report entitled, "California's Low Carbon Fuel Standard: Evaluation of the Potential to Meet & Exceed the Standards" dated February 2, 2105, as well as another NRDC-sponsored TetraTech report, "   PetroTech provided comments that are summarized below on the two referenced report's conclusions which were that ARB's refinery investment credit option has significant credits to contribute to the pool.

A relevant subset of PetroTech's comments are:

<u>*Different base years used*</u> LCFS 40-109

Even though the base year for measuring CI reductions under the LCFS is 2010, the currently proposed regulation uses 2011-2013 refinery energy consumption data as the basis for estimating the CI of the petroleum refining process, not 2010. Furthermore, the regulation limits credit generation only to energy efficiency projects that are ***permitted*** *after December 31, 2014. Credit generation is also limited by ARB to capital projects or those using renewable feedstocks that do not increase criteria or toxic pollutants. Capital projects normally take at least one year to implement. Thus, any energy efficiency improvements that were implemented in petroleum refineries between 2010 and 2016 cannot generate credits even though they have reduced the CI of the products.*

<u>*Potential refinery energy efficiency improvements*</u>

Refiners are in the business of transforming and delivering energy. Refinery energy use for the conversion of crude oil to finished products is their second largest cost behind feedstock (crude oil and blendstocks) acquisition. Energy usage and cost is monitored very closely within each refinery and has been for many years. Converting crude oil to *finished products requires energy. There is a theoretical minimum amount of energy required for the conversion that depends on the quality of the crude oil, product specifications and refinery configuration. More complex refineries generally require more energy to operate.*

Two recent studies commissioned by NRDC, one by Promotum[2] and one by Tetratech[3], have greatly overstated the energy efficiency improvements that are still available to the petroleum refineries in California. Both studies use the same 2013 CARB study of California refinery energy efficiency[4] as a basis. In this CARB study, the 12 largest refineries were required to report their 2009 energy usage as well as past and potential energy efficiency projects. This report stated,

> *"The estimated GHG emission reductions are approximately 2.8 MMTCO2e annually. Approximately half of the GHG emission reductions identified were completed before 2010 and are reflected in the 2009 GHG totals shown in Table IS-1. The other half of the GHG emission reductions are from projects that were completed during or after 2010, scheduled, or under investigation and are not reflected in the 2009 GHG values shown in Table IS-1."*

The total emissions reported in Table IS-1 were 31.4 MMTCO$_2$e per year. 50% of the projects were completed prior to 2010, so the remaining potential reductions for 2010 and beyond would be 1.4 MMTCO$_2$e per year. 80% of the projects were listed as competed or ongoing in the report, so the remaining reductions that could potentially be permitted after 2015 would result in a reduction of about 0.5 MMTCO$_2$e per year. The CARB report goes on to state: LCFS 40-109 cont.

> *"However, implementation of some projects may preclude the implementation of other projects that deal with the same equipment or processes. Therefore, these estimated reductions do not necessarily represent readily achievable on-site emission reductions."*

These identified projects with a total reduction of 2.8 MMTCO$_2$e per year were estimated to cost $2,600 million and result in annual savings of $200 for a simple payback of 14 years or a first year rate of return of about 7.7%. The highest rate of return projects would be implemented first, so the rate of return for the remaining projects would be lower.

The Tetratech report estimates that a 5-10 percent reduction in refinery GHG emissions from 2010 levels (1.6 to 3.2 MMTCO$_2$e per year) is easily attainable by 2020. Even their low estimate is higher than the CARB study estimates as a remaining potential. Tetratech justifies their higher estimate as follows:

> *"We note that these estimates [estimates reported in the CARB study] are likely conservative, given that (1) the information is based on self-audits and (2) the estimates do not include the off-site production of electricity, steam, or hydrogen,*

which is a potential major source of emissions and would be included in a life-cycle assessment."

Regarding item (1) in the Tetratech justification, refineries continuously evaluate their energy use and invest in projects to improve energy efficiency. Most of the refining capacity in California is owned by publicly traded corporations. As such, their stockholders (including many public pension funds) expect a minimum rate of return on their investment. Management's fiduciary responsibility limits potential energy efficiency investment to those that meet the minimum return requirements, but also encourages them to invest in projects with good rates of return. The CARB report does state that some of the identified projects will not be implemented but does not state the reasons. There is no logical reason to assume that potential energy efficiency projects would be underreported.

Regarding item (2), refineries do not purchase any significant amount of steam except from co-located cogeneration facilities which are relatively new and efficient. Total electricity usage (both internally generated and purchased) is only 4% of refinery energy usage as identified in the CARB report. Purchased electricity is at grid average GHG levels, so measureable reductions in GHG emissions through purchased electricity are unlikely. The recently issued CARB report on energy efficiency in hydrogen production concludes that the merchant hydrogen plants in California are relatively new and very efficient. Future potential GHG reductions from merchant hydrogen production are only 1-2% of the energy used to produce hydrogen.

LCFS 40-109 cont.

CO2 capture and storage for hydrogen plants is often quoted as an easily implemented GHG reduction technology for refineries. CO2 capture from hydrogen plants will not further the objectives of the current California LCFS. The California oil deposits are too shallow to benefit from CO2 based enhanced oil recovery techniques. Futhermore, the U.S. DOE has recently stated that widespread use of large scale CO2 storage facilities is not expected to be ready for dissemination until 2030[5]*.*

The Promotum report estimates a potential reduction in refinery GHG emissions of 4.3 MMTCO_2e per year by 2025 (~14% reduction from 2010) primarily based on the added value of the emission credit.

"For refinery energy efficiency (EE) investments, it is assumed that at $100/ton, the incentive is sufficient to more than double the payback of EE, such that a reduction of 1.5% per year improvement in GHG emissions at refineries across the industry. We estimate that reductions from EE investments grow linearly from 2017 to 2025, reaching 4.3 MMT in annual reductions by 2025."

According to the 2013 CARB energy efficiency report, 80% of the potential 2.8 MMT of annual CO2e reductions would have been implemented by now, leaving only 0.5 MMT of potential reduction projects that could be permitted in 2015 or beyond and eligible for the credit. The $100/MT of CO_2 credit is about $50 per barrel of crude. Although this *would change the rate of return for energy efficiency projects, the magnitude of this credit would not be sufficient to "more than double the payback of EE."*

Furthermore, there is no technical basis for Promotum's estimated total potential reduction of 4.3 MMT CO_2e per year. There is a theoretical amount of energy required to refine crude oil into saleable products. Neither the Tetratech nor Promotum studies recognize this fact. They both use arbitrary percentage reductions with no theoretical basis for the values.

Allowing full credits for refinery efficiency improvements implemented since 2010 is consistent with the objectives of the LCFS. As stated in the subject document,

> *"The LCFS is performance-based and fuel-neutral, allowing the market to determine how the carbon intensity of California's transportation fuels will be reduced."*

Refinery efficiency improvements since 2010 have reduced the carbon intensity of fuels produced within California relative to the base year of 2010 and should receive full credits under the program. Furthermore, all future projects, not only those that are permitted in 2015 or later should receive full credits. As highlighted by Promotum, the credits raise the rate of return and will cause more projects to be implemented, although not to the extent estimated by Promotum.

LCFS 40-109 cont.

2. Promontum, California's Low Carbon Fuel Standard: Evaluation of the Potential to Meet and Exceed the Standards. http://docs.nrdc.org/energy/files/ene_15012801a.pdf
3. CARB, "Energy Efficiency and Co-benefits Assessment of Large Industrial Sources, Refinery Sector Public Report," June 6, 2013.
4. U.S. DOE, National Energy Technology Laboratory, "Carbon Storage Technology Program Plan," September 2013., http://www.netl.doe.gov/File%20Library/Research/Coal/carbon-storage/Program-Plan-Carbon-Storage.pdf

Therefore, due to our industry's prior investments, the proposed limitations and restrictions staff has developed for the Refinery Investment Credit option are too high, create arbitrary inequities, or are inconsistent with existing programs and law.

We propose modifying the proposed section to address several of the restrictions and thresholds for the following reasons:

a. Limiting onsite increases of criteria air pollutants and toxics unreasonably excludes offsets of criteria and air toxic pollutants
b. 0.1 gCO2e/MJ threshold is too stringent and unfairly penalizes larger, more efficient refineries
c. Investments should not be limited to capital or onsite projects
d. Eligibility cutoff date does not recognize improvements made since program adoption
e. Biofeedstock 10% threshold is too restrictive and unfairly penalizes larger, more efficient refineries.

Incorporating criteria and air toxic pollutant controls in LCFS is misguided

California's long-standing framework of stringent air quality programs must remain the primary tool to regulate local and regional air pollutants rather than grafting co-pollutant measures or requirements onto the LCFS. The proposed limitation in attempt to address criteria and air toxic emissions is complex, unnecessary, and inequitable:

- Complex – there are volumes of regulations, guidance documents, and court cases related to air quality permitting where various methodologies are employed for determining what constitutes an increase. For example, some of the questions that arise are: Is it only direct emissions from the source or indirect emissions? Should the increase be in terms of mass or concentration at sensitive receptors? What is the baseline for determining an increase? What if there is an increase – but it is still within the permitted limit for that source or facility? How is it enforced after-the- fact – when other non-related changes at the refinery may occur that impact emissions year to year? This is a regulatory quagmire for ARB since any attempt to address or clarify these issues in the regulation could double the size of the regulation and create substantial litigation risk from various parties.

- Unnecessary – the CEQA process and robust air quality permitting processes are more than sufficient to reduce the likelihood of an increase, mitigate any increase, or ensure that the increase is within regulatory limits that are protective of the community and the environment. LCFS 40-110

- Inequitable – there is no effort by ARB to address contemporaneous criteria and toxic emission impacts for any of the other credit generating parties/mechanisms in the LCFS regulation (e.g., innovative crude projects or modifications, alternative fuel facilities applying for fuel pathway CI improvement, construction of natural gas fueling stations, or power plants that generate the electricity for new charging stations).

WSPA asks that ARB eliminate the requirement to address criteria pollutant or toxic emissions. ARB could adopt a monitoring approach similar to the approach in their cap and trade program to satisfy itself that its own non AB 32 air programs are effective. At a minimum, ARB should follow its own air pollution policies which provide refiners with the flexibility to offer mitigations offsetting any potential increase in criteria pollutants or toxics.

CI reduction project threshold of 0.1 gCO2e/MJ will unnecessarily eliminate legitimate projects

The threshold for efficiency projects of 0.1 gCO_2e/MJ is overly restrictive and potentially inequitable. For larger refineries, the absolute quantity of emissions reductions required to qualify a project (i.e., satisfy this threshold) will be larger and thus more difficult to meet. Some refineries may be more efficient (from a carbon intensity standpoint). This LCFS 40-111 restriction may preclude such refiners from making further energy efficiency improvements.

Staff's proposed CI calculation in determining project credit also arbitrarily assigns credits based on product slate rather than GHG reduction. If project CI threshold is calculated based on volume percent of gasoline and diesel produced, a refinery's product slate will affect its ability to receive LCFS credits for energy efficiency projects. For example, if two hypothetical refineries have total emissions of 4 MMT each, but one produces 10% diesel, while the other produces only 5%, the number of tons of emissions reductions necessary to meet the minimum diesel CI target will be different for each refinery (40,000 or 20,000 tons).

Furthermore, the 0.1 gCO_2e/MJ reduction represents a substantially higher hurdle (in terms of absolute quantity of CO_2 reductions required) than is expected for other products' pathways in the regulation. This is due to the substantially larger throughput volumes of petroleum refineries and the fact that many petroleum refineries have already implemented energy efficiency improvements to lower their production CI. As a result, the use of a 0.1 gCO_2e/MJ may prevent refiners from making further reductions and, thusly, disadvantage them versus higher carbon intensity manufacturing processes for other products**.**

WSPA proposes eliminating the threshold altogether. If this is not feasible, an absolute value threshold (e.g. 1000 $MTCO_2e$/year) would incentivize reductions in a more equitable manner. In addition, ARB could also allow bundling of smaller projects to further incentivize energy efficiency where there may not be many large projects available.

LCFS 40-111 cont.

Limitations on project type will eliminate valuable GHG reducing projects

The refinery investment mechanism should recognize non-capital but sustained improvements that reduce GHGs in addition to capital projects and co-processing. Many energy efficiency upgrades are considered non-capital. For example, replacement of equipment such as pumps, compressors, seals and blowers may include upgrades with lower greenhouse gas emissions. Insulation projects also may not be considered a capital project. These upgrades may not be considered capital expenses, and individually have relatively low greenhouse gas emission reductions. However, cumulatively, the cost of upgrades and insulation replacement can be significant, and the emissions reductions can add up. Since additional effort may be needed to upgrade rather than replace equipment "in kind", and to undertake insulation replacement, incentives from the LCFS program could help refineries take these actions.

LCFS 40-112

Project eligibility should extend to early actors and at least to new construction.

The time limitation for eligibility of projects penalizes early actors contrary to AB 32 statutory provisions 38560.5(b)(1) and (3). We suggest that the deadline for project eligibility be based on the start of the LCFS program. At a minimum, WSPA believes

LCFS 40-113

that ARB should allow a refinery greenhouse gas emissions reduction project to be eligible if it is implemented (i.e., started up) after January 1, 2015, regardless of when permits for the project were initially filed. LCFS 40-113 cont.

<u>Ensure that biofeedstock co-processing projects have a chance to qualify</u>

Staff should reconsider and remove the proposed 10% biofeedstock threshold as it is inequitable. Percentage throughput limits are unfair to larger refineries, since the absolute volume of biofeedstock must be larger as facility size increases. We do not understand the basis for this threshold and believe that several potentially viable options would become essentially "non-starters" as a result. LCFS 40-114

Co-processing biofeedstocks is generally practical at far lower than 10% refinery throughput, especially for larger refineries. The proposed high thresholds for co-processing will discourage innovation and reduction in greenhouse gas emissions. WSPA recommends that this threshold be removed or that an absolute threshold (such as 1000 $MTCO_2e$/year) reduction should be used.

<u>Other Comments</u>

1) In the proposed section "95489(f) Refinery Investment Credit, the term "$Volume^{Total}$ *= total volume of product output in bbls (bbl).*" could be problematic to define (e.g., does it include only finished fuels or also refinery intermediates requiring further processing at another location? Are sulfur or butane production included?) WSPA would prefer a simple approach and, as an alternative to a potentially complex definition of refinery "products," WSPA recommends that ARB change the denominator in the term, "T = percentage of transportation fuel produced" *from* "total volume of <u>product output</u>…" to the "total volume of <u>crude oil and intermediates supplied to</u> the refinery (bbl)." LCFS 40-115

2) Currently in 95489(f)(1)(D) it states the refinery must annually replace a minimum of 10% of the fossil based feedstock. The regulation should clarify whether the 10% is based on volume of energy. WSPA would like ARB to provide a comparison of the 10% level to the 0.1g/MJ threshold for other projects. The 10% threshold seems to be a high threshold that will not help encourage such projects. LCFS 40-116

3) ARB should consider an option for CI reduction credits to be allocated more specifically to the units and products to which they apply (versus overall for the refinery). LCFS 40-117

Section 95490 – Requirements for Multimedia Evaluation

Please see the Legal comments section.

Section 95491 - Reporting and Recordkeeping

WSPA notes ARB's addition of the 45-day initial reporting deadline and subsequent 45-day reconciliation period. This will enable more immediate reconciliation of discrepancies between reporting parties.

We do not agree that unclear transmission of information on product transfer documents is a key cause of such discrepancies. The primary drivers for reporting discrepancies to date have been confusion regarding changes to regulatory requirements (particularly the nature and timing of the 2011 program amendments), and a steep learning curve for new regulated parties joining the program. LCFS 40-118

We object to the change proposed to the definition of Product Transfer Document (PTD) to refer to a newly created, single document rather than a collection of documents that transmit the required information. The term "PTD" has been used by several regulatory agencies over the years to refer to any document or documents that recognize a transfer of ownership/custody and includes certain required information. The very general nature of this definition has always been intended to allow flexibility in the execution of compliance and cause minimal disruption to operations. Establishing a narrow definition that requires a single, discrete document causes unnecessary additional cost while adding little or no benefit. LCFS 40-119

In the ISOR, ARB states the original transferor of fuel sold without obligation must report any export of that fuel by any subsequent owner or supplier. However, there is no regulatory language on this item in the draft text presented in Appendix A. Assuming that staff will develop language to reflect their intention in this regard and include it in the final regulation order, we have concerns about the practicality and fairness of this requirement. We find it impractical as it will be very difficult for fuel suppliers to ensure that the ultimate exporter communicates their activities backward through the supply chain. It also puts an unfair compliance burden on the original transferor by potentially taking credits away from that transferor because of another party's decision to export. It is understandable that ARB would want to track the export of such fuels, but the compliance cost/benefit of that export should accrue to the exporter and not to another party who has no control over their decision to export. LCFS 40-120

Section (a)(3) – WSPA does not believe the production facility ID and the Company ID should be included in all transaction documents. In many cases, multiple facilities and companies could produce biofuel with the same CI. Once these fuels are introduced into fungible systems where biofuels of the same CI cannot be distinguished, it should no longer be required to be tracked. This information should be included only for the initial transaction in the state of California (either production or importation), but not in further transactions, as the recordkeeping burden and the potential for mistakes and associated non-compliance penalties outweighs the perceived benefit of tracking this information. LCFS 40-121

Section (a)(7) **-** Provision (7) provides for quarterly and annual report corrections with proper substantiation to ARB, but it does not preclude enforcement. WSPA does not agree with this concept related to quarterly progress reports. Entities should be able to make changes to the quarterly reports with enforcement penalties provided the LCFS 40-122 corrections do not material impact a credit transaction relying on the information submitted in the quarterly report. For example, there could be many, non-substantive changes to what is reported with no impact on credit balance – or perhaps the company does not complete any credit transactions between the completion of the quarterly report and when the correction is made. Promoting corrections to these quarterly progress reports is in ARB's best interest and imposing penalties will inhibit such corrections. LCFS 40-122 cont.

Section 95492 – Enforcement Protocols

Section 95493 - Jurisdiction

Section 95494 - Violations

Section 95495 – Authority to Suspend, Revoke or Modify

Section 95496 – Regulation Review

The proposed regulation includes a regulation review and a presentation to the Board by January 1, 2019. WSPA has several concerns with this section:

- The first concern is that this date is too late to effect change in the program. Since the compliance curve accelerates substantially in the final few years prior to the 2020 goal, it is highly likely there will be problems and issues with the program in this time period that will begin to manifest themselves beforehand. By the time the Board meets during 2019 to discuss the E.O. Review and determine if revisions to the regulation are needed, it will be too late. LCFS 40-123
- There is a substantial gap in time between the recent January 1, 2015 review and the January 1, 2019 review. The historical periodicity of regulation review has been more frequent, and as evidenced by several hearings to date held to make changes to the regulation, these more frequent reviews are needed to make changes to the program in a timely way. LCFS 40-124
- The list of issues that are identified as part of the review have been reduced from 13 items to 8. WSPA requests reinstatement of the items that have been proposed for removal from the review list such as:

  (3) Advances in full, fuel lifecycle assessments;
  (4) Advances in fuels and production technologies, including the feasibility and cost-effectiveness of such advances;
  (6) An assessment of supply availabilities and the rates of commercialization of fuels and vehicles; LCFS 40-125
  (8) The LCFS program's impact on state revenues, consumers, and economic growth;
  (9) An analysis of public health impacts of the LCFS at the state and local level, including the impacts of local infrastructure or fuel production facilities in place or under development to deliver low carbon fuels, using an ARB approved

method of analysis developed in consultation with public health experts from academia and other government agencies; LCFS 40-125 cont.

WSPA requests the ARB Board ask staff to revise the regulation to include the review items that were removed, LCFS 40-126 and importantly, that the former Periodic Reviews be replaced with annual staff reports to the Board that provide a detailed synopsis of the health of the program, the challenges, and any need for program changes. LCFS 40-127

WSPA
Western States Petroleum Association

vised CARB Low Carbon Fuel Standard FS) Illustrative Compliance Scenario

ary 12, 2015

THE BOSTON CONSULTING GROUP

tive summary

er as part of its Initial Statement of Reasons (ISOR) for LCFS re-adoption, CARB presented ive LCFS compliance schedule (2016-2020)[1] and forecasted volumes of low-carbon ow-CI) fuels allowing regulated parties to comply through 2020.

believes that these volumes and this schedule are overly optimistic and do not reflect a true "P50" ario. It is more likely that volumes will fall short rather than exceed those predicted by CARB.

falls in any of the fuel pathways would hasten the expected shortage of low-CI fuels and create a ion where there are not enough credits available to regulated parties for compliance

tailed methodology from CARB, this document suggests reasonable volumes of low-CI fuels r when using the CARB compliance schedule

ntent is to consider volumes with competing factors in mind:

- Assume healthy growth rates due to technology advances and potential value of LCFS credits
- Retain some conservatism based on high capital costs, uncertainty regarding vehicle availability, and a poor track record of low-CI fuel production versus expectations

iance schedule suggested by CARB using BCG forecasted volumes results in using all edits by 2020; the year 2020 credit deficit is 10.7 MT.

reduction in the total fuel pool is sustainable[2] by 2020 based on credits available through ow-CI fuels (e.g. renewable diesel, biodiesel) and purchasing credits (e.g., elec., natural gas)

onsiders only the recommended "gradual" compliance scenario recommended by CARB in the ISOR. 2. Slowly using up banked credits up until 2020, and retaining the argeted CI reduction in a given year without relying on credits earned in previous years starting in 2020.

stic (FAPRI) projections of sugarcane
imports to the US. Created a blended
on of 50% EIA and 50% FAPRI.
ed that California could get 25% of US
in 2015 with increases of 5% each year up
by 2020.
cent high of US share to the US West Coast
s ~35%

Renewable Diesel

2013-14
- Used CARB volumes/projection

2015-2016
- Assumed that renewable diesel usage would be limited to 5% of the diesel pool due to logistical issues of supplying blends >5% to market + limited availability

2017-2020
- Assumed that the overall percentage would rise above 5%, ramping up to 6% with isolated usage of R100 or other blends

2017-2020 (Sensitivity Case)
- Assumes linear growth in volumes available to California up to a 2020 maximum. This maximum volume includes:
  – 180 million gallons sourced from Singapore
  – California can get 35% of all announced US renewable diesel capacity

40_OP_LCFS_WSPA Responses

223. Comment: **LCFS 40-23 through 40-37**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

224. Comment: **LCFS 40-1**

The commenter alleges that the LCFS program and compliance schedule is not feasible.

Agency Response: ARB staff disagrees with the comment that the LCFS program and compliance schedule are infeasible. As described in the Initial Statement of Reasons, staff used a step-by-step approach to determine the feasibility of complying with an LCFS CI reduction goal of ten percent by 2020. The Appendix B of the ISOR provides further details of how this evaluation was performed, including an illustrative compliance scenario of how the target can be achieved. See response to **LCFS 38-1**.

225. Comment: **LCFS 40-2**

The comment is primarily an introduction to the more specific comments and suggestions that follow, noting that now is the time to look at what has and has not worked to date, and consider slowing the program down or scaling back its goals pending further research.

Agency Response: The more specific comments are addressed separately below. To the extent that this introduction suggests ARB has proceeded without evaluating what has and has not worked, and to the extent the comment hints that the program is too ambitious, ARB staff disagrees. As extensively set forth in the ISOR and its appendices, the LCFS has been carefully developed based on science, economics, and experience. In ARB's expert judgment innovations in fuel production and type will allow the LCFS to function successfully. We note that the LCFS has built into it review functions as well as self-correcting features, so ARB disagrees that an infeasible and unchangeable program has been developed.

We note that in the subsequent comments, the commenter nowhere claims that its members are not able to produce or cannot purchase the necessary fuels. See the response to **LCFS 38-1 and LCFS 40-1**.

226. Comment: **LCFS 40-3**

The comment states that the current proposal is infeasible because of the slow development progress of low-CI fuels and that staying the course with the current design of the program could result in disruptions to the transportation fuels market.

Agency Response: ARB staff disagrees and believes that the targets are feasible. In addition, we believe the LCFS program in the long-term will provide greater supply reliability due to a diversity of fuels in the market. See response to **LCFS 38-1.**

227. Comment: **LCFS 40-4**

The comment requests program reviews on an annual basis.

Agency Response: Staff understands the desire for a clear schedule for program review but does not believe annual staff reports to the board are needed. In response to the commenter's concerns, staff added a 15-day change that creates a "progress report" to the Board about the program in 2017. A full program review will occur prior to January 1, 2019. For more details see response to **LCFS 38-2.**

228. Comment: **LCFS 40-5**

The comment requests no further efforts to create post-2020 LCFS reduction targets until the pre-2020 program is proven feasible.

Agency Response: See response to **LCFS 40-2** regarding feasibility and continued review. Regarding post-2020 reduction targets, see response to **LCFS 5-2**.

229. Comment: **LCFS 40-6**

The comment states that there will be insufficient credits to achieve the 2020 goals and beyond.

Agency Response: ARB staff disagrees that there will likely be insufficient credits to achieve the required 10 percent reduction in 2020 and at least maintain that level beyond 2020. See the response to comment **LCFS 38-1**.

Staff disagrees that the issues identified relative to the availability of either Renewable Diesel (RD) or Renewable Natural gas (RNG) will significantly reduce the ability to use these fuels to produce LCFS credits. See the response to comment **LCFS 38-6, LCFS 40-9 and LCFS 40-10**.

230. Comment: **LCFS 40-7**

The comment questions the assumptions ARB used in analyzing LCFS compliance curves and presents the results of their own analysis.

Agency Response: See response to **LCFS 40-6**.

231. Comment: **LCFS 40-8**

The comment claims a lack of credible ARB assessment and forecast of the availability and costs of low carbon fuels and credits.

Agency Response: ARB staff provided extensive information in the ISOR on the potential volumes of low CI fuels. See the response to comment **LCFS 38-1**.

ARB staff disagrees that the plant-by-plant detailed assessment of where low-CI fuels might come from requested in the comment is either necessary or feasible. The LCFS is a very flexible program that allows regulated parties wide discretion in their choice of compliance paths and fuel choices and, in fact, is designed to encourage *new* development and production. The ISOR identifies a wide variety of sources of low-CI fuels that are expected to be available to fuel suppliers in California and which, collectively if they all were to be used in California, have the potential to create far more credits that needed for LCFS compliance in 2020 and beyond.

Regarding the concern about competition for low CI fuels from other programs, ARB staff and others have assessed the impact of other Pacific Coast jurisdictions adopting the LCFS. These assessments show that the demand for low-CI fuels by these programs is far less than that in California for two reasons. First, these entities markets combined are significantly smaller than California's. Second, the LCFS phase-in schedules for CI reductions in these jurisdictions are being implemented approximately five years behind California. As a result, the fuel supplies identified in the ISOR are far more than adequate to meet all of the programs' goals well beyond 2020.

232. Comment: **LCFS 40-9**

This comment addresses two main points: 1) supply availability for renewable diesel and 2) availability of renewable diesel blends above 5 percent.

Agency Response: See response to comment **LCFS 38-6**.

233. Comment: **LCFS 40-10**

The comment cautions against reliance on large-scale production of renewable natural gas as a supply of LCFS credits, notes that landfill gas (LFG) to compressed natural gas/liquefied natural gas (CNG/LNG) for transportation fuel is uneconomic without state and federal incentives.

Agency Response: ARB staff agrees that state and federal policies, including LCFS, help drive LFG projects. In fact, the figures mentioned in the comment provide a clear example of the LCFS program improving the economics and incenting low-carbon fuel production. Staff disagree that expecting more projects of this type is unreasonable because of the significant potential LFG waste resource, which is currently unutilized.

Staff acknowledges that investors consider the risk of regulatory change before undertaking LFG projects. This argues for the creation of stable policies that provide consistent investment signals to reduce this regulatory risk. The LCFS endeavors to become such a policy, but has faced uncertainty in the past, primarily due to legal challenges.

The commenter states that repurposing of LFG from onsite electricity generation to transportation fuel is not correctly accounted for in the GHG calculation of the program, and that the fuel pathway should appropriately account for the substitution of average grid electricity generation for the LFG displaced from power production. In consideration of this, LFG pathway applicants must present evidence to ARB staff for the fuel pathway evaluation to demonstrate that the specific source of LFG would likely remain un-utilized in the absence of the proposed project or that the associated processing system was developed for the purpose of providing transportation fuel.

Staff proposes the commenter consider an alternate substitution, where the renewable power previously provided by the landfill project is replaced by renewable power from solar or wind generation (perhaps because these resources are now more competitive in the California Renewable Portfolio Standard program). In this scenario the landfill project may have considered halting cleanup and pipeline injection if not for the LCFS existing as an alternate program incenting the continued use of this low-carbon fuel.

234. Comment: **LCFS 40-11**

This comment addresses two main points: 1) increases in advanced biofuel supply as a result of the LCFS and 2) the methodology for projecting future biofuel supply.

Agency Response: See response to **LCFS 38-6**.

235. Comment: **LCFS 40-12**

The comment states that the LCFS program should undergo a Major Milestone review to inform transportation fuel consumers and state policymakers of the program's progress over the first 5 years of its existence.

Agency Response: This comment does not make a specific suggestion for inclusion in or changes to the proposal, rather it suggests an additional non-regulatory action by an unstated actor. As such, no response is necessary. We do note that in effect, the lengthy public LCFS re-adoption process has served as a major review of the program. Moreover, the re-adopted LCFS calls for review in 2017 and 2018.

236. Comment: **LCFS 40-13**

The comment states that "there appears to be a false sense of the degree of updates staff has provided," that an analysis promised in 2011 "has not materialized," and that the LCFS program 2009 economic analysis is outdated and a new economic analysis should be performed.

Agency Response:

No response is necessary because the comment does not address the proposal. Nor is it clear who holds a "false sense." We note that the December 2014 ISOR contains an economic analysis of the proposed LCFS. For more information on the economic analysis for the regulation, please see Chapter VII of the ISOR and the updated inputs and outputs for macroeconomic modeling found in Appendix F.

237. Comment: **LCFS 40-14**

The comment objects to the use of the credit clearance market and argues that this cost containment mechanism may act as a price floor.

Agency Response: With respect to the general thrust of the comment pertaining to the design of the Credit Clearance Market and the concern that the price cap could act as a floor, see responses to **LCFS 32-9 and 38-3.** Relative to the other concerns expressed:

WSPA suggests that the cost containment provision be voluntary. Staff's analysis indicates that a voluntary cost cap is unlikely to be as effective at containing the cost of compliance and providing certainty on the upward bound for credit prices as a cost cap that applies to all credits in the LCFS market.

