23. In sum, the CARB staff's unequivocal statements regarding the impact of biodiesel on NOx emissions from all vehicles with NTDEs is simply not reasonable based on data from (1) a single study that (2) that tested only two urban buses equipped with the same engine and (3) used instrumentation that was, at best, barely able to measure NOx emissions from the test vehicles in general, and clearly was not sensitive enough to reliably detect changes in NOx emissions due to use of different fuels. Nothing else in the rulemaking file supports the CARB staff's claim that there will not be increased NOx emissions from the use of biodiesel in NTDEs.

Fax: (916) 444-8373
Ann Arbor, MI
Tel: (734) 761-6666
Fax: (734) 761-6755

Education

1985, M.S., Chemical Engineering, University of California, Los Angeles

1983, B.S., Cum Laude, Chemistry, University of California, Irvine

Professional Experience

4/91 to present — Senior Engineer/Partner/Senior Partner
Sierra Research

Primary responsibilities include oversight and execution of complex analyses of the emission benefits, costs, and cost-effectiveness of mobile source air pollution control measures. Mr. Lyons has developed particular expertise with respect to the assessment of control measures involving fuel reformulation, fuel additives, and alternative fuels, as well as accelerated vehicle/engine retirement programs, the deployment of advanced emission control systems for on- and non-road gasoline- and Diesel-powered engines, on-vehicle evaporative and refueling emission control systems, and Stage I and Stage II service station vapor recovery systems. Additional duties include assessments of the activities of federal, state, and local regulatory agencies with respect to motor vehicle emissions and reports to clients regarding those activities. Mr. Lyons has extensive litigation experience related to air quality regulations, product liability, and intellectual property issues.

7/89 to 4/91 — Senior Air Pollution Specialist
California Air Resources Board

Supervised a staff of four professionals responsible for identifying and controlling emissions of toxic air contaminants from mobile sources and determining the effects of compositional changes to gasoline and diesel fuel on emissions of regulated and unregulated pollutants. Other responsibilities included development of new test procedures and emission standards for evaporative and running loss emissions of hydrocarbons from vehicles; overseeing the development of the state plan to control toxic emissions from motor vehicles; and reducing emissions of CFCs from motor vehicles.

4/89 to 7/89 Air Pollution Research Specialist
California Air Resources Board

Responsibilities included identification of motor vehicle research needs; writing requests for proposals; preparation of technical papers and reports; as well as monitoring and overseeing research programs.

9/85 to 4/89 Associate Engineer/Engineer
California Air Resources Board

Duties included analysis of vehicle emissions data for trends and determining the effectiveness of various types of emissions control systems for both regulated and toxic emissions; determining the impact of gasoline and diesel powered vehicles on ambient levels of toxic air contaminants; participation in the development of regulations for "gray market" vehicles; and preparation of technical papers and reports.

NOx Emission Impacts of Biodiesel Blends:

Technical Summary

Prepared by Robert Crawford
Rincon Ranch Consulting
Tucson, AZ 85730

October 20, 2014

Issues Addressed

- Biodiesel NOx impact
  - How large is it?
  - Does it depend on dataset selection (which blend levels and studies to include)?
- Differences by blendstock type
  - Soy-based blends
  - Animal-based blends
- Emissions differences among animal-based feedstocks
- Are soy- and animal-based blends categorically different in their impact on NOx?
- Some implications for allowing biodiesels into California market

Datasets Used in Analysis

- ARB Individual Test Run Dataset ("raw data")
  - 4 tables: B5-soy, B10-soy, B5-animal, B10-animal
  - Individual test run measurements for the 3 UCR studies
  - Emission averages for other literature sources
- ARB Literature Dataset
  - Emission averages by engine, test cycle, and blend
  - Through B20 blend level
- We have added the following
  - Number of test replications for emission averages (estimated in some cases)
  - Cetane number for CARB Diesel, biodiesel blends, biodiesel feedstocks
  - Additional testing at B50 and B100 levels (where available).

NOx Impact of Soy-based Biodiesels

- The literature on soy-based blends is large and diverse (see Table 1):
  - 10 different studies (3 UCR studies sponsored by ARB)
  - 13 different vegetable feedstocks (10 soy, 2 UCO, 1 canola)
  - Conducted on a wide variety of engines in different labs
  - 7 different test cycles
- In spite of the diversity, the 3 UCR studies dominate the dataset.
  - The number of test replications (NReps) is used as a weighting factor in this analysis to reflect the better precision of results based on more tests.
  - When this is done, the UCR studies account for 82.5% of the literature dataset. The weight is even larger at the B5 and B10 levels, which come almost solely from the UCR studies.
- It is important to recognize that the effective diversity is less as a result of the weighting. The UCR studies examine only 3 different soy feedstocks.

Table 1: Scope of Emissions Testing for Soy-based Biodiesel

Test Replications on Biodiesel	3	9	9	3	9	16	12	172	36	80

NOx Impact of B5 Soy Blends Compared to CARB Diesel

- All B5 blends are soy-based
- The T-Test is the most direct method to assess the difference in mean NOx emissions (B5 vs. CARB Diesel) for individual engines
  - Requires that individual test runs (or standard deviations) be available. Cannot be applied to the Nikanjam data.
- B5 Soy blends clearly increase NOx emissions (see Table 2):
  - In 9 of 12 cases, NOx emissions are observed to increase
  - The NOx emission increases are statistically significant in 6 of the 9 cases (highly significant in 5 cases)
  - All NOx emission increases on the FTP cycle are statistically significant (when the test can be made)
  - None of the 3 observed NOx decreases is statistically significant.
- Conclusion: B5 Soy blends increase NOx emissions across a range of engines and test cycles.

Table 2. T-Test Results for NOx Impact of B5 Soy-based Blends

Source	Feedstock ID	Engine	Cycle	NReps (total)	ΔNOx (gm/bhp-hr)	Prob > |t|	Statistical Significance
Nikanjam 2010	Soy	1991 DDC 60	FTP	8	T-Test not applied. Requires test runs or standard deviations.		
Nikanjam 2010	Soy	1991 DDC 60	ESC	8	T-Test not applied. Requires test runs or standard deviations.		
Durbin 2011	Soy #1	1999 Kubota TRU	ISO 8178-4 C	19	+ 0.084	$p = 0.41$	Not significant
Durbin 2011	Soy #1	2006 Cummins ISM	40mph Cruise	5	+ 0.034	$p = 0.14$	Not significant
Durbin 2011	Soy #1	2006 Cummins ISM	50mph Cruise	12	- 0.020	$p = 0.59$	Not significant
Durbin 2011	Soy #1	2006 Cummins ISM	FTP	39	+ 0.046	$p < 0.001$	Highly significant
Durbin 2011	Soy #1	2007 MBE4000	FTP	12	+ 0.011	$p = 0.001$	Highly significant
Durbin 2013A	Soy #2	2006 Cummins ISM	FTP	12	+ 0.026	$p = 0.002$	Highly significant
Karavalakis 2014	Soy #3	1991 DDC 60	FTP	16	+ 0.045	$p < 0.001$	Highly significant
Karavalakis 2014	Soy #3	1991 DDC 60	SET	8	- 0.030	$p = 0.36$	Not significant
Karavalakis 2014	Soy #3	1991 DDC 60	UDDS	16	+ 0.035	$p = 0.05$	Significant
Karavalakis 2014	Soy #3	2006 Cummins ISM	FTP	16	+ 0.021	$p < 0.001$	Highly significant
Karavalakis 2014	Soy #3	2006 Cummins ISM	SET	8	- 0.011	$p = 0.16$	Not significant
Karavalakis 2014	Soy #3	2006 Cummins ISM	UDDS	17	+ 0.066	$p = 0.23$	Not significant

Note: The t-test analysis uses the ARB dataset of individual test runs ("raw data")

Composite NOx Impact of B5 Soy Blends Compared to CARB Diesel

- To estimate a composite impact across engines, a different statistical approach is needed that will account for the varying NOx emission levels of the engines and test cycles.
- Weighted regression analysis with dummy variables for N-1 engine/test cycle combinations "*i*" has been used to estimate Regression Model 1:

$$\log NOx = a + \sum_{i=2}^{N} \delta_i + b \cdot \delta_{B5}$$

where:

- Coefficients a and δ_i represent the average log *NOx* emission level on CARB Diesel for each engine/test cycle combination. (These values are not reported in the summary of results that follows.)
- $\delta_{B5} = 0$ for CARB Diesel tests; $\delta_{B5} = 1$ for B5 Soy tests
- Coefficient b gives the composite NOx impact of B5 Soy across engines/test cycles.

- The log *NOx* formulation assumes that the emissions impact on a percentage basis is proportional to blend level. The percentage impact on NOx emissions equals $100 \cdot [\exp(b)-1]$

Result for Composite B5 Soy Impact on NOx

- Based on the ARB test run dataset ("raw data")
  - The Nikanjam 2010 B5 testing (with weight of 4 for its NOx averages) can be included with the UCR testing (with weight of 1 for each test run).
- Regression Model 1 Result:
  - $R^2 = 0.9995$ (dominated by the dummy variables that represent the differing NOx emission levels among engines and test cycles)
  - Coefficient b for the δ_{B5} effect has the value: +0.0096 ± 0.0026. The statistical significance is $p = 0.0003$ (highly significant).
- The equivalent percentage NOx increase is **+0.96%** at the B5 level
  - or 0.19% for each 1 percent biodiesel in a blend.

Composite NOx Impact of Soy Blends Through B10

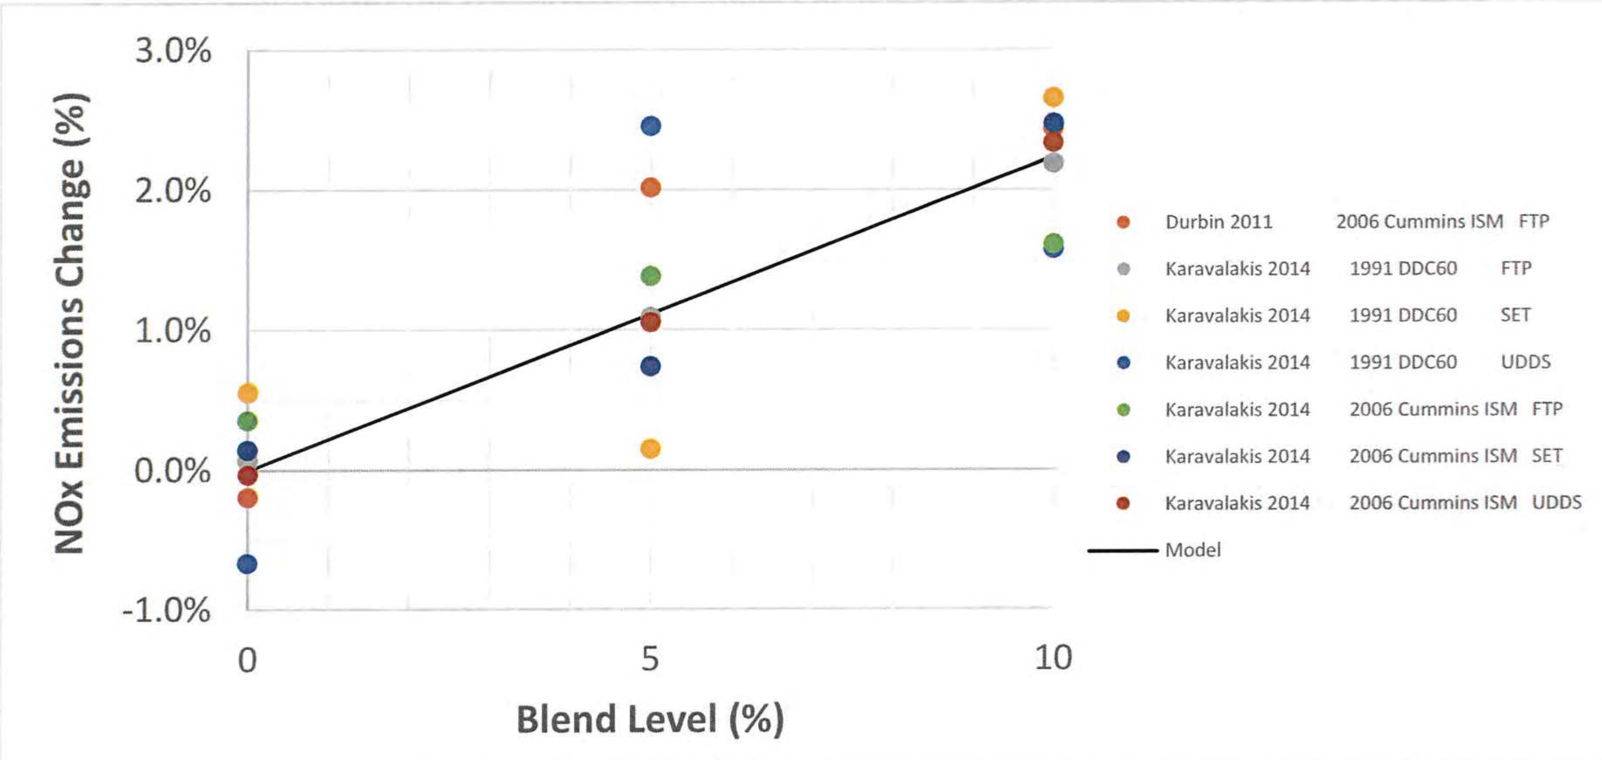
- To assess the composite NOx impact through B10, the regression model is modified to use blend level as the predictive variable. Here, the revised model is fit using the subset of data where individual tests are available ("raw data").
- Unweighted regression analysis with dummy variables for N-1 engine/test cycle combinations "*i*" has been used to estimate Regression Model 2:

$$\log NOx = a + \sum_{i=2}^{N} \delta_i + b \cdot BioPct$$

where:

- Coefficients a and δ_i represent the average log *NOx* emission level on CARB Diesel for each engine/test cycle combination. (These values are not reported in the summary of results that follows.)
- BioPct is the blend level (percentage biodiesel in the blend). CARB Diesel is BioPct = 0; B5 is BioPct = 5.
- Coefficient b gives the composite NOx impact across engines/test cycles for each 1 percent biodiesel in a blend.

Soy biodiesels cause statistically significantly increases in NOx emissions at B10, B5 and Lower blend levels



NOx Impact of Vegetable Biodiesels At Higher Blend Levels

- To include more sources, blends and feedstocks, we shift to analysis of the literature dataset with blend levels above B5. NOx emissions are reported as averages on CARB Diesel and for each BioPct blend level tested.
- Regression Model 2 is fit using emission averages weighted by the number of replications on each blend:

$$\log NOx = a + \sum_{i=2}^{N} \delta_i + b \cdot BioPct$$

where:

- Coefficients a and δ_i represent the average log *NOx* emission level on CARB Diesel for each engine/test cycle combination. (These values are not reported in the summary of results that follows.)
- BioPct is the blend level (percentage biodiesel in the blend). CARB Diesel is BioPct = 0; B5 is BioPct = 5.
- Coefficient b gives the composite NOx impact across engines/test cycles for each 1 percent biodiesel in a blend.

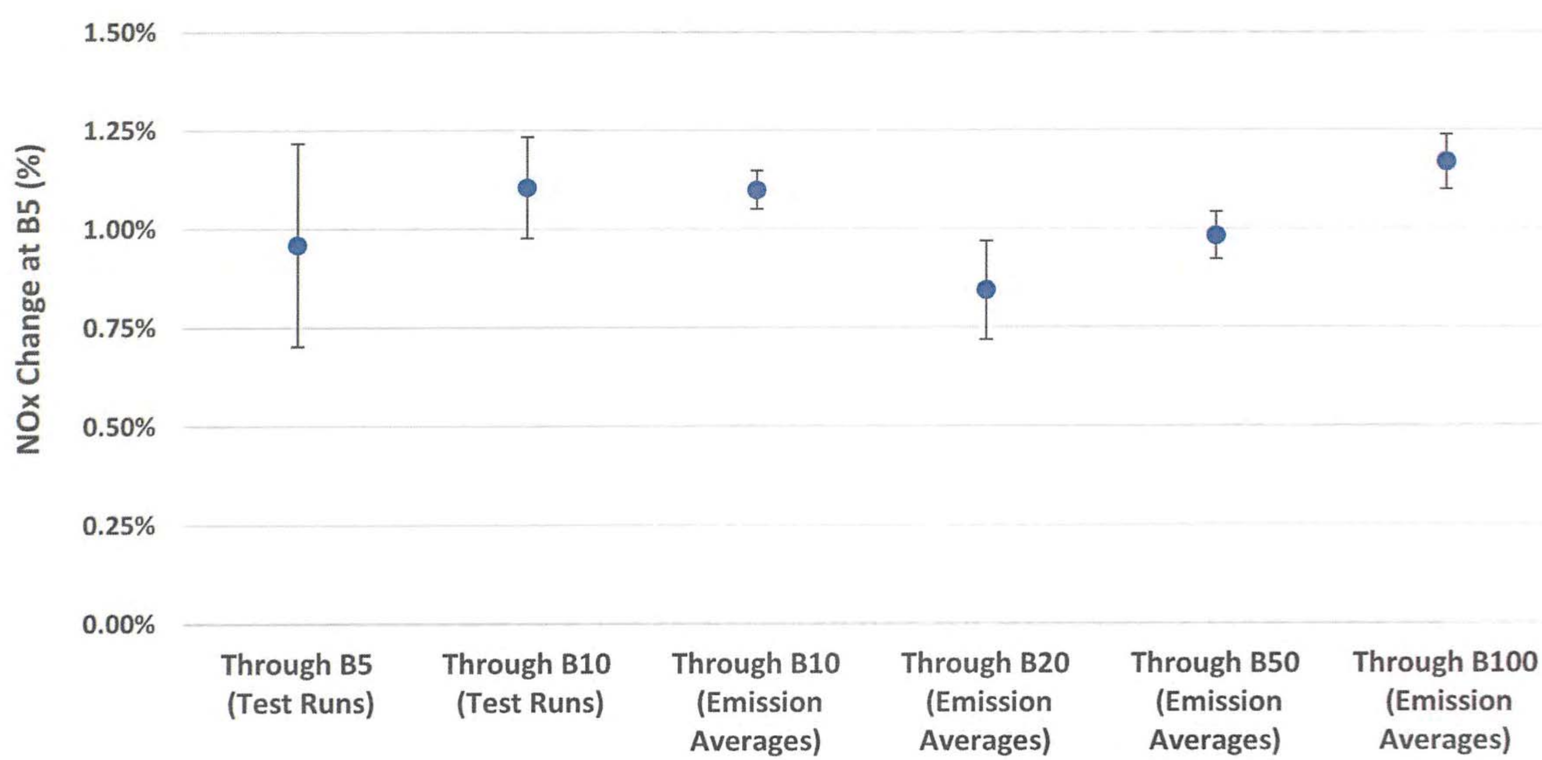
Composite Soy Impact on NOx at Higher Blend Levels

- Including all data through B100 gives the greatest diversity in sources, blends and feedstock.
- Result:
  - $R^2 = 0.9990$ (dominated by the dummy variables that represent the differing NOx emission levels among engines and test cycles)
  - Regression coefficient b for the BioPct effect has value: $+0.00220 \pm 0.00016$. The statistical significance is $p < 0.0001$ (highly significant).
- The equivalent percentage NOx increase is **+1.10%** at the B5 level
  - Or, 0.22% for each 1 percent biodiesel in a blend.
- This result is nearly the same as given by the regression analysis of the individual runs dataset through B5.

Composite Soy Impact on NOx at Higher Blend Levels

- The composite soy impact is also robust with respect to data selection (see Figure 1)
- Different choices for the dataset (test runs versus emissions averages) and the highest blend level to include (through B10, through B20, through B50, and through B100) give different results for the NOx slope with BioPct blending level. However, the results all fall within the errors bars of the estimate based on the B5 test runs alone.
- This indicates that the NOx response is linear with BioPct through high blend levels and that systematic differences among the studies are not large.
- Statistical tests show no difference among soy, UCO, and canola in their NOx impact. However, the UCO and canola samples are small and capable of detecting only large differences.

Figure 1: The NOx Impact of B5 Soy as a Function of Dataset Selection



Conclusions for Soy-based Biodiesels

- Soy biodiesel increases NOx emissions by amounts that can be estimated with good statistical confidence.
- NOx will increase ~1% on average at the B5 level and ~2% at B10.
- The NOx response is linear with the BioPct blend level. <u>There is no threshold level where soy biodiesel does not increase NOx.</u>
- This result is supported by all of the available studies and data (none disagree substantially)
  - Individual blends, engines and test cycles may still vary to some extent.
- NOx increases may be expected for UCO, canola and other vegetable biodiesels, but the data are very limited.

NOx Impact of Animal-based Biodiesel

- The literature on animal-based blends is much smaller than for soy (see Table 3):
  - Only 4 studies (3 UCR studies sponsored by ARB)
  - Only 4 animal feedstocks in total
  - Conducted primarily on engines at UCR CE-CERT (only 6 test replications conducted elsewhere)
  - A variety of test cycles
- The 3 UCR studies dominate the animal-blend dataset to a greater extent than for soy:
  - Counting test replications, the UCR studies account for 97.5% of the dataset. All of the data at the B5 and B10 levels comes from the UCR studies.
- There are notable differences among the four studies on the size of the NOx impact and its relationship to BioPct.
  - *The available studies may not permit a reliable, general understanding of the impacts of animal-based feedstocks.*

Table 3: Scope of Emissions Testing for Animal-based Biodiesels

	McCormick 2005	Durbin 2011	Durbin 2013A	Karavalakis 2014

Above B10	Yes	Yes	–	–

NOx Impact of B5 Animal Compared to CARB Diesel

- The T-Test is the most direct method to assess differences in mean NOx levels between B5 and CARB Diesel for individual engines.
- The McCormick 2005 study tested the Animal #1 feedstock at the B20 level and found a statistically significant increase in NOx, but did not test at the B5 level considered here.
- Table 4 reports this comparison for animal-based biodiesels. Results:
  - Animal #2 *increases* NOx in 2 of 3 engines. The increase is highly significant for 1 engine.
  - Animal #3 *decreases* NOx in one engine. The increase is statistically significant at the $p=0.05$ level. The blend was certified as NOx neutral at B5.
  - Animal #4 *increases* NOx in 3 of 6 cases and *decreases* NOx in the other 3 cases. The results are inconclusive as none of the changes are statistically significant. The blend may or may not change NOx.

T-Test for NOx Impact of B5 Animal Blends

Source	Feedstock ID	Engine	Cycle	NReps (total)	ΔNOx (gm/bhp-hr)	Prob > |t|	Statistical Significance
Durbin 2011	Animal #2	2006 Cummins ISM	FTP	12	+ 0.0067	p = 0.29	Not Significant

Karavalakis 2014	Animal #4	2006 Cummins ISM	UDDS	16	- 0.0993	P = 0.16	Not Significant

Notes: The t-test analysis uses the ARB dataset of individual test runs ("raw data")

NOx Impact of Animal Biodiesels Through B10

- Only Karavalakis 2014 reports testing on B5 <u>and</u> B10 to support an assessment of NOx impacts through B10. This involves a single animal feedstock (Animal #4) and cannot be generalized to a wider range of biodiesels.
- The analysis is based on Regression Model 2 which is linear in BioPct.
- For Animal #4, the NOx trend with BioPct is relatively flat through B10 (see Table 5).
  - The NOx slope is positive (NOx is increased) in 3 of 6 cases and negative (NOx is decreased) in 3 of 6 cases.
  - One slope (1991 DDC 60 on SET cycle) is positive and statistically significant.
- Conclusion: Animal #4 increases NOx through B10 in at least one engine and test cycle.

Table 5. NOx Trend Results Through B10 for An Animal Feedstock

Regression Model 2: $\log NOx = a + \sum_{i=2}^{N} \delta_i + b \cdot BioPct$

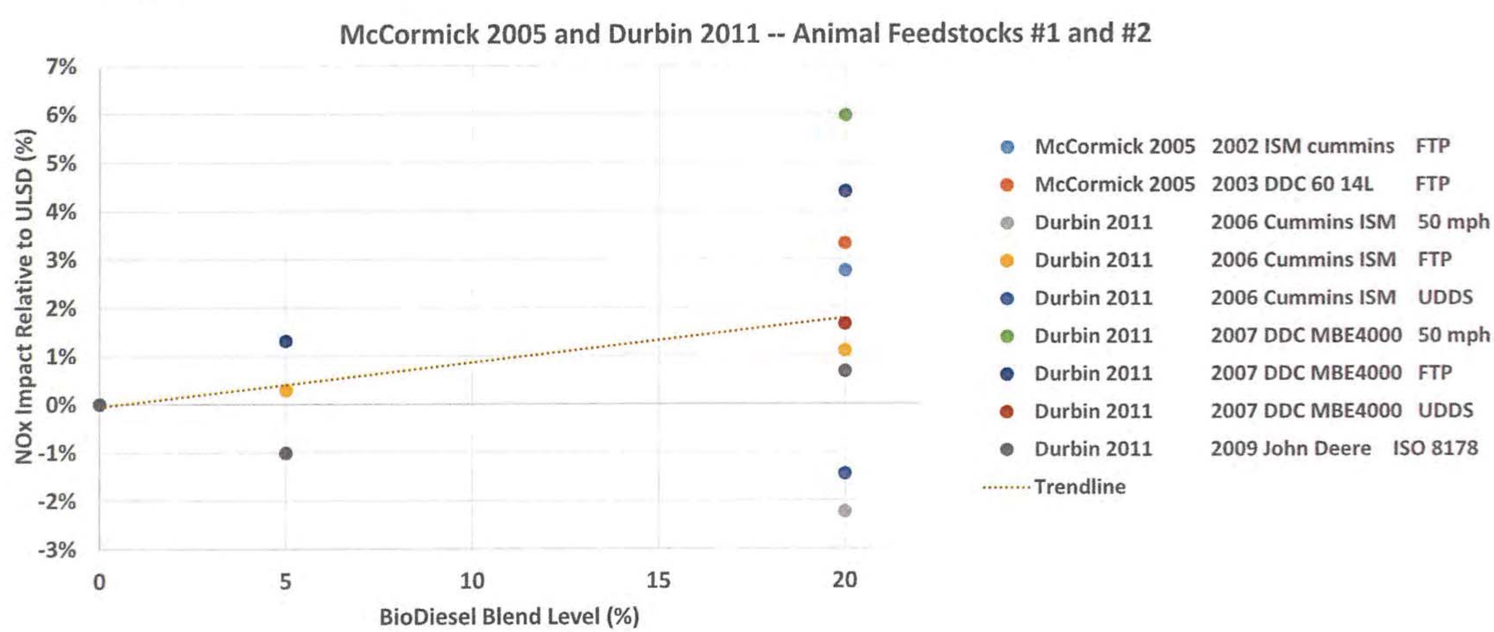
Source	Feedstock ID	Engine	Cycle	BioPct Slope (B) (gm/bhp-hr per % Biodiesel)	Prob > |t|	Statistical Significance
Karavalakis 2014	Animal #4	1991 DDC 60	FTP	+ 0.0012	p = 0.33	Not Significant
Karavalakis 2014	Animal #4	1991 DDC 60	SET	+ 0.0069	p = 0.05	Significant
Karavalakis 2014	Animal #4	1991 DDC 60	UDDS	- 0.0051	p = 0.67	Not Significant
Karavalakis 2014	Animal #4	2006 Cummins ISM	FTP	- 0.0006	p = 0.59	Not Significant
Karavalakis 2014	Animal #4	2006 Cummins ISM	SET	+ 0.0006	p = 0.77	Not Significant
Karavalakis 2014	Animal #4	2006 Cummins ISM	UDDS	- 0.0088	p = 0.19	Not Significant

Note: The regression analysis uses the ARB dataset of individual test runs ("raw data").

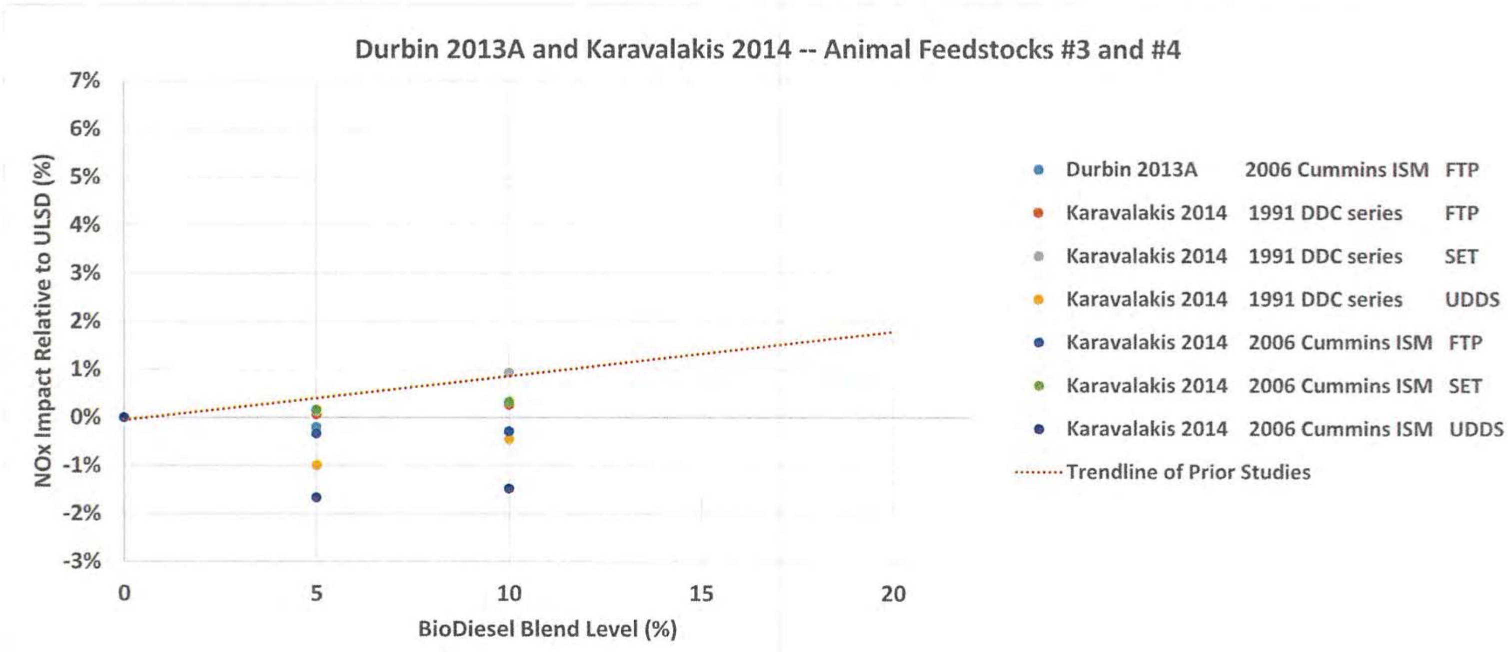
NOx Impact of Animal Biodiesels Through B20

- To include more sources, blends and feedstocks, we shift to analysis of the literature dataset. NOx measurements are reported as averages on CARB Diesel and for each BioPct blend level tested.
- Only graphical analysis is presented through B20 because most sources tested only two blend levels per feedstock (so regression analysis is not useful).
- As the following charts show, the latest ARB studies show substantially lower NOx impacts than the earlier studies and no clear trend with BioPct blend level.
- Each study tested a different animal feedstock. We interpret these results as indicating that the NOx impact can vary in important ways from one animal feedstock to another.

- In the first two studies of animal-based biodiesel:
  - NOx is significantly increased at B20
  - A smaller increase is observed at B5 consistent with a linear model



- In the two most-recent studies of animal-based biodiesel:
  - No appreciable NOx increase is observed through B10
  - NOx impacts are below the trendline of the two prior studies



What is the Composite NOx Impact for Animal-based Biodiesel?

- It depends on the blend level range that is considered
- This choice determines the influence given to each study and animal feedstock in the estimate.
- Including higher blending levels (more studies, more feedstocks) gives a better ability to resolve the slope with blend level and may yield a more general result.
- Including only lower blending levels reduces the number of feedstocks and blends considered. Results may not be general.

	Highest Blend Level Considered			
	B10	B20	B50	B100
Weight Given to Studies				
McCormick 2005	0%	2%	2%	2%
Durbin 2011	15%	59%	63%	67%

Prob > |t|	p = 0.35	p = 0.15	p < 0.01	p = 0.01
Statistically Significant?	No	No	Yes	Yes

A Better Understanding of Cetane Effects is Needed

- The higher cetane number of animal feedstocks is a likely reason that animal-based blends have lower NOx impacts than soy-based blends.
- Cetane is complicated and may or may not blend linearly with volume.
- The following chart shows that <u>all</u> of the UCR animal-based blends have a large cetane benefit, achieving most (or all) of the B100 cetane at low blend levels.
  - Lab differences could be involved. Durbin 2011 measured cetane for the blends at CE-CERT, while cetane for CARB Diesel and B100 was determined by an outside lab.
  - The large cetane boosts at low blend levels help to offset NOx increases.
- The McCormick 2005 animal feedstock behaves differently, with cetane blending linearly with BioPct in the B20 blend. The cetane benefit of this feedstock expected at the B5 level is small compared to the three UCR feedstocks.
- *What is the evidence that the rapid cetane boost observed for the UCR blends is real and representative of the cetane behavior of animal feedstocks available in the California market?*

What Do We Know About the Animal-based blends?

- Not enough to fully understand the emissions results. ARB should release all available information on its animal feedstocks and blends, including the distillation curves and the FAME and oxygen content analysis (if performed).
- ARB should clarify how it has determined cetane number in the 3 UCR studies and confirm its animal-blend cetane numbers with outside testing.

Conclusions on NOx Impact of Animal-based Biodiesel Blends

- Animal-based biodiesels have smaller NOx impacts than soy-based blends. The tendency of animal feedstocks to increase cetane is a likely reason.
- The animal-blends dataset is much more limited than for soy, with only four different feedstocks examined in the entire literature.
- There is disagreement among the studies on the NOx impact of B5 animal blends:
  - One B5 blend has significantly increased NOx on one engine and test cycle.
  - One B5 blend has been certified as NOx neutral on one engine and test cycle.
  - Other B5 blends may or may not increase NOx depending on engine and test cycle
- We need to understand the cetane behavior in the UCR blends and what is representative of animal biodiesels in California before more general conclusions can be drawn for animal-based blends.

The Influence of Cetane on Biodiesel NOx Impacts

Cetane is a Key Driver of the NOx Impact for Biodiesel

- This section presents an analysis that demonstrates that soy- and animal-based blends are <u>not categorically different</u> once their differing effect on blend cetane is accounted for.
  - Soy-based feedstocks have more unsaturated carbon bonds and tend to reduce cetane below that of CARB Diesel, although some soy and other vegetable feedstocks can increase cetane.
  - Animal-based feedstocks are more highly saturated and tend to increase cetane above that of CARB Diesel in most cases.
- When a cetane term is added, soy- and animal-based blends can be represented by the same model.
- The preliminary analysis indicates a method of predicting which biodiesel blends will have the greatest impact on NOx emissions.

Cetane-based Model of the Biodiesel NOx Impact

- The analysis uses the complete literature dataset – all blends at blending levels through B20 – in a modified regression analysis.
- Regression Model 3 is fit using emission averages weighted by the number of replications on each blend:

$$\log NOx = a + \sum_{i=2}^{N} \delta_i + b \cdot BioPct + c \cdot \Delta Cetane$$

where:

- Coefficients a and δ_i represent the average log NOx emission level on CARB Diesel for each engine/test cycle combination. (These values are not reported in the summary of results that follows.)
- BioPct is the blend level (percentage biodiesel in the blend). CARB Diesel is BioPct = 0;

  B5 is BioPct = 5.
- ΔCetane is the change in cetane number of the blend compared CARB Diesel
- Coefficient b gives the composite NOx impact across engines/test cycles for each 1 percent biodiesel in a blend at constant cetane (i.e., ΔCetane = 0).
- Coefficient c gives an adjustment to NOx emissions in proportion to ΔCetane.

Result for Cetane-based Model of Biodiesel NOx Impacts

- Result: $R^2 = 0.9948$ (dominated by the dummy variables that represent the differing NOx emission levels among engines and test cycles)

Coefficient	Estimate	Prob > |t|	Statistical Significance
b	+ 0.00156	$p < 0.0001$	Highly Significant
c	- 0.00303	$p < 0.0001$	Highly Significant

- The NOx increase is 0.16% for each 1 percent biodiesel in a blend, or 0.8% for B5 <u>at constant cetane</u>.
  - – Soy blends have an additional, adverse cetane effect on average that increases the NOx impact to ~1%.
  - – Animal blends tend to increase Cetane, so have reduced NOx impacts in comparison.

Result for Cetane-based Model of Biodiesel NOx Impacts

- The *c* coefficient estimates that +5 Cetane Numbers will decrease NOx emissions by 1.5%.
  - Other work* also finds a 1.5% NOx reduction for +5 Cetane Numbers in base blends with Cetane levels of ~50.
- An increase of $-b/c = 0.5$ Cetane Numbers is needed to offset the NOx increase expected from each 1% biodiesel added. For B5, an increase of 2.5 Cetane numbers is required to offset the NOx increase.
- Statistical tests of the residuals indicate that the model explains all of the observed differences among biodiesel types (animal, soy, UCO, canola) and among studies.

* *The Effect of Cetane Number Increase Due to Additives on NOx Emissions from Heavy-Duty Highway Engines.* EPA420-R-03-002. February 2004. Figure IV.A.-1.

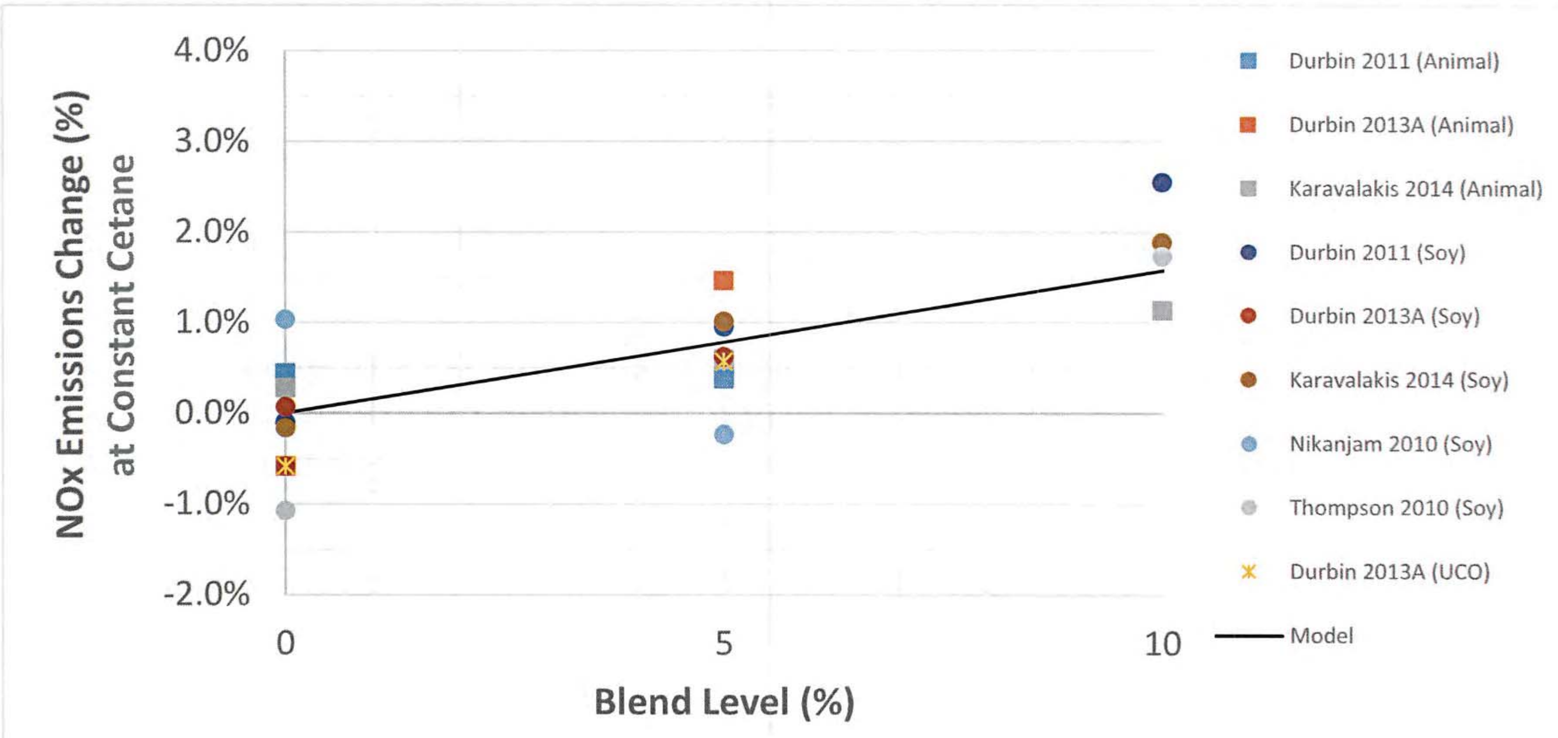
NOx Emission Changes At Constant Cetane

- The *c* coefficient can be used to remove the effect of cetane changes from the measured NOx emission values. The adjustment takes each biodiesel blend back to the cetane number of the CARB diesel used as the base blend in its testing.
- For each combination *i* (study, feedstock, engine, and test cycle), the percent change in NOx emissions at blend level *j* can be estimated as follows:

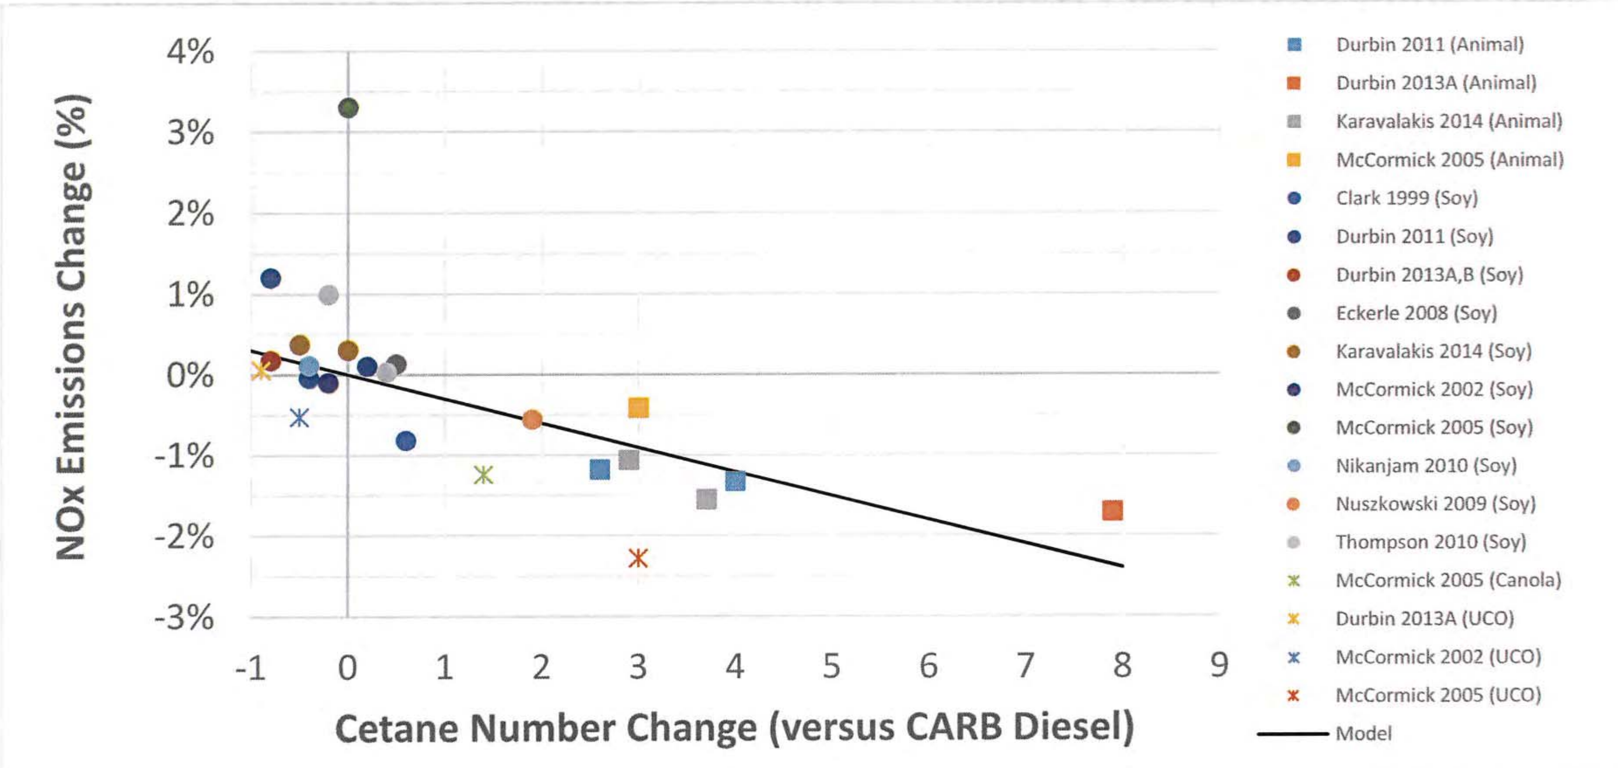
$$\Delta NOx_{i,j} = \exp\left[\ln NOx_{i,j} - (a_i + \textstyle\sum_{i=2}^{N} \delta_i) - c \cdot \Delta Cetane_i\right] - 1$$

- This approach references the percent change in NOx to the emission intercept $a_i + \sum_{i=2}^{N} \delta_i$ estimated on CARB diesel for each engine/test cycle.
- Average percentage changes for each study, feedstock, engine, test cycle, and blend level are then plotted in the following figure.

There is no detectable difference among feedstock types when NOx emission changes are adjusted to constant Cetane Number



The Response of NOx to Cetane Number is the Same for Soy- and Animal-based Biodiesel Blends (When Adjusted for Blend Level)



Cetane-based Model of Biodiesel NOx Impacts

- Our preliminary analysis suggests a method of predicting the NOx emission impacts of biodiesel blends.
- Further work is needed:
  - To demonstrate that blends mitigated using DTBP or by co-blending with renewable diesel obey the same model
  - To assess whether the four animal feedstocks that have been tested are representative of all animal feedstocks available in the California market.
  - Additional emissions testing may be needed if we see that the four animal feedstocks are not fully representative.
- More advanced statistical techniques (Mixed Effects modeling) may also be needed, as used in the Predictive Model for gasoline.

Some Implications for Biodiesel in California

- Soy- and animal-based blends are not categorically different fuels once their differing effect on blend Cetane is accounted for.
- There is no threshold blend level where biodiesel fuels as a group do not increase NOx, whether soy- or animal-based.
- Soy-based blends clearly and significantly increase NOx by ~1% at B5 and by correspondingly larger amounts at higher blend levels. Soy blends <u>require</u> mitigation at all levels to offset increased NOx emissions.
- Animal-based blends are more complicated. The current research is limited and the evidence is mixed:
  - At least one B5 animal blend significantly increases NOx, while another has been certified as NOx neutral.
  - Other B5 animal blends may or may not increase NOx depending on their effect on Cetane Number (and possibly other factors).
- Animal-based blends cannot be assumed to have no impact on NOx emissions without an assessment of the impact of feedstock blending on Cetane number.

ATTACHMENT F

NOx Emission Impacts of Biodiesel Blends

1. Introduction

In the Alternative Diesel Fuels rulemaking, the California Air Resources Board (ARB) is attempting to create a regulatory framework that will permit biodiesel and other alternative diesel fuels to increase their penetration of the California market. Biodiesel is known to increase emissions of nitrogen oxides (NOx). NOx emissions are an important precursor to smog and have historically been subject to stringent emission standards and mitigation programs to prevent growth in emissions over time. A crucial issue with respect to biodiesel is how to "... safeguard against potential increases in oxides of nitrogen (NOx) emissions."[1] ADF B3-137

In July 2014, ARB released two datasets that represent the fruit of their efforts to compile biodiesel NOx emissions test data available in the literature on heavy-duty truck (HDT) engines. This document and the companion file *"Biodiesel Emissions Analysis Technical Summary 102014.pdf"* present the results of a statistical analysis of the data sets released by ARB that was performed by Rincon Ranch Consulting at the request of Growth Energy.

This analysis focused on whether soy and animal blends will increase NOx at low blend levels. The following issues were examined:

- The NOx impacts of soy and animal blends at B5 and B10;
- The NOx emission differences observed among animal feedstocks and blends;
- For animal blends, the effect on NOx emissions of the Cetane Number (CN) change relative to base fuel that is caused by blending of the animal feedstock; and
- The development of a cetane-based model of the biodiesel NOx impacts of soy and animal blends.

The key results and conclusions of the study are summarized here. For additional information, the reader is directed to *"Biodiesel Emissions Analysis Technical Summary 102014.pdf"* which has been provided along with this document.

2. Data Used in the Analysis

As noted above, in July 2014, ARB released two datasets of NOx emissions data from testing of biodiesel blends in HDT engines. One file ("B5 & B10 Raw NOx Data") contains the subset of testing for B5 and B10 blends (soy and animal). The test data generated in the four ARB-sponsored UCR studies are present in the form of the individual test run measurements. Because test run information was not reported in their publications, the B5 soy data from Nikanjam 2010 and the B10 soy data from Thompson 2010 are present in the form of emission averages. No animal blends have been tested at the B5 or B10 levels except in the ARB-sponsored emissions testing. A second file ("2014 Biodiesel ADF B3-138

[1] "Proposed Regulation on the Commercialization of New Alternative Diesel Fuels. Staff Report: Initial Statement of Reason." California Air Resources Board, Stationary Source Division, Alternative Fuels Branch. October 23, 2013. http://www.arb.ca.gov/regact/2013/adf2013/adf2013isor.pdf.

Literature Search Database") contains all of the biodiesel testing available in the literature through the B20 level (soy and animal), including ARB-sponsored testing and the literature search. The data are in the form of emission averages by engine, test cycle, feedstock type, and blend level.

For purposes of this analysis, the following information was added to the ARB datasets:

- The number of test replications for emissions averages for each study (estimated when the source did not report the number);
- The CN for CARB diesel, the biodiesel blends, and the biodiesel feedstocks; and
- Additional NOx emissions testing at the B50 and B100 levels (where available).

ADF B3-138 cont.

Appendix Table A presents a list of the studies included in the dataset and the author references used in citations here.

3. NOx Emissions from Soy Biodiesel Blends

Most past research on biodiesel emissions has focused on soy blends. As a result, the literature is relatively large and diverse. The dataset assembled by ARB is derived from 10 different studies, covers 13 different vegetable feedstocks (10 soy, 2 used cooking oil [UCO], 1 canola), and was conducted using 7 different test cycles on a wide variety of engines in different labs. Most of the data, in terms of number of data points, is derived from the three UCR studies (Durbin 2011, Durbin 2013B, and Karavalakis 2014) sponsored by ARB.

We subjected the soy dataset to a number of different analyses using different statistical techniques and selections of the data to ensure that the conclusions we drew were robust across analytical techniques and datasets. The statistical analysis included the T-Test for the difference in mean values (e.g., between B5 and CARB diesel) and linear regression analysis using several different models. The data subsets were selected to use either individual test runs or emission averages and to contain testing through maximum blend levels of B5, B10, B20, B50, and B100.

ADF B3-139

Our analyses show that there is a consensus among the studies on the NOx impact of soy biodiesel without regard to the specific analytical methods or data used. Soy biodiesel increases NOx emissions by amounts that can be estimated with good statistical confidence because of the large size of the available dataset. The key conclusions are as follows:

- Soy biodiesel increases NOx emissions by ~1% at B5 and ~2% at B10;
- NOx emissions increase in a linear fashion with increasing blend level to reach ~4% at B20 and proportionately larger values at higher blend levels; and
- There is no evidence in the data for a threshold level below which soy biodiesel does not increase NOx.

These conclusions are supported by all of the available studies and data. None of the studies disagree substantially, and while the results for individual blends, engines, and test cycles will vary to some extent, the evidence across a wide range of engines and test cycles is clear. NOx increases can be expected for UCO, canola, and other vegetable biodiesels, but the data are very limited and it is not possible to draw definitive conclusions for these blends.

4. NOx Emissions from Animal Biodiesel Blends

The literature on NOx emissions from animal blends is much smaller. It consists of only four studies, three of which (Durbin 2011, Durbin 2013A, and Karavalakis 2014) were sponsored by ARB. Except for the McCormick 2005 study, the emissions testing was conducted at the UCR CE-CERT lab. A variety of test cycles were used, but most of the testing was conducted on the hot-start FTP cycle. Table 1 presents a summary of the emissions studies for animal biodiesel.

Table 1. Scope of Emissions Testing for Animal Biodiesel

	McCormick 2005	Durbin 2011	Durbin 2013A	Karavalakis 2014

ADF B3-140

It is important to understand the limitations of this small dataset. Without the ARB-sponsored testing, we would have only the six test replications (individual runs) conducted in the McCormick 2005 study. While the three UCR studies accumulated 232 test replications, the work involved only three different animal feedstocks. Including the McCormick 2005 study, the entire literature on NOx emissions from animal biodiesel is based on only four different animal feedstocks. The small number is an important limitation because animal feedstocks are much less homogenous than soy due the greater variety possible in animal sources and compositions. Further, there are notable differences among the four studies as to whether animal biodiesel increases NOx at the B5 and B10 levels (as indicated by the red circles in the table).

As in the soy analysis, we subjected the animal biodiesel data to a number of different analyses using different statistical techniques and selections of the data to ensure that the conclusions we drew were robust. The T-Test is the most direct method to assess whether NOx emissions are higher at B5 compared to CARB diesel. Using the individual test run data available from the three UCR studies, we find the following for animal biodiesel at the B5 blend level:

- The animal feedstock used in Durbin 2011 increases NOx in 2 of 3 engines. The increase is highly significant[2] statistically for one engine.

[2] The term "significant" is used in this report only to refer to statistical significance. When a result reaches the p=0.05 level, we can be 95 percent confident that it is real. In such case, and at smaller p values, the result is said to be statistically significant. "Significant" has been used by others to indicate that an emissions increase, even if real, is too small to warrant concern. For example, the Predictive Model for RFG will permit alternative gasoline formulations to increase NOx emissions by up to 0.05% and still be classified as emissions compliant. To our

- The animal feedstock used in Durbin 2013A decreases NOx in one engine. The decrease is statistically significant at the p=0.05 level and the blend was certified as NOx neutral at B5.
- The animal feedstock used in Karavalakis 2014 increases NOx in three of six cases and decreases NOx in the other three cases. None of the changes are statistically significant. The blend may or may not change NOx.

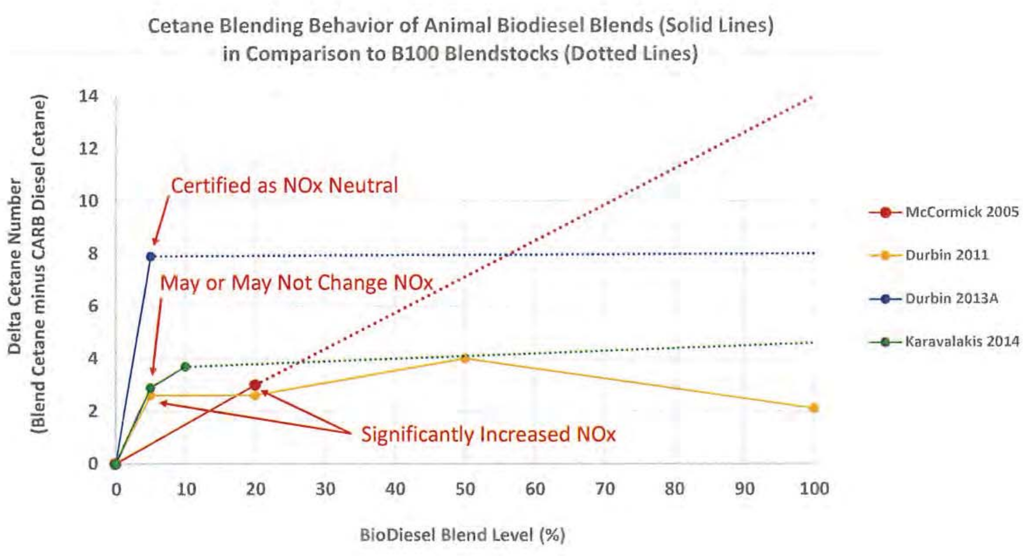
ADF B3-140 cont.

Contrary to Staff's assertion that no NOx increase occurs in B5 animal blends, it is clear that <u>some animal blends will significantly increase NOx emissions, while other animal blends will not</u>. The fundamental issue is then understanding what the NOx impact of a particular animal biodiesel blend will be.

The effect of feedstock blending on the CN of the resulting animal blend is the reason for the apparently discordant results among the studies. Figure 1 plots the four series of animal blends in the literature with the blend level on the horizontal axis and the change in blend CN (relative to CARB diesel) on the vertical axis. CN blended linearly to B20 for the McCormick feedstock, which showed a much smaller CN benefit than the feedstocks used by UCR – only three numbers at B20 (0.6 numbers at B5). In contrast, all three UCR animal blends achieve a large CN boost at low blending levels in which most or all of the CN benefit of the feedstock is achieved at B5.

ADF B3-141

Figure 1. Cetane Blending Behavior of Animal Blends (Solid Lines) Compared to B100 Feedstocks (Dotted Lines)



In Durbin 2011, the CNs for the blends are above that of the B100 feedstock. This result is probably caused by lab-to-lab differences (blend CN was determined at CE-CERT, while CN for CARB diesel and the

knowledge, ARB has not formulated a position on the level of NOx increase from alternative diesel fuel that is too small to warrant concern.

B100 feedstock were determined by an outside lab). The actual CN changes are surely lower than shown here – at or below +2 CNs.

The two animal feedstocks that caused statistically significant NOx increases have the smallest CN benefits: McCormick 2005 (red) at B20 and Durbin 2011 (yellow) at B5. The animal B5 blend that passed certification testing as NOx neutral in Durbin 2013A (blue) has the highest CN benefit, where it achieved the entire B100 CN at just 5 percent blending. The Karavalakis 2014 B5 blend (green) had an intermediate CN benefit and may or may not change NOx.

The blending behavior of the UCR blends is surprising in comparison to the McCormick study, and we find relatively little research on the CN blending behavior of animal feedstocks. All conclusions from this dataset will be influenced by the CN blending behavior of the specific animal feedstocks involved. For such conclusions to be reliable, we must be confident that the large CN boost reported for the UCR blends is both real and representative of all animal feedstocks in California. Also, only limited information is available on the sources and characteristics of the animal feedstocks. ADF B3-141 cont.

To permit all parties to better understand the animal feedstocks that were tested, ARB should release all information that it has on the following:

- CNs (methods of determination and measured values) for the Durbin 2011 and other UCR studies;
- Physical and chemical properties of the animal feedstocks and biodiesel blends tested;
- The distribution of sources, characteristics, and properties in the population of animal feedstocks that are available for use in the California market; and
- How the specific animal feedstocks tested at UCR were selected, including any information that would demonstrate that the feedstock properties and their CN blending behavior are representative of the animal feedstock population available for use in California.

5. Development of a Cetane-based Model of NOx Impacts from Soy and Animal Biodiesel

The results presented above indicate the important role that CN plays in determining the NOx response for animal blends. Animal feedstocks tend to increase the CN of the blend above that of the CARB diesel and the CN change can be large at low blend levels. Soy feedstocks have generally adverse effects and tend to decrease the CN of the blend below that of the CARB diesel; for soy, the CN change at low blend levels can be smaller than the uncertainty in determining CN. The result of our work on a cetane-based model demonstrates that soy and animal blends are not categorically different fuels once their differing effect on CN is accounted for. Their NOx impacts can be represented by the same model as a function of blend level and the change in CN compared to CARB diesel. ADF B3-142

The document that accompanies this report explains the development of the cetane-based model in some detail. In brief, it was developed using conventional linear regression analysis with log(NOx) emissions as the dependent variable. Intercept terms were included to represent the varying emission levels on CARB diesel for each combination of study, feedstock type, engine, and test cycle. A *b* coefficient was included to represent the change in NOx emissions for each 1 percent biodiesel in a blend at constant CN. A *c* coefficient was included to represent the change in NOx emissions for each 1 number change in CN compared to CARB diesel at constant blend level. Both soy and animal blends ADF B3-143 were included in the estimation, along with the small number of canola and UCO data points, at blend levels up to (and including) B20.

The model estimation shows that the *b* and *c* coefficients are highly significant statistically ($p < 0.0001$). The estimation results also show the following:

- The *b* coefficient has a value of +0.00156, which estimates that soy and animal biodiesel will increase NOx emissions by 0.16% for each 1 percent biodiesel at constant CN or by 0.8% at B5.
- The *c* coefficient estimates that +5 CNs will decrease NOx emissions by 1.5 percent at constant blend level. This result is completely consistent with earlier work[3] on the relationship between CN and NOx emissions in HDT engines, which also found that +5 CNs will decrease NOx emissions by 1.5 percent in base fuels with CN ~50.
- An increase of $-b/c = 0.5$ CNs is needed to offset the NOx increase expected from each 1% biodiesel added. For B5, an increase of 2.5 CNs is required to offset the expected NOx increase.

The results explain why soy and animal blends appear to be different fuels. Soy blends have an additional, adverse CN effect that increases their NOx impact to ~1% at B5. Animal blends will generally increase CN and that reduces their NOx impact to about one-half the soy level or less depending on the CN change caused by blending. The results also explain why some animal blends do not increase NOx emissions. If an animal feedstock increases CN by more than ~0.5 numbers for each 1% biodiesel blended, then the resulting fuel may not increase NOx emissions. ADF B3-143 cont.

To demonstrate these conclusions, Figure 2 presents NOx emissions as a function of blend level for all fuels used to estimate the model once NOx emissions are adjusted for the CN change observed for each blend (animal blends are plotted as squares, soy blends as circles, and the non-soy vegetable blends as asterisks). For example, if an animal blend increased CN, then its NOx impact is increased as we return it to the base fuel CN. If a soy blend decreases CN, then its NOx impact is decreased as we return it to the base fuel CN. Once adjusted, percent changes in emissions are calculated. As seen in the figure, there is no discernable difference among feedstock types once CN changes are taken into account. Animal and soy blends scatter on both sides of the regression line, indicating that they obey the same blend level model.

Note the scatter of points around the regression line (which gives the "average" response). Some of the scatter is due simply to emissions measurement error. But other factors may be involved in determining the NOx impact for a given feedstock, including differences in the FAME composition and uncertainty in determining CN for the blends. If ARB were to adopt a predictive model to determine the CN improvement needed to mitigate NOx, it should use the model to evaluate a "worst case" feedstock, meaning a point near the upper end of the range at each blend level.

The most important conclusion of this work is that soy and animal biodiesel blends are not categorically different fuels. Their emissions effects are similar, but they show different NOx impacts because they have different effects on CN. Further, this work provides a potential answer to the problem that some animal blends will significantly increase NOx emissions, while other blends will not, by indicating what individual blends may do.

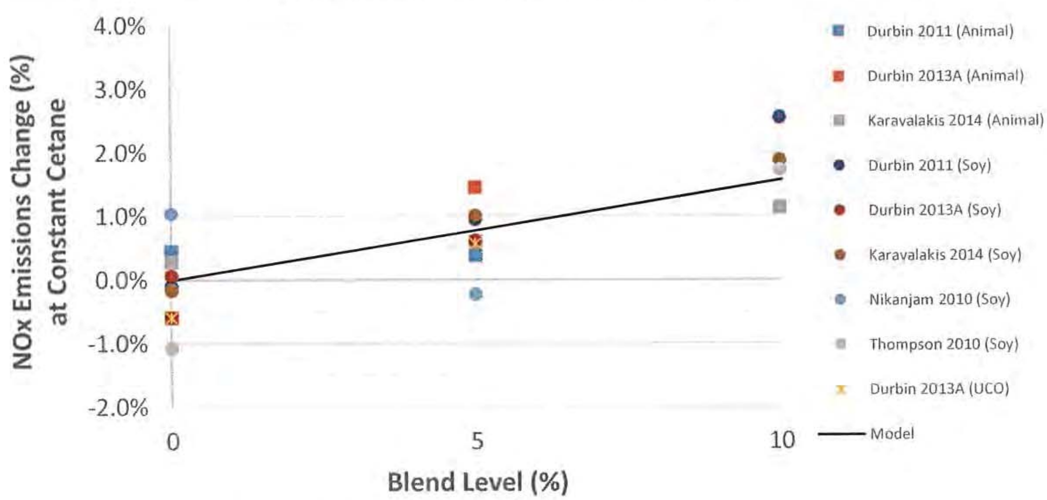
Figure 2. There Are No Detectable Differences Among Feedstock Types Once NOx Emissions Are Adjusted to Constant CN



Note: Animal blends are plotted as squares, soy blends as circles, and the non-soy vegetable blends as asterisks.

6. Summary and Conclusions

Based on the results summarized above, ARB must consider as part of the current rulemaking a regulatory structure in which the NOx impacts of soy and animal biodiesel are accounted for using a statistical model analogous to the Predictive Model for RFG. We see the cetane-based model presented here as a possible draft for a biodiesel predictive model, but further work is needed to: ADF B3-144

- Demonstrate that blends mitigated using DTBP obey the same model; and
- Assess whether the four animal feedstocks that have been tested are representative of all animal feedstocks available in the California market.

Additional emissions testing may be needed if it is determined that the four animal feedstocks that have been tested are not representative of the population of animal feedstocks available for use in the California market. ADF B3-145

Further, more advanced statistical techniques should be used as was done in developing the Predictive Model for California Reformulated gasoline. The dataset used here is highly unbalanced, meaning that there are varying numbers of data points for each combination of study, feedstock type, engine, and test cycle. In fact, only a fraction of all possible study/feedstock/engine/test cycle cells are represented by one or more data points. A technique known as Mixed Effects Modeling is appropriate in such cases and its use will assure that coefficient estimates are not biased by the unbalanced distribution of the data. ADF B3-146

The key conclusions of this study are summarized below.

- Soy and animal blends are not categorically different fuels once their differing effects on blend CN are taken into account. ADF B3-147
- There is no evidence in the data of a threshold level below which biodiesel fuels as a group do not increase NOx, whether soy or animal. However, individual blends may not increase NOx if the CN gain caused by blending is sufficiently large to offset the underlying tendency of all biodiesel blends to increase NOx emissions. ADF B3-148
- Soy blends clearly and significantly increase NOx by ~1% at B5 and by proportionately larger amounts at higher blend levels. Soy blends <u>require</u> mitigation at all levels to offset increased NOx emissions. ADF B3-149
- Animal blends are more complicated. The current research is limited and the evidence is mixed. At least one B5 animal blend significantly increased NOx, while another has been certified as NOx neutral. Other B5 animal blends may or may not increase NOx depending on their effect on CN (and possibly other factors). ADF B3-150
- Staff's assertion that no NOx increase occurs at B5 in animal blends is incorrect. <u>Some animal blends will significantly increase NOx emissions, while other animal blends will not</u>. ADF B3-151
- Animal blends cannot be assumed to have no impact on NOx emissions without a determination of the impact of feedstock blending on CN. ADF B3-152

RE: "Comments on the LCFS and ADF rulemaking proposals."

Dear Clerk of the Board:

I have discovered that one attachment to my Declaration included in electronic filing for Growth Energy that Josh Wilter of my staff made yesterday was not included in the upload. I am enclosing the attachment here and am emailing it to Jim Aquila and Lex Mitchel who are listed as the staff contacts for this item in the Hearing Notice. The contents of this attachment do not differ from the content of my Declaration, and the bulk of the analysis in the attachment was provided to the ARB staff on October 24, 2014 as workshop comments.

Sincerely,

Jim Lyons
Senior Partner

NOx EMISSION IMPACTS OF BIODIESEL BLENDS

1. EXECUTIVE SUMMARY

The purpose of the Alternative Diesel Fuels (ADF) rulemaking, according to the Air Resources Board (ARB), is to create a regulatory framework that will permit biodiesel and other low-carbon, alternative diesel fuels to "enter the commercial market in California, while mitigating any potential environmental or public health impacts." [1]

The work presented in this report assesses the impacts of biodiesel use on NOx emissions from conventional and new technology diesel engines. It was performed by Rincon Ranch Consulting under subcontract to Sierra Research at the request of Growth Energy.

At present, most diesel fuel and biodiesel is consumed in conventional diesel engines that do not have exhaust gas after-treatment to reduce NOx emissions. The consensus of the literature is that biodiesel will increase NOx emissions by amounts that depend on the blending percentage (how much biodiesel is present in the diesel fuel) and the type of biodiesel feedstock (soy versus animal sources). NOx increases of 1-2% are expected from soy biodiesel at blend levels of B5 to B10 with smaller increases expected, in general, from animal biodiesel at the B5 to B10 level. ADF B3-153

Over time, new technology diesel engines (NTDEs) equipped with exhaust gas after-treatment controls for NOx will increasingly make up the heavy duty fleet in response to other ARB programs. While baseline emissions from these engines will be reduced compared to conventional engines, the consensus of the literature available today is that use of biodiesel will still increase NOx emissions above the reduced baseline. At the B20 level, the NOx increase appears to be greater on a percentage basis than would be expected in conventional diesel engines. ADF B3-154

The results of this work indicate the following with respect to conventional diesel engines:

- Soy biodiesels will increase NOx emissions at the B5 and B10 levels by approximately 1% and 2%, respectively. This work and Staff's analysis concur in both the conclusion and the estimated levels of NOx increase at B5 and B10. Soy biodiesels in this blend range require NOx mitigation on a per-gallon basis in order to prevent increases in NOx emissions. ADF B3-155

- The consensus of the research community is that the effect of soy biodiesel on NOx emissions is continuous and linear with respect to the blending percentage. NOx ADF B3-156

[1] "Proposed Regulation on the Commercialization of New Alternative Diesel Fuels. Staff Report: Initial Statement of Reason." California Air Resources Board, Stationary Source Division, Alternative Fuels Branch. January 2, 2015. http://www.arb.ca.gov/regact/2015/adf2015/adf15isor.pdf. Page 11.

increases have been observed at levels as low as B1.[2] The statistical analysis performed for ARB by Rocke supports this conclusion and estimates that soy biodiesel will increase NOx emissions by about 0.2% for each 1% biodiesel in the blend (0.99% for each 5% biodiesel). ADF B3-156 cont.

In spite of this consensus, the Staff proposal requires NOx mitigation for soy-based biodiesel only above the B5 level in summer months and above the B10 level in winter months. Soy biodiesel blended at the B5 and lower levels would not require mitigation in any circumstance. The ADF regulatory framework must require mitigation of soy-based biodiesels at all blend levels if it is to ensure that such fuels do not increase NOx emissions. ADF B3-157

- The effect of animal-based biodiesel on NOx emissions is more complicated than for soy-based blends. As the available literature demonstrates, some animal-based biodiesels will increase NOx emissions while other animal biodiesels will not. While Staff's proposal would establish B10 as the control level for animal-based biodiesel (e.g., mitigation would be required year-round for blends above B10), the available data do not support Staff's conclusion that there will not be increases in NOx emissions from B10 and lower blends. Given the Staff proposal, the only way to ensure that animal-based biodiesel does not increase NOx emissions is to require mitigation at all blend levels. ADF B3-158
- Staff presents information indicating that animal biodiesels decrease NOx by 0.2% on average and that the emissions change in comparison to CARB diesel fuel is not statistically significant. The average and the test for statistical significance are both flawed by the failure to consider the varying effects that animal feedstocks have on Cetane Number (CN). The absence of CN as a variable in Staff's analysis leads Staff to wrongly conclude that animal biodiesels will not increase NOx below the B10 level. ADF B3-159
- It is well established that increasing CN will reduce NOx emissions from diesel engines. Whether an animal biodiesel will increase NOx depends primarily on the extent to which the feedstock blending increases the CN of the blended fuel. Soy and animal biodiesel blends are not categorically different fuels once the differing effect of soy- and animal-feedstocks on CN is taken into account. ADF B3-160

With respect to new technology diesel engines (NTDEs):

- Staff is incorrect in concluding that biodiesel use will not increase NOx in NTDEs. This conclusion is based on a highly selective reading of the technical literature (choosing one of four available studies) and relies on the one study in which the laboratory was not well equipped to measure the low levels of tailpipe NOx emissions from NTDEs. ADF B3-161
- A fair reading of the technical literature indicates that B20 biodiesel will increase NOx emissions by about 20% in NTDEs. The four best studies estimate that B20 biodiesel ADF B3-162

---

[2] McCormick 2002 tested a Fisher-Tropsch (FT) base fuel blended at the B1, B20, and B80 levels. Although the very high FT cetane number (≥75) takes it out of the range of commercial diesel fuels, the study nevertheless measured higher NOx emissions at the B1 level than it did on the FT base fuel.

increases NOx by 18-22% in NTDEs and that the increase is statistically significant. This is a greater percentage NOx increase in proportion to blend level than the increase caused by soy biodiesel in conventional diesel engines (1% at B5, 2% at B10 and ~4% at B20). ADF B3-162 cont.

- The technical literature also indicates that one should expect NOx emissions to increase at blend levels below B20, with the size of the NOx increase being proportionate to blend level. At the B5 level, NOx emissions from NTDEs are expected to increase by about 5%. ADF B3-163

- Staff makes no mention of the concern that use of biodiesel fuels in NTDEs may lead to the loss of NOx conversion efficiency in urea-SCR systems by shifting the NO_2/NOx ratio to lower values. Staff's proposal to allow B20 biodiesel to be used in NTDEs without mitigation potentially places at risk the investment in NOx after-treatment systems to meet the stringent NOx certification levels now in effect. ADF B3-164

This analysis demonstrates that the proposed regulations will not "ensure that the use of biodiesel due to LCFS will not result in increases in NOx emissions in California." In fact, the regulations will result in increased NOx emissions in California from the following: ADF B3-165

- B5 and lower soy biodiesels year round;
- B6 to B10 soy biodiesels in winter;
- At least some B10 and lower animal biodiesels year-round; and
- B20 and lower biodiesels of all types in NTDEs.

To our knowledge, ARB has not formulated a position on the level of NOx increase from alternative diesel fuel that is too small to warrant concern. A point of comparison for the NOx increases permitted by the proposed ADF regulations is the ARB program for Reformulated Gasoline (RFG). The RFG program permits alternative gasoline formulations to be sold in the California market provided they are demonstrated to be emissions equivalent to a reference gasoline using the Predictive Model for RFG. The emissions analysis differs somewhat for winter and summer gasoline, but in no instance may the alternative formulation increase emissions of the pollutants considered by more than 0.05%. ADF B3-166

The biodiesel NOx emission increases permitted under the proposed ADF regulations dwarf the 0.05% threshold applied to RFG. Soy biodiesel will increase NOx by more than 0.05% at blend levels above 0.25% biodiesel (B0.25). Some animal biodiesels will increase NOx by 0.05% or more at blend levels twice as high (B0.5). The NOx emissions increase in NTDEs appears to be substantially greater on a percentage basis, so that biodiesels will exceed the 0.05% threshold at much lower blend levels. ADF B3-167

In the ISOR, Staff uses the term "low saturation" to refer to soy and other feedstocks with CN < 56 and "high saturation" to refer to feedstocks, including animal sources, with CN ≥ 56. Classification based on saturation is useful because of its association with CN. By itself, however, it does not alleviate the concerns regarding NOx increases from unmitigated fuels. ADF B3-168

The analysis presented here indicates that CN changes induced by biodiesel blending have a large influence on the size of the NOx increase that is observed. Soy (low saturation) biodiesels adversely affect CN leading to larger NOx increases; animal (high saturation) biodiesels increase CN leading to smaller NOx increases. In fact, soy and animal biodiesels are not categorically different fuels once their differing effect on blend CN is taken into account. ADF B3-169

It is strongly recommended that ARB consider as part of the ADF rulemaking a regulatory structure in which the NOx impacts of soy and animal biodiesel are accounted for using a statistical model analogous to the Predictive Model for RFG. The analysis documented in this report provides a possible form for a biodiesel predictive model. ADF B3-170

2. NOX EMISSIONS FROM CONVENTIONAL DIESEL ENGINES

2.1 ARB Analysis in Support of the Proposed Regulations

In support of the proposed regulations, ARB commissioned an analysis of the available NOx emissions data by David M. Rocke, PhD. The results of the analysis are reported in Appendix G: Supplemental Statistical Analysis[3] to the ISOR. The analysis used NOx emission measurements on ULSD, B5, and B10 fuels in conventional diesel engines from five studies. The dataset is substantially the same as that used by Rincon Ranch Consulting in the analysis presented later in this section.

The Rocke analysis formulated a series of statistical models involving log(NOx) as the dependent variable and used a statistical approach termed Mixed Effects modeling to estimate the coefficient values. The Mixed Effects approach has statistical advantages over more commonly used methods when dealing with unbalanced datasets, as is the case here. A number of different models were specified, estimated, and the results compared in order to ensure that conclusions drawn from the analysis do not depend upon the model specifications. ADF B3-171

For soy-based biodiesel, the Rocke study concludes that soy fuels increase NOx by 1% at B5 and by 2% at B10. The study also demonstrated that the NOx increase is linearly related to the blend level. The slope was estimated to be 0.99% for each 5% biodiesel in a blend and was highly significant statistically ($p \ll 0.001$). These results agree with the Rincon Ranch analysis presented later in this report. <u>There is no controversy with regard to the NOx impact of soy-based biodiesel.</u> Soy biodiesel will increase NOx emissions at all blend levels by about 0.2% for each 1% biodiesel in the blend.

With respect to animal biodiesel, the Rocke study concludes that animal biodiesel does not increase NOx emissions at B5 or B10. The emission changes that are observed are not statistically significant. <u>There is controversy here because the Rocke analysis did not account for the effect of feedstock blending on the CN of the tested fuels</u>. The CN change compared to ULSD is a fixed effect that must be accounted for because the four animal feedstocks that have been used in the technical literature show substantially different cetane behavior in blending. ADF B3-172

---

[3] http://www.arb.ca.gov/regact/2015/adf2015/adf15appg.pdf.

The case for cetane as an explanatory variable for NOx emissions in animal blends is made in Section 2.2.4 of this report. It is well established that increasing CN will reduce NOx emissions from diesel engines. For example, ARB has shown that the additive DTBP can be used to raise CN and mitigate NOx increases caused by biodiesel blending. Whether an animal biodiesel will increase NOx depends primarily on the extent to which the feedstock blending increases CN of the blended fuel. The two animal blends that showed the smallest CN gain over ULSD caused statistically significant NOx increases in the engines tested. The one animal blend that showed the largest CN gain was certified to be NOx neutral, while the animal blend with the next largest CN gain may or may not be NOx neutral. Cetane appears to blend linearly when using soy feedstocks, so that the CN gain over ULSD is highly correlated with blend level. The same is not true for animal feedstocks, where highly non-linear blending behavior has been observed.

The Rocke analysis used a Mixed Effects model to estimate the NOx emissions change at B5 and B10. For animal blends, it concluded that the observed emission changes are not statistically significant. Implicit in the approach is the assumption that the fuels being tested are different, individual realizations from a homogenous population. In this instance, the residual variation not accounted for by the blend level is a random effect representing the scatter in test results due to a variety of factors. The statistical significance of the blend level effect (a fixed effect) is judged in comparison to the residual variation. When the residual variation is large in comparison to the fixed effect, the latter is said to be not statistically significant.

The assumption of a homogenous population is appropriate for soy-based biodiesels. One soybean is much like the next, and the only appreciable differences among soy fuels will result from the methods of preparation. However, the assumption of homogeneity is not appropriate for animal-based biodiesels, which can be drawn from a variety of animal sources and prepared in different ways. The non-homogeneity is seen most readily in the greatly different cetane responses of biodiesel fuels:

ADF B3-172 cont.

- In the McCormick 2005 and Durbin 2011 studies, the animal feedstocks increased the CN of the biodiesel blends by small amounts. These fuels led to statistically significant increases in NOx.
- In the Durbin 2013A study, blending at the B5 level was sufficient to raise the CN of the blend by 8 numbers to reach the cetane level of the feedstock itself. This fuel was certified as NOx neutral at B5.
- The animal feedstock used in the Karavalakis 2014 study was intermediate in its CN effect and also intermediate in its NOx effect.

Because the ARB and Rocke studies have not included cetane as an explanatory variable for animal-based biodiesels, the residual variation term has been enlarged since a portion of it could be accounted for by including a fixed-effects term for cetane. With an enlarged estimate of the residual variance, the studies more easily find that the fixed effect of blend level is not statistically significant.

The absence of cetane as an explanatory variable also affects other methods of analysis used by Rocke. In a t-test comparison of emission differences between biodiesel and ULSD, Rocke finds two cases in which animal B5 changes NOx by statistically significant amounts (one increasing NOx and the other decreasing NOx) and one such case in animal B10 (decreasing NOx), while the other cases show no statistically significant change compared to the base fuel. The study wrongly concludes that these results demonstrate no or little systematic evidence for B5 or B10 animal to increase NOx emissions. In fact, these cases are systematically related to the CN gain of the animal blends in comparison to the base fuel. ADF B3-172 cont.

The Rocke analysis was well planned and executed, and we concur with the conclusions drawn for soy-based blends. Because the analysis for animal-based blends is flawed by omission of a cetane variable, it should be revised to address CN gain. We expect that a revised analysis will shed further light on the circumstances in which animal-based biodiesels will and will not increase NOx emissions.

2.2 Rincon Ranch Analysis of ARB NOx Emissions Data

In July 2014, ARB released two datasets that represent the fruit of its efforts to compile the available biodiesel NOx emissions test data on conventional heavy-duty truck (HDT) engines. This report and the companion file *"Biodiesel Emissions Analysis Technical Summary 102014.pdf,"* which is attached to and incorporated in this report, present the results of a statistical analysis of the data sets released by ARB that was performed by Rincon Ranch Consulting at the request of Growth Energy.

The analysis presented below focused on whether soy and animal blends will increase NOx at low blend levels in conventional diesel engines. The following issues were examined:

- The NOx impacts of soy and animal blends at B5 and B10;
- The NOx emission differences observed among animal feedstocks and blends;
- For animal blends, the effect on NOx emissions of the CN change relative to base fuel that is caused by blending of the animal feedstock; and
- The development of a cetane-based model of the biodiesel NOx impacts of soy and animal blends.

2.2.1 Data Used in the Analysis

As noted above, in July 2014, ARB released two datasets of NOx emissions data from testing of biodiesel blends in HDT engines. One file ("B5 & B10 Raw NOx Data") contains the subset of testing for B5 and B10 blends (soy and animal). The test data generated in the four ARB-sponsored UCR studies are present in the form of the individual test run measurements. Because test run information was not reported in their publications, the B5 soy data from Nikanjam 2010 and the B10 soy data from Thompson 2010 are present in the form of emission averages. No animal blends have been tested at the B5 or B10 levels except in the ARB-sponsored emissions testing. A second file ("2014 Biodiesel Literature Search Database") contains all of the biodiesel ADF B3-173 testing available in the literature through the B20 level (soy and animal), including ARB-sponsored testing and the literature search. The data are in the form of emission averages by engine, test cycle, feedstock type, and blend level.

For purposes of this analysis, the following information was added to the ARB datasets:

- The number of test replications for emissions averages for each study (estimated when the source did not report the number);
- The CN for CARB diesel, the biodiesel blends, and the biodiesel feedstocks; and
- Additional NOx emissions testing at the B50 and B100 levels (where available).

Appendix Table A presents a list of the studies included in the dataset and the author references used in citations here.

ADF B3-173 cont.

2.2.2 NOx Emissions from Soy Biodiesel Blends

Most past research on biodiesel emissions has focused on soy blends. As a result, the literature is relatively large and diverse. The dataset assembled by ARB is derived from 10 different studies, covers 13 different vegetable feedstocks (10 soy, 2 used cooking oil [UCO], 1 canola), and was conducted using 7 different test cycles on a wide variety of engines in different labs. Most of the data, in terms of number of data points, are derived from the three UCR studies (Durbin 2011, Durbin 2013B, and Karavalakis 2014) sponsored by ARB.

We subjected the soy dataset to a number of different analyses using different statistical techniques and selections of the data to ensure that the conclusions we drew were robust. The statistical analyses included the t-test for the difference in mean values (e.g., between B5 and CARB diesel) and linear regression analysis using several different models. The data subsets were selected to use either individual test runs or emission averages and to contain testing through maximum blend levels of B5, B10, B20, B50, and B100.

ADF B3-174

Our analyses show that there is a consensus among the studies on the NOx impact of soy biodiesel without regard to the specific analytical methods or data used. Soy biodiesel increases NOx emissions by amounts that can be estimated with good statistical confidence because of the large size of the available dataset. The key conclusions are as follows:

- Soy biodiesel increases NOx emissions by ~1% at B5 and ~2% at B10;
- NOx emissions increase in a linear fashion with increasing blend level to reach ~4% at B20 and proportionately larger values at higher blend levels; and
- There is no evidence in the data for a threshold level below which soy biodiesel does not increase NOx.

These conclusions are supported by all of the available studies and data. None of the studies disagree substantially, and while the results for individual blends, engines, and test cycles will vary to some extent, the evidence across a wide range of engines and test cycles is clear. NOx increases can be expected for UCO, canola, and other vegetable biodiesels, but the data are very limited and it is not possible to draw definitive conclusions for these blends. ADF B3-174 cont.

2.2.3 NOx Emissions from Animal Biodiesel Blends

The literature on NOx emissions from animal blends is much smaller—it consists of only four studies, three of which (Durbin 2011, Durbin 2013A, and Karavalakis 2014) were sponsored by ARB. Except for the McCormick 2005 study, the emissions testing was conducted at the UCR CE-CERT lab. A variety of test cycles were used, but most of the testing was conducted on the hot-start FTP cycle. Table 1 presents a summary of the emissions studies for animal biodiesel. ADF B3-175

Table 1. Scope of Emissions Testing for Animal Biodiesel

	McCormick 2005	Durbin 2011	Durbin 2013A	Karavalakis 2014
Biodiesel Feedstock	Animal #1	Animal #2	Animal #3	Animal #4
Blend Levels Tested	B20	B5, B20, B50, B100	B5	B5, B10
Engines Tested	2 on-road	3 on-road, 1 off-road	1 on-road	1 on-road
Test Cycles	FTP	FTP, UDDS, 50 mph, ISO 8178	FTP	FTP, SET, UDDS
Test Replications on Biodiesel	6	126	26	80
Is NOx Increase Observed?				
At / Below B10	–	Yes	No	No
Above B10	Yes	Yes	-	-

It is important to understand the limitations of this small dataset. Without the ARB-sponsored testing, we would have only the six test replications (individual runs) conducted in the McCormick 2005 study. While the three UCR studies accumulated 232 test replications, the work involved only three different animal feedstocks. Including the McCormick 2005 study, the entire literature on NOx emissions from animal biodiesel is based on only four different animal feedstocks. The small number is an important limitation because animal feedstocks are much less homogenous than soy due the greater variety possible in animal sources and compositions. Further, there are notable differences among the four studies as to whether animal biodiesel increases NOx at the B5 and B10 levels (as indicated by the red circles in the table).

As in the soy analysis, we subjected the animal biodiesel data to a number of different analyses using different statistical techniques and selections of the data to ensure that the conclusions we drew were robust. The t-test is the most direct method to assess whether NOx emissions are higher at B5 compared to CARB diesel. Using the individual test run data available from the three UCR studies, we find the following for animal biodiesel at the B5 blend level:

- The animal feedstock used in Durbin 2011 increases NOx in 2 of 3 engines. The increase is highly significant[4] statistically for one engine.

- The animal feedstock used in Durbin 2013A decreases NOx in one engine. The decrease is statistically significant at the p=0.05 level, and the blend was certified as NOx neutral at B5.

- The animal feedstock used in Karavalakis 2014 increases NOx in three of six cases and decreases NOx in the other three cases. None of the changes are statistically significant. The blend may or may not change NOx.

ADF B3-175 cont.

Contrary to Staff's assertion that no NOx increase occurs in B5 animal blends, it is clear that some animal blends will significantly increase NOx emissions, while other animal blends will not. The fundamental issue is then understanding what the NOx impact of a particular animal biodiesel blend will be.

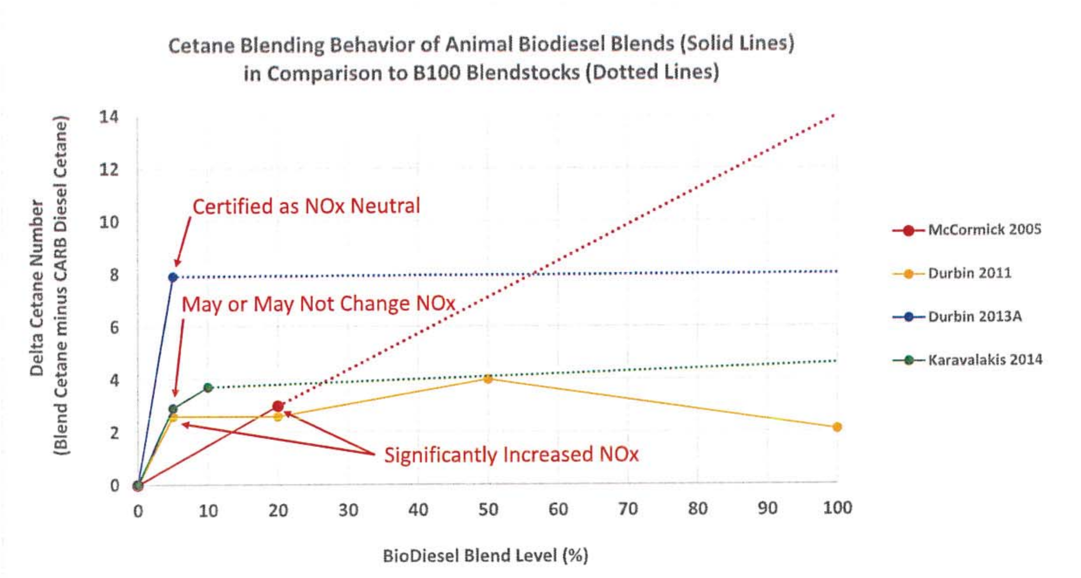
The effect of feedstock blending on the CN of the resulting animal blend is the reason for the apparently discordant results among the studies. Figure 1 plots the four series of animal blends used in the studies, with blend level on the horizontal axis and the change in blend CN (relative to CARB diesel) on the vertical axis. CN blended linearly to B20 for the McCormick feedstock, which showed a much smaller CN benefit than the feedstocks used by UCR—only three numbers at B20 (0.6 numbers at B5). In contrast, all three UCR animal blends achieve a large CN boost at low blending levels in which most or all of the CN benefit of the feedstock is achieved at B5.

In Durbin 2011, the CNs for the blends are above that of the B100 feedstock. This result is probably caused by lab-to-lab differences (blend CN was determined at CE-CERT, while CN for CARB diesel and the B100 feedstock were determined by an outside lab). The actual CN changes are surely lower than shown here—at or below +2 CNs. ADF B3-176

The two animal feedstocks that caused statistically significant NOx increases have the smallest CN benefits: McCormick 2005 (red) at B20 and Durbin 2011 (yellow) at B5. The animal B5 blend that passed certification testing as NOx neutral in Durbin 2013A (blue) has the highest CN benefit, where it achieved the entire B100 CN at just 5% blending. The Karavalakis 2014 B5 blend (green) had an intermediate CN benefit and may or may not change NOx.

[4] The term "significant" is used in this report only to refer to statistical significance. When a result reaches the p=0.05 level, we can be 95 percent confident that it is real. In such case, and at smaller p values, the result is said to be statistically significant.

Figure 1. Cetane Blending Behavior of Animal Blends (Solid Lines) Compared to B100 Feedstocks (Dotted Lines)



The blending behavior of the UCR blends is surprising in comparison to the McCormick study, and we find relatively little research on the CN blending behavior of animal feedstocks. All conclusions from this dataset will be influenced by the CN blending behavior of the specific animal feedstocks involved. For such conclusions to be reliable, we must be confident that the large CN boost reported for the UCR blends is both real and representative of all animal feedstocks in California. Also, only limited information is available on the sources and characteristics of the animal feedstocks. ADF B3-176 cont.

To permit all parties to better understand the animal feedstocks that were tested, ARB should release all information that it has on the following:

- CNs (methods of determination and measured values) for the Durbin 2011 and other UCR studies;
- Physical and chemical properties of the animal feedstocks and biodiesel blends tested;
- The distribution of sources, characteristics, and properties in the population of animal feedstocks that are available for use in the California market; and
- How the specific animal feedstocks tested at UCR were selected, including any information that would demonstrate that the feedstock properties and their CN blending behavior are representative of the animal feedstock population available for use in California.

Staff's use of the terms low saturation (for soy) and high saturation (for animal) to classify biodiesel is useful to differentiate between feedstocks that will tend to decrease CN and those that will tend to increase it. However, it is not a sufficient step in that the CN change at each blend level is the determinative factor for NOx emissions, not the CN of the feedstock itself. Soy feedstocks appear to blend linearly with respect to cetane; however, animal feedstocks often lead to a highly non-linear CN response, as shown in Figure 1. ADF B3-176 cont.

2.2.4 Development of a Cetane-based Model of NOx Impacts from Soy and Animal Biodiesel

The results presented above indicate the important role that CN plays in determining the NOx response for animal blends. Animal feedstocks tend to increase the CN of the blend above that of the CARB diesel and the CN change can be large at low blend levels. Soy feedstocks generally decrease the CN of the blend below that of the CARB diesel; for soy, the CN change at low blend levels can be smaller than the uncertainty in determining CN. The result of our work on a cetane-based model demonstrates that soy and animal blends are not categorically different fuels once their differing effect on CN is taken into accounted. Their NOx impacts can be represented by the same model as a function of blend level and the change in CN compared to CARB diesel.

The document that accompanies this report explains the development of the cetane-based model in some detail. In brief, it was developed using conventional linear regression analysis with log(NOx) emissions as the dependent variable. Intercept terms were included to represent the varying emission levels on CARB diesel for each combination of study, feedstock type, engine, and test cycle. A *b* coefficient was included to represent the change in NOx emissions for each one percent biodiesel in a blend at constant CN. A *c* coefficient was included to represent the change in NOx emissions for each one number change in CN compared to CARB diesel at constant blend level. Both soy and animal blends were included in the estimation, along with the small number of canola and UCO data points, at blend levels up to (and including) B20. ADF B3-177

The model estimation shows that the *b* and *c* coefficients are highly significant statistically ($p < 0.0001$). The estimation results also show the following:

- The *b* coefficient has a value of +0.00156, which estimates that soy and animal biodiesel will increase NOx emissions by 0.16% for each one percent biodiesel at constant CN or by 0.8% at B5.
- The *c* coefficient estimates that +5 CNs will decrease NOx emissions by 1.5% at constant blend level. This result is completely consistent with earlier work[5] on the relationship between CN and NOx emissions in HDT engines, which also found that +5 CNs will decrease NOx emissions by 1.5% in base fuels with CN ~50.

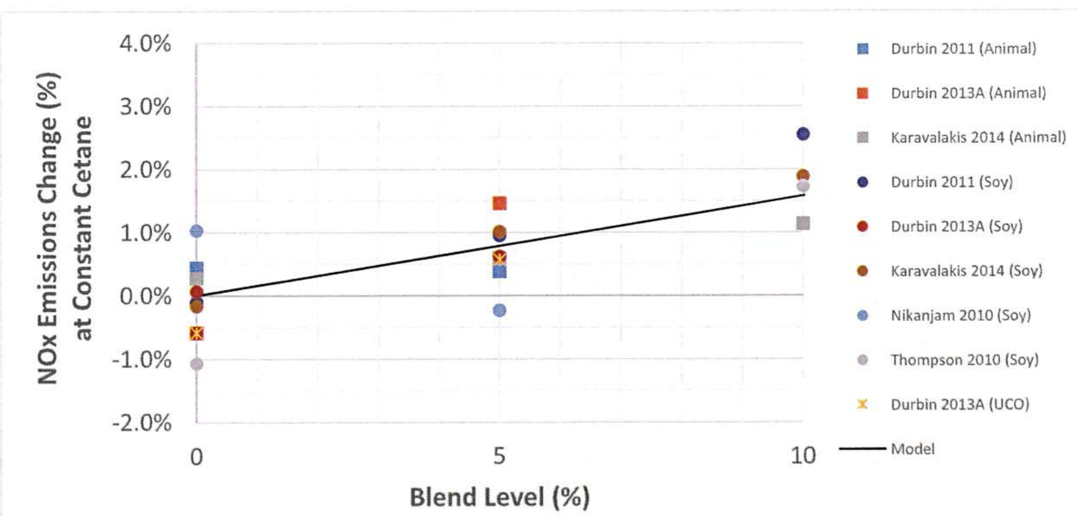
[5] The Effect of Cetane Number Increase Due to Additives on NOx Emissions from Heavy-Duty Highway Engines. EPA420-R-03-002. February 2004. Figure IV.A-1.

- An increase of -b/c = 0.5 CNs is needed to offset the NOx increase expected from each 1% biodiesel added. For B5, an increase of 2.5 CNs is required to offset the expected NOx increase.

The results explain why soy and animal blends appear to be different fuels. Soy blends have an additional, adverse CN effect that increases their NOx impact to ~1% at B5. Animal blends will generally increase CN and that reduces their NOx impact to about one-half the soy level or less, depending on the CN change caused by blending. The results also explain why some animal blends do not increase NOx emissions. If an animal feedstock increases CN by more than ~0.5 numbers for each 1% biodiesel blended, then the resulting fuel may not increase NOx emissions.

To demonstrate these conclusions, Figure 2 presents NOx emissions as a function of blend level for all fuels used to estimate the model once NOx emissions are adjusted for the CN change observed for each blend. For example, if an animal blend increased CN, then its NOx impact is <u>increased</u> as we return it to the base fuel CN. If a soy blend decreases CN, then its NOx impact is <u>decreased</u> as we return it to the base fuel CN. Once adjusted, percent changes in emissions are calculated. As seen in the figure, there is no discernable difference among feedstock types once CN changes are taken into account. Animal and soy blends scatter on both sides of the regression line, indicating that they obey the same blend level model.

Figure 2. There Are No Detectable Differences Among Feedstock Types Once NOx Emissions Are Adjusted to Constant CN



Note: Animal blends are plotted as squares, soy blends as circles, and the non-soy vegetable blends as asterisks.

Note the scatter of points around the regression line (which gives the "average" response). Some of the scatter is due simply to emissions measurement error; however, other factors may be involved in determining the NOx impact for a given feedstock, including differences in the

ADF B3-177 cont.

FAME (fatty acid methyl ester) composition and uncertainty in determining CN for the blends. If ARB were to adopt a predictive model to determine the CN improvement needed to mitigate NOx, it should use the model to evaluate a "worst case" feedstock, meaning a point near the upper end of the range at each blend level.

The most important conclusion of this work is that soy and animal biodiesel blends are not categorically different fuels. Their emissions effects are similar, but they show different NOx impacts because they have different effects on CN. Furthermore, this work provides a potential answer to the problem that some animal blends will significantly increase NOx emissions, while other blends will not, by indicating what individual blends may do.

ADF B3-177 cont.

3. NOX EMISSIONS IN NEW TECHNOLOGY DIESEL ENGINES

Staff's position is that biodiesel will not increase NOx emissions in NTDEs at levels up to and including B20. Its assessment is stated in the ISOR as follows:

> *Engines that meet the latest emission standards through the use of Selective Catalytic Reduction (SCR) have been shown to have no significant difference in NOx emissions based on the fuel used. A study conducted by the NREL looked at two Cummins ISL engines that were equipped with SCR, and found that NOx emissions control eliminates fuel effects on NOx, even for B100 and even in fuels compared against a CARB diesel baseline.*[20] *However, a recent study at UC Riverside tested B50 blends and found a NOx increase with a 2010 Cummins ISX.*[21] *The UC Riverside study did not look at blends below B50. Staff proposes to take a precautionary approach and in the light of data showing there may be a NOx impact at higher biodiesel blends but not at lower biodiesel blends, Staff is limiting the conclusion of no detrimental NOx impacts in NTDEs to blends of B20 and below. Additional studies on NTDEs have been completed, however since they included either retrofit engines or non-commercial engines Staff did not include their results in this analysis.*[22,23,24] (Page 24)

Staff's reliance on Lammert 2012 (Ref. 20) is misplaced because the NREL lab was not equipped to measure the low NOx emission levels of the test vehicles, as the abstract of the Lammert paper clearly notes.[6] In fact, none of the emission changes observed in the study (with one exception) were statistically significant due to the high standard errors that necessarily exist when measurements are made close to the level of detection. In this instance, the failure to observe statistically significant NOx emissions increases from biodiesel at the B20 level is not a demonstration that such increases do not exist.

ADF B3-178 cont.

This specific shortcoming of the Lammert study is why its negative results are in conflict with the finding of the UC Riverside study (Gysel 2014) cited by Staff and the three other studies (Walkowicz 2009, McWilliam 2010, Mizushima 2010) that Staff dismissed. With respect to the

ADF B3-179

[6] "SCR systems proved effective at reducing NOx to near the detection limit on all duty cycles and fuels, including B100." Lammert 2012, Abstract.

three other studies, we see no reason why they should be dismissed. It is not the case that factory-designed NOx after-treatment systems will reduce NOx levels to below the detection limit of well-equipped labs (see Gysel 2014 and engine certification testing). Testing conducted using retrofit NOx after-treatment systems that achieve representative levels of NOx control, as in these studies, is entirely suitable for determining whether biodiesel increases tailpipe NOx emissions on a percentage basis. Having a different absolute level of emissions does not preclude reliable measurement of a percentage change.

ADF B3-179 cont.

When all available studies are included, a consensus of the literature is that biodiesel at the B20 level will increase NOx emissions from NTDEs in most, if not all cases. Lammert 2012 is the one study at odds with the rest of the literature. A range of biodiesel types were used in the studies. NOx increases should be expected at the B20 level for all biodiesel types until such time as additional research indicates differential impacts for biodiesels derived from different sources

3.1 Review of the NTDE Literature

The following sections briefly summarize the NTDE testing conducted in the studies and the conclusions drawn on the NOx emissions impact of biodiesel fuels. Testing of conventional diesel engines without NOx after-treatment is not considered, nor is testing on non-California fuels (low aromatics ULSD was considered equivalent to CARB ULSD). Appendix Table B presents a list of the studies included in the NTDE dataset and the author references used in citations here.

Walkowicz 2009. Chassis dynamometer testing was conducted using a 2005 International 9200i tractor equipped with and without a retrofit diesel oxidation catalyst (DOC) and urea-SCR NOx after-treatment system. On-road emissions measurements also were made using a RAVEM portable emissions measurement system. A ULSD base fuel was tested, as were B20 and B99 biodiesel blends. The type of biodiesel (soy or animal) was not specified, but was mostly likely soy-based as this is the feedstock most common in the market and in engine research.

- Under loaded, on-road conditions, biodiesel increased NOx by 17% at B20 and by about 40% at B99. At B20, the increase was marginally significant ($p=0.10$); at B99, the increase was statistically significant ($p=0.05$).
- Chassis dyno testing was done 24 months later at an ARB lab. The vehicle was determined to have high oil consumption, and lubricating oil was likely present in the exhaust stream. On the UDDS cycle, biodiesel increased NOx by 7% at B20 (marginally significant at $p=0.07$) and by 35% at B99 (highly significant, $p<0.01$).

The authors concluded "The use of biodiesel did result in higher NOx emissions than the use of ULSD (in tests with statistical significance)." The B20 test results did not reach the usual $p=0.05$ level for statistical significance, but were marginally significant ($0.05 < p \leq 0.10$).

McWilliam 2010. A Caterpillar 6.61 engine equipped with DOC and urea-SCR NOx after-treatment was tested using the European non-road transient cycle (NRTC). The fuels used were ULSD plus B20 and B100 biodiesels blended from a rapeseed methyl ester. Figure 9 of the paper shows tailpipe NOx emissions of the vehicle in g/kWh units. Reading from the graph because numerical emission values were not given, tailpipe NOx emissions increase ~15% at B20 and ~150% at B100. Based on the narrow error bars shown in the figure, both of these increases are statistically significant.

This study was conducted by Caterpillar because previous work had highlighted the potential for biodiesel to have an adverse impact on the NOx conversion efficiency of urea-SCR after-treatment systems. Thus, reductions in conversion efficiency have the potential to increase NOx emissions by amounts that exceed that caused by the biodiesel itself. At B20, only a 1% loss of conversion efficiency was noted, but a substantial 6% loss was observed at B100.

The authors of this paper concluded "Additional control strategies will be necessary to correct for NOx increases during biodiesel operation on installations requiring compliance regardless of fuel used."

Mizushima 2010. An inline 4-cylinder diesel engine equipped with DOC, diesel particulate trap (DPT), and urea-SCR NOx after-treatment system was tested using the JE-05 exhaust emissions test cycle used for heavy-duty vehicles in Japan. The fuels used were ULSD plus B20 and B100 blended from waste vegetable oil (WVO). Figure 4 of the paper shows tailpipe NOx emissions of the engine in g/kWh units. NOx emissions are highly linear with biodiesel blending level. Reading from the graph because numerical emission values were not given, tailpipe emissions increase ~20% at B20 and ~100% at B100. The paper does not address the statistical significance of these results.

With respect to NOx conversion efficiency, the study noted a drop from 76% on ULSD to 47% at B100, with a smaller but still measurable drop at B20. The impact on NOx conversion efficiency was linked to the effect of biodiesel in lowering the overall NO_2/NOx ratio at the SCR inlet leading to reduced conversion efficiency.

The authors drew no conclusions regarding the NOx emissions effects of B20 biodiesel as the focus of their research was on the B100 fuel.

Lammert 2012. The NREL study examined NOx emissions from transit buses on both EPA and CARB diesel fuels, B20 soy blends of each, and B100 soy. Chassis dynamometer testing was conducted using the Manhattan Bus (MAN), Orange County Transit Authority (OCTA) and UDDS test cycles. Two of the buses were NTDEs, including a 2010 Cummins ISL and 2011 Gillig/Cummins ISL. Only the 2010 Cummins was tested using the CARB ULSD base fuel and the biodiesel fuels.

NOx emission results for the 2010 Cummins bus are shown in Figure 10 of the paper. For B20, NOx emissions decreased compared to CARB ULSD on all three cycles (MAN, OCTA, and UDDS), and for B100 on the MAN cycle (OCTA and UDDS were not tested). None of the differences were statistically significant except for B20 on the UDDS cycle, and the standard errors plotted in the figure are large in comparison to the emission averages.

The authors explain the non-significance of their results as follows:

> *For much of the cycle NOx would be at or near the detection limit of the laboratory equipment, which resulted in a 95% confidence interval error that was high relative to the value of the cycle emissions.* (Page 6)

One of the authors' conclusions is that SCR NOx after-treatment appears to nearly negate the effect of fuels on NOx emissions. Another conclusion is that SCR NOx after-treatment also negates any duty cycle effect on NOx. (Page 8) For buses without NOx after-treatment, NOx emissions are strongly related to the kinetic intensity (load) of the test cycle. This result is consistent with all past vehicle and engine research studies, which show that NOx emissions are increased when a diesel engine is operated under increased load. However, no such relationship is observed for SCR-equipped buses. Increased load will increase engine-out NOx levels in an SCR-equipped bus. Unless this is accompanied by an increase in NOx conversion efficiency, tailpipe NOx emissions should also increase. <u>Neither conclusion is reliable because of the study's problems in measuring NOx emissions even on ULSD fuel</u>.

<u>Gysel 2014</u>. A 2010 Cummins ISX-15 equipped with DOC, DPF and urea-SCR NOx after-treatment was tested on CARB ULSD and B50 biodiesel blended from soy, waste cooking oil (WCO) and animal fat feedstocks. Chassis dynamometer testing was performed at CE-CERT using the UDDS test cycle.

Figure 7 of the paper shows the NOx emissions measured on ULSD and the three B50 biodiesel blends. The soy and WCO B50 blends increased NOx by 43% and 101%, respectively, with both increases being highly statistically significant ($p<0.01$). The animal B50 blend increased NOx by 47%, which was marginally significant ($p=0.065$). The authors' conclude that "Overall, NOx emissions exhibited increases with biodiesel for both vehicles with the differences in NOx emissions relative to CARB ULSD being statistically significant for the new Cummins ISX-15 engine." (Page 6)

The authors note the negative results reported by Lammert 2012 as being in contrast to those of their study, "which shows that there is a relatively strong fuel effect with the B50 blends compared to CARB ULSD from the Cummins ISX-15 engine with SCR." (Page 6). They also note the following:

> *The NOx increase with biodiesel for SCR-equipped engines is usually attributed by a reduction of exhaust temperature and the change of NO_2/NO ratio in NOx emissions [38]. In general, the lower exhaust temperatures with biodiesel will lower the oxidation rates of NO to NO_2 from the DOC. It has been shown that a NO_2/NOx ratio below 0.5 significantly changes SCR reaction chemistry lowering the SCR removal efficiency of NOx [39]. Walkowicz et al. [40] found increases in NOx emissions of 7% with B20 and 26% with B99 compared to ULSD for a heavy-duty diesel vehicle equipped with a 2004 Caterpillar 400 hp C13 engine. For the same vehicle equipped with a urea-based SCR system, NOx increases were very similar on a percentage basis, with B20 and B99 having 7% and 27%, respectively, higher NOx than ULSD.* (Page 6)

The authors continue to say:

> *The trend of increasing NOx emissions for biodiesel blends is consistent with a wide range of studies found in the literature. Comprehensive investigations conducted by Mueller et al. [41] and Sun et al. [42] confirmed that biodiesel promotes a combustion process that is shorter and more advanced than conventional diesel, which contributes to the formation of thermal NOx. The higher NOx emissions with biodiesel for both vehicles could also be a consequence of the higher oxygen content in biodiesel, which enhances the formation of NOx. The lower volatility of biodiesel compared to diesel fuel could also contribute to decreased fractions of premixed burn, as a result of fewer evaporated droplets during the ignition delay period [43]. Another contributing factor for NOx emissions increase could be the engine control module (ECM), which may dictate a different injection strategy based on the lower volumetric energy content of biodiesel. Eckerle et al. [44] suggested that a higher fuel flow is required with biodiesel compared to diesel fuel for an engine to achieve the same power. The ECM interprets this higher fuel flow as an indicator of higher torque, and therefore makes adjustments to engine operating parameters that, under certain operating conditions, increase NOx emissions.* (Page 6).

The engineering mechanisms described by the authors indicate that <u>biodiesel should be expected to increase NOx emissions in NTDEs at blend levels below the B50 examined in the study</u>. There is no basis in these mechanisms to believe that biodiesel <u>will not</u> increase NOx emissions at B20 but <u>will</u> increase NOx emissions at B50. ADF B3-180

3.2 Consensus on Biodiesel NOx Impacts

Table 2 presents a summary of the available literature on the NOx emissions impact of biodiesel at the B20 blend level. Four of the five studies tested B20 fuels on NTDEs. Staff choose to rely on the one study in which NOx emissions were at or near the detection limit of the laboratory equipment for much of the test cycle on each fuel and to dismiss the other three studies "… since they included either retrofit engines or non-commercial engines …". The study that was retained did not observe a NOx increase because it had trouble measuring NOx emissions from the NTDE tested. The studies that were dismissed showed consistent NOx emission increases in the range of 10-20% at B20.

Staff notes the Gysel study, which found significantly increased NOx emissions at B50 compared to CARB ULSD, as its reason for setting the biodiesel control level at B20 for NTDEs. ADF B3-181
However, Staff did not note the study's discussion indicating that the Lammert results were in contrast to their results and to the results of other studies in the literature. Nor did Staff note the discussion of mechanisms by which biodiesel is believed to increase NOx emissions in NTDEs. These mechanisms include a reduction of the NO_2/NOx ratio that leads to loss of NOx conversion efficiency in urea-SCR systems, promotion of a combustion process that contributes to increased formation of thermal NOx, higher NOx emissions due to the oxygen content of biodiesel, and the lower volatility and lower volumetric energy content of biodiesel. <u>These mechanisms indicate that biodiesel can be expected to increase NOx emissions in NTDEs at blend levels below the B50 examined in the study</u>.

Table 2. Summary of NTDE Literature on NOx Emissions Impact of B20

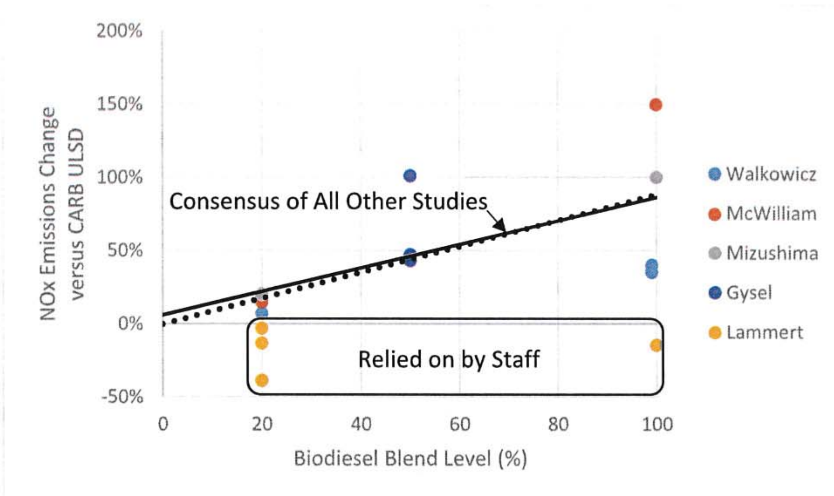
	B20 NOx Emissions Change (%) versus CARB ULSD	Comments
Studies Relied on by Staff		
Lammert 2012	NOx emissions decrease on three cycles	UDDS cycle decrease is statistically significant. NOx emissions on all fuels were at or near the detection limit of the laboratory equipment.
Gysel 2014	B20 not tested	The paper discusses how biodiesel effects NOx emissions. These mechanisms suggest that biodiesel <u>should</u> increase NOx emissions at levels below B50.
Studies Dismissed by Staff		
Walkowicz 2009	+17% on-road + 7% chassis dyno	Both results are marginally significant ($0.10 \leq p < 0.05$)
McWilliam 2010	~15% increase	European transient cycle
Mizushima 2010	~20% increase	Japanese heavy-duty test cycle

ADF B3-182

Figure 3 summarizes the impact of biodiesel on NTDE NOx emissions at all blend levels. The four studies (excluding Lammert 2012) establish a linear relationship between NOx emissions and blend level. The first trend line (solid black) passes very nearly through the origin without being constrained to do so. The second trend line (dotted black) is constrained to pass through the origin. While there is substantial scatter around the trend lines, the consensus of the four studies is that biodiesel increases NOx by 18-22% at B20, by 45-50% at B50, and by 90-100% at B100.

In spite of this consensus, Staff chose to rely only on the Lammert 2012 study, which shows that biodiesel <u>decreases</u> NOx emissions at both the B20 and B100 blend levels. This is the study that had difficulty measuring NOx emissions because NOx was at or near the detection limit of the laboratory equipment for much of the test cycle on all fuels.

Figure 3. The Impact of Biodiesel on NTDE NOx Emissions



To test the statistical significance of the trend lines shown in the figure, conventional regression analysis was conducted using the data reported by four of the studies (Lammert 2012 excluded) as summarized in Table 3. Regression A corresponds to the figure's solid trend line and is not constrained to pass through the origin. Its slope is +0.80% increase per 1% biodiesel in the blend; it is statistically significant at the p=0.035 level. Regression B corresponds to the dotted trend line and is constrained to pass through the origin. Its slope is +0.89% increase per 1% biodiesel, and it is statistically significant at the p<0.001 level. The two regression models predict a 22% and 18% increase, respectively, in NOx emissions at B20 in NTDEs.

ADF B3-183

Table 3. Statistical Significance of Biodiesel NOx Effect in NTDEs

	Intercept	Significance	Slope (% NOx Increase per 1% biodiesel)	Significance	Predicted NOx Increase at B20
Regression A	6.4	p = 0.80	+0.80% (±0.32%)	p = 0.035	22%
Regression B	None	n/a	+0.89% (±0.16%)	p <0.001	18%

A fair reading of the technical literature would lead Staff to expect that biodiesel will increase NOx emissions in NTDEs by about 20% at B20 and by proportionately smaller amounts at blend levels below B20. At the B5 level, the impact is expected to be an increase in NOx emissions of about 5%. At the B20 level, the NOx increase appears to be greater on a percentage basis than would be expected in conventional diesel engines (1% at B5, 2% at B10, and ~4% at B20). The loss of NOx conversion efficiency when biodiesel fuels are used is one likely reason for the greater impact. ADF B3-183 cont.

4. SUMMARY AND CONCLUSIONS

The key conclusions of this study are summarized below with respect to conventional diesel engines and new technology diesel engines.

Conventional Diesel Engines

- Soy and animal blends are not categorically different fuels once their differing effect on blend CN is taken into account. ADF B3-184
- There is no evidence in the data of a threshold level below which biodiesel fuels as a group do not increase NOx, whether soy or animal. As shown here, the magnitude of the NOx impact observed depends on both the blend level and the change in CN that results from blending of the biodiesel feedstock. ADF B3-185
- Soy blends clearly and significantly increase NOx by ~1% at B5 and by ~2% at B10. The effect is continuous and linear with respect to the blend level at all levels above ULSD. Soy blends require mitigation at all levels to offset increased NOx emissions. ADF B3-186
- Staff's proposal requires NOx mitigation in summer months for soy fuels at blend levels greater than B5. Because soy fuels increase NOx at all blend levels, mitigation should be required for B5 and lower blends to prevent increased NOx emissions. ADF B3-187
- Animal blends are more complicated. The current research is limited, and the evidence is mixed. At least one B5 animal blend significantly increased NOx, while another has been certified as NOx neutral. Other B5 animal blends may or may not increase NOx depending on their CN effect (and possibly other factors). ADF B3-188
- Staff's assertion that no NOx increase occurs at B5 in animal blends is incorrect: some animal blends will significantly increase NOx emissions, while other animal blends will not. ADF B3-189
- Animal blends cannot be assumed to have no impact on NOx emissions without a demonstration that feedstock blending raises CN enough to offset potential NOx increases. ADF B3-190

New Technology Diesel Engines

- Staff is incorrect in concluding that biodiesels will not increase NOx in NTDEs. The Staff conclusion is based on a highly selective reading of the technical literature that relies on the one study in which the laboratory was not well equipped to measure the low levels of tailpipe NOx emissions from NTDEs. ADF B3-191

- There is greater reason to exclude the study Staff relied on than the three studies that Staff excluded. If that is done, there are no test data at the B20 level or below in NTDEs and no basis whatsoever to permit biodiesel fuels in NTDEs in California. ADF B3-192

- While the available data are limited, the four best studies (excluding Lammert 2012) support the conclusion that biodiesel increases NOx by 18-22% at B20 and that the increase is statistically significant. Staff has no basis to claim that no NOx impacts are associated with biodiesel at the B20 level and below in NTDEs. ADF B3-193

- A fair reading of the technical literature would lead Staff to expect that biodiesel will increase NOx emissions by about 20% at B20 and by proportionately smaller amounts at lower blend levels. This is a greater percentage NOx increase in proportion to blend level than the increase caused by soy biodiesel in conventional diesel engines (1% at B5, 2% at B10, and ~4% at B20). ADF B3-194

- Staff makes no mention of the concern that the use of biodiesel fuels may lead to the loss of NOx conversion efficiency in urea-SCR after-treatment systems by shifting the NO_2/NOx ratio to lower values. Conversion losses were observed at B20 in two of the studies. ADF B3-195

Based on the results summarized above, it is strongly recommended that ARB consider as part of the ADF rulemaking a regulatory structure in which the NOx impacts of soy and animal biodiesel are accounted for using a statistical model analogous to the Predictive Model for RFG. We see the cetane-based model presented here as a possible draft for a biodiesel predictive model, but substantial additional work is needed to: ADF B3-196

- Demonstrate that blends mitigated using DTBP obey the same model; and

- Further assess the impacts of biodiesel produced from animal feedstocks on both CN gain in blends as well as NOx emissions.

Further, more advanced statistical techniques should be used as was done in developing the Predictive Model for California Reformulated gasoline. The dataset used here is unbalanced, meaning that there are varying numbers of data points for each combination of study, feedstock type, engine, and test cycle. In fact, only a fraction of all possible study/feedstock/engine/test cycle cells are represented by one or more data points. Mixed Effects modeling is appropriate in such cases and its use will assure that coefficient estimates are not biased by the unbalanced distribution of the data. ADF B3-197

Subject: Comments on the LCFS and ADF rulemaking proposals

Jim and Lex:

Just wanted to let you know that we'll be filing the report in hard-copy form tomorrow at the hearings. We tried to file a hard copy version today with the Clerk of the Board, but were instructed instead to bring hard copies tomorrow to the hearing room for filing.

I'd only planned to bring two copies tomorrow (one for each rulemaking file based on my conversation today with Steve Adams) as we don't plan to offer oral testimony on this issue and therefore don't plan to ask that the report be handed around to the Board members. However, please let me know if you'd like me to bring hard copies for you. If you were able review to our October 24 post-workshop comments that were submitted to you then as part of the ADF rule development process, you've already seen the Rincon Ranch analysis of the biodiesel test data and the related literature, which I had summarized at the October 20 workshop. The only new thing in this version of the report is the NTDE discussion, which is also covered in my Declaration that was filed yesterday.

PROCEEDINGS

CHAIRPERSON NICHOLS: Good morning, everybody. The February 19th, 2015, public meeting of the Air Resources Board will come to order. We will begin with the Pledge of Allegiance. And Mrs. Riordan is going to lead us in that.

(Thereupon the Pledge of Allegiance was Recited in unison.)

CHAIRPERSON NICHOLS: Thank you.

Madam Clerk, would you please call the roll?

BOARD CLERK JENSEN: Dr. Balmes?

BOARD MEMBER BALMES: Yes. Here.

BOARD CLERK JENSEN: Ms. Berg?

BOARD MEMBER BERG: Here.

BOARD CLERK JENSEN: Mr. De La Torre?

BOARD MEMBER DE LA TORRE: Here.

BOARD CLERK JENSEN: Mr. Eisenhut.

BOARD MEMBER EISENHUT: Here.

BOARD CLERK JENSEN: Supervisor Gioia?

BOARD MEMBER GIOIA: Here.

BOARD CLERK JENSEN: Ms. Mitchell?

BOARD MEMBER MITCHELL: Here.

BOARD CLERK JENSEN: Mrs. Riordan?

BOARD MEMBER RIORDAN: Here.

BOARD CLERK JENSEN: Supervisor Roberts?

BOARD MEMBER ROBERTS: Here.
BOARD CLERK JENSEN: Supervisor Serna?
BOARD MEMBER SERNA: Here.
BOARD CLERK JENSEN: Dr. Sherriffs?
BOARD MEMBER SHERRIFFS: Yes.
BOARD CLERK JENSEN: Professer Sperling?
Chairman Nichols?
CHAIRPERSON NICHOLS: Here.
BOARD CLERK JENSEN: Madam Chairman, we have a quorum.
CHAIRPERSON NICHOLS: Thank you. Very nice to have you all here.
I have a few announcements, which I want to relate before we begin. A reminder in case there is anyone who is new to these proceedings that if you want to testify, we appreciate it if you fill out a request to speak card. These are available in the lobby outside or with the clerk. We appreciate it if you turn it into the Board Clerk over here before we actually begin the discussion of that particular item.
Also, we will be imposing a three-minute time limit on all speakers. We appreciate it if you summarize any written testimony that you've already submitted or are going to be submitting because we can read a lot faster than you can talk. So it helps us if we have the written

testimony, but then if you just summarize it in your own words.

Also, I want to point out the exits in this room. There are two at the rear and two on either side of the dais here. If there is a fire alarm, we are required to evacuate the room immediately and go down the stairs and exit the building until we hear the all-clear signal that allows us to come back to the hearing room. And that actually has happened in my time here. So I can appreciate it if everybody will follow that instruction.

And with that, we'll begin this morning with one consent item. I understand no one has signed up to testify on it. This is a minor revision to the South Coast 2012 PM2.5 State Implementation Plan. So unless there is anyone on the Board who wishes to take the item off consent, I would appreciate a motion to approve.

BOARD MEMBER MITCHELL: I move approval.

BOARD MEMBER RIORDAN: Second.

CHAIRPERSON NICHOLS: Very good. All in favor please say aye.

(Unanimouse aye vote)

(Board Member Sperling not present at vote)

CHAIRPERSON NICHOLS: Any opposition or abstentions? Great.

We'll move on to the public hearing to consider the adoption of the evaporative emissions control requirements for spark ignition marine watercraft. I'll ask the staff to begin that presentation.

I want to just comment that this is an area where I know staff has been working with industry for a long time on this issue. We still need more reductions in reactive organic gases to achieve our federal health standards for ozone and spark ignition marine watercraft, which includes inboard, outboard, stern drive, and personal watercraft are a major source of reactive organic gases. So the proposal here today is something that will be an important step on one of our most vexing air quality issues, which is ozone.

So with that, Mr. Corey, would you please introduce the item.

EXECUTIVE OFFICER COREY: Yes, thank you, Chairman.

Mobile sources have historically been the largest source of reactive organic gas emissions in California. With the success of our control programs for on-road vehicles, the emissions contribution from less well controlled off-road categories has become relatively more important.

Reducing reactive organic gas emissions from marine watercraft is key to meeting our air quality goals in ozone non-attainment areas, such as South Coast.

Today, staff will present a regulatory proposal for reducing evaporative emissions from spark ignition marine watercraft configured with engines greater than 30 kilowatts. By setting more stringent evaporative emission than those adopted by U.S. EPA, this regulation is expected to further reduction. This regulatory proposal requires both builders to certify spark ignition marine watercraft to ensure the enforceability of the proposed standards.

Now I'd like to ask Scott Monday to begin the presentation. Scott.

(Thereupon an overhead presentation was presented as follows.)

AIR RESOURCES ENGINEER MONDAY: Thank you, Mr. Corey.

Good morning, Chair Nichols and members of the Board.

Today, I will present the proposed regulation to control evaporative emissions from spark ignition marine watercraft. For purposes of the Board presentation today, we will be using the term "watercraft."

--o0o--

AIR RESOURCES ENGINEER MONDAY: Today's presentation will cover the watercraft regulatory background followed by the details of watercraft emission control. And then I will present the regulatory proposal, and finally staff's recommendation.

Staff evaluated innovative technology solutions and also updated the watercraft emissions inventory to quantify the cost effective emission reductions from this category. The proposed regulation is a result of extensive collaboration between ARB and stakeholders and will yield needed emission benefits.

I will now begin presenting the background for the watercraft regulatory proposal.

--o0o--

AIR RESOURCES ENGINEER MONDAY: The goals of the watercraft regulatory proposal are first to harmonize, where possible, federal watercraft regulation, including elements such as regulatory format, test procedures, and labeling. This will have the benefit of minimizing the regulatory burden on stakeholders.

And second, to obtain additional emission reductions beyond those being achieved with the federal rule in order to meet California's unique air quality needs and State Implementation Plan, or SIP, commitments.

--o0o--

AIR RESOURCES ENGINEER MONDAY: Evaporative emissions from motor vehicles have been controlled for more than 40 years. However, evaporative emissions from watercraft were not controlled until U.S. EPA adopted a rule for new watercraft in 2008. The federal regulations were fully implemented by 2012 and are expected to reduce reactive organic gas emissions by more than eight tons a day in 2037.

Now we are proposing the next step to further reduce evaporative emissions starting in model year 2018. ARB's proposal will provide an additional one ton per day above and beyond the U.S. EPA existing rule. As with the federal rule, the proposal we present today will apply to new watercraft only.

--o0o--

AIR RESOURCES ENGINEER MONDAY: The types of watercraft this proposal would reduce evaporative emission from are gasoline-powered marine watercraft with install fuel tanks. This includes outboard boats, personal watercraft, inboard stern drive and jet drive boats.

As boat sales recover in California, without new controls, evaporative emissions from watercraft will increase.

--o0o--

AIR RESOURCES ENGINEER MONDAY: Dr. Haagen-Smit identified reactive organic gas emissions as ozone precursors. Together with oxides of nitrogen and sunlight, they create ground level ozone.

Reactive organic gas emissions also contain toxic components like benzene, which is known as a public health risk.

Watercraft are a source of reactive organic gas emission statewide. Their control is especially important in non-attainment areas, such as the South Coast. The 2007 SIP calendar commits ARB to developing a regulation to reduce reactive organic gas emissions from watercraft. The proposal we are outlining today meets the commitment described in the 2007 SIP.

--o0o--

AIR RESOURCES ENGINEER MONDAY: In order to determine the best approach for controlling evaporative emissions from watercraft, it is important to understand how the emissions are generated. There are three driving mechanisms of evaporative emissions: Permeation through the fuel tank and fuel lines; venting out of the fuel tank vent; and liquid fuel leakage from the carburetor and connectors.

--o0o--

AIR RESOURCES ENGINEER MONDAY: The three mechanisms, permeation, venting, and liquid leakage, occur in various magnitudes during three distinct usage modes.

Running loss emissions occurring occur during engine operation. Hot soak emission are generated immediately after engine operation when the fuel system heats up. And diurnal emissions are generated when the watercraft is stored.

Current federal regulations that were promulgated in 2008 control these evaporative processes. However, more stringent standards are technically feasible.

--o0o--

AIR RESOURCES ENGINEER MONDAY: I will now discuss the technical basis for controlling watercraft evaporative emissions.

--o0o--

AIR RESOURCES ENGINEER MONDAY: This chart highlights the need for evaporative emissions control and specifically diurnal emissions control. Diurnal, or storage emissions, make up two-thirds of watercraft evaporative emissions. Diurnal emissions are doubly important because of usage patterns. Watercraft are often used in ozone attainment areas. However, they are predominantly stored in urban non-attainment areas where diurnal emissions contribute to ambient ozone formation.

With this as background, we can start to look at how the proposed regulation was developed.

--o0o--

AIR RESOURCES ENGINEER MONDAY: Staff conducted extensive testing and assessment of technology that can be applied to watercraft to determine an appropriate evaporative emission standards. Based on this evaluation, we developed prototype watercraft evaporative emission control systems. The control technology was transferred from on-road vehicles. This technology includes low permeation fuel hoses and fuel tanks, carbon canisters and pressure relief valves, and fuel injection.

--o0o--

AIR RESOURCES ENGINEER MONDAY: On-road vehicles have used similar control technology for over 20 years to greatly reduce evaporative emissions.

--o0o--

AIR RESOURCES ENGINEER MONDAY: To evaluate the optimized evaporative emission control, staff conducted extensive emissions testing of a representative sample watercraft in California using a sealed housing for evaporative determination or, shed, as shown in this slide.

Staff identified representative watercraft populations through the Department of Motor Vehicles, or DMV, database and then procured the watercraft from California boat owners. Over 30 watercraft were tested at ARB's facilities in El Monte.

In-use watercraft were tested to develop base line emission factors, and watercraft were tested with and without emissions control technology. This process provided ARB with a comprehensive understanding of the watercraft evaporative emissions and their sources.

Once the testing was complete, the watercraft were either transferred to other state agencies or sold. The difference between the shed results from watercraft with and without evaporative emission controls demonstrates the overall emission benefits.

--o0o--

AIR RESOURCES ENGINEER MONDAY: A number of factors, such as the decline of watercraft sales during the economic recession, compelled staff to re-evaluate and update the emissions inventory. The improved emissions inventory developed by staff incorporates new evaporative emission factors measured using the shed method described in the previous slide and watercraft usage and storage patterns derived from the California State University Sacramento survey.

The updated forecast reflects the recession and future year marine watercraft population and sales, which are based on the most current boater registration data from the DMV, the housing start data provided by the UCLA Anderson School of Business and human population growth provided by the California Department of Finance. The updated inventory was used to evaluate base line and control emissions.

--o0o--

AIR RESOURCES ENGINEER MONDAY: This slide shows the actual and projected sales data of outboard marine watercraft in California, which accounts for about 55 percent of total sales. Similar projections were developed for other watercraft categories, including inboard stern drive, personal watercraft, and jet drive.

Historical DMV registration data represented in this slide by the black line shows a large decline during the recession. As a discretionary item, the watercraft sales were hit hard by the recession, especially for small boat builders.

However, the past five years indicate a recovery in watercraft sales due to the improved economy. Our analysis found a strong correlation between US housing starts and outboard watercraft sales.

Our near-term forecast shown here by the dashed red line to 2019 assumes this relationship continues during the economic recovery. Our long-term forecast, shown by the solid green line, begins in 2020 and assumes new watercraft sales grow at the same 1.2 percent rate as the human population in California.

--o0o--

AIR RESOURCES ENGINEER MONDAY: The projections made in the inventory are further supported by the June 2014 publication of the UCLA Anderson forecast, which shows a strong rebound in housing starts both nationally and in California. As the proposed regulation is implemented in model year 2018, emission benefits will be generated through sales of new watercraft that comply with the more proposed stringent evaporative standards.

--o0o--

AIR RESOURCES ENGINEER MONDAY: Implementing this proposal would reduce reactive organic gas emissions from watercraft. However, the emission benefits will not be fully realized for almost 20 years due to the long ownership periods.

On average, boat owners keep their watercraft for about 30 years, with some keeping a boat for 50 to 60 years. Since watercraft has a longer lifetime, emission benefits will phase in gradually over time, which is expected to be proportional to new watercraft sales.

Therefore, it is particularly important to start controlling evaporative emission from this category now. This proposal pays off in the long term by reducing reactive organic gas emission by about one ton per day in 2037 time frame and beyond. Reduced benzene exposure is also an important co-benefit of this proposal.

--o0o--

AIR RESOURCES ENGINEER MONDAY: I will now present details of the regulatory proposal, including the implementation schedule, control technology, and cost effectiveness.

--o0o--

AIR RESOURCES ENGINEER MONDAY: Here is an overview of the standards implementation dates and applicable categories. Most watercraft can be divided into smaller watercraft with portable marine tanks and larger watercraft with install tanks, where the dividing line between the two is about 30 kilowatts, which is equivalent.

For most watercraft with engines less than or equal to 20 the Board adopted a regulation and harmonize awarded the U.S. EPA. Staff determined that it was not cost effective to seek further reduction from the smaller engine category because it would require significant engine design and retooling.

For watercraft with engines greater than 30 kilowatts more stringent standard for fuel hose fuel tank venting control and fuel injection begin in model year 2018. Upon commercial availability, a more stringent fuel hose requirement will be implemented in model year 2020.

These standards are more stringent than the current U.S. EPA evaporative standards and provide a cost effective way to reduce reactive organic gas emissions. So to better illustrate --

--o0o--

AIR RESOURCES ENGINEER MONDAY: -- what control technology the ARB standards will require, this slide shows the anticipated components that will be likely used for the proposed regulation. Staff anticipates that to meet the proposed new standards, manufacturers would use low permeation fuel tanks, carbon canister, or pressure relief valve, lower permeation fuel hose, and fuel injection or low evaporative emission carburetors. We estimate the total cost of regulatory control will be about $50 for an average boat price of 30,000, which is less than two-tenths of a percent of the total cost. We believe that manufacturers are migrating to fuel injection with new watercraft to meet consumer preferences and needs. And therefore staff does not see this as a cost associated with the proposed regulation.

--o0o--

AIR RESOURCES ENGINEER MONDAY: Carbon canisters are expected to be the primary vented emissions control technology used to comply with stringent diurnal standards. However, pressure relief valves may be used for diurnal control as well. The proposed test procedures require that the evaporative emission control system be designed to withstand exposures consistent with typical operation in California.

The ultimate goal of this regulation is to control evaporative emissions over the entire life of the watercraft. Durability performance criteria are required for all new watercraft to ensure that the added cost of control technology results in real-world emission reductions.

--o0o--

AIR RESOURCES ENGINEER MONDAY: This regulatory proposal has been carefully developed to be cost effective by maximizing emission reductions while avoiding unnecessary costs. It is not expected to limit the types of watercraft available in California. The cost effectiveness was calculated using industry reported costs and accounts for industry markup. The cost of this regulation is balanced by the benefits of the proposal.

--o0o--

AIR RESOURCES ENGINEER MONDAY: In this final segment, I would like to present the staff recommendation for the regulatory proposal.

--o0o--

AIR RESOURCES ENGINEER MONDAY: The proposed regulation was collaboratively developed with the stakeholders beginning in 2006. Five public workshops and over 40 stakeholders meetings were held. We included manufacturers of watercraft in these discussions as they had extensive experience complying with similar emission standards.

--o0o--

AIR RESOURCES ENGINEER MONDAY: During the regulatory process, staff worked with stakeholders to develop the most cost effective proposal. Industry provided valuable input and suggestions for improving the regulatory proposal.

As a result, staff was able to mitigate concerns without compromising the integrity of the proposal, including harmonizing test procedures to reduce cost to manufacturers, delaying implementation during economic recession, and reducing the scope of the proposal.

--o0o--

AIR RESOURCES ENGINEER MONDAY: We have become aware that the regulation needs a few minor modifications. To accommodate industry's comments and suggestions, we are proposing a 15-day change that will modify the regulation and test procedures to improve clarity for manufacturers. These changes include clarifying the requirements to certify pressure relief valves and clarifying design specifications for fuel fill deck plates.

--o0o--

AIR RESOURCES ENGINEER MONDAY: In summary, controlling evaporative emissions from watercraft will provide emission reductions that are critical for ARB to meets its air quality goal. ARB has tested prototype evaporative systems on watercraft that demonstrate the proposed standards are feasible with available control technology. The proposal was developed with extensive stakeholder participation and is cost effective relative to comparable evaporative emission regulations adopted by the Board.

The proposal will improve public health by reducing ambient ozone concentrations and exposure to benzene.

Staff recommends that the Board adopt the proposed regulation with the 15 day changes.

This completes the watercraft presentation. I'll be happy to answer any questions you may have.

CHAIRPERSON NICHOLS: Thank you. Why don't we go to testimony. We have two witnesses who have signed up on this one. The first is Dr. Joseph Kubsh and the second is John McKnight. So we will listen to you.

Hi. Good morning.

Dr. KUBSH: Good morning, Madam Chair and members of the Board.

My name is Joe Kubsh. I'm the Executive Director of the Manufacturers Emissions Controls Association. Our association includes many of the major manufacturers of both exhaust and evaporative emission controls for mobile sources, and I'm here today to indicate my industry's strong support for the staff proposal.

MECA agrees with the staff assessment that proven cost effective evaporative emission control technology derived from the automotive sector can be implemented on spark ignited marine engines to comply with the staff proposal.

In our written comments, we highlight these available evaporative emission control technologies, and we also provide some suggested modifications to some of the test procedures aimed at making these regulations more easily implementable.

I'd like to thank the staff for their efforts in bringing this proposal forward, and I would ask the Board to adopt the proposal as presented to you this morning. I would be happy to answer any questions. Thank you.

CHAIRPERSON NICHOLS: Thank you. I don't see any questions.

MR. MCKNIGHT: Good morning, Madam Chair and members of the Air Resources Board. I'm John McKnight. I'm with National Marine Manufacturers Association, and we represent the boat builders in the United States and here in California. Want to thank you for the opportunity to testify here today.

NMMA did write a letter supporting the rule. That's pretty much for the record. I do want to say while I have a chance here at the podium to tell you the history of what hapened here. We started working with CARB and EPA in 2001. We put a boat in the shed like Scott showed. We got our own boat, because we wanted to make sure what they were doing was the right thing and we started working on this. We were moving pretty quickly on the rule. Things were looking good.

Around 2007-2008, we had a thing called the recession. And what happened here in California was absolutely devastating. I mean, sales nationwide for boats were down 80 percent. Here in California, we had some engine manufacturers who sold less than 100 engines in that year. I mean, dealers were closing. Fifty percent of the dealers in California had closed. And your two trade associations out here, Southern California Marine Association and the Northern California Marine association went bankrupt, closed their doors. And since that time, NMMA has come in and helped bring those associations back to life.

What does that mean like in the sense of business out here? Well, you have a San Diego Boat Show. That closed. The L.A. Boat Show, that closed. You had the Long Beach Boat Show and the San Francisco Boat Show. All those boat shows closed out here. The association has stepped in and they are back and running. The L.A. Boat Show opened yesterday.

And our association is bullish on California. We figure 38 million people have to start having fun out here.

Anyway, on the flip side, I'm on the business side. Look on the flip side. The ARB, I kind of had to be sympathetic to them because we were the last unregulated category for emissions as far as evap emissions. We would be happy to stay that way, but we know it's not going to happen with these guys.

So anyway, we also know that we are a significant source of emissions. You know, you take a fuel tank on a boat, 40 gallons is small. We had fuel tanks on boats 250 gallons. That's a lot of gasoline ends up in your air. Creates pollution. So we knew we had to be regulated, and we also knew that the technology exists, because like I said, we threw a boat in the shed in 2001, start taking a look at it.

So, you know, there's been a lot going on here. Like I say, we now are running the boat shows out in

California. We're supporting. We're bringing jobs back to California. We are part of the California business community out here.

And staff understood that. That's the first thing I went in to talk to Dr. Ayala and said, "We want to make it happen for you. You have to help us make it happen for us." There was -- staff worked with us on a lot of flexibility on the rule. Much more flexibility than I've ever seen on other rules. I've been doing this for a quarter of a century.

And also, we have a novel approach. I think it's a better approach for us and them.

I want to thank you. Thank all the staff here. And also I would like to ask one thing of the Board, and that is in closing to just kind of direct the staff to work with us between now and 2008 as we implement this rule to help us with training and education. I got about 3,000 boat builders worldwide. I want to make sure they know what they have to do to sell into California.

CHAIRPERSON NICHOLS: Where are you based? Where's your office?

MR. MC KNIGHT: Our main office is in Washington, D.C. We have a California office in Riverside to run the boat shows.

CHAIRPERSON NICHOLS: So you'll come back to

California?

MR. MC KNIGHT: I love coming out here. Invite me back, I'm your man.

CHAIRPERSON NICHOLS: Good. That's excellent. That helps our tourism, helps our economy.

MR. MC KNIGHT: Thank you very much.

CHAIRPERSON NICHOLS: Thank you.

Well, that is it as far as the list of witnesses is concerned. And I do want to close the record at this point, but we can open it up for Board discussion. And I see at the far end, Dr. Sherriffs.

BOARD MEMBER SHERRIFFS: Thank you. Thanks for all that enthusiasm.

You know, this is very important in the San Joaquin Valley, because the boats are not only operated in areas of ozone challenge, they're stored in areas of ozone challenge. So it's a big issue.

Mostly, we're worrying about NOx, but the reactive organics are very important in that, too. So it's a small very important contribution. So it's great that we're finally addressing it, and it's great that the industry is on board and enthusiastic.

One question. You know, it actually took us a long time to get here. And 2018 is a long way away. And I'm wondering is there any way to move this up a little bit. The technology is there. It's not a fancy technology. And it would appear to be pretty easy to apply, as long as people understand. It's not a terribly expensive -- not a big proportion of the overall cost of these things. That's one question.

The other, what are we doing to be sure that when the people are fixing their old boats that, in fact, they're using better equipment? If they have to replace a gas tank or go down and get a new hose for my gas line, I hope we're thinking about, if we haven't already, ensured that we're selling the best stuff out there to help clean the air and improve our health.

CHAIRPERSON NICHOLS: Good questions.

Mr. Monday, do you want to answer?

MLD DIVISION CHIEF BENJAMIN: This is Michael Benjamin, Chief of the Monitoring and Lab Division.

In the first question regarding potentially moving up the implementation date, you're correct that technically it would be possible. But I think the challenge here -- and this is highlighted by the testimony that we heard from NMMA and Mr. McKnight, is that implementation in the phase-in of this is going to be critical so that we don't hurt the boat builders in California.

And so there is still some issues that we need to work through on the labeling side, on the certification side. And those details, even though 2018 may sound like it's not very far away, it's going to take us a couple years to finalize and work through some of those issues with industry and also do the outreach that Mr. McKnight referred to.

So I think what we want to do is to have a regulation that will get the emission reductions that we need as soon as possible, but do it in a meaningful way with stakeholder buy-in and with appropriate outreach. So the time line that we developed really tried to take all of that into account. So that's the response to the first question.

On the second one regarding replacement of parts, you're correct that as parts wear out -- and on boats, typically fuel tanks don't wear out very quickly. They have a lifetime that oftentimes is the life of the boat or maybe even at a minimum 20 or 30 years. Those don't tend to get replaced on existing boats. What tends to get replaced are the hoses. The hoses that are available right now comply with the low permeation standards established by U.S. EPA. And what would be available in the market as this rule gets ruled out would be CARB certified components.

So we fully anticipate that existing boat owners will be using the lower -- the new lower permeation of hoses that are available.

One of the challenges that we had will be though addressing things like Internet sales and boat owners purchasing potentially non-compliant replacement parts that don't meet our standard. So that's going to be a challenge we'll have.

CHAIRPERSON NICHOLS: Given the cooperation that we seem to have established with the industry, hopefully we can get them to help us get the word out through these to the owners about the boats and about the benefits of going with the better ARB certified equipment.

MLD DIVISION CHIEF BENJAMIN: I agree absolutely. I think one of the things we've achieved through this rulemaking process is having a very collaborative relationship with NMMA and other boat builders and associations. And I think that that relationship will enable us to really role this out in a way where we get maximum benefits, both from new boats and potentially additional emission reduction opportunities from existing boats.

CHAIRPERSON NICHOLS: Okay. Any other questions or comments before we go to a Resolution?

If not, I think Mr. Roberts is ready. Supervisor.

BOARD MEMBER ROBERTS: Thank you.

I would guess, although I'm not certain, we have a disproportionately high number of boats in San Diego. So I'm enthusiastic about this. I have to observe I don't -- given the last speaker, I don't think I've ever seen anybody happier as we lead them to the gallows here. We appreciate that kind of cooperation, and I'll move the Resolution.

BOARD MEMBER RIORDAN: I'll second.

BOARD MEMBER BALMES: Second.

CHAIRPERSON NICHOLS: In that case, I'll call for a vote. All in favor please say aye.

(Unanimous aye vote)

(Board Member Sperling not present for vote)

CHAIRPERSON NICHOLS: Any opposed?

Any abstentions? All right. Thank you all very much.

The next item is an informational item on some significant findings from recent climate change assessments, both national and international. And I think it's a good opportunity for the Board to be updated on some of the most important recent findings as we strive to make decisions that are based on the best possible science.

We've invited one of the top experts on climate change science and communication, Dr. Susan Moser, to speak to us today. And I will ask Mr. Corey to introduce the item.

EXECUTIVE OFFICER COREY: Thank you, Chairman.

Today's presentation will be a brief overview of the headline statements from the recent Intergovernmental Panel on Climate Change, or IPCC report. The presentation will also provide an overview of the national climate assessment, with an emphasis on the finding and implications for California and the west coast.

By way of introduction, Dr. Susan Moser formerly served as research scientist at the National Center for Atmospheric Research in Bolder and a Research Fellow at Harvard Kennedy School of Government and Heinz Center in Washington, D.C. She's now a Social Science Research Fellow at the Woods Institute for Environment at Stanford University and a Research Associate at the University of California Santa Cruz Institute for Marine Science.

Dr. Moser's work focuses on adaptation to climate change, resilience, communication, and decision support. She contributed to the IPCC's fourth and fifth assessment reports. She's also the lead author for the Coastal Chapter of the third U.S. national climate assessment and has been involved in California's climate impacts and vulnerability assessments since 1999.

I'll now ask Dr. Moser to please begin the presentation.

(Thereupon an overhead presentation was presented as follows.)

DR. MOSER: Thank you very much, Chairman Nichols and Board members.

Good morning. It's a great pleasure to be here and have this honor to brief you on the IPCC and the national climate assessment. I want to do that by placing --

--o0o--

DR. MOSER: -- this briefing in a long history of California climate policy being deeply informed and motivated by the latest findings on the climate science. So let me just give you a very brief overview of that history --

--o0o--

DR. MOSER: -- and place the IPCC findings in that context.

As you know, the IPCC was formed founded in 1988 and then produced its first assessment in 1990. And about every five, six years, it comes out with another assessment. The most recent one, IPCC AR-5, the assessment report number five, in 2013 and '14. That, of course, has been paralleled. As you are well aware with assessments done here for California, and that actually goes back also as early as the 1990s, the first-ever assessment led back then by the California Energy Commission, a study by the Union of Concerned Scientists and the Ecological Society of America, often known here in the state as the Green Book, that was very influential in shaping early policy and then it goes on from there.

I mentioned just briefly that as part of the first national climate assessment, which of course is a Congressly mandated process, a first report on California was produced in 2002. For the second assessment, there was no such California assessment, but there was one conducted just more recently in 2014 for the southwest, which includes California.

So I want to put that in the context of the big milestones, if you will. And I, of course, was selective in putting these forward. But you are familiar with them. And they have become successively more stringent are have put in place the implementation of these ambitions. And of course, after IPCC, the most recent report came out and the national climate assessment, Governor Brown in his inauguration state of the state was very ambitious and that's been followed now by legislation. So we're -- this is the sort of history that I want to lay out in terms of how much it's been motivated.

--o0o--

DR. MOSER: Let me begin in a brief retrospective by thinking back to the 1990s when the IPCC first talked about climate change. The headlines back in the 1990s -- I don't know if you recall this -- was basically, yep, I think something is going on. We think we're seeing something, but we're not quite sure.

--o0o--

DR. MOSER: That and the second assessment in 1995 was really strengthened and the headlines back then in the news media was really about a discernable human influence. That was not there in the first assessment. At that point, we thought maybe we could see that humans are having something to do with the kinds of changes that were observed.

--o0o--

DR. MOSER: And at that point, the IPCC established sort of a nomenclature for its level of confidence about the scientific findings. I want to put them out here for you to review. To the extent it was possible, you know, just to assign confidence levels which are based on the laws of physics and the extent of the evidence, the theories and the model projections ranging from very low to very high. And where we could, we attached actually probabilistic likelihoods, which it's always important to put numbers with those names because it's actually known that the public when you say likely understand, it can mean anything from one percent chance to 99 percent chance.

So in the IPCC nomenclature, likely means at least a chance of two-thirds or very likely at least a nine out of ten chance of actually being true.

And to the extent we are really certain, we use the terms unequivocal. So you'll find these words here in a minute.

But in the third assessment, those terms were not yet fully applied. When the IPCC came out, the big headlines back then were not just we can now demonstrate show the earth's climate has changed, but we had so many different pieces of evidence that we could say there is a collective picture of a warming world. That was really at that point what we could say. And just think back, you know, this is about the time when the Pavely bill was being written.

So then the second most important finding at that time was that most of the warming observed, just the warming, was attributable to human activity. So that much we could say about 12, 13 years ago.

By the time of the fourth assessment, there was really a sea change in the amount of evidence available, the quality of the models available, so much so that the IPCC concluded warming is unequivocal. That's the top level of certainty that scientists are happy to express. They said that at that point they attached a probabilistic likelihood to the fact that the observed increases in temperature are very likely, that is, more than 90 percent chance due to the increases in human emissions, and a greater than 66 percent chance that there is also a discernable influence on the impacted systems, the physical systems like the water resources, the biological systems, ecosystems, and so forth both on land and in the ocean.

Now it's important here to just point out that there is a lower likelihood because, of course, the temperature changes in rainfall, they all need to translate into the impacts on the physical or natural systems. So that is at least where we could now see an influence.

--o0o--

DR. MOSER: And now we come to the fifth assessment, what is -- is there anything more to say, if you will.

--o0o--

DR. MOSER: Well, it is very significant I think what the IPCC is now willing to say. One is that the human influence on the climate system, the entire climate system, is clear and greenhouse gases are the highest in history. And we see now widespread impact on human and natural systems. That is yet another layer further down in the chain of impacts now of widespread impacts on human and natural systems. The warming is unequivocal. And many of the observed changes are unprecedented over a decades to millennium. That's important, and I'll come back to that in a moment here.

--o0o--

DR. MOSER: This is what it looks like. You see the temperature curve. You've probably seen these many, many times. And of course, you know, it was in the news that even after the IPCC was released that 2014 is the warmest year since temperature referenced with thermometers have begun, 38th consecutive year the warming average is -- the global average is above average. Nine out of the ten warmest years all have occurred since 2000. So you know, it's just -- I think this is becoming no more news, you know. It's like on an exponential curve. Every next year is going to be higher than the last. So I think this is something you must get used to.

--o0o--

DR. MOSER: This is what it looks like when you spread it out over geographically. And what I want to point out here, very important point, is that the land areas warm faster than the oceans. Of course, that means when I give you global temperature projections, that you should add a few degrees for the land areas, which is where we all live.

And you know, the right-hand graphic here shows that it's quite a significant amount warmer on land than it is over the ocean areas.

--o0o--

DR. MOSER: As I said, this set of indicators that we now use, it is that collective picture of the warming world, the glaciers are going down on land over the sea ice as well as the big ice sheets, temperature records in every arena. And of course, then we see it in the natural systems, the spring is coming sooner. Species are migrating cold-ward or upward in altitude.

I always like to point out that they're not republican or democratic. They don't have an agenda. They simply go where they're most comfortable. So I think it is pretty hard to dispute that some major changes are underway.

--o0o--

DR. MOSER: Important also to point out that the drivers behind this warming are unprecedented, at unprecedented levels in at least 800,000 years.

And I like to put that in perspective. The human species actually only has been around for 200,000 years of that period. Or if you maybe want to put this even in starker perspective, 10,000 years ago at the end of the last ice age, there were about five million people, members of that homosapien species on the entire planet. That's about the size of L.A. and San Diego combined, spread out over the entire planet. Now we have how many L.A.s and San Diegos on this planet. And that is why these numbers of CO2 methane and nitrous oxide are going up.

--o0o--

DR. MOSER: Let me show you in these terms here. What you see on the top of this graphic is very clearly since the industrial revolution how the use of fossil fuels -- they also include cement there which emit CO2, has just been growing exponentially. And what you see in the bottom there is that the proportion of emissions from land use changes, such as deforestation, has actually been going down. We are no longer on an upward trend in that. Even though it is in many ways unacceptable for biodiversity reasons and whatnot. But that amount of CO2 increase is relatively smaller compared to those from fossil fuels.

But importantly, at the same time, the natural sinks that we have, the forests, the oceans that take up our CO_2, that capacity is going down. They are basically -- the sewers are filling up, if you will. They shouldn't be considered sewers, but we seem to have done that.

--o0o--

DR. MOSER: That means that you see the amount of CO_2 that is accumulating in the atmosphere is actually growing faster.

So this is a good graphic here. I'll date myself here. I put that little red quote there about half of the cumulative human emissions of CO_2 have occurred just in the last 40 years. I'm 48 years old. That's my lifetime. So most of what we've put in the atmosphere we've done over my lifetime.

You see it in every record that we've been tracking, whether it's land use, whether it's population growth, whether it's any of the emissions that you see depicted here. They see the area that is now mainly driven by the human impact on the planet not likely to stop any time soon, given economic and population drivers behind that.

--o0o--

DR. MOSER: Now, as a result of these kind of changes, we are now observing that many, many extreme weather events are actually increasing over that same time period. That was much harder to say even five years ago because the evidence was simply not in. We hadn't had as many good data. And many of these now also can be linked to human influences. You know, climate change did not invent hurricanes. It did not invent draughts. But we can now say with confidence that many of these events actually have an influence of humans behind it. And you see them listed here, cold extreme are going down, warm extremes increasing, higher sea levels. And the number of days with extreme rain events are increasing, at least in several regions.

--o0o--

DR. MOSER: That brings up the question is what we're currently seeing here in California, is that due to climate change? There was a study that was actually put forward by NOAA more recently than the IPCC. I just want to put it forward. They did try to model basically with natural or anthropogenic forces, whether this particular draught can be attributed to global warming. And they found it cannot.

So interestingly enough, this type of event falls within the envelope of natural variability. We cannot discern this has been given solely by the human causes. Very important finding. Now what makes it worse, however, is that we have much higher temperatures.

--o0o--

DR. MOSER: I'll show you that in a moment what it looks like for California. When you have higher temperatures, of course, the demand for water is much higher. And so we see worsening conditions.

But I think the bigger issue is not just can we attribute any one of these events to human causation. The big issue is the last time we had this kind of a draught in the state, we're about five million people here, in 1927. So at that point, much fewer -- far fewer people wanted that little water we have. Now we have 35 million. So that's the issue that you have the extreme events, plus the growing vulnerability that makes these events much more severe and in terms of impacts for us than otherwise.

Let me very quickly mention a couple of other findings from the latest IPCC before turning into the things that happen here in the state.

For the first time, we actually see the IPCC say something very strong about severe, pervasive, and irreversible impacts. Irreversible impacts is not the word you want to see in an assessment like this. That's the stuff that really should keep you all up at night. Irreversible impacts on people, on ecosystems. Irreversible losses in the species in the systems that support our economy, our livelihoods.

And of course, the other thing that we have from the IPCC is a very clear assessment. Mind you, they're not policy prescriptive. But they're trying to assess for you basically whether or not we can reach emission reductions, substantial ones. And basically what they're saying is the only way to get below a two degree warming above pre-industrial conditions is if there are substantial and sustained reductions in greenhouse gas emissions, very much like California is considering.

Let me just say, so you're already at the forefront of this. Some other states and nations are beginning to take some efforts.

What the IPCC is saying that without additional efforts -- so if you're thinking you're doing much, yes, you do. But without additional efforts, we're going to see warming on the magnitude of the kind of warming we've seen since the ice ages.

I'm basically pulling this together, five degrees of warming since the last ice age to pre-industrial conditions. Well, another three and a half to four or five almost over just 100 years, if that's the median range here. We say that with high confidence. So something that should keep you up at night.

Mitigation scenarios that have a greater than 66 percent chance of staying below that two degree guardrail, if you will, need to end up with no more than 450 parts per million concentrations of CO_2 in the atmosphere. You see the past way they describe here, 40 to 70 percent below greenhouse gas emission reductions by the middle of the century and near zero or below -- in other words taking CO_2 back out of the atmosphere -- by 2100 to get to that. That's just a 66 percent chance. But you know, that would be really great if we would get there.

I don't want to spend a lot of time on this particular question or set of projections that they put forward that these represent the emissions pathways that are associated with these different temperature projections I just put forward.

The point I simply want to make, if we want to get to that two degree chance of achieving two degrees of warming, most of the curves bend very significantly downward by 2020. That's tomorrow. You pointed out 2018 is far out. For emission reductions, it's about yesterday. So I think this points to the fact that there is no time to lose if you want to get there.

--o0o--

DR. MOSER: Of course, we know that these -- many of these environmental changes, for example, sea level rise, will continue for centuries to millennium. We are putting in place changes that will effect generations to come. And the more we push the system, I guess the bottom line here is that these abrupt and irreversible changes are becoming more likely.

--o0o--

DR. MOSER: I want to say one thing here about as a result of this, that the longevity of this, it's not like an air pollutant where you cut it and it is gone out of the air. CO2 and other greenhouse gases stay in the atmosphere for decades to centuries. And of course, that commits us to having to deal with the impacts as well as dealing with the emission reductions.

What this graphic here is trying to show is that we sort of have a space, if you will, between the societal stressors we already experience and between the climate stressors and other biophysical stressors that might impinge on us. In that squeeze space between them, we might have a resilient future. And the more we take care of the emissions and lower the risks of severe climate change, the greater that space from the outside, if you will, of the envelope. The more we reduce through adaptation and other measures societal stressors and non-complimental environmental stressors, the more we have, if you will, the breathing space to actually deal with these impacts. It's the combination between mitigation and adaptation that we both need to have a livable and thriveable situation.

--o0o--

DR. MOSER: Let me turn very quickly to the third assessment that came out last May. And of course, one of the chapters focuses on the southwest. I want to emphasize that underneath that is the third climate assessment that was done here for the state. That was a big technical input into the larger assessment for the region. And of course, you know that --

--o0o--

DR. MOSER: -- California is currently working on or beginning to work on its four assessment.

Here, just the key findings from the southwest chapter. None of them will surprise you. You've heard them many times. I think the pictures probably speak much louder than the particular words.

Last year, when we had a bad snow pack, you saw that kind of picture, satellite picture of the sierra. This year, at the same time, it looks like this. Basically no snow in the sierra. This summer will be a very difficult summer for anyone depending on that.

--o0o--

DR. MOSER: And of course, it is not just our problem. What happens to California, you all know this, happens to the bread basket, the food basket of the nation and beyond. It is the number one producer of many high-value specialty crops. Of course, that means many people's livelihoods depends on it. It is the water deficiency and the increasing temperatures that make the difference for many --

--o0o--

DR. MOSER: -- in California.

I want to point out this graphic here produced or based on data from the California climate tracker. It shows basically the temperature increases over the last century in California. And you see here that this past year was exceptionally the warmest ever year, not just in the world, but in California as well, and making the problems with the draught much worse. And this part here is climate driven, even if the draught, per se, we cannot attribute to the problem. It is the combination of those two factors that creates the problems we see and we need to take care of it.

--o0o--

DR. MOSER: You know, these problems, the less snow pack there is, the higher the temperature, the longer the snow-free season, dry season. We have many more wild fires. We also have a track record that twelve is the largest fires we've ever seen in the state have occurred since 2000. So there is much that forest managers in this state need to deal with.

And of course, this effects also any efforts that we might want to do to manage our public lands and private forest lands for carbon sequestration. Very important to consider that the impacts are already effecting the very systems that we now want to capture more.

--o0o--

DR. MOSER: On the coast, these are the pictures. And I guess I should have maybe taken a picture right now driving up from Santa Cruz and showing the king tides currently going on in the delta. You see the water standing everywhere. And this is, if you will, the sunny day inundation. You don't need a big storm anymore to have severe erosion and flooding impacting people's lives in California.

--o0o--

DR. MOSER: Lastly, the finding here relates to the combination of heat and air pollution. I was very glad to see what you just decided just before my speech here, because ozone basically is a greater risk with higher air temperatures. And you see that this is going to be particularly important for urban areas, but also for people who work outside in our fields. So very important impacts on our public health systems as well as electricity and water supplies that all depend on functioning energy supplies.

--o0o--

DR. MOSER: Just very briefly want to point out we're now working on the fourth assessment, which is this time led by the Natural Resources Agency, but the EPIC program from the California Energy Commission will contribute major new studies on impacts on the energy sector. Very important how this has changed over time. You know, originally, we just sort of did these top-down impact studies on different sectors. Now we're looking at multi-sectoral impacts and what happens in the water sector happens and so on, so forth.

We're looking more at extreme events because they cost the most. They cost the most lives. And we try to create much more adaptation related information for policy makers at all levels, which then becomes available through Cal Adapt as many of you know and is widely used in the state by local policy makers.

--o0o--

DR. MOSER: So I want to close here with that there is -- your efforts and what has just been put forward by the Governor and the Legislature cannot come soon enough. I think it's essential that you succeed as a model for the world. You've seen the sort of ever-growing urgency in the tone of the IPCC and reflected in the national climate assessment.

So I thank you and really appreciate the opportunity to brief you on this. I'm happy to answer any questions. Thank you.

CHAIRPERSON NICHOLS: Thank you, Dr. Moser.

First of all, thank you for being with us and for your work and contributions as well. As you have pointed out, this Board has been working on this issue for quite a long time. And we're very proud I would say of the role that California has played in this area and everybody who is on this Board has had an opportunity to be a participant in acting on the kind of good information that you have brought us.

We don't have any public witnesses who have signed up today, and I doubt that's an indication of the fact there is nobody in California who is a climate skeptic or who has doubts, either about whether it's real or whether there is anything that can be done.