ARB staff analysis regarding the availability of low-CI fuels indicates that there will be sufficient credits available through 2025 from existing low-CI fuel technologies and promising low-CI fuels on the horizon. See response to **LCFS 38-1**.

238. Comment: **LCFS 40-15**

The comment asserts that the Credit Clearance Market does not stipulate a mechanism for retiring deficits.

Agency Response: ARB staff analysis regarding the availability of low-CI fuels indicates that there will be sufficient credits available through 2020 from existing low-CI fuel technologies and promising low-CI fuels on the horizon. Please also see responses to **LCFS 32-9 and 38-1**.

In the event that the targets in the program prove to be more than the market can deliver in a given year, the cost containment provision will ensure that orderly compliance is possible without extreme measures. The Clearance Market will allow the market to determine the 'feasibility' of low CI production in an orderly fashion: the Clearance Market greatly reduces the potential for chaos or extreme volatility in the market should a shortfall occur, and the resulting increase in regulatory certainty should produce a corresponding increase in investment in low CI fuel technologies and projects – thereby serving to 'close the gap' on needed fuels.

Given the flexibility of the LCFS, regulated parties may account for compliance in their books differently, as this is a business-specific decision. ARB staff anticipates that most regulated parties will carry accumulated deficits as liabilities, which can be repaid when the market becomes more fully supplied. Typically, market forces respond to increased demand with resultant supply increases in subsequent years. It take approximately two to three years to build a new advanced biofuel facility, which is why staff proposes that regulated parties have up to five years to repay any accumulated deficits.

239. Comment: **LCFS 40-16**

The comment argues that the Credit Clearance Market will drive the credit cost up.

Agency Response: The structure of the clearance market does not require that additional credits are offered for sale during the year-end clearance market in order to contain costs. The cost containment provision (CCP) is designed to provide an effective cap on credit prices in the event of a short supply: if demand for credits outpaces supply in the year-end credit market, regulated parties are able to roll over any remaining deficits to be repaid in future years, preventing a situation in which a shortage of credits might result in regulated parties bidding up the price of credits above the ceiling price.

ARB staff analysis indicates that it is unlikely that the amount of credits pledged to the clearance market will be significantly lower than the amount of credits available for sale because low-CI fuel producers will have incentive to pledge all or most of the credits they are hoping to sell. This is because the credit clearance process would (1) guarantee their credits will be purchased, and (2) that they will receive the best price possible for their credits, because credits are likely to be purchased at or near the maximum price through the CCP. The quantity of credits pledged under the credit clearance process is likely to be a function of how many credits remain available for sale at the end of the year, so the credit price will be primarily determined by the amount of low-CI fuels that have made it to market, rather than the willingness of credit-holders to pledge.

The LCFS contains numerous design features to help minimize the cost of compliance, including the ability for regulated parties to self-generate credits, at costs potentially lower than the market price for credits – for example, by purchasing low-CI fuels for blending with traditional hydrocarbon fuels. As credits and deficits are generated by regulated parties selling transportation fuels in the California market, the quantity of deficits and credits available each year is determined by the actions of regulated parties – namely, the quantity and carbon intensity of fuels sold in the California market. Major regulated parties thus have the ability to greatly influence the quantity of credits provided in future years, for example, by investing in facilities to self-produce low-CI fuels, or by entering into agreements with low-CI fuel producers to ensure their future supplies of credits.

WSPA's comment that the quantity of credits is fixed is predicated on the notion the quantity of low-CI fuels produced is unaffected by both the demand for that fuel and how profitable it is to produce that fuel. Historical data from the LCFS Reporting Tool – and fundamental economic theories of supply – contradict this assertion. The volumes of low-CI fuels consumed in California indicate a strong market response to the regulation stimulating demand for low-CI fuels. A LCFS has been continuously implemented in California since 2010, and regulated parties have generated more credits than needed every year. Since 2010, the production of low-CI fuels has increased in response to the financial incentives provided by the existing LCFS regulation. Many innovative, low-CI fuel technologies have moved past the demonstration stage, and have overcome techno-economic challenges that have in recent years limited the supplies of innovative, very-low CI fuels such as cellulosic ethanol, renewable diesel, and renewable natural gas. Staff analysis indicates that the supplies of low-CI fuels in future years will continue to exhibit the existing trend of increasing production.

For further response to this comment, please see response to Comment **LCFS 38-3**.

240. Comment: **LCFS 40-17**

The comment contends that the Credit Clearance Market provides no liability protection against invalid credits.

Agency Response: ARB disagrees that the government, as opposed to buyers and sellers making commercial arrangements – which could include insurance, bonding or indemnification provisions – needs to protect parties who purchase invalid credits. Parties offering credits for sale in any credit clearance market will have to generate those credits through fuel transactions reported under penalty of perjury through the LCFS reporting tool; this data is subject to ARB staff's process for data review and reconciliation. The penalties for filing false or fraudulent reports (which can include criminal and civil penalties under federal and state law) should also deter false reporting to generate fraudulent credits. ARB cannot guarantee that credits offered through the credit clearance market are valid and will not be invalidated because ARB needs the flexibility to determine, on a case-by-case basis, what party or parties should be required to replace credits that are discovered to be based on inaccurate or fraudulent information. Without replacement of any faulty credits, the goals of the program could be endangered, as compliance with the LCFS would be based in part on low-carbon fuels that were not brought to market in the quantities reported, or with the carbon intensities reported. In most cases, a regulated party will be able to decide for itself whether it will participate in the credit clearance market; if the party believes the clearance market carries unacceptable risks due to more limited opportunity to conduct a review of the credits being offered for purchase, that party can avoid the credit clearance market altogether simply by producing low CI fuels in the compliance period in question, or banking or purchasing enough credits in advance of the compliance deadline.

For further response to this comment, please see response to Comment **LCFS 40-39**.

241. Comment: **LCFS 40-18**

The comment states that the Credit Clearance Market has no connection between its outcome, program off-ramp, and future CI reduction.

Agency Response: ARB staff analysis regarding the availability of low-CI fuels indicates that there will be sufficient credits available through 2025 from existing low-CI fuel technologies and promising low-CI fuels on the horizon. The cost containment provision will ensure that – in the event that the targets in the program prove to be more than the market can deliver in a given year – orderly compliance is possible without extreme measures. Additionally, LCFS staff monitors the demand for and supply of credits in the LCFS Reporting Tool, and will conduct a mid-program review. These activities provide ongoing opportunities to monitor the market and assess whether a sustained shortage is occurring.

242. Comment: **LCFS 40-19**

The comment argues that the Credit Clearance Market proposal is lacking implementation details and will reveal confidential business information.

Agency Response: Additional clarity was provided in a 15-day change through the addition of 95485(c)(5)(C). This new provision explains that repayment of accumulated deficits is permissible only after the regulated party meets 100 percent of its current compliance obligation.

With respect to concerns about confidentiality, see response to **LCFS 40-69**.

243. Comment: **LCFS 40-20**

The comment argues that the Credit Clearance Market should offer annual program review, triggers for early program reviews, and a carryover rule for company imbalances.

Agency Response: The Cost Containment Provision (CCP) is designed to enhance the program's ability to encourage investment in low-CI fuels and to provide regulated parties with increased certainty regarding the maximum cost of compliance. ARB staff analysis and feedback from LCFS market participants has underscored the importance of regulatory consistency in order to facilitate business planning, particularly regarding the stringency of the program's CI reduction targets. The commenter proposes eliminating the CCP and potentially changing the compliance targets annually. Rather than strengthening the market signal provided by the LCFS, the commenter's suggestion of setting CI reduction targets only one year in advance would reduce the incentive for innovation and investments in low-CI fuels, increase administrative burden, weaken the market signal provided by the LCFS, and increase uncertainty and undermine long-term planning for regulated parties. As it can take two to three years to build a new low-CI biofuel facility, for example, investment decisions require greater confidence in the future demand for low-CI fuels than could be provided by CI reduction targets that are known only one year in advance.

Also see response to **LCFS 40-15**.

244. Comment: **LCFS 40-21**

The comment argues that the Credit Clearance Market should offer annual program review, triggers for early program reviews, and a carryover rule for company imbalances.

Agency Response: Regarding the commenter's recommendation that participation in the Credit Clearance Market should be voluntary, see response to LCFS **40-14**.

The commenter recommends that regulated parties who pledged credits to sell into the Clearance Market and have not sold or contractually agreed to sell all their pledged credits be prevented from rejecting an offer to purchase the pledged credits at the maximum price. In the proposed regulation, section 95485(c)(3)(E) Selling in the Clearance Market specifies that, "Regulated parties that have pledged credits to sell into the Clearance Market cannot reject an offer to purchase pledged credits at the Maximum Price."

Regarding the commenter's recommendation that the LCFS credit balance and individual entity names should be treated as confidential, see response to **LCFS 40-68** and **LCFS 40-69**.

The commenter requests that the deficit carry-over provision be reinstated on the basis of planning or operational reasons that may cause regulated parties to wish to carry deficits from one year to another. Regulated parties can still carry deficits from one year to the next if the clearance market is triggered, although any accumulated deficits carried over to subsequent years will be assessed the five percent interest rate. Accumulated deficits are subject to the requirements of Section 95485(c).

245. Comment: **LCFS 40-22**

The comment argues that LCFS overlaps with the cap-and-trade program; and LCFS does not generate additional emission reduction, but may raise costs.

Agency Response: See response to **LCFS 32-7.**

246. Comment: **LCFS 40-38**

The comment argues that key formulas and their data for the regulation have changed without appropriate level of transparency.

Agency Response: ARB's process for explaining anticipated changes to the LCFS regulation, including changes to the values used in its California-modified Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (CA-GREET), the Oil Production Greenhouse Gas Emissions Estimator (OPGEE), and indirect land use models, has not only met requirements of the Administrative Procedure Act, but has far exceeded the minimum requirements. ARB staff held 20 workshops to share its thinking about planned changes to the LCFS before ARB filed its Notice of Proposed Rulemaking, and held another workshop on CA-GREET prior to a 15-day change. These workshops – most, if not all, of which were attended by representatives of the companies represented by the commenter – included staff presentations describing significant changes contemplated as part of the proposed rulemaking, and attendees were given the opportunity to ask as many questions of staff as they wished in person and on the web. In addition, ARB staff and managers fielded many questions from stakeholders outside of publicly-noticed meetings. Similarly, staff produced documentation to explain these changes in some detail. The document cited by the commenter (Appendix C of the Initial Statement of Reasons) included 78 pages to explain changes that the proposed regulation would make in the model currently being used.

While it is undisputed that the LCFS proposal – just as the existing LCFS regulation – is a highly technical and complex regulation, the parties subject to the LCFS are generally familiar with the scientific and technical underpinnings of the regulation and have provided informative and helpful feedback to ARB staff during the workshops and other informal rulemaking activities that stretched over many months before the filing of the notice with the Office of Administrative Law. Far from lacking transparency, the process used to develop the proposed LCFS regulation has featured long and productive dialog with stakeholders, including both the commenter and the large petroleum companies that are represented by the commenter.

The models used in both the current and proposed LCFS regulations are adapted from models developed elsewhere. For example, the GREET model used in LCFS is an adaptation of the model developed and updated by Argonne National Laboratory. Businesses and individuals with an interest in the LCFS proposal, or more specifically in how carbon intensities are computed, also have an opportunity outside of the rulemaking process to participate in development of the underlying models through other venues.

After the Notice of Proposed Rulemaking was published, ARB staff realized that additional provisions were needed in the regulation to properly adjust carbon intensity values for indirect land use changes that occur during the production of biofuels. These indirect changes are computed through the Global Trade Analysis Project (GTAP) model. Staff consequently revised the proposed regulation to include more detailed provisions governing these adjustments for indirect land use changes. Public comments were taken on these changes during a supplemental 15-day comment period.

The formulas used to compute carbon intensity values and specific carbon intensity values that are available for general use are included in the proposed regulation and will only be changed through amendment of the regulation, once adopted. The commenter appears to believe that these formulas and general carbon intensity values will be amended outside the rulemaking process, but this is not the case. For example, the commenter states that the change in the formula for computing the annual crude average value has changed and takes this as an example of "changes to key formulas outside of the rulemaking process and without the opportunity for public comment." In fact, the referenced change in the annual crude average formula is included in the proposed regulation – not outside the rulemaking process – and is explained in the Initial Statement of Reasons. Furthermore, even though the formula is set forth in the regulation, the regulation also provides that the result of the annual computation will be posted on the internet and subjected to public comment before the value is actually used in computing LCFS compliance obligations. Again, the proposed regulation not only meets the standard of the Administrative Procedure Act, but exceeds it by allowing for public review and comment where it would not otherwise be required.

247. Comment: **LCFS 40-39**

The comment argues that ARB should not compel regulated parties to purchase credits since ARB does not verify the credits; the comment also requests changes to limit the bases for credit invalidation.

Agency Response: ARB disagrees with the commenter's reading of the LCFS. Regulated parties are not compelled to purchase credits; if such parties choose to sell high-CI fuels, they may balance any resulting deficits by producing or buying and blending low-CI fuels. Moreover, if credits are determined to be invalid after they have been sold, the regulation provides ARB staff with the ability to require that various affected parties take corrective action. Whether

ARB staff will require the entity that generated and sold the credits or the entity that currently holds the credits to replace invalid credits will depend on the circumstances of the particular case. However, any credits determined to be invalid – whether after or before sale of the credits – must be replaced to ensure that GHG reductions are achieved and that other LCFS program goals are met, even if that requirement falls to a buyer of credits who failed to determine the validity of credits before purchase.

Health and Safety Code section 38562 does not require ARB to verify LCFS credits; it requires that GHG reductions be *verifiable*. In any event, LCFS credits are verifiable given the fact they are generated through transactions posted by regulated parties in the LCFS Reporting Tool, and ARB staff has the ability to audit or require additional supporting records to verify the reported transactions. Furthermore, the requirement that any credits determined to be invalid must be replaced, even if good-faith purchasers are required to pay for replacement credits, is necessary to ensure that the LCFS program meets its goals as well as AB 32's requirements. Indemnifying credit purchasers from any financial losses associated with the purchase of invalid credits, by contrast, would tend to disincentivize credit buyers from exercising due diligence to ensure the credits they are purchasing are valid, and result in the loss of emissions reductions associated with the invalidated credits.

The commenter is correct that independent (or third-party) verification is not required by the proposed regulation. However, nothing in the regulation prohibits a buyer from voluntarily undertaking verification of credits prior to purchase, or from negotiating contractual terms with the seller to address respective liabilities between the parties if credits are later invalidated. ARB staff notes the commenter's point about the U.S. Environmental Protection Agency's action to invalidate credits under the federal Renewable Fuels Standard, and agrees it is an example – an exceptionally serious example – of the type of situation that can lead to invalidation of credits.

ARB staff's response to the specific changes requested by the commenter to section 95495 of the proposed regulation follows:

1) *Add new* subdivision *(a)(2) to limit ARB enforcement actions to a period of one year or, in the* case *of failure to produce records, six months.*

The balance between the government's ability to address and remedy errors or fraudulent conduct versus private parties' desire for finality and certainty is one that the Legislature has already addressed. The law provides three years in which the People may file an action, dating from the time a violation is discovered or reasonably could have been discovered. (Cal. Civ. Proc. Code §338, subd. (k).) For the reasons described above, ARB believes it is important to the integrity of the program to ensure that flawed or false credits are invalidated and replaced, even if fraud or error comes to light after one year. Establishing a one-year time limit for enforcement action could result in a loss in GHG emissions reductions for problems that are discovered more than one year after the credit is generated or transferred, for example. ARB staff expects that most problems will come to light and be enforced within the time periods proposed in the comment, and ARB staff expects to consider the amount of time that has lapsed as it decides what enforcement action to take in a particular case. However, ARB staff does not agree that all enforcement actions should be confined to these time windows in every case.

2) *For incorrect* information *used to generate or support a carbon intensity value, limit enforcement to the two examples listed in subdivision (b)(1)(A).*

It appears the change urged by the commenter would replace the word "including" with the phrase "due to." The practical effect of this change would be to limit ARB enforcement action for incorrect information supporting a carbon intensity value to situations that either involve the omission of material information or changes to the process following submission of information to obtain a carbon intensity value. ARB staff believes these two circumstances should merely be illustrative of the types of inaccuracies that could lead to invalidation of credits or deletion of an approved carbon intensity value, as the proposed regulation is currently written. Limiting this provision to just those two circumstances could leave ARB without recourse if it determines a carbon intensity is based on faulty information or does not accurately reflect actual processes, so ARB staff declines to make the suggested change.

3) *Under subsection (b)(1)(E), limit enforcement action based on violation of other laws, statutes, and regulations to those laws, statutes, and regulations that are "*directly *applicable to the credit generation or transfer."*

It is not clear what laws the commenter believes are "directly applicable," or indeed whether such a category is sufficiently clear. In any event, by definition no other law could be brought to bear unless it did apply, so adding the word "directly" does not appear to yield a real change. ARB staff believes that the proposed change is unnecessary and would serve no purpose. The existing staff proposal allows enforcement action when "credits or deficits were generated or transferred … in violation of other laws, statutes or regulations..."This requires that the generation or transfer itself has violated such a law, statute, or regulation; in that case, the law, statute, or regulation will always be "directly applicable" to the LCFS transaction that violated it. Moreover, an agency does not have the power by regulation to alter the applicability of federal or state statutes.

4) *Add a definition of "material" to subdivision (b)(1) to include only* information *that is "directly* relevant*" to the generation or calculation of credits.*

The definition as proposed by the commenter is too narrow because information relating to approved carbon intensities, the generation of LCFS deficits, and credit transactions are also relevant to the actions described in this subdivision. But more fundamentally, ARB staff does not believe the term "material" needs to be defined because it is generally understood to include only information that is relevant to the issue being considered.

248. Comment: **LCFS 40-40**

The comment argues that enforcement provisions regarding credits and CI are deficient, and proposes a hearing and appeals procedure within the regulation on them.

Agency Response: ARB staff does not agree that an appeal process is needed. Staff anticipates working with all affected parties after an initial enforcement notice is issued; parties can submit information for consideration before the Executive Officer makes his/her final determination. Moreover, the ARB's procedures and staffing have been developed over recent decades with the Board's quasi-legislative role in mind; assigning the Board a new quasi-judicial role might require adoption of additional procedures as well as hiring new staff or reorganizing existing staff. Additionally, the LCFS Program includes a Program Review Process with the purpose of evaluating the implementation of the Program. If affected parties find the process detailed in section 95495 to be inadequate, the review would be an appropriate public forum to raise those concerns. See response to comment **LCFS 38-42.**

249. Comment: **LCFS 40-41**

The comment recommends the alternative penalties where a party does not show a balanced account at year end – per day or per deficit – be limited to per deficit-penalties only.

Agency Response: ARB accepts that recommendation and revised the regulation's section 95494(c) accordingly to eliminate the per-day alternative. For the type of violation in question, the consequences should relate to the number of deficits.

250. Comment: **LCFS 40-42**

The comment requests that the requirement that refinery investment credits only be approved for reductions from projects with no increase in criteria or toxic emissions be eliminated.

Agency Response: See response to **LCFS 38-9**.

251. Comment: **LCFS 40-43**

The comment proposes changes to some definitions and acronyms in the regulation.

Agency Response: ARB accepts the commenter's recommended changes to the definitions and acronyms in the regulation and circulated amended language in a 15-day change package. With respect to the biodiesel and biodiesel blend definitions, staff modified the regulatory text to align more closely with the alternative diesel fuel regulation. Staff, however, does not agree with the suggested change to the definition of "reporting party." Staff feels the definition already adequately addresses the transfer of obligation.

252. Comment: **LCFS 40-44**

The comment proposes changes to the language in Section 95481(a)(3)(B).

Agency Response: ARB staff acknowledges the recommendation and provided updated language in a 15-day change package.

253. Comment: **LCFS 40-45**

The comment states that there is an incorrect reference in Section 95481(a)(5).

Agency Response: ARB staff acknowledges the referencing error and corrected the reference in a 15-day change package.

254. Comment: **LCFS 40-46**

The comments states that there is an incorrect reference in Section 95481(c)(2&3).

Agency Response: ARB staff acknowledges the referencing error and corrected the reference in a 15-day change package.

255. Comment: **LCFS 40-47**

The comment requests that ARB include the definition of "Account Administrator" in the definition section (95481).

Agency Response: ARB staff accepts the recommendation to include a definition for the Account Administrator and included a definition in a 15-day package.

256. Comment: **LCFS 40-48**

The comment opposes the requirement for buyer to notify the seller as to whether a company is a producer or importer.

Agency Response: ARB staff is proposing to modify the section of concern to the commenter to remove the requirement that the recipient "producer or importer" of a fuel transfer be required to notify the transferor whether the recipient is a producer or importer for purposes of establishing compliance obligation and regulated party. The recipient "producer or importer" of California Reformulated Blendstock for Oxygenate Blending (CARBOB), Diesel Fuel or Diesel Fuel Blends will no longer automatically become the regulated party as indicated in the previous regulation order.

257. Comment: **LCFS 40-49**

The comment opposes the change in regulatory language in Section 95481(a)(1).

Agency Response: ARB staff disagrees that the language is unnecessary as it provides clarity regarding situations where diesel or diesel fuel blends obligation may be passed to downstream entities. This provision would align diesel obligation transfers with the current gasoline provision where end users and retail outlets could not receive an obligation. The obligation would stay above the rack where the wholesale purchaser of the fuel has the capability to blend biomass-based diesel fuels to offset diesel deficits.

258. Comment: **LCFS 40-50**

The comment opposes including electricity as part of the LCFS program.

Agency Response: Staff disagrees with this comment. Although the electric grid is ubiquitous, electricity is hardly a ubiquitous fuel used in the transportation sector at the present time. Currently, less than 0.5% of on-road light-duty vehicles are driven by electricity. The number of heavy-duty trucks fueled by electricity is an even smaller percentage. In fact, as a transportation fuel, the infrastructure needed to charge vehicles, especially in multi-unit dwellings and workplaces, is lacking and lagging.

One of the objectives of the proposed Low Carbon Fuel Standard is to foster investments in the production of the low carbon intensity (CI) fuels. Electricity has the lowest carbon intensities among commonly available fuels and, therefore, should be included in the LCFS provisions as an option to move California toward a low-carbon transportation future.

259. Comment: **LCFS 40-51**

The comment challenges ARB's statutory authority to allow credit from sources that pre-date the LCFS. The comment also argues that LCFS will create an un-level playing field.

Agency Response: See response to **LCFS 38-21**.

260. Comment: **LCFS 40-52**

The comment opposes the removal of the direct metering requirement due to concerns related to credit validity, ARB's authority, and an un-level playing field.

Agency Response: Staff disagrees with this comment. See response to **LCFS 32-11**.

Regarding the authority concern, in the current LCFS regulation, no-direct residential EV metering was required for the period of 2011-2014. Staff simply proposes to continue this current practice and not require separate metering post-2014. The authority to structure the calculation in this way is consistent throughout the various LCFS rulemakings.

The credits generated through EV charging will be calculated by ARB staff using the method laid out in the 15-day changes. This will enhance the credit generation process for electricity providers, and reduce the probability of credit invalidation. If fraud is discovered; the Health and Safety Code and a host of other state and federal statutes may apply, and provide for civil and criminal consequences.

261. Comment: **LCFS 40-53**

The comment opposes the inclusion of new Heavy Duty EERs.

Agency Response: Please see response **LCFS 38-21**. Use of *electricity* for transportation, not use of particular *equipment*, is what LCFS incentivizes. Staff acknowledges that the energy used in heavy duty EVs was not included in the LCFS 2010 baseline. Staff proposes to adjust the credit calculations for existing and new electric heavy duty vehicles to account for the exclusion of the pre-LCFS off-road electricity applications in 2010 baseline. The LCFS credit formulas for existing electric heavy duty vehicles such as electric fixed guideways do not include credits for fuel displacement, which substantially reduce the number of credits these electrical applications generate. In contrast, the LCFS credit formula for new electric fixed guideway system does have the fuel displacement credits. Such approaches address the concerns of allowing these sources to generate credits without including them in the 2010 baseline.

The commenter objects that the EER calculations for heavy-duty electric buses is not adequately explained or documented. ARB has added two studies to the record as part of a 15-day change. The commenter has offered no contrary information, indeed no information at all. ARB disagrees with the commenter's implication that data must be available for every individual bus model before that model can use an EER calculated for the vehicle class. EERs applicable to other fuel/vehicle combinations are not calculated for each individual vehicle, but rather for vehicle classes such as those that are heavy-duty and natural gas fueled.

The proposed EERs for electric buses are necessarily conservative and are based on testing of 3 different buses (including 2 electric buses operating in California: Proterra Electric Bus Model BE-35, and BYD Motors Electric Bus) performed at the Altoona Pennsylvania Transportation Institute (PTI) at Penn State Test Track. The testing was conducted using a Transit Coach Operating Duty Cycle that comprises of 3 Central Business District (CBD) phases, 2 Arterial (ART) phases and 1 Commuter (COM) phase. Testing started on April 25, 2011 and was completed on March 5, 2012. As stated in the reports[10], "The results of the test may not represent actual mileage but will provide objective data that can be used to compare buses tested under this procedure." As such, sufficient testing data were used to establish the EERs for electric buses.

262. Comment: **LCFS 40-54**

The comment opposes credit for off-road pre-LCFS electrical transportation applications.

Agency Response: See response to comment **LCFS 38-21**.

263. Comment: **LCFS 40-55**

The comment opposes the removal of the direct metering requirement due to concerns related to credit validity, fairness issue, and ARB's authority.

Agency Response: See response to comment **LCFS 40-52**.

264. Comment: **LCFS 40-56**

The comment argues that the calculation method problematically allows using the metered EV charging data as a proxy for unmetered charging.

Agency Response: In response to this comment and feedback from other stakeholders, staff included an adjusted calculation method directly in the rule through 15-day changes. The method is robust, since it would be based on best available data for electricity usage and EV populations in each utility's service territory. See the response to comment **LCFS 32-11** and **LCFS 40-52**.

[10] http://www.altoonabustest.com/buses/reports/404.pdf?1340301410

265. Comment: **LCFS 40-57**

The comment argues that any utility that lacks directly metered data for EV charging should be excluded from generating credit.

Agency Response: Across all LCFS life cycle analysis of fuel pathways, if no specific energy use data are available, average values are used. The use of statewide average daily charging data is consistent with such an approach.

Currently, among the utilities that have opted into LCFS, only City of Palo Alto Utilities does not have direct metering data. Considering its small number of EVs, ARB allows it to use the statewide average EV charging data. Staff will continue to monitor other sources of data for updated information on daily electricity usage of EVs and incorporate those into the calculation method.

266. Comment: **LCFS 40-58**

The comment questions the source and validity of data used to determine the numbers of PEV customers.

Agency Response: The estimation methodology referred to in this comment was used in past years by CalETC.

Historically, ARB staff has supplied some of this data to CalETC. To estimate the number of PEVs in each utility service territory, staff uses two databases: the California Vehicle Rebate Project (CVRP) database, and California Department of Motor Vehicle (DMV) registration data. The CVRP database is updated twice monthly, and DMV registration data is provided to ARB in April and October of each year. ARB staff analyzes both databases and consults with staff working on the Zero Emission Vehicle regulation to determine best estimates of PEVs charging in each service area.

In response to this comment and similar comments, in the proposed regulation ARB staff, instead of CalETC or utilities, is responsible for the determination of the final credits to utilities. Specifically, in 15-day change of the regulation, staff proposed to add the entire calculation method, including the determination of the number of non-directly metered residential PEV, into the regulation language.

267. Comment: **LCFS 40-59**

The comment raises questions on separate charging data for PHEVs and BEVs and concerns about the validity of applying metered data to unmetered fleet. Based on the commenter's unfamiliarity with electric vehicle charging, the commenter suggests that ARB reduce any electricity calculations to make them come out lower.

Agency Response: ARB staff disagrees that its calculation method is so uncertain that it should be artificially skewed downward. As the State's (and arguably the nation's) leading regulator focused on automobile emission-reducing technology, ARB is familiar with the electric vehicle use patterns and associated studies. Currently available data from select, early model year plug-in electric vehicles shows similar electricity consumption across technology type. However, per the direction in Board Resolution 12-11, ARB staff is conducting an evaluation of the charging behavior of both battery electric vehicles (BEV) and plug-in hybrid electric vehicles (PHEV) with an assortment of battery capacities and will report to the Board by 2016 as part of the midterm review for the Advanced Clean Cars program. Additional findings from this assessment will be incorporated into the calculation method per the 15-day changes that provide flexibility to adjust for any future observable differences if future data demonstrates a shift in this area. See response to **LCFS 40-52** regarding unmetered charging.

268. Comment: **LCFS 40-60**

The comment raises concerns about the availability of data to confirm the validity of applying the metered PHEVs results to that of the unmetered fleet.

Agency Response: See response **to LCFS 40-59**.

269. Comment: **LCFS 40-61**

The comment raises concerns about "double counting" of credits, especially in the public sector and the work place.

Agency Response: A comparison of the home based charging and non-residential charging is available from the EV Project Infrastructure Reports, which shows that 83% of the electricity use is acquired through residential charging.

Currently public and workplace charging has very little potential to be double counted in the LCFS because: (1) unmetered residential charging is extrapolated from metered residential charging data and (2) almost no workplace or public charging entities have opted in to generate credits. Therefore it is likely that the total amount of electric vehicle credits is underrepresented to date, rather than double counted as the commenter suggests. Staff will consider how to adjust the residential charging estimation method further if needed as significant levels of public and workplace charging entities opt in to the program.

270. Comment: **LCFS 40-62**

The comment raises concerns about the validity of applying the metered BEV and PHEVs data to that of the unmetered fleet.

Agency Response: See response to **LCFS 40-59**.

271. Comment: **LCFS 40-63**

The comment raises concerns about "double counting" of credits, especially in the public sector and the work place.

Agency Response: See the response to **LCFS 40-61**.

272. Comment: **LCFS 40-64**

The comment opposes the removal of report obligations on information such as number of EVs in a service territory and requests adding the reporting obligation to PHEVs.

Agency Response: The current LCFS regulation requires regulated parties for residential and public EV charging to include public accounting of the number of credits generated, sold, and banked in annual compliance reporting. Public credit accounting is not required for regulated parties of other fuels. Staff proposed to remove the requirement of public credit accounting to make the reporting requirements consistent among regulated parties. Since the most important information included in the public credit accounting is already covered in the annual compliance reporting of electricity providers, removing this requirement would not erode credit validity.