I think if anything, the situation may have become more polarized in recent years with those who are either denying the existence of a problem or don't think anything can be done about it. Simply going back to their respective barricades and not wanting to deal with the situation at all. Clearly, that's not the view of the

Governor or the leadership of the Legislature. So there is going to continue to be activity in this area.

But those of us who have positions of responsibility also have a role in the community. And we talk to people. And people talk to us. And I think it's important that we be armed with the best information that we have and also with the best wisdom that's out there about how to effectively communicate about the nature of the problem and what's being done about it.

So in addition to your presentation today, I think it would be helpful if the staff could be providing all the members of the Board at a minimum with these California climate assessment documents that are out there as kind of a basis for all of our libraries and presumably they can then access more copies if they need that sort of thing to make available to others.

And I would welcome any thoughts or suggestions from my fellow Board members about additional ways to act on this, starting with you, Mr. Gioia.

BOARD MEMBER GIOIA: Thank you, Chair Nichols.

I really do think this was an important presentation to have.

As Chair Nichols has said, it is incumbent on all of us working with others to continue to get information out. I think so often people have become unfortunately more skeptical of even very clear scientific conclusions of evidence. I think that's really unfortunate.

And what's so important often is the messenger becomes as important as the message. So that's why all of us folks here and many of the groups that we work with are important messengers. Because often times, people will believe things more when they hear it from somebody they trust, which is often someone they know, as opposed to someone who should be trusted like a scientist, including a few folks, physicians on our Board here.

So I think the issue is about increasing the universe of messengers who have relationships with others to be able to convey this information. I think that's important. The messenger is as important as the message. I appreciate the comments of the Chair in really encouraging this.

BOARD MEMBER BALMES: May I follow up?

CHAIRPERSON NICHOLS: Yes, Dr. Balmes.

BOARD MEMBER BALMES: Well, again, I'd like to add my thanks to Dr. Moser for that very good overview of mostly threats to the environment related to climate change, the environment that we have to live in. And you touched on some health issues.

But I would be remiss if I didn't stress that there are major public health issues related to climate change. You mentioned I think very importantly that farm workers in the valley will not be able to work on the future scenarios that you outlined so well. But it's not just the farm workers. We won't be able to have construction workers work in the Central Valley without space suits. So there is that occupational health component which often is ignored when talking about climate change.

But in terms of cardiovascular and respiratory disease, there are major impacts from the heat, from the air pollution, from increased allergen exposure. And eventually, the people most vulnerable would get the double whammy of worse air quality and heat stress. So I I just wanted to underline that sort of area of climate change impact.

Now in response to Supervisor Gioia, there are groups that are working to try to get physicians to get out there with the message. The Lung Association of California has doctors for Climate Health Social Network. I just added my state photo and a little blurb about the importance of --

CHAIRPERSON NICHOLS: Dr. Sherriffs has already been featured.

BOARD MEMBER BALMES: I know. I'm just trying to play catch up.

But there is actually a national effort out of George Mason University. It's a Climate Change Communications Center, and there is a physician who just spoke at U.C. Berkeley yesterday who's been doing outreach to various physician groups, including the professional organization that I work with as a pulmonologist, the American Thoracic Society. We just published a survey of pulmonary physicians around the country, which no surprise most pulmonary physicians think that climate change is a problem. They believe it. And that they're actually already starting to see the effect in some of their patients. She's working with other physician groups as well.

So it's only one communications pathway, but I think it's an important one for the reasons that Supervisor Gioia mentioned.

And the final thing I want to say is something I learned for a fellow faculty member at Berkeley Robert Rice, who said, it's one thing you can get elected with ideology, but you have to govern the effects. So --

CHAIRPERSON NICHOLS: Good comment.

BOARD MEMBER GIOIA: Well stated.

CHAIRPERSON NICHOLS: Ms. Berg.

BOARD MEMBER BERG: Yeah, thank you very much for this update. And I just would like to piggy-back on the outreach.

For most of us, the overwhelmingness of climate change is difficult to put into some sort of context or some kind of focus about what to do. And as these reports are critical for policy and government and leadership, as we're delivering the message, I think it's really, really important that we're delivering a message of what needs -- of what we're facing, but also what is being done. But more important, what one or two steps could every citizen take that would truly make a difference, that that way they have something to engage in.

As you were going through and it was really helpful to me as an ARB Board member to hear this, but quite frankly overwhelming and under what context as a citizen do I start other than the work that I'm doing here. And I know there are some things I could do. I know there's some choices as a consumer I could be making.

But when I look at things that suggest that we could be a day late and a dollar short and so what's the point, I've got other things that are facing me right now today I've got to make decisions on.

So I think in this education, if we really truly want to embrace and to engage citizens, that we really need to look at an educational mechanism that allows people to put this in context and really make two, three, five critical behavioral changes that they make a difference today for their grandchildren tomorrow. So I'd really encourage that. And thank you so much for this report.

DR. MOSER: May I respond? I would love to respond, because we have two physicians here, I would like to relate this to work I've been doing as a communication expert on hope. What gives people hope.

Well, medical psychology is actually a treasure trove for that. I want to tell you what the ingredients of true hope, because I think all of you can include that in your outreach, in your speeches, in whatever you do.

It begins with a real diagnosis. No rosy, oh, it's not so bad. No. You tell people really what the issue is.

And the next thing is that you paint a picture of what is achieveable. What is the possible. This is work that's been done with terminally ill patients where basically the outlook is pretty dire. So what do you tell someone like that? Well, you might be healed. You might become well. You might have a longer life. You might die without pain. Whatever the achieveable goal is, be very clear about that.

And then paint a picture of the path. How do we get from this diagnosis to that positive outcome that is realistically achieveable? And then how people understand that echoes very much what you just said, what can you do to help get there. What is my role as a patient to be part of this? And what will you do as the doctor?

So for you to say to people what they can do and what you, as Commissioners, as Board members will do or what the State does already is enormously important. So people see themselves as being part of a bigger solution. Changing a lightbulb will not answer that question if you are confronted with the kind of facts I just put there.

The next ingredient is what you will do in case of a setback. Because, you know, sometimes the chemo doesn't work. What do you do? Well, tell people what your plan is. And tell them they're not alone, that you will work with them to do this. So those are the actually five or six ingredients of any message of hope in a very severe circumstance. And I encourage you to use that recipe for your own communication.

CHAIRPERSON NICHOLS: There are actually some groups that are coming together to help, particularly, I know advocates to craft those kinds of messages. So this is a topic that we should perhaps take up later, either at a workshop or in a Board meeting, because I think there would be a lot of interest in that.

Any -- I'm sorry. Supervisor Roberts and that Ms. Mitchell.

BOARD MEMBER ROBERTS: Well, thank you.

One of the strengths of this Board is we all look at things somewhat differently. I would share with you I've been on the Board for a long, long time. This was without a doubt one of the best, most sobering presentations we've had on this subject. Appreciate that.

While I was sitting here, I was thinking sort of the opposite and Sandy was, how do we get people -- I'm thinking how do we get this message out? You've got a lot of information here. And what I usually see is Twittered about and these social media things where it's just sound bytes with no comprehensive picture here doing just the opposite. I was thinking we need to package a video. You've got great information. And I think in the right form, we can reach a lot of people. And I think everybody is looking for content that lasts more than a few minutes.

It could form the basis of -- I mean, I could see this thing being done, taken around and shared with people in other places that would be very effective. So I don't know what production capability we might have, but I sure think that would be -- maybe there is a way to --

CHAIRPERSON NICHOLS: I was chuckling because we have actually increased our ability to produce pretty good quality material of that sort within the last couple of years. So there is some -- we may not be at the Hollywood studio level yet, but we can do videos.

BOARD MEMBER ROBERTS: I would really think about -- because you've got the information. You're a terrific presenter. I would like to encourage us to give some thought. I'd like to have to have access to something like that that I could share in all different kind of ways. So I would encourage staff to work with you to see what our almost Hollywood level production can do.

CHAIRPERSON NICHOLS: Thank you.

Ms. Mitchell.

BOARD MEMBER MITCHELL: Thank you.

Thank you so much for your presentation this morning. And as several people have noted, it's very sobering information.

And I think for us, we're sitting on this Board and thinking what an overwhelming task that we have before us. But one of the things that comes to mind as I think all of us sit here is here we are in California and we are working as hard as we can on these issues. One of the reasons we work so hard on it is because we also have air quality issues here. And we can see co-benefits on working on reducing greenhouse gases and reducing the pollutants that we are trying to reduce.

But we also sit here and think what is the rest of the nation doing? What is the rest of the world doing? I know there are some strides being made other places. But I also hear from our east coast friends what a bunch of kooks you are out in California doing some of the things you're doing. And I'd like to get your input on how that is going across our nation and what more can we do. I know we can do things in California. But how can we bring the rest of the world along with us and certainly the rest of our nation?

DR. MOSHER: It's a very good question. Just as a summative approach, the National Climate Assessment did have for the first time a chapter on mitigation. Not to tell anybody what to do, but it basically looked at do all these efforts that are going on at the local level, at the state level, do they add up to what they need to do? Basically they found that we're barely scraping sort of the bottom of this problem with what we're doing already.

I mean, this goes right back to the message that the IPCC had without additional efforts you will still see something like three and a half to five degrees of warming globally. We're actually not doing nearly enough. For me, the hope comes out of the history of environmental policy making in this country. And it typically goes like this. The state's, California among them, typically as the leading ones, a few in the northeast, maybe eventually someone in the Midwest, starts to do something different. Then you have the different rules all over in these state laboratories, if you will, that basically make business very, very challenging. Because the rules change every time you cross the state line. And eventually, that really upsets the people in Congress or basically the business community that then go to Congress and say could you please level the playing field.

And then your experiments, the ones that are successful, are the ones that actually then will model what will be implemented nationally. This is how we got the Clean Air Act, the Clean Water Act, and many others.

So what more can you do? I think working with your neighboring states to bring them on board to show them how you're accomplishing what you're doing. Literally being out and showing the how-to of how you got to making these changes both politically, but also technically.

And those, to me, are the two key features. Figuring out the financing is obviously a big challenge. I don't need to tell you that. But I mean, that's what many of them are seeing, of course. It helps us with the natural gas prices where they are, the renewables becoming more affordable. So I think, you know, those are the kinds of things that, in general, move the ball forward.

But I think your showing by example is probably the most important and forming coalitions with your neighbors that you already are tied with in the electricity and transportation, those are the kinds of things that at least from my perspective that have worked and I encourage you to do more of.

CHAIRPERSON NICHOLS: Supervisor Gioia.

BOARD MEMBER GIOIA: One additional thought. I think it is really important for us also to show that the steps that are being taken to address long-term climate change issues are having immediate benefits on residents of the state of California. I think that -- and they are. And the co-benefits that are achieved from many of the steps that have been taken on the energy efficiency side, just one example.

So I think drawing that link between the benefits we're getting today that we're not necessarily waiting for the benefits to occur decades down the road while they will. We're getting immediate benefits today. And I think that is important, because you're right. People look at how is this effecting me today. There will be people who will obviously adjust their actions because they want to make a difference long term. Others who will adjust their actions to get the immediate benefit. So we need to show both. And I know we're doing that in some ways, but I think we can do even better.

CHAIRPERSON NICHOLS: One more, yes. Dr. Sherriffs.

BOARD MEMBER SHERRIFFS: It's such an important topic, I can't not. I also can't let the American Thoracic Society down. To remind people this is physicians everywhere, the California Academy of Family Physicians is on record. I'm looking at the California Medical Association. 40,000 doctors in California two years ago reiterated through its House of Delegates its support for the work of AB 32, our work here, and not incidentally coming up later today, stay tuned, low carbon fuel standard programs. So that's very important.

I really am looking forward to do a YouTube with Supervisor Roberts. And I really do appreciate these comments, because this is so constant with the kinds of things we do as doctors that we have to do. And it's such a great model in terms of a clear diagnosis, engendering hope, looking at not just the immediate benefits but the long-term benefits, and walking the talk, doing what we're doing. And demonstrating clearly to people what they can do and having a Plan B. I think that's also an important thing, because I think many people who are concerned and are terrified think, you know, this mitigation stuff, wait a minute. That takes our eyes off the ball. We have to be doing prevention. We can't be spending a penny on mitigation.

I think the answer is no. There is a very good case we have to be doing both. We have to focus on prevention because in the long term that is the most cost-effective, the most important, leads to the fewest disruptions. But we do need that whole package. Thank you very much for your presentation.

CHAIRPERSON NICHOLS: I'm going to draw this to a close, only because we have a couple of other agenda items to address this morning. But I want to make just a couple of very short comments.

First of all, I'm delighted this presentation has set off a healthy competition on my Board. There is nothing like competition bring out the best in all of us. Thank you for that.

And thank you for a really thought-provoking presentation and for being available to us through your work as part of the California Climate Assessment as well. This is not the last time we will have an opportunity to take advantage of Dr. Moser's work.

In that regard, I want to just say two quick things. First of all, with respect to the fact that we are part of a global problem here and a lot of global effort, I do want to call out the fact that going back to the original signing really of AB 32 by Governor Schwarzenegger and now intensified and given more concrete steps by Governor Brown, we have been engaged internationally in working with other regions of the world, work that California has done has been not only an inspiration and a model for programs in other places, but we have increasingly direct engagement at ARB and some of our sister agencies as well in technology transfer and benchmarking and communications with others, which has just expanded the importance of the work that we've been doing here at ARB.

And the other thing I want to say is that in your presentation -- and you pass over this somewhat lightly -- you noted that there is one area of at least somewhat good news mitigating all of this bad news, which is the apparent slowing or reduction of loss of forests and therefore the potential that there's some more ability to reverse what looked like a really terrible situation not that long ago and to come up with some ways to restore our ability to store carbon in our land and forests.

And this is an area where California is I think really just beginning to comprehensively take a look at other ways in which we can be a model. We have not had a comprehensive policy in this regard. The Governor did mention it in his inaugural speech, and there's now a great deal more activity going on. Edie Chang is representing us with the Forestry Climate Action Team, which is working with the Resources Agency and that whole area of California's tremendous natural resource base that we begin with is really just kind of beginning to emerge as a full element of our climate thinking and planning.

And even though it's not as easy for us, particularly as ARB, to directly be involved in because we don't have the parts per million or the direct emissions to work with, we do actually have a responsibility in our role as the keepers of the AB 32 Scoping Plan for assessing, documenting, and monitoring what's going on in that area.

So just a thought really to plant here with everyone that I think this is going to be something we're going to increasingly be talking about in the years to come.

And with that, I want to thank you. And hope we'll see you again.

DR. MOSER: thank you so much.

CHAIRPERSON NICHOLS: We have the proposed readoption of the low carbon fuel standard.

For those planning their day, we are planning to take a lunch break. There is going to be an executive session at lunch today. So we certainly will not get to the alternative diesel fuels item until after the lunch break.

Okay. New team taking their places here. We now proceed to the proposed readoption of the low carbon fuel standard. We're hearing this proposal today in response to a decision of a State Appeals Court that dealt with the procedural issues regarding our original adoption of the rule.

But in addition to the procedural aspects of this, we're also going to hear some proposed amendments that are designed to strengthen the rule and to make sure that it's sending the strongest signals for ongoing investment in low carbon fuels in California.

As I think everybody knows, the overall goal of this low carbon fuel standard is to reduce the carbon intensity of transportation fuels in California 10 percent by 2020. It's a key piece of the portfolio of AB 32 policies to cut greenhouse gas emissions to 1990 levels by 2020.

As we look beyond 2020, increasing volumes of low carbon fuels will be needed to meet the Governor's recently announced goal of cutting petroleum consumption in the state by 50 percent by 2030.

It's been five years since the Board originally adopted the low carbon fuel standard. But the core principles that were embodied in the regulation remain valid. And the basic framework of the rule, including the use of life cycle analysis, as well as the creation of a credit market and a reporting tool, have been working -- have all been working quite well, despite the efforts over the years to undermine this rule or challenge its existence in a variety of different forums.

One of things we hear most frequently from businesses that we regulate is a need for certainty. And that's a very valid concern and one that we need to pay attention to. Certainty allows businesses to plan over the long term, gives each individual business the ability to comply in the ways that make the most sense for them. And right now, we think the best thing that can be done is to move forward in a way that will create as much certainty as we can, given that we have to always remain open to things that happen in the world of science, the world of technology, but we need to make sure that we are, in fact, sending a signal that includes as much certainty as possible.

We will be monitoring and adjusting elements of the program as necessary as we always do at ARB, but particularly given the sensitivity of gasoline as a commodity if the people in this state are perhaps disproportionately reliant on. We need to be making sure that we continue to be watching what's going on out there.

But at the same time, we also can see there is a framework here that's needed and that we need to make sure that we're communicating and implementing in ways that will allow us to bring volumes of cleaner as well as increasingly affordable low carbon fuels into California.

So before turning this item over to the staff, the Executive Officer will introduce the item as usual. Just want to make sure that people understand the context that we're in today. The Board today will not be voting on the actual proposal. We will be listening and paying attention to the comments that we received already as well as those we'll get today and the written and the oral testimony as well as the written testimony. And we will be acting on a Resolution that will direct the staff to make any additional changes that are needed and to bring this item back for a formal vote a few months from now.

So this is a two-step process that we have to engage in as a result of the procedural requirements, which we are now fully implementing and so we will be listening. We'll be learning. We'll be directing the staff via a Resolution. The actual final adoption of the rule will not happen until there is an opportunity for one more hearing.

So with all of that, Mr. Corey, would you please introduce this item.

EXECUTIVE OFFICER COREY: Yes, thank you, Chairman.

As you stated the low carbon fuel standard is intended to reduce the carbon intensity transportation fuels used in California. Reducing carbon intensity will reduce greenhouse gas emissions and support the development of cleaner fuels with the attended co-benefits. Low carbon fuel standard is one of several California programs to reduce GHG emissions from transportation by improving vehicle technology, reducing fuel consumption and the carbon content, as well as increasing transportation options.

When the Board approved the regulation in 2009 and then its 2011 amendments, the Board directed staff to consider various aspects of the regulation, many of which are addressed in this readoption. Additionally, staff included updates and revisions compared to the original regulation to strengthen the signal for investments in the cleanest fuels, offer additional flexibility, update technical information, and provide for improved efficiency and enforcement for the regulation.

Now before I turn this over to staff, I'd like to note that Mike Waugh, many of you know is the face of the low carbon fuel standard program for many years here retired at the end of 2014. And he helped us get the publication of this report, and we really appreciate the tremendous contribution Mike made and wish him well.

I'd also like to acknowledge Sam Wade, who has capably taken over the fuels group for Mike.

And with that, I'll introduce Katrina Sideco, who will give the staff presentation. Katrina.

(Thereupon an overhead presentation was presented as follows.)

AIR RESOURCES ENGINEER SIDECO: Thank you, Mr. Corey.

Good morning, Chairman Nichols and members of the Board.

We are pleased to have this opportunity to present staff's proposal on the readoption of the low carbon fuel standard, or LCFS.

We want to remind the Board that this is the first of two Board hearings for this rulemaking and the Board is not being asked to consider adoption of the proposed regulation today.

--o0o--

AIR RESOURCES ENGINEER SIDECO: In today's presentation, we will first provide background information on the LCFS as well as its current status. We will discuss the proposed regulation, followed by its environmental and economic impacts.

We will then present areas of potential 15-day changes and conclude with a proposed time line for this rulemaking.

--o0o--

AIR RESOURCES ENGINEER SIDECO: The Board approved the LCFS regulation in 2009 to reduce the carbon intensity, or CI, of transportation fuel used in California by all least ten percent by 2020 from a 2010 base line. The Board then approved amendments to the LCFS in 2011. This program is one of the key AB 32 measures to reduce greenhouse gas emissions in California.

The LCFS also has other significant benefits that are sometimes overlooked. It transforms and diversifies the fuel pool in California to reduce petroleum dependency and achieves the air quality benefits, which are two state priorities that precede the LCFS.

--o0o--

AIR RESOURCES ENGINEER SIDECO: The LCFS is designed to reduce greenhouse gas emissions in the transportation sector, which is a responsable for about 40 percent of the greenhouse gas emissions, 80 percent of ozone-forming gas emissions, and over 95 percent of diesel particulate matter.

It is a key part of a comprehensive set of programs in California to reduce emissions from the transportation sector, including the Cap and Trade Program, Advanced Clean Car Program, and SB 375.

The LCFS is also a key program to achieve the Governor's goal of cutting petroleum use in half by 2030.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Other jurisdictions are following California's footsteps, which is evident in the Pacific Coast Collaborative, a regional agreement between California, Oregon, Washington, and British Columbia to strategically align policies to reduce greenhouse gases and promote clean energy.

One of provisions of this collaborative explicitly addresses low carbon fuel standard programs. Oregon and Washington have committed to adopting LCFS programs, while California and British Columbia have existing LCFS programs.

Staff has been routinely working with these jurisdictions, providing assistance where we can. Over time, these LCFS programs will build an integrated west coast market for low carbon fuels that will create greater market pull, increased confidence for investors of low carbon alternative fuels, and synergistic implementation and enforcement programs.

--o0o--

AIR RESOURCES ENGINEER SIDECO: In addition, recent ICCT research finds that the clean fuel goals of all jurisdictions can be achieved simultaneously.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Now I want to briefly touch on how the LCFS works. The LCFS has a couple of key requirements. It sets annual carbon intensity standards, which reduce over time, for gasoline, diesel, and the fuels that replace them.

Carbon intensity is expressed in grams of carbon dioxide equivalent per megajoule of energy provided by that fuel. CI takes into account the greenhouse gas emissions associated with all the steps of producing, transporting, and consuming a fuel, also known as a complete life cycle of that fuel.

The LCFS is fuel neutral and lets the market determine which mix of fuels will be used to reach the program targets.

--o0o--

AIR RESOURCES ENGINEER SIDECO: The LCFS accounting system is pretty straight forward. Fuels and fuel blend stocks introduced into the California fuel system that have a CI higher than the applicable standard generate deficits. Similarly, fuels and fuel blend stocks with CIs below the standard generate credits. Compliance is achieved when a regulated party uses credits to offset its deficits.

Since the regulation was first adopted, the compliance curves have been back-loaded to allow time for the development of low CI fuels in advanced vehicles. Due to this program's design choice, there has always been the expectation that excess credits generated in the early years of the program would be available for use in more stringent future years, if needed.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Since the regulation went into effect, low carbon fuel use has increased due to the LCFS, the federal renewable fuel standard, and other factors.

Staff have continually monitored the program and found that regulated parties in the aggregate have over-complied with the LCFS standards in every quarter since implementation.

Even with the standards frozen at one percent, tangible results can be seen today. For example, the amount of renewable natural gas used in vehicles in California has increased by over 700 percent since the program started. The amount of biodiesel has quadrupled. Renewable diesel has grown dramatically to become more than three percent of the total diesel market in California in 2013. And the average crude CI used by California refiners has remained below the 2010 base line, meaning that the carbon footprint of the crude slate has not increased.

--o0o--

AIR RESOURCES ENGINEER SIDECO: This figure shows the total credits and deficits reported by regulated parties through 2011 up to the third quarter of 2014. For reference, one credit equals one metric ton of carbon dioxide equivalent. Cumulatively, through the end of the third quarter of 2014 there has been a net total of about 3.9 million excess credits.

--o0o--

AIR RESOURCES ENGINEER SIDECO: This is the slide we've borrowed from our colleagues at the California Energy Commission who work on the Alternative and Renewable Fuel and Vehicle Technology Program, also known as the AB 118, which offers grants for low carbon fuel projects. The dots show the location of some of the major low carbon fuel investments that have been made in California.

As you can see, there is a lot of private and public capital flowing to this industry throughout the state.

--o0o--

AIR RESOURCES ENGINEER SIDECO: This slide focuses on the shift of fuels generating credits in the program between 2011 and 2014. Credits so far have been generated primarily from low CI ethanol. The carbon intensity of ethanol has continued to decline, demonstrating that the LCFS incentives significant innovation, even for established biofuels like ethanol. The contributions from non-ethanol fuels, such as biodiesel, renewable diesel, and renewable natural gas continue to expand.

We've also seen a small but increasing contribution from electricity and hydrogen. We expect LCFS credits from these fuels to continue to increase as electric and fuel cell vehicles come into the California market in greater numbers.

I would also like to highlight the major contribution of renewable diesel at 16 percent of the credits in 2014. These charts demonstrate the ability of the LCFS to pull low carbon fuels to California.

--o0o--

AIR RESOURCES ENGINEER SIDECO: The LCFS has two lawsuits, one federal and one state. These legal challenges have caused uncertainty in low carbon fuel investment.

The Federal Court of Appeals ruled in favor of ARB on some claims and remanded the other claims back to the district court for further proceedings. The State Court of Appeal found procedural issues with the way in which ARB complied with the California Environmental Quality Act, or CEQA, and the Administrative Procedures Act.

Specifically, the state court felt ARB did not fully consider the fact that the low carbon fuel standard may incentivize additional biodiesel use, which could potentially have a negative impact on air quality due to increased emissions of nitrogen oxides from higher blends of biodiesel compared to conventional diesel fuel.

Although the decision found ARB improperly deferred mitigation of biodiesel, the court allowed ARB to enforce the program at 2013 CI levels while addressing the court's concerns.

To address the ruling, ARB staff conducted an environmental analysis of the proposed LCFS regulation and proposes that the Board re-adopt the regulation and adopt the alternative diesel fuel regulation that directly mitigates potential NOx impacts from higher blends of biodiesel.

As we will describe later in this presentation, staff has conducted a joint environmental analysis of the two rules to study this interaction and you will hear more about this during the alternative diesel fuel presentation later today.

--o0o--

AIR RESOURCES ENGINEER SIDECO: In response to the lawsuit, we are proposing to re-adopt the entire LCFS regulation.

In addition to addressing the legal challenge, staff is also proposing revisions to improve the current LCFS. Although implementation of the LCFS has gone smoothly, there are opportunities to improve the rule.

Several factors are driving the staff's proposed revisions. First, based on stakeholder comments received in both the original 2009 rulemaking and the 2011 amendments, the Board directed staff to consider revisions to the regulation in specific areas.

Additionally, staff has received feedback from regulated parties and other stakeholders throughout the implementation of the LCFS, to which staff has been responsive.

Staff also identified proposed revisions for clarity and enhancement to the regulation based on our experience from five years of implementation of the LCFS.

Also, staff is incorporating the latest science and technical knowledge to update the tools used to calculate the carbon intensity of fuels.

Finally, the readoption along with proposed revisions will provide certainty as we move forward.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Staff went through an extensive public process to engage stakeholder participation for this readoption. In addition to conducting 20 public workshops in 2013 and 2014, staff also conducted two advisory panel meetings in 2014. Staff has also initiated an external scientific peer review of staff's methodology in calculating Carbon intensity values. This process will be completed before the second Board hearing.

--o0o--

AIR RESOURCES ENGINEER SIDECO: We will now discuss the proposed regulation.

So summarize the readoption of the LCFS, it is important to note that the LCFS is working and the core concepts remain unchanged. However, staff identified key areas of improvement, including updating the tools used to calculate carbon intensity to reflect the latest science, adjusting the 2016-2020 carbon intensity targets, and capping the credit price at $200 dollars per credit. We'll be talking more in detail about each of these improvements in the upcoming slides.

--o0o--

AIR RESOURCES ENGINEER SIDECO: One of the key areas of improvement is our proposal to adjust the compliance curve. As mentioned, there has been an uncertain investment market due to the standards being frozen by the court to 2013 levels.

Thus, staff is proposing to adjust the target stringency from 2016 through 2019 to allow the market time to get back on track. However, the requirement to reduce the average carbon intensity by ten percent by 2020 will be retained.

--o0o--

AIR RESOURCES ENGINEER SIDECO: So how do we see low carbon fuel deployment changing to meet our proposed compliance curve? This slide shows the current sources of LCFS credits in 2014 on the left and the projected sources of credits in 2020 in staff's illustrative scenario on the right.

In this scenario, we expect to see strong contributions from a balanced portfolio of low carbon fuels. Since this program is market-based, this is unlikely to be the actual fuel mix by which we achieve compliance in 2020, but it serves to illustrate staff's current best guess as to which low carbon fuels will be the strongest contributors.

--o0o--

AIR RESOURCES ENGINEER SIDECO: The major 2020 sources of credits in this scenario include renewable diesel, biodiesel, renewable natural gas, and a different ethanol slate. Since we are benefitting from the zero emission vehicle program, electricity is also more significant in contributing them today.

This scenario includes a significant use of bank credits in 2020. This is due to the scenario's relatively conservative assumptions about low carbon fuel volumes. Staff felt it was appropriate to use more conservative volume estimates, due to the legal challenges to LCFS mentioned previously, and regulatory uncertainty in the federal renewable fuel standards.

If low carbon fuel investments accelerates faster than shown in this scenario, to 10 percent reduction could be achieved without banked credits used in 2020.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Another key area of improvement is updating the tools used to calculate the carbon intensity for each fuel.

In general, the CI includes a direct effects of producing and using the fuel, as well as indirect effects that are primarily associated with crop-based biofuels.

Two models are used to calculate the direct effects which are the GREET model and the OPGEE model. To calculate the indirect effects, the GTAP model was updated and the AEZ-EF model was created to supplement GTAP's estimates of greenhouse gas emissions from various types of land conversions.

Staff conducted a robust stakeholder process to update these tools to reflect the latest science and is in the process of subjecting these updated tools to a final peer review.

--o0o--

AIR RESOURCES ENGINEER SIDECO: The next two slides show the carbon intensity for both gasoline substitutes and diesel substitutes used in staff's illustrative scenario. This slide shows the changes between 2014 and 2016 for a few gasoline substitutes, with the existing values shown on the left and an updated value shown on the right for each fuel or blend stock.

Note that the emissions associated with indirect land use change, shown in orange, have gone down for all crop-based biofuels.

--o0o--

AIR RESOURCES ENGINEER SIDECO: This slide shows the changes in staff's scenario for diesel substitutes.

Given the continuously evolving research in this area and recent written comments received from the Natural

Gas Vehicle Coalition, we do believe some continued technical work between the first and second Board hearing is warranted, especially for natural gas fuels. So we expect these values to change during the 15-day process.

Finally, we should note again that most of these CIs are merely representative values. Individual low carbon fuel producers have the ability to improve the specific carbon intensity value assigned to their fuel by demonstrating improvements through the pathway application process, which I'll discuss on the next slide.

--o0o--

AIR RESOURCES ENGINEER SIDECO: To date, the fuel pathway application process has successfully determined individual CIs for over 230 unique fuels. Through this process, fuel producers have been able to receive credit for both incremental improvements to existing methods and innovative new production processes. However, the process has proven to be more resource intensive for all participants and staff than originally anticipated.

It is important to simplify this process for stakeholders in California's program and so other jurisdictions can adopt our approach. But an inherent trade-off exists between the simplicity and recognition of all actions that reduce carbon intensity.

Staff is proposing to streamline this process using a two-tiered system to focus greater attention on next generation fuels, such as cellulosic alcohols, biomethane from sources other than landfill gas, hydrogen, electricity, and drop-in fuels. These advanced fuels will be eligible for a process very similar to the one currently in place.

Conventionly produced first generation fuels, such as corn ethanol, will still be able to receive credit for incremental improvements, but this recognition will be given using a simplified calculator, which will shorten staff review of these applications.

Helping all market participants adapt to this new approach and familiarize themselves with the updated tools will be challenging in the short-term, but is expected to create significant improvement in the long term.

--o0o--

AIR RESOURCES ENGINEER SIDECO: The staff proposal includes new cost containment features. But before we cover the new addition, we'd like to first review the cost containment provisions we currently have in place and explain how useful they've been to the program so far.

One example is the trading of credits. The program has seen 530 credit transactions from 2012 through November of last year and about 2.7 million metric tons of credits were traded in that time frame. Presumably, the purchasers of these credits saw these purchases as a lower cost compliance option than directly reducing the CI of the fuels they control.

Another example is that credits are fungible between the gasoline and diesel pools. In staff's illustrative scenario, over-compliance from diesel fuel substitutes is expected to help with compliance on the gasoline side.

The voluntary opt-in provision allows credits to be generated from sources not required to participate in the regulation. The carry-back provision also provides additional flexibility.

Finally, credits have no expiration date, so unlimited banking of credits is also permissible, which we will cover in detail on the next slide.

--o0o--

AIR RESOURCES ENGINEER SIDECO: This slide shows more detail on how the credit banking provides flexibility in staff's illustrative scenario.

Here, you see the initial compliance curve prior to the litigation depicted by the gray dotted line. Here is what actually happened to the compliance curve so far, which is illustrated by the black line. You can see that the standards are frozen at one percent until 2015 due to the lawsuit.

This green line shows the percentage of carbon intensity reductions so far. Due to the frozen standards, we can see a significant bank of credits being built up.

The percentage of carbon intensity reduction from staff's illustrative scenario is depicted by the green dashed line. We believe this scenario is a reasonably conservative estimate of how carbon intensity would change in the future, given the proper programmatic signals. Note that we show the rate of CI reduction increasing slightly in 2016 due to program readoption and again post-2020.

The black dotted line shows the compliance curve as adjusted by the readoption proposal. As you can see, there is a period where the projected CI may be higher than the standard. During this period, the credit bank allows time for low carbon fuel investments to accelerate.

Also, this figure makes it clear that future adjustments are likely needed post-2020 to address the Governor's 2030 petroleum reduction goals.

--o0o--

AIR RESOURCES ENGINEER SIDECO: We are proposing to add a new cost containment provision called the credit clearance market to prevent price spikes in the unlikely event the market experiences credit shortages.

This provision provides consumer protection by establishing a maximum credit price, and thus a maximum impact on fossil fuel prices from the program. This also prevents short-term price issues that reduces the potential for market manipulation.

In the unlikely case there are not enough low carbon fuels in the market to comply, this provision will give regulated parties and ARB up to five years to make adjustments.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Staff is proposing to add a provision to give credit for greenhouse gas emission reductions made at refineries that supply fuel to California. This provision adds flexibility to the regulation and can also be thought of as additional cost containment as it introduces new potential sources of lower cost abatement into the program.

Example project types that would be eligible include solar steam generation or biogas to hydrogen for the refining process. Clear eligibility threshholds are established, and projects cannot increase criteria or toxic emissions.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Similar to the new refinery crediting provision, staff is also proposing refinements to the existing crediting program to support innovative technologies for crude oil production.

The proposal refines the provision to better promote the development and implementation of innovative crude oil production methods. Major changes include an adjustment to the eligibility threshhold and the addition of new project types.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Per Board direction, staff is proposing to add a low complexity-low energy use refinery provision to this regulation to provide a benefit to smaller refineries.

A refinery would have to qualify as a low complexity-low energy use refinery by being below the threshold for both complexity and energy usage. If a refinery qualifies for this provision, it will be able to receive a credit for the refining step carbon intensity and will have a one-time opportunity to have a crude oil incremental deficit calculated on a refinery-specific basis.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Staff is proposing minor refinements related to electricity as a transportation fuel.

First, the proposal adds fixed guideway transit systems and electric forklifts as eligible to generate credits. Fixed guideway transit includes electric light rail, trams, and buses.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Secondly, the proposal adds specific vehicle efficiency values for electric fixed guideway, buses, forklifts, and trucks.

Finally, due to the fact that consumer preferences of electric vehicle owners have not resulted in widespread installation of separate metering in residences, the proposal removes the transition to direct-metering in 2015 required by the existing rule and instead continues the current practice of applying estimation methods to calculate electric vehicle crediting.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Finally, staff is proposing to enhance the enforcement provisions of the program. Among these enhancements is clarifying the jurisdiction to include opt-in parties, registered brokers, and entities applying for fuel pathway certification.

Staff also clarified that the Executive Officer has authority to suspend, revoke, or restrict an account when violations have occurred or when an account is being investigated. Staff also defined a per-deficit violation with a maximum penalty of $1,000.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Now we will go into the environmental and economic impacts associated with this regulation.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Staff prepared one draft environmental analysis, or EA, that covered both the proposed LCFS and ADF regulations because the two rules are inter-connected.

The draft EA was prepared according to the requirements of ARB's certified regulatory program under the California Environmental Quality Act, or CEQA. The analysis focused on changes in the fuel production, supply, and use.

The existing regulatory and environmental setting in 2014 is used as the base line for determining the significance of the proposed regulations impacts on the environment.

--o0o--

AIR RESOURCES ENGINEER SIDECO: The LCFS and ADF will result in beneficial environmental impacts to greenhouse gases, air quality, and energy. In combination with other state and federal GHG reduction programs, implementation of the proposed LCFS and ADF regulations is anticipated to result in environmental benefits that included an estimated reduction in greenhouse gas emissions of more than 60 million metric tons of carbon dioxide equivalent from transportation fuels used in California from 2016 through 2020.

Lower carbon diesel fuel substitutes would result in beneficial air quality impacts for particulate matter, carbon monoxide, toxic air contaminants, and other air pollutants. Specifically, the estimated total reduction of PM2.5 emissions would be more than 1200 tons from transportation fuels in California from 2016 through 2020.

--o0o--

AIR RESOURCES ENGINEER SIDECO: The draft EA identified less than significant impacts to certain resources, such as minerals and recreation. However, potential significant impacts were identified in a number of resource categories, such as agricultural, biological, hydrology and water quality. Significant cumulative impacts were also identified for many resources.

While some of these identified impacts are related to long-term operational changes, others are potential short-term effects related to construction of new fuel production facilities.

This is a programmatic analysis. To the extent new fuel production facilities are built, the location of the facilities and consequently their specific environmental impacts will not be known until development plans are announced and local permits are sought. The site-specific environmental impacts would be analyzed at that time by the permitting authorities, which will typically include local air districts and land use agencies.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Because the ADF and LCFS proposals were so interlinked, the macro-economic impacts of the proposals could not be disaggregated. Therefore, the evaluation was completed using the simultaneous effects of both proposals on the fuel volumes and prices.

Staff employed a conserve extensive automotive framework. It assumed all costs to the regulated parties are passed on to customers. It does not assign a monetary value to climate protection benefits associated with fewer greenhouse gases, health benefits associated with reduced criteria pollutants, and toxic air contaminants or benefits due to reduced oil dependence. Also, unlike the environmental analysis, it does not account for interactions with other policies.

Finally, it does not assume any reduced cost due to innovation and low carbon fuels.

All of these assumption directionally reduce the estimated economic benefits of the proposed rule but capture the potential costs of the rule.

--o0o--

AIR RESOURCES ENGINEER SIDECO: The macro-economic portion of the economic analysis was conducted using the regional economic models incorporated, or REMI, tool.

Together, the LCFS and ADF were found to have very small impact on California's gross state product and have very small impacts on employment. Even under the conservative assumptions employed by staff, impacts of the proposed rule are very small, considering the size and diversity of California's economy.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Taking a simplified firm-level view of the economics of the proposed rule, we can see how the value of the LCFS credits creates a shift in fuel producer costs. The LCFS credit value benefits the producers of low carbon fuels significantly on a cents per gallon basis. For example, if credit prices were to rise to $100 per ton, the average biodiesel producer would benefit by emission inventory than a dollar per gallon in 2020, as shown in the orange bars.

Even if credit prices were to remain near current levels around $25 per ton through 2020, the benefit to low carbon fuel producers is noticeable, as shown in the blue bars.

However, covering LCFS deficits increase the cost of traditional fossil fuels only slightly on a cents per gallon basis because the costs are spread over such a larger volume of fossil fuels.

Also remember that these values are presented for the full 10 percent reduction in carbon intensity in 2020. For a fixed credit price, benefits to low carbon fuel producers at a given CI are larger in the earlier years of the program because they generate more credits relative to the more lenient early years of the standard. Costs associated with high carbon fuel producers are lower in earlier years because they generate fewer deficits relative to the standard in the early years.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Moving forward, the second Board hearing is tentatively scheduled in the summer of this year. Between now and the second Board hearing, staff is planning additional stakeholder coordination to further refine the proposal we presented today. We are also proposing 15-day changes which we will cover in the next slide. Should the Board re-adopt the

LCFS with proposed revisions, the implementation of the improved LCFS would begin on January 1, 2016.

--o0o--

AIR RESOURCES ENGINEER SIDECO: As I mentioned, staff has identified a few areas of potential 15-day changes. Staff will continue to update the GREET model with a special attention to natural gas vehicle issues. Staff will also work to clarify the refinery investment provisions further.

We've listed a few minor areas of possible adjustments, including the inclusion of indirect land use change CI values in the regulation, revising the reporting parameters for electricity, and moving the program review forward to 2017.

--o0o--

AIR RESOURCES ENGINEER SIDECO: Finally, these are our next steps before the next Board hearing. The environmental review of the proposed LCFS and ADF regulations will be completed.

Staff will prepare written responses to environmental comments and undertake any needed updates to the draft environmental analysis released in December. We will also complete the external per review and work with stakeholders to draft any 15-day changes needed.

This concludes my presentation. And we thank you again for the opportunity to present staff's proposal on the readoption of the low carbon fuel standard.

CHAIRPERSON NICHOLS: Thank you.

I have a list in front of me of 41 witnesses, and I understand there is another page coming. So we have some work to do here.

I would note with our Board packet we received a list of the written comment log, which is also very extensive. I actually had an opportunity to look at a number of these. But there is about 65 of them at last count. And so for those who have already commented in writing, just know that this material is also in front of the Board.

BOARD MEMBER SHERRIFFS: Can I ask a short question?

CHAIRPERSON NICHOLS: Yes, sir.

BOARD MEMBER SHERRIFFS: Thank you for that. Actually clarified a lot.

On your slide about the impact on gross state product and deployment, that is all cost. There is no consideration of potential benefits in terms of decreased health costs; correct?

TRANSPORTATION FUELS BRANCH CHIEF WADE: That's correct.

CHAIRPERSON NICHOLS: Okay. Thank you. So let's begin. And our first witness -- the list is broadcast up there on the wall, so you can keep track of where you are on the left. Begin with Tim Taylor and then Matt Miyasato.

DIVISION CHIEF FLOYD: Madam Chair, we asked our colleagues from the Energy Commission to speak.

CHAIRPERSON NICHOLS: Of course. Yes. Mr. Olson, sorry. I had a note and I forgot about it. Welcome.

MR. TAYLOR: Thank you, Chair Nichols and members of the Board. Tim Taylor. I'm the Division Manager at the Sacramento --

CHAIRPERSON NICHOLS: I apologize. We're going to call on our colleague from the Energy Commission first. Another Tim.

MR. TAYLOR: Which Tim was it?

CHAIRPERSON NICHOLS: The better looking one.

(Laughter)

01_T_LCFS _TOlson

MR. OLSON: Thank you very much for allowing us to make a comment here.

LCFS T1-1

The California Energy Commission supports the proposed action over the next few months to re-adopt the low carbon fuel standard. And we'd like to note the success of the Energy Commission's incentive funding, you had a brief look at it here in the presentation, the

Alternative Renewable Fuel Vehicle Technology Program is dependent on and compliments the LCFS.

Just to give you -- you had some information on some of the projects. Over the last five years, the Energy Commission has awarded over $547 million in awards and matched with an equal amount of private investment for projects in California. Of that amount, over close to $160 million awarded for 43 biofuel, biomethane projects, with average carbon intensities of 28 grams of CO_2 per megajoule. There's some negative and some a little higher than that. But that's the average.

And they all qualify for LCFS credits. All those projects are in various stages. Some of them are advanced in commercial. Some of them are pre-commercial. Most of them are expected to produce pretty significant quantities in the next -- by 2020. So we're going to be adding more performance there.

That's significant for another reason. Right now, California imports 80 percent of its biofuels that we use today, and we think that in-state development is an important aspect. LCFS is a big contributor to that to make that work.

Also would like to -- we also appreciate the ongoing interaction with ARB staff mutual exchange of information and analysis, which has been used in our

LCFS T1-1 cont.

policy documents, notably the integrated energy policy report, our annual report to the Governor and Legislature. We use your analysis a lot in that process, particularly the LCFS and the ZEV mandate and other programs. And it helps us in justifying the expected forecast of transportation energy supply. And what we're seeing is a shift from petroleum to alternative fuels. And we look forward to that continued interaction.

LCFS T1-1 cont.

And at this point, we just wanted to Support your activity. Thank you very much.

CHAIRPERSON NICHOLS: Thank you very much.

By way of a partial explanation from my factitiousness there, it is a fact that the relationship between the Energy Commission and the Air Resources Board around this program is a very close and interdependant one. But the Legislature in its wisdom chose to give ARB the regulatory authority and the Energy Commission the money. So there we go. That's why we call them good looking.

02_T_LCFS _TTaylor

MR. TAYLOR: Thank you so much for clarifying that. Now I can say the nice things about the Energy Commission that I was planning to say.

I'm Tim Taylr, Division Manager at the Sacramento Metropolitan Air Quality Management District here today to speak in strong support of the low carbon fuel standard.

LCFS T2-1

As you heard in your staff report, transportation is a very significant part of the greenhouse gas emission inventory. Reducing the greenhouse gases from this sector of the economy is critically important if we're going to meet the standards that have been set. Your Board in cooperation with handsome folks from the California Energy Commission has accomplished a great deal toward lowering these emissions through programs encouraging more efficient vehicles, electric and alternative fueled vehicles, and regional transportation planning to reduce VMT. But as your own staff's analyses have shown, without lowering the carbon content of the fuels themselves, it will not be possible to achieve the standards that have been set.

LCFS T2-1 cont.

The low carbon fuel standard creates regulatory certainty and will spur economic and technology development. In our region alone, we have hundreds of natural gas vehicles currently ruining on renewable natural gas from food waste and landfill gas. We have electric vehicles running on electricity that's made from renewable electricity, solar, wind, and from renewable methane. We're working to develop a pilot renewable diesel project here in Sacramento. E85 is readily available in our region.

In summary, the technologies exist and they're increasing. The need is obvious. The Sacramento Air District strongly supports the low carbon fuel standard, and we encourage you to adopt it when it comes back to you for adoption. Thank you very much.

LCFS T2-1 cont.

03_T_LCFS _MMiyasato

CHAIRPERSON NICHOLS: Thank you, Mr. Taylor.

Mr. Miyasato.

MR. MIYASATO: Thank you, Madam Chair, members of the Board. Also want to acknowledge Council Member Mitchell who also sits on our Board.

So by way of for the record, I'm Matt Miyasato, the Deputy Executive Officer for Science and Technology Advancement at the South Coast Air Quality Management District.

I'm here on behalf of my boss, my Executive Officer Dr. Barry Wallerstein. That's to voice our support for the low carbon fuel standard and your staff's recommendation to re-adopt the standard. We believe this regulatory mechanism is important not only for reducing greenhouse gas emissions, but more importantly for our region for getting co-benefits and reducing criteria pollutant emission benefits that your staff highlighted in the environmental impact assessment.

LCFS T3-1

In particular, we believe the widespread use of fuels that you've identified in particular, natural gas and hydrogen, those that give us zero tailpipe emissions, reduce toxics, reduce PM, but especially for our region, reducing NOx emissions will help us meet our attainment goals to achieve federal standards.

We support the LCFS adoption, and we urge your approval when it ultimately comes back for your vote. Thank you.

CHAIRPERSON NICHOLS: Thank you.

MS. Passero.

MS. PASSERO: Good morning. Michelle Passero with the Nature Conservancy. Thank you for the opportunity to comment.

I'm here on behalf of the conservancy to voice our strong support for the readoption of the low carbon fuel standard. It's critical to the programs, both the short-term and long-term goals of reducing emissions in California and in setting a precedent for other regions.

And as you already mentioned, there is a need for certainty for investments in new technologies and transitions to an expansion of low carbon fuels.

So being optimistic about the readoption of the LCFS, we also want to continue working with ARB staff and the Board to encourage implementation of best practices for these new technologies and new fuels to help minimize any trade-offs and also to encourage multiple benefits.

And also, we hope to consider third party

LCFS T3-1 cont.

04_T_LCFS_MPassero

LCFS T4-1

certification programs that can help with implementation of best practices. We did submit a letter along with other NGOs, so there's details in that, and we're certainly happy to follow up and help. So thank you very much.

LCFS T4-1 cont.

05_T_LCFS _GGrey

CHAIRPERSON NICHOLS: Thank you.

Mary Solecki. Is she here?

Gina Grey, WSPA.

MS. GREY: Good morning, Madam Chair, Board members, and staff.

My name is Gina Grey. I'm with the Western States Petroleum Association. We have submitted about 93 pages of written comments for the record, so I'll just try to touch on a few points today.

First, I'd just like to say in case there is any doubt on the member -- the Board member's part about what our position is in our industry, we do still oppose the low carbon fuel standard, as you can imagine. Not so much for the actual goal, which is to reduce obviously transportation sector emissions, but it's more about the policy structure.

LCFS T5-1

Originally, ARB had a lot of optimism in 2009 when the program was cast as a transformative regulation that was going to save the State approximately $11 billion in the ten-year period, as well as produce obviously a lot of in-state jobs and low carbon fuel facilities.

From what we see in this proposed program today seems to be a bit of emission creep whereby the original central goal was to foster innovation and transportation fuels. It seems to have morphed into a program that attempts to satisfy ever-more objectives.

LCFS T5-1 cont.

The staff now proposes to include several credit-generating measures in the reauthorization package, along with a cost containment mechanism to fill what we credit to be the fuel CI gap.

LCFS T5-2

And we still believe the compliance schedule is infeasible, which I'm sure you've heard a lot of. Very low CI fuels, such as cellulosic ethanol, have not materialized in the forecasted volume, but there is an over reliance as well on the significant volumes of credits that have been generated early in the program.

We contracted again with the Boston Consulting Group to update a number of studies that we have been doing with them since 2010. And they have concluded that approximately 5.1 percent is the sustainable reduction that can be achieved by 2020 through the use of both fuel and the credits.

LCFS T5-3

To touch on cost, I would just say that some folks are now saying that credit costs must rise to around $200 per metric ton in order for the program to be

LCFS T5-4

effective and transformative. In addition, there seems to be a duplicative accounting taking place by other states that are embracing the LCFS. The increased competition for the limited fuel volumes and the credits may lead to some interesting market dynamics.

LCFS T5-4 cont.

There have been several recent ARB presentations characterizing the LCFS program as a success. Although there has been movement in lower CIs in terms of corn-based ethanol, an increase in renewable diesel and biodiesel use, for example, we basically don't feel that this defines success while we're under a one percent compliance target at the moment in that kind of a world.

LCFS T5-5

And as well, we don't believe that having credit costs rise to approximately $85 a ton during the initial part of the program before the credit freeze and having them draw it back down defines success.

LCFS T5-6

To summarize, we have two things to ask of the Board today. One is we obviously request ongoing staff reviews. And rather than what was in the program in terms of the dates in there, we would like to have those be on an annual basis that would allow stakeholder input and also help the Board help track of the health of the program.

LCFS T5-7

The second is that we request no further effort on ARB's part to create any post-020 LCFS targets. That's

LCFS T5-8

it.

CHAIRPERSON NICHOLS: Okay. Thank you.

Mr. Clay.

MR. CLAY: Good morning. Thank you for the opportunity to testify today.

I'm Harrison Clay, the President of Clean Energy Renewable Fuels. We are the largest producer, marketer, and distributer of biomethane vehicle fuel in the state of California. We produce and sell biomethane under the trademark Redeem.

In 2013, we sold 14 million gasoline gallon equivalents of Redeem in California. In 2014, we sold 20 million gasoline gallon equivalents. This year, we project we will exceed 40 million gasoline gallon equivalents of biomethane vehicles sold through clean energy stations.

This growth is a sign the LCFS program is working. It's creating incentives for companies like ours to get ultra low carbon fuel out to California's fleets. All of the CNG, LNG, the clean energy sales today from our retail CNG and LNG fuel stations is biomethane. That's a tremendous accomplishment and one we're very proud of and one that wouldn't have been possible without the LCFS program. As such, we are obviously strong supporters of the program and encourage the Board to re-adopt the rule.

06_T_LCFS _HClay

LCFS T6-1

We do have concerns about the administration of the rule. Really, there are two fundamental principles which I think are vital to the continued success of the the LCFS from the perspective of fuel producers like us. One of them is the regulation continues to be technology neutral. It is crucial that the staff and the Board administer the regulation in a way that allows for the lowest cost best performing low carbon fuels to come to market without interfering with the process or, for example, setting carbon intensity numbers based on political preference or an idea of what would be ideal under the right circumstances.

Regulatory stability and certainty is crucial. When CI numbers are published for fuel pathways, the business community, the fuel producers, we depend on those numbers. We count on those numbers. We have investment expectations that are set based on those numbers. And those numbers need to stay the way they are unless or until there is overwhelming unambiguous third-party scientific evidence they need to be changed. That is really crucial. If we end up in a situation where carbon intensity numbers become a matter of advocacy or subjective opinions of what kind of fuel is the best fuel for California, the regulation will really be threatened and the ability to raise money and put money into

LCFS T6-1 cont.

production of low carbon fuels will be compromised.

LCFS T6-1 cont.

With that, I would like to again thank you for the opportunity to testify and that concludes my remarks.

CHAIRPERSON NICHOLS: Great.

Before we get to the next witness, Ms. Solecki who was number four, returned. Please come forward and we'll hear from you now.

07_T_LCFS _MSolecki

MS. SOLECKI: Sorry about that. I was just trying to make an entrance earlier.

My name is Mary Solecki, and I'm the Western States Advocate for E2. And I'm here on behalf of E2's 600 California members that believe that the LCFS is a vital way for us to reduce our greenhouse gas emissions and to diversify our transportation fuels in the state.

And we have been really enjoying working with staff over the past -- well, not just this year, many years to refine and enhance the LCFS.

LCFS T7-1

We are looking forward to continuing to work with staff to refine and enhance the LCFS. And we would just urge you to re-adopt the LCFS when it is time for your vote. And we look forward to continuing to work on this really important program and support it. Thank you very much.

CHAIRPERSON NICHOLS: Thank you.

Mr. Heller.

08_T_LCFS _MHeller

MR. HELLER: Good morning, Madam Chair, Board members and staff. Miles Heller with Tesoro. We are a supplier of fuels in California and obligated party in the LCFS.

CARB staff has worked extremely hard to craft this regulation to meet the Board's goals. However, in our opinion, this is an impossible, given the availability and blending constraints of alternative fuels and the complexities of this proposed regulation.

LCFS T8-1

Given the brief comment time today, I ask the Board carefully consider the written comments submitted by WSPA and other obligated parties as the compliance buck stops with us. Tesoro's door is always open should you have questions about our comments.

Putting aside our view of fuel constraints, I would like to discuss CARB's illustrative compliance scenario which can be found in Appendix B, Table B 22. Taking their numbers at face value and focus on the reliance of banked credits. CARB's own numbers indicate some infeasibility. That by 2019, the credits that are generated from available fuels will not be adequate to offset the deficits generated in that year.

By 2020, there is a considerable gap. Only 70 percent of what is needed will be generated and the availability of credits for gasoline is only 36 percent of

LCFS T8-2

what's needed. That is the light green pie slice you saw in our presentation.

The only way the obligation is met in these years and beyond is by utilizing banked credits. These will run out. This is not sustainable. And we do not think that designing a program to rely on banked credits is wise. This is like telling a student at the beginning of a semester they will fail the final exam, but they can still pass the class if they do extra credit projects throughout the semester.

This does not bring certainty. And moreover, we believe overreliance on banked credits is flawed. First staff projections of credit accumulation in this scenario have already proven to be overly optimistic. Based on the most recent quarter, the projection is already off.

LCFS T8-2 cont.

Secondly, CARB presumes all credits will flow to match the need in both quantity and timing. It is not prudent to assume that obligated parties holding credits will sell to competitors at any price, particularly when they believe the credits will run out. Tesoro recommends CARB set the compliance schedule based on reasonable assumptions of fuel availability and blending capabilities and allow extra credits to be used for compliance margin in the hedge of future shortages.

LCFS T8-3

On a positive note, Tesoro appreciates CARB staff

LCFS T8-4

including language enabling refinery GHG reduction projects. We think this is a level playing field for all the other components and the life cycle analysis. While we support the concept, we find that some of the provisions CARB has proposed creates barriers that will significantly limit the credits from these projects. I cannot go through these limitations now, but we discussed solutions in our written comments. We discussed our concerns with staff and have expressed the willingness to work on these in the 15-day process. We ask the Board direct staff to help us in this regard.

LCFS T8-4 cont.

Thank you for your time.

CHAIRPERSON NICHOLS: Thank you.

Mr. Miller, could I -- since you're the first individual company to come up, I want to just clarify one thing.

As I read the staff report, they're not suggesting that you should comply using credits. They're just showing that as sort of the default if you will that indicates that the 2020 goal is not out of sight or out of reach.

But I hope you don't take this as meaning that we don't think you should be accelerating your efforts to develop and bring in other lower carbon alternatives that would help you comply. I mean, that's not the goal to

LCFS T8-1 cont.

have credits be the major way in which companies comply.

MR. HELLER: No. I certainly understand that. We've been bringing in the fuels to meet our compliance obligation and exceed it in some cases.

But the question becomes in the future when there is not even enough fuels available to do that, then you're left with using whatever credits have been banked in the system. And that's what I was trying to highlight.

LCFS T8-1 cont.

CHAIRPERSON NICHOLS: Okay. Thank you very much. Appreciate that.

09_T_LCFS _NEconomides

MR. ECONOMIDES.

MR. ECONOMIDES: Good morning, Madam Chair, members of the Board, staff.

My name is Nick Economides. I'm the Manager of state fuels regulation at Chevron. We, too are a regulated party under LCFS and a member of WSPA. And we have submitted extensive written comments for the record that we are sure you are going to take a look at. I will try to summarize some of my key points from that submission.

Chevron has worked closely with ARB over the period going back to last March on the proposed LCFS readoption, and we have outlined our concerns on the proposed revisions of the program. We appreciate staff's openness throughout that process, and we recognize that

LCFS T9-1

substantial refinements have been made in some areas. For example, the target CI reduction goals for 2016 through 2019. We remain hopeful that we will be able to continue working closely with staff in the coming months as the final package is prepared for your consideration.

Having said that, the LCFS program in our view will likely fall short of its original intended targets and should be adjusted to more accurately reflect the real world rate of development in market penetration of advanced low carbon intensity fuels.

Simply put, advanced cellulosic fuel development has not proceeded at the rate originally envisioned by ARB, and Chevron has first-hand knowledge of this. We have invested heavily in aggressive programming technology and regretfully we have not been successful. Staff's recognizes a challenges that lie ahead of us. Unfortunately, they're insufficient, as the previous speaker said, to establish the sustainability of the program. The Board should look beyond targets that are met largely through accumulated credits and weigh heavily where the program can stand on its own two feet. I.e. in any one single year, will there be enough CI reductions generated to match what is needed for that year?

LCFS T9-1 cont.

Chevron's view is that the proposed 2020 target of 10 percent is essentially aspirational. It depends on

LCFS T9-2

unrealistic credit build up leading up to 2016, bigger than justified contributions from renewable biogas and renewable diesel and unsubstantiated credits from refinery efficiency projects.

LCFS T9-2 cont.

I will conclude by coming back to something that was said earlier regarding strategy and certainty. We advocate that this program should bring certainty to the regulated community. We know you share that objective. But this strategy of setting higher-than-achieveable goals denies the regulated community the strategy needed to go forward. And it continues the climate of uncertainty that has shrouded this program since its inception.

We would like to be able to turn our attention to compliance, to implementation, to know that we have something that we can achieve and to go off and get it done. And until this happens, I'm afraid we will be here again meeting you shortly to discuss further adjustment to the program's goal. Thank you for your time.

LCFS T9-3

CHAIRPERSON NICHOLS: Thank you.

Melinda Hicks and then Dayne Delahoussaye.

10_T_LCFS _MHicks

MS. HICKS: Chairman Nichols, members of the Board, thank you for the opportunity to come before you today and provide testimony.

My name is Melinda Hicks. I'm the Environmental Health and Safety Manager for Kern Oil and Refining

LCFS T10-1

Company, a small independently-owned refinery located in Bakersfield.

Kern refines approximately 26,000 barrels per day of crude oil for the production of CARB gasoline and diesel. And Kern is proud to say that we have continuously operated without fail since the 1930s, surviving a difficult industry through economic downturns and increased regulatory burden. Where many others cannot say the same.

Further, Kern is proud to say we have embraced the LCFS, being the first refiner in the state to produce renewable diesel and one of the first to blend biomass-based diesel with CARB diesel.

Overall, Kern is supportive of the proposal. We would like to highlight our support in three separate specific provisions today:

First, Kern strongly supports the low complexity, low energy use refinery provision. This provision addresses an inequality inherent to the program's reliance on the average refinery to fit the extremely broad range of refineries that operate in California.

Kern is grateful that the Board previously directed staff to consider such amendments. Certainly, years of extensive staff analysis using refinery data and stakeholder input have resulted in the low complexity, low

LCFS T10-1 cont.

energy use refiner provision. And the ISOR clearly lays the strong scientific and technical basis for both the magnitude of the credit and the criteria for eligibility. The provision will correct what has been a disproportionate negative impact on refineries like Kern that do not fit the average.

LCFS T10-1 cont.

Second, Kern supports the refineries specific incremental deficit option. Kern is encouraged that staff acknowledges that refiners like ourselves can be adversely impacted by the California average crude CI, but themselves cannot effect the sector-wide average. This provision gives us the option to be individually evaluated based on our own base line.

LCFS T10-2

Third, Kern supports the refinery investment credit and appreciate ARB's incentive to perform projects that will reduce a facility's carbon intensity through real GHG reductions.

LCFS T10-3

Of course, I would be remiss this morning were I not to say many thanks to staff for all of their dedication and endurance in working with Kern over the past few years. Thank you.

CHAIRPERSON NICHOLS: Great. Thanks.

Mr. Delahoussaye.

11_T_LCFS _DDelahoussaye

MR. DELAHOUSSAYE: Good morning. My name is Dayne Delahoussaye, and I'm here on behalf of Neste Oil.

LCFS T11-1

Neste Oil is supportive of the readoption program, and I just want to take the time to testify to give additional context for your consideration.

We, along with many other low carbon fuel producers, made significant capital investments in response to the LCFS implementing the demand for renewable and low carbon fuel. Specifically, we invested well over two billion dollars as part of our global capacity. Changing the course or significantly alter the goals of the program at this late stage will have a severe chilling effect on any future potential investments as participants, investors in capital markets will lose confidence in California's commitment to follow through with its policy goals.

According to readoption of a stable LCFS is necessary as a next step to fulfill the commitment California has made to those producers to support those investments and realize true change in the air quality resulting in California's transportation fuels.

Implementation of a stable low carbon fuel standard in California will send a proper signal to fuel producers like Neste Oil and will provide a significant driver to draw low carbon fuels to the state and adequate volumes to comply with the target of 10 percent carbon reduction.

LCFS T11-1 cont.

In addition, the stabilization, the ARB should use this readoption conversation as a spring board to begin to formulate and implement longer-term targets. Producers cannot recoup large capital investments in short economic cycles. We support the investments and continue growth and production of low carbon fuels. The market will require signals effective and robust beyond the 2020 time frame currently at issue here. LCFS T11-2

Additionally, proper implementation of the program is paramount to the success of the LCFS, not just design. The LCFS receives staff's continued ability to timely process and approve complete pathway applications as an obstacle to additional volumes of carbon fuels to be available to California.

Fuels with lower carbon intensity by definition have a higher economic return on the system. However, absent the confirmed CI determination, a producer might reduce fuel production or send the fuel to a more economical market outside of California. Removal of those barriers to otherwise credit generating fuels through the California transportation fuel could generate shortage not because of a failure of the market or program design, but again as a failure of just timely implementation. LCFS T11-3

And we encourage the Board to work with staff to put an approval process in place to make new fuels that LCFS T11-4 are compliant yet timely and prompt CI scores so they can participate in the fuel to generate credits.

LCFS T11-4 cont.

The final thing I want to talk about is I heard some potential comments about the blend levels of renewable diesel and that can be an obstacle. I would encourage the Board to not give that significant value, that that are high values and renewable diesels being available as compliant within California.

LCFS T11-5

Additionally, we see the path forward for getting different labeling solutions being feasible and something that can be likely achieved in the short term and not going to be a long-term detriment to the 2020 goals and the use of this particular combined fuel.

LCFS T11-6

I'm available for any questions, should you have any.

CHAIRPERSON NICHOLS: Yes.

BOARD MEMBER SPERLING: One quick question.

What do you think of the $200 price cap for credits?

MR. DELAHOUSSAYE: The $200 price cap I don't have a basis for and it the current economic it makes sense. But that assumes that there is a valid rent in place with the federal program and that. Absent the federal program that seems to be an arbitrary number that does not support California on its own. So 200 dollars I

LCFS T11-7

would say is only valid in this up to 2020 period anything beyond that I think need to be re evaluated and needs to be viewed in cooperation with the federal mandate that already exists for these fuels.

LCFS T11-7 cont.

CHAIRPERSON NICHOLS: Thank you.

Mr. Grimes.

MR. GRIMES: Good morning, Chairman Nichols and Board members. I'm Gary Grimes, Director of Technology at Paramount Petroleum, an Alon USA company. Alon owns and operates two small refineries in Southern California. We strongly support the Board's decision over two years ago to recognize the differences between the state's smaller lower complexity refineries in its larger higher complexity brethren.

We wish to thank your staff for quantifying this difference and developing a workable regulatory mechanism that is included in today's proposal.

12_T_LCFS _GGrimes

The LCLE provision, as it's known, appropriately accounts for the reality of California's two distinct refinery populations. Lower complexity refineries produce gasoline and diesel fuel using less than half the energy in carbon intensity per gasoline of the larger complex refineries. This is the sound technical reason behind the policy recognized in the LCLE category. Alon supports the inclusion of the LCL provisions.

LCFS T12-1

Although our Bakersfield refinery has not been in full operation since the bankruptcy proceeding a few years ago, the facility still maintains small operation and contractually delivers fuel from its racks.

Also, there is considerable engineering and permit work being done at the local level to allow restoring much of its previous operations. At such time when it comes back, its carbon intensity profile will fit within the small refinery grouping. Therefore, it's important to get the eligibility criteria right during this rulemaking.

LCFS T12-2

On that front, Alon has been working with staff to ensure that the LCLE provisions incorporate all facilities that should be considered LCLE. These discussions are ongoing, and we look forward to positive resolution before the next Board meeting.

Besides the enormous local benefit to Bakersfield of operating this existing energy asset, there will be an ongoing benefit as well to the state. Annually, the refinery emissions associated with the fuel production from the Bakersfield refinery are expected to be 350,000 metric tons of CO_2 lower than the fuel that was produced by an average California refinery. This is clearly a significant and material reduction for this program.

LCFS T12-3

In conclusion, Alon's respectfully supports the

LCLE provision and looks forward to a continue dialogue on this issue. Thank you.

CHAIRPERSON NICHOLS: Great. Thanks.

Celia.

MS. DU BOSE: Good morning, Chair Nichols, Board members, and staff.

My name is Celia DuBose. I'm the Executive Director of the California Biodiesel Alliance. We are the industry trade association for biodiesel. We represent over 50 stakeholders, including feedstock suppliers, distributors, marketers, retailers, and all of the state's producers.

So I'm happy to be here today in support of comments from the National Biodiesel Board, which will be coming up, and to stand with the low carbon fuel sector in urging your support of the readoption of the low carbon fuel standard.

First, I want to thank staff for the extraordinary effort that they put out in gathering comments, incorporating these comments, drawing on your own experience from running the program to build a better LCFS. And we value very much in all of this there is a high priority placed on creating a stable regulatory environment as key to the investor community.

13_T_LCFS
_CDuBose

So our industry has gone on record in support of LCFS T13-1 the compliance curve, the price cap. And we've let you know just how much biodiesel is available to reach program targets. In addition to our 59 million capacity in state, there is over 1.5 billion gallons of biodiesel. And to put a very fine point on this, this is an advanced bio fuel. It's renewable. It's non-toxic. It's biodegradable. It's American made.

LCFS T13-1 cont.

So bio diesel has generated an increasing number of LCFS credits since the program began. Our cumulative number is up to 13, as of the third quarter in 2014. And we are growing. Our industry in the state has grown as a result of LCFS as an incentive. We expect that to continue. We are really happy about our ability to bring the low carbon profile of biodiesel, this emissions profile, to the goals of LCFS. And we look forward to being able to provide more biodiesel benefits to other programs, which we'll talk about later. So thank you very much.

CHAIRPERSON NICHOLS: Thank you.

Ms. Case.

14_T_LCFS _JCase

MS. CASE: My name is Jennifer Case. I'm one of the founders of New Leaf Biofuel, a biodiesel refinery in San Diego.

Thank you for the opportunity to speak today. And thank you to staff and leadership who has spent

LCFS T14-1

countless hours coming up with solutions that help lower greenhouse gases here in California.

I was working as one of California's many lawyers when AB 32 was signed. And don't hold that against me. But due to the groundbreaking legislation and a grant from this agency, the alternative fuels incentive program, my friends and I were able to come together and build our biodiesel refinery in San Diego in the disadvantaged community of Barrio Logan.

Our business plan has always focused on recycling a low value feedstock into an ultra low carbon fuel that we sell back to the community in blends up to and including B20. Our community scale model allows local fleets to reduce their carbon footprint and support a local business at a cost that is comparable to the petroleum diesel alternative.

LCFS T14-1 cont.

I fully support the readoption of the low carbon fuel standard, and I look forward to continuing to work with this agency on the alternative diesel fuel regulation, specifically with regard to finding solutions that allow my business to continue its mission to work with my local community to improve air quality and public health. Thank you.

CHAIRPERSON NICHOLS: Thank you.

Mr. Neal.

MR. NEAL: Thank you, Madam Chair and members of the Board. My name is Shelby Neal. I serve as Director of State Governmental Affairs for the National Biodiesel Board.

For those of you that may not know, the NBB is the national trade association for both the biodiesel and renewable hydrocarbon biodiesel industries. We added renewable diesel to our membership about a year and a half ago.

In order to be brief, I'll just confine my comments to one particular issue. Sometimes I find in a matter of when we have long protracted discussions and debates, the simple facts of the matter are lost or at least obscured. I think sometimes that's happened a little bit here with regard to fuel availability, which is really what I want to focus on. LCFS T15-1

So just a few verifiable facts about fuel availability on the diesel side. So you can go on U.S. EPA's website and check these out.

So when we look at what's happened in biodiesel and renewable diesel space in the U.S. the last couple of years, in the U.S. domestically, we produce 1.4 billion gallons of product. In 2013, we produce 1.5 billion gallons of product. That's a lot of product, considering especially ten years ago you were buying biodiesel by the jar. Now we're at 1.5 billion gallons. If you look at the U.S. market, it's been 1.8 billion gallons the past two years. There was already a lot of biodiesel and renewable diesel in this country. California would only require a fraction of that.

But the real story is not production. The real story is capacity. Capacity -- this is registered, verifiable on U.S. EPA's website -- is over 3 billion gallons. That's 3 billion gallons of product in potentially California we require one-eighth of that.

So we're here today and we're affordable. If you look at pricing across the country, for the past three years, we have this data biodiesel has been 22 cents cheaper than petroleum at the wholesale level. So I think the story with fuel availability -- and I'll confine my comments to the diesel fuel side because that's our particular expertise, is a real positive one.

In the biodiesel industry, our motto from the beginning has always been local feedstock, local production, local markets. So the question is what's happening in California. Again, very positive story. I pulled our production data from last year so pre-LCFS, California really, with all due respect to our members, was not on the national radar screen on production. Now California ranks 13th out of 46 states in biodiesel

LCFS T15-1 cont.

production. We're nearly in the top quartile. And we moved from the bottom quartile in a very short period of time.

Now, by 2018 and 2020 with these regulations based on our experience and other states, we would expect California to possibly enter into the top five of production.

So one final thing. Again, there has been a lot of -- I think there there is some areas of this regulation that are extremely complex. And it's necessary to engage in informed speculation. But this isn't one of them.

And I'll continue.

So if you look at the state of Illinois, Illinois has a very strong biodiesel use policy. Three quarters of the --

BOARD MEMBER BERG: If you could give us a concluding statement, that would be helpful.

MR. NEAL: Illinois has a biodiesel policy that's providing between a nine and ten percent GHG benefit. So there is already a state that on the diesel side is meeting the 2020 requirement here. There should be no need for speculation.

LCFS T15-1 cont.

BOARD MEMBER BERG: Great. Thank you very much.

16_T_LCFS _RTeall

Russell Teall.

MR. TEALL: I was going to say good morning. I

LCFS T16-1

guess it's not anymore.

My name is Russell Teall. I'm the President of Biodico. We're a sustainable biodiesel facility using anaerobic digestion, gasification, and solar. So 100 percent renewable.

I'm also the president of the California Biodiesel Alliance and have been on both advisory panels for the low carbon fuel standard. So I've watched this program evolve over time and with the trials and tribulations of the lawsuit.

Richard Corey and his staff should be commended for hazardous duty being in the line of fire, having to negotiate between the biofuels groups, the NGOs, the oil companies, et cetera. I think they've actually done an excellent job. And it goes all the way down through the staff level. The staff people that we've dealt with have been open, receptive, trying to operate on a factual basis. And, you know, nothing is perfect. But I think it's a good compromise.

Our particular facilities are being expanded as a result of the low carbon fuel standard. So we began in California in 2003 with the US Navy as part of a cooperative research development agreement. And the secretary of the Navy six years ago set a goal by the year 2020 of a 50 percent reduction in fossil fuel use. So

LCFS T16-1 cont.

it's a very strong leadership position. That facility also happens to be or was until redistricting in 600 Pavely district.

So our other facility is in Henry Perea's district in the Central Valley in western Fresno County. That's a new facility. Construction is going on right now. That's slated to be a ten million gallon a year facility.

So I've been talking about biodiesel. But I think that it's going to take, as President Obama said, an all of the above approach. All the biofuels, electricity, hydrogen, fuel cells, renewable diesel, all the alcohols, ethanol, and advanced alcohols, those are all part of the fuel mix and part of the diversity. So I think that the low carbon fuel standard readoption process is setting the right message and the right tone at the right time to stimulate further market capabilities.

LCFS T16-1 cont.

Thank you.

BOARD MEMBER BERG: Thank you. So everybody can check their time, we are at about a few minutes after noon. We're going to take our lunch break at 12:30. And that will go until 1:30. We'll probably get through the next eight speakers, if we kind of look at where you are on the list and we can kind of get lined up. And so that's what we can kind of expect for the next half hour

17_T_LCFS _JLevin

or so. Thank you.

Julia.

MS. LEVIN: Members of the Board, I'm Julia Levin with the Bioenergy Association of California. We represent more than 50 public agencies, local governments, and private companies that are converting organic waste to energy. And we strongly support the readoption of the low carbon fuel standard. We believe it is very much achieveable.

Organic waste alone in California, the organic part of the waste, livestock waste, agricultural waste, wastewater treatment facilities, together those facilities produce enough organic waste to generate two and a half billion gasoline gallons equivalents of very low carbon and sometimes carbon negative transportation fuels. Two and a half billion gasoline gallons equivalents, that's enough to replace three-quarters of all the diesel used by motor vehicles in California.

So in addition to meeting the low carbon fuel standard, we would provide enormous benefits to public health by reducing NOx and particulate matter and toxic air contaminants.

In order to achieve those benefits, California needs to continue to invest not just in a low carbon fuel standard, but specifically in natural gas vehicles and

LCFS T17-1

natural gas infrastructure. Natural gas and biogas are inextricably linked. We use the same vehicles. We depend on much of the same infrastructure.

So we urge the Board not only to re-adopt the low carbon fuel standard, but to continue to invest in natural gas vehicles and the natural gas infrastructure that makes it possible to use biogas, the very lowest carbon transportation. Thank you.

LCFS T17-1 cont.

MS. MENDOZA: Good afternoon, Jerilyn Lopez Mendoza representing the Southern California Gas Company.

I first of want to apologize for my expression today. I'm very stuffed up and my ears, I can't hear anything because of the flight. So I can't even hear my voice. So if I'm speaking really loud, I apologize.

So first of all, I want to begin my comments by saying Southern California Gas Company is very much in favor of this Resolution moving forward and the Board approving the readoption of the low carbon fuel standard. We believe it's the right way, one of the right ways to get us to the low carbon fuels in the state where we continue to be very supportive.

18_T_LCFS _JMendoza

However -- you know there was going to be a however. We have two concerns moving forward. In terms of the implementation of the program between now and July, the final vote will be as well as beyond July and

LCFS T18-1

implementing the program into the future.

First of all, we want to make sure and we want to emphasize to the Board and to staff that we would like the GREET model to be based on the best available data that we have available to all of us. Meaning, objective scientific analysis, data that's recent, that's from third parties, and from academics and folks who have a lot of expertise in the field with respect to methane leaks and with respect to natural gas and its efficacy within this framework.

LCFS T18-1 cont.

Secondarily, we're also concerned about stakeholder engagement as we move forward. During the presentation in PowerPoint slides number 20 and 37, there were verbal references to engaging stakeholders in the process moving forward between now and July and then beyond July.

But in the next steps articulated by staff in slide number 39, there is no bullet point that specifically relates to stakeholder engagement, stakeholder dialogue. So it's not clear to those of us who are very invested in the process and invested in this program moving forward how can we most appropriately and formally engage with staff and get our concerns on the table before you and have it be part of the ongoing process to ensure that that scientific analysis is as

LCFS T18-2

rigorous as possible. So we just want to make sure there is no confusion as it relates to public review and engagement.

LCFS T18-2 cont.

And finally, we look forward to working with staff towards the continued success of this program. I believe over the past year that I've been working at the gas company we've built up some great relationship. There have been educational dialogues back and forth. And we're learning from each other in terms of staff, from ARB and staff from Southern California Gas. We like to continue to move that forward.

LCFS T18-3

And just my final point I just wanted to appreciate all the time taken by Board members and staff in the last few weeks, particularly in terms of engaging in a meaningful discussion with us about the program. Thank you very much.

CHAIRPERSON NICHOLS: Thank you. Matthew Plummer.

19_T_LCFS_MPlummer

MR. PLUMMER: Matthew Plummer, Pacific Gas and Electric Company.

First, PG&E would like to express its support for the low carbon fuel standard and encourage the Board to move forward with readoption.

Like my colleague at So Cal Gas, we have a number of technical issues we'll need to continue to work with

LCFS T19-1

staff on between now and the Board vote. We also like to thank staff and thank the Board for their continued willingness to meet with stakeholders. We look forward to many more constructive conversations in the months to come. Thank you.

LCFS T19-1 cont.

20_T_LCFS _CWright

BOARD MEMBER BERG: Thank you.

MR. WRIGHT: Good afternoon. I'm Curtis Wright. I manage the biodiesel operations Imperial Western Products. We're a biodiesel plant located in Coachella, California. We've been in operation since 2001. Over this time, we made over 55 million gallons of biodiesel, all from used cooking oil we collect in the area. What's interesting is that since the introduction of the low carbon fuel standard and the last four years we made more than half of that 55 million gallons. It's given our business a lot more certainty and more of a market out there. So we strongly support readoption of the low carbon fuel standard. That will help us to continue to grow, add jobs, and provide clean, low carbon biodiesel to Californians. Thank you.

LCFS T20-1

BOARD MEMBER BERG: Thank you very much, Mr. Wright.

John O'Donnell.

21_T_LCFS _JO'Donnell

MR. O'DONNELL: Good afternoon. My name is John O'Donnell with the Glass Point Solar. We are a leading

LCFS T21-1

provider of solar steam generators for the oil industry.

And I'm here to speak in support of the modifications and the specifically innovative crude provisions of the low carbon fuel standard.

The use of solar energy represents the largest lowest cost and lowest risk approach to reducing the carbon intensity of petroleum fuels produced here in California.

And as part of our written comments, we submitted an economic impact study that was carried out for us recently by ICF, which found that if the identified market opportunity here in California, if those solar projects were built, we would be delivering over their construction and operations some 45,000 cumulative job years and some five billion dollars of increased economic activity, increased gross state product here in California. We believe that the modifications in streamlining and simplification to the innovative crude provisions that are included in the current package set the stage so that our contribution can be brought to reality. And we look forward.

LCFS T21-1 cont.

BOARD MEMBER BERG: Thank you very much.

Ross Nakasone.

MR. NAKASONE: Happy new year to every one. My name is Ross Nakasone with the Blue Green Alliance. We're

22_T_LCFS _RNakasone

a national coalition of labor and environmental groups including the United Steal Workers and Natural Resource Defense Council.

Our mission is to really try to encourage folks to address their environmental challenges in ways that create and maintain sustainable jobs. To that end, Blue Green Alliance supports the readoption of the low carbon fuel standard.

I'd like to thank Richard Corey and the rest of CARB staff for their hard work. Over the past three years, steal workers, NRDC, and Blue Green Alliance have worked together to provide recommendations to CARB staff particularly on program flexibility that encourages investments in refinery projects that reduce GHG emissions.

LCFS T22-1

Credits for refinery improvements represent, we believe, a significant opportunity to spur additional investments that can improve environmental performance of refineries and create secure refinery jobs while reducing the carbon intensity transportation fuels, and of course, fostering additional benefits such as reductions in criteria pollution.

We appreciate staff willingness to hear our ideas and to incorporate them. Steal workers, NRDG, BGA, believe the improvements to the low carbon fuel standard further our shared vision of better jobs and a better environment. With that, BG urges you to approve this Resolution.

MR. UNNASCH: I'm Stefan Unnasch with Life Cycle Associates. Thank you for the opportunity to speak.

I've been involved in fuel LCA issues for the ARB since 1994, including presenting on the environmental impact of ZEVs in 2000 and developing the California GREET model in 2009.

Since that time, the ARB staff has come a long way. They've learned, you know, virtually every aspect of fuel LCA. And I would like to commend their efforts and the whole process of understanding biofuels and petroleum fuels has really moved along. And the LCFS is doing a good job.

23_T_LCFS
_SUnnasch

There are some areas of improvement. I submitted some comments. One of them has to do with the effect of the nitrogen cycle on biofuels. And the other has to do with marginal electricity. Basically, the idea with electricity is we're getting the cleanest electricity into the electric vehicles and into the hydrogen electrolysis in California. There is no nuclear. There is no whole power that's going into those. If you run an electric car, you're not making a coal power plant go on. You're not making a nuclear power plant go on either. What's on

LCFS T23-1

the margin is, you know, fairly well understood. And it's important for several fuel pathways. So those comments should be considered.

LCFS T23-1 cont.

So on balance, you know, we've gone through a lot in the past seven years. And I think we understand a lot more about indirect land use, a lot about all of the fuel pathways, and encourage the ARB Board to readopt the LCFS this summer.

CHAIRPERSON NICHOLS: Thank you very much.

Chuck White.

MR. WHITE: Thank you very much, Chairman and members of the Board.

Chuck White representing Waste Management. Waste Management is a strong supporter of the readoption of the low carbon fuel standard. Waste Management provides comprehensive recycling and solid waste services throughout California and the U.S. And you're probably familiar with my big green heavy duty refuse and recycling trucks you see throughout California. One half that fleet in California is natural gas. In fact, the vast majority of that natural gas fleet is being fueled by renewable natural gas. And a large part of that is being produced -- as far as we know, the only very low carbon fuel production facility here in California that produces LNG or CNG. That's our Altamont landfill, producing

24_T_LCFS
_CWhite

13,000 gallons a day.

Waste Management can build a lot more of these facilities, both in California and fuel is brought to California if we had certainty and security of the price we need to repay the capital cost and operational costs of these ventures.

Unfortunately, the political and legal challenge that the low carbon fuel standard has faced over the last years has created the level of uncertainty that really has deferred us from making further developments until we can see a pathway to get a return on our investments for these. We're anxious to do so and strengthen and readopt a low carbon fuel standard will certainly do that.

We have been unable to get long-term contracts for the production of credits, both green credits and LCFS credits to be able to cover our cost. Without that degree of certainty, we've been unable to do that.

We first saw the LCFS credit for $10 and then $80 a ton and now back down to about $25. We do produce a lot of fuel for California, well less than $200 per LCFS credit, I can assure you of that.

LCFS T24-1

The uncertainty is, like I said, also due to the political and legal uncertainty. But also has to do with the uncertainty over the CI values. I'm glad staff is looking at that during the 15-day re-notice period, the CI

LCFS T24-2

adjustments. That's created a lot of nervousness on the natural gas sector. We're not opposed to the right number being used for the carbon intensity renewable natural gas. It's just making sure it is the right number and making sure it's based upon best science available to ensure that is being supported.

LCFS T24-2 cont.

In summary, it's most important today that you readopt the low carbon fuel standard. I originally thought I would be arguing for a floor. I'd like to have a floor on the price to complement the ceiling on the price at 200, but get the thing readopted. Get it functioning, back on track again. That is by far and away the most important part.

LCFS T24-3

And again, making sure that if you change the CI number, particularly if you increase the CI number on a fuel, you make sure it's the right CI number that's well based on fact and size. Thank you very much.

LCFS T24-4

CHAIRPERSON NICHOLS: Thank you.

Mr. Darlington.

MR. DARLINGTON: Thank you. Good afternoon. My name is Tom Darlington. I'm President of Air Improvement Resource, consulting firm providing engineering and consulting services in the area of alternative fuels.

25_T_LCFS _TDarlington

I'm here to address the modeling indirect land use changes. As indicated, I'm here on behalf of the

LCFS T25-1

POET, which operates 26 corn ethanol bio-refineries in the United States and is a pioneer in the effort to bring cellulosic biofuel to the market.

POET has participated in the rulemaking process on the proposal being considered today and concurs with Growth Energy's comments that were submitted. Our company has participated in all of the ARB workshops on land use emissions and the GREET life cycle model and has provided detailed written comments.

As indicated in those comments, we do not agree with the land use change emissions factor that the staff is proposing for corn starch ethanol.

LCFS T25-1 cont.

The main point I'd like to make today is that the staff has deferred, we feel, too many significant issues raised in the technical literature and by stakeholders since 2009 for future research. Many of these issues were identified several years ago.

LCFS T25-2

The table on the screen shows the status of some of the items that we have recommended. And as you can see, some of these items have been deferred for future research. The most serious of these is the emission of the multi-cropping effect, but others are important as well. We and others, including the expert working group, recommended that ARB include the effects of double and multi-cropping, which refers to the common practices in

LCFS T25-3

certain regions of harvesting more than one crop on the same land per year.

Multi-cropping uses existing crop land more intensively, thereby reducing the need for land conversions from both forest and pasture to crops. The economic model used by ARB does not include double or multi-cropping. This is a serious shortcoming that leads to higher land use emissions from all feed stocks.

LCFS T25-3 cont.

The omission of idle and fowl land is also a serious concern in this model. The importance of including multi-cropping was clearly illustrated by a study recently released by Professor Bill Babcock of Iowa State University. I'll quote a little section, but, "The contribution of this study is to confirm that the primary land use change response of the world's farm is from 2004 to '12 has been to use available land resources more efficiently than to expand the amount of land brought into production. This finding has not been recognized by regulators who calculate indirect land use."

LCFS T25-4

So in sum, if the land use emissions of corn ethanol are over-estimated, then the carbon intensity of corn ethanol is too high, leading to a reduction in corn ethanol in California without a accompanying greenhouse gas reduction. This is not only a problem for POET. It is a problem for California because it leads to

LCFS T25-5

unnecessary fuel shuffling and a loss of greenhouse gas emission benefits. Thank you, again.

LCFS T25-5 cont.

CHAIRPERSON NICHOLS: Thank you for wrapping up.

Jessie David. And then Perry Simpson and Todd Campbell. And then we're going to take our lunch break.

26_T_LCFS _JDavid

MR. DAVID: Thank you.

Again, my name is Jessie David. I'm an economist and partner at Edgeworth Economics Consulting Firm with offices here in California. I received my Ph.D. from Stanford, and I specialize in environmental economics and public finance. I've been doing regulatory evaluation for about 18 years.

I was retained by Growth Energy, an association representing producers and supporters of alternative fuels to analyze the impact of the LCFS on ethanol producers. I'd like to summarize my analysis, which is included as an appendix to Energy's extensive written comments.

I was asked to consider what the analysis in the Initial Statement of Reasons, the ISOR, says regarding the impact of the new program to Midwestern corn-based ethanol in California's motor fuel mix. The ISOR presents an illustrative compliance scenario we heard about today, which is CARB staff's projection of one potential pattern of compliance that we meet the proposed standard.

Staff projects a reduction in corn ethanol

LCFS T26-1

consumed in California by almost half by 2020, with most of that being replaced by cane ethanol from Brazil.

Staff also assumes that the credit price would be $100 in 2016 through 2020. This value presumably would provide the impetus for switching from a less expensive to what's currently more expensive type of ethanol that is currently the primary choice of fuel marketers in California.

So to determine whether credit price of $100 would, in fact, cause marketers to switch in this manner, I analyze the total delivered cost of both types of fuels and their various assumptions. I use data on current projected fuel prices, REN values, and freight rates from public sources. And I supplement it with information about freight patterns and costs. I use CARB's projections of the future average CI level for those fuels.

LCFS T26-1 cont.

I calculated based on currently available forecasts which shows a narrowing of the price spread between corn and cane ethanol in 2016, a credit price of about $36 would lead to a switch from corn ethanol with CI ratings in the low 90s to cane ethanol with a CI rating of 72. A credit price of around $77 would cause a switch from corn with CI ratings in the low 80s to cane ethanol.

Moreover, if cane ethanol can attain the average

LCFS T26-2

ratings predicted by CARB, then the switch to cane from corn would occur at even lower credit prices. For example, CARB projects Brazilian cane ethanol with an average CI rating of 40 by 2016. At this level, a credit price of only $23 would result in a switch from corn to cane, which CARB projects would have a CI rating of 70. That is corn as of 2016.

LCFS T26-2 cont.

CARB's illustrative compliance scenario indicating a substantial decline in the use of corn ethanol with replace it. Cane ethanol is therefore not only plausible, but likely, if assuming the availability of sufficient Brazilian ethanol is rejected by CARB. This is true, even assuming credit prices well below $100.

In sum, based on the current ratings predicted by the ISOR, the future midwest corn ethanol is at risk in California. Even ratings as low as 70 would be at risk under these conditions. And if the industry can't achieve those ratings, the impact could be more severe. Thank you.

LCFS T26-3

CHAIRPERSON NICHOLS: Mr. Simpson.

MR. SIMPSON: Hi. I'm Harry Simpson from Renewable Energy. I am the President. And we, last year, had the distinction of being the largest biodiesel producer in California.

So, first, I want to thank the ARB staff and leadership for their consistent engagement over the last many years and really reaching out to all stakeholders to get that input to craft the proposed regs that we have before us today.

And I also want to thank them on behalf of our employees here in California and the local community that we serve in the valley for their commitment to a more sustainable and broadly beneficial future for transportation fuels in California.

Secondly, I'd like to say that LCFS is working. It has been working as intended as originally envisioned. The credit generation thus far has been consistent with ARB staff projections. Credit generation through Q3 of 2014 was nearly four million metric tons of excess credits, which was consistent with the original projections once the compliance requirements froze one percent.

27_T_LCFS _HSimpson

We strongly urge the Board to accept the staff recommendations to stay with the original time line of a ten percent reduction in 2020. We believe that this is fully achieveable and echo the comments that you've heard from various industry groups and individual companies concerning different types of alternative fuels, be it biodiesels, renewable diesel, biogas, electric vehicles, and I'm sure some others that I haven't come up with yet.

LCFS T27-1

We believe this is critical to send a strong market signal. Indeed, the only reason why we chose o build this plant this California back in 2008 and '09 was because of LCFS. If it wasn't for LCFS, we wouldn't be here and I wouldn't be speaking today.

Having the certainty of this time line will inspire additional investment on a broadly macro level if you will, but also on an individual company level. In the case of a company like ours, it may inspire additional investment in the form of expansion or taking on new projects to reduce our CI, to take advantage of lower CI feed stocks, or to engage in the development of renewable energy sources to a few more plants, such as biogas from a co-gen turbine system.

I urge the Board to consider ongoing carbon reductions beyond 2020 to keep the momentum moving forward and send those market signals as well. Thank you.

LCFS T27-2

CHAIRPERSON NICHOLS: Thank you.

Mr. Campbell.

MR. CAMPBELL: Good afternoon, Madam Chair and members of the Board.

28_T_LCFS _TCampbell

Todd Campbell, Vice President of Public Policy and Regulatory Affairs for Clean Energy. Clean Energy has been an original supporter of AB 32 and the low carbon fuel standard. And we are proud to remain in strong

LCFS T28-1

support of the rule's re-adoption. The fuel neutrality of the standard is perhaps the most attractive to Clean Energy because it encourages innovation of fuels and processes.

LCFS T28-1 cont.

And Clean Energy, as you know, has been a leader in developing not just natural gas in the conventional sense, but also renewable natural gas on a broad scale. So much so that when you pull up to our station, any station within California and fill your natural gas vehicle up, it is being fueled with renewable natural gas and ultra low carbon fuel. None of this, of course, would be possible without your collective leadership, staff's and Board's. And so I want to congratulate you on that.

In an effort to support the Air Resources Board further, clean energy has been actively engaged in supporting other low carbon fuel markets in Oregon and Washington, and we believe those markets will succeed as well.

However, it is critical that we get the carbon intensity values of natural gas and renewable natural gas correct. We have been working extensively with staff over the last few months. We believe that we've achieved some success with the staff. We do believe that we need to continue to work with staff.

LCFS T28-2

I want to acknowledge the several mentionings of staff during the presentation that they recognize that there is a continuing effort to or a need to continue to work on these CI values. We at Clean Energy significantly appreciate that ability or that willingness to continue to work with us before the rule is finally adopted.

I also like to say that just so the Board understands why we care so much about this, we have ICF International and GNA working with us closely on trying to help ARB staff get to the right number. And for every gram per megajoule that is added from the original GREET model showing our carbon intensity, using a medium value or base case scenario of a credit value of $50, it could mean a 15 to $58 million potential economic benefit or loss for our industry. And if we're going to help achieve 2020 values -- and I suspect this agency is going to look for 2030, 2040, 2050 -- we need to be able to have certainty, and we need to be able to continue investing in ultra low carbon fuels that will get us to where we need to be to prevent climate change. Thank you.

LCFS T28-2 cont.

BOARD MEMBER SPERLING: One tiny question.

What percentage of your gas that you're supplying to vehicles is biomethane renewable gas?

MR. CAMPBELL: In California and all our public stations it's 100 percent.

BOARD MEMBER SPERLING: What about going forward?

MR. CAMPBELL: In other words, if you looked at other fuels that use blends, we can also in future years as you go further up in carbon intensity reductions, you know, the blend probably will go down. But we will do our best to maintain 100 percent, of course.

But as Julia mentioned earlier, this is not just a 20 or 40 million gallon market where just for clean energy delivery alone. It's several billion gallons potentially, if not more. And I think staff -- I think we're helping staff become believers in renewable natural gas as a transportation fuel, because in the past, if you looked at the proposed scenarios, you wouldn't see very much renewable natural gas in there. But you're starting to see a significant slice of the pie in those forecasted scenarios.

BOARD MEMBER SPERLING: I like it. Thank you.

CHAIRPERSON NICHOLS: On that note, we're going to take a lunch break. We're going to try to keep it to an hour. The Board will be in executive session during that period. And we'll see you all back here at 1:30. Thanks.

(Whereupon a lunch recess was taken at 12:32 p.m.)

CHAIRPERSON NICHOLS: Welcome back, everybody. Before I forget, if you didn't sign up on the list and you've suddenly been inspired with a desire to speak to us on this issue, would you please sign up with the Clerk over here, because we would like to close off the list just so we can know that we actually could close off the hearing on this item. We do have a couple of Board members who have to leave and who really want to be able to speak to this issue and to participate in the Resolution.

CHIEF COUNSEL PETER: Madam Chair, you need to report on the closed session.

CHAIRPERSON NICHOLS: I will. We had a closed session. Thank you. And it was Board members only. No staff were included. The topic was a personnel review. It was a report by two Board members on the review they had been asked to do. They reported successfully. No action was taken. Thank you.

Okay. Let's continue with Jonathan Lewis.

29_T_LCFS _JLewis

MR. LEWIS: Thank you and good afternoon. My name is Jonathan Lewis. I'm Senior Counsel at Clean Air Task Force. CATF is a nonprofit organization that works to help safeguard against the impacts of climate change by catalyzing the rapid global development and deployment of low carbon energy and technologies. CATF has submitted written comments and made several points. First and foremost, that ARB should adopt the LCFS through 2020.

LCFS T29-1

Achieving compliance with the 2020 target would be difficult. The LCFS remains the most promising policy available nationwide for reducing climate impacts in the transportation sector.

LCFS T29-1 cont.

The issue that I'd like to draw the Board's attention to today has to do with the model relationship between corn ethanol production, food consumption, and net CO_2 emissions.

The key point I hope to make is that by developing the relevant data and determining which data sets to use and which to exclude in the life cycle model are subjective exercises, as are processes of choosing a programming relational assumptions that drives the model. Viewed in this context, the proposal to reduce corn ethanol to indirect land use change or ILUC score can be more appropriately understood as the product of subjective process, one that reflects the current availability of certain data analyses that would contribute to a lower ILUC score, but fails to account for a host of counter-vailing factors that ARB knows are significant but has not yet modeled.

An important way in which ILA's estimates are the product of subjective decisions and not just objective calculations relates to the treatment of reductions in food consumption associated with the policy and reduced

LCFS T29-2

demand for biofuels. As explained in a recently published paper that looked at ILUC analysis and used by ARB, ILUC emissions estimates depend on various modeling choices such as whether reduction of food consumption resulting from biofuels expansion is treated as climate benefit. ARB currently chooses to count GHG reductions that result from reduced food consumption when analyzing the life cycle emissions of biofuels. But that again is a subjective decision.

Several studies indicate that if ARB instead chose to assume society woul limt the extent to which food consumption would decline, ARB estimates corn ethanol ILUC emissions would increase substantially as detailed in our written comments.

The highly subjective treatment of reduced food consumptions reinforces the point that ARB is not obligated to reduce the ILUC score for corn ethanol on the basis of the most recent highly and complete modeling results.

LCFS T29-2 cont.

CATF urges the Board to recognize these limitations as well as the necessary role that it and ARB staff play in interpreting and acting upon the modeling results. The Board should exercises its best judgement in light of the overarching policy objectives of the LCFS and CATF, which CATF understands to be a meaningful reduction

LCFS T29-3

in GHG emissions from the transportation sector. Because corn ethanol's life cycle GHG emission reductions, which are very modest to begin with, depend on an assumption of reduced food consumption in developing countries and because increased reliance in corn ethanol would frustrate the development of more innovative and effective compliance options, the proposal to reduce ILUC score for corn ethanol undermines the objectives of the LCFS.

LCFS T29-3 cont.

Accordingly, the CATF urges the Board to table any proposal to reduce the carbon intensity value ARB uses for corn ethanol.

LCFS T29-4

Thank you for the opportunity to comment on this critically important policy.

CHAIRPERSON NICHOLS: Thank you.

MS. PHILLIPS: Good afternoon, Madam Chairman, fellow members of the Board, ladies and gentlemen. It's a pleasure to be here today speaking in support of the low carbon fuel standard.

I represent the Brazilian Sugarcane Industry Association, Unica, and my members are the largest ethanol producers in Brazil. And we represent about 50 percent of all the ethanol production in the country.

Today, sugarcane ethanol is a modest but important role in supplying the U.S. in general and California in particular with low carbon clean fuel. From

2012 to 2014, Brazilian sugarcane ethanol supplied 13 percent of the total U.S. supply in spite of use.

As the low carbon fuel standard readoption process takes place over 2015, we believe sugarcane ethanol is uniquely positioned to help reduce transportation fuel emissions. And that's because CARB studies considered sugarcane ethanol the best performing low CARB liquid fuel commercially available today to contribute to the program. This distinction is important as CARB considers more stringent life cycle carbon intensity rules for transportation fuel, which are projected by CARB to increase sugarcane ethanol use to 400 million gallons per year by 2020.

California can rely on Brazilian sugarcane ethanol. That's because for the past ten years we've been making the necessary investments to increase supply in the country. We know by the profile of our companies and the companies invested in the sector that Brazil can quickly ramp up production to meet higher market demand. This is very important as Brazil's expected to move into higher blend as early as next month. We know that there is capacity in Brazil to supply California with the volumes that CARB has projected. And we know we can do this in a very sustainable way.

I have submitted comments -- written comments on

30_T_LCFS _Phillips

two technical items that I think needs a little bit of reveal from the staff before you can readopt this. And I just wanted to conclude with these points. We know that electricity cogeneration by sugarcane mills in Brazil are replacing fossil fuel sources of power in the country. We urge CARB staff to factor in this marginal displacement rather than using an average electricity mix for Brazil. At the very least, we ask CARB to update the EIA electricity production numbers for Brazil that right now are for 2011. And we have more updated numbers that we have shared with staff that reflects the sharp decrease in hydroelectricity power in Brazil. Another point is --

LCFS T30-1

CHAIRPERSON NICHOLS: Please finish up.

MS. PHILLIPS: Sure. We are very glad to see that ILUC reduction for cane ethanol, but would love to ask the staff to capture the double cropping in Brazil. It's been a pleasure for us to contribute to CARB and with the staff for these past years. We think the low carbon fuel standard is a model to be emulated by the rest of the country. And we ask you to readopt it. Thank you.

LCFS T30-2

MR. KOEHLER: Thank you. My name is Tom Koehler with Pacific Ethanol. I'm representing today the California low carbon ethanol producers, all of whom are producing in the Central Valley over $500 million worth of investment for plants, 200 million gallons. We have been

31_T_LCFS _TKoehler

from day one and continue to be big supporters of the LCFS, and we urge the readoption today. We also are supporting a further signal beyond 2020 and would urge the Board to do that as well.

LCFS T31-1

We have been part of a larger coalition of alternative fuel providers and a lot of the providers other than ethanol you're hearing from today. And we're proud to be with them all because we realize it's going to take all of the fuels to succeed to their fullest to meet the goals, not only the low carbon standard, but the Governor's goals as well.

I would like to flag the ILUC issue, the gentleman just spoke about it. There is -- since the staff proposal came out, there is new data which is actually real world data, so not dependent upon one person's assumptions, of actual land use change that has occurred worldwide over the last ten years. And Wally Tiner from Purdue and GTAP, Son Ye from U.C. Davis are embarking on a study to calibrate the GTAP model, back cast it. And I would urge the Board to ask for the results of that to come back. It's too late for the 15-day notice. But when that study is done, I would urge the Board to ask to review the ILUC.

LCFS T31-2

CHAIRPERSON NICHOLS: Thank you.

MS. HOLMES-GEN: Good afternoon. I'm Bonnie

Holmes-Gen, Senior Director, Air Quality and Climate Change for the American Lung Association in California.

And on behalf of the American Lung Association in California and health and medical groups throughout the state, I urge your readoption of the low carbon fuel standard as soon as you can vote on it. Since its original adoption in 2009, public health and medical groups and our organization have supported the LCFS as a critical component of California's visionary clean air and climate strategy. And we see the LCFS as a critical tool to help Californians kick their addiction to petroleum fuels and transition to a cleaner future. The LCFS is bringing real and measurable health benefits a long way.

Our research has evaluated benefits from the tons of pollution reduced through the low carbon fuel standard and fuels under the cap and found over eight billion in avoided health costs by 2025, including over 800 avoided death and thousands of avoided asthma attacks and many other avoided health emergencies, as you can see here. And this is just a down payment on the tremendous benefits to come.

This version of the LCFS before you has substantial improvements from the earlier regulation, including expanded electric transportation credits and their refinery investment provisions that will help to accelerate clean fuels progress to while protecting community health. And we are pleased to have over 30 health and medical organizations that are signed onto the letter that you've received, including the American Cancer Society, Cancer Action Network, Blue Shield of California, California Thoracic Society, Dignity Health, American Academy of Pediatrics, and many others. Our groups stand behind the LCFS as a vital and proven strategy that's transforming our transportation here and being pursued now in other western states.

32_T_LCFS_BHolmes-Gen

And as we go forward, we know there will be additional improvements. One area we have flagged is the need to update the biorefineries guidance document to incorporate updated tools that evaluate community impacts. And we look forward also to setting the post-2020 targets.

LCFS T32-1

I would like to close with a brief quote from Dr. Perdiga who's a physician and participant in our Doctor's for Climate Health Campaign picture here and would like to note we greatly appreciate the engagement of Dr. Sherriffs and Dr. Balmes also in this campaign. And here's Dr. Perdiga's quote. "We have no control over the air we breathe. But we do have a say in what pollutes it. My patients in the San Joaquin Valley suffer the side effects of pollution every day, whether they live in cities or rural areas. They have the most to lose in we don't continue pushing for cleaner air. Their health is at stake and we must do more. That is in I support California taking the lead in reducing carbon pollution from transportation fuels."

Thank you again. And as always, we look forward to working with you.

CHAIRPERSON NICHOLS: Great. Thank you.

Tim Carmichael.

MR. CARMICHAEL: Good afternoon. At the risk of another zinger from the Chair, I want to stand in solidarity with all the Tims that are going to testify today.

33_T_LCFS
_TCarmichael

More seriously, Tim Carmichael with the California Natural Gas Vehicle Coalition. We are here to support the program. And I want to encourage all of you to feel empowered to support this. And one of the measures that leads me to that comment is the breadth of the portfolio of alternative fuels that you are not speaking here today, but engaged in the market already.

And you know, this is a good program. ARB has programs that tend to go up and down based on one technology's success or not. That is not the case here. You have a lot going in the right direction with this program. And that gives you all the confidence to continue to support it.

LCFS T33-1

For the natural gas industry specifically, I just want to mention a couple of things. We've made good progress over the last several months working with the staff on some technical issues related to the model and carbon intensities. Those have been referred to. I want to thank Richard Corey for his personal engagement on these issues and the whole LCFS team's hard work. It's not easy stuff. We are talking about technical calculations and a lot of moving pieces. But as I said, we've made a lot of progress.

We have a handful of issues we haven't resolved yet. The staff have referred to those. They mentioned they're committed to working with us to resolve those.

In your resolution package, there is a reference to this as an attachment, a suggestion that you add a bullet that relates to these on going conversations and supports the staff continuing to have those conversations.

We respectfully ask that you include that in your Resolution today as part of your direction of staff. I think that request is consistent with what the staff shared earlier. We just think it's so important to get it right for the reasons that have been mentioned, the financial impacts within the state, as well as the impacts that our success in California is going to have on other states.

LCFS T33-2

One quick detail on that. You have literally dozens of people that are working on this issue in California. Many other states have one or two people assigned to this program. So California getting it right is going to -- just that much more important. So those other states can rely on our technical work.

LCFS T33-2 cont.

Thank you very much. Appreciate your time.

CHAIRPERSON NICHOLS: Thank you. Tim is actually one of my favorite names.

David Cox.

MR. COX: Thank you, Chairman Nichols, Board members, staff.

My name is David Cox. I'm the Director of Operations for the Coalition for Renewable Natural Gas.

I'd like to begin by complimenting Mr. Corey on his leadership. And at the risk of leaving someone out specifically, I just want to publicly thank and knowledge Mr. Vergara, Mr. Kitowski, and Mr. Imgrahm, and your very capable team in the front row. You guys have really done a great job.

The Renewable Natural Gas Coalition advocates for advanced applications of renewable natural gas derived from cellulosic waste sources. We do this so present and future generations have access to domestic, renewable clean fuel and energy supply.

We represent the leading renewable natural gas companies and organizations who collectively they produce and distribute more than 90 percent of the transportation fuel from renewable natural gas delivered in North America.

Ms. Sideco mentioned earlier that R&G volumes have grown about 70 percent since LCFS was first adopted. This is tremendous growth for our economy and for our environment. We also like this particulate stat because it also correlates with the founding coalition and our respective growth.

34_T_LCFS _DCox

I'd like to focus my comments today on the GREET cost containment provisions on a going-forward basis. I think we have a come a long way. I'll just echo everything that Mr. Carmichael just mentioned.

But specifically, the importance of having a sound process to deal with these, because I think they are the two issues that will most impact renewable natural gas on a going-forward basis.

LCFS T34-1

And as to the GREET model, I'm certain by now you're familiar with how highly we consider the stakes of the GREET model. We appreciate your commitment to fuel neutrality and also to ensuring the GREET is driven by sound data and ask for your continued commitment on those points.

LCFS T34-2

As to cost containment, staff has proposed a $200 cap on credit prices. We think that should absolutely be paired with a provision and cost containment on the low end in the event that credit prices go down.

LCFS T34-3

And so we thank you. We have submitted comments and talked with staff throughout the workshop process on specifics on how to do that. And we just encourage you to continue to address cost containment on a going-forward basis. That will conclude my comments.

CHAIRPERSON NICHOLS: Thank you.

35_T_LCFS _JBarbose

MR. BARBOSE: Good afternoon. My name is Jason Barbose. I'm with the Union of Concerned Scientists. And on behalf of our 73,000 supporters in California, speaking in support of moving forward with the readoption process for low carbon fuel standard.

About a year ago, more than 150 California climate scientists and economists sent a letter to Governor Brown and the Legislature urging the state continue to be a leader in addressing climate change and to adopt 2030 carbon emissions targets that put the state on a path to meeting our 2050 goal of 80 percent reductions.

LCFS T35-1

And in that letter, the researchers also highlighted the need for additional policies that promote low carbon fuels and cleaner transportation. And with

LCFS T35-2

that back drop in mind, we view the LCFS as a critical element of the State's approach to reducing greenhouse gas emissions while continuing to thrive economically.

We also view it as an important part of Governor Brown's new goal to cut petroleum use in half by 2030, which echoes my organization's half the oil plant of the United States.

LCFS T35-2 cont.

I'd like to note three important technical changes that are being proposed that UCS supports.

One is the update to the life cycle analysis that's been based on the best available science.

LCFS T35-3

The second is the innovative crude and refinery provisions that will encourage the oil industry to reduce emissions from its own supply chain.

LCFS T35-4

And the third is the cost containment mechanism that will maintain a stable investment plan for low carbon fuel production while ensuring that any unforeseen delays would not destabilize the policy of California consumers.

LCFS T35-5

UCS has been performing analysis and providing technical feedback on the LCFS since its inception. We are confident the diverse sources of the low carbon fuel are available to achieve the ten percent carbon intensity target by 2020.

Earlier the month, we released a study on LCFS compliance from the consulting form Provoto that we co-commissioned with NRDS and EDF, and that study finds first and foremost that compliance, is indeed, feasible through 2020 and beyond. The study also demonstrates that in order to ensure investment in the cleanest fuels, it is important as well that the State establish regulatory stability out beyond 2020.

LCFS T35-6

By maintaining a stable science-based policy framework that recognizes that cleaner rules are indeed more valuable than dirtier fuels in conjunction with similar policies being adopted or pursued in our neighboring states, the LCFS will create a large stable and steadily growing market for clean fuesl, providing investment and innovation and bring down the cost of cleaner alternatives.

And for those reasons, we support moving forward with the readoption process. Thank you.

CHAIRPERSON NICHOLS: Thank you.

MS. MORTENSON: Hello, Chairman Nichols and members of the Board. I'm Lisa Mortenson with Community Fuels. And I'm so excited to be here today and commenting on the low carbon fuel standard.

If you're not familiar with Community Fuels, we produce advanced biofuels at our refinery at the Port of Stockton. Our fuel is primarily sold to major oil companies and refineries for blending with petroleum.

This is exciting because each gallon of our fuel that's blended with petroleum is displacing diesel fuel and is increasing the volumes of clean fuel being used in California. And I hope it's of no surprise to you when I say that petroleum companies do not voluntarily purchase our fuel since our fuel is displacing a portion of the product that they produce.

36_T_LCFS
_LMortenson

And it really underscores the importance of the low carbon fuel standard and programs similar to this. I think some people who don't participate in the market each and every day like Community Fuels does forget that, first on a positive note, we leverage the existing diesel infrastructure by selling our fuel to the petroleum industry. But second, the petroleum industry only purchases our fuel because it enables them to meet multiple compliance obligations. So it is so important -- and I say this strongly and passionately -- it is so important that we have regulations like the low carbon fuel standard to force the existing infrastructure to incorporate higher volumes of clean fuel.

LCFS T36-1

As a California-based business, we need strong and supportive and consistent regulations. When we built our biorefinery, our company was started in 2004 and the refinery was built in 2007 when that construction was complete. We needed a long-term trajectory for planning

LCFS T36-2

and to be able to finance the project. We can't work with one, two, three, or even five-year time frames for planning.

LCFS T36-2 cont.

So not only do we support the readoption of the low carbon fuel standard, we encourage you to look far beyond 2020 and let's be ambitious. Let's seize the opportunity to get really aggressive targets that change the way we fuel vehicles in California. Our U.S. biodiesel industry is three billion gallons strong. We have three billion gallons of existing infrastructure. Our industry is ready to deliver. We are ready to deliver high volumes of low carbon fuel to California. So again, we strongly support the readoption, and I hope that we go further.

LCFS T36-3

CHAIRPERSON NICHOLS: Great. Thank you.

I'm making an announcement we're about to close off the list of witnesses. We've got 50 people, and we're now at number 36. And I think we probably covered pretty much or will have covered pretty much every topic by then. Just so you know, we're coming to the end of the list. Okay.

37_T_LCFS _JGershen

MR. GERSHEN: My name is Joe Gershen. I'm a 15-year biodiesel veteran. Also Vice Chair of the California Biodiesel Alliance.

I'd like to thank ARB Board and staff for all

LCFS T36-1

your hard work on these issues, which are vitally important to Californians. I'm very supportive of the readoption of the LCFS. And I commend you on inspiring other low carbon initiatives on the west coast and around North America.

As I've mentioned, I spent nearly 15 years in the California biodiesel industry. And I've been committed to education, fleet transition, and biodiesel acceptance and implementation. I've watched this industry grow from a fledgling idea of a few pioneering environmentalists scientists, engineers into a robust and growing industry providing hundreds of high paying green California jobs in some of the most disadvantaged communities in the state.

Today, the California biodiesel industry is capable of reducing over 600,000 metric tons of carbon emissions, which is also equivalent to taking about 140,000 cars off California roads. These metrics take on important and measureable meaning in the context of the low carbon fuel standard. So thank you.

This ground-breaking and critical policy demonstrates California's commitment to environmental and energy sustainability and simultaneously sends a strong and stable signal to business, which encourages investment and innovation, which will help achieve further carbon reduction goals. Thank you again.

I'm confident that working together with ARB, the California biodiesel industry can build on our successes. Last year, about 16 percent of all LCFS credits were generated by biodiesel industry, which also contributed about $350 million to California economy.

We look forward to contributing over even more to reducing carbon emissions, displacing petroleum usage, lowering emissions, and creating good high-paying green jobs somewhat characteristics of the California's most disadvantaged communities. Thank very much.

38_T_LCFS _CMurphy

CHAIRPERSON NICHOLS: Thank you.

MR. MURPHY: My name is Colin Murphy. I'm a Policy Advocate for Next Gen Climate America. Thank you to the Board for the opportunity to speak.

In recognition of the long list, I'm going to make most of my comments in one sentence summaries. We support readoption of the low carbon fuel standard. We support the cost containment mechanism. We think there probably should be a price floor to go with the price ceiling.

LCFS T38-1

LCFS T38-2

LCFS T38-3

On one other subject, I need a little more depth. We think on the subject of carbon intensities, there needs to be a regular and systematic mechanism for review of the carbon intensity numbers. This recognizes the developing nature of some of the science behind things, particularly

LCFS T38-4

biofuels in areas like indirect land use change and oil sequestration. In the written comments we submitted, we gave you some research regarding oil carbon. We recognize the science is still open on this and there needs to be a balance between giving a target to producers but also recognizing that understanding may change over time. And we think that's such a balance can be achieved through a periodic review. Thank you for your time.

LCFS T38-4 cont.

CHAIRPERSON NICHOLS: Thank you.

Susan Frank.

MS. FRANK: Thank you, Madam Chair and Board members.

I'm Susan Frank, Director of the California Business Alliance for a Clean Economy. I'm here actually just to reference a letter that was submitted on the record this week with a few numbers attached. There were 98 signatories to this letter. If you take a look, you'll see the diversity of signors from all sectors of the state from business and faith and labor and environmental groups, et cetera. At least half of the speakers speaking today have signed the letter. So I will not read the letter. There are at least four people named Tim on the letter. So that should count, too.

39_T_LCFS _SFrank

Really, I just wanted to express the strong support that you have across the state of California and

LCFS T39-1

really across the region for what the action you're going to be taking today and over the next several months. And really proud to be able to be a signor to the letter. So thank you very much.

LCFS T39-1 cont.

CHAIRPERSON NICHOLS: Thank you.

MR. MUI: Good afternoon, members of the Board, Chairman Nichols.

I want to thank you for the opportunity to speak on behalf of Natural Resources Defense Counsel. First off, I do want to wish you a happy Chinese New Years today, a Lunar New Years, the year of the goat, which is an auspicious year, one that is meant to be filled with prosperity and promise. So I do think it is quite fitting that today we are hearing about the proposal to readopt the low carbon fuel standard.

While I don't have red envelopes or dim sum for you, what is impressive to me as a clean fuels and vehicles scientist is that the LCFS standard is already working today, despite the speed bumps and the barriers that have been laid down before it to slow it down. We've now seen ten million tons of reductions by the program, the equivalent of taking two million cars and trucks off the road for a year. And industry has exceeded the standard already by nearly 70 percent, despite the regulatory uncertainty.

40_T_LCFS_Mui

And you know, Tim -- one of the Tims -- mentioned the portfolio approach of the standard. We've already seen and heard today from biodiesel and renewable diesel producers reaching record levels in California. Biomethane an being produce today supply a huge chunk of the natural gas fuel mix. Ethanol producers diversifying to lower carbon feed stocks. And even technology companies finding ways and stepping in to find ways to reduce the carbon intensity from petroleum operations. We've only just begun to see the promise of the LCFS. It's time to clear the path forward. It's time to allow the LCFS and companies to accelerate.

LCFS T40-1

We do strongly support the staff's proposal to maintain the strong standards and to go forward beyond 2020. There are now three separate independent reports and analyses demonstrating ARB's proposed targets are, indeed, achieveable. One of those, a recent consulting report that we commissioned together with Union of Concerned Scientists and EDF, shows that we cannot only meet the standards, but we can exceed and reach higher targets by 2025.

LCFS T40-2

The missing ingredient, however, is regulatory certainty. Let's add that key ingredient today or when you vote in moving forward with the readoption.

LCFS T40-3

We also commend and thank the staff for their very hard work on this program and enhancing the program. These enhancements will make the LCFS more robust, fully capture technology options, provide greater flexibility to the program, and help deliver criteria co-benefits as well.

And it will also work to promote and avoid what if scenarios on extreme credit prices or fuel shortfalls. The proposal staff has laid out very carefully is reasonable, is technically supportable, and should be adopted.

LCFS T40-4

We've now demonstrated that we can protect the environment, public health, and grow the economy. You've now heard from a long list of supporters who are standing together to support the Board and staff to move forward. It's time to clear the path and get moving. In the words of Mike Waugh, it's time to giddy-up. Happy new years and thank you.

CHAIRPERSON NICHOLS: Thank you for that quote.

MS. TUTT: Good afternoon, Madam Chair and members of the Board. My name is Eileet Tutt. I'm with the California Electric Transportation Coalition. Our members include five of the largest utilities in California, as well as many of the smaller utilities, a number of auto makers that are committed to clean technologies and alternative fuel vehicles. We work very closely with the California Municipal Utilities Association on this issue.

We come to you today, not surprisingly, in support of the low carbon fuel standard and its readoption.

I do want to say that I want to really thank staff. Staff has been amazing. And thank you, Mr. Corey, for particularly recognizing Mike Waugh. He was incredible.

We are a small part of the credit values today. We hope to be a lot bigger in the future. The staff never treated us as if we were small. Spent a lot of time working through our issues. You'll read our very brief comments, so I'm not going to reiterate them. But part of the reason they're brief is the account of time that staff spent with us.

41_T_LCFS _ETutt

There is a couple of things I want to just say just to reiterate Simon Mui. We also conducted a study with ICF and a number of the alternative fuels folks indicating very clearly that we can meet this standard by 2020. And to Dr. Sherriffs, your question earlier about the economic assessment, our economic assessment did include the health impacts. And we showed that in certain cases you can certainly improve the economy by sticking to the LCFS course. So again, thank you for your time and

LCFS T41-1

consideration today.

CHAIRPERSON NICHOLS: Thank you.

Mr. Moran.

MR. MORAN: Good afternoon. Ralph Moran with BP America.

We did submit very detailed written comments, so I hope you get a chance to take a look at those. But today wanted to focus on two items. That's the cost of the program and the greenhouse gas emission reductions that are attributable to the program.

42_T_LCFS _RMoran

A lot has changed since 2009 when the LCFS was first adopted. And along with that are the conclusions from the original economic analysis supported the adoption. Back then, it was suggested that the program was going to save fuel consumers billions of dollars because these new fuels are going to be cheaper than the conventional fuels. That analysis also concluded that there was going to be a negative carbon price associated with the low carbon fuel standard, somewhere between negative 120 and negative $140 per ton.

LCFS T42-1

So now the regulation puts in place a cost cap of $200 per ton. And in reading some of the written comments submitted by others, I notice that some of the proponents of low carbon fuel standard are expressing their concern that $200 is not high enough because it's not enough to bring these new fuels to market.

Now I know that there is uncertainty in models and in economic analyses, but we should at least be able to rely on them to get the sign read. There is a big difference between saving billions of dollars and costing billions of dollars. And I hope that difference would cause the Board to pause and at least reflect on where is this going cost-wise.

LCFS T42-1 cont.

Secondly, there's sort of a concept is not very well understood about greenhouse gas reductions and the low carbon fuel standard. Simply put, there are no incremental greenhouse gas reductions that come from the low carbon fuel standard. And the reason for that is the sources of emissions covered under the LCFS are already covered under the cap and trade. So the low carbon fuel standard only displaces emissions reductions that would otherwise occur in the cap and trade program. And those reductions that come from the cap and trade program would also produce co-benefits, so it's even difficult to say there is any co-benefits, incremental co-benefits that come from the low carbon fuel standard.

LCFS T42-2

So what the low carbon fuel standard really does is shift reductions from occurring in a very cost-effective, efficient cap and trade program and forces them to occur in a complex, high cost program. How high

LCFS T42-3

is that cost? Right now, the emission reductions cost about twice as much in the low carbon fuel standard. And people are expecting that that range -- that gap will increase. That's why we have a $200 per ton cost cap in the low carbon fuel standard when we only have about a $40 per ton minimum cost in the low carbon fuel standard.

LCFS T42-3 cont.

So going forward and to conclude, we have a lot of work to do in meeting the state's long-term greenhouse gas policies. We would rather the state focus on the most efficient and cost effective ways to do that, like a well-designed cap and trade program. Thank you.

LCFS T42-4

CHAIRPERSON NICHOLS: Thank you.

Mr. Magavern.

MR. MAGAVERN: Madam Chair and Board members, Bill Magavern with the Coalition for Clean Air.

I was part of the group that stood with then Governor Schwarzenegger when he first announced the low carbon fuel standard to the world. I think it was eight years ago. And I continue to think that this is a valuable policy and the Coalition for Clean Air supports the readoption of the low carbon fuel standard. It now, in fact, looks even more important, given as many speakers have pointed out the governor's goal of reducing oil use in cars and trucks 50 percent by 2030, which is a very important goal and one that we certainly want to help all of you and the other agencies in trying to realize.

One of the main benefits of the low carbon fuel standard has been that it for the most part keeps the dirtiest highest carbon fuels out of California, like the tar sands oils that our friends in Canada so very much want to export to us but would have major consequences to our air and climate.

In addition, as air advocates, we are particularly attracted to the value of the low carbon fuel standard in bringing in cleaner fuels to reduce criteria air pollution. As the South Coast Air Quality Management District pointed out, this standard helps us get closer to attainment of our air quality standards.

43_T_LCFS _BMagavern

California's LCFS has also made a major contribution by being I think the very first jurisdiction to consider indirect land use conversion. And we continue to support that element of this standard.

You've made a couple good additions I think on this round. The recognition of the value of electricity used in transit and in forklifts will help us to continue to clean up those sectors. And we also appreciate the incentives for the refineries to clean up their operations, which as you know, tend to be in communities that have suffered from some of the worst environmental injustices. So this should help some with those

LCFS T43-1

fence-line communities.

So we support and thank the Board and staff for your work.

CHAIRPERSON NICHOLS: Great. Thank you.

MR. NOYES: Good afternoon, Madam Chairm, members of the Board and staff.

Thank you for the opportunity to introduce and speak to this hearing. I'm standing in today is attorney for the law firm of Keys, Fox, and Wheatman and also Executive Director for the Low Carbon Fuels Coalition and like to speak in strong support of the readoption.

It's been said before, but I think recognizing Mike Waugh's work and all the staff and high level leadership that went into the program can't be emphasized enough. Mr. Waugh really set the standard out there in terms of being truly receptive to input, constructively engaged with stakeholders, and Ms. Sideco and others managed the really massive organizational task of keeping these multiple -- what I viewed as multiple rulemaking reallys integrated sufficiently but addressing the very particular details of stakeholders out there and met what I call the gold standard of rulemaking as a regulatory attorney. So really appreciate that.

44_T_LCFS
_GNoyes

The program is working well, as has been emphasized by many. There was no way at the beginning to

LCFS T44-1

predict exactly what the fuel mix was going to be. Of course, we need to try to do that. We need to do our best models. We've heard that cellulosic biofuels have been slow to commercialize. That's certainly the case. However, renewable natural gas and renewable diesel have been fast to commercialize.

So with the kind of portfolio approach that we have here, there is that kind of flexibility. And it's clear from all the objective analysis that's gone in out there that these fuels are available. They're driving the clean economy. They're also driving the political discussion, particularly in the western states right now. We see some real paralysis around the renewable fuel standard on the federal side. So California's market signal is very important out there to the continued growth of the clean economy and all of the different low carbon fuels are out there.

We have seen -- this program is really one of the key workhorses of AB 32. We have seen ten million metric tons in reductions already. That is simply astounding. And ARB holds a unique responsibility and leadership role under the greenhouse gas revenue fund and essentially investment portfolio. And I would recommend that as the Board takes really the benefits of this program and looks at what to do with what's probably going ton in excess of

LCFS T44-1 cont.

two billion dollars in year into the greenhouse gas revenue fund, really think about that as a wise investor, look at this wide portfolio of solutions in the transportation sector of the toughest sector out there and figure out how to get the most cost effective reductions possible. Thank you for your time.

LCFS T44-1 cont.

CHAIRPERSON NICHOLS: Thank you.

Jamie Hall.

MR. HALL: Good afternoon, Madam Chair and members of the Board.

45_T_LCFS _JHall

My name is Jamie Hall, Policy Director for CALSTART. We are a non-profit organization that works with almost 150 companies bringing cleaner transportation solutions to market, here, today, as you can imagine in strong support of the low carbon fuel standard. Want to thank Board and staff for leadership on this. It's been a lot of hard work and it's good to be here today.

The LCFS provides a really important market signal for this industry that's driving investment. It's driving innovation and driving market penetration of cleaner fuels. Readopting the LCFS will make this signal even stronger and will accelerate the progress we're already making.

We held a summit on clean low carbon fuels earlier this month. Many of you were there. We had 50

LCFS T45-1

companies that were engaged in biofuels, natural gas, and electricity and other fuels. The clear signal from this very diverse group was that the LCFS is working.

Of course, there are a lot of other things people would like to see. They would like to see more investments, as Graham just mentioned, like the very successful CEC investments that handsome Tim Olson mentioned this morning. They'd like to see stronger longer-term targets and signals. But the number one message across the board was that the LCFS needs to move ahead. We need to get back on track. So happy to be here in support, and we look forward to working with you on the next steps.

LCFS T45-1 cont.

LCFS T45-2

CHAIRPERSON NICHOLS: Thank you.

Mr. Hedderich.

46_T_LCFS _SHedderich

MR. HEDDERICH: Chair Nichols, members of the Board, thank you. In particular, you pronounced my name right.

I'm Scott Hedderich with Renewable Energy Group. We are North America's largest biodiesel producer, over 350 million gallons of fuel. We also produce renewable hydrocarbon diesel. Also pleased to say we have a significant R&D operation in California in south San Francisco that looks at renewable chemicals and other advanced products.

47_T_LCFS
_KPhillips

When you're 45th on the list, you're expected to be brief. So is this perfect? No. Is it really good? Absolutely. Absolutely. Have staff been responsive? They've been the epitome of professional in dealing with all stakeholders.

So with that, please move forward with the adoption. Thank you.

CHAIRPERSON NICHOLS: Thank you.

Katherine Phillips.

MS. PHILLIPS: Feel like I'm on the Price is Right.

Katherine Phillips with Sierra Club, California. I'm going to keep this very sweet. Thank you for all the work you put into this. Thank you for persisting, despite the court challenges. And there is an expression. It's time to fish or cut bait. I say let's fish.

Thank you. My members support this.

CHAIRPERSON NICHOLS: Okay. Mr. O'Connor.

MR. O'CONNOR: Chair Nichols, distinguished Board members, Tim O'Connor, Environmental Defense Fund.

Environmental Defense Fund has participated in studies showing the feasibility of this standard. We've documented the tremendous health and economic savings that are associated with the full implementation of this alongside cap and trade.

We've shown the dramatic growth of businesses throughout California that are engaged in the value chain of delivering these fuels up and down the state. And we've profiled the amazing innovation that California businesses and business leaders have brought forth to bring these fuels.

48_T_LCFS _TO'Connor

And for that reason, we, of course, see that this standard is working and support its continued readoption. But as an attorney that's been following the court cases of this regulation, I must say that there, of course, have been some comments filed today that assert that what we're doing is still not going to comply with what the court had wanted or what CEQA requires.

And I must say in this readoption process, which is now over a year in the making and which piles onto a tremendous process that went into the first standard adoption, that I have not seen a record of decision and a level of analysis such as which has been brought by the staff and by the Board. And I'm continually impressed with all the work that continues to go in. And I'm confident that as the Board comes to a decision on this, it will be based on reason and sound analysis that's presented to it and should hold up with all the legal standards which the court will require. Thank you.

LCFS T48-1

CHAIRPERSON NICHOLS: Thank you.

Kirsten James.

MS. JAMES: Good afternoon, Kirsten James representing Ceres and Bicep.

So for those of you who with us, we are a nonprofit organization working to mobilize the investor and business communities with policy members to pass meaningful energy and climate legislation and help a thriving sustainable global economy.

Bicep stands for the Business for Innovative Climate and Energy Policy. And this is a project of Ceres. It's a coalition of 34 mainstream businesses which are committed to the efforts on passing meaningful climate and energy policies.

So together, these 34 businesses represent over $350 billion in annual revenues and coalition members range from Nike to Patagonia to Gap to Ebay, to just name a few.

So Ceres combined with Biceps and our investor network have long recognized the significant economic risks and opportunities associated with climate change. Thus, we strongly support the readoption and extension of the LCFS program as it's a proven market-based technology neutral tool. The LCFS will reduce climate risk and foster economic opportunities.

49_T_LCFS _KJames

LCFS T49-1

So you've already heard today about the

feasibility of the program, and I'm going to focus really quickly on the economic benefits. So from the business and consumer side, we see that this is an important route for it in order to insulate businesses and consumers from the oil price volatility and we need that diversity in our fuel supply.

LCFS T49-1 cont.

Secondly, from the societal benefit standpoint, we believe the LCFS will result in an estimated 1.4 to $4.8 billion in societal benefits by 2020 from the reduced air pollution, for example, an increased energy security.

LCFS T49-2

Next on the job side, in addition to the growth of the clean fuels industry, we'll move California forward economically. Currently, 40,000 California businesses serving advanced energy markets, employing roughly 430,000 employees. So the LCFS alone could contribute at least 9100 jobs in our estimation.

LCFS T49-3

And then finally on the investor side, Ceres has a strong and extensive investor network, and we truly believe that in order to spur innovation and allow the clean fuels industry to continue to grow, the investors need these long term policy signals. And to provide these signals, it is critical not only to readopt the LCFS, but to extend the program as well.

LCFS T49-4

So in conclusion, we strongly support the readoption of the LCFS as it's an effective and necessary tool for reducing carbon emissions in addition to bringing significant economic benefits. Thank you.

CHAIRPERSON NICHOLS: Great. Thank you.

Mckinly Addy, and our last witness is Christopher Hessler.

MR. ADDY: Good afternoon, Madam Chair and Board members. It's McKinly Addy.

CHAIRPERSON NICHOLS: I'm sorry.

MR. ADDY: That's okay. A lot of people tend to turn the name around.

But I'm the Vice President of the company called Adtra. We are virtual integraters of low carbon high efficiency technologies at scale. That's what differentiates us from a lot of other companies in the clean energy space.

But our company supports the objectives of the low carbon fuel standard and its readoption. I want to commend the staff for their very hard work. Many of them I worked with when I was at the California Energy Commission.

50_T_LCFS _MAddy

I also particularly want to highlight John Corey, Neal as well as Katrina Sideco, but particular John and Neal because of their very hard work on dealing with the treatment of indirect land use change emissions. We started sort of working on that

LCFS T50-1

LCFS T50-1 cont.

when I was at the Commission as well.

But we believe that transportation natural gas is a strong candidate for helping compliance with the low carbon fuel standard. Combined with next generation natural gas engines, which are near zero emission for NOx and PM, but also when combined with renewable natural gas, you have a real option for true zero emission transportation propulsion solutions. Near zero greenhouse gas emissions, near zero NOx, near zero PM.

LCFS T50-2

I want to highlight a cautionary note here, and it's the enthusiasm for the readoption. In other meetings that I've attended, many of the participants talk a lot about the need for government incentives to get a lot of these low carbon transportation fuel solutions into the marketplace. What you don't hear about are the private capital requirements for the successful penetration of these technologies at scale that would move forth the policy objectives that the low carbon fuel standard and the State alternative fuels plan have laid out.

LCFS T50-3

So I'm wondering whether it made sense for the staff to consider as a contingency what might happen if some of the key players in low carbon transportation fuel space don't have access to capital and therefore might not be viable. What might that do with the possibilities for compliance with the low carbon fuel standard. That's the

LCFS T50-3 cont.

recommendation. And with that, thank you for the chance to give input here.

CHAIRPERSON NICHOLS: Thank you, Mr. Addy.

Last witness, Mr. Hessler.

MR. HESSLER: Good afternoon. I'm Christopher Hessler with AJW. Our firm's expertise is around advising clients regarding how public policies will influence market demand for innovative energy and environmental technologies.

51_T_LCFS _CHessler

A couple quick points. Number one, the program as many have said is working. And it is influencing market demand.

LCFS T51-1

And secondly, I want to talk about scarcity and the issue of this $200 pricing, what we would expect in the market as a result.

On the first, about five years ago, one of my friends in the petroleum industry when I said, you talk about feasibility and this program is feasible, define feasible to me. And he said, one and a half percent reduction, that's as far as we can see it going. Today, the oil industry testified that five percent was as far as they could see it going. So by my math, we keep going on that progression by 2020, we'll be at 15 percent. So everything is fine.

Little more seriously, this program draws its DNA in many ways from the acid rain program, the first program that really allowed for credit trading as a compliance tool. And that's important because there was at the time of the adoption of the acid rain program one compliance strategy. And that was basically putting bag houses on the back of coal-fired incinerators. That program was the single most successful environmental program in the United States. If we measure success by early compliance, by over compliance, and by the relative cost of compliance, relative to initial estimates. Here in this technology neutral platform the low carbon fuel standard, we have -- and you've heard today -- dizzying array of fuels that five years ago people weren't talking about as real potential fuels. We've got renewable diesel. We've got the real potential that renewable natural gas can overtake fossil natural gas. We have renewable hydrogen being explored for decarbonizing our base fossil fuel gasoline and diesel. That's happening very rapidly.

LCFS T51-1 cont.

On this question of $200, what the staff has proposed is effectively a cap on the marginal cost of this program. The concern in the petroleum industry legitimately is at some moment in the program we don't have -- there is a scarcity. There is not enough fuel or credits for us to comply. Well, in the scarce market, prices go up. And what the staff is proposing is to limit

LCFS T51-2

how high those prices can go. It does two things. It is tremendous consumer protection. It prevents this program will ever having a very adverse consumer effect in the worst case scenario.

The other thing it does is provides the level of confidence and stability of the program that investors and all market actors need to proceed with the program.

So it's an excellent draft. Your staff is indefatigable in terms of their work trying to investigate the best options here. It's a great product. And it will lead the world in the right direction. Thank you very much.

LCFS T51-2 cont.

CHAIRPERSON NICHOLS: Thank you very much.

That concludes the witnesses. I'm going to close the record on this agenda item at this point. But the record will be reopened when the 15-day notice of public availability is issued. Written and oral comments received after this date but before the 15-day notice is issued will not be accepted as part of the official record on this agenda item. But when the record is reopened for the 15-day comment period, the public will then be able to submit written comments on the proposed changes.

This will be considered and responded to in the Final Statement of Reasons for the regulation. And if you followed that, you're definitely a pro and probably has spent more time than you should have at ARB.

But we really do appreciate the importance of this regulation. I can assure you that the amount of time that's gone into it is perhaps more than most regulations I've ever dealt with. But it is proportional to how innovative it is, as well as intellectually challenging. We've had a history of really terrific people working on it.

I would actually like to return to the Board for questions and comments now, but I'm going to call on -- I didn't warn him of this, but I know he's always prepared, fellow Board Member Dan Sperling, because Dan is one of the people who from his post in far distant academia was responsible for helping to design this program, at least conceptually along with colleagues. But I'd like to give him an opportunity to reflect at this stage.

BOARD MEMBER SPERLING: You did surprise me. But I did have actually so many pages of notes that I can consolidate.

You know, looking back historically, it is remarkable how the original concept of this has been robust and has actually been implemented. Mike Scheible was there at the beginning also when we were thinking about this. And really the basic structure has held up, which is really impressive for such a unique, innovative, hugely important program.

Because what we're talking about here is we're debating details. And even the oil industry as they said, you know says, okay, we don't like some of the details and we think the target is too high, but is pretty much acknowledging that this is a good program for going -- good structure for going forward. And if I go back to those original discussions that we had actually with the oil companies in particular -- and at that time, this is 2007, and they were saying, okay, we see climate is important. Actually, they thought it was more important than now. And they said this is -- this does look like -- if we're going to focus on climate, this is probably about the best way to do it. We can't come up with any better ideas. And through all these years, I've given many, many talks. And people always criticize it. I say, well, do you have a better idea? And I have to report after, what, eight years now. I haven't heard anyone come up with a better idea, except maybe carbon tax or oil industry now likes cap and trade I noticed.

So you know, I'll summarize. But I think I like all the changes that the staff has proposed here. I think the three most important are the cost containment provision, the price cap, the streamlining of the certification process. And that one in particular is because what we have here is not only something important for California, but to the U.S. and the world. It has to work elsewhere. It has to be easily replicated or compatible in some way.

So this effort to streamline the administrative part of it I think is really important. And in fact, if I said anything, you know, if I suggest anything big, it is that going forward we keep thinking about how can we streamline it even more. How can we make it so it really is compatible with other stats and can be scaled up nationally and internationally.

And the third part that I did want to strongly support is the idea of incentives at the refinery level and upstream. And in terms of encouraging carbon capture and sequestration and other kinds of improvements. I think all of those are really important as we go forward.

So I guess one other comment and that is there was a lot of discussion that really dealt with the idea of making it science based, but at the same time others talk about certainty. And there is a tension there. And we're I think the staff has been working hard at trying to figure that out. Just the ILUC is a good example of it is going -- to get precision on that means -- to bring science to that, we are going to be updating it over time as we learn more. But it would change it then we're reducing certainty and regulatory certainty. So how do we manage that process going forward.

And I think we stick to the numbers as much as possible. We stick to the process and the methods as much as possible. And we deviate only when the scientific evidence is really strong for making it different. And so in the case of ILUC, there is a proposal to reduce the ILUC, as many have suggested and the science as I see it supports that. And so there will be that.

So the only other thought I would have is that it has been -- there is a question is it really successful or has staff overstated it by saying it's been a very successful program so far. And depends how you define success, of course.

But as we heard here, there's so many companies and so many processes and so many fuels that are being developed that we did not anticipate at the beginning. And we have been disappointed the cellulosic technologies have not gone forward as much and as fast as we hoped for at that time as expected. On the other hand, a lot of these biodiesel renewable, diesel have gone forward much more so.

We always thought in the beginning the diesel part of this was going to be a really hard part and the gasoline part was going to be the easy part. Turned out to be just the opposite. And that just lends more support for the whole structure of this is that we have created something that is technology neutral, that does provide incentive, that is market based to a large extent. And you know, in that sense, it's working now. Yes, we're only at one percent reductions, so I don't think we should be claiming too much credit yet, because we have a long ways to go.

But it is headed in the right direction, and I don't -- I personally don't see any major speed bumps along the way. And so I look forward to this as it evolves over time and will be thinking in a couple years from now what next.

CHAIRPERSON NICHOLS: Great. Thank you.

Mrs. Riordan.

BOARD MEMBER RIORDAN: Yes. I have a question to the staff.

Attachment A is I think important to us. And I wondered after listening to the testimony if your bullet points coverevery thing that you feel needs to be covered there or if there is something you would wish that the Board might add to give you some latitude to deal with something you might not necessarily have thought of at the time of the printing, but after the hearing, you feel might be helpful to you.

BRANCH CHIEF WADE: We feel like the list you have in front of you is relatively inconclusive. We'd like to highlight a few things on that list.

First, we believe a targeted public process on the GREET changes, especially with respect to natural gas vehicles, is essential. And we plan to conduct that prior to releasing a 15-day package.

Secondly, we feel the refinery investment provisions do deserve a little bit more attention as well in that time period. So we'll be going through the 65 or so written comments we received. Go out and have that dialogue with stakeholders on those issues. Release a 15-day package and return to the Board tentatively in July or so.

BOARD MEMBER RIORDAN: Thank you.

CHAIRPERSON NICHOLS: So just to an addendum to that. It's probably included in this, but this vexing issue which Dr. Sperling also mentioned of how you update based on new information, but not do it so often that you create uncertainty, have you thought about or are you prepared to think about including a specific provision on how frequently this matter will come back with amendments?

BRANCH CHIEF WADE: Certainly. We do believe having additional certainty for a period of essentially around three years or so would be useful. The work that's done on these complex models takes a huge amount of staff resources and does take away from the implementation of the program or the day-to-day running of the program. So --

CHAIRPERSON NICHOLS: From the time of adoption, whenever that is, hopefully this summer, you would then put in that regular three-year process for updating the science?

BRANCH CHIEF WADE: I think we have a time line for general program review. But we feel like the revisiting of the models is separate from --

CHAIRPERSON NICHOLS: Are two different things. Right. Right.

BOARD MEMBER SPERLING: To follow up on that, there has been a question that a lot of the -- some of the stakeholders have talked about, the natural gas the most, about the process part of that.

And I do -- so the question is should there be a more formal process or the stakeholder engagement in dealing with these GREET numbers and perhaps others. And I'm up of the mind that it should not be a formal process. But I think that's probably something that should be considered at some point. It really -- I think that the stakeholders pretty much feel comfortable that the staff has done a very good job of incorporating it. But in this modern day and age of transparency and so on, I think it is something that should be considered.

CHAIRPERSON NICHOLS: I think we should at least address the type of review and the process for review in a more robust way than we have until now.

Other comments at this point?

Yes, Ms. Berg.

BOARD MEMBER BERG: I'd just like to follow up on the timing of the actual review. If we look at we are in 2015 now, and I know in the staff report we have 2017, it feels to me that the first getting back on track is 2016 and we'll be circling back.

I think it would be helpful maybe to distinguish the type of informational how we're going to come back to the Board. For example, I would be interested -- very interested around the '17 time to understand how the investments are doing, to look at how the program is now ramping up or any challenges that we're having. But as far as doing a program review, much before we have a couple of years under our belt, I think would be more uncertain than creating the certainty. So I'd like to look at --

CHAIRPERSON NICHOLS: A progress report.

BOARD MEMBER BERG: Exactly. Rather than a review. So in looking at the 15-day changes, I would encourage instead of as outlined in the staff report that we're looking at an update in 2017 that you come back to us with a mix maybe of Board briefings on particular topics that are of interest to the Board and then actual program review and model review. So when we're voting on it, that it's a little bit more clear both for us and expectations that we're setting for the stakeholders and the market really what we're looking at. Thank you very much.

CHAIRPERSON NICHOLS: I see a head nodding there. I think that's acceptable.

BRANCH CHIEF WADE: That makes a lot of sense to us. We're happy to pursue the details of that with you moving forward.

CHAIRPERSON NICHOLS: Great. Other comments or questions before we call the question?

Yes. Supervisor.

BOARD MEMBER ROBERTS: I'll go quickly. It's obvious from the review we're talking about if there are things that are not going as we think, we want to highlight those for sure.

On one of the slides, there was a comment about add electric transit systems and electric forklifts. I don't want to leave that out. I'm sure that's important to somebody who is eligible to generate credits. Can somebody elaborate more on what are the rules? I presume we're talking about public transit systems.

BRANCH CHIEF WADE: That's right. So we're talking about light rail or electric buses with fixed guideways. And essentially, this is a new crediting provision for those types of transit systems. Do you want me to go into details of how?

BOARD MEMBER ROBERTS: Would it be on existing systems?

BRANCH CHIEF WADE: Yes, on --

BOARD MEMBER ROBERTS: And new systems?

BRANCH CHIEF WADE: -- are eligible, yes.

BOARD MEMBER ROBERTS: I'm curious about that. We're just getting ready to --

CHAIRPERSON NICHOLS: San Diego is looking for some new investments here.

BOARD MEMBER ROBERTS: That may be the nicest thing that happened. But I know I can provide a slide, but we're also exploring a new overhead electric system, a gondola, an urban gondola. I presume since that's all electric, that would apply.

BRANCH CHIEF WADE: We would happy to evaluate that project when it comes forward.

BOARD MEMBER ROBERTS: I seems we're beyond the exploring state. I presume that would fit into the category also.

CHAIRPERSON NICHOLS: Yes, the general category.

BRANCH CHIEF WADE: The general category, yes. We have to look at the actually --

BOARD MEMBER ROBERTS: We're not just saying light rail.

CHAIRPERSON NICHOLS: If it doesn't have wheels that go along the ground.

BRANCH CHIEF WADE: There is none of that in the definition. It believe that's the first case of this that we've seen it.

BOARD MEMBER ROBERTS: You'll see more of them I think. But that's far more efficient and cleaner than any other kind of transportation that we're aware of.

BOARD MEMBER SPERLING: Just to encourage you more, if you look at how much these credits could be worth -- so bring this back to San Diego -- is that these are worth in the tens of thousands of dollars. It depends on how much they're used and what the credit value is. We're talking about tens of thousands of dollars over a 10 or 15-year period for each, like a bus equivalent. So it's not trivial, but it's substantial. So what we'd like to see is cities making these investments, this will stimulate more investment

BOARD MEMBER ROBERTS: No, you know, I can share with you. Any of these things, they don't cover their operational expenses. So anything that can go to further that will be an incentive to increase those systems. It's at 26, $27 dollars right now as I understand it with the $200 cap. I'm not trying to push to get it out. But we'll see how the market works. I promised everybody that's involved in light rail that we --

CHAIRPERSON NICHOLS: You're down at the other end looking at starting up a bus company. So --

BOARD MEMBER MITCHELL: I'm thinking the gondolas at the ski resorts.

CHAIRPERSON NICHOLS: Supervisor Gioia.

BOARD MEMBER GIOIA: It was really good to hear from the range of speakers and really the excitement about this whole new field of alternative fuel development. I mean, it truly shows this when it was an active fuel neutral and something happened that sounds like this Board when it passed expected and some of the things happened that it didn't expect. That's sort of the true measure of the fuel neutrality.

But I think this is a very important rule regulation. And it's part of a whole suite of measures this Board has adopted to really encourage the development and demand for alternative fuels and alternative vehicles. I think it's accomplishing that. They all don't -- each of them don't achieve success on their own. It's all how they work in tandem in conjunction with each other, the cap and trade program, the clean cars program, low carbon fuel standard. And we understand that, that they're all intertwined. They're all important. And we need them all in order to achieve success. It was great to hear the excitement and the positive successes that have happened as a result of this original regulation.

CHAIRPERSON NICHOLS: Other comments.

Mr. Balmes.

BOARD MEMBER BALMES: I actually have a question. And it may be more appropriately addressed in the future. I don't want to hold us up.

But on slides 19 and 20 of the staff presentation, you show fairly impressive decreases in the carbon intensity for sugar cane ethanol, corn ethanol on the gas substitutes. And likewise for soy bean biodiesel.

And I realize this comes from a re-evaluation of the -- probably comes from a re-evaluation of indirect land use, but could you -- I don't need sort of a super detailed answer with regard to the model. But in terms of the major changes in the model, could you summarize what those are? Since there's been a lot of controversy over how we calculate the carbon intensity values. So this is a big picture answer, not down in the details of the model.

BRANCH CHIEF WADE: Let me open it up by saying the ILUC changes are some of the major drivers we've seen. If you'd like a bullet list of what some of those are --

BOARD MEMBER BALMES: A bullet list would be good.

MANAGER SINGH: Let me just say briefly -- and I can go more on this. Between 2009 -- I'm very passionate about what I do. I could go on forever.

Between 2009 when we first presented in '09 ILUC was something, you know, nobody had heard of and there was a lot of controversy. And over the course of the last five years, people have embraced indirect land use change.

In terms of the model, land use science has improved tremendously between 2007 through 2014. We have incorporated several of the changes in new data sets that have come out and new science that has come out with land use change.

To sort of summarize the critical changes that have impacted the indirect land use change results that we are presenting today is we made structural changes to the model to reflect how land conversion happens in the world. Originally, one of the contentions was we're changing a lot of forests in a lot of the countries of the world. We made structural modifications to account for more of the changes going to pasture land and land that is comparable to pasture land, which is used for crop growing. That was one of the biggest drivers that lowered land use change numbers.

The other one was the productivity of existing and new crop land. When you have new land that is converted, in the 2009 analysis, we had just an average number. But we had a lot of science and work that went into. Of course, we have to give consider to Purdue University and we implemented some of those changes.

Overall, our methodology and understanding of indirect land use change has tremendously changed between 2009 and today. And we've implemented sort of what we call harmonization of treatment across all biofuels that we've analyzed. That's sort of a quick summary.

BOARD MEMBER BALMES: That was just what I asked for and only a passionate person could have given it to me.

CHAIRPERSON NICHOLS: Great. Yes, Dr. Sherriffs.

BOARD MEMBER SHERRIFFS: Actually going back to a comment I made earlier. In terms of the reviews -- not the word we want to use -- but in 2017 report, I would like to be sure that staff looks at, in fact, trying to measure some of the health benefits that have come out of this and reporting back on that because I do think that's an important aspect of what we do with this.

BRANCH CHIEF WADE: Let me just ask you, so quantifying health benefits and assigning them economic value or quantifying them?

BOARD MEMBER SHERRIFFS: Boy, if you can do both, go ahead.

The other thing I would want to say, Mr. Corey, there was lots of thanks for all your work here. I think you can acknowledge that thanks by taking a weekend off.

CHAIRPERSON NICHOLS: The whole weekend? Wow. Okay. I think we're nearing time for a vote on the Resolution here.

I do have just one additional comment that I want to make. And I hope it's taken in the right spirit. But obviously, we did not hear a lot of support from major oil companies here at today's hearing. We heard a lot of support from others, but continued if not more serious I would say opposition to the very concept of a low carbon fuel standard, which is disappointing. And I'm not going to try to debate that politics or the economics of it really at all. But just to talk a little bit about the fact that there was a comment -- and I can't remember -- I think it was Chevron commented about the fact that we weren't really creating certainty because in the mind of the witness they didn't know how they were going to comply and, therefore, the technology is uncertain. And, therefore, there was not such a thing as certainty.

It just made me want to reflect and comment that this Board has for decades now been in the business of setting technology-forcing standards that were ahead of exactly where the people who were regulated knew how they were going to comply, but were based on a substantial knowledge and analysis of the potential for technology, as well as increasingly more sophisticated economic analysis, which doesn't mean that we're perfect or that we're ahead of where companies are in terms of analyzing their own businesses, but just that we think we are well rounded in terms of what the potential is for compliance here.

And I think it's important that perhaps this is not an area that the petroleum industry is accustomed to being pushed in. And I just want to say that I think we have a good track record of working with the regulated community and adjusting regulations, when it turns out that our predictions were wrong. But that overall by pushing towards goals that we believe are achieveable and occasionally adjusting time lines, if we had to, that we've achieved just tremendous progress and we look forward to doing the same thing here.

BOARD MEMBER SPERLING: So let me just elaborate just a bit on this.

This being serious, this really is hard. The challenge we've laid out really is a huge, challenge and we shouldn't understate that. And we should also appreciate -- and for the oil industry, I mean, we're basically telling them, you know, we want you to change your business model and your main product. And that's pretty tough stuff.

But at the same time, this is the larger social goal of the goal we're aiming for. So you know, I can sympathize with the oil industry. We're attacking their basic business model. But we are as, Chairman Nichols was saying, we are providing a lot of flexibility. We're providing -- the staff is creating incentives for doing things like CCS. So I think we are going out of our way to try to make this transition and this transformation as smooth and as efficient as possible while still achieving the goals that we're aiming for.

CHAIRPERSON NICHOLS: Thank you. Without further ado, do I have a motion?

BOARD MEMBER GIOIA: I'll make a motion.

BOARD MEMBER SERNA: Second.

BOARD MEMBER GIOIA: And a comment.

And I think it's important to acknowledge you were on a panel with an executive from Shell on alternative energy. Frankly, it is entirely possible for the oil companies to do more of what Shell's doing, which is looking at alternative opportunities, alternative fuel opportunities. So while it may be a challenge to their existing business model, it will help develop a new business model. So or help move toward a new business model.

CHAIRPERSON NICHOLS: Okay. We have a motion and a second.

All in favor please say aye.

(Unanimous aye vote)

CHAIRERSON NICHOLS: Any abstentions? All right. Thank you very much. Everybody.

And we'll be back. We have one item related to this one. The last item today is the proposed regulation on commercialization of alternative diesel fuels. And this is the issue that was directly connected with the challenge to the low carbon fuel standard. Because of the successful implementation of renewable fuel policies like the low carbon fuel standard, a variety of innovative alternative diesel fuels are currently in the marketplace or in development.

People, please if you're going to chat, do it outside because we are taking up the next item.

There is a variety of new types of diesel fuels that are currently in the marketplace or in development in laboratories and demonstration settings. To ensure that these fuels are available to help us transition to a low carbon future, staff is proposing new regulations that streamline the requirements for emerging alternative diesel fuels. It also will provide for robust environmental review of these fuels before they enter the market to ensure that current environmental protections are maintained.

Mr. Corey, please introduce this item.

EXECUTIVE OFFICER COREY: Yes, thank you, Chairman Nichols.

Since the initial implementation of low carbon fuel standard, significant changes have started to occur in California's fuel market which we talked about that for a while. The carbon intensity of our state's fuel pool is declining. As fuels like renewable diesel, biodiesel, natural gas, ethanol, electricity, and hydrogen are more prevalent, today's proposed regulation represents a vital step in supporting this important transition.

Staff's proposal today provides a clear pathway of commercialization of alternative diesel fuels, incorporates the best available science, and maintains our current environmental protections. In particular, the proposal will address NOx emissions related to the use of biodiesel.

The proposal works in conjunction with proposed low carbon fuel standard re-adoption you just heard about to ensure that we deploy fuels that contribute to our climate and as well as our air quality goals.

In addition, staff's proposal is part of ARB's response to the State Appeals Court decision we talked about earlier.

Now I'd like to invite Lex Mitchell of the Industrial Strategies Division to begin the staff presentation.

(Thereupon an overhead presentation was presented as follows.)

MANAGER MITCHELL: Good afternoon, Chair Nichols and members of the Board.

Today, I will presenting the proposal to establish a regulation on the commercialization of alternative diesel fuels, also called ADFs. As with the earlier item on the LCFS, we will not be asking the Board to take any approval action today.

--o0o--

MANAGER MITCHELL: As an overview, there will be five portions of this presentation which are listed here. We will first discuss the need for the proposal, then provide background, and outline our regulatory development process. We will then discuss the proposed process for approving alternative diesel fuels, the specific requirements for biodiesel as an ADF, and the impacts and benefits of the proposed regulation.

Finally, we will present potential 15-day changes.

--o0o--

MANAGER MITCHELL: We will start the presentation with the need for the ADF proposal

--o0o--

MANAGER MITCHELL: In order to minimize confusion, we will first cover what is and isn't considered an alternative diesel fuel under the current proposal. Examples of ADFs include biodiesel, which is already being used and is the first ADF proposed to be regulated under this process, and dimethyl ether, an ADF in the beginning stages of the environmental review process.

Both of these fuels are chemically different than conventional diesel and neither has an existing ARB specification. Examples of compression ignition fuels that are not ADFs include renewable diesel, which is a liquefied hydrocarbon chemically indistinguishable from conventional diesel and natural gas, which already has an ARB specification.

From here on, blends of ADFs, primarily biodiesel blends, will be discussed and some familiarity with how blends are referred to as needed. Biodiesel blends are referred to as BXX, where X represents the percentage blend level. For example, B10 is a blend of the 10 percent biodiesel and 90 percent conventional diesel.

--o0o--

MANAGER MITCHELL: Before we go any further, I'd like to spend some time clarifying the difference between biodiesel and renewable diesel, two terms that frequently get intermixed. Biodiesel is a fatty acid methyl ester and is chemically different from conventional diesel.

The biodiesel molecule contains two oxygen groups, unlike conventional diesel, which contains none.

Renewable diesel, on the other hand, is a hydrocarbon chemically indistinguishable from conventional diesel, but with lower aromatic content that is typically found in petroleum diesel.

Despite their differences, biodiesel and renewable diesel are complimentary fuels. Biodiesel's good lubricity and renewable diesel's good cold temperature performance can complement each other.

--o0o--

MANAGER MITCHELL: Now that we've covered what ADFs are, why do we think an ADF regulation is necessary?

First of all, ADFs can deliver significant environmental benefits. And we expect to see their volumes grow as both state and federal policies drive their supply and demand.

In order to encourage this expected increase in ADF volumes, it is essential that market certainty and regulatory clarity be provided to emerging ADFs. As these volumes increase, it is essential that ARB ensure their commercialization is done in a manner that protects environmental and public health.

The ADF proposal is designed to address all of these objectives. In addition the proposed regulation addresses one of the problems a court found with ARB's adoption of the original LCFS regulation in 2009 by addressing potential NOx impacts from biodiesel use.

--o0o--

MANAGER MITCHELL: Staff has extensively studied biodiesel and renewable diesel emissions and has found that both lower GHG, PM, and toxic emission. For example, a blend of 20 percent biodiesel has been found to decrease PM by about 20 percent.

Additionally, renewable Diesel decreases NOX relative to petroleum diesel primarily due to its lower aromatic content.

Staff has found that biodiesel can increase NOx in some situations in older heavy-duty vehicles. The ADF proposal applies the lessons learned from the evaluation process for biodiesel in order to develop a process to evaluate future ADFs. In addition, the proposal allows biodiesel use while addressing the NOx concerns recognized during biodiesel testing, maximizing environmental benefits.

--o0o--

MANAGER MITCHELL: This table shows the LCFS credits generated by biodiesel and renewable diesel in 2014 and 2020. Biodiesel and renewable diesel make up a large and increasing portion of the total LCFS credits as time goes by and significantly contribute to the success of the program.

--o0o--

MANAGER MITCHELL: In addition to biodiesel, which is already contributing to the LCFS, other ADFs are expected to emerge as incentives continue. Current evaluation of these fuels involves various regulations and statute. The ADF proposal would take these requirements, clarify them, and compile them into one regulatory framework, which will provide additional certainty for proponents of upcoming ADFs, such as dimethyl ether, which is currently undergoing evaluation.

--o0o--

MANAGER MITCHELL: Let's move now to the

regulatory development process.

--o0o--

MANAGER MITCHELL: ARB has spent the last eight years developing and conducting studies on biodiesel emissions and analyzing the results of these studies, including spending about three million for testing to understand biodiesel's impact.

In addition to the original research conducted by ARB, staff conducted a literature review and sponsored an independent statistical analysis of the data. Staff has had extensive interaction with stakeholders on our biodiesel program, including 13 public meetings to discuss testing and seven reg development workshops.

The combination of comprehensive biodiesel testing and continual stakeholder involvement and feedback led to the ADF proposal presented today.

--o0o--

MANAGER MITCHELL: During the multimedia evaluation and additional review of biodiesel emissions, nitorgen oxides, or NOx, was found to be a pollutant of concern whose emissions varied by feedstock.

For example, on this graph, you can see that biodiesel derived from soy feedstocks leads to greater NOx increases than biodiesel derived from animal feedstocks. Whereas, renewable diesel decreases NOx. All of these impacts were measured for pre-2010 heavy-duty engines. Light-duty, medium-duty, and new technology heavy-duty diesel engines have been found to have no biodiesel NOx impacts.

We'll come back to this slide later in the presentation.

--o0o--

MANAGER MITCHELL: Moving on to the objectives of the proposed regulation. In development of the ADF proposal, ARB has adhered to the following objectives:

Establishment of a clear pathway for commercialization of ADFs in order to provide regulatory certainty and encourage the use of ADFs. Ensuring public health and air quality protections from ADFs used as a replacement for conventional diesel in order to ensure the integrity of our existing air pollution reduction programs. And establishment of criteria for biodiesel use and NOx emissions control, to ensure that the benefits of biodiesel use can be realized without associated degradation in ozone-related air quality.

--o0o--

MANAGER MITCHELL: We will now go through an overview of the ADF proposal. The ADF proposal includes two main provisions, the general evaluation process for environmental analysis of emerging ADFs and the fuel specifications and in-use requirements for biodiesel.

The environmental evaluation process for emerging ADFs consists of three stages, following ADFs from lab to demonstration to commercial scale.

The proposal will limit fuel volumes and consider test location. Through this review and evaluation process, the conclusion may lead to staff to develop additional in-use controls and specifications for that fuel, or if there are no detrimental effects found, only reporting may be required.

The fuel specifications being proposed for biodiesel and, in fact, the three-stage evaluation requirements are based on staff's multimedia evaluation of biodiesel, as well as renewable diesel, both of which are nearing completion and will be completed by the follow up Board hearing.

--o0o--

MANAGER MITCHELL: Let's move on to the evaluation process for emerging ADFs.

--o0o--

MANAGER MITCHELL: The three stage evaluation process for commercialization of ADFs was developed to evaluate environmental impacts and control potential detrimental impacts prior to the widespread use of an emerging fuel.

During this process, staff would complete a multimedia evaluation of the fuel to determine adverse emission impacts for any pollutants of concern considering offsetting factors to determine the need for in-use requirements or fuel specifications for the ADF. The mechanism for dealing with pollutant increases would be to set a pollutant control level above which pollutant reduction strategies would be required.

--o0o--

MANAGER MITCHELL: This graphic shows the three stages and hypothetical volumes of fuel distributed as the fuel progresses through the stages. Initially, an ADF proponent would apply for a pilot program under Stage 1, which would include disclosure of ADF composition, preliminary emissions testing, evaluation of potential environmental and health effects, and volumetric limit of no more than one million gallons per year.

In Stage 2, the focus is on fuel specification development and would include a full multimedia evaluation, consensus standards development, consideration of engine concerns, determination of potential adverse emission impacts, and volumetric limit of 30 million gallons per year.