In 15-day change of the regulation, staff proposed to add the entire estimation method, including the determination of the number of non-directly metered residential PEV, into the LCFS regulation language, which is subject to public comment. Staff further proposed in the 15-day change that ARB shall calculate the generated credits for estimated electricity use in each utility's service area based on best available data that are relevant to the calculations.

Please also see response to **LCFS 40-59**.

273. Comment: **LCFS 40-65**

The comment expresses concerns about allowing off-road electric applications to generate credit and questions the sufficiency of data for allowing EER values for electric buses.

Agency Response: See response to **LCFS 40-53.**

The proposed EERs for electric buses are based on the testing data of 2 electric buses: Proterra Electric Bus Model BE-35, and BYD Motors Electric Bus. The testing was conducted between 2011 and 2012. The 2 models are actually operated in California now. Therefore it is reasonable to apply the EER to existing electric buses.

274. Comment: **LCFS 40-66**

The comment expresses concerns about allowing off-road electric applications to generate credit and questions the sufficiency of data for allowing EER values for electric buses.

Agency Response: See response to **LCFS 40-65**.

275. Comment: **LCFS 40-67**

The comment requests information on the derivation of CI for CaRFG.

Agency Response: In the past the CI of California Reformulated Gasoline (CaRFG) was not included in the regulation because regulated parties report volumes of California Reformulated Gasoline Blendstocks for Oxygenate Blending (CARBOB) and denatured ethanol that make up CaRFG. Credits and deficits are calculated on the basis of those component fuels, rather than the blend.

Calculation of the "effective" CI of CaRFG is possible through the CA-GREET2.0 model (incorporated by reference into the regulation and fully documented through Appendix C of the Initial Statement of Reasons). To further assist stakeholders on this issue staff released the California Reformulated Gasoline and Ethanol Denaturant Calculator (XLS) which walks through this calculation in a more straightforward fashion.

Further, in response to this comment staff included CaRFG values as a footnote to Table 1 in §95484(b) of the regulation.

276. Comment: **LCFS 40-68**

The comment raises several concerns about the Credit Clearance Market proposal such as complexity and infeasibility of the regulation, and how the $200 credit ceiling is developed. The comment also recommends some revisions.

Agency Response: See response **LCFS 40-15** to **40-17**.

Staff analyzed a range of possible repayment schedules for accumulated deficit accounts. That analysis indicates that a 5% annual interest rate balances concerns that the interest rate be both sufficiently high to incent timely repayment of accumulated deficits when the market is fully supplied and sufficiently low so that it is not punitive.

The price cap is proposed to be set at $200 / credit in 2016 and increase at the rate of inflation in subsequent years. Staff analysis of the price cap indicates that $200/ton is high enough to provide a sufficient value added to stimulate the investments in and production of low-CI fuels, and sufficiently high to attract these fuels to California if they are produced elsewhere. The proposed price cap is anticipated to result in multiple, ancillary market benefits, including reduced price uncertainty, and reduced regulatory uncertainty. Reducing both these sources of uncertainty is anticipated to increase the incentives for investment. Potential investors may be hesitant to invest in low-CI fuel production facilities given conditions of undue uncertainty, particularly because production facilities for low-CI fuels are typically capital-intensive projects with relatively long payback periods.

ARB staff agrees with the commenter's suggestion to add clarifying text to Section 95485(c)(3)(E)(5) of the proposed regulation and proposed in a 15-day change the following addition:

> Section 95485(c)(3)(E)(5)
> Regulated parties that have pledged credits to sell into the Clearance Market cannot reject an offer to purchase pledged

credits at the Maximum Price, provided they have not sold or contractually agreed to sell the pledged credit(s).

277. Comment: **LCFS 40-69**

The comment opposes the removal of the Deficit Carryover provisions and recommends changes to the proposed regulatory language. The commenter also opposes this requirement and states that LCFS credit balance and individual entity names should be treated as confidential because the information could adversely impact business operations

Agency Response: Regarding the deficit carryover provision, see response to **LCFS 40-21**.

Section 95485(c)(4)(B) of the proposed regulation specifies that the Executive Officer will, on or before June 1, post:

- The name of each party that did not meet the requirements of section 95485(a) and the number of credits that each party is obligated to acquire as their pro rata share; and

- The name of each party that has pledged to provide credits for sale in the credit clearance market and the number of credits that each party has agreed to provide.

Publishing the names of regulated parties and their pro-rata share of the credit obligation does not provide the public or competitors with the full position information of regulated parties. The information specified in Section 95485(c)(4)(B) is not sufficient information for the public or competitors to infer an individual entities' compliance strategy and will not compromise a regulated parties' competitive position. Publishing this information ensures that the clearance market functions smoothly by providing the requisite information for regulated parties to conduct transactions, but protects confidentiality by not releasing additional information beyond the minimum information required to conduct transactions in the Clearance Market.

The commenter's rationale for these concerns is that a regulated party may be unable to purchase their pro-rata share of credits in the clearance market, but the Clearance Market is specifically designed to prevent this from occurring by setting the number of credits pledged for sale exactly equal to the total amount of credits that are required to be purchased (i.e., the sum of all pro-rata obligations equals the sum of all credits pledged for sale). As regulated parties are prohibited from purchasing more than their pro-rata share of credits through the Clearance Market, this ensures that regulated parties will have certainty regarding both the availability of credits and the maximum price of credits offered in the Clearance Market.

Given the deliberate structure of the Clearance Market, it is unclear what type of situation would prevent a regulated party acting in good faith from being able to purchase their pro-rata share of credits offered in the clearance market. Nonetheless, even if a regulated party is unable to purchase their pro-rata share of credits through the Clearance Market, there are no clear reasons why ARB providing information regarding a regulated party's pro-rata share would cause regulated parties' to withhold offering their credits for sale during the subsequent year, or to withholding credits until the Clearance Market, as the comment suggests:

- In a year of shortage, demand outpacing supply of credits is likely to result in a credit price that is at or very near that year's price cap. Low-CI fuel producers with excess credits will have incentive to sell as many credits as possible because: (1) they will benefit from increased revenues from selling credits at or near the maximum price; and (2) the price cap is constant in real terms, so low-CI fuel producers' have no incentive to withhold credits to try and sell in subsequent years at a higher price.
- In a year of sufficient supply, low-CI fuel producers with excess credits will have incentive to sell as many credits as possible during the course of normal market operations because it is unlikely that a Clearance Market will occur that year. If the market is fully supplied, there is little rationale for a low-CI fuel producer to withhold their credits for sale, waiting for a Clearance Market that is unlikely to occur.

278. Comment: **LCFS 40-70**

The commenter requests written guidance confirming their understanding of the details of the provision which prohibits transferring/selling credits to another party when they have a deficit themselves.

Agency Response: The prohibition of trading credits does not negate the ability of affected parties for transferring credit generating fuels, by transferring the LCFS obligation at the time title to the fuel is transferred. However, once credits have been separated from a fuel, those credits cannot be transferred so long as the affected party has an outstanding deficit balance.

279. Comment: **LCFS 40-71**

The comment proposes allowing 30 days instead of 15 to record in the LRT-CBTS transactions made during Extended Credit Acquisition Period.

Agency Response: ARB staff disagrees with the proposed change to a 30-day period. Recording transactions promptly in the LRT-CBTS facilitates administration of the program and efficient function of the market for credits. 30 days is not necessary. ARB is not persuaded by commenter's point that an earlier LCFS allowed a lengthy period. Prompt reporting could eventually support more frequent posting by ARB of credit trades to facilitate price transparency. In a 15-day change, trades are required to be completed in 10 days.

280. Comment: **LCFS 40-72**

The comment recommends changes to Section 95486(a)(4)(B)(2).

Agency Response: ARB staff agrees with the commenter and recognizes that regulated parties may not meet their compliance targets for a specified year and therefore would need to retire all credits available to them; this includes any credits that would be available through the credit carry back process. Staff has included a revision that would allow a party to use carryback credits to meet a portion of its compliance shortfall so long as the party minimizes its shortfall by also retiring all credits it possess that are eligible for use in the prior compliance year.

281. Comment: **LCFS 40-73**

The comment proposes changes to the Credit Generation Frequency.

Agency Response: ARB staff disagrees with the recommendation, as regulated parties will have two 45-day periods to submit an accurate quarterly report that aligns with their business partner. The first 45-day reporting period will allow regulated parties to enter their information into the reporting tool while the second 45-day period will allow a regulated party and their business partner(s) to correct any errors in fuel pathway codes, volumes or other information, which was not properly passed along in the product transfer document.

282. Comment: **LCFS 40-74**

The comment requests that ARB include a contingency plan for initiating and completing credit transfers.

Agency Response: ARB staff understands that there is always the concern if an electronic tool goes down for any extended period. Staff already has an old system of credit transfers that was used prior to the development of the LRT-CBTS. Therefore, if the tool were to be under maintenance for longer than a seventy-two hour period, staff could send out a notice and release the manual documentation necessary to complete a trade, which can then be entered into the system at a later date.

283. Comment: **LCFS 40-75**

The comment proposes a sunset date of one year after the regulation effective day for all fuel pathways.

Agency Response: The proposal was modified consistent with the commenter's recommendation.

ARB staff concurs that re-certification should not necessitate re-submission of physical transport mode application material if transport modes and distances have not changed. Provisions that will make this unnecessary were included in the 15-day change package that will go to the Board for approval.

284. Comment: **LCFS 40-76**

The comment states that ARB should include a reference to the denaturant calculator spreadsheet in the regulation.

Agency Response: It is not necessary to include a reference to the denaturant calculator spreadsheet in the regulation. The calculator merely duplicates calculations that are present in CA-GREET-2.0. These calculations were placed into a separate spreadsheet for the convenience of stakeholders.

285. Comment: **LCFS 40-77**

The comment recommends changes to the corn ethanol iLUC value.

Agency Response: The corn indirect land use change (iLUC) value is a topic under consideration of the LCFS and has been revised under the proposed regulation.

286. Comment: **LCFS 40-78**

The comment asserts that the content of denatured ethanol is not characterized based on industry practice.

Agency Response: See response to **LCFS 8-12**.

287. Comment: **LCFS 40-79**

The comment recommends that ARB change the term “regulated parties” in section 95488(c) (6)(A) to “fuel producers.”

Agency Response: The LCFS regulation states:

> LCFS CIs represent the life cycle greenhouse gas emissions, expressed in a per-megajoule of finished-fuel-energy basis, associated with long-term, steady-state fuel production operations. Actual CIs vary over time due to a variety of factors, including but not limited to seasonality, feedstock properties, plant maintenance, and unplanned interruptions and shutdowns. A fuel production operation will not be found to be in violation of its operating conditions unless a CI calculated from production data covering a full year of operations is higher than the certified CI reported for that fuel in the LRT-CBTS system. Fuel producers labeling fuel sold in California with LCFS CIs (in product transfer or similar documents), and regulated parties reporting those CIs in the LRT-CBTS system, must ensure, therefore, that the fuel so labeled and so reported will be found to have a life cycle CI, as calculated from production data covering a year of operations, that is equal to or less than the CIs reported in the LRT-CBTS system and on product transfer documents. Regulated parties shall not report fuel sales under any LCFS CI unless they have determined that the actual CI of that fuel, calculated as described in this section, is equal to or less than the LCFS CI under which sales of that fuel are reported in the LRT-CBTS system. (95488(c)(6)(A))

ARB rejects commenter’s suggestion, because it would significantly diminish the regulation’s enforceability. In many instances only the regulated party reports information to ARB, and the regulated party might be the sole cause of a reporting error. In other instances, a regulated party might report incorrect information provided to that party by a fuel producer, as where the regulated party did not verify the information's accuracy. Finally, there may be instances where it can be said that the fuel producer was solely responsible. In any of the above examples, ARB staff will attempt to take enforcement action against the party primarily responsible for the violation. Regulated parties reporting fuel transactions are nonetheless liable if the CIs they report do not comply with this section. With more parties potentially liable for incorrect information, ARB expects that the accuracy of reports will be improved.

288. Comment: **LCFS 40-80**

The comment opposes the re-submittal of initial or updated demonstrations of fuel transport modes to ARB.

Agency Response: Staff agrees with the commenter and made a change during the 15-day comment period so that if the applicant has previously submitted the physical transport mode information, and there are no changes to the fuel transport mode, there is no need for re-submittal of fuel transport mode information. In addition, ARB staff provides flexibility on the submission of out-of-state fuel transport mode by offering two application options: 1) CA-GREET user default, and 2) use of alternative bill of lading for new fuel pathways. In all such cases, staff will continue to work with the stakeholders on a case-by-case basis, upon request, during the application evaluation process.

289. Comment: **LCFS 40-81**

The comment requests that ARB identify the contributions of changes in the GTAP model and emission factors to changes in iLUC values.

Agency Response: See response to **LCFS 38-30**.

290. Comment: **LCFS 40-82**

The comment questions the removal of ILUC values in the regulation.

Agency Response: In response to this comment, and similar concerns from other stakeholders, a table of the iLUC values was added to the regulation in the 15-day changes.

291. Comment: **LCFS 40-83**

The comment raises questions about how the iLUC emission is calculated for sugarcane ethanol.

Agency Response: See response to **LCFS 38-31**.

292. Comment: **LCFS 40-84**

The comment asks why the means of the Monte Carlo simulations were not used for establishing the iLUC values.

Agency Response: See response to **LCFS 38-32**.

293. Comment: **LCFS 40-85**

The comment questions the use of cropland pasture elasticity to account for endogenous yield adjustments.

Agency Response: See response to **LCFS 38-33**.

294. Comment: **LCFS 40-86**

The comment raises questions about formalizing an iLUC value for cellulosic ethanol.

Agency Response: See response to **LCFS 38-34**.

295. Comment: **LCFS 40-87**

The commenter argues that the degree of crude differentiation within the LCFS should be significantly reduced.

Agency Response: See response to **LCFS 32-10**.

296. Comment: **LCFS 40-88**

The commenter agrees with staff's decision not to propose refinery-specific incremental deficit accounting for large, complex refineries and looks forward to working with ARB on a less complex alternative to crude differentiation.

Agency Response: ARB staff appreciates the commenter's support of our decision not to recommend refinery-specific incremental deficit accounting. Staff remains open to further constructive dialogue on issues of concern to stakeholders.

297. Comment: **LCFS 40-89**

The commenter expresses concerns about the proposed changes to the calculation of the Annual Crude Average CI value.

Agency Response: See response to **LCFS 38-15**.

298. Comment: **LCFS 40-90**

The comment includes two recommendations for modeling of crudes with OPGEE.

Agency Response:

1. *Revise OPGEE using more realistic input values such as for steam generator feed water temperature*.

   See response to **LCFS 38-24**. ARB staff looks forward to working with and receiving data from the commenter to improve the default parameters used in OPGEE as part of future revision cycles.

2. *ARB should pursue collecting the same composition, quality, and environmental profile data for other domestic and imported crudes as is available for California produced crude*.

   See response for **LCFS 37-3**.

299. Comment: **LCFS 40-91**

The commenter recommends that ARB be required to calculate and post quarterly Crude Average CI values.

Agency Response: ARB staff disagrees with this recommendation for mandatory quarterly calculation of crude average CI values as staff believes that the use of the three-year rolling average provides sufficient information for compliance planning and execution. However, staff agreed in 2014 to provide a mid-year, non-regulatory estimate of the crude average CI for the first six months of the compliance period (see http://www.arb.ca.gov/fuels/lcfs/crude-oil/mid-2014-crude-ave-ci.pdf). Staff intends to continue providing this calculation as a service to regulated parties, but do not believe it should be required by the regulation as this mid-year crude average carbon intensity estimate is posted for informational purposes only and provides no regulatory function.

300. Comment: **LCFS 40-92**

The comment suggests all LCFS regulatory revisions should occur no more frequent than once every 5 years and specifically proposes that the frequency of overall revisions to Table 8 or the OPGEE model to be less than every 5 years.

Agency Response: This comment seems at odds with the request to have staff reports to the Board on an annual basis (see **LCFS 40-4**). What would be the purpose of annual reviews of the rule if no changes were ever made? Regardless, the prior changes made to the LCFS regulation have been necessary to ensure a robust market and provide improved program functionality. Further, the historic credit price has been well within expected levels.[11]

As we move forward, we will continue working to refine emission estimates and continue to analyze relevant scientific studies and make appropriate adjustments in the future if deemed necessary. Updating OPGEE and Table 8 on a three-year cycle rather than annually will provide more certainty to refineries for crude purchases as well as allow limited staff resources to be redirected to other LCFS tasks. Updating no more frequently than every three years is consistent with the recordkeeping provisions, and allows for the production of new fuels to be added to the table more frequently than the commenter's proposal of five years, providing up-to-date production information for existing and new fuels to ensure the proper CI values are being used in the market.

301. Comment: **LCFS 40-93**

The commenter expresses support for the revisions to the innovative crude provision.

Agency Response: ARB staff appreciates the commenter's support for the revisions proposed for the innovative crude provision.

[11] From 2012 through 2013, while the LCFS standards for gasoline and diesel were declining, the average credit price reported in the LCFS Reporting Tool (LRT) was $57.70. Weighted average of quarterly LCFS credit prices reported through the LRT available at: http://www.arb.ca.gov/fuels/lcfs/lrtmonthlycreditreports.htm

302. Comment: **LCFS 40-94**

The commenter disagrees with staff's proposal to limit CCS as an innovative crude method to only those instances where the carbon capture occurs onsite at the oil production facility.

Agency Response: See response to **LCFS 37-12**.

303. Comment: **LCFS 40-95**

The commenter objects to staff's proposal to require that CCS projects comply with a Board-approved quantification methodology to qualify for innovative crude production method credit.

Agency Response: ARB staff disagrees with the objection and believes that it is wholly reasonable that a quantification methodology establishing requirements for approving wide ranging and complex carbon capture and storage (CCS) projects under both the Cap-and-Trade and LCFS programs should require a full regulatory process and Board approval. Additionally, the Board approval is already a requirement for the CCS quantification methodology under the Cap-and-Trade Regulation.

Once the CCS quantification methodology is approved by the Board, approval of individual CCS projects under the innovative method provision will occur through the Executive Officer approval process described in the regulation, as long as the project meets the requirements of the quantification methodology.

304. Comment: **LCFS 40-96**

The commenter recommends that the quantification methodology for CCS projects be expedited and only require Executive Officer approval and not the entire Board.

Agency Response: See response to **LCFS 40-95**.

305. Comment: **LCFS 40-97**

This comment includes three objections/recommendations for the innovative crude provision.

Agency Response:

1. *“The proposal should include an option for Crude Production companies to apply for this credit for other GHG reduction projects above and beyond the four envisioned by ARB and included in the regulations. There are other technologies (e.g., solvent extraction) that may result in reduced energy usage and/or GHG from crude oil production. Limiting credits to solar and wind eliminates credits for other renewable energy, such as land fill gas, tidal power, etc*.”

   See response to **LCFS 38-37**. ARB staff believes that fully evaluating a proposed innovative method for inclusion in the regulation requires a deliberate process involving one or more workshops and discussions with stakeholders. Although ARB does not yet have sufficient information on which to evaluate those additional innovative technologies, staff will consider each of these in the next regulatory amendment process.

2. *“We feel the use of renewable electricity transmitted through an electricity grid should be eligible for this credit.*”

   It is our understanding that the commenter is suggesting that the crude producer be able to indirectly purchase offsite renewable electricity that is supplied to a utility distribution system rather than directly consuming the renewably-generated electricity at time of production. Purchase of renewable electricity could be verified and tracked through the generation, transfer, and retirement of renewable energy certificates or RECs. ARB staff has concluded that use of grid electricity together with RECs should not be used to reduce the CI of process electricity under the LCFS or qualify for innovative method credit. The reasons include the following:

   a. RECs are designed to reflect changes in the electricity sector, whereas LCFS is designed to change the transportation sector.

   b. If approved for use, RECs would reduce the CI of the crude and earn innovative credit without in any way changing the pathway itself. Moreover, available RECs can cover generation that occurred many months in the past, at some distance from California, or both. The innovative crude provision is designed to incent CI-reducing innovations in actual crude production pathways. Requiring that the renewable electricity be directly consumed by the crude oil producer at time of production provides a direct link between the crude production and the renewable electricity generation.

c. RECs are tracked in a number of regional systems. The largest and most mature is the Western Renewable Energy Generation Information System (WREGIS), but several others are also in operation. If WREGIS RECs were approved for use in LCFS pathways, requests to use RECs from the other regional tracking systems could be expected. Although these various exchanges have much in common, there are likely important differences that would have to be understood.

ARB staff believes that significant potential exists for renewable electricity generation at or near crude oil production facilities and requiring direct supply of renewably generated electricity does not impose an unreasonable barrier to development and use of this innovative method. Moreover, requiring direct supply of renewably generated electricity helps to ensure that the project was specifically developed for reducing emissions from crude oil production, and therefore represents additional GHG emissions reductions directly attributable to the LCFS program.

3. *"We oppose the requirement that third parties providing either innovative steam or electricity must be co-applicants, especially given that co-applicants are not able to generate credits under the proposal. Any recordkeeping or regulatory requirement would be more appropriately managed through contractual language between third party providers and crude producers*."

ARB staff disagrees with the comment and the recommendation allowing application and recordkeeping to be managed exclusively through contractual language between the third party and the crude producer. Because much of the application and recordkeeping requirements for innovative projects that involve third parties (e.g., producers of steam or electricity or receivers of CO_2) is under the jurisdiction of the third party and not the crude producer, staff believes that the third party should be a co-applicant in order for ARB to have direct regulatory access to the third party.

306. Comment: **LCFS 40-98**

The commenter opposes the LC/LE Refinery provisions.

Agency Response: See response to **LCFS 38-35.**

307. Comment: **LCFS 40-99**

The commenter objects to the refinery-specific incremental deficit option for low-complexity/low-energy-use refineries.

Agency Response: ARB staff disagrees with the commenter's objection. Staff's rationale for including the provision is discussed on pages II-15 and II-16 of the ISOR. Moreover, the inclusion of the refinery-specific option does not affect the California Average provision for the large refineries that the commenter represents. See also the response to **LCFS 32-10**.

308. Comment: **LCFS 40-100**

The commenter expresses several concerns regarding the option for refinery-specific incremental deficit accounting for low complexity, low energy use refineries.

Agency Response: See response to **LCFS 32-10**.

Furthermore, ARB staff see no logical reason why "allowing some refiners to opt-out of the industry-wide average approach creates a bifurcated market and introduces the potential for fraud given the chain of custody for crude and feed stocks is immensely complex and there is no uniform, verifiable certification scheme." The refinery-specific option requires more onerous field-level crude reporting and does not affect the calculation of incremental deficits under the California Average provision.

While staff acknowledges the commenter's objection that the refinery-specific accounting "could reward a refinery for past high CI crude use while penalizing a refinery with historically low CI crudes", staff believes this objection is primarily germane to a refinery-specific accounting scheme that is mandatory for all refineries. Staff disagrees that this presents a significant issue for an optional program that is only available to a limited number of small refineries. Any of the qualifying refineries that believe the refinery-specific accounting would be "penalizing" in any way can simply remain under the California Average provision.

309. Comment: **LCFS 40-101**

The commenter believes the definition of "LE refineries" should be based on the lifecycle carbon intensity of the transportation fuels produced. A LC/LE refiner that uses more energy per gallon of transportation fuel ***produced from crude oil*** [emphasis in original comment] should not be granted special treatment.

Agency Response: Staff was directed by the Board to consider the lower energy inherently embedded into the transportation fuels from refineries that use simple processes to refine transportation fuel. See response to **LCFS 38-35**.

310. Comment: **LCFS 40-102**

The comment states that it is not clear from the ISOR how ARB calculated the LC/LE refiners transportation fuel CI.

Agency Response: ARB staff calculated the carbon intensity of CARBOB and diesel refining from all California refineries using Mandatory Reporting Requirement (MRR) data. Staff then compared the average CARBOB and diesel carbon intensities of complex refineries to those of the LC/LE refineries and found the difference to be about 5 gCO2e/MJ. This calculation was outlined the ISOR and in three workshops: April 18, 2014, July 10, 2014, and September 29, 2014.

311. Comment: **LCFS 40-103**

The comment states that it is not clear if the calculation of LC/LE overall CI includes the transportation fuels produced from all feedstocks to the LC/LE refineries or just the transportation fuels produced from crude oil. If the overall CI used to calculate the 5 gCO_2e/MJ "adjustment" includes the processing of feedstocks other than crude oil, the commenter believes ARB staff should modify the adjustment to only take into account the transportation fuels produced from crude oil.

Agency Response: As outlined in the ISOR, the calculation of LC/LE overall CI does include fuels produced from all feedstocks. There is language in the LC/LE provision that assigns additional deficits for fuels made from sources other than crude oil.

312. Comment: **LCFS 40-104**

The comment requests ARB staff include a methodology for calculation of the volumes of CARBOB, diesel, and transmix in the regulation.

Agency Response: Under section 95483(e)(4)(B) of the regulation states the LC/LE credit is given only to CARBOB and diesel fuel produced from crude oil. As part of the LC/LE provision all applicants must report their volumes of CARBOB and diesel fuel produced from crude, transmix, Petroleum Intermediates, and purchased CARBOB and diesel fuel for blending.

313. Comment: **LCFS 40-105**

The commenter requests that the regulatory language should indicate that the sale and/or trade of any credits generated under the Low Complexity-Low Energy Use Refinery provisions are prohibited.

Agency Response: This language was inadvertently omitted. ARB staff has added 15-day language that prevents the credits from being sold or traded.

314. Comment: **LCFS 40-106**

The comment identifies a typographical error and suggests that 95481(a)(57) should be 95481(a)(55)

Agency Response: This change has been made in the 15-day language.

315. Comment: **LCFS 40-107**

The comment suggest that in 95489(e)(2)(c) intermediate feedstocks should be Petroleum Intermediate feedstocks.

Agency Response: This change has been made in the 15-day language.

316. Comment: **LCFS 40-108**

The comment requests a formatting change.

Agency Response: ARB staff does not see any need for a formatting change in the refinery-specific incremental deficit calculations as staff sees no confusion between subscripts and superscripts in the equations

317. Comment: **LCFS 40-109**

The comment proposes five modifications of the Refinery Investment Provision.

Agency Response:

1) *Limiting onsite increases of criteria air pollutants and toxics unreasonably excludes offsets of criteria and air toxic pollutants.*

See response to **LCFS 38-9.**

2) *The 0.1 gCO_2e/MJ threshold is too stringent and unfairly penalizes larger, more efficient refineries.*

See response to **LCFS 38-10.**

3) *Investments should not be limited to capital or onsite projects.*

See response to **LCFS 38-11**.

4) *The eligibility cutoff date does not recognize improvements made since program adoption*.

See response to **LCFS 38-12**.

5) *The biofeedstock 10% threshold is too restrictive and unfairly penalizes larger, more efficient refineries.*

See response to **LCFS 38-13**.

318. Comment: **LCFS 40-110**

WSPA asks that ARB eliminate the requirement to address criteria pollutant or toxic emissions.

Agency Response: See response to **LCFS 38-9**.

319. Comment: **LCFS 40-111**

The comment asserts that the CI reduction threshold (0.1 gCO_2e/MJ) will unnecessarily eliminate legitimate projects.

Agency Response: See response to **LCFS 38-7** and **LCFS 38-10**.

320. Comment: **LCFS 40-112**

The comment asserts that limitations on project type in the Refinery Investment Credit Provision will eliminate valuable GHG reducing projects

Agency Response: See response to **LCFS 38-11**.

321. Comment: **LCFS 40-113**

The commenter requests that the project eligibility for the Refinery Investment Credit Provision should extend to early actors and new construction.

Agency Response: See response to **LCFS 38-12**.

322. Comment: **LCFS 40-114**

The commenter requests that ARB staff reconsider and remove the proposed 10% biofeedstock threshold as it is inequitable.

Agency Response: See response to **LCFS 38-13**.

323. Comment: **LCFS 40-115**

The commenter recommends that ARB change the denominator in the term, "T = percentage of transportation fuel produced" *from* "total volume of product output…" to the "total volume of crude oil and intermediates supplied to the refinery (bbl).

Agency Response: ARB staff has made a 15-day change to clarify that "$Volume^{Total}$" is the total output of transportation fuels in barrels.

324. Comment: **LCFS 40-116**

The commenter requests that ARB staff provide a comparison of the 10% level to the 0.1g/MJ threshold for other projects. The 10% threshold seems to be a high threshold that will not help encourage such projects.

Agency Response: See response to **LCFS 38-13**.

325. Comment: **LCFS 40-117**

The comment suggests that ARB consider an option for CI reduction credits to be allocated more specifically to the units and products to which they apply (versus overall for the refinery).

Agency Response: ARB staff will consider examining this for the future, but this change would require more analysis and would not be appropriate as a 15-day change. ARB staff did not want to see this provision result in increases elsewhere in the refinery. Any change would need to account for the linked aspect of refinery processes and ensure the project truly reduce GHGs at the refinery as a whole.

326. Comment: **LCFS 40-118**

The comment does not agree that unclear transmission of information on product transfer documents is a key cause of discrepancies.

Agency Response: See response to **LCFS 38-39**.

327. Comment: **LCFS 40-119**

The comment objects to the change proposed that would change the definition of Product Transfer Document (PTD) to refer to a newly created, single document rather than a collection of documents that transmit the required information.

Agency Response: See response to **LCFS 38-39**.

328. Comment: **LCFS 40-120**

The comment expresses concerns about the practicality and fairness of requiring the original transferor of fuel sold without obligation to report any export of that fuel by any subsequent owner or supplier.

Agency Response: See response to **LCFS 38-40**.

329. Comment: **LCFS 40-121**

The comment states that the production facility ID and the Company should not be included in all transaction documents.

Agency Response: Having the Company ID and Facility ID included with each reported transaction where an alternative fuel (e.g., biofuel) is involved is necessary for effective auditing. For example, reporting of Facility ID and volumes would allow ARB staff to detect fraudulent reports totaling 50 million gallons in a given year from Facility X, when Facility X is in fact capable of producing only 20 million gallons per year. Knowing the production facility is also the best way to substantiate the carbon intensity (CI) and volumes of the alternative fuel volumes reported.

Alternative fuel providers maintain Company ID and Facility ID information as part of their business management systems, where it is also available for LCFS reporting. Incorporation of these ID's is readily transferrable to downstream parties via the Product Transfer Document (PTD). It is apparent to ARB staff that the Company ID and Facility ID information is available and can readily remain associated with multiple fuel volume transactions during downstream fuel transactions. The Company ID and Facility ID information is currently being reported in the LCFS Reporting Tool and Credit Bank & Transfer System (LRT-CBTS) as part of fuel transaction reporting in the vast majority of reported transactions (>92 percent) and in 100 percent of all fuel transactions reported by greater than 75 percent of regulated parties.