After completing Stage 2, a fuel may advance to either Stage 3A or 3B, depending on its environmental impacts. If adverse emission impacts are found, the fuel would be regulated under Stage 3A, which includes development of in-use requirements and fuel specifications. If a fuel is found to have no detrimental impacts, it would be eligible for Stage 3B, where only reporting is required.

As noted earlier, this three stage process is reflective of current regulatory requirements and policies already in place.

--o0o--

MANAGER MITCHELL: Let's move now to the biodiesel specific requirements of the proposal.

--o0o--

MANAGER MITCHELL: In order to control the NOx increases from biodiesel, staff developed specific in-use requirements and fuel specifications. The proposal included reporting provisions which begin in 2016, but in-use requirements do not begin until 2018. This time lime allows for implementation of mitigation options for compliance pathways.

A pathway for certification of additional in-use options has been included to allow testing of novel methods the offset NOx emission, including novel Additives, blend stocks, or production methods.

The biodiesel in-use requirements will sunset when vehicle miles traveled in the on-road heavy-duty fleet is greater than 90 percent new technology diesel engines. This is currently anticipated to occur by 2023. Additionally, the biodiesel provisions will undergo a program review to be completed by 2020.

--o0o--

MANAGER MITCHELL: Beginning in 2018, biodiesel would be limited to B5 or B10, depending on feedstock and season. Feedstocks under this proposal would be distinguished by cetane number rather than prescription of feedstock source and cetane cutoff for determining feedstock is 66.

Higher cetane biofuels such as animal-based biodiesel tends to produce less NOx than lower cetane biodiesel, such as soy-based biodiesel, and therefore be used in higher blends.

Additionally, blends up to B20 could be sold if they use an additive or other certified control. Biodiesel used in light-duty and medium-duty vehicles has been shown not to increase NOx. Newer heavy-duty vehicles have been shown not to experience the NOx increase from biodiesel as well that is seen in older heavy-duty vehicles due to the use of selective catalytic reduction emission controls. The ADF proposal includes an exemption process for these vehicles.

--o0o--

MANAGER MITCHELL: You'll recall this slide from earlier. The important point here is that our extensive testing showed that biodiesel are not created equally and the different feedstocks result in different NOX effects. Just as importantly, our testing also showed the offsetting effect on NOx from the use of renewable diesel. These two findings informed the proposed regulation.

--o0o--

MANAGER MITCHELL: As part of staff's analysis of the effects of biodiesel use, offsetting factors were considered to determine the real world effect of its use, rather than simply the lab results of engine testing.

Most importantly, it was found that new heavy-duty new technology diesel engines or or NTDEs do not experience a NOx increase with biodiesel up to B20 due to SCR emission controls and the heavy-duty market is substantial and increasingly complied of NTDEs.

Additionally, the NOx decrease from renewable diesel means that some of the emissions from biodiesel are offsetting, leading to less need for in-use requirements on biodiesel, especially considering the recent and expected continual increase in volumes of renewable diesel. These offsetting factors combine to eliminate the NOx increase from biodiesel over time, hence the sunset provisions, by in the mean time controls on NOx are needed.

--o0o--

MANAGER MITCHELL: This graph shows the increase in vehicle miles traveled by new technology diesel engines as well as the NOx increase from biodiesel.

As newer vehicles become an increasingly large contributor, the vehicle miles traveled in the on-road heavy-duty diesel fleet as shown by the shaded bars. The corresponding NOx increase from biodiesel becomes increasingly reduced.

As you can see, in 2023, when newer vehicles are expected to contribute more than 90 percent VMTs, the NOx increase from biodiesel becomes negligible. At that point, we are proposing to sunset the biodiesel in-use requirements.

--o0o--

MANAGER MITCHELL: Practically speaking, we expect regulated entities to comply with the regulation primarily by selling biodiesel blends at or below a B5 blend level.

However, the proposed includes other options that will increase flexibility for compliance which are listed here. For example, for businesses geared toward B10 sales, either a high cetane feedstock may be used or any feedstock may be used in the winter.

For businesses geared toward B20 sales, either targeted sales to exempt vehicles or additive use will accommodate these sales. The table on this slide shows the NOx control level by both feedstock and time of year, which lead to these compliance options.

--o0o--

MANAGER MITCHELL: As was mentioned earlier, the NOx emissions from biodiesel are expected to decrease over time leading to a sunset of the in-use requirements when new heavy-duty on-road trucks are more than 90 percent of vehicle miles traveled. This is expected to occur by 2023.

Additionally, as the fuel market is still in flux in its transition to diesel substitutes, a review of the program will be completed by 2020. This review will consider a variety of factors, such as SCR adoption and fuel volumes, and whether we are on the right trajectory toward the projected sunset of biodiesel blend limits.

--o0o--

MANAGER MITCHELL: Let's move now to the impacts and benefits of the alternative diesel fuels proposal.

--o0o--

MANAGER MITCHELL: Staff prepared one draft environmental analysis, or EA, that covered both the proposed LCFS and ADF regulations because two rules are interconnected. The draft EA was prepared according to the requirements of ARB's certified regulatory program under the California Environmental Quality Act, or CEQA. The analysis focused on changes in fuel production supply and use. The existing regulatory and environmental setting or the actual physical environmental conditions in 2014 is used as a base line for determining the significance of the proposed regulations impacts on the environment.

--o0o--

MANAGER MITCHELL: As discussed in the previous presentation for LCFS, the draft environmental analysis identified both beneficial impacts and adverse environmental impacts from the proposed regulation.

Beneficial impacts were identified in the areas of reduced GHG emissions, reduced criteria pollutants, including reduced PM2.5 emissions and energy. The draft EA identified less than significant impacts to certain resources such as minerals and recreation.

Potential significant impacts were identified in a number of resource categories such as agriculture, biological, and hydrology and water quality. Significant cumulative impacts were also identified for resources.

While some of these identified impacts are related to long-term operational changes, others are potential short-term effects related to construction of new fuel production facilities.

--o0o--

MANAGER MITCHELL: The economic impacts of the ADF proposal were evaluate in two ways, as part of a state-wide macro economic evaluation of the effects of the ADF and LCFS proposals and as the direct costs of the ADF proposal provisions.

Because the ADF and LCFS proposals were so interlinked, the macro and economic impact of the proposals could not be desegregated and therefore the evaluation was completed using the simultaneous effects of both proposals on fuel volumes and prices.

As was discussed in the LCFS presentation, the macro economic evaluation employed a conservative framework and found that the combination of proposals would have a very small impact on the overall state economy.

Compliance with the ADF provisions are expected to result in costs of about one-tenth of a cent per gallons on B5 diesel in 2018. And as the fleet transitions to newer engines is expected to shrink and eventually be eliminated by 2023. For biodiesel producers whose business is reliant on sales of higher biodiesel blend levels and who are not located near a terminal with biodiesel blending facilities, there are will be additional challenges to the regulation.

Staff continues to work with stakeholders to identify additional flexibility to address this challenge while maintaining the NOx protections of the proposal.

--o0o--

MANAGER MITCHELL: The primary reason why alternative diesel fuels and other diesel substitutes are important and should be encouraged is due to their variety of beneficial impacts. For example, biodiesel, renewable diesel, and dimethyl ether can all reduce PM and toxics compared to conventional diesel, leading to lower localized toxic exposure, and renewable diesel can reduce NOx emissions.

All of these fuels can be produced from feedstocks that lower greenhouse gas emissions and are capable of contributing to our 2020 and 2030 air quality goals. Additionally, all of these fuels can be produced from domestic sources produced in the USA, leading to increased energy security.

--o0o--

MANAGER MITCHELL: We will now move on to 15-day changes and next steps.

--o0o--

MANAGER MITCHELL: Staff has included some potential 15-day changes for consideration in Attachment A of the Resolution. Examples of potential changes include further flexibility for captive fleets that would not adversely effect air quality, clarification of certification procedures, definitional changes, and minor clarifications, and corrections.

--o0o--

MANAGER MITCHELL: This is the first of two Board hearings so the Board will not adopt the ADF today. We recommend that the Board direct staff to continue working with stakeholders to refine the proposal and coordinate development with the LCFS team.

--o0o--

MANAGER MITCHELL: Going forward, staff will complete and respond to comments on the environmental analysis document. The peer review of our biodiesel multimedia evaluation is in progress and the multi-media process will be completed by the second Board hearing.

Staff will also propose 15-day changes for comment prior to the second Board hearing.

Thank you for your attention. This concludes staff's presentation. I would be happy to answer any questions you may have.

CHAIRPERSON NICHOLS: We do have 14 witnesses who have signed up. But yes.

BOARD MEMBER SERNA: Thank you, Madam Chair.

Quick question for staff on the chart that you showed twice that showed the NOx effect of biodiesel in older heavy-duty vehicles, are you encouraging us not to get too hung up on the soy feedstock biodiesel because that's only applicable to the older engines. And with the introduction of newer engines that that NOx concern will go away?

MANAGER MITCHELL: I wouldn't characterize it as the difference in the feedstocks. We think that the NOx effect goes away over time, like you said, due to the newer vehicles. More or less what the proposal does is it assumes that unless you take an action and use a cleaner feedstock that you're using one of the soy feedstocks, which we consider the lower cetane fuels.

ASSISTANT DIVISION CHIEF KITOWSKI: Maybe I can recharacterize that a little bit.

The use of soy and animal as part of the testing programs, but they weren't very good metrics for regulation. So in moving from the test program to the regulation, we shifted from soy and animal feedstocks to high saturation or high cetane and low saturation low cetane. They're area pretty much analogous.

BOARD MEMBER GIOIA: Thank you.

CHAIRPERSON NICHOLS: Before we go, you have a question?

BOARD MEMBER ROBERTS: You'll have to indulge me. I know I'm the only one that doesn't know the answer to this.

The difference between biodiesel and renewable biodiesel? And why do they call it renewable because it doesn't seem like it's renewable?

MANAGER MITCHELL: Biodiesel and renewable diesel are both produced from the same feedstocks. Those are any fat or oil that you can find.

The difference is in the processing. So the biodiesel process is it takes this kind of lighter chemical treating to create this fatty acid methyl ester, which is a distinct type of chemical.

Renewable diesel takes those same feedstocks and it uses a more similar to a refinery process a hydro treating process to create a fully non-oxygenated saturated fuel.

The reasoning why they're called something different I think is that biodiesel was kind of the first adoptor of this technology so that biodiesel was there first. And then to distinguish, they just wanted to make sure that what people are calling fatty acid methyl esters is biodiesel and it's different from renewable diesel, which came along later. So it's not that one is renewable, one's not.

CHAIRPERSON NICHOLS: Renewable sounds good and --

BOARD MEMBER ROBERTS: It sounds like it's going to be there after you use it. So --

CHAIRPERSON NICHOLS: It's just terminology.

BOARD MEMBER ROBERTS: It's in the process you're starting with similar products. And that's where the --

MANAGER MITCHELL: Transetherification is the chemical process for producing biodiesel and hydro treating is the chemical process for producing renewable diesel.

BOARD MEMBER ROBERTS: You made it so crystal clear.

CHAIRPERSON NICHOLS: The whole concept of fatty acids is not really worth talking about.

BOARD MEMBER GIOIA: There is a good band name in there somewhere.

CHAIRPERSON NICHOLS: With that, I think we should proceed to hearing from the witnesses. So we'll start with Matt.

MR. MIYASATO: Thank you, Madam Chair.

For the record, Matt Miyasato, the Deputy Executive Officer for Science and Technology Advancement at the South Coast Air Quality Management District.

I'm here to voice our support for the staff recommendation and your ultimate approval of the ADF regulation.

I also want to point out that you've heard a lot of accolades about your staff. They continue to work, go out of their way to work with us. We brought up the concerns we had over NOx increases or potential for NOx increases. And they do what we do, they rely on data to make the recommendations before your Board which is in your package today. So we appreciate staff continueing to work with us.

So again, we urge your ultimate approval when this comes before you for a vote. Thank you.

CHAIRPERSON NICHOLS: Thank you. Ms. Case.

MS. CASE: I'm going to sound like a broken record when I thank everybody again.

CHAIRPERSON NICHOLS: Could you raise the mike?

MS. CASE: Richard Corey and Lex Mitchell and everybody on the staff for all the work that they've put into this, because it really has been a lot of work. And I do appreciate it.

As I said in my earlier testimony, my biodiesel plant is in San Diego, which is one of the smaller diesel markets that is not at this point terminal blending. We make our biodiesel from 100 percent used cooking oil captured from restaurants. So we convert french fry oil into biodiesel.

The biodiesel that we make on the our plant is one of the lowest carbon biodiesels out there, because we are making it from the used cooking oil. And it's soon to be lower as we are in the middle the project to install cogeneration at our plant, which we are really proud of.

This regulation I know was pain-stakenly arrived at over a long period of time, and I believe it represents a great compromise for all sides. I particularly support that there is the in-use time line, which will allow our business to adapt. We do sell a lot of our fuel into the B20 market. So we do need to make some changes to our business plan. And we look forward to continuing to work with staff on finding ways that we can target fleets that will not cause increased NOx and in addition work with our trade industry group on developing additives.

So thank you for everything that you've done to get to this point. And in this spirit of the Chairman's comment earlier, I'm very confident that we will innovate and adapt to these changes as we have in the past and everyone should to protect our environment. Thank you.

CHAIRPERSON NICHOLS: Okay. Thank you.

Curtis Wright? Curtis Wright here?

Celia DeBose.

MS. DE BOSE: So this is Celia DeBose again with the California Biodiesel Alliance, the industry trade association representing over 50 stakeholders.

And again, we're supporting the comments of the National Biodiesel Board and urging the adoption of this regulation. So if staff needs more kudos, kudos.

And the interesting thing about this is that it's not just you guys, but it's generations before because we really have been working on this for about ten years. What we've been engaged in is a process of bringing in new fuel to market in California. So we've marked with State agencies, helped them check off what they need to check off. And what's important now is that the Air Resources Board moved forward with this important step so that we can move forward with a structure and a process that allows us to deal with this one criteria pollutant.

So we really appreciate the exemption, the exemption for the 90 percent new technology diesel engines for heavy-duty fleets, the exemption for the light and medium duty fleets, the opportunity to create our own additive. And I was very happy to see further blend level flexibility for captive fleets as something that we can talk about. So thank you again. We really look forward to continued engagement as we finalize and implement this.

Just on another note, it's great to have our fuel recognized for its beneficial qualities. And we know that we do well under the low carbon fuel standard because we reduce greenhouse gases. But it's nice to hear you guys also recognize all the other benefits. We really look forward to bringing the health benefits to California as much as possible and especially the PM reductions that have been really noted -- Richard Corey mentioned this at our conference on February 4th saying that biodiesel is important for reductions in toxic diesel particular matter. So we do this already. We want to do it more. We want to help provide solutions in the communities that are most impacted that suffer the most from the diseases caused by diesel pollution. And a lot of our plants are located in these areas. So we're going to accomplish this by creating more good family supporting jobs. So thank you guys so much.

CHAIRPERSON NICHOLS: Thank you.

MR. NEAL: Thank you, Madam Chair and members of the Board.

Shelby Neal with the National Biodiesel Board representing the biodiesel and renewable diesel industries. We are not quite as excited to be headed to the gallows as the gentleman was this morning. But we are never the less excited.

We would like to thank the ARB Board and especially staff and particularly Richard Corey for really in my 17 years in and around government unprecedented level of focus and work on an extraordinarily dull topic. So thank you really all of you for doing that.

I'm no expert in business, but Warren Buffet it often says this, he says capital goes to where it can get the highest return with predictable risks. So it's the last clause in that sentence where we've had trouble. Predictable risk. But this regulation along with LCFS readoption fixes that.

So this should move our industry from survival mode, which is surviving is better than the alternative, but it's no way to live long term. So this should move us into a more comfortable area. And in 2023, or when we can develop an additive so-called solution which we are working on already, we can thrive and we can flourish in the state. I think we will.

I want to thank ARB staff for just doing an incredible job. We stated in our public comments that we didn't think this regulation was necessary in a perfect world. But that's not intended to be a criticism. ARB has a very different mission than our industry does or other scientists who look at this. And every step they took the most conservative path, the most protective of public health. We support that view. That's why we willingly accept these limitations. Thank you very much for your time.

CHAIRPERSON NICHOLS: Mr. Teall.

MR. TEALL: Russ Teall, Biodico and currently President of the California Biodiesel Alliance.

I will try not to repeat the things that have been already said. I agree with them entirely.

But the history of this goes back to 1993. That was our first meeting with the Air Resources Board to talk about biodiesel. It was brand-new at the time. And so it's been a 22-year journey up to this point. And is it perfect? It's as close to perfect as you can get. There's been a lot of give and take, back and forth. And the complexity of the regulation reflects a desire I think to get it right. You know, it's a complex topic. And in order to balance the needs of industry with the needs of the environment, I think it's a well crafted decision.

One point that needs to be made is that biodiesel substantially reduces air toxics, other than the criteria pollutants, all the polyaeromatic hydrocarbons, et cetera, we're the only fuel that's been through Tier 1 and Tier 2 health effect testing the U.S. EPA successfully. So that's a point that was recognized by staff.

Thirteen public meetings, seven ADF workshops, countless private meetings, phone calls, e-mails, I'm going to look forward to getting back to Santa Barbara at the end of this journey.

Other than thanking Richard, Floyd, and Jack have done a tremendous job, you know, transitioning Floyd in the beginning directing this entire process, setting a mood that was correct in terms of listening to industry, reacting. And I think as a two-way learning, we learn things along the way that about ARB and what the objectives are. And I think they learned as well.

So I guess in conclusion, we whole heartedly support the ADF program in part because of staff. You know, we know that staff is there. They're listening. And we look forward to continuing the dialogue during this 15-day notice period. Thank you.

CHAIRPERSON NICHOLS: Thank you.

Mr. Von Wedel.

MR. GERSHEN: I think Randall left.

Thank you again. At the risk of sounding a little repetitive, the development of this ADF regulation has been a challenging process. We appreciate ARB has been mindful of all the stakeholder interests.

As I'm sure you know by now, California biodiesel industry is made up of independent producers marketers, feedstock suppliers, a variety of stakeholder feedstock, all sizes and shapes. A big challenge has been to be inconclusive, and ARB staff has been very attentive to our needs and demonstrating the willingness to work with our industry to help develop a variety of compliance options. And we really do appreciate that. Thank you.

As mentioned in my prior comments, I'm confident that working together with ARB, California biodiesel can build on our successes. We look forward to continue working with you even more to reducing carbon emissions, lowering emissions, and creating high paying green jobs in disadvantaged community across the state. Thanks.

CHAIRPERSON NICHOLS: Lisa Morenton again.

MS. MORTENSON: Hello, Chairman Nichols and members of the Board.

I sincerely appreciate the opportunity to talk about the ADF. This is a very personal issue for me. I cannot count the number of sleepless nights that I have had during the twists and turns of the development of the ADF rulemaking. So this is very important to our industry.

As you know, biodiesel use in California has made a positive impact. It reduces harmful emissions and it also stimulates the economy. It's important to remember that biodiesel is an advanced biofuel that is proven. It's reliable. And it is available in commercially significant volumes. And it is our commercial success is why we are in the Stage 3 as a commercial fuel under the ADF rulemaking. So part of this is very positive. The commercial success of biodiesel have moved us into this new level of regulation.

Biodiesel does have strong public and bipartisan support, and that's because it has so many terrific benefits. It has wonderful performance benefits. It has very strong lubricity properties, which reduces wear and tear on engines, and it also has strong detergent properties.

It has terrific environmental benefits reducing harmful emissions which improve human health. And we heard from Lex Mitchell earlier that biodiesel lowers localized toxic exposure. That is so important to protect our most impacted communities. And it's also important to remember that the diesel engine is 20 to 30 percent more efficient than electric engine.

And we, of course, can't forget the economic benefits. Biodiesel creates jobs, revenues, and taxes. When you have in-state production such as what we do at Community Fuels, you're creating advanced manufacturing jobs, which have the highest multiplier effect of any industry. So biodiesel is really exciting and really good for California.

I ask you to put on your imagination cap and imagine if biodiesel were the typical diesel fuel used in California and petroleum diesel were trying to gain approval. Imagine how different that conversation would be.

We spoke about how biodiesel is ready to deliver significant volumes to California. The ADF proposal will impose limitations and constrain how biodiesel is used within the state. While I understand why the alternative diesel fuel rulemaking is necessary, I do request that CARB pay very close attention to this ADF rulemaking and to work hard to sunset this regulation at the earliest possible opportunity.

We want to grow biodiesel in California. We want to realize all the benefits that biodiesel has for this state. And to do that, we need more flexibility and higher volumes of biodiesel. And just quickly, I want to thank Mr. Corey for his personal involvement in this very important issue. He made a big impacts in the direction of this regulation. Thank you.

CHAIRPERSON NICHOLS: Okay. Thank you. Extra time always allowed for thanks.

MR. SIMPSON: Madam Chair and members of the Board. Harry Simpson with Crimson Renewable Energy, biodiesel producer here in California.

Obviously, we paid very close attention over this marathon process that we've gone through in getting to where we are today with the ADF regs. I think in our company was formed in '07, and I think some of the stuff started even before that.

So we would certainly like to thank Mr. Corey and Lex and Floyd and the many others who have been on this road to get us to the proposed regs today.

I know that sounds like a broken record, but you guys really do deserve a hand for that. You guys have consistently engaged with all the different stakeholders and that was certainly no easy feat. And your willingness to do it on a very regular basis and hear what everyone had to say went to I think what many of us would call a grand compromise in terms of the regs that we have before us today.

That compromise was the product of a lot of strong data, a lot of technical analysis, a lot of fighting back and forth as to how that shook out. In the end, I think you were able to acknowledge the significant health and carbon reduction benefits that biodiesel offers and reconcile that with any issues and the need to safeguard air quality in terms of NOx.

So while it's not ideal, we fully support it. And I think it provided much needed regulatory certainty.

Like Lisa said, I, too, have had many sleepness nights wondering if the close to $30 million we have invested in our plant is going to go up in smoke. And we get essentially regulated out of business.

So I'm happy to say that's not the case, and I think the community in which we in the state of California I think last year we contributed about $40 million directly into the economy. When we're done with our expansion, it will be $80 million in 2016. It's good to see that investment will continue to make a contribution and bring much needed carbon reduction benefits to the LCFS. Thank you. We support the regs.

CHAIRPERSON NICHOLS: Great. Mr. Barrett.

MR. BARRETT: Good afternoon. I'm Will Barrett with the American Lung Association of California.

And as noted in the letter that we submitted along with our colleagues that CERT, the Coalition for Clean Air, NRDC, we support the proposed diesel regulation. You'll hear from some of the other signors of that letter in a few minutes.

We believe the proposal successfully addresses the need for cleaner alternatives to harmful fossil fuels, with the need to ensure that no additional harm is caused by these alternatives as they come into the market or the market expands because of the potential for biodiesel to increase smog-forming NOx emissions under certain formulations or engine models or operating conditions put forward by CARB set to avoid backsliding on NOx is appropriate.

We also do appreciate that the proposal and Lex's presentation included compliance strategies to maximize the greenhouse gas and particulate benefits of buy diesel. We encourage ARB to explore additional opportunities to capture NOx neutral and NOX reducing particulate and carbon pollution benefits of this alternative.

The air pollution public health and health equity impacts of petroleum fuels are well documented and must continue to be addressed through strong regulations that get all fuels impacts on lung health in our climate. We believe the ADF proposal is an important step in this process of curbing many harmful pollutants at once and protecting the health of future generations of Californians. So I just wanted to add to the chorus and thank for the staff's work on this. And thank you all.

CHAIRPERSON NICHOLS: Great. Mr. Magavern.

MR. MAGAVERN: Bill Magavern, Coalition for Clean Air in support. I did not go through all the ins and outs of this long regulatory process. I have a lot of respect for those who did. I'm very impressed with the final result.

For years, we've had this tension. I think as we heard earlier today just, about everybody other than the oil companies wants to bring lower carbon fuels to market. And we need to reduce our reliance on petroleum so there are a lot of good arguments for alternative fuels.

At the same time, as air advocates, we want to make sure we're not unintentionally increasing any air pollutants. And of course, it's your mission to prevent that from happening. So I think that this balance has been struck and this regulation really achieves that. Petroleum diesel is a plague on our health, so let's bring on the biodiesel with the appropriate protections. Thank you very much.

CHAIRPERSON NICHOLS: Okay.

MR. DELAHOUSSAYE: Good afternoon. Dayne Delahoussaye representing Neste Oil. Neste Oil support supports the ADF regulation and and we're advocating the Board continue forward with it.

We're glad and proud that the findings of the NOx reductions agrees with our research and our experience as well. So we are supportive of California moving forward with that step.

The one technical comment I would point out and I made this in more detail in my written submissions for both the LCFS and the ADF because they tie together is the definitional language specifically when you're discussioning this fuel.

I believe one of them calls them non-renewable diesel. The other calls it renewable. At a minimum, encourage the same terminology for both of these funds referring to the same fuel.

Additionally, the ADF goes into great pains to describe -- the fuel they described was the hydrocarbon fuel. And so we would encourage as we're trying to develop a right technology for this and consistency that renewable hydrocarbon diesel be the term we're describing so we can avoid any confusion between different usage and different markets of other uses and that kinds of stuff. For example, some Canadian jurisdictions define renewable diesel as both hydro treated and biodiesel stuff. I think having a more clear definition of what it is renewable as opposed to what it's not non-ester renewable diesel being a more appropriate and simple definition for that kind.

And as well as then align the two definitions. They both have different public parts and things like that and there is a lot of overlap, but they're not unanimous. I would encourage being at least under the same division to have a definition that is in line and in agreement with each other. And you don't have two jurisdictions within the Air Resources Board playing that game. Other questions, I'm happy. Otherwise, thank you for your time.

CHAIRPERSON NICHOLS: Good point. Probably requires the equivalent of a spell check to be used. And make sure we use the same terms each time. Okay.

Mr. Hedderich.

MR. HEDDERICH: So 13 is much better than 45 or 46. Moving up in.

And I understand why, Chair Nichols, you pronounced my name correctly. It's misspelled. It ends in an H.

I'm not going to repeat the comments you heard from other folks. We're very supportive as the nation and north America's largest biodiesel producer and also a significant producer of renewable hydrocarbon biodiesel. Very supportive of all the comments that you heard. Agree there is some definitional issues we need to work out to make sure we're using the same language.

I was going to offer to Supervisor Roberts if he wants to see what the different plants look like, happy to show him. This has been a torturous process, I'll say. It needs to come to conclusion so our industry can move forward, so we can move forward with the LCFS, so we can have some certainty. Very much appreciate all the effort that staff did to bring this issue to closure. And with that, let's move forward and get closure. Thank you.

CHAIRPERSON NICHOLS: Okay. Thank you.

Mr. Mui.

MR. MUI: Good afternoon. Simon Mui with NRDC.

We also support the adoption of the ADF regulation. And like Bill Magavern, I've been on the periphery and following and reading.

But I do have to commend staff and management for really balancing the need to achieve the GHG reduction goals while mitigating any NOx issues. And we do think that ARB -- this is one great example where ARB has really ensured as we transition to new energy sources, we are managing the trade-offs.

So I really commend staff. And I know that often times industry may have sleepless nights. I can guess that ARB and staff has had sleepless nights. Maybe as a Resolution Richard can actually take a weekend off.

But I do want to say that this is reasonable. Our understanding is looking at the science that this is based on the best available technical studies and work. And we are very enthusiastically supporting this as maximizing both the LCFS and ADF together are really maximizing the public health benefits of these programs. Thank you.

CHAIRPERSON NICHOLS: Thank you.

And last, Mr. Fulks, from the Diesel Technology

Forum.

MR. FULKS: Madam Chair, Board members, always awesome to be batting cleanup, standing between you and going home. So I will be as brief as I possibly can.

The Diesel Technology Forum is not taking a position on ADF, but we did want to come in and acknowledge the professionalism, the courtesy, and the just plain decency of your staff in the development of not just the ADF, but also the LCFS. It's been a pleasure to work with your staff. I'm just piling on, I know.

I did want to take a yellow highlighter to the precedent-setting policy that you were engaging here with the ADF in that it is an acknowledgement that emission control systems for diesel engines will be used as a NOx mitigant for this fuel moving forward after 2018.

We did note that under the LEV III development process the notion of using fuel as a NOx mitigant for vehicle hardware was never even allowed to be considered. So this is a precedent-setting policy change that we will be taking note of as we move into the future trying to reach the Governor's 50/50/50 by 30 goals. We're going to be relying on diesel for a while to get some of these fuel economy gains.

And as there may be a clash between those goals and the ultra low NOx rule that is a voluntary rule now but may be coming back to you as a mandatory measure. So therefore, I just wanted to plant the seed that now that the precedent has been established that you can use hardware to mitigate NOx from fuel, it may come back to you some day that maybe perhaps we can consider using fuel as a NOx mitigant for hardware down the line.

So thank you for your attention. And again tip of the hat to your staff.

CHAIRPERSON NICHOLS: Well, it's an interesting comment, but I'm not really buying it.

MR. FULKS: I'll put it in the record anyway.

CHAIRPERSON NICHOLS: I'll tell you why, because I think that there is a lot of precedent for recognizing that emissions occur when fuel is used in an engine. And when you're projecting emissions, you have to look at what the engine is doing as well as what the fuel is doing.

So I don't think that position that the staff has taken here -- and I could be corrected on this -- is that the new vehicle standards are a mitigation for the fuel any more than the fuel is a mitigation for the engines when we're certifying engines. We certify engines based on a type of fuel that we assume is going to be in the marketplace. And this is the same thing in reverse.

MR. FULKS: Understood. We wanted to open the dialog as we move forward with ultra low NOx.

CHAIRPERSON NICHOLS: Always good to see you. Mr. Corey needed another round of thanks. That's great. Thank you.

Okay. That's it for the witness list. And are there any additional comments by the Board? Question, Mr. Dr. Sperling.

BOARD MEMBER SPERLING: I'm not speaking as a Board member yet. As a scientist, I look at Table 12 and I see these are really very small differences when you take into account we're talking about 50, 90, 95 percent reductions otherwise. So are there -- there's uncertainty. There has to be a lot of uncertainty here. So I'm wondering if I was looking as a scientist, I would say, okay, what are the confidence intervals here. What's probablistically, what are we talking about here. But one percentage? Two percentage? I know there is judges involved and that stuff. So that's why you I'm asking this as a scientist first.

MANAGER MITCHELL: I can parrot some of what we put in the staff report. We did do an ARB staff level statistical analysis and we commissioned a statistical analysis from an independent researcher, and they both found basically that we've got these results are statistically significant.

BOARD MEMBER SPERLING: At what level? At 90 percent?

MANAGER MITCHELL: Generally, we look if you want to, P values of .05 or less.

BOARD MEMBER SPERLING: Yeah. Okay. I had to ask that.

CHAIRPERSON NICHOLS: What does that lead you to think?

BOARD MEMBER SPERLING: That it's unfortunate we got to put it. We created this complex set of rules and, you know, burdens on companies. And it's a small effect. And I know, you know, we don't want to be -- our goal is to reduce NOx, not to increase it. But it really is a tiny amount, and it's not even relevant to anything except old engines. We've created this complex rule. So I'm kind of holding my -- I'm trying to accept it because I know we need to do it or that's my understanding because of lawsuits. But as public policy, it's kind of questionable.

CHAIRPERSON NICHOLS: Well, it's what happens when you get mixed up with CEQA.

BOARD MEMBER SPERLING: I know. That's why I don't want to be part of the next lawsuit either.

CHAIRPERSON NICHOLS: But it is -- isn't just lawsuits. But it is the law actually that requires that we be able to say with more certainty than you might like that it will not be an increase in NOx as a result of what we're doing. That's a hard thing to prove, I know.

BOARD MEMBER SPERLING: I'll say one last thing. You could look at electric vehicles and say some -- I'm not going to go there.

CHAIRPERSON NICHOLS: You're not going there. You can think whatever you like.

Ms. Mitchell.

BOARD MEMBER MITCHELL: Thank you.

I also wanted to thank staff for working on this. And Jack Kitowski, I know he put a lot of time in it. And as you all know for South Coast, it's really important that we prevent further NOx -- increases in the NOx emissions. We have a fairly daunting task ahead of us for 2016 AQMP and our reductions that are needed by 2023 and 2032. I talked about it many times sitting on this Board. So this was a hard thing to do.

It does result in some complexity, but I think staff did a really good job working it out. And I know they worked very closely with staff at South Coast to iron out all the little wrinkles in this to get to a point where it's acceptable and will help South Coast reach the targets that we have to reach. So thank you for all the work that you've put in on it.

CHAIRPERSON NICHOLS: Thank you.

BOARD MEMBER BERG: I'd like to just make one observation as I was listening to the testimony and the regulated community, it really came to mind as I look at this and saw all of the support and the accolades for staff, but actually the accolades for the industry, because I did hear how challenging -- it was a marathon. It was torture. It's not ideal. It caused sleepless nights. And then from the environmental of our NGO friends that, you know, the tension of finding balance, the managing of trade-offs. And all of this very rarely produces a public testimony sheet of all support. And it made me think, you know, a roomful of an entrepreneurs and a roomful of people that really want to get the job done, this is what it looks like. So congratulations.

CHAIRPERSON NICHOLS: Okay. With that, did you properly close the record or did I never do that? Well, I should have.

The record is closed for this agenda item, but again, it's going to be reopened when the 15-day notice of public availability is issued.

So once again, we will not be receiving comments after today on this item. But after the 15-day notice there will be an opportunity for comment on the 15-day notice items. And they will be responded to in the Final Statement of Reasons for the regulation, which will also come back to the Board. And we're planning on doing these again in tandem so this rule accompanies the low carbon fuel standard rule and that will keep everything neat. So

we have a before us resolution Number 15-5. And do I have a motion?

BOARD MEMBER BERG: So moved.

BOARD MEMBER SHERRIFFS: So moved.

BOARD MEMBER RIORDAN: A second.

CHAIRPERSON NICHOLS: A second, Mrs. Riordan.

All in favor, please say aye.

(Unanimous aye vote)

(Dr. Balmes not present at vote)

CHAIRPERSON NICHOLS: Any opposed? Any abstentions? Okay. Great. Good work.

This really is a culmination of a lot of work, but it isn't over. There's more still to be done. But we're well on our way. So thanks to all. Before we can adjourn, we do have to make time for any public comment. There's no general public comment today. All right. Then we are adjourned.

BOARD MEMBER GIOIA: Chair Nichols, I certainly would be remiss given the team of today's hearing thanking Mr. Corey on several accounts. I want to add to that at the previous meeting last month staff gave a very detailed presentation on our 2015 priorities which I think we all appreciated.

I made the comment after the presentation and I think it was some public testimony that it would be nice to see some accounting of what we are doing to advance environmental justice kind of cross-pollinated across all the programs and rulemakings and the policies that deal with the Air resources Board. I just wanted to thank them because I'm in receipt of a slide he took it very seriously and sent me a slide doing exactly what I had suggested.

So I wanted to thank you, Richard, for doing that and I think it demonstrates how serious not just Richard but all of our staff take that particular aspect of what we do here.

BOARD MEMBER GIOIA: Can you send that slide to all of us, Richard?

EXECUTIVE OFFICER COREY: Will do. It will be posted as well.

CHAIRPERSON NICHOLS: Oh, good. Everybody will be able to take advantage of it. Thank you all. Safe travel.

(Whereupon the Air Resources Board adjourned at 4:06 p.m.)

CERTIFICATE OF REPORTER

I, TIFFANY C. KRAFT, a Certified Shorthand Reporter of the State of California, and Registered Professional Reporter, do hereby certify:

That I am a disinterested person herein; that the foregoing hearing was reported in shorthand by me, Tiffany C. Kraft, a Certified Shorthand Reporter of the State of California, and thereafter transcribed into typewriting.

I further certify that I am not of counsel or attorney for any of the parties to said hearing nor in any way interested in the outcome of said hearing.

IN WITNESS WHEREOF, I have hereunto set my hand this 4th day of March, 2015.

____

TIFFANY C. KRAFT, CSR, RPR
Certified Shorthand Reporter
License No. 1227

1_T_LCFS_TOlson

743. Comment: **LCFS T1-1**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

2_T_LCFS_TTaylor

744. Comment: **LCFS T2-1**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

3_T_LCFS_MMiyasato

745. Comment: **LCFS T3-1**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

4_T_LCFS_MPaserro

746. Comment: **LCFS T4-1**

The comment supports the re-adoption of the LCFS regulation and looks forward to contributing to future development of certification requirements.

Agency Response: ARB thanks the commenter for the support, and looks forward to working on future regulatory improvements.

5_T_LCFS_GGrey

747. Comment: **LCFS T5-1**

The comment contends that the LCFS regulation is an attempt to satisfy too many objectives, and misses the original goal.

Agency Response: ARB disagrees. The goal of the LCFS regulation continues to be the same, namely to reduce the carbon intensity of transportation fuels used in California by at least ten percent by 2020 from a 2010 baseline, thereby reducing greenhouse gas emissions, among other benefits. The basic framework of the LCFS is working and will continue. The primary objective of the proposed revisions to the current LCFS are to clarify, streamline, and enhance certain provisions of the regulations. The goal of the LCFS regulation to reduce the carbon intensity of transportation fuels is still the driving force informing this rulemaking.

748. Comment: **LCFS T5-2**

The comment alleges that the credit generating measures and the cost containment mechanism are not necessary to meet the program's original objectives.

Agency Response: Please see responses to **LCFS T5-1** regarding additional credit-generating mechanisms, and **LCFS 32-9**, **LCFS 37-11**, **LCFS 38-3**, **LCFS 40-14**, **LCFS 40-16**, and **LCFS 40-18** regarding the cost containment mechanism.

749. Comment: **LCFS T5-3**

The commenter states that the compliance schedule is infeasible.

Agency Response: The schedule is feasible. Please see responses to **LCFS 38-1**.

750. Comment: **LCFS T5-4**

The comment argues that there is a risk that credit costs must rise in order for the program to be effective, and that duplicate accounting may be taking place in other states that embrace the LCFS regulation.

Agency Response: The price cap provides an upper bound on the potential cost of credits, and should not be construed as a projection of future credit prices or as a projection of future cost of compliance. ARB does not project future credit prices.

Even with a series of conservative assumptions informing the economic analysis, the results indicate that with an illustrative credit price of $100 LCFS encourages the production and consumption of innovative, low-CI transportation fuels. Historically, the volumes of low-CI fuels consumed in California indicate a strong market response to the regulation stimulating demand for low-CI fuels. The LCFS has been continuously implemented in California since 2010, and regulated parties have generated more credits than needed every year at prices much lower than $200. Since 2010, the production of low-CI fuels has increased in response to the financial incentives provided by the existing LCFS regulation. Many innovative, low-CI fuel technologies have moved past the demonstration stage, and have overcome techno-economic challenges that have in recent years limited the supplies of innovative, very-low CI fuels such as cellulosic ethanol, renewable diesel, and renewable natural gas. Staff analysis indicates that the supplies of low-CI fuels in future years will continue to exhibit the existing trend of increasing production.

751. Comment: **LCFS T5-5**

The comment questions whether or not the LCFS regulation has been successful.

Agency Response: The LCFS is working as designed and intended. To date, more than 155 active entities have registered for reporting in the LCFS Reporting Tool, and since the regulation went into effect, regulated parties have successfully operated under the LCFS program. Furthermore, fuel producers are innovating and achieving material reductions in their fuel pathways' carbon intensity, an effect the LCFS regulation is expressly designed to encourage. Credits have been generated from ethanol (60 percent), renewable diesel (15 percent), biodiesel (13 percent), natural gas (ten percent), and electricity (two percent). Despite the standards being frozen at one percent, the regulated parties are still over-complying, which is reflected in the amount of excess credits (4.33 million by the end of the fourth quarter of 2014) that have been generated.

752. Comment: **LCFS T5-6**

The comment states that the fluctuation of the LCFS credit costs should not be considered a success.

Agency Response: The value of the LCFS credit does not define the success of the program. Instead, achieving the goals as outlined in Executive Order S-01-07 (2007) is the aim of the regulation. However, the fact that credits have exceeded deficits in every compliance period of the program and that there is activity in the credit market are indicator of a successful working policy.

753. Comment: **LCFS T5-7**

The commenter requests that the Board require ongoing staff reviews of the LCFS regulation on an annual basis that would allow stakeholder input.

Agency Response: See response to **LCFS 38-2**.

754. Comment: **LCFS T5-8**

The comment asks that no further effort be made to create post-2020 LCFS targets.

Agency Response: See response to **LCFS 5-2**.

6_T_LCFS_HClay

755. Comment: **LCFS T6-1**

The comment supports the re-adoption of the LCFS regulation and expresses concerns with how the LCFS regulation is administered, with regards to technology neutrality and maintaining regulatory stability.

Agency Response: The proposed LCFS is a fuel-neutral, performance-based regulation that allows regulated parties to find the most cost-effective approaches to compliance. The proposed regulation provides the incentive structure to foster the low-CI fuels market; individual business decisions and the economics of producing the low-CI fuels will determine where the resultant increases in supplies come from.

As set forth in the ISOR, and its appendices and references, ARB has relied on the best available economic and scientific analyses it could find (or perform, in instances where no prior researcher had addressed a particular topic).

The direct CI values are provided by the GREET-2.0 model and were updated for this rulemaking to account for the additional information obtained since the 2009 rulemaking.[55] These direct CI values will only change if and when the GREET model is updated which has only occurred once since the beginning of the LCFS program. To the extent that the GREET model needs to be updated, ARB will undertake another regulation to update the

[55] See page ES-5 of Staff Report for additional information.

model. ARB agrees that stability is desirable, and has no plans to change CI scores lightly or frequently.

7_T_LCFS_MSolecki

756. Comment: **LCFS T7-1**

The commenter supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

8_T_LCFS_MHeller

757. Comment: **LCFS T8-1**

The commenter states that it is impossible to meet the goals for the LCFS regulation given the availability and blending constraints of alternative fuels and the complexity of the LCFS regulation.

Agency Response: The schedule is feasible. Please see responses to **LCFS 38-1**. The compliance schedule included in the regulation was explicitly designed to enable over compliance in the 2016 to 2018 period so that sufficient credits can be accumulated and banked for later year use. ARB staff agrees that some companies may desire to carry substantial amounts of banked credits to ensure future compliance or lower the credit costs they might otherwise encounter. Unlike the commenter, who sees banking as a sign that LCFS is not sustainable, ARB sees credit purchases and banking as a market force to spur innovation and production of low CI fuels.

758. Comment: **LCFS T8-2**

The commenter states that the overreliance on banked credits to meet future obligations is flawed.

Agency Response: See response to **LCFS 38-1**.   ARB also recognizes that the estimate of credit generation in the second half of 2014 was lower than projected in the ISOR, but disagrees with the commenter's pessimistic interpretation. Staff has reassessed the feasibility of the compliance curve in light of 2014 results and found that the prospects for compliance with the 10 percent standard in 2020 are not impacted in any significant manner.

759. Comment: **LCFS T8-3**

The commenter recommends that ARB staff set the compliance schedule based on alternative assumptions of fuel availability and blending capabilities, allowing extra credits to be used for compliance margin in the hedge of future shortages.

Agency Response: See response to **LCFS 38-1**.

760. Comment: **LCFS T8-4**

The commenter states that there are limitations to the Refinery Investment Credit provision that they have provided in written comments.

Agency Response: See response to **LCFS 38-7**, **LCFS 38-9**, **LCFS 38-10**, **LCFS 38-11**, **LCFS 38-12**, and **LCFS 38-13**.

9_T_LCFS_NEconomides

761. Comment: **LCFS T9-1**

The commenter states that the development of lower CI fuels has not proceeded as originally envisioned and that the compliance schedule should be modified.

Agency Response: ARB staff provided extensive information in the ISOR on the potential volumes of low CI fuels that are expected to be available over the next ten years and does not concur with the claim that the 2020 compliance targets are higher-than- achievable. See response to **LCFS 38-1**.

762. Comment: **LCFS T9-2**

The commenter states that the 2020 target of 10 percent reduction is aspirational.

Agency Response: See response to **LCFS 38-1**.

763. Comment: **LCFS T9-3**

The commenter states that the LCFS regulation's goals deny the regulated community the strategy and certainty that is needed to move forward.

Agency Response: See response to **LCFS 38-1**.

10_T_LCFS_MHicks

764. Comment: **LCFS T10-1**

The commenter supports the LC/LE refinery provision.

Agency Response: ARB staff appreciates the support for the LC/LE provision.

765. Comment: **LCFS T10-2**

The commenter supports the refinery-specific incremental deficit option.

Agency Response: We acknowledge the commenter's support for the refinery-specific incremental deficit option.

766. Comment: **LCFS T10-3**

The commenter supports the Refinery Investment Provision

Agency Response: ARB staff appreciates the support for the Refinery Investment provision.

11_T_LCFS_DDelahoussaye

767. Comment: **LCFS T11-1**

The commenter supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

768. Comment: **LCFS T11-2**

The commenter requests that ARB staff use re-adoption as a springboard to discuss and formulate longer-term targets.

Agency Response: See response to **LCFS 5-2**.

769. Comment: **LCFS T11-3**

The commenter states that timely processing and approval of a complete pathway application is important to the success of the LCFS regulation.

Agency Response: See response to **LCFS 61-2**.

770. Comment: **LCFS T11-4**

The commenter encourages the Board to work with ARB staff to include an approval process to provide new fuels with a prompt CI score.

Agency Response: See response to **LCFS 61-2**.

771. Comment: **LCFS T11-5**

The comment recognizes that some parties may feel that there are issues with availability of RD, and encourages the board to disregard that opinion.

Agency Response: Staff's opinions about the availability Renewable Diesel (RD) are expressed in Appendix B of the Initial Statement of Reasons. Further, see response to comment **LCFS 38-6.**

772. Comment: **LCFS T11-6**

The commenter states that labeling solutions for renewable diesel can be achieved without causing detriment to the 2020 goals.

Agency Response: Staff agrees with the commenter. In the Alternative Diesel Fuel Initial Statement of Reasons, we identified several ways that renewable diesel use in the State could increase within the confines of the labeling requirements, including some pathways that would be low to no cost and would not require any regulatory changes.

773. Comment: **LCFS T11-7**

The commenter states that the price cap seems arbitrary in absence of a federal program. However it will work until 2020, needing re-evaluation after that point.

Agency Response: Please see the response to comment **LCFS 6-4.**

12_T_LCFS_GGrimes

774. Comment: **LCFS T12-1**

The comment supports the Low Complexity/Low Energy use provision in the LCFS regulation.

Agency Response: ARB staff appreciates the support for the proposed Low Complexity/Low Energy Use provision.

775. Comment: **LCFS T12-2**

The commenter states that it is important to get the eligibility criteria right for the LC/LE provision.

Agency Response: See response to **LCFS B5-1**, **LCFS FF9-6**, and **LCFS FF9-8**.

776. Comment: **LCFS T12-3**

The commenter asserts that the Alon refinery will emit less GHGs than the average refinery in California.

Agency Response: See response to **LCFS B5-1**.

13_T_LCFS_CDuBose

777. Comment: **LCFS T13-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

14_T_LCFS_JCase

778. Comment: **LCFS T14-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

15_T_LCFS_SNeal

779. Comment: **LCFS T15-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

16_T_LCFS_RTeall

780. Comment: **LCFS T16-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

17_T_LCFS_JLevin

781. Comment: **LCFS T17-1**

The comment urges the Board to re-adopt the LCFS regulation and to continue to invest in natural gas vehicles and infrastructure.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS.

18_T_LCFS_JMendoza

782. Comment: **LCFS T18-1**

The comment directs ARB staff to ensure that the CA-GREET model is based on the best available data.

Agency Response: ARB staff shares with the commenter a desire to continue basing the CA-GREET model on the best available scientific data. Maintaining a technically sound scientific basis for the LCFS continues to be one of our highest priorities.

783. Comment: **LCFS T18-2**

The commenter requests an avenue for stakeholder engagement during the ongoing process, presumably referring to the period between the first and second board hearing.

Agency Response: ARB is and has been committed to engaging in a robust public process to develop the most effective regulation. Between the February and September 2015 Board Hearings, staff conducted a public workshop to discuss changes to the CA-GREET 2.0 model and continued its collaboration with stakeholders.

784. Comment: **LCFS T18-3**

The commenter hopes that ARB staff and stakeholders continue to engage in future discussions regarding the LCFS regulation.

Agency Response: Staff acknowledges the comment and is committed to an extensive public process to develop and implement the LCFS regulation.

19_T_LCFS_MPlummer

785. Comment: **LCFS T19-1**

The commenter supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

20_T_LCFS_CWright

786. Comment: **LCFS T20-1**

The commenter supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

21_T_LCFS_JO'Donnell

787. Comment: **LCFS T21-1**

The commenter supports the innovative crude provision and the re-adoption of the LCFS regulation and discusses some of the economic benefits.

Agency Response: ARB staff appreciates the support for the proposed innovative crude provision.

22_T_LCFS_RNakasone

788. Comment: **LCFS T22-1**

The commenter supports re-adoption of the LCFS regulation particularly refinery investment provisions.

Agency Response: ARB staff appreciates the support for the proposed refinery investment provision.

23_T_LCFS_SUnnasch

789. Comment: **LCFS T23-1**

The commenter supports the LCFS program and discusses marginal electricity uses.

Agency Response: Staff appreciates Life Cycle Associates' support of proposed LCFS regulation. Please also see responses to **LCFS 62-1** and **LCFS 65-1**.

24_T_LCFS_CWhite

790. Comment: **LCFS T24-1**

The commenter supports re-adoption of the LCFS regulation and requests more certainty for investors. He also states that they can produce a significant amount of fuel for less than $200 per ton.

Agency Response: Staff is analyzing the potential benefits of a price floor to send a stronger price signal to increase investments in low-CI fuels and to further reduce market uncertainty and credit price volatility. Staff appreciates the ongoing dialogue with, and feedback from, stakeholders regarding whether this topic should be proposed as a future LCFS amendment.

791. Comment: **LCFS T24-2**

The comment supports the ARB continuing to evaluate the natural gas CI values.

Agency Response: ARB staff has made adjustments to the natural gas CI values as part of a 15-day change.

792. Comment: **LCFS T24-3**

The commenter supports re-adoption of the LCFS regulation, but encourages ARB staff to consider a price floor provision.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS. With regards to the price floor, see response to **LCFS 6-5**.

793. Comment: **LCFS T24-4**

The commenter reminds ARB staff to use best available data to support any CI value updates.

Agency Response: ARB staff makes every effort to both base our CIs on the best available science and to consistently conduct our lifecycle analyses in an objective, uniform, and fuel-neutral manner.

25_T_LCFS_TDarlington

794. Comment: **LCFS T25-1**

The commenter disagrees with the land use change emissions factor by ARB staff for corn starch ethanol.

Agency Response: See response to **LCFS 8-1**.

795. Comment: **LCFS T25-2**

The commenter claims that ARB staff has not considered significant issues raised in technical literature and by stakeholders.

Agency Response: The current approach used by ARB is appropriate since it uses the most current data and the latest modeling structure. Any specific issues that were not considered for the current analysis were either due to lack of detailed data or because modeling structure did not allow for the inclusion of a particular effect.

796. Comment: **LCFS T25-3**

The comment states that the current economic model used by ARB staff does not include double or multi-cropping.

Agency Response: See responses to **LCFS 46-102**, **LCFS 46-112, LCFS 46-114**, **LCFS 8-5** and **LCFS 8-10**.

797. Comment: **LCFS T25-4**

The commenter states that the current GTAP model should account for idle and fallow land as well as multi-cropping.

Agency Response: The claim that idle/fallow land should be accessed by GTAP land pool is questionable. See responses to **LCFS 8-5**, **LCFS 46-83**, and **LCFS 46-113**.

798. Comment: **LCFS T25-5**

The comment alleges that the inflated iLUC emissions will lead to high CI values for corn ethanol fuels and a reduction in corn ethanol us with no emission benefits.

Agency Response: ARB does not agree with commenter that the analysis conducted inflated iLUC emissions. See response to **LCFS 8-1**, **LCFS 29-2**, and **LCFS 46-216**.

With respect to concerns about fuel shuffling, see response to **LCFS 46-40**.

26_T_LCFS_JDavid

799. Comment: **LCFS T26-1**

The commenter discusses their economic analysis of expected behavior of the Midwestern corn ethanol market as it relates to CI values and Brazilian sugar cane imports.

Agency Response: The LCFS program is designed to encourage reductions in the overall CI of transportation fuels. Corn ethanol plants in particular have been successful in changing their practices to reduce the CI at their facilities. While this comment presents two static alternatives, the world post-regulation is dynamic and will likely yield very different results. For instance, the CI values presented in this comment are much higher than the values that will be realized post-regulation as the land use CI for corn ethanol is much lower in the current proposal.

Over time we are seeing that the value of credits appears to be leading to lowering of CI values for many alternative fuels. The regulation will further incentivize reductions, especially as the required CI reduction increases over time. The more strict the standard, the higher the value on the low-CI fuels, and the larger the incentive for investment in reducing the CI values for all fuels. Additionally, the Midwestern corn ethanol plants could lower their CI by using innovative strategies, for example Poet[56] who put in an application for a facility-specific CI based upon their diversion of methane from a city landfill to power their ethanol plant. This large infrastructure cost is estimated to give them a CI of 63.88 for corn ethanol (and with the new land use values, this could potentially be

[56] http://www.arb.ca.gov/fuels/lcfs/2a2b/apps/poet-cha-sum-022014.pdf

less than 53). Corn ethanol plants that invest in cleaner energy will be able to compete more easily in California.

800. Comment: **LCFS T26-2**

The commenter states that the switch to cane ethanol from corn ethanol may occur at lower than expected credit prices.

Agency Response: This is the result of the commenter's analysis that does not constitute an objection or recommendation on the proposal.

801. Comment: **LCFS T26-3**

The commenter agrees that ARB's illustrative scenario is plausible with regard to corn ethanol and sugar cane ethanol and expresses concern that the Midwest corn ethanol industry may be at great risk of losing the ability to participate in the California market.

Agency Response: See response to **LCFS 46-27** and **LCFS 46-28**.

27_T_LCFS_HSimpson

802. Comment: **LCFS T27-1**

The commenter expressed support for the proposed timeline.

Agency Response: ARB staff appreciates the support for the compliance curve.

803. Comment: **LCFS T27-2**

The commenter states that keeping the current compliance schedule is critical and that the Board should consider ongoing reductions beyond 2020.

Agency Response: ARB staff appreciates the support for the proposed timeline. With regard to post-2020 reductions, see response to **LCFS 5-2**.

28_T_LCFS_TCampbell

804. Comment: **LCFS T28-1**

The commenter supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

805. Comment: **LCFS T28-2**

The commenter states that it is critical for ARB staff to correctly determine CI numbers for renewable natural gas. They also add their willingness to work with staff toward that goal.

Agency Response: ARB staff also looks forward to continued participation and would like to maintain an open collaborative public process. ARB staff makes every effort to base our CIs on the best available science.

29_T_LCFS_JLewis

806. Comment: **LCFS T29-1**

The commenter states that while achieving compliance with the 2020 target would be challenging the LCFS regulation remains the most promising policy available for reducing climate impacts in the transportation sector.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

807. Comment: **LCFS T29-2**

The comment alleges that choosing which data sets to use or exclude in a life cycle model is a subjective exercise.

Agency Response: ARB does not agree with commenter that the use of data sets and inputs are subjective exercises. In the current analysis, ARB evaluated all available data and used data as appropriate within the current modeling limitations. The ARB proposed carbon intensity (CI) targets and standards for biofuels are designed to be fuel neutral. In other words, all biofuels including corn ethanol, sugarcane ethanol, sorghum ethanol, soy oil biodiesel, canola biodiesel, and palm oil biodiesel have the opportunity to contribute to LCFS and their CI is estimated using the same methodology. The adjustments to the carbon intensity (CI) of corn ethanol as well as the adjustments for other biofuels are based on the latest and improved modeling analysis.

ARB recognizes that some effects such as from fertilizers, reforestation related to forest products using the current structure for forest land cover, food security, etc. have the potential to increase iLUC values for biofuels. Limitations related to the structural aspects of the GTAP model and lack of comprehensive data did not allow ARB to consider modeling some of these effects related to the items detailed above. When detailed data becomes available and relevant structural modifications to the GTAP model can be accomplished, the impacts of such effects on iLUC values will be considered.

The non-inclusion of food effects is not a subjective decision. The model as currently structured has limitations and it does not allow a detailed evaluation of the impacts of biofuels on global food security. To evaluate such effects we must collect and include in the analysis, data for calorific content of food and feed production, and the modeling structure needs to be modified accordingly. When these data become available and are collected, future revisions of the model would allow the evaluation of global food security effects and the effect will be incorporated into the iLUC analysis. See also responses to **LCFS 8-1**, **LCFS 29-3**, **LCFS T29-3**, and **LCFS T29-4**.

808. Comment: **LCFS T29-3**

The commenter claims that reducing the iLUC score for corn ethanol undermines the objectives of the LCFS regulation.

Agency Response: ARB does not agree with commenter that the current analysis is likely to undermine the LCFS by over reliance on corn ethanol to comply with the regulation. ARB's approach is based on performance standards and is fuel-neutral. Corn ethanol or other fuels are evaluated on the basis of GHG emissions potential and their participation in the program is based on carbon intensity values. To specifically address the comments, ARB has detailed below:

1. *The reason for deferring the consideration of food security*.

   The adjustments to the carbon intensity (CI) of corn ethanol as well as the adjustments for other biofuels are based on the latest and improved modeling analysis. Please see response to **LCFS 35-4** on the reason to defer the food issue.

2. *Non-reliance on corn ethanol for compliance, particularly as the standard gets stricter starting 2016-2017*.

   The use of corn ethanol as part of the compliance strategy does not undermine the LCFS targets. The ARB proposed carbon intensity (CI) targets and standards are designed to be fuel neutral. See also responses to **LCFS 8-1**, **LCFS 29-2**, **LCFS 29-3** and **LCFS T29-2**.

809. Comment: **LCFS T29-4**

The commenter requests that the Board resist any proposal to reduce the CI value for corn ethanol.

Agency Response: ARB does not agree with commenter that the iLUC value changes in the current proposal should be postponed. ARB's analysis represents the culmination of several years of refinements to the iLUC analysis originally proposed in 2009. The current analysis uses the latest data and updates to land use science and represents the best estimate for iLUC value for corn ethanol and 5 other biofuels considered for this rulemaking. See also response to **LCFS 8-1** and **LCFS 29-2**.

30_T_LCFS_Phillips

810. Comment: **LCFS T30-1**

The commenter requests ARB staff to factor in the marginal displacement of electricity cogeneration by sugarcane mills in Brazil.

Agency Response: See response to **LCFS B1-2**.

811. Comment: **LCFS T30-2**

The commenter requests that ARB staff account for double cropping in Brazil in the iLUC score for cane ethanol. The commenter also supports re-adoption of the LCFS regulation.

Agency Response: ARB recognizes support offered by the commenter to readopt the LCFS regulation. Regarding double cropping, see responses to **LCFS 8-1, LCFS 8-9, LCFS 8-10** and **LCFS B1-3**.

31_T_LCFS_TKoehler

812. Comment: **LCFS T31-1**

The commenter supports both the re-adoption of the LCFS regulation and the development of further requirements beyond 2020.

Agency Response: See response to **LCFS 5-2**.

813. Comment: **LCFS T31-2**

The commenter requests that ARB staff incorporate recently released data regarding actual land use change over the last ten years into the GTAP model.

Agency Response: The iLUC analysis as currently proposed by ARB is based on the latest and best available scientific and economic information. ARB is aware of the proposed study to calibrate the GTAP model using new data. When this study is completed, ARB will conduct a comprehensive review and consider refinements if warranted. See also response to **LCFS 8-5**.

32_T_LCFS_BHolmes-Gen

814. Comment: **LCFS T32-1**

The commenter directs ARB staff to update the biorefinery guidance document.

Agency Response: See response to **LCFS 42-17**.

33_T_LCFS_TCarmichael

815. Comment: **LCFS T33-1**

The comment supports the re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

816. Comment: **LCFS T33-2**

The commenter requests that ARB staff add a statement to the Resolution, requiring ongoing communication between staff and stakeholders.

Agency Response: In response to Board direction in Resolution 15-6, as well as this comment and other similar requests for further dialogue from the natural gas vehicle coalition, staff held a workshop on March 3, 2015 to discuss natural gas carbon intensity and other CA-GREET model adjustments.

34_T_LCFS_DCox

817. Comment: **LCFS T34-1**

The commenter stresses the importance of having a process to deal with cost containment for the LCFS regulation.

Agency Response: Please see response to **LCFS T33-2**.

818. Comment: **LCFS T34-2**

The commenter requests a continued commitment by ARB staff to fuel neutrality and ensuring the CA-GREET model is driven by sound data.

Agency Response: ARB staff's commitment to high quality technical data and to fuel neutrality will continue to be unwavering.

819. Comment: **LCFS T34-3**

The commenter supports the $200 credit price cap and suggests that ARB staff also incorporate a price floor.

Agency Response: See response to **LCFS 6-5**.

35_T_LCFS_JBarbose

820. Comment: **LCFS T35-1**

The comment states support for continued efforts to decrease carbon emissions to meet the 2050 goal of 80 percent reductions.

Agency Response: See response to **LCFS 5-2**.

821. Comment: **LCFS T35-2**

The commenter states that the LCFS is a critical element of California's approach to reducing GHG emissions while continuing to thrive economically.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation**.**

822. Comment: **LCFS T35-3**

The commenter supports the proposal of ARB staff, to update the life cycle analysis.

Agency Response: ARB staff appreciates the support for the proposed update to the life cycle analysis.

823. Comment: **LCFS T35-4**

The comment supports the addition of the innovative crude and refinery provision.

Agency Response: ARB staff appreciates the support for the proposed innovative crude and refinery investment provisions.

824. Comment: **LCFS T35-5**

The comment supports the addition of the cost containment mechanism.

Agency Response: ARB staff appreciates the support for the proposed cost containment provision.

825. Comment: **LCFS T35-6**

The comment states that in order to ensure investment in the cleanest fuels it is important to establish regulatory stability out beyond 2020.

Agency Response: See response to **LCFS 5-2.**

36_T_LCFS_LMortenson

826. Comment: **LCFS T36-1**

The comment states that the LCFS regulation is essential to force the existing infrastructure to incorporate higher volumes of clean fuel.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

827. Comment: **LCFS T36-2**

The comment states that industry needs regulatory certainty to perform long-term trajectory planning and investment.

Agency Response: Staff acknowledges the comment and anticipates that re-adoption of the LCFS will provide regulatory certainty. In addition to proposing to re-adopt the entire regulation, staff has proposed a suite of updates and revisions compared to the current regulation to provide a stronger signal for investments in, and production of, the cleanest fuels, offer additional flexibility, and update critical technical information, among other things.

828. Comment: **LCFS T36-3**

The comment supports re-adoption of the LCFS regulation and encourages evaluation of possible requirements beyond 2020.

Agency Response: See response to **LCFS 5-2.**

37_T_LCFS_JGershen

829. Comment: **LCFS T37-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

38_T_LCFS_CMurphy

830. Comment: **LCFS T38-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

831. Comment: **LCFS T38-2**

The comment supports the proposed cost containment provision.

Agency Response: ARB staff appreciates the support for the proposed cost containment provision.

832. Comment: **LCFS T38-3**

The comment states there should be a price floor to go along with the price ceiling.

Agency Response: See response to **LCFS 6-5**.

833. Comment: **LCFS T38-4**

The comment suggests that CI updates should follow a regular and systematic mechanism of review.

Agency Response: ARB staff concurs with commenter on the need to account for new scientific and technological advances for CI calculations. To do so, ARB staff is proposing to update the CA-GREET-2.0 model at predictable intervals – no more frequently than every three years. We will continue to thoroughly analyze and incorporate the best scientific data.

39_T_LCFS_SFrank

834. Comment: **LCFS T39-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

40_T_LCFS_SMui

835. Comment: **LCFS T40-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

836. Comment: **LCFS T40-2**

The comment states that the 2020 targets are feasible and that ARB staff should maintain strong standards and expectations going forward.

Agency Response: See response to **LCFS 5-2**.

837. Comment: **LCFS T40-3**

The commenter states that regulatory certainty will be provided by the re-adoption of the LCFS regulation.

Agency Response: Staff agrees with the comment and anticipates that re-adopting the LCFS will provide regulatory certainty. See response to **LCFS T36-2**.

838. Comment: **LCFS T40-4**

The comment states that the LCFS regulation is reasonable, technically supported, and should be adopted.

Agency Response: Staff acknowledges the comment and appreciates the support for the re-adoption of the LCFS.

41_T_LCFS_ETutt

839. Comment: **LCFS T41-1**

The comment supports the re-adoption of the LCFS regulation and adds that its requirements to 2020 are economically feasible.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

42_T_LCFS_RMoran

840. Comment: **LCFS T42-1**

The commenter asserts that the 2009 LCFS regulation was written under the assumption of saving billions of dollars while the current LCFS regulation will cost billions of dollars.

Agency Response: The baseline in the 2009 economic analysis was different than the current analysis found in the ISOR and includes many of the complimentary programs that have come into existence post the 2009 rulemaking; therefore the two analyses cannot be meaningfully compared. In addition to the billions of dollars in benefits outlined in the 2009 rulemaking, the commenter did not mention that the 2009 ISOR also describes the infrastructure and other costs of the regulation, as estimated based upon the baseline for that analysis. In the current rulemaking, the cost analysis, as presented in the economic chapter in the 2014 ISOR is a worst-case scenario that will likely over-estimate the costs, without monetizing many of the benefits. With respect to the question about the price cap please see response to comment **LCFS 32-9**.

841. Comment: **LCFS T42-2**

The comment states that there will be no incremental GHG reductions coming from the LCFS regulation because sources of emissions covered under the LCFS are already covered under the Cap-and-Trade program.

Agency Response: ARB staff strongly disagrees that there will be no incremental GHG reductions from the LCF regulation See response to **LCFS 32-6** and **LCFS 46-41**.

842. Comment: **LCFS T42-3**

The commenter argues that the LCFS regulation merely shifts reductions that would occur under the Cap-and-Trade program.

Agency Response: See response to **LCFS 32-6** and **LCFS 32-7**.

843. Comment: **LCFS T42-4**

The commenter asserts that the Cap-and-Trade program would be more effective than re-adopting the LCFS regulation, in meeting California's long-term GHG policies.

Agency Response: See response to **LCFS T42-3**.

43_T_LCFS_BMagavern

844. Comment: **LCFS T43-1**

The commenter supports the electricity and refinery investment provisions.

Agency Response: ARB staff appreciates the support for the proposed electricity and refinery investment provisions.

44_T_LCFS_GNoyes

845. Comment: **LCFS T44-1**

The commenter states that the LCFS regulation is an important signal to the market to provide certainty and supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS.

45_T_LCFS_JHall

846. Comment: **LCFS T45-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

847. Comment: **LCFS T45-2**

The comment supports re-adoption of the LCFS regulation and would like to see more investments and stronger long-term targets.

Agency Response: See response to **LCFS 5-2**.

46_T_LCFS_SHedderich

848. Comment: **LCFS T46-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

47_T_LCFS_KPhillips

849. Comment: **LCFS T47-1**

The comment supports re-adoption of the LCFS regulation.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

48_T_LCFS_TO'Connor

850. Comment: **LCFS T48-1**

The comment supports re-adoption of the LCFS regulation and adds that they believe that the new regulation will meet the CEQA requirements.

Agency Response: ARB believes the process followed to develop the LCFS and ADF proposals and the proposed regulations themselves are in compliance with California law, including CEQA, and with applicable federal law. More specifically, ARB believes the proposed rulemaking process and the proposed regulations are consistent with the rulings issued by date by both state and federal courts that have heard challenges to California's original LCFS regulation. To the extent the commenter is expressing support for the proposed LCFS regulation and the process used to bring it to the Board, the comment is noted.

49_T_LCFS_KJames

851. Comment: **LCFS T49-1**

The commenter supports re-adoption of the LCFS regulation and considers it an important route to insulate businesses and consumers from oil price volatility.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

852. Comment: **LCFS T49-2**

The commenter believes that the LCFS regulation will result in an enormous societal benefit by 2020.

Agency Response: Staff appreciates the support of proposed LCFS regulation. Staff acknowledges the societal benefits of LCFS through reducing air pollution and increasing energy security.

853. Comment: **LCFS T49-3**

The commenter states that the LCFS regulation could contribute thousands of jobs to the California market.

Agency Response: ARB staff appreciates the support for the re-adoption of the LCFS regulation.

854. Comment: **LCFS T49-4**

The commenter states that, in order to spur innovation in clean fuels, investors need long term policy signals like re-adoption of the LCFS regulation.

Agency Response: See response to **LCFS 5-2**.

50_T_LCFS_MAddy

855. Comment: **LCFS T50-1**

The comment thanks ARB staff members for their hard work on the indirect land use change emissions.

Agency Response: ARB appreciates commenter's acknowledgements of staff's efforts in addressing the challenges in developing the best estimates for iLUC emissions.

856. Comment: **LCFS T50-2**

The comment notes that getting low carbon transportation fuel solutions into the marketplace will require private capital.

Agency Response: ARB staff agrees that motivating private capital to invest in low carbon fuels is a goal of the LCFS.

857. Comment: **LCFS T50-3**

The comment suggests that industry may have difficulty complying with the LCFS regulation if insufficient capital is available.

Agency Response: Higher credit prices, particularly if they are sustained, will increase the incentive to innovate and invest because revenues generated by LCFS credit can be used to increase profit margins or to offset up-front capital costs; these additional revenues will attract investments in low-CI fuels. Many new fuels will require large capital investments; some of these fuels are eligible for government incentive programs, are part of long-term planning by California (such as AB 8 that provides infrastructure to expand distribution of hydrogen), and will be eligible for revenue increases due to LCFS credit revenues.

The supply of low-CI fuels and potential shortfall scenarios are discussed on page VII-4 of the staff report. Staff has analyzed the projected availability of low-CI fuel technologies, which is summarized in Chapter II and presented in more detail in Appendix B of the staff report.

51_T_LCFS_CHessler

858. Comment: **LCFS T51-1**

The comment states that the compliance schedule of the LCFS regulation is feasible.

Agency Response: ARB staff appreciates the support for the compliance schedule.

859. Comment: **LCFS T51-2**

The comment expresses support for the price cap provision.

Agency Response: ARB staff appreciates the support for the cost containment provision.

Sacramento, CA 95814

Subject: Low Carbon Fuel Standard Energy Economy Ratio Update

Dear Michael Waugh and LCFS Staff,

Thank you for the opportunity to provide comments on the Low Carbon Fuel Standard (LCFS) program. We strongly support the goals of the LCFS program and applaud programs within the California Air Resources Board (ARB) that provide needed incentives to reduce the carbon intensity of fuels to help achieve California's health based air quality standards and aggressive greenhouse gas emission goals.

Proterra is the leading U.S. manufacturer of zero-emission commercial transit solutions and makes the world's first all-electric, fast-charge public transit bus. These buses are currently in service in California at Foothill Transit and Stockton RTD, as well as many locations throughout the country. Proterra's buses charge along their routes in less than 7 minutes with an automated roof top charger and then continue on their routes all day long, offering functionally unlimited range. In addition, Proterra now offers range-extension on the fast-charge public transit bus to address the needs of transit operators for longer routes. Proterra's CATALYST™ bus achieves 21+ miles per gallon equivalent performance, 500%+ better than diesel and CNG buses. Proterra's advanced technology reduces carbon emissions by 70% or more compared to CNG or diesel buses. Zero-emission transit buses provide the opportunity for all Californian's to ride an electric vehicle and realize the health and other associated benefits.

We appreciate ARB updating the Energy Economy Ratio (EER) for heavy-duty battery electric vehicles and respectfully request ARB increase the EER to adequately reflect the updated miles per diesel equivalent of fast-charge battery electric compared to diesel transit buses. Proterra recently received the Altoona results of the updated CATALYST™ bus that demonstrates an increase in the average MPG diesel equivalent, thus increasing the Energy Economy Ratio (EER) for heavy-duty battery electric buses. Please see the updated Altoona Report attached.

LCFS FF1-1

In addition, the proposed EER of 4.2 for heavy-duty battery electric buses does not accurately represent the real ratio between new fast-charge battery electric buses and new diesel transit bus fleets. The proposed EER for heavy-duty battery electric buses averages the EER among battery electric buses – Proterra and BYD. To help ensure an equal comparison, we recommend averaging the fuel economy across all similar Altoona-tested diesel buses, including Gillig and Nova—in addition to New Flyer. Based on the Altoona testing for the most recent 40ft, low-floor, diesel buses over the three test cycles identified by ARB (Central Business District, Arterial, and Commuter), the Gillig bus averages 4.74 MPG, Nova 2.97 MPG, and New Flyer 4.82 MPG, generating an overall overage of 4.18 MPG. Using the updated average 20.53 MPG diesel equivalent for battery electric transit buses and the average 4.18 MPG for diesel transit buses, we respectfully request updating the EER to at least 4.91 for heavy-duty, battery electric vehicles in order to provide an equal comparison of battery electric and diesel transit buses and accurately recognize the significant fuel efficiency and air quality benefits of zero-emission transit buses. LCFS FF1-1 cont.

But even an EER of 4.91 does not accurately capture the unique fuel efficiency gains associated with Proterra's fast-charge technology. Therefore, we further request the consideration of a separate LCFS category for fast-charge, battery-electric buses, similar to ARB's additional incentive for fast-charge in the Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project (HVIP), in order to recognize the technology's functionally unlimited range, efficiency, and greater miles per gallon diesel equivalent. Charging along the route in less than 7 minutes allows the fast-charge, battery-electric buses to operate continuously – similar to a fuel cell or other long-range advanced technology. In addition, the buses have greater efficiency and MPG equivalent due to their light weight and advanced technology, as the fast-charge, battery-electric transit buses have fewer batteries and less weight on-board the vehicle. Therefore, we strongly encourage recognizing a separate LCFS category for fast-charge, battery electric buses with an EER of 5.3—using the 22.16 MPG diesel equivalent achieved at Altoona under three identified test cycles and the average diesel transit bus at the same test cycles of 4.18 MPG. LCFS FF1-2

We thank you for the opportunity to provide comments on the Low Carbon Fuel Standard, and appreciate the efforts of the California Air Resources Board to reduce the carbon intensity of fuels to support California's climate goals, help clean the air, and promote clean, low-carbon fuels to improve California's energy security and energy independence.

Sincerely,

F. Kent Leacock

Comments to the California Air Resources Board Regarding Modified Regulation Order, Low Carbon Fuel Standard

2_FF_LCFS_BE

By Beyond Energy
June 8, 2015

Elon D. Rubin, Esq.
Email: elon@evcredits.com

Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento, California 95811

Dear Madams and Sirs:

We appreciate this opportunity to comment on the Air Resources Board's ("ARB") proposed readoption of and modified regulation order to the Low Carbon Fuel Standard ("LCFS").

Beyond Energy focuses on prospective investment in EV and Electric Forklift ("EF") infrastructure and services. Among prospective partners of Beyond Energy are EV and EF electric charging infrastructure providers, distribution centers and end users. In addition, Beyond Energy evaluates investment opportunities in the renewable energy space.

We would like to express our strong concern over the proposed requirements in §95483(e)(7) of the LCFS that would restrict the regulated party definition for electric forklifts to only Electric Distribution Utilities ("EDU"), and exclude fleet operators of EF fleets from qualifying for LCFS Credits.[1]

ARB's rationale articulated in the Initial Statement of Reasoning for excluding EF from qualifying for LCFS credits and the latest regulatory modifications are most likely incorrect. As ARB may or may not know, many EFs are charged by dedicated high frequency chargers with easily obtainable data. In light of this information, we propose to amend §95483(e)(7) to allow EF fleets to opt-in, while keeping EDUs as the default regulated party ("modified §95483(e)(7) rule"). Compared to the current §95483(e)(7) rule, our proposed modification of §95483(e)(7) provides better consistency in the LCFS regulation, promotes innovation, fosters investment and affords flexibility, while still allowing for the maximum amount of EF LCFS credits to be claimed. Of equal importance, modifying §95483(e)(7) will not cause undue delay to the adoption of the LCFS for the reasons set forth below.

LCFS FF2-1

Section I provides context and background of the EF regulated party rule. Section II proposes verbiage for modifying §95483(e)(7) to enable EF fleets to opt-into LCFS. Section III expands upon high efficiency chargers and available data, articulates why the benefits of modifying §95483(e)(7) significantly outweigh the burdens previously articled by ARB, and explains why modifying §95483(e)(7) will not cause undue delay to the readoption of the LCFS. Section IV concludes with our closing thoughts. Thank you very much again for your time and attention to this comment.

[1] The latest modification of §95483(e)(7) reads "[f]or transportation fuel supplied to electric forklifts, the Electrical Distribution Utility is eligible to generate credits for the electricity, and must meet the requirements set forth in section 95483(e)(1)(B) through (D)."

I. Context of the Rulemaking

1. Public Meetings

The Board directed staff in Resolutions 09-31 and 11-39 to evaluate the feasibility of issuing credits for non-road electricity-based transportation sources to LCFS.[2] In particular, ARB considered allowing electric forklifts ("EF") to qualify for LCFS credits.[3] Staff held several meetings in 2012 and 2013 to work with stakeholders to develop EF fleet rules. On February 13th, 2013, ARB proposed "fleet operators could become the regulated parties if interested."[4] On March 5th, 2013, ARB again mentioned "regulated parties, with fleet operators able to participate if interested."[5] On April 3, 2013, ARB held another electricity workgroup meeting, not mentioning the definition of a regulated party in the workshop presentation.[6] On May 23, 2013, ARB proposed a regulated party definition for EF fleets excluding EF fleet operators.[7] ARB recommended against this approach, in part, because all credits will likely all not be realized. ARB, therefore, proposed utilities to be the regulated parties for EF.[8]

2. Low Carbon Fuel Standard Re-Adoption Paper

In the LCFS Re-Adoption Concept Paper, ARB discussed the significant impact EF fleets have in potential GHG reduction, stating that increased EF use coupled with decreased internal combustion engine ("ICE") forklift use will decrease GHG emissions and contribute to the goals of the LCFS Program.[9] ARB staff proposed Electric Distribution Utilities ("EDUs") qualify for LCFS credit generation, and excluded EF fleet operators to qualify for LCFS.[10] ARB reasoned: (1) many forklifts don't have dedicated meters, and battery chargers charge multiple equipment types; and (2) tracking down data would likely be cost prohibitive.[11]

3. Subsequent Public Meetings

ARB conducted a public EF meeting on May 30, 2014 on the LCFS Re-Adoption Paper, after the release by ARB of the LCFS re-adoption Paper. ARB presented Regulated Party definitions again on a July 10, 2014 meeting, containing the concept paper re-adoption.

4. LCFS Initial Statement Of Reasons

On January 2nd, 2015, ARB released its Initial Statement of Reasons For Rulemaking. ARB's reasoning for EDUs as regulated parties for EFs is largely identical to the re-adoption paper.[12] ARB did not discuss the previously proposed alternative definition of § 95483(e)(7), allowing EF fleets to opt in as regulated parties. In addition, there appears to be no additional supporting evidence for the rationale of the construction of §95483(e)(7).

[12] ISOR, *supra* note 2.

5. Modified Regulation Order

On June 4th, 2015, ARB modified the LCFS regulation, and provided a copy of the updated regulatory text and additional documents.[13]

6. Stakeholder Participation

Part of the purpose of the regulatory process is to involve parties who could be subject to the regulations in public discussions. It appears, however, that utilities have provided most of the input on electric forklifts in this rulemaking. Also, from our examination of the public documents released on the ARB website, it appears that there is no additional information, records or reports on the docket that shed light on the degree to which members of the electric forklift industry and related forklift stakeholders participated in the process. To the extent that electric forklift stakeholders have not participated in the rulemaking process, we are humbled at the opportunity to contribute to this process.

II. Suggested Modification To §95483(e)(7)

We believe the most equitable way to construct §95483(e)(7) would be to keep EDUs as the default party, and allow EF fleet operator to opt-in, as first proposed in the February 13th, 2013 meeting by ARB. The propose language is below:

§ 95483(e)(7)[14]

For transportation fuel supplied to electric forklifts, the Electrical Distribution Utility is eligible to generate credits for the electricity, and must meet the requirements set forth in section 95483(e)(1)(B) through (D). <u>Upon submittal to and approval by the Executive Officer of an electric forklift fleet operator's written request to opt in and generate credits associated with a specified fleet, the electric forklift fleet operator is eligible to generate the credits for the electricity. To receive credit for transportation fuel supplied to an EF fleet, an accounting of the number of EFs in the fleet must be included as supplemental information in annual compliance reporting.</u>

LCFS
FF2-2

III. Discussion

1. ARB Current Rationale For Excluding EF Fleet Operators From Generating LCFS Credits Is Incorrect

<u>i. Nearly Quarter of EF Chargers In California are High Frequency Chargers</u>

ARB may or may not know that many EFs in California are charged by high frequency chargers ("HFC"). HFCs, compared to legacy chargers[15], have "improved energy efficiency, charge control and power factor can provide energy savings, a smaller and lighter charger and better charge control and flexibility."[16] Users of HFC, compared to the poorest chargers, save approximately 10,740 kWh/yr if they were to upgrade to a HFC.[17] In fact, PG&E, in a study conducted in 2009, recommended purchasing HFC because of substantial energy savings potential.[18]

HFCs are dedicated to EFs. That is, HFCs only charge EFs.[19] HFCs produce easily retrievable data that could be submitted to ARB for compliance. HFCs produce energy reports, easily retrievable, which contain the following:

---

[13] *Modified Regulation Order* (ARB 2015).
[14] Our proposed additions are underlined.
[15] Legacy chargers are SCR, Ferroresonant and Hybrid Chargers. Ryan Matley, *Measuring Energy Efficiency Improvements in Industrial Battery Chargers* 1, PACIFIC GAS AND ELECTRIC COMPANY, May 12, 2009, *available at* http://repository.tamu.edu/bitstream/handle/1969.1/91085/ESL-IE-09-05-32.pdf?sequence=1.
[16] *Id.* at 2.
[17] *Id.* at 2.
[18] *Id.*
[19] *Id.*

(a) Amp hours used. This can be easily converted into kWh
(b) Data for each individual charge
(c) Daily usage
(d) Percent of time charging and in use
(e) Station ID number
(f) Location address
(g) Fleet operator name
(h) Number of electric forklifts used by the fleet operator

There are roughly 110,000 forklifts in California.[20] One HFC charges three forklifts. Conventional chargers charge two forklifts. **We estimate 9,000 HFCs in California in 2015, meaning 27,000, or 24.5% of EF in CA are charged by HFCs.** We find it surprising that utility stakeholders would not bring the existence of HFC to ARBs attention.

ii. We Believe ARBs Rationale For § 95483(e)(7), Therefore, Is Likely Incorrect

We would like to take this opportunity to address ARB's rationale for § 95483(e)(7) point by point in light of the existence of HFCs.

ARB Rationale #1: Many forklifts don't have dedicated meters, and battery chargers charge multiple equipment types

We found nothing on the record substantiating the above statement, aside from ARB's statement that they consulted with stakeholders. As stated above, **we estimate 24.5% of chargers in California are HFC, and 27,000 EF are charged by HFCs**.

ARB Rationale #2: Tracking down metered data for thousands of forklifts would likely be cost prohibitive

We are assuming that rationale #2 does not take into account HFCs. **As stated above, tracking down data from HFCs is not cost prohibitive.** Moreover, one could make the same statement about public electric vehicle service equipment. Yet, ARB did not state this as a reason for excluding eligibility for EVSE, and EVSE is eligible to generate credits.

2. Allowing EF Fleet Operators To Opt In To Generate LCFS Credits Better Promotes Goals of LCFS

Reason #1 - Allowing EF Fleet Operators To Opt In To Generate LCFS Credits Better Promotes Consistency and Harmonization

As ARB is probably aware, when an agency submits a regulation to the Office of Administrative Law ("OAL"), OAL reviews the submitted regulation according to several factors, including consistency.[21] In addition, in the ISOR, ARB stated that one of the goals with the Re-Adopted LCFS is to promote flexibility in rules.[22] §95483(e)(7), as currently proposed, promotes inconsistency in treatment of regulated parties in the LCFS.

EF fleet operators are treated differently than other qualifying electricity regulated parties. The statutory scheme proposed for EV fleet operators[23] and public EVSP[24] and private charging stations[25] provide that the EDU is the default regulated party, and allows fleet operators, EVSP providers for public charging stations and private business that own charging stations to opt-in to become regulated parties. Furthermore, the hydrogen forklift regulated party are the fleet owners qualify for generation of LCFS credits.[26]

---

[20] *See California Electric Transportation Coalition Electric Pathway Presentation* Slide 10 .

[23] *Attachment A, Proposed 15-Day Regulation Order,* §95483(e)(3), ARB, *available at* http://www.arb.ca.gov/regact/2015/lcfs2015/regorderfinal.pdf ("Regulation Order").
[24] *Id.* §95483(e)(4).
[25] *Id.* §95483(e)(5).
[26] *Id.* §95483(f).

Allowing EF fleet operators to opt in to generate LCFS credits mirrors the construction of other provisions in §§ 95483(e) & (f), better promoting consistency, and harmonizing LCFS with OAL review requirements. In addition, our proposed update both ensures that the maximum number of credits is claimed by EF fleet operators while furthering the goal of flexibility stated in the ISOR.

Reason #2 - Allowing EF Fleet Operators To Opt In To Generate LCFS Credits Better Encourages Innovation and Fosters Investment

As part of the regulatory process, an agency is required to prepare a regulatory impact analysis that addresses how a proposed regulation: (i) affects increase or decrease of investment in the state; and (ii) incentivizes for innovation in products, materials or processes.[27] In addition, in the ISOR, ARB mentioned a purpose of the re-adoption of LCFS is "to foster investments in the production of the low-CI fuels."[28]

Myriad scholarship has established that it is more effective to provide money directly to fleet operators in the form of credits or grants than rate reductions by utilities. For example, in a report conducted by Berkeley Transportation Sustainability Research Center for the LCFS adoption in 2007, the authors noted that consumers tend to focus on the upfront cost of purchasing a vehicle and overlook fuel efficiency as a significant vehicle attribute.[29] A report analyzing the effects of the Alternative Fuel Credit Program created by the Energy Policy Act of 1992 also concluded that incentives/grants given to fleet operators better encourages the development of electric infrastructure.[30] In addition, ARB itself has said that the best way to encourage innovation in fleets is to give credits to fleet owners.

Incentivizing electric forklifts directly through LCFS credits means more electric forklifts will be purchased. Manufacturers will have higher incentive to increase the production of electric forklifts. More entrants into the market will increase competition, thereby lowering prices. As electric forklifts become less and less expensive, manufacturers will look to provide additional value proposition, including more features, better efficiency and better financing. Accordingly, enabling EFs to be eligible to generate LCFS credits as obligated parties, will better incentivize innovation and foster investment.

3. Modifying §95483(e)(7) Will Not Cause Undue Delay In Implementation of LCFS

ARB staff mentioned to us that a potential reason, at this point in the LCFS readoption process, is that modification of rules may cause timing issues. We would like to clarify with ARB the regulatory approval process. First, a nonsubstantial modification of a regulation does not require a subsequent 15 day comment period. Even if our proposed modification of §95483(e)(7) is considered a substantial and sufficiently related modification, a second 15-day comment period would not cause undue delay to adoption of the LCFS. Regulations must be submitted and approved by OAL prior to becoming effective. In order to have a regulation become effective by January 1st, an agency must submit the adopted regulation by November 30th. OAL must review the application within 30 days. Even if, for some reason, ARB does not manage to submit the adopted LCFS regulation to OAL by November 30th, 2015, an earlier effective date may be prescribed by OAL if an agency requests an earlier effective date with good cause. Given the importance of EF to furthering the purpose of LCFS, and the impact EF fleets have on GHG emissions in California, requesting an earlier effective date, we believe, constitutes good cause.

i. ARB Must Consider Comments From 15 Day Comment Period And May Still Modify LCFS

"An agency must consider comments received during the 15-day comment period and may modify the proposed regulations."[31] "A rulemaking agency must summarize and respond on the record to timely comments that are directed at

---

[27] CAL GOV'T CODE §§ 11346.3 (c)(1)(D)-(E).
[28] ISOR, *supra note 2*, at ES-1.

[31] *The Regular Rulemaking Process*, OAL, *available at* http://www.oal.ca.gov/Regular_Rulemaking_Process.htm (referencing CAL GOV'T CODE §11346.8(c)).

the proposal or at the procedures followed by the agency during the regulatory action. With each comment, the agency must either (1) explain how it has amended the proposal to accommodate the comment, or (2) explain the reasons for making no change to the proposal."[32]

ii. Allowing EF Fleet Operators to Opt-In To Generate LCFS Credits Is Nonsubstantial, Not Requiring 15 Days Notice To Public

After receiving a comment, if an agency decides to modify a regulation pursuant to that comment, the agency must first decide if the change to the regulation is 1) nonsubstantial; (2) substantial and sufficiently related; or (3) substantial and not sufficiently related.[33] A rulemaking agency must make each substantial, sufficiently related change to its initial proposal available for public comment for at least 15 days before adopting such a change.[34]

We believe that our proposed modification is nonsubstantial because it was previously discussed by ARB and stakeholders, and therefore they have been put on notice of a potential change to §95483(e)(7) and have been given opportunity to comment on §95483(e)(7).

iii. Even if ARB Determines Our Proposal TO Modify §95483(e)(7) Is Substantial and Sufficiently Related, It Will Not Cause Undue Delay To Adoption of LCFS

The current comment period ends on June 19, 2015. An agency may conduct more than one 15-day opportunity to comment on modifications.[35] Assume, for the sake of discussion, ARB adopts our proposed modification and issues a second 15-day comment period on June 20th, the end of the 15-day period would be July 5, 2015. Assume it takes one week for ARB to evaluate the second 15-day comment period comments. This would mean that comments close on July 12, 2015.

ARB must submit a finalized report to OAL by November 30th for a January 1, 2016 effective date.[36] OAL has 30 working days to conduct a review.[37] A July 12 comment close date for a second 15-day comment, therefore, gives ARB 141 days to submit a finalized regulation and corresponding requirements to OAL. We respectfully cannot envision a situation whereby it takes more than 141 days - after all comments are received – to meet OAL requirements.

Even if, for some reason, ARB fails to submit the LCFS regulation by November 30th, adopted regulations may have an earlier effective date if an agency requests an earlier effective date and shows good cause.[38] Given the importance of EF to furthering the purpose of LCFS, and the impact EF fleets have on GHG emissions in California, requesting an earlier effective date, we believe, constitutes good cause.

Accordingly, we believe this section clarifies any ARB worry about timing, and means that amending §95483(e)(7) will not cause undue delay in implementation of the LCFS.

IV. Conclusion

The regulatory process exists as it does so that agencies, stakeholders and the public work together to refine and improve regulations prior to them going into effect. Now is our opportunity to make a common sense change that will spur innovation for electric forklifts, fleet operators and electric forklift charging stations. Now is our opportunity to ensure that §95483(e)(7) is crafted with the right rationale. Now is our opportunity to significantly impact climate change, not just for California, but also other states and the United States.

---

[32] *Id.*
[33] *Id.*
[34] *Id.*
[35] *Id.*
[36] CAL GOV'T CODE § 11343.4
[37] *Rulemaking Process*, *supra* note 34.
[38] CAL GOV'T CODE § 11343.4(B). *See Also* OAL REVIEW PROCESS, *available at* http://www.oal.ca.gov/res/docs/pdf/OAL%20Review%20Process_FINAL_June%202014.pdf.

Based on the foregoing, it appears that the rationale for §95483(e)(7) excluding electric forklift fleet operators is incorrect. We estimate 24.5% of electric forklifts – or 27,000 forklifts – are charged by high frequency chargers. These chargers produce easily retrievable data, meaning data collection will not be costly. Our proposed revision of §95483(e)(7) – allowing electric forklift fleets to opt-in, with EDUs being the default credit generator - better promotes consistency and harmonization of the LCFS, spurs innovation and investment in electric forklifts, and better incentivizes the right actors – electric forklift fleet operators and battery charging station manufacturers – to buy more electric forklifts and improve electric forklift technology. Moreover, our proposed revision of §95483(e)(7) provides more flexibility to the LCFS rules, and ensures the maximum number of EF fleet LCFS credits are generated. Finally, amending of §95483(e)(7) will not cause undue delay in the adoption of LCFS because there is still ample time prior to November 30th, and a regulation can go into effect prior to an effective date if an agency requests and has good cause.

We believe, therefore, it would be unreasonable for ARB to adopt §95483(e)(7)[39], and ARB should not make a finding that, in light of our suggested modification to§95483(e)(7), §95483(e)(7) (excluding EF fleets as eligible to generate LCFS credits) either (a) would be more effective in carrying out the purpose of the LCFS; (b) would be as effective and less burdensome to affected private persons than the proposed action; or (c) would be more cost effective to affected private persons and equally effective in implementing LCFS.[40] §95483(e)(7), in either form, only affects which regulated parties can be eligible for LCFS credit generation for electric forklifts. Affected private persons, therefore, are electric forklift fleets and electric forklift charging station providers and manufacturers. In instance b, §95483(e)(7) is more burdensome for electric forklift fleets because they cannot generate LCFS credits. In instance c, §95483(e)(7) would not be more cost effective than our proposed modification because EF Fleets cannot generate LCFS credits.

We strongly urge ARB to modify §95483(e)(7) to allow electric forklift fleet operators to be eligible to opt-in to the LCFS to generate LCFS credits with either our suggested verbiage contained herein or similar verbiage.

We conclude our comment by again applauding ARB and California for taking a lead on climate change. Every staff member we have spoke to thus far has been incredibly kind, and well intentioned. It is a testament to ARB and the CA regulatory process to have such inspired, intelligent and dedicated staff working on one of the most important regulations of our epoch. We very much welcome ARB's comments, are available to answer any questions ARB may have on these comments, and respectfully request setting up a meeting with staff as soon as practicable.

Respectfully submitted,

Elon D. Rubin

[39] CAL GOV'T CODE §11346.5(A) requires that an agency proposing to adopt a regulation to assess the potential for "avoiding the imposition of unnecessary or unreasonable regulations."

[40] CAL GOV'T CODE §11346.5 requires, in a Final Statement of Reasoning, "[a] statement that the adopting agency must determine that no reasonable alternative considered by the agency or that has otherwise been identified and brought to the attention of the agency would be more effective in carrying out the purpose for which the action is proposed, would be as effective and less burdensome to affected private persons than the proposed action, or would be more cost effective to affected private persons and equally effective in implementing the statutory policy or other provision of law."

2_FF_LCFS_BE

862. Comment: **LCFS FF2-1**

The comment suggests that ARB staff allow electric forklift fleet operators to be eligible to generate LCFS credits.

Agency Response: ARB staff considered the comments and made the corresponding changes in the second 15-day change package, which was publicly released on June 23, 2015.

863. Comment: **LCFS FF2-2**

The comment provides suggested regulation language that would allow electric forklift fleet operators to be eligible to generate LCFS credits.

Agency Response: See response to **LCFS FF2-1**.

Re: Proposed Re-Adoption of the Low Carbon Fuel Standard

To Whom It May Concern:

BNSF Railway ("BNSF") has been in communication with California Air Resources Board ("CARB") staff since approximately October 2014 regarding its concerns with the Low Carbon Fuel Standard Regulation ("Regulation") and, more specifically, its inability to take advantage of the exemption in the Regulation for fuel consumed by interstate locomotives. Despite multiple conversations and the submittal of multiple proposals, BNSF remains without a clear path to compliance that allows it to: 1) take advantage of the exemption for fuel consumed by interstate locomotives; and 2) avoid overpayment under the Regulation.

As a means to resolving this issue, BNSF is providing brief comments on the proposed additional changes to section 95483(a)(2) contained in the June 4, 2015 re-adoption package. More specifically, BNSF requests that certain language currently contained on Regulation page 17 be revised. Per the existing language, a transaction must occur above the rack in order for ownership of the LCFS obligation to be transferred. BNSF is unclear about why this language cannot apply to both above and below the rack transactions, at the buyer's discretion.

LCFS FF3-1

Such a change would give BNSF the ability to take on the LCFS obligation for all of its purchases. In doing so, BNSF would be able to avoid the scenario where suppliers pass along the cost of the obligation on all fuel, and instead, could provide an accurate accounting of what fuel purchased in California is used for intrastate and interstate consumption, respectively. Based on that accounting, it could then meet the obligation on only that portion of fuel purchased for intrastate consumption. BNSF has explored a variety of mechanisms for availing itself to the express exemption contained in the regulation and currently believes that from a practical perspective, this language change, would provide the simplest means to doing so.

Thank you for your consideration.

Sincerely,

R-h. Elgie

Rocky Elgie
General Director Fuel Management
BNSF Railway

3_FF_LCFS_BNSF

864. Comment: **LCFS FF3-1**

The comment is asking that staff modify the proposed regulation to allow the compliance obligation to be transferred below the rack so that the commenter can more easily take advantage of the exemption for fuels used in interstate locomotives.

Agency Response: ARB does not support the commenter's proposed method for tracking intrastate locomotive fuel consumption and export volumes. This method would allow railroads to remove fuel purchased without obligation from their compliance obligation. This is not possible under the LCFS because the deficits incurred on fuel purchased without obligation are the responsibility of the fuel seller to offset. No further credit/debit account balancing based on this fuel is available to the purchaser.

The current LCFS regulation allows ultra-low sulfur diesel (ULSD) purchased below the rack to be purchased with or without obligation. This provision has proved problematic for smaller entities, such as retail outlet operators, who have limited or no ability to comply with the LCFS.

The proposed regulation does not allow ULSD to be purchased below the rack (defined as a diesel fuel transaction of less than 10,000 gallons) with obligation. It also brings the diesel and gasoline provisions into conceptual alignment. In both cases, end users and retail outlets will be protected from receiving the compliance obligation. Once the proposed regulation goes into effect, therefore, with-obligation purchases may only occur above the rack.

We recognize that the commenter wishes to find an administratively simple way of claiming the interstate rail exemption. Staff is committed to continuing to work with the commenter on this issue in the future.

Re: 15-Day Amendment Package for Low Carbon Fuel Standard (LCFS)

GlassPoint Solar Inc. (GlassPoint) appreciates and supports ARB's efforts to readopt the Low Carbon Fuel Standard (LCFS) to create a workable regulatory framework. We are pleased to provide these comments on the June 4, 2015 LCFS 15-Day Regulatory amendment package. The proposed final language is the result of a cooperative rulemaking process that GlassPoint believes has made the regulation better, and specifically the Innovative Crude Provisions. We look forward to the expeditious conclusion of the rulemaking as GlassPoint is ready to build new low-carbon projects once regulatory standards are finalized in California.

GlassPoint is a California company that manufactures solar steam generators for thermal enhanced oil recovery (EOR). Our renewable energy technology has proven reliable, safe and economical in field operations in California and the Middle East. We were pleased to be selected by the U.S. State Department as one of nine finalists for the Secretary of State's prestigious 2014 Award for Corporate Excellence (ACE) for our technology and corporate behavior.

Thermal EOR, or steam injection, extends the value and the life of California's oilfields. Today, thermal EOR accounts for more than 40% of California's oil production and consumes more than 200 MM MMBTU per year of fuel for steam generation. Solar energy can replace a substantial fraction of that existing fuel use, reducing emissions resulting from upstream production. Of the potential innovative methods, the use of solar energy is the lowest-cost, lowest-risk, and largest-scale opportunity to reduce the CI of petroleum fuels produced and used in California. Solar powered oil production technologies—solar steam generation and solar electric power generation—have the potential to contribute to California's economy significantly while reducing costs and risks associated with meeting the LCFS.[1]

GlassPoint appreciated ARB's understanding of the potential impact of solar EOR. The technical amendments to the Innovative Crude portions of the regulation are technically sound and appropriate. GlassPoint also appreciates the additional category of steam quality that is now eligible for credits (55%). LCFS FF4-1

[1] January 2015, ICF Report: The Impact of Solar Powered Oil Production on California's Economy, An economic analysis of Innovative Crude Production Methods under the LCFS. Previously submitted.

GlassPoint strongly supports the Innovative Crude mechanisms and procedures as provided in the proposed regulation and amendments. LCFS FF4-1 cont.

One final reminder on regulatory timing must be noted. This regulatory adoption schedule has been delayed several times and now creates challenges for customers and project developers to harvest the benefits of the Federal solar tax incentives, which expires at the end of 2016. An effective 20% price increase will occur for projects which come online after that date. GlassPoint wishes to continue the discussion on how we can send a signal to the investment community as soon as possible about the longevity of, and the benefits of, this program. That is the easiest way to start in-state investments in lower CI fuel production. We look forward to working with ARB so that projects can capture the Federal benefits and minimize total costs. LCFS FF4-2

Thank you for the opportunity to comment and we look forward to the conclusion of this lengthy rulemaking, and to working on building a lower carbon infrastructure for California.

Sincerely,

John O'Donnell
Vice President, Business Development

Subject: CI of denaturaunt
Comment:
The denaturaunt used by domestic ethanol producers is Natrual Gasoline. This product has a lower CI than CARBOB. Brazilian Ethanol marketers use CARBOB for their denaturant. There should be a new default pathway for domestic ethanol denaturuant reflecting the use of Natural Gasoline.

867. Comment: **LCFS FF5-1**

The comment states that there should be a new default pathway for domestic ethanol denaturant reflecting the use of Natural Gasoline.

Agency Response: ARB staff is aware that there are multiple additives which qualify as denaturant under the ASTM standard. Staff will continue to monitor industry blending practices and will consider refining CIs for commonly used materials such as natural gasoline in the future. For the time being, due to a lack of reporting data on pathway-specific blending materials, all denaturant is assessed as CARBOB representing a uniform conservative assumption for all denatured ethanol consumed in California.

Subject: Comments on Low Carbon Fuel Standard's (LCFS) provisions for Low Complexity – Low Energy (LCLE) Refiners

Thank you for allowing us to provide our comments on the Low Carbon Fuel Standard's (LCFS) provisions for Low Complexity – Low Energy (LCLE) Refiners. These provisions recognize that not all refineries are the same. We believe that there are policy and technical justifications for a distinction in the LCFS. The Air Resources Board, as well as, the U.S. Environmental Protection Agency has traditionally recognized the unique value small refiners occupy in the oil and finished fuel markets, as well as, their unique configurations and operating constraints.

Given the value of LCLE Refiners, we were concerned that the proposed final regulatory proposal for the re-adoption of California's LCFS fails to recognize Alon's Bakersfield Refinery as a LCLE producer. The facility is configured and engineered to produce low carbon intensive base fuels. Board staff had an opportunity to make the LCFS's LCLE provisions work for all low carbon intensity refineries in California, but decided against various compromise proposals presented, including proposals to limit the benefit any single LCLE refiner could receive. LCFS FF6-1

As the final LCFS regulation is before you, we ask that the Board please look again at the value of all LCLE refineries and the benefits that they provide to the state. Thank you again for allowing us to provide our comments on the re-adoption of the LCFS.

Sincerely,

ANDY VIDAK
Senator, 14th District

JEAN FULLER,
Senator, 16th District

6_FF_LCFS_Vidak

868. Comment: **LCFS FF6-1**

The commenter believes that ARB has excluded the Alon Bakersfield refinery from the Low Complexity-Low Energy Use Refiner provisions of the rule despite the facility being configured and engineered to produce low carbon intensive base fuels.

Agency Response: See comment responses to **LCFS B5-1**, **LCFS FF9-6**, and **LCFS FF9-8**.

Re: Alon's Bakersfield Refinery

On behalf of the entire membership of IBEW Local 428, I would like to extend our strong support of the Low Carbon Fuel Standard's provisions for Low Complexity—Low Energy Use Refiners. Clearly, not all refiners are the same, and these provisions recognize that. Both the Air Resources Board and U.S. Environmental Protection Agency have long recognized in their regulatory programs the unique space small refiners occupy in the oil and gas industry. This distinction is a very necessary and positive step. LCFS FF7-1

Unfortunately, it seems the proposed final regulatory provisions for the re-adoption of California's Low Carbon Fuel Standard (15-day changes) fails to recognize Alon's Bakersfield Refinery as a low carbon fuel producer, even though it is configured and engineered to produce low CI base fuels. This is a huge mistake, especially in light of the fact that staff had every opportunity to make the LCFS's LCLE provisions work for ALL low carbon intensity refineries in California, instead deciding against the several compromise proposals presented. LCFS FF7-2

It is for these reasons that IBEW Local 428 strongly urges the Board to direct staff to revisit this issue at the earliest opportunity.

Sincerely,

James S. Elrod

Subject: Comments on the 15 Day Regulatory package for the LCFS Regulation

The UA Plumbers, Pipefitters & Steamfitters Local Union 460 strongly supports the Low Carbon Fuel Standard's (LCFS or regulation) provisions for Low Complexity – Low Energy Use Refiners (LCLE Refiners). These provisions recognize that not all refineries are the same. We believe that there are solid policy and technical justifications for this distinction to be codified in the LCFS. The Air Resources board (CARB or Board), as well as, the U.S. Environmental Protection Agency have traditionally recognized in their regulatory programs the unique value small refiners (LCLE) occupy in both the oil and finished fuel markets, as well as, their unique configurations and operating constraints. Recognizing that difference is a very positive step.

However, we are disappointed that the proposed final regulatory provisions for the re-adoption of California's Low Carbon Fuel Standard (15-day changes) fails to recognize Alon's Bakersfield Refinery as a low carbon fuel producer (LCLE). The facility is configured and engineered to produce low CI base fuels. It is for this reason that we are saddened that staff was unable to agree on a solution that would include all of California's truly LCLE refineries. The staff had an opportunity to make the LCFS'S LCLE provisions work for all low carbon intensity refineries in California, but decided against various compromise proposals presented, including proposals to limit the benefit any single LCLE refiner could receive in an attempt to deal with staff's concerns for "regulatory creep" and "breaking the Bank". LCFS FF8-1

UA Plumbers, Pipefitters & Steamfitters Local Union 460 strongly urges the Board to direct staff to revisit this issue at the earliest opportunity.

Respectfully submitted,

Steven Gomez
Local Union 460

ALON USA

June 19, 2015

Via electronic submittal to: http://www.arb.ca.gov/lispub/comm/bclist.php

Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Subject: Comments on the 15 Day Regulatory package for the LCFS Regulation

Alon USA Energy (Alon) strongly supports the Low Carbon Fuel Standard's (LCFS or regulation) provisions for Low Complexity – Low Energy Use Refiners (LCLE Refiners). These provisions recognize that not all refineries are the same. We believe that there are solid policy and technical justifications for this distinction to be codified in the LCFS. The Air Resources Board (CARB or Board), as well as, the U.S. Environmental Protection Agency have traditionally recognized in their regulatory programs the unique value small refiners (LCLE) occupy in both the oil and finished fuel markets, as well as, their unique configurations and operating constraints. Additionally, smaller, less complex refiners also have the added distinguishing characteristic that they produce finished fuel with a lower Carbon Intensity (CI), the heartbeat of the LCFS. Recognizing that difference is a very positive step. LCFS FF9-1

That being said Alon, is very disappointed that the proposed final regulatory provisions for the re-adoption of California's Low Carbon Fuel Standard (15-day changes) fails to recognize Alon's Bakersfield Refinery as a low carbon fuel producer (LCLE). The facility is configured and engineered to produce lower CI fuels. Alon, CARB staff and the Board have been actively discussing the concept of a LCLE refiner provision since 2011, including adopting previous resolution language on the subject matter. Over the past four years, the policy construct behind recognizing the inherently lower carbon intensity of smaller, less complex refineries has been fully agreed upon. It is for this reason that Alon is saddened that staff was unable to agree on a solution that would include all of California's truly LCLE refineries. Unfortunately, the final limited LCLE definition has several negative implications, including: creating an uneven competitiveness within the smaller refinery subsector, increasing statewide GHG emissions from California's transportation fuel sector, not recognizing the true economic impact on Bakersfield, and setting a precedent regarding use of data. Finally, it locks into place a significant regulatory and economic obstacle to restarting the Alon Bakersfield refinery. **Alon strongly urges the Board to direct staff to revisit this issue at the earliest opportunity.** LCFS FF9-2

The LCLE provision was intended to be an all-encompassing policy acknowledgment by the Board that there are refineries in California that produce transportation fuels while consuming substantially less energy per finished gallon. Nobody would ever say the Alon Bakersfield facility looks or operates like California's biggest refineries.

As we know, the LCFS regulation impacts refineries that are both operating AND may resume operations shortly by providing the "rules of the game" for many years to come. This regulation will not only impact Alon's Bakersfield refinery but could have consequences for Alon's Paramount refinery where we are in the process of modifying some of the process units to produce renewable diesel from animal and vegetable fats. [1] LCFS FF9-2 cont.

California's smaller, less complex refineries are few in number and have been historically acknowledged by CARB to operate at a market disadvantage. This historical recognition started in the earliest of CARB rulemakings on California's transportation fuel (clean diesel and reformulated gasoline). Recent regulatory actions by the agency to implement AB 32 have not been consistent in recognizing these differences. In fact, rationale provided to Alon by CARB staff for not recognizing small refiners under the Cap and Trade program was that this issue would be better suited for the LCFS regulation. Now both regulations have been updated, and both regulations leave Alon's Bakersfield refinery abandoned. LCFS FF9-3

The staff recommendation itself was disappointing, but Alon is equally disappointed that neither the Bakersfield refinery, or its data were considered when analyzing the LCLE provisions initially, even though we had been in active discussion with staff for years. At the direction of CARB Alon waited almost a year for new Mandatory Reporting (MRR) to be collected and analyzed for the statewide refinery fleet. Unfortunately, the updated MRR did not include the requirement for over-the-fence purchased hydrogen data which would further demonstrate the large difference in carbon intensity between the LCLE refineries and the other refineries in the state. Soon after learning that the data needed to help draw the distinctions wasn't coming, the draft LCFS regulation was written to exclude the Bakersfield refinery from the LCLE category without the benefit of its data. Since that point, staff has not wanted to adjust the eligibility criteria. The inertia of the initial draft was significant. Alon feels the Bakersfield refinery was a victim of the regulatory adoption system. LCFS FF9-4

Though Alon's Bakersfield refinery is currently operating in a very limited mode, Alon is actively working to bring production back to 2008 levels and has spent millions of dollars in the environmental review process. The Kern County Board of supervisors has approved an Environmental Impact Report to allow Alon to reconfigure the Refinery and the necessary engineering work has commenced. The impacts of the LCFS and the potential mitigating effects of the LCLE refiner provisions are significant economic considerations for the facility. By leaving the Bakersfield Refinery outside the LCLE universe CARB staff has substantially increased the economic impact that the facility will need to overcome and decreased the likelihood that California will receive the low carbon fuel supplies that it could provide. LCFS FF9-5

Alon believes that the inclusion of the Bakersfield refinery in the LCLE would have been a win for the environment and a win for the central valley economy -- Because the CI of the Bakersfield facility is materially lower than the average California refinery, the fuels produced by the facility would save as much as 400,000 metric tons of GHG emissions annually over what would otherwise LCFS FF9-6

---

[1] The Paramount Refinery meets the LCLE criteria and an economic evaluation will be needed to determine if it is economic to produce low carbon intensity conventional fuel at the facility.

be emitted by an average in-state refinery and its inclusion would have helped assure good middle class construction and refinery jobs in the economically hard it central valley. LCFS FF9-6 cont.

The potential loss of these GHG reductions is a significant environmental impact. In fact, it is almost equal to the GHG emission reduction benefits of an entirely new Major Regulation currently proposed—The Crude Oil and Natural Gas Operations regulation. That entire regulation, estimated to cost more than $50 million dollars to California business is anticipated to only achieve 556,000 tons of reductions The failure to analyze the environmental impacts associated with the Bakersfield refinery being in the LCLE universe is a serious CEQA issue. Alon worked diligently over the past year trying to understand CARB's concerns. The 15- Day package was an opportunity to make the LCFS's LCLE provisions work for all low carbon intensity refineries in California, and Alon offered various compromise proposals, including proposals to limit the benefit any single LCLE refiner could receive in an attempt to deal with staff's concerns regarding "regulatory creep" and "breaking the bank". Unless the Board directs staff to revisit this issue at the earliest of re-openings, Alon must wait years for the next scheduled LCFS revision in 2018. LCFS FF9-7

In summary, while Alon strongly supports the concept of LCLE provisions, the proposed LCLE provisions missed the mark because the LCLE eligibility criteria of "5/5" isn't reflective of the complete category of refineries that fit its important policy goal. **Alon respectfully asks the Board to direct staff to revisit this decision as soon as practicable.** LCFS FF9-8

If you have any questions on these comments please contact Gary Grimes at 562-531-2060 (ggrimes@ppcla.com).

872. Comment: **LCFS FF9-6 and LCFS FF9-7**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

873. Comment: **LCFS FF9-1**

Agency Response: ARB staff appreciates the support for the Low Complexity/Low Energy Use provision.

874. Comment: **LCFS FF9-2**

The comment states that the LC/LE provision as written effectively excludes the Alon-Bakersfield refinery from the benefits of the provision.

Agency Response: See response to **LCFS FF9-6**.

875. Comment: **LCFS FF9-3**

The comment states that both Cap and Trade and LCFS leave Alon's Bakersfield refinery abandoned by failing to recognize it as a smaller, less complex, and disadvantage refinery.

Agency Response: See response to **LCFS FF9-6**.

876. Comment: **LCFS FF9-4**

The commenter expresses disappointment that neither the Bakersfield refinery, nor its data were considered when analyzing the LCLE provisions initially, even though they had been in active discussion with staff for years.

Agency Response: See response to **LCFS FF9-6**.

877. Comment: **LCFS FF9-5**

The commenter states that the LC/LE provision as written effectively excludes the Alon-Bakersfield refinery from the benefits of the provision and has substantially increased the economic impact that the facility will need to overcome.

Agency Response: See response to **LCFS FF9-6**.

878. <u>Comment</u>: **LCFS FF9-8**

In summary, while Alon strongly supports the concept of LC/LE provisions, the proposed LC/LE provisions missed the mark because the LC/LE eligibility criterion of "5/5" isn't reflective of the complete category of refineries that fit its important policy goal. The commenter respectfully asks the Board to direct staff to revisit this decision as soon as practicable."

<u>Agency Response:</u> Data provided by Alon to ARB staff regarding Alon Bakersfield's future refinery operations and capacity indicate that Alon Bakersfield's carbon intensity, albeit lower than that of the statewide average, was still significantly higher than the carbon intensity of the current LC/LE qualifying refineries and equivalent to, or in some cases higher than, that of simpler complex refineries. See response to **LCFS B5-1** and **LCFS FF9-6**.

BIODIESEL® America's Advanced Biofuel

June 18, 2015

Mary D. Nichols
Chair
California Air Resources Board
P.O. Box 2815
Sacramento, CA 95814
Submitted via electronic mail.

Re: Written comments from the National Biodiesel Board on the Proposed Re-Adoption of the Low Carbon Fuel Standard.

Dear Chair Nichols:

Thank you for the opportunity to comment on this regulation. We sincerely value the job you and all ARB board members and staff undertake in protecting the state's environment and public health.

By way of background, the National Biodiesel Board (NBB) serves as the trade association for the U.S. biodiesel and renewable diesel industries. The NBB represents more than 90 percent of domestic biodiesel and renewable diesel production. In addition to governmental affairs activities, the association coordinates the industry's research and development efforts.

Our comments on this matter are brief, reflecting broad agreement with the work staff have done in crafting the regulation. Listed below are a few relatively minor matters we hope can be clarified or addressed before the regulation receives final approval.

Tier 1 and Tier 2 Classifications

Biodiesel is unique. While it is an established technology, having been in commercial production for more than a decade, the industry is, at the same time, continuing to evolve and advance in exciting ways—both in terms of feedstock development and processing technology. In addition, numerous feedstocks and processes exist for creating ASTM grade biodiesel. For these reasons, we believe that ARB should include Tier 1 pathways for integrated oil and biodiesel producers, or integrated biodiesel producers should be able to utilize the Tier 2 GREET model, should circumstances merit it. Two specific examples are provided below.

LCFS FF10-1

Used Cooking Oil (Cooking Not Required)
It appears that the pathway for "uncooked" used cooking oil (UCO) has been removed and is therefore not available under Tier 1. This pathway is particularly relevant for California biodiesel producers, some of whom collect grease directly from restaurants and do not "cook" or otherwise refine the product before inputting the UCO into their biodiesel production processes. Therefore, using the proposed Tier 1 (cooked) UCO pathway would result in a double counting penalty for these producers equating to several carbon intensity points. LCFS FF10-2

We also believe integrated operations should be accounted for in the Tier 1 pathways. For example, a biodiesel production facility that is attached to a canola processing facility should be able to input its specific feedstock processing values rather than being forced to rely on default inputs. This would provide the most accurate carbon intensity value for the fuel.

Hydrochloric Acid (HCL)
It appears that staff may develop numerous methods for HCL recording. Typically, we support this type of flexibility for a diverse industry such as ours. In this particular case, however, we think the matter sufficiently simple as to not warrant such an approach. Instead, we recommend providing guidance in the regulation that HCL should be recorded as if it were 100% HCL rather than the actual volume of diluted HCL. LCFS FF10-3

Thank you, in advance, for your consideration of our views. We very much appreciate the continued excellent work of ARB staff. If I may be of any assistance, please feel free to contact me at any time at (573) 635-3893.

Sincerely,

Shelby Neal
Director of State Governmental Affairs

10_FF_LCFS_NBB

879. Comment: **LCFS FF10-1**

The commenter believes that ARB should include Tier 1 pathways for integrated oil and biodiesel producers, or integrated biodiesel producers should be able to utilize the Tier 2 GREET model, should circumstances merit it.

Agency Response: ARB staff will be conducting workshops post Board Hearing regarding the Tier 1 and Tier 2 categories and will provide subsequent guidance regarding pathway processing between Tier 1 and Tier 2. Staff currently believes that integrated oil and biodiesel facilities, or a biodiesel facility linked with an oil production facility would likely be a Tier 2 pathway.

880. Comment: **LCFS FF10-2**

The commenter states that it appears that the pathway for "uncooked" used cooking oil (UCO) has been removed and is therefore not available under Tier 1.

Agency Response: ARB staff currently assumes that if applicants do not need to process the used cooking oil by cooking prior to biodiesel production then those applicants should apply under Tier 2 to substantiate the lack of need to cook the oil and provide the sources of the UCO. See response to **LCFS FF10-1**.

881. Comment: **LCFS FF10-3**

The commenter recommends providing guidance in the regulation that HCL should be recorded as if it were 100% HCL rather than the actual volume of diluted HCL.

Agency Response: At this time ARB does not want to amend CA-GREET so as to create confusion based on unnecessary differences between CA-GREET and ANL's widely-used current GREET model. ARB plans to work with ANL in the future to address issues related to HCL.

June 19, 2015

Mr. Richard Corey
Executive Officer
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Mr. Corey:

The development of revisions to Low Carbon Fuel Standard (LCFS) has taken years, during which time you and your staff have exhibited the highest degree of professionalism and dedication. Sustained attention to detail has been evident by Air Resources Board Staff, even regarding occasionally esoteric market issues. The highest level of public service has been a constant for staff that, like you, have been engaged on this issue for years, as well as for staff only recently added to the LCFS team.

Not surprisingly, the result is an excellent set of proposed revisions to the LCFS which should strengthen the program and quicken the private sector's efforts to supply the California market with innovative, affordable, low carbon fuels.

Today I write to you seeking clarification on one provision in the proposed 15-Day Regulation Order. One requirement of the proposed Renewable Hydrogen Refinery Credit Pilot Program is that the renewable hydrogen used "must annually replace a minimum of one percent of all fossil hydrogen in the production of CARBOB or diesel fuel."

It seems reasonable to interpret the displacement of one percent of fossil hydrogen to be measured against the hydrogen used as refining feedstock for that refinery. This seems logical given that any credits generated under this provision would accrue to the refinery as a measure of the amount of fossil hydrogen displaced in that refining process by the renewable hydrogen. That said, the language quoted above does not specify this, leaving open the possibility that the language could be interpreted more broadly. LCFS FF11-1

Could you please clarify that the one percent displacement pertains to the refining feedstock of the individual refinery, and not to the fossil hydrogen used elsewhere in the refinery for process energy, or outside the refinery gate by the same regulated party or other parties? Thank you very much.

Regards,

Christopher J. Hessler

11_FF_LCFS_AJW

882. Comment: **LCFS FF11-1**

The commenter asks for clarification on the requirement of the proposed Renewable Hydrogen Refinery Credit Pilot Program that the renewable hydrogen used “must annually replace a minimum of one percent of all fossil hydrogen in the production of CARBOB or diesel fuel.”

Agency Response: Under the Renewable Hydrogen Refinery Credit Pilot Program, one percent displacement pertains to the refining feedstock of the individual refinery. The one percent displacement does not pertain to the fossil hydrogen used elsewhere in the refinery for process energy, and also does not pertain to fossil hydrogen used outside the refinery gate by the same regulated party or other parties.

Sam

While looking at the first line (Jan 31 for Electrical Distribution Utility) in Table 12, I had a lot of trouble finding the associated rule language. I assumed it would be in the annual reporting section. I suggest inserting a reference to 95491(a)(3)(D) for this line (as footnote maybe?) or include a pointer reference in the annual compliance report section directing the reader to the quarterly report section.

LCFS FF12-1

Hi Hafizur,

I am wondering about the 3rd party option – does the auditor need to see all 2 years' worth of invoices? The only difference between the two options is one is viewed on site and the other is scanned and submitted to CARB?

We would like to understand the 3rd party option now so we have time to submit a formal comment if needed. Thanks again for answering some of our questions.

Tom:

Our apologies for the delayed response. Due to the LCFS re-adoption workload and preparing Board materials for July Board Hearing, we prefer to respond to your question via email rather than hold a conference call. The proposed regulation would require all the invoices and receipts you describe. If this is problematic we encourage you to submit a formal written comment on this issue.

In addition, I'd call your attention to the fact that the proposed regulation also provides an option for the applicant to submit an independent third-party audit report which documents all the feedstock purchases, fuel sales and co-product sales to cover a two-year period. We think this option will allow facilities to avoid extensive submission of information to ARB. We'll be working to flesh out this option in greater detail next year.

Subject: Conference call on records needed

Hafizur - We would like to schedule a conference call with you on the 17th or 18th to discuss the records request for recertifying under the new LCFS. I am suggesting these dates because at least one of us is not available on other dates in the next 2 weeks.

I will participate, along with Heather Gullick and Bob Whiteman of POET. I will prepare an agenda.

Overall, we view the records request (as we understand it) as extreme. We need to try to find a way to make it less extreme and more workable for everyone. LCFS FF15-2

Thanks,

Tom Darlington

886. Comment: **LCFS FF15-1**

The commenter asks if the auditor is required to review two years of data and invoices with the third party option.

Agency Response: Under section 95488(c)(3)(A)(3), applicants may choose to utilize a 3rd party verification in lieu of receipts or invoices for energy consumption, fuel sales, feedstock purchases, or co-product sales. The auditor is still required to review the plant's two years data and invoices.

887. Comment: **LCFS FF15-2**

The commenter believes Tier 1 application submittal documentations (such as invoices and receipts for all forms of energy consumptions, fuel production process, all fuel sales, all feedstocks purchases, and all co-products sold) to be excessive.

Agency Response: Staff has made a few adjustments in the regulation under second 15-day changes package for Tier 1 fuel pathways. Under the section 95488(a)(2) for *recertification of legacy pathways* fuel providers may apply for recertification as set forth below to replace pathway certifications subject to being deactivated.

> *(A) Applicants seeking to recertify a legacy pathway shall begin the application process by completing the online account registration process and submitting an electronic New Pathway Request Form prior to February 1, 2016, indicating that they are seeking recertification of a legacy pathway.*
>
> *(B) Recertifications will be processed by the Executive Officer using information previously supplied to the Executive Officer under the provisions of the former LCFS regulation order, provided such information was complete pursuant to the former LCFS regulation's requirements. The requirements of subsections 95488(c)(3)-(5) and subsection 95488(e) are not applicable to recertifications, unless the Executive Officer specifically requests such information from an applicant.*
>
> *(C) The Executive Officer will determine the classification of each recertification under the tier structure described in subsection 95488(b).*

(D) The result of the Executive Officer's decisions on recertifications shall be final and not subject to further appeal. Denied applicants may submit New Pathway Request Forms pursuant to section 95488.

However, if applicants submit a New Pathway Request form and have been notified by the Executive Officer that the pathway described in the New Pathway Request Form falls under the Tier 1 provisions found at section 95488(b)(1) the applicants are required to submit necessary documentations stated under 95488(c)(3). Staff currently receives process energy receipts and fuel sales information. Without other information, such as feedstock purchase/consumption documentation it is not possible to confirm the yield of the fuel. Yield is typically in terms of volume of fuel produced per mass of feedstock (corn ethanol gal/Btu). Furthermore, the co-product credits can be substantial and the only way to verify that a co-product credit is warranted is to establish that it was used for something, which can most easily be proven through documentation or receipts. Staff have been maintaining confidential business information (CBI) since the inception of the LCFS regulation and plan to keep the same strategy and treat this new category of CBI likewise.

Yes Tom, this is much, much more than a utility invoice where you would have around 24 over a 2 year period. For our larger facilities, we could be talking about well over 10,000 records for grain receipts, and DDG/ethanol sales. Even in an enforcement scenario, I would say it would be very unusual to ask for scanned copies of all records if those records weren't suspected of being fraudulent through the earlier sample.

LCFS FF16-1

It would be a more manageable request if they were going to be happy with a download of data, but a request for scanned copies of all records will result in the plants needing to actually employ an addition person(s) to assemble that volume of information. We would be happy to participate in the call with CARB if that would help.
Thanks,
Bob

Hi Tom,

Thanks for checking into this. I don't agree with their audit argument. In most audits, samples are picked and details like invoices etc are provided just for the sample transactions. I have never seen anyone ask for 2 years of invoices for every transaction. LCFS FF16-1 cont.

Could you follow up and find out what needs to be seen on the items – meaning what are we allowed to redact/black out? Providing this info would show - for example - farmers name and address, price, volume and origin. We would also be sharing all of this detail for DDG and ethanol (along with where the product is shipped). I am concerned about push back from the plants. They prefer for their business details to remain private. LCFS FF16-2

Thanks,
Heather

Subject: Re: guidance

I talked with ARB about the fact that it is a big job to scan all this information in and create these spreadsheets. But ARB does not see a way around scanning in all these invoices and creating the spreadsheets. They realize it is a lot of work, but they also note that every plant that sells into California will have to do this anyway in the future, in case ARB comes out and audits the plant. If there are are other questions about this, I would be glad to continue to contact ARB. LCFS FF16-1 cont.

On 6/4/15 11:25 AM, Sahay, Shailesh wrote:

> Thanks, Heather. I absolutely agree with your reaction, and asked Tom about this myself. I've copied the language from the proposed regs regarding what invoices need to be produced for a Tier 1 application below. It appears that, with the approval of CARB, we could produce a report by a third-party auditor documenting the sales in lieu of producing all the invoices. Of course, the third-party auditor might demand to see the invoices anyway. LCFS FF16-3
>
> Tom is calling CARB to see if he can get clarification on the invoice requirement. I've cc'd him here in case he has any other input at this point. I also am not yet comfortable with handing over this quantity of sales information to the agency. LCFS FF16-2 cont.
>
>> 2. Invoices and receipts for all forms of energy consumed in the fuel production process, all fuel sales, all feedstock

purchases, and all co-products sold. Invoices shall be submitted in electronic form. Each set of invoices shall be accompanied by a spreadsheet summarizing the invoices. Every invoice submitted shall appear as a record in the summary. Each record shall, at a minimum, specify in a separate column the period covered by the purchase, the quantity of energy purchased during that period, the invoice amount, and any special information that applies to that record (the special information column need not be populated for every record). For each form of energy consumed, the two-year total and average consumption shall be reported in the spreadsheet. These two-year totals and averages shall be used to calculate the per-million-Btu and per-megajoule energy consumption inputs used to calculate the life cycle CI of the fuel pathway.

a. *Period Covered.* The period covered shall be the most recent two-year period of relatively typical operation.

b. *Production Processes Covered.* The invoices submitted under this provision shall cover the energy consumed in all unit operations devoted to feedstock handling and pre-processing; fuel production; co-product handling and processing; waste handling, processing, and treatment; the handling, processing and use of chemicals, enzymes, and organisms; the generation of process energy, including the generation, handling and processing of combustion fuels; and all plant monitoring and control systems. If the fuel produced or any by-products or co-products receive additional processing after they leave site, such as additional distiller's grains drying or fuel distillation, invoices covering the energy consumed for those processes must also be submitted. If the fuel production facility is co-located with one or more unrelated facilities, and energy consumption invoices are not separately available for the fuel production process, the applicant shall obtain a third-party energy audit sufficient to establish the long-term, typical energy consumption patterns of the fuel production facility.

3. In lieu of receipts or invoices for fuel sales, feedstock purchases, or co-product sales, the applicant may seek Executive Officer approval to submit audit reports prepared by independent, third-party auditors that document fuel sales, feedstock purchases, or co-product sales.

Hi Shai,

I have a question. Reading pages 3 & 4, Tom says that for the renewal of pathways ALL invoices for feedstock purchases, ethanol sales, and DGS sales for a 2 year period must be submitted to CARB. Can we confirm this? The volume of this is crazy and redacting information on the invoices would be a huge undertaking. The rest makes sense, it will be a big job and we should start preparing items now if we want to be ready to submit July or shortly after.

LCFS FF16-1 cont.

Thanks,
Heather

Bob and Heather,

Our consultant Tom Darlington prepared the attached guidance for us on applying for pathway approval under the new California LCFS regs, assuming that the regs are finalized as proposed.

Please let me know if you have any questions.

17_FF_LCFS _HBC

From: Logan Caldwell, Houston BioFuels Consultants, LLC June 19, 2015

Documentation of Tier 1 Application Input Data: Chemical, Enzyme and Yeast Use

While purchase invoices show the amount of chemicals, enzymes and yeast purchased or sold by the ethanol producer during a given period, they do not indicate how much was used. To get an accurate estimate of the amount used, the starting and ending inventory of these items would be needed such that the amount used could be calculated. **What documentation would be acceptable for the starting and ending inventory?** LCFS FF17-1

Also, some of these are purchased frequently, a frequently as daily in some cases from what I understand, but others are purchased infrequently. Those with frequent purchases will have voluminous documentation. LCFS FF17-2

The regulations do not provide for the independent, third-party auditor to attest in lieu of documentation. It is proposed that attestation from the producer or attestation by an independent, third party auditor be considered as an alternative to detailed documentation? LCFS FF17-3

From: Logan Caldwell, Houston BioFuels Consultants, LLC June 19, 2015

Documentation of Tier 1 Application Input Data: Chemical, Enzyme and Yeast Use

For the DGS yield/gallon of ethanol production, what documentation will be required? LCFS FF17-4

The calculation of DGS yield requires an accurate measure of the moisture in the DGS to calculate the bone dry yield, what documentation requirements will there be, if any, for the moisture? LCFS FF17-5

DGS is often shipped by the ethanol producer by the truckload. Should documentation of each shipment be required, there will an enormous amount of documentation and there will still be an issue of documenting the starting and ending inventory in a given period. LCFS FF17-6

It is suggested that an attestation of the yield, in lieu of detailed documentation, be permitted as a means of documenting the DGS yield. Attestation could either be by the producer or an independent, third party. LCFS FF17-7

From: Logan Caldwell, Houston BioFuels Consultants, LLC June 19, 2015

Documentation of Tier 1 Application Input Data: Third Party Auditor

Third Party Auditor

95488(c)(3)(A)(3) of the proposed regulations states: "In lieu of receipts or invoices for fuel sales, feedstock purchases, or co-product sales, the applicant may seek Executive Officer approval to submit audit reports prepared by independent, third-party auditors that document fuel sales, feedstock purchases, or co-product sales."

Comments:

Presently, for 2A and 2B applications, a top company official prepares an attestation letter in lieu of submitting documentation of fuel sales, feedstock purchases, and co-product sales. **What will be the criteria to determine whether a person is a qualified independent, third-party auditor?** LCFS FF17-8

From: Logan Caldwell, Houston BioFuels Consultants, LLC June 19, 2015

Documentation of Tier 1 Application Input Data: Transportation Distances and Mode

Feedstock

Regarding transportation of corn to the ethanol plant, the Midwest ethanol producer receives corn from a storage facility on the farm where the corn is produced or from an elevator. In neither case is the truck delivering the corn going to have included on its bill of lading the distance from the field to the collection center (storage facility or elevator). Developing this information from each ethanol producer is likely to be time-consuming and the amount of documentation is going to be voluminous for a two year period. LCFS FF17-9

Regarding transportation of corn from the collection center to the ethanol plant, there are an extraordinary number of truckloads of corn, and so the documentation will be voluminous.

For both of these, how will the ethanol plant get this data going back two years if it does not yet have a system in place to document?

As an alternative to documentation of the actual distances, it is suggested that the Midwest ethanol producers (and others in similar situation) have an option of using the 1.8b default values for transportation distances, and attesting that the default values are reasonable estimates of actual distances. LCFS FF17-10

Otherwise an extraordinary amount of work would be needed to prepare the documentation, as well as to audit the documentation, whether it is the third-party auditor or the CARB compliance auditor. LCFS FF17-9 cont.

For other facility locations outside the Midwest, the plants ship feedstock and products by rail, so that is somewhat easier to document, but again the documentation is voluminous, and using the current method of having the producer attest to the accuracy would be a more practical. LCFS FF17-11

Ethanol Product

Midwest plants typically load the ethanol onto railcars at the production facility. There is normally no trucking of ethanol from the ethanol facility to the rail loading location. **What documentation will be needed to demonstrate to CARB that it is zero?** LCFS FF17-12

Midwest plants typically ship to multiple locations in California. Each will have a different distance. The physical pathway demonstration requires only one supply route. **Can the ethanol producer use the same distance as in the physical pathway demonstration, and can that documentation be sufficient for documenting this distance?** LCFS FF17-13

Midwest plants typically do not know details of transport of their ethanol once it reaches the first terminal in California. **How then are they to document the distance by truck to the blending terminal? For the transport of EtOH from the blending terminal to the retail outlet, the CA-GREET 2.0 uses a default value. How about allowing a default value for this too?** LCFS FF17-14

From: Logan Caldwell, Houston BioFuels Consultants, LLC June 19, 2015

Retroactive Credit Generation Comments

In section 95486(a)(2) dealing with "No Retroactive Credit Generation" there is the following section:

"Notwithstanding this section, the Executive Officer may convert provisional credits to fully transferrable credits at any time, pursuant to section 95488 (d) and (e). Where an application or demonstration pursuant to sections 95488 or 95489 has been completed but not yet approved, the applicant may report, and the LRT-CBTS will reflect, information supporting provisional credits/deficits. Such provisional credits may not be used for any purpose until fully recognized. When the Executive Officer approves the section 95488 or 95489 application or demonstration, the Executive Officer will recognize any such provisional credits generated during the quarter in which the approval takes place, and one previous quarter, provided that the application was complete during that previous quarter."

Two comments:

1. Please provide details on how "completed" will be determined for the purposes of this section. Often during the course of review of an LCFS Method 2A or 2B application, ARB staff will request additional information or supporting documentation. Should such a request be made, would this deem the application incomplete? It may be helpful to all concerned if CARB issued a detailed checklist of the items required to be included with the application package for it to be deemed complete. The challenge will be that new pathway features, not appearing in previous pathways, may have unique information and documentation requirements, and be difficult to know beforehand what constitutes completeness. LCFS FF17-15
2. Considering the number of applications to be considered by ARB staff when processing the "batches" of applications, it may be that more than two quarters elapses. This could mean that a significant number of carbon credits are ineligible. Please consider providing retroactive credit generation for more than two quarters in the context of processing the batches of applications. LCFS FF17-16

17_FF_LCFS_HBC

891. Comment: **LCFS FF17-1**

The comment requests clarification on what chemicals, enzymes and yeast documentation would be acceptable for the starting and ending inventory.

Agency Response: ARB staff proposes that the applicant provide the year-end facility inventory report from the company's accounting department where feedstock, fuels, and warehouse inventory should be documented. Individual receipts are not needed as long as the accounting department certifies the records provided. This proposal will be presented to stakeholders in a future workshop and draft guidance document.

892. Comment: **LCFS FF17-2**

The comment states that some of items are purchased frequently, as frequently as daily, and those will have voluminous documentation.

Agency Response: ARB staff proposes that certified accounting department data could be submitted in place of individual receipts. The company's accounting department should have a ledger book showing all transactions. If the ledger book data is certified by the accounting department, it could be used in place of receipts. This will be explored further in a future workshop and draft guidance document.

893. Comment: **LCFS FF17-3**

The comment states that the regulations do not provide for the independent, third-party auditor to attest in lieu of documentation and asks if that is something that could be reconsidered.

Agency Response: The regulation specifies that a third party verifier could be used to audit the data. As mentioned in the response to **LCFS FF17-2**, the company's accounting department could provide the values needed.

894. Comment: **LCFS FF17-4**

The comment asks what documentation will be required for the DGS yield per gallon of ethanol production.

Agency Response: Similar to the response to **LCFS FF17-2**, the accounting department should have a record of ethanol production and sales, DGS production and sales, as well as purchased bushels of corn (or feedstock) because it has to collect payment from buyers and pay the vendors. The amounts of feedstock and fuel volumes should be recorded in the ledger book for year-end tax purposes.

895. Comment: **LCFS FF17-5**

The comment asks what documentation will be required in order to determine the DGS yield per gallon.

Agency Response: Tier 2 applicants need to have the moisture content for each type of DGS (wet, modified, and dry) from the on-site facility's lab or recorder. Besides DGS, corn oil production associated with ethanol production also needs to be factored into the calculation and report. See response to **LCFS FF17-4**.

896. Comment: **LCFS FF17-6**

The comment states that DGS is often shipped by the ethanol producer by the truckload. Should documentation of each shipment be required, there will an enormous amount of documentation and there will still be an issue of documenting the starting and ending inventory in a given period.

Agency Response: See response to **LCFS FF15-1** and **LCFS FF17-2**.

897. Comment: **LCFS FF17-7**

The comment suggests that an attestation of the yield, in lieu of detailed documentation, be permitted as a means of documenting the DGS yield. Attestation could either be by the producer or an independent, third party.

Agency Response: Please see response to **LCFS FF15-1**.

898. Comment: **LCFS FF17-8**

The comment states that for 2A and 2B applications under the current LCFS, a top company official prepares an attestation letter in lieu of submitting documentation of fuel sales, feedstock purchases, and co-product sales. The commenter then asks what criteria will be used to determine whether a person is a qualified independent, third-party auditor.

Agency Response: The commenter's first statement is not accurate. The attestation letter from the company headperson certifies the accuracy of data provided to ARB but does not substitute for the need to provide documentation of fuel sales, feedstock purchases, and co-product sales in the form of accounting department records. Staff will explore the detailed criteria for determining qualified auditors in a future workshop. See response to **LCFS 7-3** and **LCFS 32-20**.

899. Comment: **LCFS FF17-9**

The comment states that documenting the transportation of corn from the field to collection center and collection center to the ethanol plant will be voluminous.

Agency Response: CA-GREET2.0 includes two corn transportation segments for ethanol produced at Midwestern facilities: from corn field to collection center over a distance of 10 miles by Medium Diesel Truck (MDT) and 40 miles to the ethanol plant by Heavy Duty Diesel Truck (HDDT). For corn transport to California, in addition to distances stated above, there is an average1,400-mile distance by rail to the California ethanol facilities from Midwest. These transportation values can be used as default parameters when accompanied by an attestation that the default values are reasonable estimates of actual distances. When the default values are not a reasonable estimate, applicants should provide an estimate of mileage which will be verified by staff based on the plant location. Please also see response to **LCFS FF15-1**.

900. Comment: **LCFS FF17-10**

The commenter requests that as an alternative to the documentation of actual distances, Midwest ethanol producers (and others in similar situation) have the option of using the 1.8b default values for transportation distances, and attesting that the default values are reasonable estimates of actual distances.

Agency Response: See response to **LCFS FF17-9**. For fuel transport to California, applicants must specify exact mileage distances from the fuel production facilities to locations in Northern or Southern California. These distances can be obtained from generic websites, for instances, truck transport from Google Maps, ship or rail transport from ship and rail companies.

901. Comment: **LCFS FF17-11**

The comment states that documenting transportation distances for facilities located outside the Midwest would be onerous and suggests that the producer use the current method and have the producer attest to the accuracy.

Agency Response: See response to **LCFS FF17-9**.

902. Comment: **LCFS FF17-12**

The comment states that Midwest plants typically load the ethanol onto railcars at the production facility. There is normally no trucking of ethanol from the ethanol facility to the rail loading location and inquires as to what documentation will be needed to demonstrate to CARB that the trucking distance is zero.

Agency Response: There are several ways to demonstrate that no trucking of ethanol from the ethanol facility to the rail loading occurs, including photos of rail loading at the ethanol plant, satellite images, the head of the facility's attestation letter, or a third party verifier.

903. Comment: **LCFS FF17-13**

The comment states that Midwest plants typically ship to multiple locations in California. Each will have a different distance. Can the ethanol producer use the same distance as in the physical pathway demonstration, and can that documentation be sufficient for documenting this distance?

Agency Response: For ethanol shipped to California, the applicant can submit the exact distance by rail from the origin to the Stockton rail yard (for Northern California unloading) and to Commerce or Los Angeles (for Southern California unloading).

904. Comment: **LCFS FF17-14**

The comment states that Midwest plants typically do not know details of transport of their ethanol once it reaches the first terminal in California. How then are they to document the distance by truck to the blending terminal? How about allowing a default value?

Agency Response: If the distance by truck to the blending terminal is unknown, the applicant can use 50 miles for 80 percent shares (20 percent is assumed to have negligible transportation).

905. Comment: **LCFS FF17-15**

The commenter requests clarification on when an application is deemed complete.

Agency Response: ARB staff currently process applications and deems them complete once all information to determine a CI has been received and the applicant has addressed all pertinent comments and questions from staff. Staff will be conducting workshops post Board Hearing regarding the Tier 1 and Tier 2 categories and will provide a staff proposal and subsequent guidance regarding pathway processing between Tier 1 and Tier 2. Issues and detailed concerns regarding a pathway application being deemed complete will be discussed with stakeholders and subsequent guidance will be provided.

906. Comment: **LCFS FF17-16**

The commenter requests that ARB consider providing retroactive credit generation for more than two quarters in the context of processing the batches of applications.

Agency Response: Staff appreciates the commenters concern regarding processing of applications and for suggesting a potential mitigating solution by allowing for retroactive credits. Staff will be conducting workshops after Board Hearing regarding pathway application processing and will discuss issues related to this timing. The LCFS does not provide for retroactive crediting due to fairness problems that would result when retroactive credits entered the LCFS credit market after market participants had made credit buying and selling decision based on data that had been timely reported in the LRT-CBTS. Under § 95486(a)(2), "Unless expressly provided elsewhere in this subarticle, no credits may be generated or claimed based on section 95489 provisions, supplying electricity for transportation, or any transaction or activity regarding a transportation fuel for any act occurring in a quarter for which the quarterly reporting deadline has passed." Staff will process applications as rapidly as possible. Tier 1 and Tier 2 fuels will likely move through the process more quickly than the commenter assumes based upon the second 15-day changes to the regulation. Under § 95488(a)(2)(B) the regulation allows recertification to be conducted using existing information for the pathways. Using the existing information supplied to staff for Method 2 or Method 1 defaults should save time when processing recertification pathways. The time saved from processing recertification pathways should also save time overall and should reduce the need for stakeholders to request retroactive credits.

Subject: Memo addressing CE's concerns and need for clarification on the 15 Day Proposed Regulation Order of the LCFS

Attachments: LCFS Re-Adoption Memo 2015 06 10 FINAL.pdf

Dear Sam and ARB LCFS Team,

First, on behalf of Clean Energy's LCFS Team, we would like to collectively thank you for your willingness to meet and discuss with us our concerns over the LCFS' 15 Day Proposed Regulation Order on Tuesday, June 9. Your immediate attention to our industry's concerns is very much valued.

Second, based on your recommendation during our meeting earlier this week, we are submitting the attached memo that outlines our primary concerns and need for further confirmation or clarification of the proposed regulation order's intent.

Finally, we would like to express our gratitude in advance for your thoughtful and timely response to the attached memo as it will provide our industry with a clear understanding of the ARB staff's regulatory intent on pathways and credit generation under the proposed rule. Thank you!

Sincerely,

Todd R. Campbell

Vice President of Public Policy & Regulatory Affairs

Re: **LCFS Re-Adoption Language; 15 Day Comment**

Date: **June 12, 2015**

We would like to thank you all for taking the time to meet with us on June 9th to address our concerns with the latest iteration of the LCFS Re-Adoption rule currently up for comment. The purpose of this memo is to memorialize the concerns and clarifications that were discussed in the meeting and to help facilitate a smooth transition to the LCFS Re-Adoption starting in 2016. Clean Energy is committed to working with the ARB to develop and implement suitable solutions to ensure the ongoing success of the LCFS program.

Topics of Discussion:

1. **§ 95488(a): Current and Pending LCFS Pathways Grandfathered into the Re-Adoption.** Our understanding is that the Re-Adoption allows for all fuel pathways that were in effect on 12/31/2015 to remain valid until ARB re-certifies the carbon intensities for CNG and LNG fuels with CA-GREET2.0. This re-certification could occur as late as Q4 2016. Upon re-certification, (no later than 12/31/2016), all "grandfathered" pathways will be deactivated and replaced by the re-certified carbon intensity pathway. We were concerned that the language for the deactivation schedule suggests that "grandfathering" may be limited to pathways certified by 12/31/2015 *and* applied for before 12/1/2014. We have a number of pathways applied for after 12/1/2014 that we were concerned would lose their ability to generate and sell credits after 1/1/2016. Therefore we were greatly relieved that the ARB confirmed in our meeting that every pathway in effect as of 12/31/2015 will be valid and remain in effect through the start of the Re-Adoption until re-certification (no later than 12/31/2016). LCFS FF18-1

   CE currently has three pathways (CERF Shelby, Westside, and EIF Kansas City) that are up for public comment and should be certified in the next month. CE also has two outstanding applications submitted after 12/1/2014 (MDU and BFI/Complexe Enviro). Both MDU and BFI/Complexe Enviro were submitted after 12/1/2014 and need to be certified in order to be grandfathered into the Re-Adoption. The ARB assured us during the meeting that all current pending applications will be approved and certified by 12/31/2015. It is our understanding that the ARB is going to spend the remainder of 2015 certifying all pending pathways under the old LCFS rule and then re-certify all those same pathways during 2016. This means that both MDU and BFI will be certified by 12/31/2015 and will be able to generate and monetize LCFS credits through 2016 while their recertification applications are pending.

LCFS FF18-1 cont.

BFI/Complex Enviro first started production around September 2014 - which means that the facility will not have the full two years of operational data to support a fully certified pathway until September 2016. However, it is our understanding that since BFI will be grandfathered under the old LCFS program, CE will be able to generate *and* monetize credits pursuant to the old LCFS regulation during 2016. Once two years of operating data is received in 2016, CE will notify the ARB to re-certify the BFI/Complexe Enviro pathway which will occur before the end of 2016.

With respect to Clean Energy's CNG and LNG sales from fossil fuel natural gas, it is our understanding that the following process will apply:

- Clean Energy's approximately 150 CNG stations will be grouped and file a Tier 1 application.
- Pending approval of the CNG stations pathway, Clean Energy will continue to be able to generate and sell credits *under the existing LCFS CNG default pathway through 2016.*
- Clean Energy LNG pathways will be filed individually by facility in a Tier 1 application.
- Clean Energy will be able to generate and sell LNG credits *under the existing LNG pathways for those facilities during 2016* while the Tier 1 applications are pending.

LCFS FF18-2

2. § 95488(d)(1-2): Monetizing Credits Generated under Temporary or Provisional Fuel Pathway Codes.

Under the current LCFS rule, facilities with pending application approvals are able to generate and monetize LCFS credits under the various ARB approved "default" pathways (CE specifically utilizes CNG006 and LNG021). Furthermore, several of these facilities are classified as provisional since they have been in operation for less than the ARB mandate of two (2) years. Nonetheless, the current regulation allows such provisional facilities to monetize credits under a default or provisional pathway regardless of the length of time in operation.

LCFS FF18-3

As discussed, the proposed LCFS Re-Adoption appears to eliminate the ability to monetize credits generated under any temporary or provisional pathways until a facility receives a certified CI and pathway. These prohibitions on monetization of provisional and temporary pathway credits carry unintentional but potentially fatal consequences to the biomethane production market. Biomethane producers rely on the revenue generated from the monetization of both LCFS credits and RINs to offset the higher costs of producing renewable natural gas. Disallowing credit sales for any period, let alone a full two years, is enough to discourage the development of these biomethane production facilities which is detrimental to the ARB's goal of increasing the flow of renewable transportation fuel in California.

It is understood that any regulatory changes at this point would require a new 15-day comment period which could also be detrimental to the LCFS program as a whole. For this reason, CARB has agreed to explore the best method to eliminate the restriction on sale of credits generated under temporary or default pathways - including potentially the issuance of an advisory opinion to clarify the language in the Re-Adoption and allow for the monetization of credits under both the temporary and provisional pathways.

LCFS FF18-3 cont.

3. § 95488(a)(3): Re-Certification of Pathways approved under old LCFS Rule

Under the Re-Adoption, all existing grandfathered pathways as well as any new pathways will have to be re-certified in 2016 under either a Tier 1 or Tier 2 pathway using the GREET 2.0 model. Tier 1 pathways apply to all conventionally-produced alternative fuels which includes biomethane sourced from landfills. In order to re-certify a pathway that was approved under the previous LCFS rule, CE will have to make a request to the ARB via the new online LRT registration system. The ARB will then automatically re-certify each requested pathway under a new Tier 1 pathway and assign a new CI. Applications for re-certification will be processed in batches following a predetermined priority order:

1. Ethanol
2. Biodiesel
3. Renewable Diesel
4. CNG
5. LNG

LCFS FF18-4

Once a pathway has been re-certified and given a new CI, the previous pathway and CI will be deactivated. The ARB will re-certify each grandfathered pathway before 12/31/2016 which will prevent any lapse in credit generation.

With respect to Clean Energy's biomethane pathways, MDU is in a unique position. Because the MDU facility is located at an unregulated landfill, CE must apply for a Tier 2 pathway in order to quantify and realize the complete value of the voluntary methane capture and destruction that occurs at the site. Based on our meeting, it is our understanding that MDU's filed Method 2 application will be approved by the ARB before the end of 2015, and MDU will be able to generate *and sell* credits under this pathway while the Tier 2 pathway is pending. CE will apply for a new pathway under Tier 2 for MDU as soon as possible which will also be certified before the end of 2016.

4. § 95486(a)(2): No Retroactive or Incremental Credit Generation

The Re-Adoption appears not to allow for any retroactive credit generation for any quarter in which the reporting deadline has already passed. The only exception to this rule applies to the initial generation of provisional credits from facilities that have been operating for less than two years. Once the provisional pathway is approved, the ARB will allow a facility to generate provisional credits for the quarter in which the approval takes place and one previous quarter (assuming the application was complete during that previous quarter). It is noted that the provisional CI is subject to change as the ARB receives more operational data. However, once the pathway is fully certified the credit generator will not be able to automatically generate "incremental" additional credits if the final CI is lower than the provisional CI – although they may be able to file a petition to do so. If the final CI is higher than the provisional CI, the ARB will automatically retire the excess credits generated.

The temporary pathways are meant to allow obligated parties that have facilities with more than two years of operating history to generate credits while the ARB processes their applications and provides full certification. However, notably for biomethane pathways, the temporary pathway CIs are representative of a "worst case" operating scenario resulting in exceedingly high CI values that are not an accurate representation of CE's actual pathways. In fact, the temporary fuel pathway CIs for biomethane CNG and LNG increased approximately 10%-15% in the newest version of the Re-Adoption. As we understand it, there is no allowance or mechanism in the rule for retroactive incremental credit generation based on the delta between the certified CI and the temporary pathway. We believe that producers should be able to retroactively claim these credits. Due to the large difference between CE's certified pathway CIs and the temporary pathway CIs, the ARB should allow for at least two quarters of retroactive incremental credit generation – automatically - in order to accurately compensate obligated parties for their true reduction in carbon.

LCFS FF18-5

CE also has serious concerns regarding retroactivity as applied the regulation prior to re-adoption and effectiveness of the new regulation. The idea of retroactive incremental credit generation has been openly discussed by CE and the ARB under the old LCFS rule. During the November 2014 LCFS workshop, the issue of retroactive credit generation was openly discussed in the context of the delayed approval of LCFS pathways due to the re-adoption process. The slide specifically stated:

No retroactive credits except for specific provisions:

- Fuel Pathway Application
- Physical Transport Mode

It was also discussed during this workshop and with ARB staff that up to two quarters of retroactivity was possible and that LCFS pathway applicants would apply for retroactivity at the time of final application approval. The application needed to justify that the delays in the pathway being approved were due to ARB and staff and not the applicant.

As such, CE has requested the ability to generate incremental credits for all newly posted pathways based on the delta between the actual CI in the posted pathway and the default number that CE used to generate credits while its pathway applications were pending with the ARB. To our surprise, our request to generate these incremental credits has been denied. CE urges the ARB to re-examine this request and approve retroactive incremental credit generation. The retroactivity should be limited to the two quarters prior to the quarter in which the pathway was certified. Since the credit generator can already use the new CI to generate credits for the quarter in which the pathway was certified (credits are generated in the two months following the quarter end) the ARB needs to define the two quarters of retroactivity as the two quarters prior to approval.

LCFS FF18-5 cont.

CE would be able to generate an additional 65,229 LCFS credits if it was allowed to generate incremental credits as described above - across six different facilities. At current credit pricing ($32/Credit) this equates to approximately $2.1MM in additional credit revenue that the producers are anticipating. There is no sound policy reason to deny the generation of these credits given that the fuel was delivered at the certified CI and achieved the reductions reflected.

5. § 95488(e): Evidence of Fuel Transport Mode (Physical Pathway Description)

Each pathway application must include a description of the physical pathway used to transport the fuel for end use to CA. Transactions for fuels in which a physical pathway demonstration application has yet to be approved must be reported using the transport code PHY10 in the LRT. According to the Re-Adoption:

"A regulated party may not generate credits pursuant to section 95486 unless it has demonstrated to the Executive Officer that a fuel transport mode exists for each of the transportation fuels for which it is responsible under the LCFS regulation, and that each fuel transport mode has been approved by the Executive Officer pursuant to this section."

LCFS FF18-6

CE has approximately 14 fuel pathways either certified or pending with the ARB. Each of these pathways needs a filed and approved physical pathway demonstration. CE was previously told by the ARB to keep the physical pathway application separate from the Method 2B application and to submit only one physical pathway application at a time. CE submitted the physical pathway for the Pinnacle LNG pathway (LNG020) over seven months ago and the ARB has yet to issue an approval. CE has demonstrated the physical connectivity between the point of production to final consumption along with providing all contracts, production reports, transaction confirmations, and bills of lading. This has created a concern about the timing of approvals and the ability to generate credits following the Re-Adoption. This first physical pathway approval needs to serve as a template for all subsequent physical pathways to ensure much quicker approval timeframes. CE will submit all remaining physical pathway applications by Q3 2015, and it is our understanding all will be approved by the ARB before year end.

Although the Re-Adoption states that LCFS credits cannot be generated without approved physical pathway applications, the ARB reassured CE that the delay in approvals will not prevent credit generation under the Re-Adoption. Furthermore, the ARB committed to reviewing the application process as a whole in an effort to streamline approvals.

LCFS FF18-6 cont.

We appreciate your review of these topics and please inform us if there has been any misunderstanding conveyed in this memo.

18_FF_LCFS_CE

907. Comment: **LCFS FF18-1**

This commenter restates its understanding of new section § 95488(a) and how it will apply to certain facilities.

Agency Response: The comment does not contain a recommendation or objection regarding the proposal, and needs no response. We note that staff will be providing guidance and conducting workshops after Board Hearing to explain the details of how provisional pathways under the current regulation will be processed under the new regulation.

908. Comment: **LCFS FF18-2**

This comment is related to pathway processing, and generation and sale of LCFS credits.

Agency Response: See response to **LCFS FF18-1**.

909. Comment: **LCFS FF18-3**

The commenter states its understanding of the current and initially-proposed-for-re-adoption LCFS. The comment further points out that an inability to sell credits for the first two years of operation would impose a significant financial burden on the commenter.

Agency Response: See response to **LCFS FF18-1**. Regarding the ability to promptly sell credits generated under temporary or provisional pathways, 15-day changes to section 95488(d) addressed the commenter's concerns, allowing the generation and sale of temporary and provisional credits under specified conditions.

910. Comment: **LCFS FF18-4**

This comment restates the commenter's understanding of the proposed LCFS and how it might apply to a particular facility.

Agency Response: See response **LCFS FF18-1**. We note that commenter's understanding is not correct in every particular.

911. Comment: **LCFS FF18-5**

This comment restates the commenter's understanding of the proposed LCFS. The commenter believes that not allowing retroactive credit for the difference between conservative temporary pathway CIs and subsequently-approved CIs should automatically be awarded. The commenter also recommends that retroactivity be expanded to cover not just the quarter in which an application is approved plus one prior quarter, but to encompass the quarter in which an application is approves plus *two* previous quarters. Failure to make that change will reduce the commenter's revenue.

Agency Response: See response **LCFS FF18-1**. ARB does not agree that the incremental CI improvements (as compared to temporary pathway values) and the associated credits should be approved retroactively after a party has reported using the temporary pathway values. The temporary pathways are already generous in the sense that they can be used promptly even in the absence of certain information. To the extent the temporary CI values are higher than the commenter would wish, that delta is intended in part to encourage parties to promptly submit and complete their applications under Tier 1 or Tier 2.

912. Comment: **LCFS FF18-6**

The commenter has expressed concern about how long certain of commenter's pathway applications and physical transport demonstrations have taken to obtain approval.

Agency Response: See response **LCFS FF18-1**.

Subject: ARB Proposed Regulation 95488(d)(2) Provisional Pathways - Question

Hello Hafizur,

Per my telephone message, I would like to gain a better understanding of how the proposed LCFS regulations would apply to a newly constructed biodiesel plant.

Duonix Beatrice is constructing a biodiesel facility that will start-up later this year. Duonix Beatrice plans to sell its biodiesel to Flint Hills Resources, who may import the biodiesel into California for sale or blend with purchased CARB diesel for sale in California. On behalf of Duonix Beatrice, we have submitted a pathway application under the existing LCFS regulations and expect to have at least three months of operation prior to the end of 2016. Our consultant, EcoEngineers, has be working with Todd Dooley on the application.

If I understand correctly, the soon to be approved proposed regulations will require us to submit another pathway application before 1/1/2016, and since Duonix Beatrice will not have achieved full commercial production for 2 years, it appears that the provisional pathway regulations would apply.

My key question is related to the restrictions related to provisional credits. The proposed rules state that provisional credits may not be sold, transferred, or retired for compliance, nor may fuel with a provisional CI be transferred with obligation, until the Executive Officer has adjusted the CI or informed the producer that the provisional CI has been successfully corroborated by operational records covering a full two years of commercial operation.

LCFS FF20-1

If my understanding is correct, it appears that Flint Hills Resources will be unable to sell biodiesel with obligation, or sell, transfer or retire credits from CARB diesel blending, until after two years of operation. This restriction seems inconsistent with the current process, whereby ARB has the discretion to allow facilities to obtain fuel pathway approvals prior to start-up, sell biofuels with obligation after start-up, as well as sell, transfer or retire credits from fuel blending, so long as quarterly data is provided to ARB continuing to support the approved fuel pathway carbon intensity.

Please give me a telephone call, when you get a chance. I am hoping that I am missing something or am not understanding the proposed regulations correctly.

Thank you for your help,
Philip

California Air Resources Board
Richard W. Corey
Executive Director
Re: Low Carbon Fuel Standard regulation
1001 I St
Sacramento, CA 95812-2815

Dear Mr. Corey and CARB staff:

Hydrogenics is pleased to provide comments on the LCFS regulatory language as posted online for 15-day comments. As a leading hydrogen technology and hydrogen fuel provider, we welcome and thank you for the opportunity to provide our input to help fostering California into a leading edge State in renewable energy technology.

Please kindly consider our following comments:

- We support the inclusion of hydrogen as a renewable fuel and energy storage medium qualifying for credits; and
- It is also important to include medium duty and heavy duty fuel cell powered vehicles using hydrogen fuel as qualifying vehicles for low carbon credits to encourage mass adoption of fuel cell powered commercial vehicles

LCFS FF21-1

Thank you for the opportunity to comment and consider our input. Your leadership and effort help shape a sustainable landscape for fuel cell electric vehicles and hydrogen as a fuel in a long term.

Please do not hesitate to contact me at (858) 386-8930 if you have any questions or require clarification.

Thank you very much again for the opportunity.

Sincerely,

Rob Del Core
Director, Business Development
Hydrogenics USA

21_FF_LCFS_HG

915. Comment: **LCFS FF21-1**

The comment suggests staff allow medium and heavy duty hydrogen fuel cell vehicles qualify for LCFS credits.

Agency Response: All hydrogen fuel cell vehicles (light/medium/heavy duties) are eligible to generate LCFS credits under current LCFS regulation.

Staff conducted Energy Economy Ratio (EER) analyses for fuel cell forklifts (medium duty), and fuel cell buses (heavy duty). Based on the results, staff created a new EER category for fuel cell forklifts. The calculated value for fuel cell buses is identical to the existing fuel cell vehicle EER, so is covered by that value. Staff acknowledges that the fuel cell vehicle technologies will continue to improve, and as a result, the EERs for medium and heavy duty fuel cell vehicles will continue to increase. Staff commits to reevaluate fuel cell vehicle EERs as newer technologies and data become available.