330. Comment: **LCFS 40-122**

The commenter believes that entities should be able to make changes to the quarterly reports with (*sic*) enforcement penalties, provided the corrections do not materially impact a credit transaction relying on the information submitted in the quarterly report.

Agency Response: ARB staff disagrees. The commenter prefers a reporting-based regulation where its members do not face any liability for misreporting in certain circumstances. Experience at ARB and in regulatory programs elsewhere indicates that complete immunity does little or nothing to deter violations, whether they are caused by accident, neglect or intent; errors are preventable. The crux of the comment goes to how ARB should exercise enforcement discretion based on different circumstances, and the commenter proposes a reasonable distinction between material errors and non-substantive errors. ARB staff has, and regularly employs, discretion to distinguish between such different circumstances in deciding whether to initiate enforcement and if so, what remedy to seek; indeed the regulation at section 95494(a) expressly incorporates specified factors for consideration.

Nevertheless, attempting to codify and completely immunize specified circumstances that sound harmless in the abstract is impossible due to the infinite variety of fact patterns. For example, reporting errors that have "no impact on credit balance" – a category for which the commenter suggests favorable treatment – could in some instances create serious impediments to the overall program's operation. If parties transacting volumes of fuel that collectively generated significant credits or deficits could report the wrong information or simply submit correct information late, significant manipulation or unintended credit market impacts could occur, even if ultimately the reports were corrected or submitted with "no impact" on the party's credit balance.

331. Comment: **LCFS 40-123**

The comment is concerned that the January 1, 2019 date for regulation review and a presentation to the Board is too late to effect change in the program.

Agency Response: ARB staff believes that the review gap is appropriate to maintain stability in the program. Staff will monitor and make public the credit transactions and prices and will report back on volumes. ARB staff has the ability to go back to the board sooner if concern develops.

332. Comment: **LCFS 40-124**

The comment expresses concern that there is a substantial gap in time between the recent January 1, 2015 review and the January 1, 2019 review.

Agency Response: See response to **LCFS 40-123**.

333. Comment: **LCFS 40-125**

The comment requests reinstatement of the items that have been proposed for removal from the review list.

Agency Response: Staff anticipates these topics being considered in the program review conducted prior to January 1, 2019 but does not believe it's necessary to call out all of the items in the rule as the commenter requests. In fact, the request for annual review of some of these items (i.e., advances in fuel lifecycle assessments) seems to conflict with comment **LCFS 40-92,** which indicates frequent changes to CI values (e.g., crude CIs in Table 8) would result in increased LCFS credit prices, compliance issues and difficulty in meeting the goals of the LCFS program and should occur no more frequently than once every five years. See response to **LCFS 38-1**, **LCFS 40-92**, and **LCFS 40-123**.

334. Comment: **LCFS 40-126**

The comment requests the ARB Board to ask staff to revise the regulation to include the review items that were removed.

Agency Response: See response to **LCFS 40-125**.

335. Comment: **LCFS 40-127**

The comment requests that the former Periodic Reviews be replaced with annual staff reports to the Board that provide a detailed synopsis of the health of the program, the challenges, and any need for program changes.

Agency Response: See response to **LCFS 38-1** and **LCFS 40-125**.

TESORO

February 17, 2015

Clerk of the Board
Air Resources Board
1001 I Street
Sacramento, CA 95814

Electronic Submittal

RE: CARB Low Carbon Fuel Standard Re-Adoption, February 19th Hearing

Dear Chairwoman Nichols and Honorable Board Members:

Tesoro appreciates the opportunity to comment on the proposed re-adoption of the Low Carbon fuel Standard (LCFS). Tesoro reliably provides a substantial volume of clean gasoline and diesel to the California market and has a tremendous interest in the implementation of the LCFS and its impacts on that reliable fuel supply.

We understand that the Western States Petroleum Association has provided comments on this re-adoption as well. Tesoro supports those comments, but wishes to focus on a few specific aspects of the proposed regulation.

Refinery Investment Credits

Tesoro appreciates the inclusion of Section 95489 (f) – Refinery Investment Credit that will allow a refinery to receive credit for reducing greenhouse gas (GHG) emissions from its facility. We believe such regulatory incentives will lead to overall statewide GHG emission reductions while concurrently lower carbon intensity of California transportation fuels. Fundamentally, such a provision makes good sense in the context of a performance and life cycle based standard. However, we believe the highly complex qualification criteria added to the proposed regulation will make it very difficult or impossible for emission reduction projects to overcome the hurdles and be qualified for the credits. Tesoro recommends the proposed regulation be modified to address the following concerns:

1. The regulation should be cost neutral related to investment.

   The objective of the proposed provision should be to provide sufficient incentives for refineries to implement emission reduction projects regardless of project costs. Innovations can come in many different forms. Some projects may require physical modification, while other projects may simply require a change in refining process or method of operations. The cost of implementing these projects and air quality permits requirements may vary significantly. We suggest the proposed regulation define capital investment project as a

LCFS 41-1

project to improve energy efficiency, or reduce GHG emissions through physical modification, change in refining process or method of operations at a refinery. LCFS 41-1 cont.

2. <u>At a minimum, projects that demonstrate GHG emission reductions or construction beginning on or after January 1, 2015 should be eligible for credits.</u>

During the workshop process, Tesoro advocated that any projects completed since 2010 achieving real, quantifiable and verifiable reductions should be eligible for credits in years following adoption of such a provision. Because 2010 is the baseline year for the LCFS, Tesoro still believes that such projects result in valid credits utilizing the lifecycle approach promoted by the LCFS.

Because CARB has been reluctant to make this change, Tesoro requests that CARB revisit the requirement that eligible projects must not have submitted permit applications prior to January 1st, 2015. Many emission reduction projects requiring air quality permits may take up to two years to permit due to various regulatory requirements. For this reason, refineries may choose to submit applications for authority to construct early in the process concurrent with internal feasibility evaluation to ensure construction can begin on schedule. Without being able to take advantage of refinery investment credits, some of these projects may not be economically feasible, resulting in missed GHG emission reduction opportunities from projects for which application for authority to construct were submitted prior to January 1, 2015. Tesoro suggests a more appropriate demarcation is a project's construction or implementation date commencing on or after January 1, 2015. LCFS 41-2

3. <u>The regulation should address the issue of criteria and toxic air contaminants by ensuring that the projects comply with applicable regulations administered by the local air pollution control agencies.</u>

Regulating criteria pollutants and toxic air pollutants to ensure no significant net increase is complex. Refineries that may implement GHG reductions under this proposed regulation are located in the jurisdictions of four of the largest air pollution control agencies with the most stringent New Source Review (NSR), Prevention of Significant Deterioration (PSD), and Toxic Air Contaminants Regulation. These regulations must meet the no backsliding requirements under state law and most regulations were reviewed and approved by the Air Resources Board as part of the State Implementation Plan (SIP) or other air toxic programs. We believe compliance with applicable regulations administered by these local air pollution control agencies should be adequate qualification for these projects. LCFS 41-3

4. <u>The carbon intensity threshold for investment project should be at 0.05 gCO2e/MJ level or below.</u>

Depending on the size of the refinery and the product outputs, it may require GHG emission reduction project in the range of 30,000 to 70,000 metric tons to achieve 0.1 gCO2e/MJ reduction in carbon intensity. Consider that the threshold for reporting under this regulation is 10,000 metric tons and the threshold for compliance obligation is 25,000 metric tons, Tesoro suggests the project qualification threshold be eliminated or set at a level below 0.05 LCFS 41-4 gCO2e/MJ reduction in carbon intensity. This level or below is a more reasonable level and will provide better incentives for emission reduction projects. LCFS 41-4 cont.

5. Conduct a survey of California refineries to develop a threshold limit for renewable feedstock that is technologically feasible and cost effective.

   We are not aware that the requirement to replace petroleum feedstock with a minimum 10% of renewable feedstock is technically achievable in the current refinery setting. We would like to suggest that ARB conduct a survey of California refineries to establish a minimum level that can be achieved by refineries within the state. At a minimum, the eligibility threshold should be set no higher than a GHG reduction threshold equivalent to the 0.05 gCO2e/MJ suggested in the prior comment. LCFS 41-5

6. Clarify and Correct Equations in the Proposed Regulation.

   In the equation for credits for diesel and CARBOB on page 119, the term $E^{XD}_{Renewable}$ should be replaced with the term $EC^{XD}_{Renewable}$ as defined on page 121. $Volume^{XD}$ should be clearly defined as the volume of certain products reported to ARB under Subpart Y including coke with a specific conversion rate from ton to barrel. LCFS 41-6

Compliance Schedule

CARB's own compliance scenario demonstrates that the LCFS target of a 10% reduction by 2020 is not feasible. Even in the most back-end loaded schedule proposed by CARB, by 2018 the level of banked credits begins to draw down. This means that by 2018 and in the subsequent years, even with ARB's overly optimistic estimates of low CI fuel availability, there are not enough alternative fuels generating credits to offset the deficits generated by ARB's predicted demand for gasoline and diesel. Based on CARB's data, it appears that only a 7% CI reduction is feasible by 2020. The remaining 3% is made up for by credits banked in the early years of the program. While 3% does not sound like much, it constitutes 30% of overall program compliance towards the 2020 goal and amounts to three times as many credits as have been required on an annual basis to date. The program is simply not feasible in the timeframe contemplated by CARB and not sustainable in the years beyond. This fact necessitates a different approach. LCFS 41-7

One solution to this issue is to understand what is feasible without banked credits and set a 2020 target (and intervening years) that is consistent with the availability of the fuel. The quantities of excess credits accumulated to date from over-compliance in the early years of the program should be viewed as providing compliance flexibility to obligated parties when the reduction obligation increases or when unforeseen incidents occur impacting low CI fuel availability. In fact, this could obviate the need for the Cost Containment Measure CARB has proposed in the amendments.

Coupled with a more feasible compliance schedule, CARB staff should annually review the status of alternative fuel developments, along with all the underlying assumptions to that compliance schedule and provide a report to the board. This way, the board can more frequently assess the volumes of alternative fuels and related credits compared to the projections that were relied upon in setting the schedule and then provide direction to staff regarding program and schedule changes. LCFS 41-7 cont.

Cost Containment Mechanism

Tesoro wants to emphasize that a cost containment mechanism, no matter how well designed, is not a substitute for ensuring a feasible compliance path in the regulation (as discussed above). Such mechanisms have their place to deal with short-term, unforeseen circumstances that can adversely impact fuel availability on consumer cost. With this in mind, Tesoro requests that CARB study the pros and cons of allowing obligated parties in the LCFS program to cover their reduction obligation with allowances and/or offsets from the Cap & Trade program as an additional cost containment option. LCFS 41-8

Tesoro appreciates the opportunity to submit comments on the draft LCFS regulation. Please contact me at (916) 462-5062 if you have any questions.

Sincerely,

Miles Heller
Director, CA Fuels and Regulatory Affairs

41_OP_LCFS_Tesoro Responses

336. Comment: **LCFS 41-1**

The commenter suggests the proposed regulation define a capital investment project as a project to improve energy efficiency, or reduce GHG emissions through physical modification, change in refining process or method of operations at a refinery.

Agency Response: See response to **LCFS 38-11**.

337. Comment: **LCFS 41-2**

The commenter requests that projects that demonstrate GHG emission reductions or constructions beginning on or after January 1, 2015 should be eligible for credits.

Agency Response: See response to **LCFS 38-12**.

338. Comment: **LCFS 41-3**

The commenter requests that the regulation should address the issue of criteria and toxic air contaminants by ensuring that the projects comply with applicable regulations administered by the local air pollution control agencies.

Agency Response: See response to **LCFS 38-9**.

339. Comment: **LCFS 41-4**

The commenter requests that ARB staff reduce the carbon intensity threshold for investment project to 0.05 gCO_2e/MJ or below.

Agency Response: See response to **LCFS 38-10**.

340. Comment: **LCFS 41-5**

The commenter requests ARB staff conduct a survey of California refineries to develop a threshold limit for renewable feedstock that is technologically feasible and cost effective.

Agency Response: See response to **LCFS 38-13**.

341. Comment: **LCFS 41-6**

The commenter requests that in the equation for credits for diesel and CARBOB on page 119, the term $E^{XD}_{renewable}$ should be replaced with the term $EC^{XD}_{renewable}$ as defined on page 121. They also request that the Volume ^{XD} term should be clearly defined as the volume of certain products reported to ARB under Subpart Y including coke with a specific conversion rate from ton to barrel.

Agency Response: ARB staff made 15-day changes to clarify the equations in section 98489(f) of the proposed regulation.

342. Comment: **LCFS 41-7**

The comment asserts that ARB's own compliance scenario demonstrates that the LCFS target of a 10% reduction by 2020 is not feasible, and requests the regulation be reviewed annually.

Agency Response: ARB staff believes there will be sufficient credits to achieve the required 10 percent reduction in 2020 and at least maintain that level beyond 2020. See response to comment **LCFS 38-1**. For a response to the request for more frequent review of the compliance schedule for the program see the response to comment **LCFS 38-2**.

343. Comment: **LCFS 41-8**

The comment requests that ARB study the pros and cons of allowing obligated parties in the LCFS program to cover their reduction obligation with allowances and/or offsets from the Cap & Trade program as an additional cost containment option.

Agency Response: The suggested consideration could take place as part of the LCFS program review in the event the commenter still sees merit in its ideas. We note, however, that ARB has no current plans to implement the suggestion. The Cap-and-Trade program has different goals than does the LCFS, thus importing credits from Cap-and-Trade will not necessarily help achieve the LCFS' goals. Moreover, LCFS already has cost containment measures both in its market-based design and the new measures denominated as cost containment. Finally, ARB staff's analysis regarding the availability of low-CI fuels indicates that there will be sufficient credits available through 2020 from existing low-CI fuel technologies and promising low-CI fuels on the horizon.

February 17, 2015

Mary Nichols, Chairman
California Air Resources Board
1001 I Street, PO Box 2815
Sacramento, CA 95812

Dear Chairman Nichols and Members of the Board:

Thank you for your commitment to cleaner, healthier air for all Californians and for your international leadership in protecting current and future generations from the impacts of climate pollution. Our organizations appreciate the work of the Board and staff to develop, implement, and defend a key policy measure under AB 32, the Low Carbon Fuel Standard, and respectfully submit these comments for consideration at your February 19 hearing. Also reflected in these comments is our support for the Alternative Diesel Fuels regulation, which is also before you on the 19th. LCFS 42-1

In January, Gov. Jerry Brown outlined a goal for California to cut in half its petroleum use in cars and trucks by 2030. The LCFS is a critical policy measure to allow the state to achieve this new goal. California remains one of the biggest consumers of petroleum nationally; the state used 14.2 billion gallons of gasoline and 3.8 billion gallons of diesel fuel in 2013.[1] Our state's current dependence on petroleum fuels generates nearly half of our climate pollution, 80 percent of smog-forming NOx emissions, and 95 percent of cancer-causing diesel particulates.[2] The state's dependence on oil is dangerous to public health and is a leading contributor to air pollution. Today, unhealthy air causes more than 9,000 premature deaths and tens of thousands of asthma attacks, emergency room visits, and hospitalizations each year in California.[3] By cutting carbon emissions from transportation fuel, the LCFS is an important piece of California's policy response to the environmental and health crisis caused by our dependence on oil. LCFS 42-2

The LCFS is a critical component of AB 32, California's Global Warming Solutions Act of 2006; it represents one of the state's largest greenhouse gas emission reduction measures. As such, it provides LCFS 42-3

the necessary foundation for meeting California's existing health-based air quality and climate goals, and puts the state on a path for meeting its long-term goals with deeper emissions cuts. The program is establishing a direct, long-term regulatory structure to transform our fuel supply in order to: LCFS 42-3 cont.

(1) enable a switch from high-carbon petroleum to ultra-low carbon fuels
(2) ensure continued reductions from all existing fuels, and
(3) protect against crude oil getting even dirtier over time and offsetting progress being made in the transportation sector.

Therefore, the LCFS must remain strong now in order to meet its 10 percent carbon reduction standard in 2020 and be enhanced in the post-2020 time period to ensure that California's 2050 climate goals are met.

1. We strongly support staff's proposal to stay the course on requiring a 10 percent reduction in fuel carbon intensity by 2020.

We strongly support staff's proposal to retain the existing requirement to reduce carbon intensity of diesel and gasoline fuels 10 percent by 2020 and ask the Board to reject long-standing efforts to weaken the standard.

We call on the Board to continue to provide greater regulatory certainty so that the industry stays on track to meet the 10 percent reduction goals. Years of accumulated experience under the LCFS show that the regulated parties continue to make significant progress in achieving the 10 percent in 2020 reduction requirement, with the current requirement being exceeded by nearly 70 percent.[4] More than ever, LCFS regulatory certainty and program stability is needed to support the transition to low-carbon fuels occurring in California and throughout the Pacific Region, where Oregon, Washington, and British Columbia are also working to implement or adopt clean fuel standards.

Furthermore, a growing body of research shows that the oil industry can meet the LCFS targets. A new study conducted by Promotum, a fuels and chemicals consultancy, and commissioned by the Natural Resources Defense Council, the Union of Concerned Scientists, and the Environmental Defense Fund, found that the oil industry can meet the 2020 LCFS standard through known, existing fuels and refinery technologies.[5] (We are also submitting the Promotum study as a separate comment in support of the proposed requirements.) These known strategies include expanding the use of lower-carbon biodiesel and renewable diesel, biomethane, electricity, and ethanol, and improving the carbon intensity of existing alternative fuels. The Promotum study also found that existing oil refineries and crude oil production facilities could dramatically cut their carbon footprint by integrating renewable energy, utilizing innovative technologies, and investing in greater energy efficiency. The Promotum results LCFS 42-4

[4] Air Resources Board (2014), *Low Carbon Fuel Standard Regulation: Initial Statement of Reasons*. December 31, 2014. http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs2015.htm
[5] Promotum. *California's Low Carbon Fuel Standard: Evaluation of the Potential to Meet and Exceed the Standards*, February 2015

complement a body of technical work, including a compliance and economic study by ICF International (2013), and a regional fuel supply study conducted by ICCT and E4Tech (2014).[6] LCFS 42-4 cont.

2. We support additional reductions and urge ARB to look beyond 2020.

Establishing strong signals now for the post-2020 timeframe is consistent with the transformation process outlined in the First Update to the AB 32 Scoping Plan. California's near-term efforts to establish a strong market for clean, low carbon fuels are critical to make sure the state is on the pathway to the deeper reductions needed to meet the 2050 goals.

Moreover, the growing body of scientific evidence indicates this is possible. Industry can meet more stringent standards and there will be enough alternative fuels available to help industry comply. The aforementioned study by Promotum finds California is capable of reaching a 15 percent reduction target for the LCFS by 2025, representing a tripling in the share of alternative fuels in the next 10 years. The study by ICCT and E4Tech finds that available low carbon fuels could grow to replace up to 400,000 barrels of gasoline and diesel use *per day*, reducing the overall carbon intensity of on-road transportation fuels in California and the Pacific Northwest by 14 percent to 21 percent by 2030.[7] LCFS 42-5

Furthermore, we support the concept of having one regulatory review or report back to the Board prior to 2020 to ensure that the regulation is on track and to incorporate any critical updated scientific data, as ARB is doing with the current regulatory update. However, we ask the Board to reaffirm that any review also be used as a process to enhance long-term regulatory certainty and stability, by including as part of the scope (1) a discussion and evaluation of potential post-2020 requirements beyond the 10 percent carbon-intensity reduction, and (2) an assessment of the LCFS's ongoing contribution and future progress toward meeting both AB 32 goals and the Governor's 2030 climate and petroleum reduction goals. LCFS 42-6

3. We support ARB's proposal to credit refinery pollution reduction improvements and innovative technologies.

We have long held that oil companies can also invest to reduce their own carbon emissions directly at their facilities, thereby lowering their own carbon intensity. A study by TetraTech, a technical consultancy, and NRDC (2013) found that implementation of just a handful of technologies could significantly contribute to meeting the goals of the LCFS.[8] This is largely because even small reductions in carbon intensity, across larger volumes of crude oil or petroleum products, can generate significant carbon reductions.

[8] Tetratech and NRDC, *Carbon Reduction Opportunities in the California Petroleum Industry*, October 2013, http://www.nrdc.org/energy/california-petroleum-carbon-reduction.asp

We commend ARB staff for their extensive work and research into the many ways that refineries and crude oil production facilities can reduce their own carbon intensity, and for developing a proposal that allows facilities to obtain LCFS credits for greenhouse gas emissions reductions achieved through their refinery improvement and capital investment projects and through incorporation of renewables. Many of these projects, including solar thermal technologies and energy efficiency at refineries, are expected to have co-benefits in terms of reduced toxics and criteria pollutants. ARB is right to ensure, however, that the additional compliance pathways provided to regulated parties are only for projects that are beyond business-as-usual; that reductions are real and permanent, and verifiable; and that additional co-benefits in terms of reduced toxics and criteria pollutants are maximized. We support ARB staff adopting the above principles as a matter of good policy, and we support ARB's proposal to ensure that that projects represent:

LCFS 42-7

- Actual capital investments or represent increases in renewable energy or feedstock use at refineries. This is to ensure that the program is not rewarding merely shutting down units, rewarding business-as-usual practices, and that actual capital investments or procurement occurs.
- Net carbon-intensity reductions at the refinery. This ensures that only the *net* reductions in carbon intensity at the refinery overall are rewarded (as opposed to only counting emissions from one unit of the refinery). Also, since a carbon-intensity approach is being utilized, the program accounting is robust against annual variations in production (or throughput) at refineries.
- Projects implemented in 2015 or later. Only new refinery carbon-intensity reduction projects, and not past projects that have already been completed, should be rewarded with credits to ensure valuable LCFS credits are not going toward "anyhow" reductions that would have occurred anyways.

Beyond general refinery improvements, ARB appropriately proposes to award credits for innovative technologies that allow crude oil producers to reduce their carbon intensity. A number of technology providers have already expressed interest and have indicated they are attempting to develop projects. The Tetratech/NRDC (2013) study found that existing oil refineries and crude oil production facilities could dramatically cut their carbon footprint by integrating renewable energy inputs, utilizing innovative technologies such as solar thermal, and investing in greater energy efficiency. The study estimated that 3 to 6.6 MMT of CO_2 emission reductions could occur from California facilities alone by 2020, representing 16 percent to 39 percent of the annual requirements that year. We note that the scope of the Tetratech/NRDC study did not incorporate opportunities to replace fossil natural gas at California refineries, which are the single largest industrial user in California.

LCFS 42-8

We note that while many California refineries have publically stated or self-reported that they have pursued all or nearly all cost-effective energy efficiency reduction opportunities, a wide array of literature points to the potential being large and highly dependent on the internal rate of return (IRR) assumed.[9] For example, Booz & Company (2010) estimated that the reduction opportunities at one

[9] Just a few examples include: Kema, Inc., Lawrence Berkeley National Laboratory and Quantum Consulting, *California Industrial Existing Construction Energy Efficiency Potential Study,* for Pacific Gas and Electric Company,

example company increased by more than 3.5 times when going from a high 51 percent IRR to a 14 percent IRR metric for projects. We also note that the carbon reduction value—as monetized by regulatory systems—also greatly affects the cost-effectiveness of projects.[10] In addition, the scopes of both the TetraTech/NRDC (2013) and Promotum (2014) studies only considered a handful of technologies, such that the inclusion of additional technologies utilized by refineries and crude oil producers could result in an even larger reduction potential. LCFS 42-8 cont.

Finally, we applaud the development of the refinery investment provision as a positive incentive to cut greenhouse gases, toxics, and other air pollutants in communities burdened by refinery emissions. While the LCFS is aimed at reducing petroleum consumption, we must also support incentives to clean up local pollution sources and improve community health as the LCFS moves forward. We strongly support ARB precluding refinery investment projects that would cut carbon but increase criteria air pollutants or air toxics from receiving credits. LCFS 42-9

4. We support ARB continuing to account for the carbon intensity of crude oils.

Since its inception, the LCFS has accounted for and protected against potential worsening of petroleum fuels, such as from high carbon-intensity crude oils. We support ARB continuing to ensure the LCFS properly accounts and protects against increases in the carbon-intensity performance of gasoline and diesel above the 2010 baseline, due in particular to increased crude oil production emissions over time. As the modeling work by ARB has shown, the carbon intensity of various crudes can vary as greatly as the carbon intensity of alternative fuels. It makes little sense to ignore those changes from petroleum fuels, which comprise 93 percent of the transportation energy mix, and is consistent with the LCFS program's intent and lifecycle approach. To meet our long-term climate goals, we need to ensure that we simultaneously move to ultra-low carbon fuels *while* preventing current petroleum-based fuels from becoming even dirtier over time. The accounting mechanism for petroleum is a key element of a strong LCFS. LCFS 42-10

5. We support the cost-containment "safety valve" mechanism. The proposed $200/ton cap is reasonable, well-considered, and supported by ample evidence.

Our organizations previously commented that we agree with a broad array of stakeholders that adoption of a well-designed cost-containment mechanism can result in a greater investment certainty and a more robust, resilient program. It can also put to rest extreme cost claims by the oil companies. Some parties, including many serving on the LCFS Advisory Panel in 2011 and the UC Davis Expert Review Panel in 2013, suggested a cost-containment mechanism may provide more price certainty and make the program more resilient in the face of credit price or fuel cost concerns. These suggestions, LCFS 42-11

May 2006.; Worrell, E. and C. Galitsky, *Profile of the Petroleum Refining Industry in California,* Lawrence Berkeley National Lab, LBNL-55450, March 2004; Zhu (2010), "Process Technology: The Key for Industrial Eenrgy/CO_2 Reduction," presentation Petrotech, UOP/Honeywell. McKinsey and Company (2007), "The Untapped Energy Efficiency Opportunity of the U.S. Industrial Sector."

[10] "Profiting from emission reductions in process industries: an oil and gas example," Booz & Company, 2010.

provided both orally and in writing to the agency form a strong record upon which the Board can make a reasoned decision.

At the same time, we noted that a variety of mechanisms built in to the existing regulation, such as credit trading and the life-long use of credits, are already helping ensure market stability in the current program. With new pathways constantly being adopted, additional compliance options provide even more market stability. As asserted in the ARB staff proposal: “The analysis that informed the proposed compliance curves was based on an informed expectation that there will be sufficient credits available through 2020 from existing low-CI fuel technologies and promising low-CI fuels on the horizon.”[11] This statement further supports our belief that a cost-containment mechanism can serve a supporting role, providing even greater market stability.

ARB’s proposed safety valve, a Credit Clearance Market, provides an alternate means to comply with the LCFS in the event that low carbon fuel supplies or pollution reduction opportunities are truly unavailable, or credits exceed $200 per ton in costs. If a regulated party is unable to meet the standard in any year, the provision allows additional time for the company to comply so long as all available credits are purchased during a “clearance period,” with the regulation stipulating the price to be at or below $200/ton. This helps ensure that regulated parties are not sitting on any credits if there is demand for them, the available supply of reductions are truly utilized, and no party would have costs exceeding the ceiling.

LCFS 42-11 cont.

If all available credits at or below $200/ton are utilized, oil companies can make up any shortfalls in emission reductions the following year, for up to five years. To ensure that companies are not simply delaying compliance, there is a 5 percent annual interest applied to any debt. This effectively provides more time to companies, preserves the environmental benefits, and ensures that other companies that invest and fully comply aren’t unfairly penalized by a lower bar provided for others.

ARB has appropriately built in safeguards to ensure that its Credit Clearance Market is transparent, ensures all LCFS credits have been purchased by regulated parties, provides long-term compliance certainty to parties, and stimulates further investment in low-carbon fuels that reduce greenhouse gas emissions.

ARB’s proposed $200/ton cap is reasonable as a “low ceiling” and could even be slightly higher while achieving the above goals. Both the aforementioned Promotum (2015) report and staff ISOR found that compliance to 2020 could be met assuming $100 per credit, providing roughly $1/gallon of gasoline equivalent of incentive for ultra-low carbon fuel providers such as cellulosic ethanol and waste-based biodiesel producers. A $200/ton cap provides a reasonable ceiling in the event of a shortfall of reduction opportunities, equivalent to twice the incentive levels. The staff’s proposal to adjust the price using a Consumer Price Index deflator in all years subsequent to 2016 is well-considered, and ensures that the mechanism keeps pace with inflation and remains at a constant price, in real terms.

[11] ARB December 2014 *Staff Report: Initial Statement of Reasons, Proposed Re-adoption of the Low Carbon Fuel Standard,* Pg ES-4

As noted in past comments, some alternative fuel producers who are interested in starting new low-carbon fuel projects have indicated that a "price floor" would be very valuable to help address uncertainty with the LCFS credit value going forward and would also allow more investors to incorporate the LCFS value when evaluating new projects. We urge ARB to continue working with stakeholders to develop a feasible, implementable, and effective floor option and return to the Board with a floor proposal to complement the cost ceiling mechanism currently being proposed.

LCFS 42-11 cont.

6. We support expanded electric transportation credits.

Our organizations support the expanded role for electrification of transportation in the LCFS. The proposal to allow transit agencies to opt-in to the LCFS for fixed guideway systems (light rail, street cars, trolleys, etc.) encourages cleaner transit that cuts carbon pollution, cleans up neighborhood traffic pollution, and supports sustainable communities as envisioned under Senate Bill 375. We support the provisions to more clearly account for the sustainability benefits of California's growing electric bus fleet. These expanded electric transportation credits provide local air quality benefits, encourage the development of more ultra-low carbon transportation options,[12] and support healthier, sustainable communities.

LCFS 42-12

7. We strongly urge ARB to develop sustainability provisions and independent verification for the LCFS by the end of 2016.

We strongly support the efforts of ARB staff to develop sustainability provisions and an accompanying independent verification process for the LCFS. Both are critical in order to realize the full environmental benefits of the program and for creating a long-term and durable policy that helps avoid negative impacts. Several of the organizations participating in the Sustainability Work Group have recommended that the sustainability provisions establish performance requirements that are equivalent to, if not more stringent than, the standards of the Roundtable on Sustainable Biomaterials (RSB).

Internationally, a large number of biofuel producers, biomass producers, commercial purchasers, government agencies, academics, and NGOs have recognized the need for and value of sustainability certification. Biofuels have tremendous potential to reduce carbon emissions and protect environmental values if developed with caution and appropriate safeguards. However, in the absence of safeguards, some actors may choose to produce biofuels in a manner that has negative environmental or social consequences, raising important questions about the long-term sustainability of the industry.

LCFS 42-13

We have worked in good faith over the past four years with ARB staff and the Board toward voluntary sustainability provisions that help encourage best practices while protecting against potential negative impacts that pose significant risks to the environment and communities. Potential negative impacts include increases in greenhouse gases that can occur if deforestation of native forests occurs for energy crops, loss of critical habitat and biodiversity, increased water consumption, conflicts over land or water

[12] California Air Resources Board LCFS/ADF Draft Environmental Impact Report. The sale of credits generated for could allow transit agencies to reduce fares, expand service or EV bus fleet or upgrade infrastructure. p.23

rights, and reduced food security. Standards such as RSB were developed because a diverse array of stakeholders agreed these impacts should and can be avoided.

Both sustainability provisions and an accompanying independent verification process are critical in order to realize the full environmental benefits of the LCFS and for creating a long-term and durable and policy that helps avoid negative impacts. They serve to:

1) Encourage producers to utilize voluntary third-party certification systems, which allow for on-the-ground measurement and verification of environmental performance (including, but not limited to greenhouse gas emissions).
2) Discourage bad actors engaged in projects resulting in significant environmental harm.
3) Build capacity for ARB to protect against actors producing fuels in a manner that may be environmentally unacceptable.
4) Help provide ARB with additional information and data around production of field, feedstock and facility parameters, which third-parties collect and audit.

LCFS 42-13 cont.

While it is true that it would take additional staff resources to establish sustainability provisions for the LCFS, once developed, existing third-party systems could in theory help reduce workloads going forward. ARB's Sustainability Work Group has made significant progress in developing a science-based definition of sustainability and the specific provisions to be included in the LCFS regulation. But its efforts have stalled, in part due to lack of resources. It is critical to the overall goals and long-term durability of the LCFS that ARB complete this work and formally incorporate sustainability provisions, along with a credible, independent verification process for those provisions, into regulation by end of 2016.

8. We urge ARB to continue reviewing and strengthening existing mechanisms over time to ensure LCFS pathways are verifiable and requirements are enforced.

As the Board considers re-adoption in 2015, we also urge ARB to prioritize its future efforts to review and strengthen verification and enforcement activities over time. In particular, staff should consider how the program could augment verification activities to ensure that in-use production practices reflect the original information submitted to establish the pathway, in order to minimize the risk of unintentional errors or even potential fraud. These comments are also made in light of the fraud that did occur with the Renewable Fuels Standard in 2011, which the U.S. Environmental Protection Agency has now addressed through subsequent requirements and changes.

LCFS 42-14

After the LCFS re-adoption process concludes, ARB should consider potential requirements that could supplement existing enforcement activities, including third-party analysis and verification. Third-party verification, such as by the RSB or an equivalent standard, as mentioned above in Section 7, could provide additional safeguards to ensure that the production methods, feedstocks, and supply chain that can affect greenhouse gas emissions is accurately reported. We also note that some third-party certification systems may also include additional sustainability information that is collected and reported as an added co-benefit. At this time, we are aware that some stakeholders have discussed in previous workshops whether the credit generator or obligated regulated party holds ultimate responsibility for LCFS credits and potential errors. We have not taken a position on this additional matter to date.

As an example of where additional verification and enforcement may be needed, we discuss used cooking oil (UCO), potentially an ultra-low carbon feedstock for the LCFS fuel mix. Converting UCO to biodiesel reuses a "waste" product and avoids displacement effects, such as indirect land use change or adverse effects on availability of food, forage, and fiber crops – if it is indeed "used." There has been some concern that the strong LCFS value may provide a perverse inducement to substitute disguised virgin oils for UCO, depending on the availability of UCO in certain supply chains and cost fluctuations in the various spot markets for oils. This might be the case for palm oil, for example, because the price has seen significant fluctuations in recent years.

Two applications for a Method 2B Fuel Pathway approval (UCO to Biodiesel) that we examined last November did not appear to offer any means of verifying that UCO was used. In fact, the information about the feedstock oil origin and supply was redacted as confidential business information, or otherwise unavailable on the application web site. Going forward, ARB should consider requiring further verification if not done already, including for co-mingling of feedstocks more generally. Thus, to help ensure the GHG benefits of the program and that all parties are utilizing the feedstocks that they are claiming credit for, ARB should consider supplementing current verification activities around feedstocks. LCFS 42-14 cont.

In this example, UCO feedstock verification can be rather simple: There is no need to trace the UCO back to the crops that produced the oil, or to document a full chain of custody farther back than the gathering of the UCO. But it does require that the users and aggregators provide data that allow a verifier to match the volumes collected and the companies collected from. Existing third-party tools, such as the RSB's system for verification and chain of custody related to "End of Life Products and Residues" RSB-STD-01-010-ver.1.6[13], provide the necessary safeguards and are tailored for the essential questions that can verify the "used" status of UCO.

9. We support the current inclusion of a public comment period for fuel pathways and request a longer time period be provided to allow for sufficient review by stakeholders.

We appreciate the opportunity to comment on proposed fuel pathway applications. We would ask, however, that under the re-adopted LCFS, a longer period be instituted for the comments. Some of us experienced difficulties in providing comments for Method 2 B fuel pathways in just the last few months; the current 10-day period is very short to assess a new pathway and gather relevant information. The 10-day period has been interpreted to include the weekend days, which means that some 10-day periods only include five working days. LCFS 42-15

[13] http://rsb.org/pdfs/standards/RSB-STD-01-010%20-%20ver%201.6%20RSB%20Standard%20on%20end-of-life-products,%20residues%20and%20by-products.pdf

10. The Board is on sound footing to adopt updated indirect land use change values.

First, we wish to thank ARB staff for their tireless work to address stakeholder and expert input on indirect land use change analysis. With the dedicated work of ARB staff and many contractors and collaborators, the models used in 2009 have been adapted and updated. They more carefully model animal feed markets, take into consideration irrigation, and adapt the model structure of both GTAP and the associated emissions factor model to take into consideration considerably more detailed information, especially about the United States and Brazil. This process enhanced the technical foundation of the LCFS, and also advanced the state of the art on the study of land use changes associated with expanded biofuels production. The Board is on sound footing to adopt updated emissions values as part of the LCFS re-adoption.

Despite this important progress, there remain areas for continued investigation. The most critical need is related to palm oil. Palm oil is one of the most important drivers of deforestation, and a significant global source of biofuel. The emissions from palm oil are relevant not only for palm biodiesel itself, but for fuels made from other fats, oils or oil byproducts that may substitute for palm oil in the marketplace. The interconnected markets for biodiesel and renewable diesel feedstocks are complicated and the data is imperfect. Moreover, as ARB staff highlighted, there are likely some structural limitations in GTAP that make it difficult to adjust the model to reflect key market dynamics. But this area of inquiry is clearly critically important going forward. Ongoing study is needed to ensure the link between palm and deforestation is understood, and that California fuel regulations do not indirectly contribute to deforestation from palm oil. LCFS 42-16

This is particularly important because forecasts indicate LCFS compliance may lead to a significant increase in the use of fuels made from vegetable oils and animal fats. We urge the ARB to seek expert input on key land use issues raised by palm oil in particular, and large increases in the use of bio-based diesel in general.

This focus on palm oil is important because it is a leading driver of deforestation, and less time has been put into this area than other areas of ARB analysis. But other areas identified are also very important. Forest land cover issues associated with the treatment of unmanaged land in GTAP are very important to ILUC for all fuels, and especially palm oil, and deserve further attention. It is also worth understanding the discrepancy between ARB's irrigation results and those of Taheripour, Hertel and Liu.[14] Analysis of fertilizer, paddy rice, and livestock emissions, and consideration of a dynamic GTAP model is also worthwhile. And, as cellulosic biofuels feedstocks scale up and begin to be significant driver of land use change, it will be important to understand their land use impacts.

Several recent papers continue to challenge ARB's analyses from both directions. One recent white paper argues that ARB's analysis has insufficiently recognized the potential for agricultural intensification, while other reports object to the use of crops to produce fuel instead of food, and

[14] *Energy, Sustainability and Society* 2013, 3:4; http://www.energsustainsoc.com/content/3/1/4

question the accounting framework of biofuels, land use, and carbon sequestration. There is a compelling moral and environmental case to prioritize food production and forest and other ecosystem protection over fossil energy displacement. Going forward it is important for ARB to consider how best to adjust its approach to include new sources of data, modelling approaches, and carbon accounting methodologies. These recent papers do not offer implementable refinements to ARB's methodology in the timeframe of the re-adoption, but suggest areas for inquiry over the longer term (beyond 2020) to ensure that California's low carbon fuels policies remain science-based and broadly sustainable. The work ARB has done to improve the treatment of ILUC over the last five years has certainly reflected a commitment to strong science-based administration of the LCFS, and puts the LCFS on solid footing through 2020.

LCFS 42-16 cont.

11. The Biorefinery Siting Guidance needs an update to incorporate new information on disadvantaged communities.

Given the focus in many AB 32 discussions on the need to protect and improve health and air quality in California's most disadvantaged communities, ARB should provide clear direction to staff on the timing to update the Siting Guidance for Biorefineries in California section on cumulative impacts. Specifically, the guidance document should be updated to reflect the development and widespread use of CalEPA's CalEnviroScreen tool for identifying communities most disadvantaged by local pollution.

LCFS 42-17

12. We support the Alternative Diesel Fuels proposal and encourage ARB to capture and monitor NOx benefits and potential impacts under the rule.

We support the Alternative Diesel Fuels proposal and believe it balances the need to encourage and incentivize alternatives to fossil fuels with the need to ensure that no additional harms are caused by these alternatives.

Because of the potential for biodiesel to increase smog-forming NO_x emissions under certain formulations, engine models, and operating conditions, we support the alternative diesel fuel pathway set forward by ARB staff.[15] To protect against NO_x backsliding under a growing biodiesel market, and as the widespread fleet turnover to NO_x-controlling engines is achieved, ARB must carefully capture the benefits of biodiesel, and monitor the benefits and potential impacts. Fortunately, the proposed ADF regulation looks for ways to maximize these benefits, including offering exemptions for biodiesel fueling stations or fleets using technologies that control NO_x. We strongly encourage ARB to explore additional opportunities to capture NO_x-neutral—and NO_x-reducing—particulate and carbon pollution benefits.

ADF 25-1

Taken together with the LCFS, the ADF will help to avoid nearly 100 deaths per year as cleaner alternatives to diesel are utilized in California.

[15] ARB January 2015 *Staff Report: Initial Statement of Reasons, Proposed Regulation on the Commercialization of Alternative Diesel Fuels*

In closing, we urge ARB to resist attempts to eliminate or weaken AB 32 fuel programs in California. Although the oil industry speaks with a loud voice, it does not speak for average Californians. The LCFS and California climate policies, in general, continue to enjoy broad public support, as evidenced in the annual Public Policy Institute of California poll, *Californians and their Environment*,[16] and other independent third-party research and opinion polls. LCFS 42-18

Climate policy solutions for the transportation sector are needed in California, in other states, across the nation, and around the world. ARB must continue its longstanding leadership role by sending a strong signal that California will not jeopardize the future health and environment of our state, our nation, or our planet for the sake of preserving the status quo. As Oregon, Washington, and other jurisdictions look to adopt and implement similar clean fuel standards, it is critical that ARB continue to build on this transformational policy by maintaining a strong, long-term signal and improving it in the areas identified in this letter. LCFS 42-19

42_OP_LCFS_NGO Responses

344. Comment: **ADF 25-1**

Agency Response: This comment is responded to in the Alternative Diesel Regulation Final Statement of Reasons under Comment Letter **25_OP_ADF_NGO**.

345. Comment: **LCFS 42-1**

The comment is supportive of the Low Carbon Fuel Standard regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

346. Comment: **LCFS 42-2**

The comment states that, by cutting carbon emissions from transportation fuel, the LCFS is an important piece of California's policy response to the environmental and health crisis caused by our dependence on oil.

Agency Response: ARB staff thanks the commenter for the support of the health benefits of the re-adoption of the LCFS.

347. Comment: **LCFS 42-3**

The comment states that the LCFS regulation is a critical component of AB 32 and represents one of the state's largest greenhouse gas emission reduction measures and provides the necessary foundation for meeting California's existing and future health-based air quality and climate goals.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

348. Comment: **LCFS 42-4**

The comment supports ARB staff's proposal to require a 10 percent reduction in fuel carbon intensity by 2020.

Agency Response: ARB staff appreciates the support for the proposed compliance targets.

349. Comment: **LCFS 42-5**

The comment supports a more aggressive regulatory target in the post 2020 timeframe.

Agency Response: See response to **LCFS 5-2**.

350. Comment: **LCFS 42-6**

The comment supports the concept of having one regulatory review prior to 2020 to ensure that the regulation is on track and to incorporate any critical updated scientific data.

Agency Response: Staff agrees that it is important to build a LCFS regulatory review mechanism into the proposed regulation. Staff included Section 95496: Regulation Review into the proposed LCFS Re-adoption to address the needs of regulatory review.

351. Comment: **LCFS 42-7**

The commenter supports the Refinery Investment Provision.

Agency Response: ARB staff appreciates the support for the refinery investment credit provision.

352. Comment: **LCFS 42-8**

The commenter supports the Refinery Investment Provision and provides information about potential GHG reduction projects at refineries.

Agency Response: ARB staff appreciates the support for the refinery investment credit provision. Staff will review the information the commenter provided about potential GHG reduction projects at refineries.

353. Comment: **LCFS 42-9**

The commenter supports the Refinery Investment Provision.

Agency Response: ARB staff appreciates the support for the refinery investment credit provision.

354. Comment: **LCFS 42-10**

Agency Response: ARB staff acknowledges the commenter's support for differentiating the carbon intensity of crude oil sources and for protecting against increases in carbon intensity of baseline fuels over time.

355. Comment: **LCFS 42-11**

The comment supports the cost-containment "safety valve" mechanism and states that the $200/ton cap is reasonable, well-considered, and supported by ample evidence. The commenter also recommends continued work to develop a price floor.

Agency Response: ARB staff appreciates the support for the cost containment provision and the proposed credit price cap. With respect to a price floor, see response to **LCFS 6-5.**

356. Comment: **LCFS 42-12**

The comment supports expanded electric transportation credits.

Agency Response: ARB staff appreciates the support for the proposed electricity provisions.

357. Comment: **LCFS 42-13**

The comment strongly supports the efforts of ARB staff to develop sustainability provisions and an accompanying independent verification process for the LCFS by the end of 2016.

Agency Response: Staff agrees that it is important to develop sustainability provisions and an accompanying independent verification process for the LCFS. As stated in the Staff Report, staff identified specific areas of the regulation for clarification and improvements in the proposed LCFS Re-adoption. These proposed improvements are expected to improve implementation of the LCFS program. Beyond this proposal, staff will continue to implement and enforce the LCFS program, monitoring its effectiveness, and will consider additional improvements for future iterations of the LCFS regulation, such as independent verification and sustainability provisions. LCFS staff will work with the staff of the verification program for the Mandatory Reporting of Greenhouse Gas Emissions under AB32, and stakeholders to develop a comprehensive, integrated strategy for the LCFS sustainability and verification programs.

358. Comment: **LCFS 42-14**

The comment states that ARB should continue reviewing and strengthening existing mechanisms over time to ensure LCFS pathways are verifiable and requirements are enforced.

Agency Response: Monitoring, auditing and enforcement of the LCFS Program are critical to ensure the emission benefits of the Program are realized. The ARB's Cap-and-Trade Program currently uses of third-party monitors.

The LCFS Program already includes some provisions that address environmental sustainability issues such that the full life-cycle of greenhouse gases is taken into account for each transportation fuel. Each fuel pathway accounts for both direct and indirect land effects in determining the carbon intensity for that fuel. Additionally, ARB has a working group comprised of interested stakeholders, regulated parties, environmental advocates, and other state agencies that work through ideas to recommend which framework (e.g., regulatory, a set of policies, or a combination of the two) would work best for all stakeholders involved. ARB staff that is working on sustainability topics are also working on verification.

ARB staff is aware of the voluntary quality assurance plan provisions that the U.S. Environmental Protection Agency (U.S. EPA) has adopted in the Renewable Fuel Standard (RFS) Program. Staff has had discussions with U.S. EPA on their implementation of this provision, as their program uses a similar "buyer-beware" approach. This approach ensures that all credits retired which are found to be invalid must be offset by honorable credits with real emission benefits. Currently, LCFS market participants can do their own due diligence to ensure the validity of the LCFS credits and these efforts will be taken into consideration if invalid credits are found.

359. Comment: **LCFS 42-15**

The comment supports the current inclusion of a public comment period for fuel pathways and requests a longer time period to be provided to allow for sufficient review by stakeholders.

Agency Response: ARB staff agrees that the comment period is extremely valuable and would like to continue to welcome comments. Staff must, however, maintain a balance between timely pathway certifications and the length of the comment period. To that end, staff will specify that the comment period last for 10-

business days rather than 10-calendar days. In addition, staff will agree to grant commenters time extensions if they can show why they are unable to submit comments within the 10-business day window

360. Comment: **LCFS 42-16**

The comment supports updated indirect land use change values.

Agency Response: Even with limitations related to the structure of the Global Trade Analysis Project (GTAP) model, the efforts by ARB staff have produced the most defensible analysis of indirect effects related to crop-based biofuels. The indirect land use change (iLUC) analysis accounts for potential deforestation and expansion into high carbon peatland in Indonesia and Malaysia. The GTAP model includes in it data from studies and reports that specifically have focused on oil palm expansion in these regions. Staff has also considered data used by the U.S. EPA in their analysis of palm oil for the 2014 Standards for the Renewable Fuel Standard Program (RFS2) program.

The iLUC analysis was subjected to peer-review by experts. ARB staff considered feedback provided by the reviewers, and will continue to consider that feedback (including any for oil palm) in evaluating future updates iLUC analysis.

All fuels including biofuels are scored on their full lifecycle analysis. Lack of data limited the inclusion of emissions from fertilizer, paddy rice, and livestock. Inclusion of unmanaged land and cellulosic biofuels will be considered when data becomes available. When a dynamic version of GTAP suitable for ARB's analysis becomes available, ARB staff is committed to completing comprehensive evaluation and testing of this model prior to considering its use in the regulation.

ARB staff is aware of reports that challenge ARB's analysis on several fronts such as discounting intensification, food issues related to biofuels etc. Many such issues were considered during the current updates but a few could not be included either due to lack of data or due to structural limitations of the model. Staff remains committed to monitoring new data and updates to land use change science and accounting for these limitations when supported by science and data.

361. Comment: **LCFS 42-17**

The comment requests ARB staff to provide clear direction on the timing to update the *Siting Guidance for Biorefineries in California* section.

Agency Response: ARB has no current plans to update the Biorefinery Siting Guidance Document, but will take this comment under consideration.

362. Comment: **LCFS 42-18**

The comment urges ARB to resist attempts to eliminate or weaken AB 32 fuel programs in California.

Agency Response: Staff appreciates the public support of the Low Carbon Fuel Standard and agrees that ARB must continue its longstanding leadership role in climate policy solutions for the transportation sector.

363. Comment: **LCFS 42-19**

The comment urges ARB to continue its longstanding leadership role.

Agency Response: See response to **LCFS 42-18**.

Re: Proposed Amendments to the California Low-Carbon Fuel Standards Regulation and the Proposed Regulation of the Commercialization of Alternative Diesel Fuels

Dear Madam:

POET LLC, a member of Growth Energy, concurs in the comments being filed today by Growth Energy, including the environmental analysis under the California Environmental Quality Act offered by Growth Energy, as well as the alternative to the above-captioned proposed amendments and regulations that have been proposed by Growth Energy. Please file this letter in the two separate dockets for the the proposed amendments to the California Low-Carbon Fuel Standards ("LCFS") regulation and the proposed regulation of the commercialization of alternative diesel fuels LCFS 43-1

POET LLC expects to file additional comments prior to the close of the record in the LCFS proceeding.

Thank you for your consideration and assistance.

Sincerely,

Shailesh Sahay
Regulatory Counsel

Re: **Notice of Public Hearing to Consider a the Low Carbon Fuel Standard (LCFS) – Phillips 66 Company Comments**

Dear Clerk of the Board,

Phillips 66 Company (Phillips 66) appreciates the opportunity to provide these comments. Phillips 66 will be directly impacted by the by the "re-proposed" Low Carbon Fuel Standard (LCFS) regulations as we are a “regulated party” under the existing regulations and will continue to be a “regulated party” as defined by these proposed regulations. Phillips 66 owns and operates refineries in the State of California. In addition, we have pipeline, terminal, and marketing assets in the State that distribute fuels produced at our refineries. We are a member of the Western States Petroleum Association (WSPA) and fully support the comments submitted by WSPA. LCFS 44-1

Phillips 66 has been engaged with CARB since the inception of the LCFS and throughout this and previous regulatory proceedings. Our staff has participated in the workshop process, participated in the “workgroup” process, held a seat on the LCFS Advisory Panel, participated in trade association (WSPA) meetings with ARB staff, has held individual private meetings with ARB staff, and has provided written comments on every regulatory proceeding.

Based upon our experience as a regulated party under the existing LCFS rules, we focus our comments in this re-adoption proceeding on three main topics:

1) the Compliance Schedule;
2) the Cost Containment Mechanism; and
3) LCFS Credit Generation from Refinery Projects.

Each of the three topics contains a Phillips 66 recommendation that we respectfully ask the Board to consider and subsequently then direct staff to reexamine their current proposals.

Compliance Schedule: Phillips 66 does not believe the compliance schedule proposed by staff is feasible or sustainable. The compliance scenario presented by staff over-estimates the near term credit build and is overly optimistic in the amount of time it will take to bring advanced fuels and vehicles to commercial scale. In the staff’s own scenario, there are not enough annual credits to LCFS 44-2 cover deficits in the 2018/2019 timeframe (and beyond) and compliance is dependent upon a massive credit build in the early years (something that has not materialized).

The downside of adopting staff's unrealistic compliance schedule is that staff will continue to return to the Board every couple of years with amendments that "kick the can down the road" and do not address the fundamental issue of feasibility. Such an approach provides little in the way of regulatory certainty and makes planning business and investment decisions difficult (if not impossible) on the regulated parties. Phillips 66, therefore, respectfully asks the Board to direct staff to develop a realistic compliance schedule that is based upon reasonable forecasts of fuel availability, vehicle penetration rates, needed fuelling infrastructure build-out and is cost-effective.

LCFS 44-2 cont.

Cost Containment – Credit Clearance Market: Phillips 66's believes that a cost containment mechanism is NOT a suitable replacement for a feasible regulation. Staff's proposed cost containment scheme, a Credit Clearance Market, contains an initial price cap on credits of $200 per credit. The staff report lacks sufficient detail regarding how this cap or ceiling price was derived and we request that staff provide a basis and rationale for the $200/crredit.

In addition, under the proposal, participation in the credit clearance market is mandatory for parties who end the year in a deficit situation. Under the existing regulations, regulated parties are allowed to carry over a 10% deficit provided they "pay-back" those deficits the following year. There may be planning or operational reasons why a regulated party may wish to carry deficits from one year to the next. We request this provision remains in the regulation and that participation in the Credit Clearance Market be voluntary for those parties in deficit.

LCFS 44-3

Staff evaluated various cost containment mechanisms before arriving at their recommendation to adopt the Credit Clearance Market. To our knowledge, staff did not evaluate the potential use of Cap & Trade credits for this purpose. Phillips 66 proposes that in lieu of adopting these proposed additional and complex regulations, the Board direct staff to instead allow Cap & Trade credits to be used for LCFS compliance in those circumstances where the Credit Clearance Market would otherwise be triggered.

LCFS Credits for Refinery GHG Reduction Projects Phillips 66 fully supports the ability to generate LCFS credits from refinery greenhouse gas (GHG) reduction projects. However, the proposed thresholds and restrictions risk eliminating many potential projects. We have identified the following elements that make the proposal problematic:

a. Limiting onsite increases of air pollutants unreasonably excludes offsets of criteria and air toxic pollutants.
b. The 0.1 gCO2e/MJ threshold is too stringent: a "tons reduced" threshold should be allowed (this concept is proposed for "innovative crude recovery" so it is only equitable to add a comparable provision here).
c. Investments should not be limited to capital or onsite projects.
d. The biofeedstock 10% threshold is too restrictive and should be eliminated
e. Application of a 50% discount in the number of credits for "less efficient" facilities serves as a dis-incentive. All reduction projects should be allowed full credit.

LCFS 44-4

Phillips 66 respectfully requests the Board to direct staff to work with refiners to streamline the process and eliminate the barriers contained in the proposal.

Thank you for considering our comments. Please feel free to contact me if you have questions regarding our comments.

Sincerely,

<H. Daniel Sinks>

44_OP_LCFS_P66 Responses

365. Comment: **LCFS 44-1**

Agency Response: The response to this comment is in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

366. Comment: **LCFS 44-2**

The commenter does not believe the proposed compliance schedule is feasible or sustainable as the compliance scenario over-estimates the near term credit build and is overly optimistic in the amount of time it will take to bring advanced fuels and vehicles to commercial scale.

Agency Response: Please see response to comment **LCFS 38-1**.

367. Comment: **LCFS 44-3**

The commenter asserts that the cost containment provision is not a suitable substitute for a feasible compliance pathway, and further requests that the cost containment provision should be amended to offer refiners flexibility to voluntarily participate or carry-over deficits

Agency Response: We agree with the comment that a cost containment mechanism is no substitute for a feasible compliance path. However, ARB staff's analysis regarding the availability of low-CI fuels indicates that there will be sufficient credits available through 2020 from existing low-CI fuel technologies and promising low-CI fuels on the horizon.

For a response to the criticism of the cost containment mechanism, and an explanation of why participation in this provision cannot be voluntary, please see the response to comment **LCFS 32-9 and LCFS 38-3, LCFS 40-8** and **LCFS 40-21**.

In response to the request to use Cap-and-Trade allowances or offsets for LCFS compliance, please see the response to comment **LCFS 32-7**.

368. <u>Comment</u>: **LCFS 44-4**

The comment lists six issues with the Refinery Investment Provision.

<u>Agency Response:</u>

1) *Limiting onsite increases of air pollutants unreasonably excludes offsets of criteria and air toxic pollutants*.

See response to **LCFS 38-9**.

2) *The 0.1 gCO_2e/MJ threshold is too stringent: a "tons reduced" threshold should be allowed (this concept is proposed for "innovative crude recovery" so it is only equitable to add a comparable provision here*).

See response to **LCFS 38-10**.

3) *Investments should not be limited to capital or onsite projects*.

See response to **LCFS 38-11**.

4) *The biofeedstock 10% threshold is too restrictive and should be eliminated*.

See response to **LCFS 38-13**.

5) *Application of a 50% discount in the number of credits for "less efficient" facilities serves as a dis-incentive*.

ARB staff is making a 15-day change to remove the 50 percent discount on credits in the Refinery Investment Credit Provision.

6) *All reduction projects should be allowed full credit*.

ARB staff is making a 15-day change to allow all projects that meet the provision's requirements will get full credit.

Comments ARB Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations
Draft Environmental Assessment due 2.17.2015

You state:

3. Additional Infrastructure Needs

Because credits could be generated through the use of solar-generation of steam, electricity, and heat in oil fields, development of these types of facilities would be incented. Potential compliance responses associated with these methods could result in modifications to ***existing crude production facilities*** *to accommodate solar, and wind electricity, heat, and/or steam generation.* ***These would be located within crude oil production facility sites.***

And

These projects could include the modification of existing or new industrial facilities to capture CO2 emissions, along with construction of new infrastructure, ***such as pipelines, wells, and other surface facilities within or near the emitting facility to enable the transport and injection of CO2 into a geological formation for sequestration.*** *The transport distances and pipeline construction requirements for the captured CO2 would vary depending on the locations of specific industrial sources of the captured CO2 and proposed underground formations, recognizing, however, that pipeline cost could reasonably limit the distance of CO2 transport. CCS would be required to be onsite at locations of oil or gas production facilities to obtain credits through the proposed LCFS.*

Comments:

LCFS ISOR report states:

Revised Annual Crude Average CI Calculation
The crude lookup table lists field-specific CI values for crudes produced in and offshore of California. Regulated parties, however, are often supplied California crude in pipelines carrying crude blended from many fields. ***Because neither staff nor the regulated parties have data that maps crude oil volumes from California fields to pipeline blends, it is not possible to match reported California crude names with CI values from the lookup table.***

Instead of using California crude names and volumes reported by refineries, staff proposes, in calculating the Annual Crude Average CI value, that volume contributions for California State fields will be based on oil production data from the California Department of Conservation, and volume contributions for California Federal Offshore fields will be based on oil production data from the Bureau of Safety and Environmental Enforcement.

LCFS 45-1

> ***Data that maps crude oil volumes from fields to pipeline blends is not available, and therefore, it is not possible to as accurately estimate CI values for California pipeline blends as for fields.***

You have no basis in fact of the Crude Oil Volumes from oil field to pipeline and cannot determine any benefit.

LCFS 45-1 cont.

Sequestration requires an Earthquake Fault Zone and municipal Circulation Elements are a necessity. Land Use Elements are also a consideration due to any proximity to population, housing and schools. The science for migration in rock formations is in the research stage, as we understand it.

LCFS 45-2

There may be no benefit if the risk is too high.

Re: Proposed Amendments to the California Low-Carbon Fuel Standards Regulation and the Proposed Regulation of the Commercialization of Alternative Diesel Fuels

Dear Madam:

Growth Energy, an association of the nation's leading ethanol manufacturers and other companies who serve the nation's need for alternative fuels, is submitting to you the enclosed materials in response to the Executive Officer's notices of proposed amendments to California Low-Carbon Fuel Standards regulation and of the proposal to adopt a regulation for the commercialization of alternative diesel fuels. These materials also include environmental comments being submitted to the Air Resources Board and the Executive Officer pursuant to the California Environmental Quality Act and the Board's implementing regulations.

The Executive Officer has created separate rulemaking files and Board hearing agenda items for these two proposals. In view of the substantial overlap between these two proposals, including in the CARB staff's environmental assessment documentation, I ask that all of these materials, including the appendices and exhibits, be included in each rulemaking file and be considered by the Board in connection with each agenda item.

Growth Energy may file additional materials in one or both rulemaking files for consideration in connection with one or both agenda items at a later time, as permitted by the California Government Code.

If there are logistical questions concerning these submittals, please contact Mr. James M. Lyons of Sierra Research, Inc., at 916-444-6666.