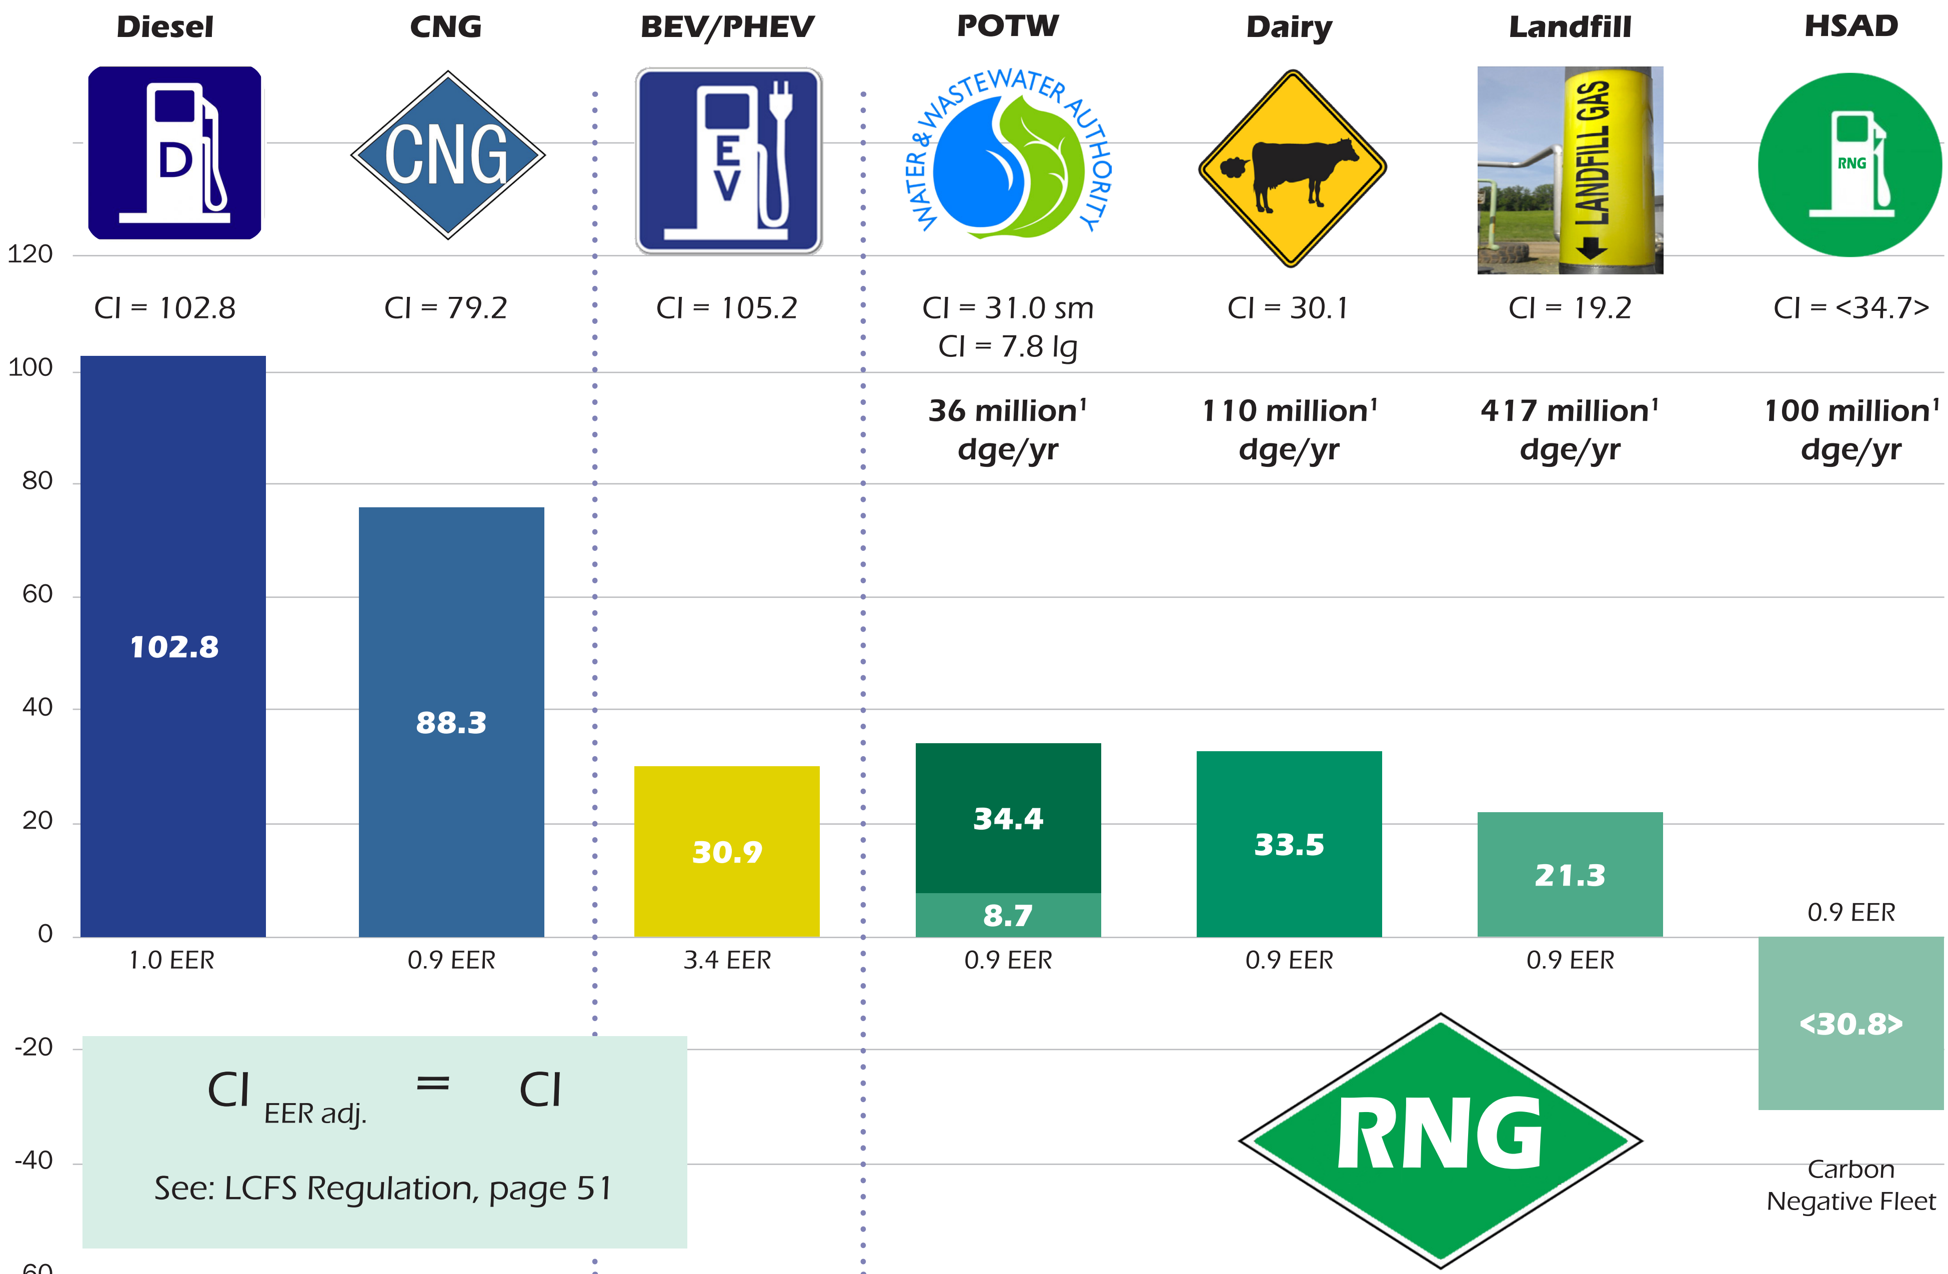
Carbon Intesity for Diesel & Substitues, grams CO2 emitted per unit of energy adjusted for energy (g CO2 e/MJ)

(June 25, 2015, California Air Resources Board Staff Report)



[1] UC Davis

Prepared by Edgar & Associates, Inc. 6/9/15

Waste Sector (Organics, Recycling, MSW)

Class 7 - 12,000 in CA still on diesel

Class 8 - 3,000 in CA - all on diesel

Incremental CNG truck cost compared to Diesel truck

$40,000 per truck average - 15,000 Class 7 and 8 trucks from Diesel to CNG

$600 million for 15,000 trucks (2015/16-2020/21) - $100 million year

CNG Fleet with RNG Off-Take Agreement

Demand 15,000 trucks - 50 dge/day/truck - 200 million dge per year

- RNG Supply - 100 million dge from Organics/HSAD (minus 21 carbon intensity)
- RNG Supply - 417 million dge from Landfills (13 carbon intensity)
- RNG Supply - 36 million dge from Wastewater Plants (9 to 34 carbon intensity)

22_FF_LCFS_EEEA

916. Comment: **LCFS FF22-1**

The commenter is suggesting that ARB publish a graphic that illustrates life-cycle CI of all fuels in a side-by-side comparison.

Agency Response: The suggestion appears to be that ARB use a particular approach to communicate with the public and those in the fuel industry, not a specific recommendation or objection concerning the proposal. Accordingly, no response is required, but the suggestion has been noted and will be considered in future public presentations regarding the LCFS.

June 19, 2015

Mary Nichols, Chairman
California Air Resources Board
1001 I Street
Sacramento, CA 95812

RE: LCFS Re-adoption

Chairman Nichols,

National Sorghum Producers (NSP) is a trade association representing the interests of over 50,000 sorghum producers on issues related to legislative and regulatory policy in Washington as well as various state capitals. NSP led efforts to secure an advanced biofuel pathway for sorghum under the RFS2 and has performed extensive analysis on several models and datasets over the last four years, including several datasets similar to those used by the Argonne National Laboratory as well as the ARB in modeling the CI of sorghum ethanol.

NSP applauds the ARB for undertaking an extensive update of the LCFS and is very appreciative of the time committed by ARB staff to ensure not only the integrity of the data used but their representativeness of real-world conditions as well. NSP also thanks the ARB for its special attention to sorghum fertilizer requirements and N_2O emissions from sorghum stover. In addition to these areas, NSP strongly recommends that the ARB focus attention on information related to sorghum root:shoot ratios, and as it becomes available, incorporate this information into future versions of CA-GREET. LCFS FF23-1

NSP also recommends that the ARB revisit sorghum iLUC as soon as possible. As we have stated previously, we do not feel the EPA's FAPRI-based analysis of sorghum iLUC was accurate, and we believe that the ARB has the opportunity to shed a correct light on the issue in future iterations of AEZ-EF. We look forward to working with ARB staff and sorghum stakeholders on this in the future. LCFS FF23-2

Thank you for the opportunity to provide feedback. We feel strongly that sorghum ethanol can play a large role in helping California meet the greenhouse gas reduction goals set by the LCFS while at the same time promoting the use of water-sipping crops like sorghum.

Please do not hesitate to let me know if you have any questions.

Regards,

J.B. Stewart

917. Comment: **LCFS FF23-1**

The commenter strongly recommends that the ARB focus attention on information related to sorghum root:shoot ratios, and as it becomes available, incorporate this information into future versions of CA-GREET.

Agency Response: ARB staff appreciates the National Sorghum Producers providing data to ARB and Argonne to update and improve agricultural phase parameters in CA-GREET. See response to comment **LCFS 9-2.**

918. Comment: **LCFS FF23-2**

The commenter recommends that the ARB revisit sorghum iLUC as soon as possible.

Agency Response: ARB staff is committed to updating iLUC values in the future and appreciates working with the National Sorghum Producers. However, updating iLUC values frequently would create regulatory risk for stakeholders required to modify their pathway CIs every time an iLUC value is updated to reflect the findings of a single report. Staff plans to review literature and reports related to advancements in land use change science and modeling methodology and update iLUC values no more frequently than once every three years. The next update will occur as part of the program review that will conclude prior to January 1, 2019. ARB is committed to working with stakeholders during the update process.

Subject: Question about proposed provisional pathway language

Hi Stephen -

Thanks for talking today. The proposed regulation order in 95488 (d)(2)Provisional Pathways states that credits generated by fuel producers with provisional pathway CI values may not be traded, sold, used for compliance for a period of 2 years or until 2 years of operational data are provided to validate the CI number. At this point the CI value is either adjusted up or left where it is and it seems the provisional credits become actual credits.

Our question is whether this provision applies to all fuel producers with provisional CI values or just newly provisional (going forward). Do these credit limitations apply to fuel producers that already have provisional pathway CI values?

LCFS FF24-1

Thanks!
Jenny

Re: Comments on Calculating GHG Reduction Credits for the Displacement of an Open Anaerobic Lagoon with an Anaerobic Digester

Dear CARB Staff,

We are submitting comments regarding the credits assigned to methane emissions from an open anaerobic waste treatment lagoons. The conversion of these operations into anaerobic digestion facilities represents a significant reduction in methane emissions from these operations as methane that was emitted to the atmosphere is captured (with the exception of fugitive emissions). Correctly accounting the credits these operations receive will have an impact on whether or not open anaerobic lagoons will be converted and will divert methane from the atmosphere.

Methane is a potent greenhouse gas that has 25 times higher global warming potential than carbon dioxide, and has been generated from anaerobic waste lagoons and emitted directly to the atmosphere at many cattle operations across the country. Diverting the manure created at these facilities to an anaerobic digester avoids releasing methane emissions to the atmosphere, and reduces the negative impact of these facilities. Therefore, we believe the avoided methane emissions should be counted as a credit towards the biogas produced from anaerobic digesters used to replace these open lagoons.

LCFS FF26-1

The current methodology adopted by CARB[1] and Argonne National Laboratory[2] for the analysis of anaerobic digestion-based renewable natural gas (RNG) production assumes that CH_4 generated is flared, and that the resulting CO_2 emissions and fugitive methane are the only credits received by the biogas produced by the digester. This assumed baseline is reasonable because the original destination of these wastes would be a landfill where the collection and flaring of biogas is feasible and has already been implemented.

However, in most current open anaerobic lagoon systems, <u>no</u> biogas is being collected. Furthermore, once the biogas is collected from a covered lagoon and/or a bio-digester, the biogas will likely be sold or used for on-site energy generation. It is <u>highly</u> unlikely that biogas collected would be flared after the capital and operational costs have been put into the facility to capture and use the gas.

LCFS FF26-2

[1] CARB, 2009. Detailed California-Modified GREET Pathway for Compressed Natural Gas (CNG) from Dairy Digester Biogas. Version 1.0

[2] Han J.,Mintz M., and Wang M., 2011. Waste-to-Wheel Analysis of Anaerobic-Digestion-Based Renewable Natural Gas Pathways with the GREET Model. ANL/ESD/11-6

In a report published by US EPA in 2010, of the 157 digester projects operating on commercial scale livestock facilities, only 15 (or 9.6%) were flaring the biogas full time[3]. Based on this information, it is at least questionable that the flaring of biogas should be used as a reference case since it does not reflect actual operations at a high percentage of digester projects.

We believe the reference case for calculating the avoided methane emissions should be that all the biogas generated from the open anaerobic lagoon is fugitive to the atmosphere. Consequently, the CH_4 emissions captured by the anaerobic digester should be accounted for as credits in the GREET model. **LCFS FF26-3**

We would like to encourage you to take this into consideration when finalizing the GREET 2.0 model to allow for reductions based on the methane emissions that are captured and utilized. This will allow for better accounting and encourage reducing ghg emissions from these operations, and from other emerging technologies. **LCFS FF26-4**

Thank you for the opportunity to submit these comments and to participate in the re-adoption of the LCFS. Please let us know if you need any additional information or have any questions on the above points!

Sincerely,

Dennis M. Langley

26_FF_LCFS_AltEn

922. Comment: **LCFS FF26-1**

The commenter is requesting recognition of avoided fugitive methane emissions from open manure-bearing lagoons as a fuel pathway credit.

Agency Response: ARB staff notes that this comment is not related to "15-day changes" being proposed in the Modified Regulation Order posted for public comment on June 4, 2015. As a courtesy however, staff is providing a response to the comments below.

Producers of renewable natural gas from anaerobic digesters using manure as feedstock should apply under the Tier 2 application process and modify CA-GREET2.0 themselves to reflect producer-specific digester design, productivity and energy consumption parameters, as well as to estimate the emissions avoided by diverting the animal waste. In order to assess the avoided emissions from manure diversion, staff suggests using the U.S. EPA emission factors for each management system and manure type which are built into GREET, along with the applicant's state-specific Greenhouse Gas Inventory[57] (or other verifiable reference source) to determine the share of manure treated by each management practice, at the state level.

923. Comment: **LCFS FF26-2**

The commenter believes it is highly unlikely that biogas collected would be flared after the capital and operational costs have been put into the facility to capture and use the gas.

Agency Response: See response to **LCFS FF26-1**.

924. Comment: **LCFS FF26-3**

The commenter asserts that the reference case for calculating the avoided methane emissions should be that all the biogas generated from the open anaerobic lagoon is fugitive to the atmosphere. And, consequently, the CH_4 emissions captured by the anaerobic digester should be accounted for as credits in the GREET model.

Agency Response: See response to **LCFS FF26-1**.

[57] See index of calculations for California animal waste operations: http://www.arb.ca.gov/cc/inventory/doc/doc_index.php.

925. Comment: **LCFS FF26-4**

The commenter urges ARB to incorporate their suggestions before finalizing GREET 2.0.

Agency Response: See response to **LCFS FF26-1**.

Sacramento, CA 95814

Re: Proposed 15-day Regulation Order containing Modified Text and Availability of Additional Documents and Information for the Proposed Re-Adoption of the Low Carbon Fuel Standard

Dear Samuel Wade:

On behalf of DuPont, thank you for the opportunity to comment on the proposed modified text for the LCFS. DuPont has significant investments in advanced biofuels that meet the specified greenhouse gas reduction threshold. These fuels will make transformative contributions to our nation's energy security, reduce greenhouse gas emissions and strengthen rural economies. These fuels represent a tremendous shift in how we energize our planet and are being commercialized due in large part to visionary state fuels programs like the CA Low Carbon Fuel Standard. We look forward to doing business in California; however, the proposed modification to Provisional Pathways in sections 95488(c)(3) and (c)(4)(I)2 will prevent any new fuel from being sold in California beyond what is being produced today and is so overly restrictive in granting approvals for CI credits that many fuel producers will likely be driven out of business. These hurdles will also discourage additional investment in cellulosic ethanol and other advanced biofuels.

LCFS FF27-1

Introduction

DuPont is an industry leader in providing products for agricultural energy crops, feedstock processing, animal nutrition, and biofuels. Our three-part approach to biofuels includes: (1) improving existing ethanol production through differentiated agriculture seed products, crop protection chemicals, as well as enzymes and other processing aids; (2) developing and supplying new technologies to allow conversion of cellulose to ethanol; and (3) developing and supplying next generation biofuels with cellulosic ethanol and biobutanol.

We bring the perspective of a company deeply involved in the agricultural and biofuels industries. Our seed business DuPont Pioneer sells corn seed to farmers growing for a variety of end-use markets, including grain ethanol production. Our intimate relationship with our farmer customers and our extensive research provides us significant insight into the agronomics of the harvest and management of corn stover as a cellulosic feedstock. We provide a variety of products for the grain ethanol business as well, including saccharification enzymes and fermentation processing aids, and so have an intimate knowledge of the operation of these relevant sugar fermentation operations.

DuPont began its research into cellulosic technology a decade ago. What started as a lab scouting project grew into a full scale commercialization effort. In 2009, DuPont opened a demonstration facility in eastern Tennessee producing cellulosic ethanol from both corn stover and switchgrass. For the past four years, we have brought together growers, academia, public institutions like the USDA and custom equipment makers to conduct harvest trials on corn stover. All this work culminated in the groundbreaking of a 30 million gallon per year facility in December of 2012 in Nevada, Iowa, located approximately 40 miles north of Des Moines. I am happy to report that we are in the very final stages of construction, commissioning has been initiated and we will be open for business later this year. We anticipate that a number of other companies in addition to DuPont will bring cellulosic volumes to the market. Multiple companies are constructing, starting up or operating facilities producing renewable fuels from a wide variety of cellulosic feedstocks including corn stover, switchgrass, wheat straw, municipal solid waste and wood fiber. Many of these are large, well-capitalized, sophisticated companies with long track records in designing, constructing and operating manufacturing facilities. This diversity of operations provides a high level of confidence for multiple technologies succeeding at commercial scale.

In addition to cellulosic ethanol, DuPont is pursuing another advanced renewable fuel with our partner BP in a 50/50 joint venture called Butamax™. The joint venture has developed and extensively tested bio-butanol, a higher alcohol fuel produced by fermenting biomass. Biobutanol has excellent fuel properties, with higher energy density than ethanol and the ability to be distributed via the existing gasoline infrastructure, including pipelines. It also reduces volatility, allowing butanol gasoline blends to be used in the summer in regions that currently require waivers from air quality regulation for the use of ethanol-gasoline blends. Because butanol has less affinity for water and is a weaker solvent than ethanol, it will be more compatible with existing equipment, including small engines.

The proposed modification to Provisional Pathways

In the Proposed 15-day Regulation Order containing Modified Text and Availability of Additional Documents and Information for the Proposed Re-Adoption of the Low Carbon Fuel Standard, the Air Resources Board proposes the following:

> (2) Provisional Pathways. As set forth in sections 95488(c)(3) and (c)(4)(I)2., LCFS fuel pathways are generally developed for fuels that have been in full commercial production for at least two years. In order to encourage the development of innovative fuel technologies, however, applicants may submit New Pathway Request Forms, as set forth in section 95488(c)(1), covering Tier 1 and Tier 2 facilities that have been in full commercial operation for less than two years, provided they have been in full commercial production for at least one full calendar quarter. If that form is subsequently approved by the Executive Officer, as set forth in section 95488(c)(2), the applicant shall submit operating records covering all prior periods of full commercial operation, provided those records cover at least one full calendar quarter. The following subsections govern the development, evaluation, and post-certification monitoring of such provisional pathways.

Following the provisional certification of a fuel pathway application, the applicants shall submit copies of receipts for all energy purchases each calendar quarter until the Executive Officer is in possession of receipts covering two full calendar years of commercial production. At any time during those two years, the Executive Officer may revise as appropriate the plant's actual operational CI based on those receipts. Based on timely reports, the applicant may generate provisional credits. Such credits may not be sold, transferred, or retired for compliance, nor may fuel with a provisional CI be transferred with obligation. The applicant may not sell credits generated under a provisionally-approved fuel pathway, or transfer the provisional fuel with obligation, until the Executive Officer has adjusted the CI or informed the producer that the provisional CI has been successfully corroborated by operational records covering a full two years of commercial operation.

(A) If the plant's operational CI is higher than the provisionally-certified CI, the Executive Officer will replace the certified CI with the operational CI in the LRT-CBTS system and adjust the producer's credit balance accordingly.

(B) If the plant's operational CI appears to be lower than the certified CI, the Executive Officer will take no action. The applicant may, however, petition the Executive Officer for a provisional CI reduction to reflect operational data. In support of such a petition, the applicant must submit a revised application packet that fully documents the requested reduction.

Analysis and Recommendations

The proposed text is overly restrictive and burdensome for both California and biofuels interests that are set to bring new technologies and fuels to market in California. DuPont fully appreciates the need for accurate CI values for fuel that is sold pursuant to the LCFS while also encouraging production and growth for the advanced biofuels sector. For this reason, we are highlighting the following major concerns with the proposed modified text from above: LCFS FF27-2

1. Requiring biofuels manufacturers to produce commercial fuel for a full calendar quarter prior to submitting New Pathway Request Forms is overly burdensome, unnecessary and does not meet the stated goal of encouraging the development of innovative fuel technologies. Fuel and plant specific data if it is required to be submitted to the Air Resources Board prior to commercial production will provide the requisite information LCFS FF27-3

needed for a Fuel Pathway. In addition, actual biofuel production for the first quarter or any period thereafter does not warrant a de facto CI value equal to gasoline. LCFS FF27-3 cont.

2. A provisional certification that prevents a biofuels producer from generating certified CI credits (not provisional credits) for any period of time will prevent fuel from being sold in California. DuPont's cellulosic ethanol is being manufactured in Iowa. Without the benefit of the CI credit, it would be unreasonable for us to make special arrangements to ship our fuel to California. In addition, obligated parties in California would have no reason to purchase fuel without CI credits. Given their obligations under the LCFS, they would need to purchase fuel with CI credits. LCFS FF27-4

3. The provisional certification covering two full calendar years of commercial production will drive many biofuel producers out of business. New technologies and plants are especially sensitive to economics. New facilities need to be able to sell fuel for full market value from initial production in order to survive. In addition, encouraging growth in the cellulosic and advance biofuels sector can only be achieved with supportive federal and state biofuels policies. A provisional certification will discourage rather than encourage growth. LCFS FF27-5

Given the concerns above, we recommend that the Air Resources Board significantly revise the details for Provisional Pathways and Fuel Pathways. While there may be some situations when provisional pathways and/or provisional certifications should apply, a blanket provisional pathway or certification is fundamentally unfair to all new biofuels facilities that are not yet producing fuel. In addition, the provisional certification would put new facilities at a disadvantage to facilities that received pathway approval prior to start-up under the current regulation. For all biofuel producers who intend to sell in California, there should be an immediate pathway to qualifying for CI credits. Any waiting period, even six months is burdensome and will discourage fuels being sold in California. DuPont absolutely supports the energy data collection via copies of receipts on a quarterly basis so that the Air Resources Board can adjust the CI value as needed. We would also support additional auditing measures if it meant that certified CI credits would be available to fuel producers upon commercial fuel production. LCFS FF27-6

Thank you for the opportunity to comment on the Proposed 15-day Regulation Order for the Proposed Re-Adoption of the Low Carbon Fuel Standard as this is an important issue for DuPont's biofuels business. Please contact me at Jan.Koninckx@dupont.com if you have any questions about the comments provided.

Sincerely,

Jan Koninckx

Jan Koninckx, Global Business Director for Biorefineries
DuPont Industrial Biosciences

27_FF_LCFS_DuPont

926. Comment: **LCFS FF27-1**

The commenter states that the proposed modification to Provisional Pathways in sections 95488(c)(3) and (c)(4)(I)2 will prevent any new fuel from being sold in California beyond what is being produced today and is so overly restrictive in granting approvals for CI credits that many fuel producers will likely be driven out of business."

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF31-1** and **LCFS FF27-3**.

927. Comment: **LCFS FF27-2**

This paragraph summarizes comments **LCFS FF27-3** through **LCFS FF27-6**. The commenter generally believes that the proposed text is overly restrictive and burdensome for both California and biofuels interests that are set to bring new technologies and fuels to market in California.

Agency Response: Please see responses to **LCFS FF27-3** through **LCFS FF27-6**. Staff appreciates the time the commenter has taken to inform staff about the burdens of the regulation from their perspective. Staff will address the applicable comments that this blocked comment introduces**.**

928. Comment: **LCFS FF27-3**

The commenter asserts that requiring biofuels manufacturers to produce commercial fuel for a full calendar quarter prior to submitting New Pathway Request Forms is overly burdensome, unnecessary and does not meet the stated goal of encouraging the development of innovative fuel technologies.

Agency Response: Staff appreciates the commenters concerns regarding being able to generate and sell LCFS credits as soon as commercial production begins. Under § 95488(d)(2) the requirement of being in commercial production for one calendar quarter in order to submit a fuel pathway remains as part of the regulation. ARB considers that period of time necessary to generate reasonably meaningful data about a production process. While an application may not be submitted until commercial production has occurred for one calendar quarter, § 95486(a)(2) states,

> "…the Executive Officer will recognize any **such provisional** credits generated during the quarter in which the approval takes place, and one previous quarter, provided that the application was complete during that previous quarter."

§ 95486(a)(2) allows the provisional applicant the ability to have their credits recognized and generated during the quarter that approval of the pathway occurs (presumably the second quarter of commercial production) and the previous quarter (presumably the first quarter of commercial production).

929. Comment: **LCFS FF27-4**

The commenter asserts that a provisional certification that prevents a biofuels producer from generating certified CI credits (not provisional credits) for any period of time will prevent fuel from being sold in California.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

930. Comment: **LCFS FF27-5**

This comment is related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

931. Comment: **LCFS FF27-6**

This comment is related to provisional pathways not being able to generate or sell LCFS credits for any amount of time and to the data requirements in the regulation for pathway applications, and is the closing paragraph for the commenter's more specific comments. The commenter also states support for the energy data collection via copies of receipts on a quarterly basis so that the Air Resources Board can adjust the CI value as needed.

Agency Response: See response to **LCFS FF31-1** and **LCFS FF56-2.** ARB staff appreciates the commenter's time to share the challenges they see with the regulation. Staff will be conducting workshops and will provide guidance surrounding the process of applying for fuel pathways. All such workshops are open to the public. Through workshops and guidance developed by staff and stakeholders, staff believes that the concerns that the commenter has with the burdens of the pathway application data and the requirement to have one quarter of commercial operation prior to applying for a provisional pathway may be less burdensome. Staff notes that the two-year prohibition on credit transfers for provisional pathways has been removed and can be reviewed in the revised regulation order released June 23, 2015**.**

Agency Response: See response to **LCFS FF17-2**.

937. Comment: **LCFS FF29-3**

The comment states that the regulations do not provide for the independent, third-party auditor to attest in lieu of documentation. Is that something that could be reconsidered?

Agency Response: See response to **LCFS FF17-3**.

Subject: Documenting transportation distances and mode for Tier 1 applications

Regarding transportation of corn to the ethanol plant, the Midwest ethanol producer receives corn from a storage facility on the farm where the corn is produced or from an elevator. In neither case is the truck delivering the corn going to have included on its bill of lading the distance from the field to the collection center (storage facility or elevator). Developing this information from each ethanol producer is likely to be time-consuming and the amount of documentation is going to be voluminous.

Regarding transportation of corn from the collection center to the ethanol plant, there are an extraordinary number of truckloads of corn, and so the documentation will be voluminous.

LCFS FF30-1

For both of these, how will the ethanol plant get this data going back two years if it does not yet have a system in place to document?

I would suggest that the Midwest ethanol producers have an option of using the 1.8b default values for transportation distances, and attesting that the default values are reasonable estimates of actual distances.

LCFS FF30-2

Otherwise an extraordinary amount of work would be needed to prepare the documentation, as well as to audit the documentation, whether it is the third-party auditor or the CARB compliance auditor.

For other facility locations outside the Midwest, the plants ship feedstock and products by rail, so that is somewhat easier to document, but again the documentation is voluminous.

LCFS FF30-1 cont.

Regards,
Logan

Lisa Draney
7160 N Dallas Pkwy Suite 300
Plano, TX 75024
June 19th, 2015

Mary Nichols, Chairman
California Air Resources Board
1001 I Street, PO box 2815
Sacramento, CA 95812

Dear Chairman Nichols:

I would like to thank you for the opportunity to comment on the proposed changes to the California Air Resources Board's Low Carbon Fuel Standard. Murex LLC is a marketing partner for ethanol producers, and in particular several low carbon producers and potential low carbon producers in the California market. We consider programs such as California's Low Carbon Fuel Standard an important element in our partners' success in bringing innovative low carbon products into the fuel market.

In regards to the proposed changes to the program for presentation to the board in July, there was one amendment that raised concern:

> (2) Provisional Pathways. As set forth in sections 95488(c)(3) and (c)(4)(I)2.,
>
> LCFS fuel pathways are generally developed for fuels that have been in full commercial production for at least two years. In order to encourage the development of innovative fuel technologies, however, applicants may submit New Pathway Request Forms, as set forth in section 95488(c)(1), covering Tier 1 and Tier 2 facilities that have been in full commercial operation for less than two years, provided they have been in full commercial production for at least one full calendar quarter. If that form is subsequently approved by the Executive Officer, as set forth in section 95488(c)(2), the applicant shall submit operating records covering all prior periods of full commercial operation, provided those records cover at least one full calendar quarter. The following subsections govern the development, evaluation, and post-certification monitoring of such provisional pathways.
>
> Following the provisional certification of a fuel pathway application, the applicants shall submit copies of receipts for all energy purchases each calendar quarter until the Executive Officer is in possession of receipts covering two full calendar years of commercial production. At any time during those two years, the Executive Officer may revise as appropriate the plant's actual operational CI based on those receipts. Based on timely reports, the applicant may generate provisional credits. Such credits may not be sold, transferred, or retired for compliance, nor may fuel with a provisional CI be transferred with obligation. The applicant may not sell credits generated under a provisionally-approved fuel pathway, or transfer the provisional fuel with obligation, until the Executive Officer has adjusted the CI or informed the producer that the provisional CI has been successfully corroborated by operational records covering a full two years of commercial operation.

(A) If the plant's operational CI is higher than the provisionally-certified CI, the Executive Officer will replace the certified CI with the operational CI in the LRT-CBTS system and adjust the producer's credit balance accordingly.

(B) If the plant's operational CI appears to be lower than the certified CI, the Executive Officer will take no action. The applicant may, however, petition the Executive Officer for a provisional CI reduction to reflect operational data. In support of such a petition, the applicant must submit a revised application packet that fully documents the requested reduction.

Murex has several concerns with the above proposal:

- It will put new fuel producers at a disadvantage in the marketplace to all competitors capable of generating carbon credits. The regulated parties that are ultimately responsible for meeting the lowered carbon standards will want to purchase fuels that produce credits that can be transferred with obligation. LCFS FF31-1

- Because of the above disadvantage, new low carbon fuel producers will not be competitive in the California market and will have to ship to other markets, slowing the introduction of low carbon fuels into California, and making the new lower carbon targets harder to meet. LCFS FF31-2

- Innovative fuel producers in and near California will be especially disadvantaged as, unable to meet the carbon requirements of California buyers, they may have to ship the product and bear transportation costs as opposed to serving the local markets. LCFS FF31-3

Given the above concerns, Murex would like to formally request that the California Air Resources Board consider allowing new producers with new technologies to produce and transfer credits at the start of production, with quarterly reviews to ensure that operations coincide with the carbon intensity allowed, and adjust the carbon intensity on a forward basis. LCFS FF31-4

Furthermore, Murex would like to propose that the California Air Resource Board consider certifying third parties to conduct these audits on new producers, within established guidelines. This will allow close monitoring of new fuels to ensure the credits generated are in line with production, without being overly burdened with the increased oversight. LCFS FF31-5

Programs like California's LCFS are essential to bringing new low carbon technologies to the fuels market worldwide. This support is most important in the first stages of the new technology. Please consider revising the above proposal to allow new fuels to produce carbon credits in California. LCFS FF31-6

If you have any further questions, I can be reached at ldraney@murexltd.com, or by phone at 972.735.3316.

Thank you,

Lisa Draney

940. Comment: **LCFS FF31-1**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

941. Comment: **LCFS FF31-2**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

942. Comment: **LCFS FF31-3**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

943. Comment: **LCFS FF31-4**

The comment is related to provisional pathways being able to generate credits as soon as commercial production begins, the quarter the provisional pathway is approved, and the prior quarter.

Agency Response: Please see response to comment **LCFS FF27-3.**

944. Comment: **LCFS FF31-5**

This comment is related to ARB certifying third parties to conduct audits on new producers.

Agency Response: ARB staff appreciates the suggestion for allowing third parties to audit new fuel producers. However, staff notes that this comment is not related to 15-day changes being proposed in the Modified Regulation Order proposed on June 4,

2015. Staff would like to direct the commenter to one example of third party auditors being allowed to conduct such audits. Section 95488(c)(3)(A)3 states:

> "In lieu of receipts or invoices for energy consumption, fuel sales, feedstock purchases, or co-product sales, the applicant may seek Executive Officer approval to submit audit reports prepared by independent, third-party auditors that document energy consumption, fuel sales, feedstock purchases, or co-product sales."

945. Comment: **LCFS FF31-6**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes. In addition, the commenter states how essential the LCFS is for new technology.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

To: Chowdhury, Hafizur@ARB
Subject: Definition and Qualifications of an Independent, Third Party Auditor?

Hafizur:
95488(c)(3)(A)(3) of the proposed regulations states: "In lieu of receipts or invoices for fuel sales, feedstock purchases, or co-product sales, the applicant may seek Executive Officer approval to submit audit reports prepared by independent, third-party auditors that document fuel sales, feedstock purchases, or co-product sales."

As you know presently for 1.8b applications a top company official prepares an attestation letter in lieu of submitting documentation of fuel sales, feedstock purchases, and co-product sales.

What will be the criteria to determine whether a person is a qualified independent, third-party auditor? Will someone with a CPA suffice? Is this definition somewhere else in the CARB regulations? If so, can you point me in the direction so I can review. LCFS FF32-1

Thanks!

Regards,
Logan

Comment 33 for Low Carbon Fuel Standard 2015 (lcfs2015) - 15-1.

First Name: Gus
Last Name: Block
Email Address: gblock@nuvera.com
Phone Number: 617-245-7553
Affiliation: Nuvera Fuel Cells

Subject: LCFS Credit Proposal
Comment:
Nuvera Fuel Cells is a provider of fuel cell systems for mobility applications and of hydrogen generation and refueling equipment. The company is owned by NACCO Materials Handling Group, a global manufacturer of industrial vehicles, including Hyster(R) and Yale(R) brand forklift trucks.

Nuvera endorses the proposed inclusion of hydrogen fuel for fuel cell-powered forklifts as a means for generating LCFS credits. We also propose extending the application beyond forklifts to other industrial vehicles, such as ground support equipment, transport refrigeration, and container handling equipment. These measures will help drive the adoption of low carbon fuel alternatives within California's large industrial vehicle sector, which includes distribution centers, warehouses, manufacturing facilities, ports, and other venues that are concentrated emissions sources.

LCFS FF33-1

Nuvera advises against the adoption of the proposed Provisional Credit clause that would allow companies to earn provisional LCFS credits but would not allow them to be traded for two years. This provision would be a significant disincentive for prospective producers.

LCFS FF33-2

Board Comments Home

33_FF_LCFS_Nuvera

947. Comment: **LCFS FF33-1**

The comment endorses the proposed inclusion of hydrogen used in fuel cell powered forklifts as eligible to generate LCFS credits and proposes expanding this provision to other vehicles use of hydrogen.

Agency Response: ARB staff acknowledges that the fuel cell vehicle technologies will continue to improve and is open to meeting with stakeholders to discuss possibilities for including more industrial fuel cell vehicles, if the LCFS reporting and record keeping requirements for hydrogen use can be met. Staff commits to revisit the hydrogen provisions as newer technologies and data become available.

948. Comment: **LCFS FF33-2**

The comment is related to provisional pathways being able to generate credits as soon as commercial production begins, the quarter the provisional pathway is approved, and the prior quarter.

Agency Response: See response to **LCFS FF27-3**.

FLINT HILLS
resources

June 19, 2015

Electronically Submitted at http://www.arb.gov/lispub/comm/bclist.php

Clerk of the Board
Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Sir or Madam:

Flint Hills Resources (FHR) is pleased to submit the following comments in response to the following Notice of Public Availability of Modified Text and Availability of Additional Documents and Information:

Proposed Re-Adoption of the Low Carbon Fuel Standard (Public Availability Date: June 4, 2015)

FHR through its subsidiaries is an industry leader in refining, chemicals, and biofuels and ingredients, with operations primarily in Texas and the Midwest. Its manufacturing capability is built upon six decades of refining experience, and the company has expanded its operations through capital projects and acquisitions worth more than $11 billion since 2002. FHR's subsidiaries produce and market gasoline, diesel, jet fuel, asphalt, ethanol, biodiesel, liquefied natural gas, olefins, polymers, intermediate chemicals, as well as base oils, inedible corn oil and distillers grains. Based in Wichita, Kansas, the company has about 5,000 employees and is a wholly owned subsidiary of Koch Industries, Inc.

FHR operates fuel ethanol plants in Iowa, Nebraska and Georgia, and manufactures significant volumes of denatured fuel ethanol. FHR is currently constructing a biodiesel plant in Beatrice, Nebraska and intends to market and distribute this fuel in California and, therefore, has a vital interest in the above referenced proposal.

<u>Provisional Pathway Provision Should be Modified to Avoid Unintended Consequences</u>

The modified Provisional Pathway provision of proposed Section 95488(d)(2) (see Summary of Proposed Modifications Item #25), which has been expanded to include Tier 1 facilities, may not fully meet its intended purpose of encouraging the development of innovative fuel technologies. Specifically, FHR believes that a restriction from selling, transferring, or retiring credits for compliance, or transferring fuel with obligation for facilities in commercial operation for less than two years will likely stymie the development and supply of Tier 1 alternative fuels. LCFS FF34-1

- 4111 East 37th Street North - Wichita, Kansas 67220 - P.O. Box 2917 - Wichita, Kansas 67201 -

FHR believes that Section 95488(d)(2) may be misinterpreted to limit the Executive Director's authority to approve fuel pathway codes and carbon intensities (CIs) for fuels produced for less than two years. Section 95488(d)(2) states, "The applicant may not sell credits generated under a provisionally-approved fuel pathway, or transfer the provisional fuel with obligation, until the Executive Officer has adjusted the CI or informed the producer <u>that the provisional CI has been successfully corroborated by operational records covering a full two years of commercial operation</u> (emphasis added)". FHR is concerned that the ending phrase, underlined above, could be interpreted to mean that an adjusted, certified CI must be supported with a minimum of two years of operational records. LCFS FF34-1 cont.

FHR believes that the Executive Officer should have the discretion to waive the two year operational records requirement and certify CIs. This discretion would mirror the current practice, whereby the Executive Officer certifies a prospective CI, after receiving a pathway application substantiated by plant engineering design mass and energy balance information, and by requiring the applicant to subsequently submit operational records on a quarterly basis, as a means to validate the CI. In the case of a prospective CI, as well as any certified fuel CI, the applicant would be subject to ARB's authority under Section 95495 to suspend, revoke, or modify an approved CI that is determined to be invalid, as well as the LCFS Fuel Producer Attestation requirement within Section 95488(c)(2)(C). LCFS FF34-2

If a determination is made that the Executive Officer must require two years of operational records, FHR believes that investments in production facilities for Tier 1 alternative fuels will be deterred and the supply of alternative fuels will be constrained, based on the following economic consequences:

1. Alternative fuel producers restricted from selling credits will have delayed income for up to two years.
2. Alternative fuel producers restricted from retiring credits for compliance may need to purchase credits from the ongoing LCFS credit market to meet an annual compliance obligation, thereby increasing expenses for up to two years.
3. Alternative fuel producers restricted from transferring fuel with obligation will need to purchase credits from the ongoing LCFS credit market and transfer the credits to fuel-buying regulated parties, thereby increasing expenses for up to two years.

LCFS FF34-3

<u>FHR Recommends Minor Text Changes</u>

FHR believes that a misinterpretation can be avoided by ARB incorporating the following minor changes in "**bold**" to Section 95488(d)(2):

> The applicant may not sell credits generated under a provisionally-approved fuel pathway, or transfer the provisional fuel with obligation, until the Executive Officer has **either: 1)** ~~adjusted~~ **certified** the CI, or **2)** informed the producer that the provisional CI has been successfully corroborated by operational records covering a full two years of commercial operation.

LCFS FF34-4

Should you have any questions, please contact FHR's VP, Quality and Compliance, Rita Hardy (rita.hardy@fhr.com, 316/828-7840), or myself, for further information or to schedule a meeting to discuss.

Sincerely,

Philip Guillemette

Richard Corey
Executive Officer
California Air Resources Board
1001 "I" Street
Sacramento, CA 95814

Re: Comments on Proposed 15-Day Regulation Order for the Low-Carbon Fuel Standard

Dear Executive Officer Corey:

The California Natural Gas Vehicle Coalition (CNGVC), NGVAmerica (NGVA), and the Coalition for Renewable Natural Gas (RNGC)[1] are pleased to provide these joint comments regarding ARB's proposed re-adoption of the Low Carbon Fuel Standard (LCFS) regulation. Specifically, this letter provides our detailed joint comments on ARB's "Attachment A: Proposed 15-Day Regulation Order," which was released for public comment on June 4, 2015.

Below, we present our joint, detailed comments and recommendations. We want to be clear that our three organizations continue to support ARB's proposed re-adoption of the LCFS regulation. We greatly appreciate the time and effort put forth by ARB staff over the last several months to meet with our representatives and address our specific concerns. We are pleased that ARB has made changes that corrected erroneous information and updated obsolete inputs in early drafts of the proposed CA-GREET model revision (version 2.0). We are committed to continue working closely with ARB staff, right up until the LCFS program re-adoption is anticipated at the Board's July 23, 2015 meeting.

A. Comments on Proposed LCFS Regulatory Changes

Our detailed comments regarding ARB's proposed LCFS regulatory changes are presented below, in six specific areas.

1. Provisional Pathway Process

Staff is proposing a "provisional pathway" process for facilities with less than two years of operational data. Under this new process, facilities with less than two years of operational data would generate provisional credits. Such credits could not be traded or sold unless certain conditions are met. One interpretation of the regulatory text might be that all credits generated under a provisional pathway may not be sold until the facility has completed the application process and received a fully certified "operational CI." This process could take up to two years, depending on the amount of operational data available for the facility at the time of application.

[1] For more information about our three organizations and respective memberships, please refer to the many previous formal comment letters that we uploaded over the last nine months to the ARB LCFS comments website.

In effect, this process would prevent new facilities from monetizing LCFS credits for up to two years. This would be disastrous for the development of new low carbon fuel sources for the California market. The development of facilities to produce low carbon transportation fuels typically requires significant upfront capital investment and risk. Further, the lowest carbon intensity fuels, such as renewable natural gas, are currently more expensive to produce than fossil based fuels. Revenue from credits generated under the LCFS and other programs help mitigate some of the project risk and are critical to creating feasible financial plans for the development of these facilities. Delaying revenue generation from credit sales significantly undermines the financial feasibility of such projects, thereby limiting the growth in supply of low carbon fuels. This is at odds with the intent of the LCFS program and the stated intent of the provisional pathways process to "encourage the development of innovative fuel technologies…" LCFS FF35-1

We believe that a strict reading of Section 95488(d)(2) <u>does allow</u> applicants to sell provisional credits during the period the facility is operating under a provisional pathway. As described in the regulatory text, "The applicant may not sell credits generated under a provisionally-approved fuel pathway, or transfer the provisional fuel with obligation, **<u>until the Executive Officer has adjusted the CI</u>** or informed the producer that the provisional CI has been successfully corroborated by operational records covering a full two years of commercial operation" (emphasis added). Further, "At any time during those two years, the Executive Officer may revise as appropriate the plant's actual operational CI based on those receipts."

Based on these elements of Section 95488(d)(2), we believe that the regulation distinguishes between an "adjusted CI" and a CI that has been corroborated by two years of operational data and, that once the Executive Officer adjusts the CI of a provisional pathway (including, but not limited to, the issuance of any CI that differs from the Temporary FPC values in Table 7), all credits generated under that pathway become available for trade, sale, or transfer. Hence, once an applicant has submitted at least one quarter (three months) of receipts and reported credits generated in the LRT, the Executive Officer should issue an adjusted operational CI, enabling the full use of the provisional credits by the applicant and any future credits generated under the provisional pathway. LCFS FF35-2

It should also be noted that the regulation does not define the terms, "Provisional CI", "Operational CI", or "Provisional Credits." For clarity, we believe that the following are reasonable interpretations of each term.

Provisional CI – A CI issued to a provisionally approved pathway. This includes CIs based on "default" values in Table 7 and Operational CIs.

Operational CI – A CI that has been issued or adjusted by the Executive Officer based on operational data submitted by the applicant. An Operational CI can apply to a Provisional Pathway or a fully approved pathway. Operational CIs for provisional pathways may be adjusted multiple times as the Executive Officer receives additional quarters of operational data. LCFS FF35-3

Provisional Credits – Credits generated under a Provisional Pathway. Provisional Credits generated under an Operational CI can be traded, sold, or transferred.

Because these elements of the provisional pathway process are potentially confusing, we respectfully request that Staff clarify the intent of Section 95488(d)(2) and confirm that the Executive officer will timely adjust the LCFS FF35-4

CI of the provisional pathway based on the receipt of at least one quarter of operational data. Further, we request that Staff clarify that such an adjustment would allow the applicant to trade, sell, or retire these provisional credits, or transfer the underlying fuel with obligation. Such a clarification is crucial to avoid harming the development of new low carbon fuel supplies and is consistent with the stated intent of the LCFS and the provisional pathway process. LCFS FF35-4 cont.

If Staff do not believe our interpretation of the regulatory text is accurate, we strongly urge ARB to modify the rule to allow the monetization of Provisional Credits immediately upon issuance of a Provisional CI, and allow generation of credits from the date the application is submitted to ARB. LCFS FF35-5

2. Temporary FPC Values

Table 7 of the regulation proposes temporary carbon intensities for fuels where a specific fuel pathway cannot be identified. These may also potentially be used as "default" values for facilities awaiting application approval or in the beginning stages of the Provisional Pathway process. Hence, the values in Table 7 have a material impact on the credits and deficits generated under the LCFS. Despite the importance of these values, ARB staff have not provided information regarding the underlying assumptions used to determine most of the values in Table 7 (excluding the CIs for diesel and CARBOB, which are clearly documented elsewhere). We believe that the values in Table 7 are not consistent with typical values expected for natural gas pathways providing fuel to California. In fact, values for LNG from North American natural gas, and CNG or LNG derived from landfill gas are significantly higher than the illustrative values provided by ARB staff at the April 3rd workshop at which updates to CA-GREET 2.0 were extensively discussed. LCFS FF35-6

In sum, the currently proposed revisions to Table 7 further increase the CIs for natural gas pathways above values previously proposed by staff, and these increases do not appear to be explainable by documented revisions to the CA-GREET model. We believe that it is inappropriate to further increase the values in Table 7 without providing details on the assumptions underlying these changes. Consequently, we request that ARB staff not modify the values in Table 7 from the values proposed in February. At the very least, we believe that any modifications to the values in Table 7 should be clearly linked to documented changes and updates to the CA-GREET model.

3. Application Review Timeline

Section 95488(c)(5)(B) proposes to eliminate the 60-day deadline for ARB staff to review an application and notify the applicant about its completeness. However, Staff is not proposing to modify the 180-day deadline for an applicant to provide a complete application. Staff notes that this change is being proposed to eliminate "unrealistic deadlines" during times when Staff will be working to recertify hundreds of existing pathways.

This removal of the 60-day deadline may be acceptable for applications covered by an existing pathway and able to generate credits as late as December 31, 2016. However, the proposed change <u>is not acceptable for new applications</u>. It is crucial that ARB continue to provide timely feedback to applicants regarding the completeness of their applications and any deficiencies that must be addressed. Delays in the review process can translate directly into lost credit generation, the associated revenue, and verified carbon reductions. LCFS FF35-7

Further, we note that the removal of the 60-day requirement is not limited to the 2016 timeframe. It is inappropriate to establish a regulation in which Staff have no obligation to complete a timely review of an application but where the applicant is simultaneously constrained to a fixed deadline and dependent on Staff's review of the application. LCFS FF35-7 cont.

Similarly, Staff propose to remove the 15-day deadline for review and notification of completeness of a fuel transport mode as defined in Section 95488(e)(5). We have similar concerns and objections to the removal of this requirement for timely review of the fuel transport mode application as we do for the pathway application review process in Section 95488(c)(5). LCFS FF35-8

We urge Staff to retain the 60-day and 15-day deadlines in Sections 95488(c)(5)(B) and 95488(e)(5), respectively, and to provide the LCFS program the necessary resources to conduct timely review of applications during the 2016 timeframe. It is critically important that industry has a process for application review that includes firm deadlines for ARB's actions. LCFS FF35-9

4. Treatment of Business Confidential Information

Staff are proposing to eliminate language providing protection of credit transaction data as Business Confidential information. Section 95487(c)(1)(B) currently requires ARB to treat all data reported in Credit Transfer Forms as business confidential, with limited exceptions for reporting of aggregated data described in Section 95487(d).

Credit Transfer Forms contain a number of sensitive pieces of information including, but not limited to:

- Names and contact information of individuals at companies involved in the transaction;
- Parties to specific transactions;
- Price and number of credits involved with a specific transaction.

LCFS FF35-10

There is no basis for broad public disclosure of the names and contact information of private persons, particularly when they are acting simply in an administrative role for a private organization. Further, the disclosure of the parties, pricing, types of credits, and number of credits associated with a particular transaction can be damaging to the business interests of regulated parties. The disclosure of such sensitive information is not consistent with other regulatory programs including the US EPA's Renewable Fuel Standard.

It should also be noted that, while the regulation allows brokers to facilitate "blind transactions," the disclosure of data in the Credit Transfer Forms would undermine blind transactions for any transactions where the broker does not first aggregate the credits from multiple buyers or sellers.

We urge Staff to retain the Business Confidential protection language in Section 95487(c)(1)(B). Confidentiality provisions are the industry standard for commodity transactions. However, we can support providing information for the sole purpose of calculating a published index.

5. Definition of L-CNG and Bio-L-CNG

The proposed regulatory text currently defines L-CNG as "LNG that has been liquefied and transported to a dispensing station where it was then re-gasified and compressed to a pressure greater than ambient pressure."

Similarly, Bio-L-CNG is defined as "biogas-derived biomethane which has been compressed, liquefied, re-gasified, and re-compressed into L-CNG, and has performance characteristics at least equivalent to fossil L-CNG."

In both definitions, it is assumed that L-CNG is created by gasifying LNG and then compressing the resulting gas to pressures suitable for CNG, typically 3,600 psi. This is not an accurate description for most L-CNG and Bio-L-CNG facilities. The pumping of liquids to high pressures is much less energy intensive than the compression of gas. Most L-CNG facilities take advantage of this fact by first pumping LNG to high pressures and then re-gasifying the LNG at pressure, ultimately producing CNG without the need for a gas compression process. Such a distinction is important because it has a meaningful impact on the carbon intensity for L-CNG fuels. We note that this issue was raised in our comments submitted to ARB on December 15, 2014. Following that submission, Staff updated the CA-GREET model to reflect the typical operation of L-CNG stations.

LCFS FF35-11

We recommend that Staff modify the definition of L-CNG and Bio-L-CNG to be consistent with the processes modeled in CA-GREET 2.0. Specifically, by eliminating the text asserting that L-CNG and Bio-L-CNG necessarily involve "compression" or "re-compression" of natural gas at the station.

6. Retroactivity

Section 95486(a)(2) limits the generation of retroactive credits to a maximum of two quarters; the quarter in which the complete application was submitted and the quarter in which the Executive Officer approves the application. Exceptions are made for provisional credits generated during the period that the applicant is accruing two years of operational data.

While the two-quarter limit on retroactive credit generation appears reasonable, it is predicated on the assumption that the Executive Officer will approve a complete application by the end of the quarter following submission of the application. Considering that Staff acknowledge the likelihood of significant delays in application processing during 2016, and in light of the proposed elimination of the 60-day and 15-day review deadlines discussed in item 3 above, we believe that retroactivity should not be constrained by a two-quarter limit. Specifically, we propose that retroactive credit generation should apply from the quarter the applicant submits a completed application or demonstration to the quarter in which the Executive Officer approves the application or demonstration. Hence, if the approval of the application or demonstration by the Executive Officer requires more than one quarter, the applicant does not lose credits due to delays outside the applicant's control.

LCFS FF35-12

This proposed change is both reasonable and important. However, we do not believe it is worth delaying the adoption of the LCFS, provided that Staff ensures the timely review of applications as noted in our comments under Item 3, above. Instead, we strongly urge Staff to consider making this change in a future update to the

LCFS, retain the 60-day and 15-day deadlines for review in the current rulemaking (or alternative reasonable timeline with a firm deadline), and ensure that the LCFS program has sufficient resources to provide timely review of applications. LCFS FF35-12 cont.

B. Comments on CA-GREET Model Update

We would like to thank Staff for their efforts to address our concerns related to the draft CA-GREET 2.0 model over the last nine months. These interactions have resulted in important improvements to the model.

In the latest draft of CA-GREET, Staff incorporated estimates of Tank to Wheels (TTW) methane and nitrous oxide emissions from natural gas vehicles, based on a recent whitepaper from Argonne National Laboratory (ANL).[2] The whitepaper provides estimated emissions for various vehicle types and applications, including combination long haul trucks, combination short haul trucks, refuse trucks, buses, heavy duty trucks and vans, and medium duty vehicles. Staff rely on the emissions rates in the ANL report, combined with estimates of the composition of the natural gas vehicle fleet, to calculate fleet-averaged TTW emissions rates for CNG and LNG.

The emissions rates calculated by ARB staff are not insignificant. As shown in Table 1, ARB assumes that the fleet-averaged emissions of methane and nitrous oxide for CNG and LNG vehicles are 4.90-4.91 gCO2e/MJ. This represents a 6% increase in pathway emissions for CNG and LNG from fossil sources, and potentially more than 25% of emissions from renewable natural gas pathways. However, as shown, emissions from some vehicle types are much lower than the calculated fleet average.

LCFS FF35-13

Table 1. Non-CO2 GHG emissions assumptions for natural gas vehicles

Vehicle Type	Non-CO2 vehicle emissions
ARB CNG Fleet Average	4.90 gCO2e/MJ
Light-Duty/Medium Duty	0.99 gCO2e/MJ
Heavy-Duty Class 8b	2.42 gCO2e/MJ
ARB LNG Fleet Average	4.91 gCO2e/MJ

Both heavy-duty class 8b vehicles and light/medium duty vehicles are estimated to have much lower TTW emissions than the fleet-average. Because of such wide variation in the emissions from vehicle types, the fleet-averaged emissions are very sensitive to the assumed fleet composition. Overestimating the fraction of the fleet in higher emitting applications raises the fleet average and potentially penalizes lower emitting applications.

We raise two specific concerns here, as described below.

1. Basis for the Current Fleet Mix

Staff calculates the current mix of applications consuming CNG and LNG based on data from the US Energy Information Administration's (EIA) Alternative Fuel User Database. The latest year for available data is 2011. LCFS FF35-14

[2] Cai, H. et al, The GREET Model Expansion for Well-to-Wheels Analysis of Heavy-Duty Vehicles, 2015

We note that the data are both out of date, and inconsistent with other industry specific data sources. As an example, we note that ARB staff estimate that transit buses consume 60% of the 55 million gallons of LNG sold in 2014. This equates to nearly 22 million GGE, or 150% more LNG for transit buses than reported by EIA. The National Transportation Database (NTDB) reports that California transit fleets consumed only 7 million gallons of LNG, or approximately 4.6 million GGE in 2011; roughly half of the fuel consumption reported by EIA. Finally, it is unclear to what extent reported LNG consumption actually reflects LNG delivered to an LCNG station.

LCFS FF35-14 cont.

The dominant purchasers of LNG in California for transit applications are Orange County Transportation Authority (OCTA) and Santa Monica's Big Blue Bus (BBB). These two agencies represent almost 95% of LNG purchased in 2011, according to the NTDB. Examination of a recent LNG purchase contract from OCTA reveals that the agency consumes roughly 22,000 gallons of LNG per weekday, or approximately 5.5 million LNG gallons per year.[3] A city council report on the BBB LNG fuel procurement for 2010-2011 reported that BBB purchases roughly 200,000 LNG gallons per month to serve a mix of BBB vehicles as well as city vehicles and the Santa Monica Unified School District.[4] BBB operates a mix of CNG and LNG buses, supplying the CNG buses through their LCNG station. Consequently, only a fraction of the BBB LNG purchases are actually used in transit applications. In total, the two largest purchasers of LNG for transit applications only represented less than 7.7 million LNG gallons in 2011. Again, this value is much lower than that reported by EIA.

Such disparities between EIA and other data sources make it clear that EIA is not a reliable basis upon which to develop a fleet-average emissions rates.

2. Evolving Fleet Mix

EIA's last available estimate of the population of NGVs in the US is 121,650 vehicles in 2011. Based on industry sales data, NGVA estimates that the current population of NGVs is in excess of 155,000 and growing. New deployments show growth in sales of Class 8 trucks in addition to sales in more traditional transit and refuse applications. It is clear that the mix of NGVs is changing and that it is not possible to accurate predict the future fleet mix. Further, because of the relatively small number of NGVs in the state (relative to traditional petroleum fueled vehicles), modest growth in any application could significantly alter the fleet mix.

LCFS FF35-15

Recommendations Regarding CA-GREET Update

Based on the two concerns described above – and the fact that the TTW emissions rates employed by ARB have non-trivial variations based on the vehicle type/application – we request that ARB allow fuel producers the option to adjust their pathway carbon intensities based on the vehicle type receiving the fuel. For example, a CNG or LNG station owner that documents the volume of fuel dispensed to Class 8b trucks would adjust their pathway CI based on non-CO2 TTW emissions of 2.42 gCO2e/MJ, rather than the fleet average of 4.90 or 4.91 gCO2e/MJ.

LCFS FF35-16

[3] Orange County Transportation Authority, Award of Liquefied Natural Gas Contract – Staff Report, 2013 http://atb.octa.net/AgendaPDFSite/10775_Staff%20Report.pdf

[4] City of Santa Monica, LNG Fuel for the Big Blue Bus, Agenda Item 3-E, February 8, 2011. http://www.smgov.net/departments/council/agendas/2011/20110208/s2011020803-E.htm

This option would help incentivize the deployment of NGVs in the lowest emitting categories by recognizing their specific emissions profiles and would require minimal changes to the data tracked in the LRT. Currently light and medium-duty natural gas consumption is tracked separately from heavy-duty natural gas fuel consumption in the LRT. Implementing the proposed recommendation would only require the separation of Class 8b fuel consumption from the remaining heavy-duty vehicle applications. Where the vehicle type cannot be determined or is not documented, the credit generator would continue to use the fleet-averaged TTW emissions rates. LCFS FF35-16 cont.

Closing Comment

Our three organizations support re-adoption of the LCFS regulation. We genuinely appreciate the cooperation that ARB staff have shown in working with our industry representatives to improve the program, especially the critically important CA-GREET model. Leading up to the July 23 Board meeting, we urge you to expeditiously address the issues identified in this letter.

Thank you for the opportunity to comment. If we can provide additional information, please contact any of us.

Sincerely yours,

Tim Carmichael, President
California Natural Gas Vehicle Coalition
916-448-0015

Matthew Godlewski, President
NGVAmerica
202-824-7360

David Cox, Director of Operations & General Counsel
Coalition for Renewable Natural Gas
916-678-1592

35_FF_LCFS_NVGC

953. Comment: **LCFS FF35-1**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

954. Comment: **LCFS FF35-2**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

955. Comment: **LCFS FF35-3**

The commenter suggests definitions for provisional and operational CIs and for provisional credits. In order to remedy the apparent error related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

956. Comment: **LCFS FF35-4**

The comment is related to provisional pathways being able to generate credits as soon as commercial production begins, the quarter the provisional pathway is approved, and the prior quarter.

Agency Response: See response to **LCFS FF27-3**.

957. Comment: **LCFS FF35-5**

The comment suggests ARB amend the proposal for monetizing provisional credits.

Agency Response: See response to **LCFS FF27-3**.

958. Comment: **LCFS FF35-6**

The comment states that the currently proposed revisions to Table 7 further increase the CIs for natural gas pathways above values previously proposed by staff, and these increases do not appear to be explainable by documented revisions to the CA-GREET model.

Agency Response: Table 7 CI values are intended for use only when no information has been provided to ARB to evaluate the fuel, as stated in the Initial Statement of Reasons (ISOR) (Summary of Section 95488(d), p VIII-11):

> A fuel provider is seeking to sell a volume of fuel which has no CI associated with it. Section (d) provides a table of temporary default CIs that can be used to report transactions involving such fuel.

These CIs must represent a conservative scenario – rather than average or typical – in order to maintain the integrity of the program and the scientific defensibility of GHG emission reductions, as well as to encourage producers who regularly wish to provide fuel for use in California to apply for a certified carbon intensity value. To model these conservative CIs, the following guidelines were utilized:

> When a range of data was available, either from the pool of existing applications, government reports or published literature, ARB staff selected the highest reasonable value for Tier 1 calculator inputs. Examples include quantities of energy consumption, material inputs, and transportation distances.
>
> If a sufficient pool of data to define a range of probable inputs was not available, average values were used and a 5 percent "safety factor" was applied to estimate the high-intensity scenario.

Changes to temporary CIs since the first Regulation Order are consistent with model changes, meaning no additional input assumptions were altered, with the exception of RNG: the pipeline transmission distance was increased to reflect the furthest likely producer. No distinction was possible between sources of RNG due to the small number of anaerobic digester pathway applications that have been evaluated by ARB.

959. Comment: **LCFS FF35-7**

The commenter asserts that it is inappropriate to establish a regulation in which staff has no obligation to complete a timely review of an application but where the applicant is simultaneously constrained to a fixed deadline and dependent on staff's review of the application.

Agency Response: The 180-day timeline for submitting a complete application remains in place to ensure timely responses for other applicants. The opportunity to reapply or submit a complete application is always available to applicants; functionally, the 180-day limit means that the application loses its priority in the queue: it will be evaluated after any other complete applications submitted in the time period following the applicant's original (incomplete) application and the final (complete) application.

ARB staff has removed the 60-day deadline for the initial ARB staff review to account for the 2016 recertification process, and to acknowledge that some pathways are simpler than others for staff to process. This change is primarily intended to allow for flexibility during the transition time period, as the commenter notes, during which time producers may continue using CIs generated using CA-GREET 1.8b which were approved under the existing regulation.

Further, staff will be setting self-imposed public deadlines for the recertification process. Staff will outline the deadlines that staff will adhere to in guidance that will be developed through stakeholder feedback and workshops after the Board Hearing. Beyond the recertification time period, staff expects timely reviews for new applications, as demonstrated in the past.

Similarly, the removal of the 15-day timeline for staff to approve demonstration of fuel transport modes is to allow for flexibility during the transition. As producers may generate credits backdated to the time of first shipment, this change will not result in a loss of credit generating potential. Historically, approval of fuel transport mode demonstration has been well within the 15-day time period which was allotted, however, many regulated parties have been delinquent in providing this demonstration to ARB. Hence, a 90-day timeline is now in place to ensure that regulated parties meet requirement within a quarter such that they will not be adversely impacted by the two quarters retroactivity limit.

960. Comment: **LCFS FF35-8**

The commenter states that staff propose to remove the 15-day deadline for review and notification of completeness of a fuel transport mode as defined in Section 95488(e)(5). They have concerns and objections to the removal of this requirement for timely review of the fuel transport mode application as we do for the pathway application review process in Section 95488(c)(5).

Agency Response: See response to **LCFS FF35-7**.

961. Comment: **LCFS FF35-9**

The commenter urges staff to retain the 60-day and 15-day deadlines in Sections 95488(c)(5)(B) and 95488(e)(5), respectively, and to provide the LCFS program the necessary resources to conduct timely review of applications during the 2016 timeframe.

Agency Response: Additional ARB staff will be allocated for pathway recertification in 2016. See response to **LCFS FF35-7**.

962. Comment: **LCFS FF35-10**

The commenter objects to the removal of language guaranteeing that credit transfer information submitted online would be treated as confidential business information (CBI). The commenter appears to assume that there will automatically be "broad public disclosure" of data reported in connection with credit transfers.

Agency Response: ARB staff disagrees. Blind transactions facilitated by brokers are still expressly allowed by the regulation. Staff disagrees that removal of language, which is duplicative of other laws, will result in public disclosure of CBI. ARB staff does not believe that the original language was necessary. State law protects trade secrets, and existing ARB regulations provide a means by which a CBI claim may be asserted. (Cal. Code Regs., tit. 17, §91011.) Moreover, it is not appropriate to predetermine that all information regarding transactions in a government-created market with a public, environmental purpose is CBI.

963. Comment: **LCFS FF35-11**

The commenter recommends that staff modify the definition of L-CNG and Bio-L-CNG to be consistent with the processes modeled in CA-GREET 2.0.

Agency Response: The structure of CA-GREET2.0 model's Tier 1 calculator allows the user to accurately calculate the impacts of energy use in the conversion of LNG to CNG using either technical approach described by the commenter: regasification to natural gas at ambient pressure followed by compression of gas to CNG, or compression as a liquid and regasification under pressure. While the L-CNG definition provided does not precisely reflect the variety of methods utilized by all L-CNG producers, ARB staff finds the distinction noted by the commenter to be immaterial, as the emissions at this stage are based on energy use which can be verified by receipts regardless of the number of steps taken or order in which they are performed. Furthermore, contrary to the statement in the comment, the CA-GREET model was not updated (individual input fields are provided for energy use in regasification and in compression; if no energy is used for one of these steps the user may enter 0.001), as it was demonstrated that this structure was sufficient to accurately reflect multiple approaches to conversion of LNG to CNG.

964. Comment: **LCFS FF35-12**

The commenter proposes that retroactive credit generation should apply from the quarter the applicant submits a completed application or demonstration to the quarter in which the Executive Officer approves the application or demonstration. However, the commenter does not believe it is worth delaying the adoption of the LCFS. The commenter also repeats the suggestion to retain deadlines for ARB review.

Agency Response: ARB staff appreciates the commenter's prioritization of proposed changes. Beyond the recertification time period, staff expects timely reviews for new applications, as demonstrated in the past. See response to **LCFS FF35-7**.

965. Comment: **LCFS FF35-13 and LCFS FF35-14**

The comment states that overestimating the fraction of the NGV fleet in higher emitting applications raises the fleet average and potentially penalizes lower emitting applications. The commenter believes that EIA data are not a reliable basis upon which to develop fleet-average emissions rates.

Agency Response: ARB staff presented the intention to use EIA fuel consumption shares representing data year 2011 in a public workshop and documented it in Appendix C of the ISOR posted in December 2014. The EIA Alternative Fuel User Database represents the most detailed and most recent data available on fuel consumption by California NGVs. Staff will continue to monitor and consider updating vehicle emissions as more recent fleet data becomes available, and invites stakeholder participation in maintaining awareness of available data sources.

Staff agrees that the “fleet average” emission factor is sensitive to the fleet mix (which is represented by the fuel consumption of each vehicle type, rather than the number of vehicles), due to the wide variation in emissions from each vehicle type and application, however, staff maintains the proposed approach for the following reasons:

> The use of a single fleet-wide average emission factor to represent the vehicle operation phase of each fuel CI is established practice for petroleum and other fuels under the LCFS. The variation among NGV types does not constitute sufficient reason to model emissions from NG vehicles differently than other fuels. Staff finds it appropriate to apply a single fleet-wide average emission factor to each fuel CI because the LCFS regulates fuels, and not vehicles. Tracking fuel distribution to each vehicle type and duty application would require an impractical level of documentation and staff believes such onerous measures would be strongly opposed, with little benefit to the accuracy and scientific integrity of the program. .

966. Comment: **LCFS FF35-15**

The comment states that the mix of NGVs is changing and that it is not possible to accurate predict the future fleet mix. The comment further asserts that modest growth in any application could significantly alter the fleet mix.

Agency Response: See response to **LCFS FF35-13**.

967. Comment: **LCFS FF35-16**

The commenter requests that ARB allow fuel producers the option to adjust their pathway carbon intensities based on the vehicle type receiving the fuel.

Agency Response: See response to **LCFS FF35-13**.

To: Chowdhury, Hafizur@ARB
Subject: Use of Revised CI values prior to recertification?

Hafizur:

Since it may not be until well into 2016 before the existing pathways are recertified, I am thinking about whether the revised CI values can be used before the CI's are certified and posted. The answer could have a significant impact on the carbon credit balances for 2016 and also 2017. From the regulations, it appears that perhaps two quarters of volume may be eligible for using the new CI value on a provisional basis before it is certified, if I am reading the proposed regulations correctly. In section 95486(a)(2) dealing with "No Retroactive Credit Generation" there is the following section:

"Notwithstanding this section, the Executive Officer may convert provisional credits to fully transferrable credits at any time, pursuant to section 95488 (d) and (e). Where an application or demonstration pursuant to sections 95488 or 95489 has been completed but not yet approved, the applicant may report, and the LRT-CBTS will reflect, information supporting provisional credits/deficits. Such provisional credits may not be used for any purpose until fully recognized. When the Executive Officer approves the section 95488 or 95489 application or demonstration, the Executive Officer will recognize any such provisional credits generated during the quarter in which the approval takes place, and one previous quarter, provided that the application was complete during that previous quarter."

LCFS FF36-1

Am I interpreting this correctly?

If existing and new pathways in the batches are eligible for this, what will constitute "completeness", which looks like will be one of the requirements?

968. Comment: **LCFS FF36-1**

The commenter is inquiring if revised CI values can be used before the CIs are certified and posted.

Agency Response: All the new and revised CIs under the proposed regulation will be available on or after the effective date of the regulation in order. During the recertification process applicants can continue to use their existing CIs to report to the LRT-CBTS to generate credits. If the applicants do not have any CIs to use, they are allowed to use the temporary CIs (Table 7) until their application is evaluated, certified, and posted.

To: Chowdhury, Hafizur@ARB
Subject: Exclusion from Resubmitting Lifecycle Analysis for Existing Tier 1 Pathways?

Hafizur:
On the phone yesterday, you mentioned that producers with existing Method 2A pathways would not need to resubmit a revised lifecycle analysis to get their pathways recertified. I am looking in the regulations for that exception and cannot locate it. Could you clarify or point me in the direction of that provision in the regulations?

LCFS FF37-1

I see the provision that the demonstration of physical pathway has been "grandfathered" for existing pathways in 95488(e), which was added as part of the changes accompanying the 15 day package, but I don't see a similar provision for the LCA.

Sorry to trouble you if it is there and I can't find it.

Regards,
Logan

37_FF_LCFS_HBC

969. Comment: **LCFS FF37-1**

The commenter is asking if the Life Cycle Analysis (LCA) report is required to process the existing Method 2A fuel pathways.

Agency Response: Applicants are not required to submit the LCA report to recertify their pathways under the legacy pathway process. The legacy pathway recertification process uses information previously submitted by the applicants, unless staff request additional or updated information. However, if applicants submit new pathway, or a revised existing pathway with new data under Tier 1, then they are required to submit the associated documentations stated under the section 95488(a)(2).

To: Chowdhury, Hafizur@ARB
Subject: Batch processing applications

Hafizur:
I would appreciate discussing this topic briefly with you. I am referring to the new section in the modified regs stating:

"Batch" processing in 2016. Applications to recertify fuel pathway certifications, registrations that were approved under the previous LCFS (and still in effect on the date this regulation goes into effect) and new applications for fuel pathways in 2016 will, to the extent feasible, be processed in groups based on fuel type in the following order of priority: ethanol, biodiesel, renewable diesel, compressed natural gas, liquefied natural gas, and all others.

LCFS FF38-1

I need to explain to clients what this means, or might mean, so any guidance would be most helpful. Does it mean there is no hurry in getting revised applications submitted because the last one to submit will get their updated application at the same time as the first? Will there be posted deadlines to be included in a batch, and if not how will it be managed?

What are the possibilities?

If you want to call me, call my cell phone. I'm available anytime today.

Thanks for the heads-up yesterday that this was coming soon!

Thanks!

970. Comment: **LCFS FF38-1**

The commenter is inquiring about fuel pathways recertification and "batch" processing by fuel type.

Agency Response: Under section 95488(a)(2) applicants are required to inform ARB through LRT-CBTS by completing the online account registration process and submitting an electronic New Pathway Request Form prior to February 1, 2016, indicating that they are seeking recertification of a legacy pathway.

In 2016 Staff will process fuel pathways by "batch" according to its fuel type (e.g., ethanol, biodiesel, renewable diesel, compressed natural gas, liquefied natural gas, and all others).

Each batch will be processed and released on the same date. For example, once all the ethanol pathways are processed, regardless of the order of submission within the proposed deadline, they will be certified and released at the same time. Simultaneously, all of the legacy ethanol pathways will be deactivated from the system. Staff selected this approach to avoid any competitiveness impacts.

Similarly, in order to avoid competitiveness impacts, staff's current thinking is that any new application that wishes to be completed prior to the conclusion of each batch must be submitted to ARB prior to February 1, 2016. New applications will, to the extent possible, be processed as part of each batch.

If the Board readopts the LCFS, ARB staff plans to hold a workshop after the board hearing to solicit additional feedback on this process (including feedback on the appropriate completion date for each batch) and provide draft guidance on the new pathway process.

Subject: CA GREET 2.0 Comments - UNICA

Dear Mr. Pham,

My name is Leticia Phillips and I serve as the North American Representative for the Brazilian Sugarcane Industry Association (UNICA).

I wanted to write you with a few comments regarding the CA GREET 2.0 documents that were posted on CARB's webpage on June 4, 2015.

While we appreciate staff's effort to update the electricity resource mix for Brazil, based on the most up to date data, we are still disappointed that CARB is proposing using energy mix all together. We believe Brazilian sugarcane ethanol pathway is only accurately represented if using the marginal electricity resource mix. LCFS FF39-1

On page 2 of the *CA GREET 2.0 Supplemental Documents and Table Changes*, CARB states that "Staff determined that the simplest, most equitable and defensible method is to apply the regional average across all pathways." We believe that the simplest method is to use the marginal values accepted by IPCC – which I believe was already provided to CARB by AgroIcone in Brazil. LCFS FF39-2 We also believe that the adoption of energy mix for Brazil unfairly penalizes the country because it benefits pathways dependant on energy in detriment of pathways that generate energy, like in our case. LCFS FF39-3 And finally, since the original GREET already has a marginal value calculated, it is hard to defend using a new number that worsens the model. LCFS FF39-4

Another point that I do not understand and would like clarification is how each mill will present its electricity credit; kWh per gallon of ethanol. The default value do not exist anymore? LCFS FF39-5

We have always admired and supported the work of CARB staff on the LCFS, we believe it is an incredible program that can curb GHG emissions and deliver better air quality for the citizens of California. We disagree from CARB's move to use electricity resource mix in the CA GREET 2.0 for Brazil. We know you are working on a tight deadline but we urge you to review this decision. LCFS FF39-6

I look forward to continue to collaborate with CARB and to hearing from you.

Best regards,

Leticia Phillips

UNICA

39_FF_LCFS_UNICA

971. Comment: **LCFS FF39-1**

The comment states that the Brazilian sugarcane ethanol pathway is only accurately represented if using the marginal electricity resource mix.

Agency Response: The comment provided is not related to any "15-day changes" being proposed in the Modified Regulation Order posted for public comment on June 4, 2015.[58] ARB staff notes that a response to the concerns re-expressed by the commenter here was provided in the staff response to **LCFS B1-2**. There is no change in staff assessment to warrant an additional response.

972. Comment: **LCFS FF39-2**

The commenter believes that the simplest method for GREET 2.0 is to use the marginal values accepted by IPCC.

Agency Response: See response to **LCFS FF39-1**.

973. Comment: **LCFS FF39-3**

The commenter believes that the adoption of energy mix for Brazil unfairly penalizes the country because it benefits pathways dependent on energy in detriment of pathways that generate energy.

Agency Response: See response to **LCFS FF39-1**.

974. Comment: **LCFS FF39-4**

The comment states that since the original GREET had a marginal value calculated they find it hard to understand using a new number that worsens the model.

Agency Response: See response to **LCFS FF39-1**.

[58] http://www.arb.ca.gov/regact/2015/lcfs2015/regorderfinal.pdf

975. Comment: **LCFS FF39-5**

The comment discusses the methodology to determine the co-product credit for Brazilian sugarcane-based ethanol pathway applicants to the LCFS program who cogenerate and export surplus electricity.

Agency Response: This comment is not related to any "15-day changes" being proposed in the Modified Regulation Order posted for public comment on June 4, 2015. As a courtesy, ARB staff is providing a response.

The co-product will now be based upon the actual surplus export rate of cogenerated electricity as opposed to a default value previously determined for ARB's internal pathway developed for Brazilian sugarcane-based ethanol.[59] Staff believes the actual co-product credit will benefit those applicants who previously could not qualify to meet the minimum, benchmarked rate of surplus cogeneration (0.96 kWh per gallon of ethanol produced), as well as those applicants who cogenerate and export larger amounts of electricity than the default value.

976. Comment: **LCFS FF39-6**

The commenter disagrees with ARB staff's decision to use electricity resource mix in the CA GREET 2.0 for Brazil.

Agency Response: See response to **LCFS FF39-1**.

RE: CARB Low Carbon Fuel Standard Re-Adoption, 15-day package release 6-4-2015

Dear Chairwoman Nichols and Honorable Board Members:

Tesoro appreciates the opportunity to comment on the proposed re-adoption of the Low Carbon fuel Standard (LCFS) and specifically on the 15-day regulatory amendments released on June 4, 2015.

We understand that the Western States Petroleum Association has provided comments on this 15-day package as well. Tesoro generally supports those comments, but wishes to focus comments on some specific implementation issues in Section 95489 (f) – Refinery Investment Credit.

Tesoro appreciates the inclusion of Section 95489 (f) – Refinery Investment Credit which may help companies justify projects to reduce the carbon intensity of transportation fuel production and greenhouse gas (GHG) emissions from the refineries. We raised concerns in our comments on the 45-day amendment package and at the hearing on the restrictive nature of the language originally proposed.

After the 45 day amendment was introduced, we met with staff to discuss specific implementation issues and have found staff to be responsive to some of our concerns and suggestions in the 15-day package. However, we are requesting clarifications on some remaining issues as outlined below.

Eligibility Criteria

95489 (f)(1)(E) precludes projects whose "primary objectives" are refinery equipment shutdowns, reductions in refinery or equipment throughput and refinery maintenance from eligibility. Under the simplest scenario, we understand that shutting down the refinery, reducing crude throughput, or a temporary shutdown of equipment for turnaround maintenance does not qualify as a refinery investment credit project. However, a refinery is a large complex operation comprised of a multitude of complex process units that facilitate complex chemical reactions to convert crude oil to transportation fuels. Consequently, a refinery may find a more efficient means to produce a similar overall volume of transportation fuels in a manner that enables shut LCFS FF40-1 down or reduced throughput at a process unit in favor of operating other units more efficiently. The term "primary objective" in this section appears subjective, to ensure correct interpretation during the implementation phase, we seek additional clarification regarding this requirement as discussed below. LCFS FF40-1 cont.

- Replacement Project: A refinery may replace an old piece of equipment with newer equipment that performs the same function but more efficiently. This may not be identical replacement, but functionally equivalent. Examples include replacing old inefficient boilers used for steam generation with new turbines that generate steam and electricity, and replacing unit heaters or furnaces with newer, more energy efficient units or improved heat integration with exchangers. It is our understanding that although the old equipment is shutdown, the credits created based on the difference between the old and the new unit emissions are qualified for refinery investment credits under CARB's proposal. Please clarify the regulatory intent with respect to this type of project. LCFS FF40-2

- Many projects must be executed when equipment is shutdown during turnarounds. The fact that the project is executed during a maintenance turnaround should not exclude it from eligibility. Please confirm. LCFS FF40-3

- Process Efficiency Improvement Project: There may be instances for which a process unit is shut down due to process efficiency optimization. For example, a refinery found a more efficient means to produce CARBOB or diesel utilizing five instead of six process units integral to the production. Although one of the process units may be shutdown, it is our understanding that this type of project would still be eligible to generate refinery investment credits based on the difference in emissions between the production process with six process units and five process units. Please clarify the regulatory intent with respect to this type of project. LCFS FF40-4

- Similar to the scenario describe above, a refinery may choose to optimize the volume of each transportation fuels produced (CARBOB and diesel.) In doing so, process unit feed volume or output volume may decrease in one process unit (perhaps the less carbon efficient unit) and increase in the other (the more carbon efficient) process unit. Although this project involves reducing throughput in one or more process units, it should qualify for the refinery investment credits. Please confirm that this type of project is still eligible for credit. LCFS FF40-5

<u>Clarification on the Refinery Investment Credit Calculation</u>

1. Additional clarification is needed regarding the definitions of $Volume_i^{XD}$, $Volume_i^{Total}$ and V^{XD} as follows:

a. Does $Volume_i^{XD}$ as expressed in subsections 95489 (f)(2)(B) and (C) represents the annual volume of CARBOB or diesel produced at the refinery including the volume exported, but excluding imported volume? LCFS FF40-6

b. $\text{Volume}_i^{\text{Total}}$ is defined in subsection 95489 (f)(2)(B) as "the total volume of CARBOB and diesel for data year i in bbl." Although the definition did not specifically refer to refinery product output, is it correct to assume that it is the total annual volume of CARBOB and diesel produced at the refinery (including volume exported, but excluding imported volume)?

c. V^{XD} is defined in subsection 95489 (f)(2)(F) as "the volume of either CARBOB or diesel in gallons." Since this is the volume used to determine the amount of refinery investment credits received, is it the intent of the regulation that V^{XD} only include fuel volumes sold, supplied, exchanged, transfer or offered for sale in California? Tesoro would appreciate clarification regarding the treatment of import and export CARBOB and diesel in the determination of V^{XD}.