Thank you for your consideration and assistance.

Sincerely,

David Bearden

STATE OF CALIFORNIA

AIR RESOURCES BOARD

PROPOSED AMENDMENTS TO THE CALIFORNIA LOW CARBON FUELS STANDARD REGULATION AND THE PROPOSED REGULATION ON THE COMMERCIALIZATION OF ALTERNATIVE DIESEL FUELS

GROWTH ENERGY'S RESPONSE
TO THE NOTICES OF PUBLIC HEARINGS DATED DECEMBER 16, 2014
2015 CAL. REG. NOTICE REG. 13, 45 (JANUARY 2, 2015)

FEBRUARY 17, 2015

For further information contact:
Mr. Chris Bliley
Director of Regulatory Affairs
Growth Energy
CBliley@growthenergy.org
202-545-4000

Executive Summary

On January 2, 2015, the Executive Officer of the California Air Resources Board commenced the formal process of proposing amendments to the California low-carbon fuel standard ("LCFS") regulation and the adoption of a new regulation to govern commercialization of alternative diesel fuels used to comply with the LCFS regulation (the "ADF regulation"). Growth Energy shares CARB's goal of promoting alternative fuels that have lower greenhouse gas impacts than fossil fuels. In fact, promotion of this goal is central to Growth Energy's purpose. Unfortunately, Growth Energy believes that CARB's execution of the LCFS program as proposed would run counter to this goal. The proposal if finalized would promote the wrong fuels based on flawed, incorrect science, and as a result impose significant costs without accompanying greenhouse gas reductions. Thus, Growth Energy opposes adoption of the proposed amendments to the LCFS regulation and the currently proposed ADF regulation. Each regulation is unnecessary to achieve the environmental benefits sought by the California Legislature in the Global Warming Solutions Act of 2006, which is the statute on which the Executive Officer is basing his proposal.

The LCFS regulation is no longer needed to achieve the greenhouse gas reductions sought in the 2009 LCFS regulation, and Growth Energy has proposed a better alternative to the LCFS through the expansion of the existing cap-and-trade program. Since the Board first adopted the LCFS regulation in 2009, much has changed in efforts by the state and federal government to reduce greenhouse gas ("GHG") emissions from motor vehicles. Growth Energy presented a proposed alternative to the LCFS regulation to CARB staff in June 2014. Following review of Growth Energy's proposal, the CARB staff agreed with Growth Energy that Growth Energy's proposal would likely achieve the same level of GHG emissions reductions as the 2009 LCFS regulation through 2020. Growth Energy's proposal had none of the unintended negative environmental consequences of the 2009 LCFS regulation, which have been the subject of litigation, and would have eliminated the need for California businesses and consumers to pay for the LCFS program ─ costs which the CARB staff now says may range up to about 12 cents per gallon by 2020. LCFS 46-1

The new justification for the LCFS regulation ignores the federal renewable fuels program. The CARB staff rejected Growth Energy's proposed alternative to the LCFS regulation in the fall of 2014 because it claimed that by enforcing LCFS requirements now, CARB could prepare the California fuels market for further GHG reductions after 2020. The CARB staff theorized that only an LCFS program can adequately assure the diversification of the sources and methods of producing renewable fuels with low carbon emissions needed to achieve GHG reductions after 2020. When it rejected Growth Energy's proposal last fall, the CARB staff did not properly account for the beneficial effects of the federal renewable fuels standards ("RFS") program in stimulating fuels diversification and in the commercialization of cellulosic renewable fuels. The CARB staff still has not done so.

By disrupting the national market for renewable fuels, the LCFS regulation may increase global greenhouse gas emissions. Under the new LCFS regulation, corn ethanol produced at Midwest biorefineries will likely be displaced in large part by sugarcane ethanol from Brazil. Midwest corn ethanol biorefineries will be forced to choose between curtailing or shutting down production, or finding other markets for the ethanol that can no longer be sold in California. Because external economic factors constrain the output of the Brazilian sugarcane ethanol industry, and may continue to do so, the practical effect of the new LCFS regulation may be the shipment of Brazilian ethanol to California and Midwest ethanol to Brazil. The ethanol would travel on oceangoing tankers powered with fossil fuels. Intercontinental shipments of ethanol in response to California's regulation would have the unintended effect of increasing global GHG emissions. LCFS 46-2

Comments of Growth Energy on Proposed Amendments to the California Low Carbon Fuels Standard Regulation and the Proposed Regulation on the Commercialization of Alternative Diesel Fuels

Growth Energy respectfully submits these comments on the proposed amendments to the low-carbon fuels standard ("LCFS") regulation and the proposed regulation on the commercialization of alternative diesel fuels. Growth Energy is an association of the leading ethanol producers in the United States and other companies that serve America's need for renewable fuels. As such, Growth Energy shares in a core goal of the LCFS program – the promotion of alternative fuels that lower transportation-sector greenhouse gas emissions, among other benefits. Growth Energy's comments for the California Air Resources Board ("CARB" or "the Board") are contained in this summary document and a number of appendices and exhibits. Growth Energy is combining in these comments its response to the notices of proposed rulemaking published for the LCFS regulation and the alternative diesel fuel ("ADF") regulation, which are both scheduled for a public hearing later this week, as well as its response to the consolidated draft Environmental Assessment ("the draft EA") for the LCFS and ADF proposals.[1]

Part I of these comments outlines some of the key statutory provisions that govern the LCFS and ADF rulemakings and identifies the CARB staff's serious shortcomings in complying with the same. Part II summarizes the analysis contained in the appendices to Growth Energy's comments on the lifecycle emissions analysis used in the LCFS regulatory proposal and the impacts of the LCFS proposal on consumers, businesses, and federal law and policy, as well as related issues. Part III and its accompanying appendices address the draft EA and other issues LCFS 46-3

[1] The public hearing notices dated December 16, 2014, and the draft EA were posted for public review and comment by the Executive Officer on January 30, 2014.

involving the environmental impacts of the two proposals and outline the Board's duties based on the record under the California Environmental Quality Act ("CEQA").[2] Part IV summarizes an alternative to the LCFS regulation that Growth Energy presented to the CARB staff, evaluates the CARB staff's response to Growth Energy's proposal, and describes the Board's legal obligations under the Government Code in light of the current record. Part IV also presents recommendations to facilitate the transparency and external review of the two current regulatory proposals. LCFS 46-3 cont.

I. STATUTORY FRAMEWORK AND BACKGROUND

The Board's consideration of the LCFS amendments and the proposed ADF regulation is governed by the California Government Code, the California Health & Safety Code, and CEQA, as well as the California and federal Constitutions. Pertinent requirements of CEQA and CARB's certified regulatory program to implement CEQA that apply to the draft EA are examined in detail in Part III and Appendix J of these comments. Because they are relevant to every aspect of these two rulemakings, it is important at the outset to identify three key provisions of the Global Warming Solutions Act of 2006 ("AB 32") and the Government Code that apply here. LCFS 46-4

Any regulation adopted by the Board must be consistent with and reasonably necessary to accomplish the purposes of AB 32. *See* Cal. Gov't Code § 11342.2. Three provisions of AB 32 are important to the Board's review of the CARB staff's proposal in order to determine whether the proposal is consistent with AB 32. First, regulations to implement AB 32 must not "interfere with … efforts to achieve and maintain federal and state ambient air quality standards" to the extent feasible, in addition to being adopted in a manner that complies with CEQA. Cal. Health & Safety Code § 38562(b)(4). Second, the emissions reductions that CARB attributes to an AB 32 LCFS 46-5

---

[2] Growth Energy may file additional materials not directly pertinent to the draft EA but relevant to other issues presented in the rulemaking prior to the start of the public hearings this week.

regulation must be "real, permanent, quantifiable, verifiable and enforceable." *Id*. § 38562(d)(1).[3] Third, AB 32 directs that the Board "shall" rely upon "the best available economic and scientific information" when adopting regulations to implement AB 32. *See* Cal. Health & Safety Code § 38562(e). For the reasons explained in these comments and the appendices, the proposed amendments to the LCFS regulation do not comply with those three central provisions of AB 32, and therefore the Board should not adopt them.

LCFS 46-5 cont.

In addition, the Executive Officer cannot demonstrate that the LCFS amendments are "reasonably necessary" to meet the purposes of AB 32, as the Government Code requires. As the CARB staff admitted during the Department of Finance's review of the proposed amendments last fall, the LCFS regulation is likely not necessary in order to reduce greenhouse gas ("GHG") emissions prior to 2020; another, less burdensome alternative identified by Growth Energy would achieve those reductions and would not have the counterproductive impact on the California environment that the LCFS regulation will create.[4] In earlier comments to the CARB staff during development of the new LCFS regulation, Growth Energy explained that the limited purposes of the LCFS regulation were already accomplished by other programs. Having been presented with Growth Energy's alternative to the LCFS regulation, CARB cannot properly claim that no alternative to the LCFS program would be "as effective and less burdensome to affected private persons and equally effective in implementing the statutory purpose or other provision of law" — an averment required by section 11346.5(a)(13) of the Government Code, and which is important in protecting the public from unnecessary regulation. Remarkably, the Executive Officer's

LCFS 46-6

---

3 Notably, the requirements in subsection (d) of section 38562 are not qualified by the limitation in subsection (b), *i.e.*, "to the extent feasible."

4 Regarding those impacts, *see* Part III and Appendix I (Declaration of James M. Lyons).

December 2014 notice proposing the LCFS amendments does not even refer to the alternative measure proposed by Growth Energy, which was presented to the CARB staff in June 2014.[5] LCFS 46-6 cont.

The Legislature heightened the importance of evaluating alternatives to proposed regulations in 2011, when it amended the Government Code in order to require agencies to present their regulatory proposals to the Department of Finance for early review of costs, benefits, and alternative methods of accomplishing an agency's regulatory objectives. The LCFS and ADF rulemakings are among the first to be governed by the 2011 amendments, contained in SB 617. For the LCFS regulation, the CARB staff disabled meaningful stakeholder input into the SB 617 review by severely limiting the time permitted for regulated parties to participate, and by failing to fully disclose all the estimated benefits or costs of the proposed regulation (an omission that continues to this day). LCFS 46-7 The shortfall in the SB 617 process for the ADF rulemaking was even greater: the version of the ADF regulation that the CARB staff submitted to the Department of Finance differed in material ways from the version of the ADF regulation that the CARB staff had under active consideration at the time of its SB 617 submission to Finance. Thus, the agency that the Legislature intended to have an active role in the development of major regulations in California — the Department of Finance — has never formally reviewed the key features of the ADF regulation. Unless the Board itself directs the CARB staff to comply with SB 617, it will be left to another agency (the Office of Administrative Law) to correct this egregious violation of SB 617. ADF 17-1

In addition to mandating early review of regulatory proposals by the Department of Finance, the Legislature requires transparency in the rulemaking process, so that the public can LCFS 46-8 cont.

---

5 *See* Appendix F and related exhibits.

participate effectively in that process. *See, e.g.*, Cal. Gov't Code § 11347.3; Cal. Health & Safety Code § 39601.5. The public rulemaking file required by section 11347.3 of the Government Code is critical to both transparency and public participation. Section 11347.3 requires, in essence, that the public have the same access to all the data and analysis used by an agency in developing regulations, as well as all external input provided to an agency in connection with the adoption or amendment of a regulation.

As indicated in Part IV of these comments, there are substantial questions concerning the Executive Officer's compliance with section 11347.3, in light of the sparseness of the CARB staff's documentation for key parts of its LCFS and ADF proposals. The CARB staff also waited until nearly the last possible moment to open the rulemaking file, which had the effect if not the purpose of limiting public analysis of the empirical and analytical basis for its proposals. While section 11347.3 of the Government Code applies to all California administrative agencies subject to the California Administrative Procedure Act (the "APA"), section 39601.5 of the Health & Safety Code was added to the Board's enabling statute in 2009 by AB 1085, when the Legislature learned of significant shortcomings in transparency in earlier rulemakings. Section 39601.5 compels CARB to provide "all information" on key aspects of its regulatory analysis "before the public comment period for any regulation" commences under the Government Code. It is unclear how the Executive Officer tried to comply with section 39601.5 in these rulemakings. What is clear, however, is that critical information about the assumptions and data on which the LCFS and ADF proposals are based has never been provided to the public.

LCFS 46-8 cont.

II. REGULATORY ANALYSIS

The use of lifecycle analysis ("LCA") in assessing GHG emissions is at the heart of the LCFS regulation. The Legislature has directed that programs like the LCFS regulation rely on the "best available economic and scientific information"; notably, this mandate applies to the carbon

LCFS 46-9

intensity ("CI") values that CARB assigns to the various renewable fuels in the LCFS regulation, as well as to all other parts of the rulemaking.[6] The use of the most scientifically defensive CI values is critical to the rulemaking effort. The CI values provide what the 2009 Initial Statement of Reasons (ISOR") for the LCFS regulation called "signals" to the downstream fuel industry that will direct them to achieve reductions in the CI of the fuels they sell in the most cost-effective manner. Insofar as the intent of the LCFS regulation is to reduce GHG emissions, the regulation must establish "the maximum technologically feasible and cost-effective" method of doing so. Cal. Health & Safety Code § 38561(a). If the CI values send the wrong "signal" to the downstream regulated parties, then the LCFS regulation will result in the use of pathways that may increase GHG emissions above the levels that would result if the best possible CI values had been assigned to various renewable-fuel pathways in the regulation. As one witness affiliated with the University of California stated at the April 2009 Board hearing on the LCFS regulation:

> [I]f we make a mistake in one direction in estimating these numbers, we'll use too much of a biofuel that's actually higher carbon [than] we thought and will therefore increase global warming. And if we use numbers that are too low, then we'll use too little of a biofuel that's lower carbon than we thought and will therefore increase global warming.

Transcript of Public Meeting of the Air Resources Board, April 23, 2009, at 73-74. As explained in Appendices A, B, and C to these comments, and as summarized below, the "signals" that CARB's new California GREET 2.0 and indirect land-use change models provide for corn-starch, corn-stover and sugarcane ethanol do not reflect the best available scientific and economic

LCFS 46-9 cont.

---

[6] *See* Cal. Health & Safety Code § 38562(e). The Legislature has not directed CARB to use carbon intensity as a regulatory mechanism; that is a choice the Board made in the 2009 LCFS regulation and that the CARB staff proposes to continue.

information, and therefore do not provide the accurate "signals" to the downstream industry that are needed to maximize GHG reductions while minimizing costs. To adapt the 2009 formulation of the issue, quoted above: the "numbers" for sugarcane ethanol are "too low" and as a result, "too little" corn-starch and corn-stover ethanol would be used in California gasoline, if the Board adopts the staff's proposal. (*See* Section A.1 & 2 below.)

LCFS 46-9 cont.

In addition, if the currently-proposed regulation were to be adopted, the displacement of corn ethanol that would result will severely interfere – once again as in earlier years of the LCFS program – with the federal renewable fuels standard ("RFS") program, in violation of federal law. No purpose is served by the State's conflict with federal law, because as also explained below, the regulation of CI at Midwest corn-starch ethanol biorefineries serves no beneficial purpose; contrary to the staff's claims in the current rulemaking, those biorefineries cannot and will not attempt to change their production methods solely to achieve lower CI scores in response to the LCFS regulation. In that particular respect the LCFS program violates an important tenet of AB 32, because it does not achieve "real" reductions in GHG emissions,[7] despite claims to the contrary. (*See* Section B below.)

LCFS 46-10

A. The CARB Staff's Lifecycle Emissions Analysis and its Consequences

1. Indirect Land-Use Change

From its inception, one of the most controversial aspects of the LCFS program has been its attempt to incorporate the theory of indirect land-use change ("ILUC") into regulation.[8] The

LCFS 46-11

---

[7] *See* Cal. Health & Safety Code § 38562(d)(1).

[8] It remains Growth Energy's position that the ILUC theory and the methods used to quantify the impacts of biofuel usage on land change, as well as the emissions model used by CARB to estimate emissions from land change, are too unreliable for use in regulation.

concept of ILUC stands at the intersection of environmental science and economics; having made the decision to try to use the ILUC theory in the LCFS program, CARB can be expected to comply with AB 32, and to use the "best available" scientific and economic information. As explained in Appendix A of these comments, the CARB staff has continued to ignore efforts by stakeholders to improve the quality of CARB's ILUC and indirect-emissions models, as well as recommendations of the Expert Working Group ("EWG") that CARB established when it first adopted the LCFS regulation. CARB must now finally address or adopt each of the recommendations presented in Appendix A, and in Growth Energy's other appendices to these comments, or explain fully why it is not doing so. *See* Cal. Gov't Code § 11346.9(a)(3). Insufficient time to address the recommendations in Appendix A is not sufficient justification for rejecting any of them; Growth Energy and other parties offered those recommendations before the staff published its current proposal and, in some instances, *at least four years ago*. (*See* Appendix A at A-2 and Table 1.) In the text below, Growth Energy summarizes some of the key deficiencies in the new ILUC analysis offered by the CARB staff for the Board's review.[9]

LCFS 46-11 cont.

These are among the recommendations in Appendix A:

- *Price-yield response facto*rs. The CARB staff's ILUC analysis for corn-starch ethanol uses a range of price-yield values, despite recommendations from the

LCFS 46-12

---

[9] Each Appendix to the main text of Growth Energy's comments are a fully incorporated part of Growth Energy's comments. The Board must respond fully to each objection and recommendation in the appendices to the main text of these comments, regardless of their placement, or, at a minimum, explain why it believes each of these objectives or recommendations to be "irrelevant." *See* Cal. Gov't Code § 11346.9(a)(3). To ensure compliance with that requirement of the Government Code, California courts will conduct *de novo* review using independent judgment. *Cf. POET LLC v. California Air Resources Bd*. (2013) 218 Cal. App. 4th 681, 747-48. Particularly when the facts concerning CARB's actions in the regulatory process cannot be a subject of genuine dispute, "the independent standard of appellate review" applies. *Id.* at 748.

LCFS 46-13

authors of the model that CARB uses, as well as the EWG, that the most scientifically defensible value is 0.25. In the ISOR for the LCFS regulation, the Executive Officer relies on a non-peer-reviewed data review by a researcher at the University of California-Davis retained by CARB to support a lower price-yield value. In addition to lacking full documentation, the Davis reviewer appears to have made unexplained, selective use of other research, by Dr. J.F.R. Perez at Purdue University. The CARB staff has not supplied critical missing information from the Davis review requested by Growth Energy, and at this juncture, Growth Energy has no choice but to question whether the Davis review used reliable methods. Certainly, the Executive Officer cannot claim that the staff's work on price-yield responses has been transparent, nor that it is based on the "best available" information: information that is not made available to the public during a rulemaking governed by the California APA is akin to having no information at all.[10]

LCFS 46-12 cont.

- *Multiple cropping*. Last year, researchers at Iowa State University ("ISU") published a study that compared the results of ILUC modeling using GTAP (the modeling system used by the CARB staff) with real data. The study showed that over the last 10 to 15 years, there has been no net land conversion from forest and pasture to cropland in many regions of the world. (*See* Appendix A, note 5.) The ISU study confirms that increases in crop prices (a theoretical result of biofuels mandates like the LCFS regulation) will result in multiple cropping. The CARB

LCFS 46-14

[10] If the Board directs the Executive Officer to provide the missing information concerning the Davis review, it must follow the procedures in section 11347.1.

staff has ignored that study in its rulemaking proposal and supporting materials. The CARB staff has also ignored a November 2014 submission by Growth Energy that demonstrated how the ISU work could be adapted to correct the results of GTAP. Since at least 2009, the CARB staff has known about the inability of GTAP to account for multiple cropping; Growth Energy supplied a method to correct that deficiency. If the CARB staff did not agree with Growth Energy's approach, it should have developed and applied its own. Choosing instead to completely ignore the ISU study violates the Legislature's requirement to use the "best available" information. If the staff's position is that it had too little time or resources to include the ISU work in its new proposal, then the solution is simple: the Board should give the staff the resources it needs and direct the staff to return to the Board, before the Board attempts to act on the current LCFS proposal.

LCFS 46-14 cont.

- *CRP Land.* A lack of time or resources to update GTAP is also not a valid reason for the CARB staff's steadfast refusal to include the effects of the Conservation Reserve Program ("CRP") land in mitigating the land-use-related emissions impacts that the CARB staff attributes to corn-starch ethanol. In March 2014, Growth Energy supplied CARB with direct evidence from U.S. Department of Agriculture statistics showing that CRP land conversion has occurred in the last five years. The GTAP system already includes computer code to "access" CRP land, as Appendix A points out. In other words, CARB has a model that can account for CRP land conversion and was provided with CRP conversion data almost a full year ago. But apparently nothing has been done with this issue in the

LCFS 46-15

CARB staff's new proposal, and the reasons why the staff has not done so are not clear in the materials provided to the public. LCFS 46-15 cont.

- *The AEZ-EF and CCLUB models*. The CARB staff's current LCFS proposal uses a model called the "Agro-ecological Zone Emission Factor" model (or "AEZ-EF") to estimate GHG release caused by various theoretical land transitions. In 2013, the researchers at the Argonne National Laboratory ("Argonne") released an updated version of an alternative model that serves the same purpose as AEZ-EF called the "Carbon Calculator for Land Use Change from Biofuels Production" model (or "CCLUB"). The 2013 CCLUB model includes more detailed emissions-related information for the United States than the AEZ-EF model. The land-use change emissions estimated with AEZ-EF and CCLUB differ substantially. (*See* Appendix A, Table 2.) Although the CARB staff has claimed in at least one stakeholder discussion to have evaluated CCLUB, there is no indication of its having done so in the AEZ-EF documentation, the ISOR for the current regulatory proposal, or the staff's accompanying materials. In order to determine whether the CARB staff is using the "best available" science, the Board and stakeholders are entitled to know why the CARB staff has chosen to use AEZ-EF rather than CCLUB. LCFS 46-16

The potential magnitude of the errors in the CARB staff's ILUC analysis, and thus in the "signals" concerning the CI of corn-starch ethanol created by the proposed new LCFS regulation, are large. These false signals threaten to undermine the very purpose of the LCFS by promoting fuels that will not necessarily reduce greenhouse gas emissions and may even increase emissions. Having now been provided with Appendix A to these comments ─ which largely restates various LCFS 46-17 objections to the staff's current approach and corrective recommendations that Growth Energy has previously presented[11] — the Board can and must address these issues. If CARB relies on information not currently in the rulemaking to explain its reasons for not accepting Growth Energy's objections and recommendations, it must place that information in the rulemaking file and allow sufficient time for public review and comment. (*See* note 9 above.) If no such information is forthcoming, then the alternate explanation is that the Board is relying on conjecture and unsupported assumptions, rather than the "best available" information. Alternatively, if the Board is convinced that more time and resources are needed to address the issues presented in Appendix A, it should either suspend the LCFS program or maintain the regulatory status quo until the staff is prepared to bring a new proposal back to the Board. LCFS 46-17 cont.

2. California GREET 2.0

In Appendices B and C, Growth Energy comments on the portions of California GREET 2.0 ("CA GREET 2.0") used in the CARB staff's new LCFS proposal to generate direct-CI values pertaining to corn and sugarcane ethanol. There are several issues identified in Appendices B and C that CARB must address:[12]

- *Impacts of land-use change on methane emissions*. Enteric fermentation, which occurs in the digestive system of ruminant animals, produces methane, which AB 32 treats as a greenhouse gas. The models used in LCA analysis that attribute the creation of additional LCFS 46-18

---

[11] Some of the relevant earlier submissions by Growth Energy are included in Appendix A. Other stakeholders may have advanced similar objections and recommendations, or commented on the same issues. It is impossible to know if that has occurred, however, because the CARB staff has apparently interpreted the Government Code not to require it to have placed all such submissions in the rulemaking file for this proceeding. *See* Part V below. LCFS 46-19

[12] *See* note 8 above.

cropland to biofuel mandates also posit that the increase in cropland will reduce the land area available for grazing animals (unless additional land is cleared for grazing); one result of that reduction in grazing area, or a need to clear more land, will be an increase in livestock prices, a reduction in demand for meat, and smaller herds. As Appendix B notes, EPA's LCA analysis has accounted for this indirect reduction in methane emissions in the RFS program's LCA analysis. The CARB staff, however, has not done so in CA GREET 2.0 or in other parts of its new LCFS proposal, even those this omission has been repeatedly called to the staff's attention. Unless the CARB staff has a sound theoretical or empirical basis for disagreeing with EPA's judgment that a sound LCA-based program should account for the reductions in total methane emissions that will result from any land-use changes predicted from biofuels policies, the CA GREET 2.0 model should be modified to come into line with EPA's approach.

LCFS 46-18 cont.

- *Credit for reductions in methane emissions resulting from the use of DGS*. Livestock fed with a coproduct of corn-starch ethanol production, called distillers grain solubles ("DGS"), experience lower rates of enteric fermentation and therefore release less methane. Accordingly, Argonne's current GREET model (called "GREET 1-2013") gives "credit" to corn-starch ethanol production that includes the production of DGS. By contrast, CA GREET 2.0 does not, ostensibly because the CARB staff does not consider the feeding of animals to fall within the LCA system boundary for corn-starch ethanol. In addition to running counter to the judgment of Argonne's experts, who included a DGS credit for reductions in methane emissions, the CARB staff's approach is arbitrary. The entire ILUC theory is itself based on economic assumptions that are untestable; if the theory itself is

LCFS 46-20

sound enough for inclusion in a regulatory program, then there is no reason to exclude the credits for DGS production recognized by Argonne. LCFS 46-20 cont.

- *Backhaul emissions.* In a regulatory program involving multiple fuel pathways, like the LCFS regulation, the LCA analysis must treat pathways that use different feedstocks in a consistent manner, unless there is sufficient basis to treat them differently. As Appendix C points out, of all the liquid fuels included in CA GREET 2.0, only one (ethanol made from sugarcane) is not charged with so-called "backhaul emissions," which are intended among other purposes to account the GHG emissions attributed to a vessel that has transported liquid fuel to a given destination after it departs for another port. In the case of sugarcane ethanol, which reaches the United States via ocean tankers, the omission of backhaul emissions has a significant impact on its assigned CI value. (*See* Appendix C, section 6.1.[13]) Consistency in the LCA analysis and in the regulatory process generally should require producers of sugarcane ethanol to account for those emissions in their applications, unless they can accurately and affirmatively show for purposes of their pathway application that no such backhaul emissions exist.[14] LCFS 46-21

- *Accuracy of inputs for shipping emissions for Brazilian sugarcane ethanol.* Basic information used in the LCA analysis must be accurate. As Appendix C indicates, CA LCFS 46-22

---

13 A screen-shot of the relevant workbook from CA GREET 2.0 is included as an Exhibit to these comments.

14 If the premise for assigning no backhaul emissions for sugarcane ethanol from Brazill is a belief that vessels that would carry sugarcane ethanol to the United States from Brazil would not leave the United States without a cargo, then (barring some explanation) the same premise should apply to the water transport of renewable diesel from the Far East, corn ethanol produced and used in the United States after barge transport, sugarcane ethanol transported by barge, and other fuels transported by barge that are included in GREET 2.0. LCFS 46-21 cont.

GREET 2.0 assumes that all sugarcane ethanol from Brazil is delivered in 22,000-ton shipments ─ an assumption that is not supported by the available data. (See Appendix C, section 6.2.) CA GREET 2.0's assumption likely understates GHG emissions from inbound ocean transport by 100 percent. CA GREET 2.0 also uses unrealistic, across-the-board assumptions about the relationship between oceangoing vessel power requirements and vessel speed. (*Id.*, section 6.4.) The appropriate course is to modify CA GREET to include default values based on the relevant real-world data (presented in Appendix C), which may be modified for pathways based on verifiable and enforceable certifications by the pathway applicant.

LCFS 46-22 cont.

Appendices B and C identify additional inconsistencies, errors and failures to use the best available information in CA GREET 2.0. Two of the world's leading biofuels experts, Bruce Dale and Seungdo Kim of Michigan State University, have identified additional errors in CA GREET 2.0 for corn ethanol, as documented in Appendix B. Such errors violate the Legislature's mandate for the use of the "best available" information in AB 32 regulations, and those errors were presented and fully documented to the CARB staff in November 2014, shortly after a draft of CA GREET 2.0 was released for public review. The impact on the direct CI emissions factors is significant, especially for corn-stover ethanol, and those errors must be addressed without further delay. Likewise, Appendix C indicates that CA GREET 2.0 does not reflect actual sugarcane farming practices, along with other errors that must also be corrected now, before the rulemaking proceeds further. (See Appendix C, sections 2-5.) Unless those errors are corrected, the new LCFS regulation will provide significantly inaccurate "signals" to downstream regulated parties, and will not maximize the program's goals in a cost-effective manner.

LCFS 46-23

* * *

In sum, the CI values assigned to corn and sugarcane ethanol are not based on reliable data and methodologies, and need to be corrected before CARB tries to move forward with the LCFS "re-adoption" process. Although the CARB staff may believe that some or all the issues identified above cannot be addressed now, given their current regulatory schedule and claimed inadequate level of resources, the Board cannot accept such a position. The Board has discretion in setting the schedule to hear items for approval and to allocate CARB's resources, but under AB 32 it has no discretion to adopt or enforce regulations that are not based on the "best available economic and scientific information." Cal. Health & Safety Code § 38562(e). Again, applying CIs that are not based on the best available economic and scientific information threatens to undermine the very purpose of the LCFS. LCFS 46-24

B. Impacts of the Current LCFS Proposal

The incorrect regulatory "signals" created by the CI values assigned to corn and sugarcane ethanol will skew the California renewable fuels market away from corn-starch ethanol, and toward sugarcane ethanol. Corn-starch ethanol will not be able to compete with sugarcane ethanol using scientifically unreliable CI values. Among other consequences, this means that the potential increase of 13 cents per gallon of liquid fuel in 2020, estimated by the CARB staff if LCFS credits cost $100 per credit, will not be spent to achieve reductions in the CI of California motor fuels in the most cost-effective manner possible and may not lead to GHG reductions at all.[15] LCFS 46-25

---

[15] The CARB staff's 13-cent-per-gallon estimate appears in the Attachment to the Form 399 (Fiscal Impact) report signed on December 15 and 16, 2014, by two CARB staff members, and which Growth Energy located in the rulemaking file at CARB in early January 2015. CARB uses the $100 per credit estimate in the ISOR for the LCFS. *See* LCFS ISOR at VII-1. According to the ISOR, the estimated fuel price increase for gasoline in 2020 using the $100 per credit estimate is 12 cents per gallon. *See id*. at VII-5, Table VII-5. While the CARB staff calls the $100 per credit estimate "conservative," considers the 12-cent-per-gallon estimate to "represent the upper bound of fuel price impacts," and urges that its estimates not be used to "determine the impact of credit prices on the final retail price of transportation fuels," *see id*.,

Despite the lack of corollary benefits, the new LCFS regulation will result in the displacement of corn-starch ethanol produced in the Midwest with other fuels. The staff has published an "illustrative compliance scenario" which projects a reduction in corn ethanol use in California gasoline from the current (2014) level of 1,250 million gallons per year to 700 million gallons per year in 2020, with an increase in consumption of cane ethanol equal to about 64 percent of that reduction. That scenario means a reduction in the use of Midwest corn ethanol in California of about 550 million gallons per year as of 2020, relative to today, equivalent to the entire output of about seven typical-sized ethanol plants.[16]

The CARB staff has based its analysis of the economic impact of the LCFS regulation from 2016 to 2020 — which is an analysis that is mandatory for any rulemaking governed by the APA, and whose reliability must be affirmed by the rulemaking agency before a final rule can be adopted[17] — on estimates of the prices of LCFS credits from 2016 to 2020. The primary case used in CARB's economic impact analysis uses, as indicated above, a $100 per credit price; the staff's analysis also examines economic impacts using lower credit prices. As explained in Appendix D, if sugarcane ethanol pathways achieve CI levels of 40 g/MJ, and corn-starch ethanol pathways achieve CI levels of 70, credit prices as low as $23 would be sufficient to induce a switch from

LCFS 46-25 cont.

---

the staff has not fully explained why it considers the $100 per credit to be "conservative" or why it believes the 12-cent-per-gallon increase to "represent the upper bound."

16 According to data published by the Renewable Fuels Association, the average output of operating corn-starch ethanol biorefineries in the United Sates is about 76 million gallons of ethanol per year. *See* www.ethanolrfa.org/pages/statistics.

17 *See* Cal. Gov't Code § 11346.5(a)(13) (requiring a determination of cost-effectiveness in an initial regulatory proposal); id. § 11346.9(a)(4)(same, in the Final Statement of Reasons for regulatory action). An agency cannot determine the cost-effectiveness of a regulation without estimating the costs of the regulation, as well as its benefits. As for the CARB staff's estimates of the benefits of the proposed new LCFS regulation, see Part IV below.

Midwest corn ethanol to imported sugarcane ethanol, assuming that the latter is available for sale to the downstream market in California. (That is an assumption that the CARB staff has made in its compliance and economic impact analyses.) As Appendix D, prepared by Edgeworth Economics, states, the CARB staff's "scenario indicating a substantial decline in the use of Midwest corn ethanol in California and an increase in the use of imported cane ethanol is therefore not only plausible, but probable if sufficient ethanol is available from Brazil, even at modest credit prices well below CARB's projected level of $100." CARB must explain whether, and if so, why, it considers this dramatic shift in the sourcing of ethanol for the California market (which its own staff's economic impact analysis confirms) to be irrelevant to its statutory mandates or objectives, and to the policies that it pursues as a matter of discretion.

LCFS 46-25 cont.

Much, if not all, of the Midwest corn ethanol eliminated from the California market would be ethanol produced at biorefineries that generate renewable fuel that is certified under the federal Renewable Fuel Standard (RFS) with the specific intent of reducing national greenhouse gas emissions, thereby putting the LCFS program into direct conflict with federal law and policy.[18] In addition to the economic impacts on corn-starch ethanol business operations, the U.S. corn-starch ethanol producers who are currently attempting to finance the development of cellulosic ethanol production capabilities at plants located in the United States may have fewer resources available for those development efforts; in that respect, the LCFS program will further interfere with the goals and purposes of federal biofuels law and policy, which include the commercialization of cellulosic ethanol.

LCFS 46-26

Unless there is a significant expansion in domestic demand for ethanol, the increased imports of Brazilian cane ethanol, combined with the proposed LCFS regulation's

LCFS 46-27

[18] 42 U.S.C. 7545(o)(2)(A)(i)

LCFS 46-26 cont.

generous allowance of credit to California electric utilities,[19] will result in a combination of (i) lost production or even shutdowns at Midwest biorefineries, and (ii) increased logistics costs as those American biorefineries seek foreign markets (potentially, and ironically, in Brazil, where ethanol is not subject to the LCFS regulation). If the Board believes that any other outcome or combinations of outcomes for the Midwest corn ethanol industry from the LCFS regulation will occur, it should explain them and estimate their likelihood of occurrence.[20] LCFS 46-27 cont.

The second outcome ─ corn ethanol export outside the United States to make up volume lost in California ─ will not produce reductions in global GHG emissions.[21] To the extent the first outcome (loss of any commercially practicable way to offset the reductions in California demand) occurs, then the LCFS regulation will have particularly grim consequences for the Midwest corn ethanol industry and those who depend on it. As Appendix D indicates:

> On average, U.S. corn ethanol facilities employ approximately 0.8 employees per million gallons of ethanol produced, or about 61 employees for a typical plant. A reduction in ethanol demand of 550 million gallons per year therefore would result in a direct loss of approximately 440 jobs at ethanol refineries. In addition to these direct effects, the regions that host ethanol production facilities would experience additional reductions in economic activity stemming from reduced purchases of locally-sourced inputs (the "indirect" impact) and reduced spending by facility employees and local vendors (the "induced" impact). These additional economic impacts are generated by the "multiplier" effect, which results from the recycling of business revenues and household income within the local region. Plausible estimates for the overall multiplier effect for employment applicable to the ethanol industry range from about 2 (indicating a total impact on employment equal to two

LCFS 46-28

---

[19] *See* Section C below.

[20] Note that this analysis of potential outcomes from the LCFS regulation assumes for present purposes that corn-starch ethanol pathways achieve the CI levels projected by the CARB staff. As to the realism of those projected reductions in CI levels, see Part III.A below. LCFS 46-27 cont.

[21] In addition to producing no net GHG emissions reductions, the second outcome will impose substantial direct costs on the Midwest corn ethanol industry. Appendix D estimates that the additional logistics costs for the transport of Midwest corn ethanol to a market like Brazil at approximately 10 cents per gallon. LCFS 46-28 cont.

> times the direct employment impact) to about 7. Applying a figure of 4 to the direct employment impacts calculated above implies a loss of approximately 1,760 jobs in ethanol producing regions.

LCFS 46-28 cont.

If CARB disagrees with that assessment or considers those outcomes to be irrelevant to its mission, the Board needs explain why those impacts in the Midwest are overstated, or why those impacts are irrelevant.

III. ENVIRONMENTAL ANALYSIS

LCFS 46-29

Two different statutes ─ AB 32 and CEQA ─ make it critical for the Board to develop a complete understanding of the environmental issues presented by the CARB staff's ADF and LCFS proposals. First and foremost, the purpose of AB 32 is to reduce GHG emissions, *see, e.g.*, Cal. Health & Safety Code § 38562(a); regulations that do not reduce GHG emissions are not "necessary" to meet the purposes of AB 32 and would violate the Government Code.[22] In addition, among other relevant requirements, including the obligation to rely on the "best available" scientific and economic information, *id.* §38562(e), AB 32 directs that to the extent feasible, the Board's GHG regulations not interfere with efforts to meet and maintain federal and state air quality standards. *See id*. § 38562(b)(4). Under CEQA and the Board's implementing regulations, the Board's obligations to protect the environment are, if anything, even more exacting: CARB "shall not" adopt or approve any action "for which significant adverse environmental impacts have been identified during the review process." if there are "feasible mitigation measures or feasible alternatives available which would substantially reduce such adverse impact." 17 C.C.R. § 60006.

LCFS 46-30

As explained below, the CARB staff's two proposals do not meet the criteria of either AB 32, or of CEQA and the Board's implementing regulations. First, the CARB staff's LCFS proposal

LCFS 46-31

[22] *See* Cal. Gov't Code § 11342.2 ("no regulation adopted is valid or effective unless … reasonably necessary to effectuate the purpose of the statute").

assumes that the current LCFS regulations have actually reduced net GHG emissions into the atmosphere; in fact, there is no evidence that the LCFS regulations have done so, to date, and the available evidence demonstrates that there have been no such GHG reductions. Second, and building its first false premise about the efficacy of the current LCFS program, the staff's LCFS proposal invites a further assumption that the new LCFS regulations will achieve further reductions in net GHG emissions, but remarkably, the *staff has offered no definitive quantitative estimate of those GHG reductions.* That proposal also makes unrealistic assumptions about how portions of the affected industries will respond to the new regulation, and fails to account for ways in which the new regulation will increase, rather than decrease, GHG emissions, as well as criteria pollutants. The proposed new LCFS regulation cannot properly be treated as a regulation that meets the purposes of AB 32 because there is no reliable demonstration that the regulation will reduce GHG emissions, and the proposal is therefore not authorized by AB 32 and is invalid under the Government Code. In addition, and in conflict with section 38562(b)(4) of the Health & Safety Code, the CARB staff has ignored alternative, "feasible" methods of obtaining the same GHG reductions that it once attributed to the LCFS regulation through 2020. (*Id.*)

LCFS 46-31 cont.

LCFS 46-32

LCFS 46-33

LCFS 46-34

The staff's two proposals (for the new ADF regulation and for the revised LCFS regulation) also conflict with the requirements of CEQA and cannot be adopted. CARB is obligated to mitigate the significant adverse environmental impacts of the LCFS regulation recognized by the Court of Appeal in *POET v. California Air Resources Bd.* (2013) 218 Cal. App. 4th 681, that will result from the use of biodiesel fuels. As explained in Appendices I and J and as summarized below, the CARB staff's two proposals and the draft EA do not properly mitigate those impacts, or comply in other important respects with CEQA and the Board's implementing regulations.

LCFS 46-35

A. The LCFS Regulation and GHG Emissions

We begin with the facts and analysis that are pertinent to an analysis of the LCFS proposal under AB 32, before turning to the CEQA analysis.

1. Background on Corn-Starch Ethanol Production: Past and Current Practices

The first step in understanding the environmental consequences of the proposed new LCFS regulation relevant to AB 32 is to consider the impacts of the current regulation, first adopted under AB 32 in 2009. The ISOR for the new proposed LCFS regulation claims that "[o]ver the first three years of the LCFS, there has been a steady decline in the average CI of the mix of biofuels used in California. Concurrently, there has been a great expansion of the applications for fuel-pathway CIs." (LCFS ISOR, App. B at B30.) On that basis, the "ARB staff expects these trends to continue and actually accelerate as the stringency of the LCFS increases and credits become more valuable." (*Id.*) The ISOR cites no facts in support of the staff's expectation, and its claim that there has been a "steady decline in the average CI of the mix of biofuels sold in California" is contradicted by the relevant evidence from the corn-starch ethanol industry. These are the pertinent facts: [23] LCFS 46-36

1. Ethanol produced from corn starch is the principal renewable fuel produced in the United States, and has been the primary alternative fuel blended into gasoline in California, both before and after the implementation of the current LCFS regulation. Members of Growth Energy and other producers in the U.S. corn ethanol industry have strong commercial incentives to LCFS 46-37

---

[23] Because Growth Energy does not have access to confidential business information of its members or any other firms in the ethanol industry, it bases these comments on information in the public record. *See* Appendix E (Declaration of Erin Heupel, P.E. (hereinafter "Heupel Decl.").

maximize yield from the feedstock they purchase and to minimize energy usage, and thus to minimize GHG emissions. Next to corn costs, energy costs are the largest variable cost in producing corn ethanol.

2. A corn-starch ethanol plant costs millions of dollars to build. Most corn-starch ethanol is produced in the Midwest, at plants that are carefully sited in order to have ready access to their feedstock, as well as competitively priced natural gas, electricity, or other sources of energy to run the plant. Ethanol plants cannot directly control and document how farmers grow and harvest corn, which the farmers grow not only to sell to ethanol plants, but also to other customers, on the best possible commercial terms for the farmers. The companies that survive and prosper in the corn ethanol industry are those whose plants are designed from the beginning for maximum efficiency in feedstock conversion and minimum energy consumption.

LCFS 46-37 cont.

3. The competitive pressure to reduce energy consumption, and not regulation, is what drives reductions in GHG emissions at corn ethanol biorefineries. For example, the current LCFS regulation has been in full effect since 2011; based on the information in the public record available to Growth Energy, ***no biorefinery*** selling ethanol for blending into gasoline has made ***any*** significant changes in its production methods, feedstocks, methods of transport, or any other factor relevant to GHG emissions, in order to specifically obtain a lower CI value for purposes of the California LCFS regulation. To be sure, as the ISOR claims, numerous plants have obtained approval for plant-specific "pathways" with lower CI values than might have otherwise been assigned to them under the California regulation. Those facilities, however, have obtained approval for those pathways by documenting production methods adopted for competitive reasons and federal policy reasons, completely independent of the California LCFS regulation.

Thus, when the ISOR claims that there has been a "great expansion" in the number of applications for new alternative-fuels pathways, in the case of Midwest corn-starch ethanol plants, it is confusing what are essentially paperwork exercises ─ when applicants are documenting production processes, methods and energy sources that have been adopted for commercial reasons ─ with reductions in CI levels driven by regulation. Because the record of "great expansion" in pathway applications appears to be one of the principal bases for predicting that the new LCFS regulation will result in reductions in the future, it is important for the CARB staff, and ultimately the Board, to identify any evidence that contradicts what Growth Energy has concluded from the information available in the open record.[24] Any such evidence should be then be placed in the rulemaking file pursuant to section 11347.1 of the Government Code for public review and comment. If, on the other hand, the CARB staff has no evidence the current LCFS regulation has driven reductions in the CI levels of corn ethanol plants in the Midwest, and the Board decides to act in reliance on the staff's speculation, then candor should require the Board to admit as much before work is completed on the new regulation.

LCFS 46-37 cont.

Of course, not all corn-starch ethanol plants that were able to participate in the California market before 2011 have been able to remain in that market, because not all such plants have been able to document production processes, methods and energy usage that would qualify them for competitive CI values. When they have been able to remain in the market, they must generally

LCFS 46-38

[24] As Appendix E indicates, Ms. Heupel of POET LLC, for her part, was able to describe the business and regulatory practice at her company in the open record. If the CARB staff believes that it cannot put any information that corroborates its position owing to concerns about business confidentiality, and that contradicts Growth Energy's understanding of how corn starch ethanol biorefineries have gained lower-CI pathways to date, it should so indicate, and include a description of its efforts to obtain permission from the owners of the putatively confidential information in the open record.

LCFS 46-39

sell their product for less than what plants with lower CI values can obtain.[25] The CARB staff has admitted as much.[26] " Some of the plants that could not document the production technologies, processes, methods, and energy inputs that the CARB staff would reward with lower CI values had previously sold a substantial volume of ethanol in California," as one industry participant has stated, and "[t]he LCFS regulation forced some of those plants entirely out of the California market."[27] As the same industry participant has explained:

LCFS 46-38 cont.

> The effect of the LCFS regulation has been to "de-commoditize" the corn ethanol market, for purposes of California -- *i.e.*, ethanol is no longer a fully fungible commodity in California, in which producers can prevail by offering the best commercial terms. Plants that were optimized for shipment of ethanol to California when they were built, but that can no longer sell their ethanol in California, now must find buyers outside California. On an industry-wide basis, the LCFS regulation has led to "fuel shuffling" that has likely increased the number of miles that Midwest corn ethanol had to travel in 2011 in order to get from the production facilities to customer destinations.

LCFS 46-40

Whiteman Decl. ¶ 18. Importantly, as that individual concludes:

> For all the disruptions in the California ethanol market created by the LCFS regulation, there has been no reduction in the overall amount of corn ethanol produced in the United States, or used as a motor fuel in this country or overseas. …. The overall production levels for corn ethanol last year, and for the foreseeable future, depend on macroeconomic factors (including demand for gasoline) that are independent of the LCFS regulation.

---

25 Growth Energy relies here on other public information. *See* Appendix E (Declaration of Robert Whiteman (hereinafter "Whiteman Decl.").

26 *See* Whiteman Decl. ¶ 17. Mr. Whiteman is a senior official in one of the largest ethanol marketing businesses in the United States, and would qualify as an expert on corn-starch ethanol marketing based on his knowledge, skill, experience and training.

27 *Ibid.*

Id. ¶ 20.[28] The CARB staff also agreed, in the 2009 rulemaking, that "fuel shuffling" would be one result of the current LCFS regulation. When taken together, the totality of the evidence thus establishes this important point: ***the current LCFS regulation has not resulted in any reductions in GHG emissions from corn starch ethanol,*** whose use in gasoline has been the downstream fuel industry's principal method of complying with the LCFS regulation.

LCFS 46-40 cont.

In sum, and contrary to what may be the position taken in the ISOR for the new regulatory proposal, there has to date been no "real" reduction, see Cal. Health & Safety Code § 38562(d)(1), in the "average CI in the mix of biofuels used in California," at least with respect to liquid biofuels used in gasoline. Here again, if the CARB staff has any actual evidence contradicting Growth Energy's understanding of how the LCFS regulation has affected the corn-starch ethanol business to date, it must provide that evidence for review under the Government Code, or instead admit that it is asking the Board to rely on unsupported opinion.

LCFS 46-41

2. Prospects for Future Reductions in the Carbon Intensity of Corn-Starch Ethanol

The ISOR also claims that the new LCFS regulation will continue the "trend" towards lower CI levels "as the stringency of the LCFS increases and credits become more valuable." (LCFS ISOR, App. B at B30.) The ISOR continues as follows:

> A two-step process was used to reflect how the trend to lower CI fuels will impact credit generation between 2016 and 2025. First, estimates of "pool-average" CIs for fuels with many different pathways were made based on the range of fuel-pathway CIs (FPCs) approved for use. The fuels studied were corn ethanol (150 FPCs), Cane Ethanol (21 FPCs), and Corn-Sorghum Ethanol (20 FPCs). In each case, the CIs of the lowest 50 percent of FPC CIs were averaged together, and this CI was then assigned (after appropriate adjustments to reflect iLUC changes) as the CI of that fuel category in 2016. Once a starting point for a fuel category's CI was determined for 2016, the CI was further lowered to reflect that higher credit values and continued plant improvements will lead to lower average CI with time. A

LCFS 46-42

[28] Mr. Whiteman prepared his Declaration in 2012.

> conservative adjustment of a one percent decrease in CI values for each category was uniformly applied to at least partially recognize this effect.

Id. at B30-31. As the ISOR adds in a footnote, "For example the average CI of corn-derived ethanol under this method changes from 82.2 grams/MJ to 70.0 grams/MJ." Significantly, the ISOR here concedes that a substantial part of the industry current serving California ─ some or all producers who are in the upper half of the current FPC distribution ─ have no future in the California market. Also significantly, the ISOR offers no technical analysis or informed expert opinion to support the speculation that remaining ethanol production processes will achieve *on average* the first lower-CI level (for corn ethanol, 70.0 grams/MJ), and then year-over-year reductions.

LCFS 46-42 cont.

In addition to lacking any apparent support, other than speculation by the authors of the ISOR, the ISOR's prediction for the future cannot be squared with what is currently known about industry conditions and the requirements of the proposed new LCFS regulation. As noted above (*see* Part II.B) and explained in Appendix D, at relatively modest LCFS credit prices, the LCFS regulation will shift demand for ethanol from corn-starch pathways to sugarcane pathways, and that shift will occur in the first year of the new program (2016). Here are some of the key facts that the ISOR's speculation about future "trends" does not address:

- The U.S. corn ethanol industry currently has enough production capacity to serve the Nation. The most competitive Midwest corn ethanol plants in operation today are built and sited for optimal logistics and energy usage in the first years of production, and not for significant future optimization.[29]

- In addition to energy, the corn feedstock is a major cost factor in corn-starch ethanol production, and corn-starch ethanol plants "cannot directly control and document how

LCFS 46-43

[29] See Appendix E (Heupel Decl.).

farmers grow and harvest corn, which the farmers grow not only to sell to ethanol plants, but also to other customers, on the best possible commercial terms for the farmer."[30]

- Corn-starch ethanol plants are also assigned by the LCFS a large ILUC emissions factor, which they are powerless to change.

- Corn-starch ethanol plants can therefore work with only a fraction of their production processes ─ chiefly, energy, for which they are already likely optimized ─ to achieve lower CI scores.

- Any costs incurred to reduce the CI score of the ethanol that corn ethanol plants would produce would have to be recovered in the California market against competition from sugarcane ethanol and electricity. The deeper the reductions in CI, assuming any such reductions were possible, the greater the costs, and the longer the period needed to remain competitive in California.

Against that backdrop, Growth Energy credits the opinion expressed in Appendix E that in order to remain in the California market, "even a very efficient Midwest corn ethanol plant would have to find and implement further efficiencies or energy reduction opportunities not driven by the nationwide market and recover the costs of the necessary changes, over a very short time frame.… Rather than incur those costs, U.S. corn ethanol plants will try to compete in markets outside California."[31] Here again, if the CARB staff has any basis either to disagree with the prediction of market exist, or to support its belief in the "trend" that the ISOR predicts, it needs to provide the information (be it facts, expert opinion, or any other type of evidence) for public comment. If the CARB staff cannot do so, then as indicated above, candor requires the Board to admit that the predicted future operation of the LCFS regulation in the ISOR is based on unsupported conjecture, at least with respect to corn-starch ethanol.

LCFS 46-43 cont.

---

[30] Heupel Decl. ¶ 10.

[31] *Id.* ¶ 11.

This issue ─ how the new LCFS regulation will affect the supply of cornstarch ethanol to California ─ needs to be addressed clearly, directly, and empirically. Corn starch ethanol remains a part of the CARB staff's compliance scenarios for many years; if corn starch ethanol cannot meet the expectations of the ISOR, then the viability of the new LCFS program as depicted in the ISOR is in serious jeopardy. If the absence of the corn starch ethanol from the California market triggers use of the cost-containment provision, as the costs of LCFS credits skyrockets, then LCFS program will not achieve the GHG reductions that CARB might otherwise attribute to the program.

LCFS 46-43 cont.

3. Greenhouse Gas Emissions and Related Impacts of the New LCFS Regulation

Despite the ejection of corn-starch ethanol from the California renewable fuels market, the new LCFS regulation will not reduce, and will likely increase, net global GHG. As explained above, "fuel shuffling" is one likely outcome of the new LCFS regulation (accompanied by potential shutdowns of biorefineries in the Midwest). To date, the fuel shuffling caused by the LCFS regulation has been confined, in the case of ethanol, to the continental United States. The new LCFS regulation will make fuel shuffling an intercontinental phenomenon, as California begins to draw sugarcane ethanol in large quantities from production sites in Brazil. As explained in Appendix G, one result of the new regulation will be increases in GHG emissions caused by the transport of large volumes of Brazilian sugarcane ethanol to the California market. Looking solely at the GHG emissions increases that should be attributed to oceangoing tankers, fuel shuffling emissions will fall in the range of 385,000 to 735,000 tons of GHG emissions per year, under the assumptions described in Appendix G.[32] If the CARB staff or the Board have any disagreement with those estimated GHG shuffling losses, it should explain them and their basis.

LCFS 46-44

[32] *See* Appendix G. Those estimates are based on necessary corrections to the CA GREET 2.0 model, described in Appendix C. Even if those corrections are not made, GHG emissions from

For its own part, the CARB staff apparently has no current estimate of the net GHG emissions impacts of the LCFS regulation ─ at least, none that it was prepared to publish. The ISOR contains a table (Table IV-2) that contains some estimates of "Projected LCFS GHG Emissions Reductions." The ISOR prefaces that table, however, with this important qualification:

> These estimates do not include a reduction to eliminate the double counting of the Zero Emission Vehicle Mandate, the federal Renewable Fuel Standard Program, the Pavley standards, or the federal Corporate Average Fuel Economy Program. (LCFS ISOR at IV-2)

That is a breathtaking admission. Growth Energy is not aware of any other major regulation that the Board has ever been asked to approve without a net emissions reduction estimate for the pollutant or substance of primary concern (here, GHG emissions). For all that the Board and the public can tell, the programs that the ISOR has failed to include would leave the LCFS program with *de minimus* GHG emissions reduction benefits. Certainly, the current analysis before the Board does not meet the most basic tests for regulatory approval under AB 32; the GHG reductions that the proposed new LCFS regulation are not "quantifiable." Cal. Health & Safety Code § 38562(d)(1). Nor, of course, can the Board claim that the LCFS regulation would be "cost-effective," *see id.* § 38562(a), because there are no quantified GHG emissions reductions benefits to be placed into a ratio with the costs of the proposal. CARB cannot approve the new LCFS program proposed in the ISOR, without contorting the statutory language to allow it to impose costs on the public without first quantifying the GHG reduction benefits for which the public must pay.

LCFS 46-45

LCFS 46-46

---

the transport of sugarcane ethanol by oceangoing tankers will rise by approximately 150,000 tons per year. *Id*. at 1.

There is no escaping the requirements of the rulemaking provisions in AB 32, and certainly none in other parts of the statute. AB 32 begins with legislative findings about the importance of addressing global warming, and urges coordination of California regulatory efforts with those of other jurisdictions. *See* Cal. Health & Safety Code § 38501(a),(b),(c),(f). Yet even if GHG reductions from the new LCFS program could be quantified, those reductions were assumed to be substantial, and they were assumed to extend nationwide ─ in other words, if every goal suggested by the statute's legislative findings were fulfilled ─ the end result would produce no appreciable effect on global warming. As explained in Appendix H, the difference in ambient temperatures could barely be resolved (in the third decimal place) by 2050, using the generally-accepted modelling system developed to assess the impacts of policies on global temperatures, and would be too small to be measured in the real world. In the 2009 LCFS rulemaking the CARB staff acknowledged this point, and suggested that the benefit to the LCFS program as a means of addressing climate change would lie in the export of the regulation outside California. Appendix H demonstrates that even under such an assumption, the LCFS program would not produce changes in the global climate. The LCFS program neither conforms with the rulemaking requirements of AB 32 nor serves the statute's highest aspirations.[33] LCFS 46-47

B. California Environmental Quality Act ("CEQA") Analysis

The core of Growth Energy's CEQA comments on the LCFS and ADF regulations is contained in Appendix I and its attachments, in Appendix J, and the other appendices specifically LCFS 46-48

[33] These observations on the lack of any change in the global climate resulting from the new LCFS program should not be taken to indicate that any regulation adopted under color of AB 32 could ever be exempt from the specific rulemaking requirements in section 38562 and other provisions of AB 32 that limit and specify CARB's authority.

referenced therein. The Board is required to consider detailed responses by the staff to each part of the Growth Energy's CEQA comments.[34] LCFS 46-48 cont.

1. Impacts of the Proposed Regulations on Criteria Pollutants

The ISOR for the ADF regulation estimates that the biodiesel use allowed by the ADF regulation, which will occur as part of efforts to comply with the LCFS regulation, will increase emissions of oxides of nitrogen ("NOx") by 1.35 tons per day in 2014 and according to the ISOR, will drop to 0.01 ton per day by 2023. Here are some of the salient problems in the ISOR for the ADF regulation and in CARB's draft EA, as explained in Appendix I and its attachments: ADF 17-2

- The ISOR and its related documents do not describe the total diesel NOx emissions inventory on which the assessment is based. ADF 17-3

- The CARB staff has erroneously concluded that the use of biodiesel in "New Technology Diesel Engines (NTDEs)" equipped with exhaust aftertreatment devices to lower NOx emissions will not lead to increased NOx emissions. The CARB staff has also incorrectly apply ratios of on-road vehicle travel by NTDEs from the now obsolete EMFAC2011 model to account for the amount of biodiesel used in all NTDEs including those found in non-road equipment. ADF 17-4

- The CARB staff has incorrectly subtracted NOx reductions from the use of "renewable diesel fuel" from increases in NOx increases from biodiesel when assessing the environmental impact of ADF regulation. ADF 17-5

- A conservative but reliable assessment of the NOx emission impacts of biodiesel use under the ADF that uses the latest CARB emissions models and corrects the flaws in the staff analysis has been performed for Growth Energy and is summarized in Appendix I (Lyons). The results of that assessment indicate that NOx increases from biodiesel will be much larger than those estimated by CARB staff and that the magnitude of the impacts will not decline as forecast by CARB staff. ADF 17-6

- In addition, the assessment performed for Growth Energy demonstrates that the ADF regulation will lead to significant increases in NOx emissions in the South Coast and San Joaquin Valley air basins which are already in extreme non-attainment of the federal ozone NAAQS and moderate non-attainment of the federal fine particulate NAAQS. ADF 17-7

---

[34] *See* 17 C.C.R. § 6007(a)

- Inconsistencies and conflicts in the treatment of diesel and biodiesel fuels in the ADF and LCFS regulations create the potential for biodiesel blends to actually contain as much as 5 percent more biodiesel by volume than will be reported to CARB under the ADF regulation. ADF 17-8

- Other errors in the CARB staff's environmental assessment include incorrectly selecting 2014 as the baseline year for the environmental analysis, a lack of documentation and use of unsupported assumption in determination of the NOx control level for biodiesel, and an unnecessary delay in the effective date for the implementation of mitigation requirements under the ADF regulation. ADF 17-9

- Last year, during the development of the ADF and LCFS regulations, the CARB staff declined to adopt a proposed alternative to the ADF regulation submitted by Growth Energy. Given that the Growth Energy alternative was designed to mitigate all potential increases in NOx emissions, it yielded greater and more timely environmental benefits than the staff proposal. The Growth Energy alternative would have required the same mitigation methods as the ADF proposal but simply expanded the circumstances under which those methods must be applied; Growth Energy's proposal had a cost-effectiveness equal to that of ADF proposal. LCFS 46-49 ADF 17-10

2. CARB's Certified CEQA Program

CARB's certified program under CEQA does not excuse it from its obligations to address those serious deficiencies in the ADF proposal and the draft EA. Although "[e]nvironmental review documents prepared by certified programs," such as that adopted by CARB, "may be used instead of environmental documents that CEQA would otherwise require," "[c]ertified regulatory programs remain subject . . . to other CEQA requirements." *City of Arcadia v. SWRCB* (2006) 135 Cal.App.4th 1392, 1421-22. CEQA documents prepared under certified regulatory programs are considered to be the "functional equivalent" of the documents CEQA would otherwise require. *Mountain Lion Found. v. Fish & Game Comm.* (1997) 16 Cal.4th 105, 113. LCFS 46-50

Agencies with qualifying certified regulatory programs are excused only from complying with the requirements found in Chapters 3 and 4 of CEQA (*i.e.*, Pub. Res. Code, §§ 21100-21154) in addition to Public Resources Code § 21167. Pub. Res. Code, § 21080.5, subd. (c). "When conducting its environmental review and preparing its documentation," however, "a certified LCFS 46-51 regulatory program is subject to the broad policy goals and substantive standards of CEQA."[35] The CEQA Guidelines implementing section 21080.5 provide that, "[i]n a certified program, an environmental document used as a substitute for an EIR must include '[a]lternatives to the activity and mitigation measures to avoid or reduce any significant or potentially significant effects that the project might have on the environment.'" (*City of Arcadia, supra*, 135 Cal.App.4th at 1422 [quoting CEQA Guidelines, § 15252(a)(2)(A)]. CARB's functional equivalent document is the "staff report," which "shall be prepared and published by the staff of the state board." 17 C.C.R., § 60005(a).[36] The regulations require the staff report to be "published at least 45 days before the date of the public hearing" on the rulemaking, and to "be available for public review and comment." (*Id.*) Staff reports must be prepared "in a manner consistent" "with the goals and policies of" CEQA, and "shall contain":

LCFS 46-51 cont.

> a description of the proposed action, an assessment of anticipated significant long or short term adverse and beneficial environmental impacts associated with the proposed action and a succinct analysis of those impacts. The analysis shall address feasible mitigation measures and feasible alternatives . . . which would substantially reduce any significant adverse impact identified.

17 C.C.R. § 60005(b).

LCFS 46-52

The regulations also provide that an action "for which significant adverse environmental impacts have been identified during the review process shall ***not*** be approved or adopted as

---

[35] Kostka & Zischke, *Practice Under Cal. Env. Quality Act* (2005) § 21.10] ["Kostka & Zischke"] [citing *City of Arcadia*, *supra*, 135 Cal.App.4th at 1422; *Sierra Club v. State Bd. of Forestry* (1994) 7 Cal.4th 1215; *Californians for Native Salmon & Steelhead Ass'n v. Dept. of Forestry* (1990) 221 Cal.App.3d 1419; *Envt'l Protection Info. Ctr. v. Johnson* (1985) 170 Cal.App.3d 604, 616].)

[36] In this case, CARB's staff report is accompanied by a draft EA.

proposed if there are feasible mitigation measures or feasible alternatives available which would substantially reduce such adverse impact." *Id*. § 60006. "Feasible" means "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, and technological factors, and consistent with the state board's legislatively mandated responsibilities and duties." *Id*) If CARB receives comments raising "significant environmental issues associated with the proposed action," staff must "summarize and respond to the comments either orally or in a supplemental written report. Prior to taking final action on any proposal for which significant environmental issues have been raised, the decision maker shall approve a written response to each such issue." *Id*. § 60007. LCFS 46-52 cont.

3. CEQA Analysis

Turning to the merits of CARB's current environmental analysis, and as explained in Appendix J, the draft EA does not comply with CEQA in several material respects. LCFS 46-53

First, the draft EA fails to consider the significant environmental effects associated with the version of the LCFS regulation currently in effect. Although the proposed LCFS regulation is nearly identical in structure to the current LCFS regulation, the draft EA fails to describe or identify impacts associated with the whole of the "project" under CEQA by ignoring recognized significant impacts associated with the existing regulation. Ignoring such impacts is inconsistent with the writ issued by the superior court in *POET, LLC v. California Air Resources Board* (2013) 218 LCFS 46-54 Cal.App.4th 681 ("*POET*"), and results in a vague and incomplete project description. The draft EA also fails to state what environmental baseline is being used in its analysis, although the substantive discussions in the EA suggest a baseline of 2014 is being used. A 2014 baseline is inconsistent with Section 15125(a) of the CEQA Guidelines because it does not accurately reflect when CARB commenced its environmental review of the LCFS regulations (2007), and obscures the amount of NOx emissions caused by the increased usage of biodiesel resulting from the LCFS LCFS 46-55 regulation. And even if CARB were able to credibly argue the current LCFS regulation is a different "project" than the nearly identical LCFS regulation proposed for "re-adoption," (1) analysis of pre-2014 impacts would nevertheless be required as "cumulative impacts," and (2) any attempt to ignore prior impacts would constitute impermissible piecemealing or segmentation of environmental review.[37]

LCFS 46-55 cont.

The draft EA's analysis of criteria pollutant emissions caused by the proposed regulations is also incomplete. The draft EA fails to analyze or discuss emissions of any criteria pollutants, other than NOx. But even the discussion of impacts associated with NOx emissions, however, is misleading and fails to consider additional NOx emissions caused by increased biodiesel usage. CARB cannot argue increased renewable diesel fuel usage will offset NOx increases associated with biodiesel. This increase is speculative, and there is no mitigation, legally-binding requirement, or other performance standard to ensure those offsets will occur. The draft EA's analysis of criteria pollutant emissions is also incomplete because fails to analyze known sources of NOx emissions, including emissions associated with biodiesel use in "New Technology Diesel Engines" (NTDEs). Notably, if a more credible analysis of NOx increases using generally accepted techniques is employed, estimated NOx emissions are calculated to be far more severe than that disclosed in the draft EA, and could total as much as 9.73 tons per day statewide in 2020, and 2.39 tons per day (or 872.35 tons per year) in 2020 in the San Joaquin Valley air basin alone. This figure is vastly higher than the 10 tons per year threshold of significant adopted by the San Joaquin Valley Air Pollution Control District for projects under CEQA, and results in emissions

LCFS 46-56

LCFS 46-57

LCFS 46-58

[37] The two regulations under consideration are also internally inconsistent, as Appendix I explains. To avoid an unstable and inaccurate project description, and to avoid additional NOx impacts associated these inconsistencies (including but not limited to the blending of "Alternative diesel fuel" mixed with "CARB diesel"), the regulations must be revised and reconciled.

that directly violate the mandate of AB32. Cal. Health & Safety Code, §§ 38562 (b)(4), 38570 (b).

LCFS 46-58 cont.

The draft EA also recognizes the proposed LCFS regulation would result in the construction of new or modified facilities to meet demand for fuels created by the regulations, including processing plants for agriculture-based ethanol, cellulosic ethanol, and biomethane. The draft EA, however, only generally describes the impacts associated with this increase in develop, although it is feasible to calculate the projected additional emissions associated with such development. Although the draft EA performs no analysis of the impacts associated with these facilities, it finds the impacts to be significant and unavoidable. This is impermissible; a lead agency cannot simply label an impact "significant and unavoidable" without first providing a discussion and analysis. *Berkeley Keep Jets Over the Bay Comm. v. Bd. of Port Comm'rs* (2001) 91 Cal.App.4th 1344, 1370.

LCFS 46-59

The failure to quantify the impacts associated with such new construction also violates CEQA because it forecloses mitigation. If the impacts were quantified, CARB could meaningfully explore ways to develop mitigation to reduce such impacts or modify the regulation to reduce those impacts. Instead, the draft EA merely sets forth "recognized practices" that are "routinely required" to avoid or minimize impacts, without requiring the implementation of any specific measure, or even evaluating whether any such measures – if incorporated – would actually reduce or minimize the impact. This is improper under CEQA because the proposed mitigation measures are not required or otherwise enforceable, there is no discussion as to the efficacy of any measure, there is no quantification of the benefits associated with any measure, and the specific mitigation to be employed is deferred to a later time.

LCFS-46-60

The draft EA also fails to identify and analyze environmental impacts associated with fuel shuffling, which CARB has elsewhere recognized as a reasonably foreseeable consequence of the LCFS regulation. For one component of the LCFS regulation – shuffling of ethanol alone by ship – shuffling would result in at least an additional 150,000 tons per year of CO2 equivalent emissions using CARB's own models, and an additional 385,000-735,000 tons per year using more accurate models. These figures do not even take into account ethanol shuffling by other modes of transportation, or crude oil shuffling. There is likewise no analysis as to whether fuel shuffling would result in increases in criteria pollutants either in-state or out-of-state. LCFS 46-61

The draft EA also fails to adequately analyze project alternatives. For example, the draft EA rejects the Growth Energy alternative, even though the alternative would significantly reduce NOx emissions associated with biodiesel. The draft EA also impermissibly rejects consideration of a Cap & Trade Alternative, even though that alternative would result in none of the numerous impacts the EA found to be significant and unavoidable. The CEQA Guidelines specifically recognize that comments raised by members of the public on an environmental document are particularly helpful if they suggest "additional specific alternatives . . . that would provide better ways to avoid or mitigate the significant environmental effects," CEQA Guidelines, § 15204, and CARB may not limit its project objectives in a way to foreclose consideration of any and all projects, with the exception of the project under consideration. It was exactly this type of pre-judgment that the Court of Appeal warned against in the *POET* decision in its discussion of *post hoc* environmental review, and impermissible delegation of environmental review authority. LCFS 46-62

In sum, CEQA places the burden of environmental investigation on government rather than the public," and the draft EA falls well short of a complete and accurate investigation of the environmental effects of the proposed regulations. *Sundstrom v. County of Mendocino* (1988) 202 LCFS 46-63

Cal.App.3d 296, 311. As a result of these failures, the EA must be revised substantially, and recirculated for public review, prior to CARB's consideration of the proposed regulations for adoption. LCFS 46-63 cont.

IV. THE BOARD'S GOVERNMENT CODE AND RELATED OBLIGATIONS

Addressing the deficiencies in the draft EA and the CARB staff's related environmental materials identified in Part III above and in Appendices I and J will require significant time and resources, if the Board decides to proceed with rulemaking based on the currently proposed regulations. Simultaneously with that effort, the Board also needs to consider whether there are less burdensome alternatives to the current staff proposals, as the Government Code requires, and also address serious problems in the transparency of the current rulemaking process. CARB's tasks under CEQA and the Government Code substantially overlap, because Growth Energy has proposed an alternative to the current LCFS regulation that would eliminate the need for NOx mitigation and thus greatly simplify the CEQA effort, while also reducing the costs and burdens of attaining the identified goals of AB 32. LCFS 46-64

A. The Analysis of Alternatives under the Government Code

The Legislature regularly gives California administrative agencies wide discretion in achieving the purposes of the statutes it enacts, but it also requires that agencies avoid unnecessary or unduly burdensome regulation. Agencies cannot first propose regulations unless they have determined that no alternative to their own proposal would be "as effective and less burdensome to affected private persons and equally effective in implementing the statutory purpose or other provision of law." *See* Cal. Gov't Code § 11346.5(a)(13). Nor can an agency finally adopt its own proposal unless it can properly affirm and explain, with "supporting information," that "no alternative" that it has considered "would be more effective and less burdensome to affected private persons than the adopted regulation, or would be more cost effective to affected private persons and equally effective" in meeting a legislative objective. *Id*. § 11346.9(a)(4).

There is no question that the proposed LCFS and ADF will impose costs on "private persons" and businesses in California, of as much as 13 cents per gallon by 2020, depending on the costs of LCFS credits. (*See* Part II.B above.) Growth Energy responded to the staff's call in the spring and summer of 2014 pursuant to SB 617 for the submission of alternatives to the current LCFS regulation, and what was understood about the developing proposed amendment to the LCFS regulation, as well as the developing proposed ADF regulation.[38] The threshold question that the Board must therefore address is whether it considers itself bound by the Government Code to consider Growth Energy's proposed alternatives to what the CARB staff has now proposed. If the Board believes it has no such obligation, Growth Energy requests that CARB explain its reasons, and specify the deficiencies in Growth Energy's proposed alternatives. LCFS 46-65

1. The Apparent Goals of the LCFS Program

Assuming that the Board agrees that it needs to consider Growth Energy's alternatives under the Government Code, the next task is to determine what benefits the CARB staff is claiming for its LCFS proposal. In that regard, the SB 617 process in 2014 was illuminating. Growth Energy's proposal would have required, depending on the CARB staff's view on the need to control upstream GHG emissions associated with the use of biofuels in California, an amendment to the current AB 32 cap-and-trade regulation applicable to the transportation fuels section.[39] The LCFS 46-66

---

[38] *See* Appendix F.

[39] *Ibid.*

CARB staff responded as follows in the Consolidated Standardized Regulatory Impact Statement ("CSRIA") for the LCFS and ADF proceedings:

> ARB is required to analyze only those alternatives that are reasonable and that meet the goals of the program as required by statute. An initial assessment of the program indicates the goals of the LCFS proposal can be achieved by keeping the program '…separate of the AB 32 Cap-and-Trade system initially (at least first 10 years) in order to stimulate innovation and investment in low-GWI [global warming intensity] fuel (or transportation) technologies.' Due to the strong justifications that the Cap-and-Trade program alone generates neither the CI reductions nor fuel in the transportation sector, this alternative will not be assessed in this document.

CSRIA at 27 (footnote omitted.). Importantly, the CSRIA conceded that Growth Energy's proposed alternative would "likely" achieve the same "estimated GHG emissions reductions" as the current regulation in the period up to 2020. (*Id*. at 26-27.)

The deficiency in the Growth Energy proposal, according to the CSRIA, was not that it created a GHG emissions reduction shortfall at any point prior to the end of the current regulatory horizon; instead, the problem is that the Growth Energy proposal did not rely on the same purported strategy of fuels diversification and achievement of GHG emissions reductions as proposed by CARB. As Appendix A of the CSRIA explained:

LCFS 46-66 cont.

> Transportation in California was powered almost completely by petroleum fuels in 2010. … Transitioning California to alternative, lower-carbon fuels requires a very focused and sustained regulatory program tailored to that goal. … In the absence of such a program, post-2020 emissions reductions would have to come from a transportation sector that would, in all likelihood, have emerged from the 2010-2020 decade relatively unchanged. ***In the absence of an LCFS designed to begin the process of transitioning the California transportation sector to lower-carbon fuels starting in 2010, post-2020 reductions would be difficult and costly to achieve.*** This is why the primary goals of the LCFS are to reduce the carbon intensity of California fuels, and to diversify the fuel pool. A transportation sector that achieves these goals by 2020 will be much better positioned to achieve significant GHG emissions reductions post-2020.

CSRIA at 27 (emphasis added). In essence, the CSRIA claimed that fuels diversification and carbon intensity requirements were necessary in order to make post-2020 greenhouse gas reductions less costly and less difficult to achieve. The text of AB 32 does not itself require the use of a fuels diversification strategy or CI indexes to achieve GHG reductions, and certainly does not mandate the use of regulations intended to reduce the carbon intensity of transportation fuels to achieve greenhouse gas reduction, in order to achieve "the maximum technologically feasible and cost-effective reductions in greenhouse gas emissions." Cal. Health & Safety Code § 38562(a). If the Board believes otherwise, Growth Energy requests that CARB identify the statutory text within AB 32 that requires the creation of a fuels diversification strategy or the use of CI regulations to reduce GHG emissions.[40]

LCFS 46-66 cont.

Assuming the CARB staff's position on the need for a LCFS program now (*i.e.*, from the present time until 2020) must be linked back to the purpose of AB 32 (which is to reduce GHG emissions), the staff's position seems to be that the regulation of the carbon intensity of transportation fuels is necessary now in order to reduce the costs or difficulties of achieving greenhouse gas reductions after 2020. Certainly, the CARB staff cannot defend its current proposal on the basis of any GHG reductions it will achieve: as noted in Part III.A.3 of these comments, the CARB staff has apparently abjured any effort to quantify the GHG reductions that the new LCFS regulation will achieve, either before or after 2020. In other words, the current LCFS program, stripped to its essential purposes, is not a measure to achieve any quantity of GHG

LCFS 46-67

---

[40] The CSRIA identified a white paper published in 2008 by researchers at the University of California (Davis) as support for the CARB staff's position on the need for CI-based regulations. If CARB believes that the 2008 white paper bears on the scope of its authority or discretion under AB 32, it should explain why.

LCFS 46-66 cont.

emissions reductions over an identified time period; it is a measure to prepare California to achieve some unspecified quantity of GHG reductions at some time in the future. LCFS 46-67 cont.

2. The Requirements of Section 11346.9(a)(4)

As also indicated in Part III.A.3 of these comments, absent some "quantifiable" GHG emissions reductions, a regulation adopted under color of AB 32 is not within the scope of CARB's authority; the proposed new LCFS regulation is therefore invalid under section 11342.2 of the Government Code. Even CARB were to take a different view of the scope of its authority under AB 32, the Board would still need, under the California APA, to prove that Growth Energy's alternative does not meet the criteria of section 11346.9(a)(4).[41] The CARB staff has given the Board no basis for claiming to have so proved. Several points are important on this issue. LCFS 46-68

First, as Growth Energy pointed out in its SB 617 proposal last year, the federal renewable fuels program provides for the production and sale of cellulosic and "advanced" biofuels in the same time frame as the LCFS regulation. While the federal program does not require the use of electricity or hydrogen as a transportation fuel, the California motor vehicle emissions control and zero-emission vehicle programs (also noted in Growth Energy's proposal) certainly do.[42] The record in this rulemaking is devoid of any demonstration that the LCFS program will increase fuels diversification more than the federal RFS program and the State's electric-vehicle and related LDFS 46-69

---

[41] The text of the APA makes it clear that the agency has the burden of proving "with supporting information" that no alternative considered by the agency would meet the criteria of section 11346.9(a)(4). If the Board does not agree that it has that burden, it should explain why not. In addition, the Board should articulate the standard that it believes would apply to judicial review of the determination required in section 11346.9(a)(4), and explain its full basis for choosing that standard. LCFS 46-68 cont.

[42] *See* Appendix F (Growth Energy's proposed alternative to the LCFS regulation, describing the programs that will achieve the fuels diversification sought by CARB, in the absence of the LCFS regulation). LCFS 46-69 cont.

programs will. To the contrary, the CARB staff has admitted that it is "unclear to what degree" the LCFS program will require "new production" of "less carbon-intensive fuels … in California or elsewhere."[43] If the record currently contains an analysis that estimates the increase in fuels diversification that the LCFS regulation will achieve compared to the federal RFS program, CARB should identify.

LCFS 46-69 cont.

Second, as should be clear from the ADF ISOR and in the ADF ISOR's accompanying materials, the use of the CI-based regulatory strategy that the CARB staff is recommending will impose costs on the California motoring public, if they bear any costs of the mitigation strategy that the use of the LCFS regulation will require. As Growth Energy has demonstrated in Part III.B and the related Appendices, those costs may be even greater if CARB adheres to its duties under CEQA (though the cost-effectiveness of the mitigation strategy will not change). In addition, the increases in GHG emissions entailed in moving sugarcane ethanol to California (see Part III.A and Appendix G) will likely need to be offset by other types of GHG controls, which will impose additional costs on California consumers and businesses. The CARB staff has not offered any analysis to the Board that explains why those ***present*** costs, along with the direct costs of the LCFS program in the near term, are worth incurring in order to make the ***future*** costs of post-2020 GHG emissions reductions less costly. Conclusory or self-serving statements by businesses who claim that they will construct facilities or produce and market advanced, diversified liquid biofuels are entitled to no weight.

LCFS 46-70

[43] *See* LFCS ISOR Appendix E at E-5.

Third, the long-run, post-2020 plans for GHG reductions developed by CARB call for the phase-out of reliance on liquid biofuels;[44] low-CI liquid fuels, however, are presumably the fuels whose production is in need of diversification, according to the CSRIA. Eventually, the State plans to eliminate gasoline, in particular, from use in California cars and trucks and to fully replace gasoline with electricity. Putting to the side whether CARB's post-2020 strategy is meritorious, the CARB staff has given the Board no basis to explain why CARB should impose costs on California consumers and businesses to foster the use of fuels that (according to CARB) are destined for a diminishing, and no long-term, role in its greenhouse gas reduction strategy. LCFS 46-71

One other important, procedural point must also be noted here. The demonstration required by section 11346.9(a)(4) that there are no superior alternatives to a proposed regulation (as the statute defines superiority) must be based on "supporting information." At present, there is no such "supporting information" in the rulemaking file of which Growth Energy is aware, perhaps because the CARB staff has looked ahead to the Board's obligations under section 11346.9(a)(4) of the Government Code. If the Board intends to add such information to the rulemaking file in order to try to carry its burden under section 11346.9(a)(4), it must comply with section 11347.1 of the Government Code. LCFS 46-72

In sum, with regard to the LCFS proposal, CARB is not currently positioned to proceed with final rulemaking because, among other reasons, it cannot discharge its obligations under section 11346.9(a)(4) of the Government Code. If the Board intends to pursue the staff's proposal, it must address the issues raised here, both substantive and procedural.[45] LCFS 46-73

---

[44] *See* http://www.arb.ca.gov/planning/vision/vision.htm.

[45] If the Board does not agree with Growth Energy's analysis of the obligations of section 11346.9(a)(4), Growth Energy requests that the Board explain its reasons for disagreement.

B. Requirements of Transparency

Section 11347.3 of the Government Code requires CARB to maintain a "file of [the] rulemaking proceeding" for any proposed regulatory action subject to the APA, including the LCFS regulation." The rulemaking file must include, among other items, the following:

> (6) All *data and other factual information***,** any studies or reports, and written comments submitted to the agency in connection with the adoption, amendment, or repeal of the regulation.
>
> (7) All data and other factual information, *technical*, *theoretical*, and *empirical studies or reports*, if any, on which the *agency is relying* in the adoption, amendment, or repeal of a regulation, including any cost impact estimates as required by Section 11346.3.

Gov't Code § 11347.3(b)(5),(6) (emphasis added). The entire rulemaking file, including the foregoing material, must be "available to the public for inspection" from the time when the first notice of the proposed rulemaking is published in the California Regulatory Notice Register, *id.* at § 11347.3(a), which here occurred on January 2, 2015.

As the above-quoted text makes clear, rulemakings at CARB must include the creation of a rulemaking file that includes "***[a]ll*** data and other factual information, any studies or reports, and written comments submitted to the agency" in connection with the proposal. Gov't Code § 11347.3(a),(b)(6) (emphasis added). To assure immediate public access to the supporting materials as soon as the 45-day materials are released, the APA requires that the 45-day notice include a statement that the agency on the date of the notice "has available *all* information upon which [the] proposal is based." *Id*. § 11346.5(a)(16) (emphasis added). A separate provision confirms that the agency must in fact make those records, and any other "public records, including reports, documentation, and other materials, related to the proposed action," available. *Id.* § 11346.5(b).

The "written comments" that must be placed in the record are not simply those submitted to the agency in a particular manner or at a particular time, such as during the period between publication of the notice of a public hearing and public hearing -- an agency must put "all" it receives "in connection with" a regulatory proposal in the rulemaking file. The Legislature's choice of words to describe what comments must be placed in the file -- "in connection with" -- sweep with intentional breadth, and require inclusion of any comments that bear on the subject of the regulatory effort. In addition, the period of public availability must "[c]ommenc[e] *no later than* the date that the notice of the proposed action is published." *Id.* § 11347.3(a) (emphasis added). The use of the term "no later than" makes it clear that the Legislature expected written comments submitted in connection with a proposed regulatory action and received before publication of the required notice to be included in the rulemaking file.

LCFS 46-74

Growth Energy has substantial concerns about the completeness of the rulemaking files for the current LCFS and ADF rulemakings, as it did in the prior LCFS rulemaking in 2009. The Court of Appeal made clear in *POET v. CARB* that neglect to include even a limited number of relevant documents in the rulemaking file would violate the Government Code. To avoid further controversy, Growth Energy requests that the Executive Officer or the CARB legal staff consider and respond to the following questions:

LCFS 46-75
ADF 17-11

1. Does the CARB legal staff agree that the rulemaking file for these two proceedings must include external communications submitted to the staff, the Executive Officer or the Board prior to the date when the rulemaking file is formally opened must be included in the rulemaking file, if those communications were submitted in connection with the adoption or amendment of ADF and/or LCFS regulation? Conversely, does the CARB legal staff believe that no such external communications submitted before the rulemaking file would come within the definition of records

LCFS 46-76

required for inclusion in the file, pursuant to section 11347.3(b)(6)? Are there any written guidelines or instructions used by the CARB staff to determine whether a communication submitted before the file is opened must be included in the file? Are there any written guidelines or instructions that the CARB staff uses in order to determine what constitutes "data … other factual information … studies or reports," or "written comments," that should be included in the rulemaking file? Will any such guidelines or procedures be made available?

LCFS 46-76 cont.

2. The ADF rulemaking was opened in 2013 and then pretermitted in 2014. What steps have been taken to assure that that all external submittals (not within the scope of section 11347.3(b)(7) concerning the 2013-2014 regulatory process were included in the ADF rulemaking file opened in January 2015? If the CARB legal staff believes that no such external submittals before January 2015 were required to be included in the "new" rulemaking file, was there any process by which the public could obtain prompt access to those materials?

ADF 17-12

Turning to the requirements of section 39601.5 of the Health & Safety Code, as noted in Part I, the Legislature in AB 1085 directed CARB to provide "all information" on key aspects of its regulatory analysis "before the public comment period for any regulation" commences under the Government Code. Growth Energy requests that the CARB legal staff explain what steps were taken to provide all the information covered by section 39601.5 in connection with the current LCFS and ADF rulemakings. Growth Energy requests that each document or other file made available to the public under section 39601.5 prior to January 2, 2015, in connection with these two rulemakings be identified, along with the date it was made available and the method by which it was made available.

LCFS 46-77

C. The SB 617 Process

As the correspondence included in Appendix F makes clear, the version of the ADF proposal on which the CARB staff invited comment and responses in the SB 617 process in 2014

ADF 17-13

differed materially from the version of the ADF proposal that the CARB staff was discussing with some stakeholders, and that the CARB staff eventually included in the current rulemaking package. Those differences related to the circumstances under which mitigation would be required, and thus both to the environmental impacts and the costs of ADF regulation. Growth Energy believes that CARB did not substantially comply with SB 617 in connection with the ADF rulemaking, and that the Department of Finance failed to perform a mandatory duty to notify CARB and the public of CARB's noncompliance and to require CARB to comply. Growth Energy therefore requests that the Board reopen the SB 617 process, and allow that process to proceed simultaneously with other work on the ADF regulation. If the Board believes there was substantial compliance with SB 617 in the ADF rulemaking process, Growth Energy requests that CARB explain the basis for that belief.

ADF 17-13 cont.

D. External Peer Review

The Executive Officer has indicated that he has sought external scientific peer review in connection with the LCFS rulemaking. The subjects of that peer review effort, however, are unknown, and it is not clear whether the Executive Officer has sought peer review under section 57004 of the Health & Safety Code for the scientific basis and scientific portions of any part of the currently proposed ADF regulation. If no such peer review has been sought and completed, Growth Energy requests an explanation of the reason why none was sought and completed.

ADF 17-14

V. CONCLUSION

Growth Energy appreciates the opportunity to participate in these rulemakings. Growth Energy believes that the current record does not enable the Board to adopt the regulatory proposals presented by the staff, and hopes that the Board will reconsider the staff's decision not to propose the alternative to the LCFS program that Growth Energy offered in the SB 617 process in 2014. If adopted, the current LCFS proposal will have a devastating impact on Growth Energy's members, who will be forced to exit from the California alternative fuels market. Such an outcome will likely trigger the cost-containment caps in the proposed regulation, and any claimed benefits of the LCFS program will be compromised or lost. By contrast, Growth Energy's alternative proposal will assure the continued supply of reasonably-priced renewable fuel to the California market, and can achieve the same overall GHG reductions as sought by the 2009 LCFS regulation while not creating any increases in criteria pollutants.

Respectfully submitted,

GROWTH ENERGY

February 17, 2015

46_OP_LCFS_GE Responses (Page 1 – 54)

370. Comment: **LCFS 46-1 through LCFS 46-5, LCFS 46-10**, **LCFS 46-29 through LCFS 46-35, LCFS 46-41, LCFS 46-44 through 46-69, and ADF 17-2 through ADF 17-10**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

371. Comment: **ADF 17-1 and ADF 17-11 through ADF 17-14**

Agency Response: These comments are responded to in the Alternative Diesel Regulation Final Statement of Reasons under Comment Letter **17_OP_ADF_GE**.

372. Comment: **LCFS 46-6**

The comment states that the Executive Officer cannot demonstrate that the LCFS amendments are reasonably necessary to meet the purposes of AB 32, as the Government Code requires.

Agency Response: As stated within the ISOR, the objective of the LCFS program is to achieve a 10% reduction in the CI of transportation fuel used in California by 2020, thereby providing multiple benefits such as GHG reductions, diversifying the state's fuel portfolio, reducing dependence on petroleum, and decreasing associated prices spikes caused by volatile oil prices. These purposes are clearly identified and are not achieved by other programs or the commenter's alternative. In fact, the comment focuses only on the GHG reduction component and disregards the fundamental objective for CI reductions and the additional benefits that result (which are also recognized or required by AB 32).

However, even focusing on just the GHG emission reductions, ARB staff disagrees with the comment. The LCFS regulation, along with other regulations, policies, planning, market approaches, incentives and voluntary efforts are combining to meet the objectives of AB32. The LCFS regulation is a core component of that, providing almost 20 percent of the emissions benefits.

373. Comment: **LCFS 46-7**

The commenter suggests that they were unable to provide meaningful input on program costs under the SB 617 process due to time constraints and due to ARB's failure to disclose all the estimated benefits or costs.

Agency Response: ARB disagrees that the commenter did not have a meaningful opportunity for input into the economic analysis of the LCFS. SB 617 and the implementing regulations[12] do not mandate a length of time or format by which the agency is required to take public input. However, upon request by Growth Energy, ARB staff extended the deadline for submittal of alternatives by over two weeks (one comment was received late but still addressed) and the merits of the alternatives were considered and analyzed in the Standardized Regulatory Impact Assessment (SRIA).[13,14]

In the response to Growth Energy's request for additional time, ARB staff also noted that failing to submit ideas at that time would not preclude later comments and suggestions from the public. The SRIA itself was posted on October 23, 2014 on the California Department of Finance (DOF) website.[15] Additional opportunities to comment continued through February 17, 2015, at the hearing on February 19, 2015, and with additional comment opportunities until it is formally adopted by the Board in 2015. Staff's approach is within the requirements and spirit of SB 617 and Department of Finance regulations. It is curious that after the passage of so much time, the commenter chose not to identify costs or benefits in any detail, instead preferring to argue that they had no opportunity to do so.

374. Comment: **LCFS 46-8**

The commenter paraphrases a number of provisions of the Government Code, adding its own summary and interpretation in places.

Agency Response: Those observations, regardless whether correct, are not objections or recommendations regarding the proposal. The letter goes on to summarize "Part IV of these comments" (Q64 et seq., below) as raising "questions concerning the Executive Officer's compliance with section" 11347.3 of the Government Code and section 39601.5 of the Health & Safety Code. Those comments are fully responded to in the sequence below.