LCFS FF40-6 cont.

2. As we understand, the value of Volume_i^{XD}, $\text{Volume}_i^{\text{Total}}$ and V^{XD} are to be derived from LCFS Reporting Tool (LRT). However, it is unclear from the proposed regulation which data elements or activities in the LRT are to be extracted from the LRT for determining Volume_i^{XD}, $\text{Volume}_i^{\text{Total}}$ and V^{XD}. We would appreciate a more detail explanation regarding application of data in the LRT.

LCFS FF40-7

Tesoro appreciates the opportunity to submit comments on the LCFS regulation 15-day amendments. Please contact me at (916) 462-5062 if you have any questions.

Sincerely,

Miles Heller
Director, CA Fuels and Regulatory Affairs

40_FF_LCFS_Tesoro

977. Comment: **LCFS FF40-1**

The commenter states that the refinery credit 95489 (f)(1)(E) precludes projects whose "primary objectives" are refinery equipment shutdowns, reductions in refinery or equipment throughput and refinery maintenance from eligibility. The term "primary objective" in this section appears subjective and the commenter seeks additional clarification as specifically cited in **LCFS FF40-2** through **LCFS FF40-5**.

Agency Response: See response to comment **LCFS FF43-47**.

978. Comment: **LCFS FF40-2**

The commenter requests clarification as to the regulatory intent with respect to replacement projects and if replacements would qualify for credit under this provision.

Agency Response: The examples cited would appear to qualify for the refinery credit. However, staff would need to see the full details of the project to make a definitive statement. See response to comment **LCFS FF43-47**.

979. Comment: **LCFS FF40-3**

The commenter requests confirmation that when a project is executed during a maintenance turnaround, this does not exclude it from eligibility.

Agency Response: The fact that a project is executed during a maintenance turnaround is not likely to exclude it from the refinery credit. However, the reduced emissions during the shutdown would also not be eligible for credits. ARB staff would need to see the full details of the project to make a definitive statement. See response to comment **LCFS FF43-47**.

980. Comment: **LCFS FF40-4**

The commenter requests clarity on specific types of refinery projects.

Agency Response: One of the purposes of the refinery investment credit is to incent innovative projects that change the way petroleum is currently refined. It is hard to say if the project mentioned in the comment would qualify for a refinery investment credit without more details. On the surface it would appear this project would qualify as a permanent equipment shutdown and would not be eligible for a refinery investment credit. However, if the applicant could show that through some revolutionary optimization technique or equipment modification, that the refinery only needed five pieces of equipment instead of six, while still processing the same inputs to produce CARBOB or diesel, then the project may qualify for a credit. However, staff would need to see the full details of the project to make a definitive statement.

981. Comment: **LCFS FF40-5**

The commenter asks that if a process unit feed volume or output volume decreases in one process unit (perhaps the less carbon efficient unit) and increases in the other (the more carbon efficient) process unit does it qualify for the refinery investment credits?

Agency Response: As mentioned above, the objective of the credit is to incentivize innovative projects and one output to another would not qualify. However, staff would need to see the full details of the project to make a definitive statement. See response to **LCFS FF40-4**.

982. Comment: **LCFS FF40-6**

The commenter requests clarification of the following terms: $Volume_i^{XD}$, $Volume_i^{Total}$_, and V^{XD}.

Agency Response: $Volume_i^{XD}$ represents the annual volume of CAROB or diesel produced at the refinery, excluding imported volumes of finished CARBOB or diesel.

$Volume_i^{Total}$ is meant to represent the total annual volume of CARBOB and diesel produced at the refinery (including volume exported, but excluding imported finished CARBOB or diesel).

V^{XD} in 95489 (f)(2)(F) is meant to represent the total annual volume of CARBOB or diesel produced at the refinery that is sold, supplied, exchanged, transfer or offered for sale in California. Import and export volumes of finished CARBOB and diesel are not meant to be a part of V^{XD}.

983. Comment: **LCFS FF40-7**

The comment states that it is unclear from the proposed regulation which data elements or activities in the LRT are to be extracted from the LRT for determining $Volume_i^{XD}$, $Volume_i^{Total}$ and V^{XD}.

Agency Response: ARB staff is currently working to update the LRT to incorporate amendments to the LCFS regulation. That process is ongoing and staff will provide additional detail in the near future.

California Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: Proposed 15-Day Regulation Order, Low Carbon Fuel Standard

Dear Mr. Waugh and LCFS Staff:

We appreciate this opportunity to provide the comments of ChargePoint, Inc. (ChargePoint) on proposed changes to the regulations governing California's Low Carbon Fuel Standard (LCFS) issued on June 4, 2015 pursuant to the Notice of Public Availability of Modified Text and Availability of Additional Documents and Information (Notice) relating to the Proposed Re-Adoption of the LCFS. We strongly support the goals of the LCFS program, and recognize the California Air Resources Board (ARB) as a national leader in implementing this important program as part of the state's larger effort to reduce the carbon intensity of transportation fuels and decrease greenhouse gas (GHG) emissions for the benefit of all Californians. For the reasons discussed below, ChargePoint urges you to modify the proposed changes in the regulations addressing requirements for Regulated Parties for Electricity.

Introduction

Headquartered in Campbell, California, ChargePoint is the world's largest and most open EV charging network with more than 22,000 level 2 and DC fast charging spots. Every 6 seconds, a driver connects to a ChargePoint station and by initiating over 9.65 million charging sessions, ChargePoint drivers have driven over 210 million gas free miles.

Since 2009 ChargePoint has been actively participating in the development of the LCFS regulations before the ARB, and in proceedings at the California Public Utilities Commission to establish procedures for use of the revenues from sale of LCFS credits by the jurisdictional investor-owned utilities.

ChargePoint has not yet registered as a regulated party, but is preparing to do so. In fact, ChargePoint has been involved for some time in evaluating approaches to participation in the market for LCFS credits, and considering how it may effectively monetize the value of LCFS credits for the benefit of EV drivers and site hosts under the regulations applicable to public access, workplace and multi-unit dwelling locations. This process has taken time for two reasons: (1) As a business participating in an expanding and competitive market, ChargePoint has had to weigh the initial and ongoing costs of participation in the LCFS program as a regulated party against the benefits to the company and its customers, EV drivers and site hosts. (2) It was unclear in the very early period of LCFS credit market development how the market would function and what opportunities would be available to third parties. As market growth accelerates, third parties like ChargePoint are now in a position to begin participating in the LCFS program, using the network functions and embedded metering in networked charging stations to facilitate participation and deliver value to EV drivers and the site hosts that have invested in EV charging infrastructure and services.

The key to facilitating participation by third parties will be clear rules and a simple, straightforward process. If the procedures for opting in as a regulated party for electricity are burdensome or administratively complex, third parties cannot be expected to participate in the program, and the value of their participation will be lost. For this reason, ChargePoint opposes the proposal to alter the current default designations in Section 95483(e) of the LCFS Regulations.[1]

LCFS FF41-1

The default provisions for Regulated Parties for Electricity should not be changed.

On June 4, 2015 ARB issued a Notice of Public Availability of Modified Text proposing modifications to the current LCFS regulations. These reflect modifications discussed in the February 19, 2015 public hearing process, and additional changes subsequently proposed by ARB staff.

Among the new proposed changes are modifications to Section 95483(e) of the LCFS Regulations that will impose additional obligations on non-utility providers of EV charging services at public charging, EV fleet and non-public workplace locations. Specifically, Sections 95483(e)(2), (3)(A) and (4) of the LCFS Regulations have each been revised to designate the Electrical Distribution Utility as the default regulated party rather than the Electric Vehicle Service Provider (EVSP) (in the case of public access EV charging), the fleet operator (in the case of fleet charging), and the site host (in the case of private access EV charging equipment at a business or workplace. These proposed revisions are not supported by factual explanation or statement of reasons, and could disadvantage third party providers of charging services. There is no need for "clarification" since the existing regulations clearly establish the utility's ability to generate LCFS credits at sites where the EVSP, fleet operator, or workplace site host chooses not to participate in the program.

LCFS FF41-2

Public Access EV Charging

Under the existing regulations, an EVSP "that has installed the equipment, or had an agent install the equipment, and who has a contract with the property owner or lessee where the equipment is located to maintain or otherwise service the charging equipment" is eligible to generate LCFS credits if it complies with applicable registration and reporting requirements.[2] If the EVSP is not reporting or has not complied with the requirements to opt in as a regulated party, the Electric Distribution Utility is entitled to generate credits at the location, provided it requests and receives Executive Officer approval.

The proposed regulations reverse the current default provision, obliging the EVSP to request and obtain approval by the Executive Officer in order to opt in and generate credits at a public access EV charging location.[3] It is unclear whether an EVSP must go through this process on a location by location basis, or whether a single submittal may cover multiple locations. The ARB staff has previously observed that the non-utility EVSPs were designated as the default regulated parties for public access charging because "[t]he credit revenue that they will be eligible for will reward them for establishing the public charging network that is required to support a successful EV market."[4] This reasoning remains sound.

LCFS FF41-3

In order to effectuate the purpose of rewarding third party EVSPs for their investments and provide an incentive for further private sector investment in public EV charging, the regulations should remain unchanged. EVSPs already must comply with all applicable registration and reporting requirements in order to receive LCFS credits from public access EV charging stations. Imposing the additional step of requesting

[1] 17 CCR §95483.
[2] LCSF Regulations § 95483(e)(2).
[3] Proposed LCFS Regulations p. 20.
[4] State of California, Air Resources Board, Staff Report: Initial Statement of Reasons for Proposed Rulemaking (October 26, 2011) p.45.

–chargepoint.

Executive Officer approval on the EVSP is unnecessary and could serve as a disincentive to participation. This proposed change has already raised questions among industry participants currently considering participation in the program. The utilities have ample resources to meet this requirement in the event that the EVSP serving a public access location chooses not to participate in the program, and so there is no reasonable justification for change. The regulations should retain the EVSP as the default party. LCFS FF41-3 cont.

If the proposed change is adopted and EVSPs are obliged to submit a written request for Executive Officer approval in order to opt in and generate LCFS credits, the process should be simple and streamlined. For example, an EVSP should be permitted to seek and be granted approval for multiple locations in a single request.

EV Fleet Charging

In a manner similar to the proposed change applicable to public access charging, the proposed regulations would shift the obligation to seek Executive Officer approval to generate credits associated with fuel supplied to a fleet of EVs onto the fleet operator rather than the Electric Distribution Utility.[5] For the reasons discussed above, this proposal should not be adopted.

LCFS FF41-4

If the proposed change is adopted and fleet operators (or their agents) are obliged to submit a written request for Executive Officer approval in order to opt in and generate LCFS credits, the process should be simple and streamlined. For example, a fleet operator with EVs at multiple locations, or an agent representing fleet operators at multiple locations should be permitted to seek and be granted approval for multiple locations in a single request.

Private Access EV Charging

The proposed regulations also shift the obligation to seek Executive Officer approval from the utility to site hosts at a business or workplace offering EV charging services.[6] For the reasons discussed above, this change has not been justified. Again, in order to appropriately reward site hosts for their willingness to provide a location for on-site charging to employees and visitors, and to encourage such private investment, the process through which the site host can receive and monetize LCFS credits should be as simple and straightforward as possible.

LCFS FF41-5

If the proposed change is adopted and site hosts are obliged to submit a written request for Executive Officer approval in order to opt in and generate LCFS credits, the process should be streamlined and user-friendly. Businesses or workplace owners (or their agents) should be permitted to seek and be granted approval for multiple locations in a single request. It is not clear why the term "business owner" has been replaced with "site host." It will be important for ARB to recognize that site hosts' arrangements with providers of EV charging equipment and services vary, and the term "site host" should be interpreted inclusively.

Let the Market Grow

As noted above, the Notice does not explain why the staff is proposing changes to section 95483(e) when the market for EVSE, EV charging services, and LCFS credits are just beginning to grow and flourish. This would seem the right time to take exactly the opposite approach, and avoid unnecessary regulatory changes that may send mixed signals to new market participants. LCFS FF41-6

[5] Proposed LCFS Regulations p. 21.
[6] Id. p.22.

If the proposed changes in default provisions in Section 95483(e) are due to a misperception that only utilities are interested in participating as regulated parties, or that third parties are unable or unwilling to consider participating in the LCFS program, ChargePoint encourages further discussion and fact finding. As discussed above, we are actively engaged in preparation to register as a regulated party, and are aware that other third party providers of EV charging services are as well. We urge ARB not to make assumptions based on an early and undeveloped market, but rather to make every effort to facilitate broader participation by providers of public and private access charging, fleet operators, and site hosts.

LCFS FF41-6 cont.

Conclusion

ChargePoint appreciates this opportunity to provide comments on the current proposed revisions of the LCFS Regulations.

Sincerely,

Colleen Quinn

Colleen Quinn
Vice President, Government Relations and Public Policy
ChargePoint

41_FF_LCFS_CP

984. Comment: **LCFS FF41-1**

The commenter opposes the proposed 15-day change they believe sets Electrical Distribution Utilities (EDUs) as the default credit generators for many of LCFS electricity provisions, since it will increase burdens and administrative complexities of EVSP.

Agency Response: ARB staff agrees that the process for opting in as a regulated party for electricity should not be burdensome or administratively complex. Staff disagrees that the changes to Section 95483(e) have increased the administrative burden on EVSPs. See the response to **LCFS FF41-2** below for more details.

985. Comment: **LCFS FF41-2**

The comment states that the proposed 15-day will impose additional obligations on non-utility providers of EV charging services at public charging, EV fleet, and non-public workplace locations and that the regulations have been revised to designate the Electrical Distribution Utility as the default regulated party rather than the Electric Vehicle Service Provider (EVSP) (in the case of public access EV charging), the fleet operator (in the case of fleet charging), and the site host (in the case of private access EV charging equipment at a business or workplace.

Agency Response: We believe the commenter may have misinterpreted the intent of the rule language. The final proposal does not set Electrical Distribution Utilities (EDUs) as the default credit generators for public charging, EV fleet and non-public workplace charging. It merely clarifies the eligibility framework and streamlines the reporting requirements for all parties.

EDUs are eligible to generate credits from these EV charging activities if no other party is interested in generating the credits. The prior language was unclear as to how this lack of interest from other parties would be communicated so that a utility knew to request credits for public, workplace and fleet charging (e.g., the utility had no way of knowing if an non-utility Electric Vehicle Service Provider (EVSP) was opting not to participate in the program).

The changes in the final proposal clarify that the utility is eligible to claim the credits for charging that it has accurate data for on its system, until another party steps forward and opts in to supersede the utility's claim. Under such a circumstance, the EDUs are no longer eligible for the credits, and ARB staff will make administrative changes to the LRT accounts of the EDUs and EVSP to inform both parties and avoid double counting of the credits.

Staff also notes that under the current LCFS regulation, the EVSP has to opt in to the LCFS to be eligible to generate credits. In the proposed rule, more detail is provided about this opt-in process. Specifically, the EVSP is eligible to generate credits, "upon submittal to and approval by the Executive Officer of its written acknowledgement that it will opt in and generate credits." Therefore the proposed 15-day change neither increase burden nor imposes additional obligations for EVSPs. The adjustments merely provide additional clarity about the process for opting in.

Currently, public, workplace and fleet charging activities have not been an active source of credit generation in the program. Staff believes these clarifications will encourage utility participation in these areas and help avoid "stranded credits" associated with public, workplace and fleet EV charging that is currently occurring.

It is ARB's intention to keep the approval process for EVSP requests as simple and streamlined as possible. We encourage the EVSPs to include multiple locations in a single application.

986. Comment: **LCFS FF41-3**

The comment states that, for public EV charging, the proposed 15-day will impose additional step for the EVSPs to request and obtain approval of the Executive Officer in order to opt in and generate credits. The comment further states that there is no need to make such change since under current LCFS regulation as the utilities can generate the credits if EVSPs choose not to. The comment states that if the proposed regulation is adopted, the process for EVSP to request ARB approval should be simple and streamlined.

Agency Response: See response to **LCFS FF41-2**.

987. Comment: **LCFS FF41-4**

The comment repeats similar concerns to comment **LCFS FF41-3** for EV fleet charging. The comment states that if the proposed regulation is adopted, the process for EV fleet owner to request ARB approval should be simple and streamlined.

Agency Response: See response to **LCFS FF41-2**.

988. Comment: **LCFS FF41-5**

The comment repeats similar concerns for **LCFS FF41-3** and **LCFS FF41-4** for EV fleet charging.

Agency Response: See response to **LCFS FF41-2**.

989. Comment: **LCFS FF41-6**

The comment urges ARB not to make assumptions based on an early and undeveloped market, but rather to make every effort to facilitate broader participation of providers of public and private access charging, fleet operators, and site hosts.

Agency Response: ARB staff agrees and commits to make every effort to facilitate broader participation of providers of public and private access charging, fleet operators, and site hosts.

Comments to the California Air Resources Board

Modified Text and Availability of Additional Documents and Information for the Proposed Re-Adoption of the Low Carbon Fuel Standard

NexSteppe Inc. (NexSteppe) appreciates the opportunity to submit comments on the Low Carbon Fuel Standard Proposed 15-Day Regulation Order (LCFS). NexSteppe, headquartered in South San Francisco, California, is a developer and producer of high performance sweet sorghum and biomass sorghum hybrids. Our sweet sorghum hybrids are grown as feedstocks for advanced ethanol (as a supplement to sugar cane) and our biomass hybrids as a feedstock for cellulosic ethanol on a worldwide basis.

We commend the collaborative nature of CARB's rulemaking process. We have reviewed the LCFS and offer the following comments:.

1. We note that in Table 7 of the LCFS there is no default pathway for new cellulosic feedstock crops being converted to ethanol nor for sugar crops being converted to ethanol (similarly to sugar cane). The only feedstock listed is corn stover, a feedstock that is not optimized for ethanol production and is not available in many parts of the United States. We do not believe that the cellulosic ethanol industry will be able to supply sufficient fuel at competitive prices using only corn stover as a feedstock- and the omission of all other cellulosic feedstock crops from this table disadvantages many of the feedstocks that will be used in the production of cellulosic ethanol. Examples of those feedstocks would be biomass sorghum, arundo donax, switchgrass, miscanthus, woody biomass among others. LCFS FF42-1

2. In Table 5 there is an iLUC number quoted for "sorghum ethanol." We assume that this refers to ethanol derived from the grain of the sorghum plant—not ethanol produced from the cellulosic sugars present in biomass sorghum or the free sugars LCFS FF42-2

LCFS FF42-2 cont.

present in sweet sorghum. We request that this iLUC value be accordingly limited to grain sorghum.

3. Under Section 95488(d)(2) the LCFS proposes to issue "provisional certification of a fuel pathway application" but only in the event that the facility has been "in full commercial production for one full calendar quarter." We interpret this as requiring any cellulosic ethanol facility (regardless of how long it has been in operation) to report data for a full calendar quarter of operation with any new feedstock before a provisional certification is issued. To put this in perspective; we would estimate that to operate a 30 million gallon per year commercial cellulosic ethanol facility for 90 days would require nearly 100,000 dry tons of feedstock—or in the case of biomass sorghum— approximately 4,000 to 5,000 hectares of production. The story would be similar for other feedstocks—switchgrass, miscanthus, arundo donax etc. We do not see how, under this requirement, any producer could reasonably be expected to add new feedstocks to its supply chain given the significant cost of such a trial. The proposed regulation entrenches feedstocks and appears to create a significant barrier to the adoption of new feedstocks.

LCFS FF42-3

4. We also note that the LCFS appears to require two years of "full commercial production." For reasons driven by cost, land required for storage of biomass and risk many cellulosic ethanol producers will use a mix of feedstocks delivered on a "just-in-time" basis. The same will occur in cane-to ethanol plants that adopt sweet sorghum as a supplementary feedstock. In these scenarios one feedstock will be used for only part of a year—if "two years of commercial production" were in fact to be required (aggregating that part of any year in which a feedstock is used) we anticipate that provisional status would persist for some feedstocks anticipated by the LCFS. Indeed, if a plant were to use a mix of biomass sorghum, corn stover, switchgrass and wood chips (a supply chain design that is not uncommon) it would take nearly 8 years for any feedstock to move off provisional status. If cellulosic ethanol plants want to use new feedstocks as they become available during the course of their operational life it's possible that they could be on permanent provisional status.

LCFS FF42-4

5. In order to solve this problem we request that CARB consider issuing "feedstock-only" pathways that would allow existing conversion plants to implement new feedstocks without the one calendar quarter or two-year requirement. Feedstock only pathways would allow the rapid and broad adoption of new, innovative feedstocks with pre-determined cabon intensity scores without years of uncertainty connected to provisional LCFS credits. LCFS FF42-5

We hope that you find these comments useful and look forward to working with CARB on the implementation of the LCFS. Please do not hesitate to contact us if we can be of any assistance in this matter.

Respectfully submitted,

990. Comment: **LCFS FF42-1**

This comment is related to temporary fuel pathway codes in Table 7 as they relate to cellulosic feedstocks.

Agency Response: ARB staff notes that this comment is not related to 15-day changes being proposed in the Modified Regulation Order proposed on June 4, 2015. As a courtesy however, staff is providing a response to the commenter's comment.

Staff apologizes for the oversight. A cellulosic ethanol producer may use the corn stover temporary FPC in Table 7, if necessary, and can obtain a specific feedstock/fuel pathway under Tier 2 through the normal pathway application process. Similarly, regarding other sugar based feedstocks/fuels, an applicant can use the, "any starch or sugar feedstock" as a temporary fuel pathway code until the applicant obtains a specific pathway and CI for their feedstock/fuel.

991. Comment: **LCFS FF42-2**

The commenter notes that in Table 5 there is an iLUC number quoted for "sorghum ethanol." They assume that this refers to ethanol derived from the grain of the sorghum plant—not ethanol produced from the cellulosic sugars present in biomass sorghum or the free sugars present in sweet sorghum. The commenter requests that this iLUC value be accordingly limited to grain sorghum.

Agency Response: The iLUC values published for sorghum ethanol represents grain sorghum derived ethanol.

992. Comment: **LCFS FF42-3**

This comment is related to the requirement that fuel production facilities be operating for one calendar quarter prior to applying for an LCFS fuel pathway.

Agency Response: ARB staff notes that this comment is not related to 15-day changes being proposed in the Modified Regulation Order proposed on June 4, 2015. As a courtesy however, staff is providing a response to the commenter's comment. The commenter is not correct with respect to the length of time a facility is in commercial production. A facility must be in commercial production for one full calendar quarter prior to being able to apply for an LCFS fuel pathway. If a pathway applicant changes their process significantly in order to process a different feedstock that they did not apply under an existing pathway then staff will work with the applicant to determine what must be done. In general, staff will be conducting workshops after Board Hearing and providing guidance for many circumstances that stakeholders have questions and comments about. Please refer to the response under comment **LCFS FF27-3** for further explanation.

993. Comment: **LCFS FF42-4**

This comment is related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes. In addition, the commenter questions how new feedstocks could be brought into production if two years of data is required.

Agency Response: See response to **LCFS FF20-1**.

Regarding using supplementary feedstocks in current pathways that reduce the CI, staff is intrigued but needs to evaluate a proposal in more detail before we can develop a framework for such an approach. We would be happy to engage with the commenter further about how to appropriately balance the commercial needs of this business model with the need to have accurate (or at least conservative) CI values in the program.

994. Comment: **LCFS FF42-5**

The commenter suggests that staff provide for feedstock only pathway as a way to solve problems related to the provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: See response to **LCFS FF20-1** and **LCFS FF42-4**.

Dear Clerk of the Board,

Re. Proposed Re-Adoption of the Low Carbon Fuel Standard
Notice of Public Availability of Modified Text and Availability of Additional Documents and Information

The Western States Petroleum Association (WSPA) is a non-profit trade association representing twenty-five companies that explore for, produce, refine, transport and market petroleum, petroleum products, natural gas and other energy supplies in California and 5 western states.

Attached is a set of comments – both general and specific – that continue to concern WSPA. We support the inclusion of an additional Periodic Review of the LCFS in 2017. We are prepared to engage again next year, in advance of the 2017 review, in updating the data relative to the projected feasibility and health of the program. LCFS FF43-1

If there are any questions or a need for additional clarification of our comments, please contact Gina Grey of my staff (ggrey@wspa.org) to arrange for further dialogue with WSPA.

Sincerely,

c.c. S. Wade – ARB

<u>Western States Petroleum Association's Comments on ARB's 15-day Notice of Public Availability of Modified Text and Availability of Additional Documents for the Amendments to the Low Carbon Fuel Standard Regulation.</u>

General

WSPA believes that regulations should be based on sound science and free market principles, including a level playing field for all parties. Regulations should also include cost/benefit considerations and provide a clear and reasonable regulatory framework. Several elements of the amendments in the ARB's LCFS 15 day package do not satisfy these criteria; thus we respectfully request ARB revise this package to include these considerations.

Some of our core comments are presented below, with more detailed comments included in the following pages:

- WSPA continues to strongly object to the extremely limited accountability placed on electricity providers in generating LCFS credits. This is in dramatic contrast to the extremely rigorous application process and detailed record-keeping and reporting required on the part of liquid fuel suppliers and does not support the notion of a "fuel neutral" program as the LCFS is purported to be. LCFS FF43-2

- ARB proposes several new and modified methods of credit generation, but with arbitrary and disparate effective dates. This seems to serve no purpose other than to favor one credit generation methodology over another. Staff should move immediately to align the effective dates of all applicable segments of the regulation (e.g., electricity, refinery investments, and innovative crude pathways) to ensure fairness in the treatment of compliance options. LCFS FF43-3

- Credit accounting continues to be exceedingly complex, and the amendments in this 15-day package exacerbate these issues. With over 250 pathways approved by ARB, the lack of ARB oversight as to the validity of those credits and pathways, and a changing regulatory environment in which all fuel pathways must be recalculated using new model criteria, ARB cannot reasonably expect fuel suppliers to verify those credits with such an overly complex accounting system. LCFS FF43-4

- Credit generation from light and heavy duty rail use is inconsistent with both the intent and the ISOR for the LCFS, and should be removed from the program. LCFS FF43-5
    - The use of light and heavy duty rail existed prior to the implementation of the LCFS; as such, its use is not further reducing GHGs from the transport sector.
    - If ARB chooses not to remove these provisions, then ARB must account for such credits distinctly in ARB's quarterly summaries from other electricity credits so stakeholders can understand the contribution from these pre-existing sources.

- The Credit Clearance Market, in which deficit holders must participate, exacerbates an infeasible target, is not market-based, and does not provide the opportunity for fuel suppliers to evaluate the validity of credits. In addition, the publication of a list of Credit Clearance Market LCFS FF43-6 participants and each party's outstanding deficit obligation violates confidential business information practices. The inappropriate disclosure of this information has the distinct possibility of harming a given participant's competitive position in the market. LCFS FF43-6 cont.

- It is critical that staff clarify the language in §95488 apparently prohibiting the sale of credits or fuel with obligation associated with new fuel pathway applications for up to two years. Staff has acknowledged that the currently proposed draft language does not represent what was intended and a very clear message must be issued to allow fuel producers some certainty. LCFS FF43-7

- WSPA does not believe credits generated from the refinery investment credit provisions (as written) will contribute substantially to meeting fuel suppliers' compliance obligation. Despite some positive changes in the 15 day package, the characterization of these provisions as "pilot programs" and the significant barriers that still exist in the draft language substantively impede valid credit generation in apparent conflict with what ARB hopes to incentivize with the measure. LCFS FF43-8

- ARB should not delete the multimedia evaluation provisions from the proposed regulations; to the contrary, ARB should be undertaking a multimedia evaluation for the LCFS as required by California Health & Safety Code. Multimedia evaluations are necessary in order to obtain a full and independent assessment of the range of potential environmental impacts of any newly proposed fuel regulations across all media. ARB's ADF multimedia evaluation and failure to undertake the required multimedia evaluation for the LCFS have not addressed the significant water demands associated with the production and use of biofuels under the LCFS, which may potentially exacerbate the severe drought California currently faces. LCFS FF43-9

Specific

Revised Compliance Schedule

WSPA received confirmation from ARB staff that new compliance information will be provided to the ARB Board at the July 23rd hearing, and we'd like ARB to once again confirm that this information will be provided prior to the July hearing. Additionally, the revised compliance schedule is missing from the staff package. WSPA requests it be re-included. LCFS FF43-10

Arbitrary Dates for Credit Generation

The LCFS reauthorization regulations contain multiple internal inconsistencies with respect to measuring CI reductions and the generation of credits. For example, even though the base year for measuring CI reductions under the regulations is 2010, the regulation as proposed uses refinery energy consumption data from 2011 through 2013 as the basis for estimating the petroleum refining process CI, rather than 2010 data. LCFS FF43-3 cont.

Further, credit generation for fixed guideway systems and electric forklifts is permitted without regard to when these projects began operation. Yet, energy efficiency improvements implemented in petroleum refineries between 2010 and 2016 cannot generate credits, despite the fact that they have reduced the CI of the products.

Innovative crude production credits are available for solar steam and carbon capture and sequestration (CCS) projects that became operational as early as 2010, but are not available until January 1, 2015 for all other innovative crude production projects. There appears to be no consistency in the regulation's various segments as to a common date threshold of eligibility for credit generation.

The following chart illustrates this observation:

Element	***Proposed Code Section***	***Effective Date After Which Credits Can Be Generated***
Fixed guideway systems	95483(e)(6)	No threshold for eligibility—credits can be generated regardless of when operation began
Electric forklifts	95483(e)(7)	No threshold for eligibility—credits can be generated regardless of when operation began
Solar steam and CCS projects	95489(d)(1)(B)	2010
All non-solar steam and carbon capture and sequestration innovative crude projects	95489(d)(1)(B)	2015
Low-energy intense refineries	95489(e)(4)(B)	2015
Refinery investment credits	95489(f)	2017 (Permits received by 1-1-2016 –projects take at least 1 year to construct)

LCFS FF43-3 cont.

It is well-settled under California law that "logic and reason demand that [an] agency explain the basis for its decision." *McBail & Co. v. Solano County Local Agency Formation Com'n* (1998) 62 Cal.App.4th 1223. During the rulemaking process, an agency must provide a rationale for the elements of the proposed regulations; to be valid, regulations must be consistent. *Harris Transportation Co. v. Air Resources Board* (1995) 32 Cal.App.4th 1472, 1479; *see also Voss v. Superior Court* (1996) 46 Cal.App.4th 900, 916.

Federal courts agree that "an internally inconsistent analysis is arbitrary and capricious." *National Parks Conservation Association v. EPA*, Case No. 12-73757 (9th Cir. June 9, 2015), *see also Gen. Chem. Corp. v. United States*, 817 F.2d 844, 857 (D.C. Cir. 1987). An agency cannot simply mandate key elements or formulas within a regulation without an explanation of the basis for that decision. *National Parks Conservation Association, at *15-16*. Instead, an agency must explain the basis for exercising its discretion to craft a regulation in a particular manner; failure to do so will render the regulation invalid as arbitrary and capricious. *Id. at *17*.

But here, ARB proposes an internally inconsistent regulation with no explanation regarding the selection of incongruous dates to serve as the bases for credit generation for certain elements of the regulation. WSPA objects to this level of inconsistency between elements and proposes that ARB adopt consistent dates for credit generation across the board. At the very least, ARB must offer its basis for the existing inconsistency between dates. LCFS FF43-3 cont.

California Reformulated Gasoline and Ethanol Denaturant Calculator Spreadsheet

WSPA understands staff has made changes to the California Reformulated Gasoline and Ethanol Denaturant Calculator Spreadsheet since it was last posted. Since this spreadsheet is used not only to calculate the new baseline CaRFG values but also the new ethanol CI values, WSPA requests that the final version of this spreadsheet be posted for public review. LCFS FF43-11

§ 95481.(a) Definitions

(9) "Biodiesel Blend" - The term "biodiesel blend" is not used anywhere in the LCFS regulation outside this section. The definition should be deleted.

(63) "Petroleum Product" - It is inappropriate to include co-processed biomass in the definition for "petroleum product." Staff should consider a broader term like "refinery product" to avoid confusion.

(67) "Product Transfer Document" - We continue to object to the redefining of "product transfer document" as a single document consolidating information from existing documents. This term should follow the traditional definition to allow flexibility for regulated parties. LCFS FF43-12

(71) "Renewable Hydrocarbon Diesel" – we would prefer the definition include a reference to "elemental composition primarily of hydrogen and carbon". We also have concerns with the definition indicating that a fuel additive may be defined as "Renewable Hydrocarbon Diesel" as currently written.

Suggested language:

(71) "Renewable hydrocarbon diesel" means a diesel fuel that is produced from nonpetroleum renewable resources but is not a mono-alkyl ester, with an elemental composition primarily of hydrogen and carbon, and which is registered as a motor vehicle fuel under 40 Code of Federal Regulations Part 79.

§95483 (a)(2)(A-D). Regulated Parties

We are opposed to the deletion of this section and the associated edits in this section.

Striking a significant block of language related to the identification of regulated parties under the LCFS as part of a 15-day package, with no prior discussion of the change in the many workshops on the LCFS re-adoption, is arbitrary and capricious. Furthermore, this change does not add value to the program and does not address any issues with current compliance. What it does do is introduce an element of risk into compliance by removing the automatic transfer of obligation between regulated parties as product moves through the distribution system upstream of the terminal rack. Summarily removing this language increases the risk of discrepancies between the reports of regulated parties and unnecessarily complicates the nature of transactions between regulated parties. While staff characterizes this as "an unnecessary and complicated provision" in their explanation of the proposed change, the time to address such an issue would have been at the establishment of the program, not several years after the regulated community has developed business processes based upon the provision. LCFS FF43-13

§95483. (e)(2), (e)(3)(A), (e)(3)(B), (e)(4), (e)(5)

As WSPA has stated numerous times in the past, we strongly oppose ARB's electricity provisions, and continue to propose that electricity NOT be part of the LCFS program. ARB should account for the GHGs from electricity separately and reduce the compliance obligation within the LCFS proportionally based on ARB's anticipated success of the roll-out of electric vehicles (EVs). LCFS FF43-14

In addition, we have new concerns specifically related to changes in the 15-day proposed rulemaking package. In general, WSPA feels these changes:

- Are substantive and should not be included in a 15-day regulatory package, LCFS FF43-15
- Are not explained or justified in the Notice of Public Availability, LCFS FF43-16
- Exasperate the un-level playing field for electricity providers, by further reducing their public accountability, recordkeeping, and metering requirements. LCFS FF43-17
- Increase concern regarding validity of credits generated from the electricity sector, and the decreasing amounts of due-diligence and reporting required by providers of electricity as a "transportation fuel". LCFS FF43-18
- Are not clear in regards to whether anyone will make sure there is a true accounting of credits generated from electric vehicle charging. LCFS FF43-19
    - If electricity providers are generating credits from residential charging from registration records and average electricity demand, will ARB subtract credits generated from private / workplace charging?
    - From fleet charging?
    - From public charging?

WSPA strongly opposes the following 15-day changes related to §95483(e) provisions:

1. ***Removal*** of the requirement that Electrical Distribution Utilities to "Use all credits proceeds to benefit current or future EV customers" (§95483(e)(1)(A)) from credits generated from public access charging, EV Fleets, or private EV charging (§95483(e)(2 - 4)). We urge ARB to correct the following reference in all parts of §95483(e) from: LCFS FF43-20

   "must meet the requirements set forth in section 95483(e)(1)(B) through (D)."

   To:

   "must meet the requirements set forth in section 95483(e)(1)(A) through (D)."

2. Under §95483(e), ARB's modifications make the electric distribution utility the default credit generator in essentially all EV charging cases. This approach could have the consequence of the utilities using their power to restrict innovation and experimentation within the electric vehicle charging industry. Instead, ARB should allow the market and customer choice to guide development by allowing companies installing electric vehicle charging stations to generate credits by default. LCFS FF43-21

3. Removal of the list of efforts that may be used to educate the public in 95483(e)(1)(B). LCFS FF43-22

4. Removal of the requirement that ARB post supplemental information for public review each year. LCFS FF43-23

5. The modification to allow investor owned utilities to use Public Utility Commission reporting in lieu of LCFS specific supplemental information. LCFS FF43-24

Furthermore, technology exists to directly measure residential EV electricity use and therefore should be required, consistent with recordkeeping required for other LCFS pathways. We incorporate by reference our February 2015 comments on the electricity provisions in our response to comments for the 45-day rulemaking package. LCFS FF43-25

Combined, these proposed modifications further reduce the standards that electricity providers are held to, as compared to liquid fuel providers. As WSPA has stated in the past, there is also a fairness issue. Liquid fuel providers are expected to submit extremely detailed records for reporting and comply with extensive application processes for obtaining a CI pathway (and the record-keeping requirements for some pathways). The proposed reduction in accountability and reporting requirements for electricity providers, combined with the "estimates" of electricity used for residential charging, does not support the notion of a "fuel neutral" program, and provides inconsistent treatment at best. LCFS FF43-26

In addition, it is not clear from the proposal whether a proper accounting of total credits from electric vehicle charging will be performed by ARB. LCFS FF43-27

§95485. Demonstrating Compliance (Cost Containment Mechanism)

WSPA's concerns regarding the Cost Containment Mechanism (CCM) contained in the LCFS re-adoption package remain, as the proposed 15-day package revisions do not implement any substantial modifications to address the previously-raised concerns regarding this tool's ability to accommodate systemic and prolonged LCFS credit shortages. WSPA remains opposed to the inclusion of the CCM in the LCFS because we do not believe that it will accomplish its stated objective (contain prices) and will instead have a number of undesirable (and unintended) consequences. More specifically, the Credit Clearance Market (CCM): LCFS FF43-28

Offers no certain path to retire carryover deficits

The CCM provisions in the LCFS re-adoption package (post the proposed 15-day package revisions) continue to obligate parties to participate in the year-end credit clearance market at prices as high as the pre-determined "cap" price and parties have no recourse but to carry over any remaining deficit into the following year with interest. The CCM provisions stipulate a five-year maximum deficit carryover period but no specific pathway to retire deficits if shortages persist year to year. Instead, obligated parties face the prospect of an ever-increasing accrued financial liability that is essentially outside their control. In a market that is consistently short credits year after year, the ability to defer unsatisfied obligations (with interest) offers little comfort to the regulated community who remained concerned with the possibility of ever-increasing deficits with no method to retire part of the obligation generated by an infeasible standard. LCFS FF43-29

May drive credit costs up

The CCM provisions in the LCFS re-adoption package (after the proposed 15-day package revisions) may not keep credit prices in check during periods of rising prices (i.e., credit shortages in the open market). The CCM to clear the market at the end of the year is meaningless during a credit-short environment as there will not be any remaining credits to be brought to the table by sellers. The LCFS FF43-30 compounding of interest on the carryover/deferred balances will make it likely that credit buyers will soak up the available pool of real LCFS credits in the market during the year and not wait for the CCM. The pool of real LCFS credits available is fixed – it is only their price that remains in question. Staff's setting of the price cap at $200/ton will likely serve as the benchmark for credit prices in that environment.

LCFS FF43-30 cont.

Conversely, during periods of stable or declining prices (i.e., credit surplus in the open market), the CCM cap price creates an artificial "floor" value below which sellers may be hesitant to offer real LCFS credits for sale to the regulated community at substantially lower prices. This may artificially increase compliance costs – as credit prices could be artificially raised to (or near) the ARB cap with the likely result of fewer transactions taking place before the end-of-year sale. Credit trading could be seriously impaired as the open market may not be allowed to function as it should.

<u>Provides no liability protection against invalid credits</u>

The LCFS re-adoption package (after the proposed 15-day package revisions) continues to lack an acceptable liability defense provision or protocol to protect obligated parties from potentially fraudulent credit sellers. The only protection buyers of credits have is to perform due diligence and carefully screen the parties they choose to engage as partners in LCFS credit-buying transactions. It appears that buyers will not be afforded this luxury in the credits they are obligated to purchase (pro-rata share) through the CCM. Moreover, the timetable being put in place by ARB to organize and complete the CCM does not give parties comfort that the agency will be doing any such screening of the credits that are pledged by sellers for the CCM. WSPA objects to the fact that parties may potentially wind up in a position of non-compliance through no fault of their own simply because there is a credit shortage and buyers need to participate in the CCM where they have no control over what credits they buy and from whom.

LCFS FF43-31

<u>Offers no connection to LCFS program sustainability</u>

LCFS credit market liquidity (measurable potentially through a number of different indicators) is not only essential to the program's success but, also, the absence of such liquidity (as evidenced through the CCM) should be viewed as a clear signal that the program's CI reduction targets are overly aggressive and that the regulated community is finding it difficult to meet its obligations and remain in compliance. There is no connection in the CCM provisions of the
LCFS re-adoption package (after the proposed 15-day package revisions) to bring about a comprehensive program review should the potential trend of systematic credit shortages materialize and persist.

LCFS FF43-32

<u>Does not clarify the mechanics of deficit carryover</u>

The CCM provisions of the LCFS re-adoption package (after the proposed 15-day package revisions), while improved over the initial ISOR version, remain lacking in the execution/implementation details that would allow parties to understand exactly how the CCM would work. We recognize that staff has added some clarification to indicate that parties cannot retire accrued previous years' obligations until they have satisfied (met) their obligation for the immediately previous year. Staff has also included clarification of when the interest on accumulated carryover obligations will occur (i.e., in May each year prior to the start of the CCM in June).

LCFS FF43-33

While this seems to be pointing to a Last-In-First-Out (LIFO) accounting method, it does not explicitly indicate how older obligations are to be addressed. For example: Can parties retire (through blending or purchases) obligation carryover from four years ago before they retire corresponding deficits carried over from two years ago? Moreover, the application of a LIFO method (if indeed that is staff's intent) appears punitive in that it would maximize the accrued interest on obligation deficits carried over from previous years. We emphasize that such obligation carryovers could occur through no fault of the parties (i.e., even after they have made every best faith effort to cover their annual obligation) and find it objectionable that, not only will there be an interest penalty levied for carryovers through the CCM, but that this penalty will be maximized by not allowing the oldest obligations to be retired first. LCFS FF43-34

Furthermore, while we understand at what point during the year the interest will be levied (i.e., in May), we are uncertain as to whether the immediately preceding year's unmet obligation will also be included in the calculated interest. We do not believe that should be the case as parties should be given the opportunity to cover an additional part of any such remaining obligation from the immediately preceding year through the CCM. We believe this to be staff's intent but request clarification that interest will be applied the May following the Credit Clearance Market or one year after the initial annual report is submitted. We propose the following language for section 95485.(c)(5)(A): LCFS FF43-35

(A) Compound Interest on Accumulated Deficits. Regulated Parties with an Accumulated Deficit will be charged interest to be applied annually to all deficits in a regulated party's Accumulated Deficit account. Interest will be applied in terms of additional deficits that must be retired pursuant to section 95485(c)(1)(B), above, at a rate of 5 percent annually, applied May 1, 20XX, where 20XX = compliance year +2.

Based on the proposed 15-day package revisions, the criteria and conditions for retiring deficit carryovers in paragraph 95485(c)(5)(C) appear confusing in that they could be interpreted to limit a regulated party's ability to retire older deficits through the CCM. While we disagree with staff's apparent selection of the LIFO credit accounting method as indicated above, we would like staff to explicitly indicate their intent that regulated parties can buy more credits from the CCM than their immediate prior year's obligation shortfall as long as: a) they have used up all their accumulated credits and still have a carryover balance from years other than the immediately preceding year, and b) they first retire their immediate prior year's obligation through the credits obtained through the CCM. LCFS FF43-36

Additional comments on specific provisions under the CCM are as follows:

<u>§95485. (c)(4)(B)</u>

WSPA continues to strongly object to ARB publishing a list of Credit Clearance Market participants and each participating party's pro-rata share of pledged credits, and WSPA feels ARB's decision to list this information without any explanation or basis is arbitrary and capricious. LCFS credit and/or deficit balances and the individual entity names should be treated as highly confidential business information because the release of this information could adversely impact business operations. This proposal to make public the long and short credit positions of regulated parties violates the principles underlying protection of confidential business information. A regulated party's competitive position could be seriously compromised by the publication of this information. In addition, this information would give competitors both an understanding of a regulated party's compliance strategy and a view LCFS FF43-37 into the regulated party's fuel and credit acquisition activity for the year. Using this information and average market pricing, one could estimate the financial impact of LCFS compliance on a regulated party. It is well-established that this information is protected from disclosure under California law, and ARB should treat it as the highly confidential information it is. *See, e.g*, Cal. Gov. Code § 6254; Cal. Evid. Code §1060. **LCFS FF43-37 cont.**

<u>§95485. (c)(5)(D)</u>
WSPA understands ARB is proposing to prohibit entities that have a roll-over deficit under the credit clearance approach from transferring/selling credits to another party until the deficit is "paid back." WSPA understands this prohibition is only intended to apply to "separated" credit transactions and not to the transfer of obligation with physical fuel. We are requesting that ARB confirm this in writing. WSPA still requests clarification that the prohibition on credit transfers and sales does not include credits attached to biofuels that move by default in the transactions. This could be handled in a response to comment or guidance. **LCFS FF43-38**

<u>§95486. (a)(4)(B)(4)(b) Generating and Calculating Credits and Deficits</u>
WSPA supports ARB allowing regulated parties to use Carryback Credits to minimize any compliance shortfalls.

Section 95486(c) - Credit Generation Frequency. Beginning 2011 and every year afterwards, a regulated party may generate credits quarterly after data are reconciled with its business partner.

WSPA believes the new proposed language is unworkable in its current form. WSPA supports the goals of staff of accurate reporting, and we support the new reporting provisions requiring an initial report followed by a 45 day reconciliation period. Section 95491 Reporting and Recordkeeping (a)(1)(A) calls for reporting parties to "work in good faith with their counter parties to resolve any fuel transaction discrepancies between the parties". WSPA supports this but notes this does not ensure there will not be any discrepancies between reporting parties. To be consistent with section 95491, WSPA believes the language of 95486(c) should be modified to state (proposed change in red): **LCFS FF43-39**

> (c) Credit Generation Frequency. Beginning 2011 and every year afterwards, a regulated party may generate credits quarterly after ~~data are reconciled with its business partner.~~ <u>the quarterly report has been submitted in the LRT. Regulated parties shall</u> **<u>make a good faith effort to</u>** <u>reconcile their data with their business partners before submission.</u>

<u>§95487. (c)(1)(B) Credit Transactions - Confidentiality</u>
ARB proposes to remove the following language from the regulation:

> "Except as provided in section 95487(d) below, the Executive Officer will treat information submitted in the online Credit Transfer Forms as Confidential Business Information."

WSPA objects to ARB's removal of the language and requests that it be reinstated. Protection for such information is well-established under California law. Pursuant to the Government Code, such confidential business information is excluded from responses to Public Records Act requests. *See, e.g,* Cal. Gov. Code § 6254; Cal. Evid. Code §1060. This information has always been designated as Confidential Business Information under the LCFS, and ARB has provided no explanation as to why it **LCFS FF43-40** should be classified differently as part of this rulemaking. Removal of this language without explanation is arbitrary and capricious, and ARB must continue to fulfill its statutory obligation to protect such information from disclosure. Accordingly, WSPA requests that the stricken language be added back into section 95487(c)(1)(B). LCFS FF43-40 cont.

§95488. (a)(3) Obtaining and Using Fuel Pathways.

During the original revisions to the LCFS re-adoption, released in December, 2014, there were apparently significant revisions to Section 95488 relating to Provisional Pathways. The 15-day package released in June of 2015 further revised this section by including Tier 1 pathways. While the regulation does say that "Based on timely reports, the applicant may generate provisional credits", it also says, "such credits may not be sold, transferred, or retired for compliance, nor may fuel with a provisional CI be transferred with obligation." The revised regulation also goes on to say that "The applicant may not sell credits generated under a provisionally-approved pathway, or transfer the provisional fuel with obligation, until the Executive Officer has adjusted the CI or informed the producer that the provisional CI has been successfully corroborated by operational records covering a full two years of commercial operation".

Upon becoming aware of this revision (with respect to the addition of Tier 1 pathways in the 15-day package as well as the original language apparently revised in December 2014), understandable concern was raised by fuel investors and compliance entities alike as this section could be interpreted to mean that start-up facilities and pathways cannot sell credits or sell fuels (with an obligation) until they have operated for 2 full years. Obviously if this interpretation were to hold, this section of the regulation would significantly undermine the innovation that the LCFS itself seeks to encourage. Few, if any, plants or new pathways would be economic if they were not able to sell credits – or sell fuel with obligation– within the first 2 years of operation – a critical time period in the lifetime of a new operation. An Argus article dated June 11 discussed the potential impact of these revisions on the market as follows: LCFS FF43-41

> *The point of the program is to help commercialize new low-carbon fuels, but the provisional credit provision creates two years of uncertainty for affected producers unless they are comfortable with waiting up to two years before they can sell the credits and bank their cash value.*

> *The regulations could lock up significant amounts of credits or actual fuel supplies from new conventional low-carbon fuel producers, said Philip Sheehy, a technical specialist at consultant ICF. Credit prices could rise up to near the program's price cap of $200/t in 2018 or 2019, according to recent ICF forecasts that account for the provision credits system.*

In subsequent conversations, staff acknowledged that this section of the regulation was poorly drafted and that it is not the intent of the regulation to prohibit generation of credits or sale of fuels from start-up operations. It is crucial that staff <u>immediately</u> clarify the language of this section of the regulation by an appropriate mechanism. It is critical that both investors and regulated parties clearly understand the intent of this section of the regulation.

§95489. Provisions for Petroleum-Based Fuels (Refinery Investment Credit and Hydrogen Co-processing)

WSPA's primary concern throughout the process of developing the specific provisions and eligibility criteria related to the refinery investment credit and hydrogen co-processing provisions has been that the stringency of the provisions and criteria not be so restrictive that no projects will be eligible to generate credits. Most of the changes WSPA recommended leading up to the February Board meeting and in subsequent discussions with staff on the 15-day package were aimed at preserving the ability to generate credits from eligible projects.

Staff has made some improvements in addressing our comments consistent with the idea that more projects will be eligible. Unfortunately, some provisions remain problematic despite the changes CARB has proposed; and CARB has added new provisions that go in the wrong direction with respect to enhancing opportunities for project eligibility.

Improvements in the Proposal

- We appreciate staff's revision to allow potential criteria pollutant and/or toxics increases associated with candidate projects to be offset as provided in the applicable project permitting requirements. This was one of the key changes WSPA had identified as necessary to make the proposal viable and equitable. LCFS FF43-42

- WSPA is also in agreement with staff's decision to remove the proposed 50% discount for any credits generated by "less efficient refiners," as the methodology employed was rather arbitrary and had the potential to discriminate against complex refineries or penalize refineries that may have made prior investments in GHG reduction projects. LCFS FF43-43

- WSPA also appreciates staff's decision to reduce the 10% bio-feedstock minimum in the Hydrogen Co-processing provision which should make it more likely for such projects to move forward. LCFS FF43-44

Provisions that were not Sufficiently Addressed

- Staff did not act to avoid other arbitrary restrictions and thresholds to encourage innovative GHG reductions, most notably the 0.1 gCO2e/MJ minimum CI improvement for RIC project eligibility. This remains an inequitable provision as the standard will be much more difficult to meet for larger, fully integrated refineries. WSPA continues to maintain that supplementing this standard with an alternative flat 5,000 metric ton of CO_2e per year project impact threshold would allow more credit generation without unduly burdening staff with an overwhelming number of applications involving small projects. LCFS FF43-45

- While we are well aware of staff's unwillingness to provide retroactive credit for projects that have already started up (even if the start date was after the start of the LCFS program), we are completely puzzled by staff's refusal to implement a simple, practical and equitable criterion for project eligibility pivoting off the project's start date, i.e., the date GHG reduction benefits LCFS FF43-46 begin to accrue. We also highlight the potential unintended adverse impact that the current criterion (permit to construct issued after January 1, 2016) might have on projects currently underway in that it could provide an incentive to delay such projects and potentially withdraw/refile permit applications to ensure that the permit to construct is not issued before January 1, 2016 (rendering the project ineligible for RIC credits). We believe that this was not staff's intent. WSPA continues to maintain that staff's proposed RIC eligibility criteria penalizes early actors. LCFS FF43-46 cont.

As stated above, WSPA feels the base year should be consistent across all elements of the LCFS. However, at a minimum we recommend that, if staff wants to utilize the permit to construct data issuance (instead of project startup date) as the eligibility threshold, at a minimum staff should utilize January 1, 2015 as the associated date and not January 1, 2016.

- Lastly, WSPA notes staff's reiteration in the LCFS 15-day package of the earlier attempt to differentiate RIC candidate projects based on whether they are capital projects or part of routine refinery turnarounds and/or maintenance. We remain uncomfortable with the lack of specificity of the proposed language that calls for identification of the primary purpose or intent of a candidate project. We continue to believe that non-capital projects that offer sustained GHG improvements should be included since many energy efficiency upgrades are considered non-capital and may be part of a multi-pronged refinery strategy to simultaneously upgrade equipment for improved reliability, reduced maintenance and enhanced energy efficiency. Such projects could include shutdowns (i.e., replacement of a fired heater with heat exchangers) and should not be excluded from generating a credit. Staff should clarify that projects whose primary intent is increased energy efficiency but involve equipment shutdowns are not excluded. LCFS FF43-47

<u>New Provisions or Changes that are Problematic</u>

- Staff has removed entirely the ability to generate RIC credits from co-processing liquid bio-feed stocks at facilities, leaving Hydrogen co-processing as the only viable option available to some. While the opportunity to seek dedicated pathway approvals for such applications is still provided, staff's action eliminates substantial flexibility for parties' smaller scale projects/applications that may not warrant the dedication of time and resources to the rigors of the specified pathway approval processes. LCFS FF43-48

- WSPA is disappointed with staff's apparent "change of heart" regarding the RIC as evidenced by staff's recasting of this provision (as well as the Hydrogen Co-processing provision) as "pilot programs" designed to allow staff "time to evaluate the credit potential from these provisions and prevent any unanticipated impacts, if the volumes outstrip current expectations." LCFS FF43-49

  In WSPA's view, this is a fundamental change in staff's approach to what had been a significant part of the LCFS 45-day proposal– one that was discussed extensively during the nearly year-long workshop process leading to the February Board hearing and one that our industry had invested extensive time and resources to ensure it is a workable and practical provision. The implication of a pilot program designation is one of potentially temporary provisions that may be terminated in future program revisions. This leaves our industry with uncertainty as far as proceeding with the necessary investments to implement GHG reduction projects at facilities where projects may be consistent with what was perceived as the original intent of including the RIC provision in the LCFS. LCFS FF43-49 cont.

- Further evidence of staff's concern in this regard can be found in the implementation of largely unsubstantiated "caps" on the potential contribution from the RIC (at 20% of a regulated party's annual credit obligation) and the Hydrogen Co-processing provision (at 10%) whose sole purpose appears to be to provide further "insurance" that our industry could not actually rely on these provisions for anything more than a small percentage of the overall compliance obligation. Such an approach is inconsistent with the concept of 'neutrality" that staff (and the Board) have reiterated upon numerous occasions involving the variety of LCFS compliance options available to regulated parties. . LCFS FF43-50
- The RIC and Hydrogen Co-processing provision included in the LCFS 15-day package go even further in curtailing the practical utility of these provisions in limiting the ability of a party that generates such credits to do anything other than use them for their own compliance purposes, (i.e., prohibiting the sale of such credits in the marketplace). LCFS FF43-51

  We understand that this may not be staff's intent and that this flexibility-limiting provision may be simply the result of limitations in staff's ability to bring about the necessary LRT revisions in a timetable consistent with the LCFS re-adoption schedule. Nevertheless, WSPA once again needs to point out the rather arbitrary application of "neutrality" in that other eligible credit generating mechanisms in the regulations (e.g., electricity) are not limited in the volume of credits that can be generated, or in their ability to participate in the credit markets. LCFS FF43-52

Despite some improvements made by staff in the 15-day package, WSPA still believes that the current proposal substantively impedes valid credit generation in conflict with what ARB hopes to incentivize with the measure. These impediments not only manifest themselves as direct limitations to the quantity of credits that can be generated, but also by creating uncertainty that erodes credit generation prospects. As a result, few, if any, credits are likely to be generated from the provision as written – particularly while the provision remains a "pilot" program. LCFS FF43-53

§95490. Multimedia Evaluation

WSPA strongly disagrees with ARB's decision to completely eliminate the multimedia evaluation provisions in section 95490, as well as the proposed elimination of the definition of "multimedia evaluation" from section 95481(a)(59) and the proposed deletion of the application requirements related to multimedia evaluations in section 95488(c)(4)(G)6.d. LCFS FF43-54

WSPA also strongly disagrees with ARB's statement, in its Notice of Public Availability of Modified Text, that the LCFS "does not establish any fuel specifications." *Notice of Public Availability at 9.* As discussed in our February 17, 2015 comments on the proposed regulations, carbon intensity as established by the LCFS is a criterion or "specification" to which motor vehicle fuels must comply. The Health & Safety Code itself recognizes a fuel specification for light-duty vehicle exhaust emission standards—standards that, like the LCFS, are based on overall emissions from fuels as opposed to quantification of their particular components. Cal. Health & Safety Code § 43018(d)(1). Even the Ninth Circuit has already considered the LCFS to be a fuel control measure. *See Rocky Mountain* LCFS FF43-55

LCFS FF43-55 cont.

Farmers Union v. Corey, 730 F.3d 1070 (9th Cir. 2013) (recognizing that the LCFS is "a control respecting a fuel or fuel additive and was enacted for the purpose of emissions control").

ARB should not delete the multimedia evaluation provisions from the proposed regulations; to the contrary, ARB should be undertaking a multimedia evaluation for the LCFS as required by California Health & Safety Code. Multimedia evaluations are necessary in order to obtain a full and independent assessment of the range of potential environmental impacts of any newly proposed fuel regulations across all media. ARB has enough information regarding the types and blends of fuels that will likely be used to meet the LCFS to conduct a multimedia evaluation for the regulation. LCFS FF43-56

Given the severe drought conditions California currently faces, the multimedia evaluation must take into account the significant water demands associated with the use of biofuels, which are outlined in more detail in the peer-reviewed study by Julian Fulton of the Energy and Resources Group at U.C. Berkeley and Heather Cooley of the Pacific Institute. The multimedia evaluation for the ADF regulations fails to evaluate these potential impacts. LCFS FF43-57

The LCFS' carbon intensity fuel specifications stand to promote the use of multiple types of fuels that have not been fully evaluated for potential water impacts. As Fulton and Cooley note:

> "California's Low Carbon Fuel Standard…has reinforced demand for bioethanol as a means to reduce the greenhouse gas intensity of transportation fuels. Although early LCFS policy assessments raised the issue of water demands and impacts from increased biofuel production, any subsequent efforts to track or address those impacts through policy have been lacking." Fulton and Cooley, The Water Footprint of California's Energy System, 1990-2012 (February 26, 2015) at 10.

LCFS FF43-58

The potential for significant impacts makes a multimedia evaluation for the LCFS all the more critical. The evaluation should be completed as soon as feasible to comply with the Health & Safety Code. LCFS FF43-59

<u>§95491. Reporting and Recordkeeping - Table 12</u>

- WSPA recommends that the requirements for ARB in determining the annual average crude carbon intensity be included in Table 12. LCFS FF43-60

<u>§95491(a)(7) Reporting and Recordkeeping</u>

We object to the removal of annual reports from the section related to Correcting a Previously Submitted Report. There may be instances in which an annual report may also need to be re-opened for corrective edits and resubmittal. The removal of annual reports from this section essentially dis-allows regulated parties to correct previously submitted annual reports. LCFS FF43-61

<u>§95494. Penalties</u>

As discussed in WSPA's comments of February 17, 2015, WSPA opposes a per-day penalty, but does not oppose a maximum penalty of $1000 per tonne of deficit. While AB 32's enforcement provisions provide for per day penalties when a violation results in the emission of an air contaminant, where, as here, no actual emission of air contaminant is occurring on a per day basis, the imposition of such a penalty would be unjustifiably punitive, excessive and onerous. *See* Cal. Health & Safety Code §§ LCFS FF43-62

42400.1, 42400.3. A per deficit penalty approach is authorized by the Health & Safety Code. *See* Cal. Health & Safety Code § 38580(b)(3).

The proposed changes to section 95494(c) appear to embrace a per-deficit penalty, but the vague language needs to be clarified. The proposed language currently reads:

> "Each deficit that is not eliminated at the end of a compliance period or carried over as permitted by section 95485 constitutes a separate day of violation, subject to a penalty not to exceed $1000 per deficit."

LCFS FF43-62 cont.

The addition of the words "day of" essentially turns the per deficit penalty into a per-day penalty for each deficit, which WSPA strongly opposes as unduly onerous and unjustifiably excessive —all the more so because ARB has removed regulated parties' ability to request that their annual reports be re-opened for correction. WSPA suggests the following language be adopted:

> "Each deficit that is not eliminated at the end of a compliance period or carried over as permitted by section 95485 constitutes a separate ~~day of~~ violation, subject to a penalty not to exceed $1000 per deficit."

§95495. Defining "Material Information"

Including in the definition of "material Information" "information that would affect by any amount the Executive Officer's determination of a carbon intensity score…" potentially broadens ARB's authority to suspend, modify, or revoke credits. As discussed in WSPA's February 17, 2015 comments, the regulations penalize credit holders if they hold invalid credits, even if that occurs despite a regulated party's best efforts to hold valid credits. ARB may not require entities to participate in the credit scheme without providing some level of certainty that credits validly represent the reductions they purport to represent. *See* Cal. Health & Safety Code § 38562(d)(1) ["Any regulation adopted by the state board pursuant to this part or Part 5 [market-based compliance mechanisms] shall ensure all of the following: (1) The greenhouse gas emission reductions achieved are real, permanent, quantifiable, ***verifiable***, and enforceable by the state board …"] [emphasis added].

LCFS FF43-63

An appropriate definition of "material information" as used in the subsection would help to minimize the risk of arbitrary invalidation by limiting the bases for invalidation under proposed section 95495(b)(1). WSPA therefore requests that section 95495(b)(1)(G)1 be stricken from the regulation.

§95496. Regulation Review

Assuming continuation of the LCFS program, we support the addition of a 2017 Progress Report on the LCFS to the ARB Board and the inclusion of public review of the Progress Report findings. LCFS FF43-64

43_FF_LCFS_WSPA

995. Comment: **LCFS FF43-9, LCFS FF43-54 through LCFS FF43-59**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

996. Comment: **LCFS FF43-1**

The commenter supports the addition of the program "progress report" in mid-2017.

Agency Response: ARB staff appreciates the support. We look forward to the commenter's engagement in the program going forward.

997. Comment: **LCFS FF43-2**

The commenter strongly objects to the limited accountability placed on electricity providers in generating LCFS credits.

Agency Response: ARB staff disagrees with the comment that there is limited accountability. In the proposed 15-day changes, the credits generated through estimated EV charging will be calculated by ARB staff and well documented within the Electrical Distribution Utility's LRT-CBTS account. This would enhance the credit generation process for electricity providers, and reduce the probability of credit invalidation. If fraud is discovered; the Health and Safety Code and a host of other state and federal statutes may apply, and provide for civil and criminal consequences.

998. Comment: **LCFS FF43-3**

This comment states that ARB staff proposes arbitrary and disparate effective dates for various methods of credit generation under the regulation.

Agency Response: ARB staff disagrees that the dates in question are arbitrary. The effective dates of various types of crediting in the regulation are the result of: (1) various crediting options being proposed for addition to the program at different dates, and (2) different sources of credits requiring different constraints to incent action beyond common practice.

As an example of the first issue, crediting for solar steam projects existed under the prior rule, but crediting for renewable power projects in oil fields was a concept added in this rulemaking. As a result, the effective date for credits generated from solar steam projects is 2010, so as to not exclude any solar steam projects that were under development and anticipating receiving credits under the prior rule. The cut-off for renewable electricity projects is 2015 to incent new renewable capacity beyond what is already built and operating.

As an example of the second issue, a 2015 “project operation” effective date was chosen for innovative crude projects because they all involve technologies that are not common practice in oil extraction currently. In contrast, some refinery investment credits may involve achieving GHG reductions from technologies that are common practice. In order to have greater confidence that the credits value will drive a change in behavior related to these projects, a later eligibility date (2016) and a “permit approval” method of assessing the cut-off was selected.

999. <u>Comment</u>: **LCFS FF43-4**

The commenter believes that the credit accounting is overly complex and the 15-day package made it worse.

<u>Agency Response:</u> In many cases, the final proposal represents a simplification relative to prior mechanisms for credit accounting, therefore, we disagree that the credit accounting is overly complex under the new proposal.

We encourage fuel suppliers to continue to perform their due diligence with respect to verifying the validity of the credits they purchase. We also look forward to the commenter continuing to propose simplifications to the program framework that maintain the environmental integrity of the program.

1000. <u>Comment</u>: **LCFS FF43-5**

The commenter states that the credit generation from electricity use in light and heavy duty rail is inconsistent with both the intent and the ISOR for the LCFS, and should be removed from the program.

<u>Agency Response:</u> The Board directed ARB staff (in Resolutions 09-31 and 11-39) to evaluate the feasibility of issuing credits for non-road, electricity-based transportation sources, including mass transit. These vehicles, such as light and heavy duty rails, displace

gasoline and diesel fuel transportation energy, and use significant and quantifiable electricity for transportation. Therefore they should be allowed to generate LCFS credits.

The credit generations for the light and heavy duty fixed guideways are well documented within the transit agencies' LRT-CBTS accounts. Stakeholders should always be able to identify the sources of the credits. For more information please see response to **LCFS 38-21.**

1001. Comment: **LCFS FF43-6**

The commenter believes the credit clearance market exacerbates an indefensible target and does not provide the opportunities to evaluate the validity of the credits. Finally, the commenter objects to publishing a list of participants in the Credit Clearance Market.

Agency Response: This comment is not directed to any change in the 15-day changes proposal, and as such needs no response. We note that similar comments and responses can be found at **LCFS 40-14** and **LCFS 40-69**.

1002. Comment: **LCFS FF43-7**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

1003. Comment: **LCFS FF43-8**

The commenter does not believe credits generated from the refinery investment credit provisions (as written) will contribute substantially to meeting fuel suppliers' compliance obligation. Despite some positive changes in the 15 day package, characterization of these provisions as "pilot programs" and the significant barriers that still exist substantively impede valid credit generation.

Agency Response: ARB believes that the term "pilot program" is an appropriate term for the new refinery investment credit. It is not meant to imply that this provision can't contribute substantially to meeting fuel suppliers' compliance obligation, especially in the long-run, only that the provision may need updating in the future as experience is gained through evaluating actual projects, dialoging with stakeholders about these projects, and making future rule changes if needed. The refinery investment credit is consistent with ARB's goals by incentivizing measures to lower the CI of transportation fuels while still being quantifiable and verifiable.

1004. Comment: **LCFS FF43-10**

The commenter requests that the revised compliance schedule be posted prior to the board hearing.

Agency Response: This comment is not directed to any change in the 15-day changes proposal, and as such needs no response. Staff will continue to release compliance information publicly after it has been subject to an internal quality control process. Staff will continue to ensure the Board is aware of compliance trends in the program.

1005. Comment: **LCFS FF43-11**

The commenter requests that the final version of the California Reformulated Gasoline and Ethanol Denaturant Calculator Spreadsheet be posted for public review.

Agency Response: The final version of the denaturant calculator was posted June 4, 2015. See http://www.arb.ca.gov/fuels/lcfs/ca-greet/ca-greet.htm. We reiterate for the commenter that identical calculations are embedded within the CA-GREET2.0 model (which is incorporated by reference into the rule), and that the denaturant calculator itself is not used to calculate the CaRFG baseline but merely to make the calculation more transparent.

1006. Comment: **LCFS FF43-12**

The commenter suggests modification to definitions for four diesel related fuels.

Agency Response: ARB staff disagrees with the commenters suggested changes to the four definitions.

The "Biodiesel Blend" was included to align with ADF. Although this definition is not included elsewhere in the regulation staff elects not to remove it. This definition provides general clarity for stakeholders who may go through the GREET lifecycle pathway assessment.

The "Petroleum Product" definition aligns with U.S. EPA's definition.

The Product Transfer Document requested change is a repeated comment from the commenter's submittal during the 45-day comment period. See response to **LCFS 38-39**.

The "Renewable Hydrocarbon Diesel" definition is worded as is in order to align with the Alternative Diesel Fuel Regulation (ADF). Staff elects not to change the definition to maintain harmony with that regulation. The ADF regulation includes a definition for Hydrocarbon, and as the RHD definition in the LCFS aligns with the RHD definition in the ADF regulation, the additional clarity requested in the comment is unnecessary.

1007. Comment: **LCFS FF43-13**

The commenter believes that striking portions of the proposal governing the transfer of regulated party status between upstream parties was arbitrary and capricious, implying that it was inappropriate to make the change as part of a "15-day package."

Agency Response: ARB staff disagrees. The commenter's position appears to be that ARB could not alter the transfer provisions after proposing them, but the law clearly allows ARB to do so. ARB's changes to the proposal were based on experience implementing the current LCFS and feedback from several WSPA members who separately suggested to ARB staff that the 'default obligation transfer' provision was not needed because contractual arrangements addressed the transfer issue. ARB believes that parties transacting in fuels should have the freedom to transfer regulated status, or not, by contract. ARB staff expects that by removing the default that applies only some of the time, reporting parties will be more aware of their transactions in a way that facilitates accurate reporting. The comment goes on to state that such a change should have been made, if at all, years ago. ARB staff disagrees with the notion that once a provision is placed in a regulation, it should not be amended or stricken, regardless whether it has worked poorly in practice.

1008. Comment: **LCFS FF43-14**

The commenter strongly opposes ARB's electricity provisions, and continues to propose that electricity not be part of the LCFS program.

Agency Response: ARB staff disagrees with this comment. One of the objectives of the proposed Low Carbon Fuel Standard is to foster investments in the production of the low carbon intensity (CI) fuels. Electricity has the lowest carbon intensities among commonly available fuels and therefore should be included in the LCFS provisions to move California toward a low-carbon transportation future.

1009. Comment: **LCFS FF43-15**

The commenter states that changes to the provisions setting out regulated party status for various contexts in which electricity is provided as transportation fuel "are substantive" and thus inappropriate as 15-day changes.

Agency Response: While the changes are substantive, ARB staff disagrees with the implication that 15-day changes should be non-substantive. In fact, under the Administrative Procedures Act, non-substantive changes need not even be circulated for 15 days, whereas substantive changes related to the initial proposal must be circulated for a 15-day comment period. (Gov. Code 11346.8, subd. (c).)

1010. Comment: **LCFS FF43-16**

The comment states that the changes to Sections 95483(e)(2) to (e)(5) are not explained or justified in the Notice of Public Availability.

Agency Response: The rationales for the proposed 15-day changes are for clarifications, such as clarifying the Electricity Distribution Utility's role in the regulation to reduce ambiguity and facilitate implementation. Sections 95483(e)(2) to (5) of the LCFS cover the public EV charging, EV fleet charging, and private access EV charging at a business or workplace. Currently, no such EV charging service providers have opted into the LCFS program for credit generation. The main reason of the proposed 15-day change is to facilitate credit generation and avoid credit losses for private access EV charging, EV fleet charging, and private access EV charging at a business or workplace. See **LCFS FF41-2** for further explanations.

1011. Comment: **LCFS FF43-17**

The comment states that the changes for Section 95483(e)(2) to (e)(5) exacerbate the un-level playing field for electricity providers, by further reducing their public accountability, recordkeeping, and metering requirements.

Agency Response: ARB staff disagrees with this comment. ARB does not favor one alternative transportation fuel providers over others. The requirements for application, reporting, and recordkeeping are consistent across all alternative fuel providers. The parameters for credit estimation, however, may differ from one alternative fuel to another, due to the fuel-specific manufacturing, blending, distributing, and marketing processes. Additionally, please see the responses to comments **LCFS 32-11** and **LCFS 40-52**.

1012. Comment: **LCFS FF43-18**

The comment states that the changes to Section 95483(e)(2) to (e)(5) increase concern regarding validity of credits generated from the electricity sector, and the decreasing amounts of due-diligence and reporting required by providers of electricity as a "transportation fuel".

Agency Response: Staff disagrees with the comment. In the proposed 15-day changes, the credits generated through estimated EV charging will be calculated by ARB staff and well documented within the Electrical Distribution Utility's LRT-CBTS account. This would enhance the credit generation process for electricity providers, and reduce the probability of credit invalidation. If fraud is discovered; the Health and Safety Code and a host of other state and federal statutes may apply, and provide for civil and criminal consequences. See response to **LCFS FF43-17**.

1013. Comment: **LCFS FF43-19**

The comment states that the changes to Section 95483(e)(2) to (e)(5) are not clear in regards to whether anyone will make sure there is a true accounting of credits generated from electric vehicle charging.

Agency Response: In the proposed 15-day changes, the credits generated through estimated EV charging will be calculated by ARB staff and documented within the Electrical Distribution Utility's LRT-CBTS account. This enhances the credit generation process for electricity providers, and reduces the probability of double counting or credit invalidation. In the implementation of the LCFS, staff commits to ensure a proper accounting of total credits from electric vehicle charging, and appropriate credits generated from public EV charging, EV fleet charging, and private access EV charging at a business or workplace be subtracted from the credits generated by the residential charging estimation. See response to **LCFS 32-11**.

1014. Comment: **LCFS FF43-20**

The commenter strongly opposes the removal of the requirement that Electrical Distribution Utilities to “Use all credits proceeds to benefit current or future EV customers”.

Agency Response: One of the objectives of the proposed Low Carbon Fuel Standard is to foster investments in the production and delivery of low carbon intensity (CI) fuels. Such investments are not always from current or future EV customers. For example, a site host or business owner of a private access EV charging place that has invested in charging infrastructure should benefit from the LCFS credits proceeds. They may not be an EV customer. Therefore staff only keeps such requirement for residential EV charging, where the investments for low carbon transportation fuel use are purely from EV customers.

1015. Comment: **LCFS FF43-21**

The commenter opposes the proposed 15-day change to make Electrical Distribution Utilities (EDUs) the default credit generators in most settings.

Agency Response: See response to **LCFS FF41-2**.

1016. Comment: **LCFS FF43-22**

The commenter opposes the proposed 15-day change to remove the list of activities constituting public education under 95483(e)(1)(B).

Agency Response: In the current LCFS regulation, Section 95483(e)(1)(B) includes specific efforts that “may include, but are not limited to …”. Such language has little or no effect. The requirements to educate the public remain the same in Sections 95483(e).

1017. Comment: **LCFS FF43-23**

The commenter opposes the proposed 15-day change to remove the requirement that ARB post supplemental information for public review each year.

Agency Response: ARB staff made the change because some of the supplementary information, such as the monetary value returned to each driver, is confidential. ARB must sign a Confidentiality

Agreement with the EDUs before obtaining the reports. See response to **LCFS FF43-24**.

1018. Comment: **LCFS FF43-24**

The commenter opposes the proposed 15-day change to allow investor owned utilities to use Public Utility Commission reporting in lieu of LCFS specific supplemental information.

Agency Response: In the current LCFS Section 95483(e)(1)(D), the supplementary information included in the annual compliance report of electrical distribution utility (EDU) is described as: “an itemized summary of efforts to meet requirements subsections (A) through (C) above and costs associated with meeting the requirements.”

The annual implementation report required under Order 4 of Public Utilities Commission of California (PUC) Decision 14-12-083 for investor owned utilities (IOUs) must include:

- A description of the program, including how electric vehicle drivers were identified;
- the volume of LCFS credits generated and sold; the means by which the credits were sold;
- the amount of revenue generated; the number of drivers to whom LCFS credit revenue was returned;
- the monetary value returned to each driver;
- how the program was marketed to drivers;
- administrative and marketing expenses;
- any other costs, including outreach to auto dealers.

It is clear that such a report includes much broader and more detailed information than the supplementary information requirements under current regulation. Some information in this report, such as the monetary value returned to each driver, is even confidential. ARB must sign Confidentiality Agreement with the EDUs before obtaining the reports. Therefore the proposed 15-day changes will enhance the reporting requirements of the EDUs.

1019. Comment: **LCFS FF43-25**

The commenter states that technology exists to directly measure residential EV electricity use and therefore should be required.

Agency Response: Currently, many EV drivers have elected not to install dedicated EV meters at their residences. The percentage of directly metered EV charging residences varies from 5% to 10% in big utility service territories. Therefore it is necessary to allow estimation to be continued. Installing a separately dedicated meter for residential EV charging can be costly for EV customers. Adding a cost barrier to EV adoption runs counter to the LCFS' goals. The estimation method is sufficiently accurate in calculating the actual electricity use of non-metered residential EV charging**.**

1020. Comment: **LCFS FF43-26**

The commenter states that the proposed 15-day changes reduce the standards that electricity providers are held to, as compared to liquid fuel providers.

Agency Response: ARB staff disagrees. See responses to **LCFS 32-11**, **LCFS 40-52,** and **LCFS FF43-17**.

1021. Comment: **LCFS FF43-27**

The commenter states that it is not clear from the proposal whether a proper accounting of total credits from electric vehicle charging will be performed by ARB.

Agency Response: In the implementation of the LCFS, staff commits to ensuring a proper accounting of total credits from electric vehicle charging and providing adequate public transparency as this calculation is conducted.

1022. Comment: **LCFS FF43-28**

The commenter expresses concern that the 15-day package did not contain any modifications to the cost containment provision.

Agency Response: This comment is not directed to any change in the 15-day changes proposal, and as such needs no response. We note that similar comments and responses can be found at **LCFS 32-9** and **LCFS 40-14**.

A cost containment mechanism is an essential component of the market rules governing the LCFS fuel market. The Cost

Containment Mechanism (CCM) is designed to provide a limit on credit prices in the event that the near-term demand for tradable credit exceeds the supply. If that were to occur regulated parties are allowed to roll over any remaining deficits to be repaid in future years, preventing a situation in which a shortage of credits might result in regulated parties bidding up the price of credits above the ceiling price. Investment decisions in new fuel supplies will depend on having clarity regarding how the program will manage price volatility or shortfalls in low CI fuel. Implementing a clear, predictable provision to handle any credit shortage or price spike reduces the risk of supply shortages or price spikes driven by fears about the long-term viability of the policy. This means that cost containment actually increases the likelihood of meeting the standard by providing regulatory certainty for investors that the LCFS will continue to provide a predictable price premium for low-CI fuels in the future, under all possible outcomes.

1023. Comment: **LCFS FF43-29**

The commenter expresses concern over the possibility that the CCM means there will be chronic shortages of credits.

Agency Response: This comment is not directed to any change in the 15-day changes proposal, and as such needs no response. We note that similar comments and responses can be found at **LCFS 32-9** and **LCFS 40-14**.

The CCM provides a strong price signal that values LCFS credits at up to $200 per metric ton in the case that near-term demand for credits needed for compliance exceeds the supply of credits offered for sale. If this situation occurs and one or more parties must defer repayment of deficits the CCM allows up to five years for full repayment of any one year's deferred deficits. Thus the CCM provides a bridge to full compliance by providing a substantial, but acceptable credit price to motivate the needed production of low CI fuels.

In the case of a chronic, rather than a temporary credit shortfall, ARB staff anticipates that a wide variety of low CI fuels in sufficient quantities to meet the proposed will be feasible and cost-effective to produce at well below the $200 credit price within the five year "payback" period provided by the regulation. As a further backstop the ARB will conduct periodic evaluations that would allow for stringency adjusts within the five year repayment period if the price incentive provided by the CCM proves to be insufficient to incent the needed production and use of low CI fuels.

1024. Comment: **LCFS FF43-30**

The commenter expresses concern that the credit clearance market will not keep prices in check during periods of rising prices.

Agency Response: This comment is not directed to any change in the 15-day changes proposal, and as such needs no response. We note that a similar comment and response can be found at **LCFS 32-9** and **LCFS 40-16**.

1025. Comment: **LCFS FF43-31**

The commenter repeats its concern with possible liability for fraudulent credits it acquires, especially in connection with the Credit Clearance Market, when the time and opportunity for due diligence is compressed.

Agency Response: See response to **LCFS 40-17**. ARB staff disagrees, because WSPA members are in an excellent position to comply with the regulation by making low-CI fuels or long-term contracts, exercising due diligence, with producers of such fuels.

1026. Comment: **LCFS FF43-32**

The commenter believes that there is no connection in the Credit Clearance Market (CCM) provisions of the LCFS re-adoption package to bring about a comprehensive program review should the potential trend of systematic credit shortages materialize and persist.

Agency Response: This comment is not directed to any change in the 15-day changes proposal, and as such needs no response. We note that a similar comment and response can be found at **LCFS 40-18**.

1027. Comment: **LCFS FF43-33**

The commenter asks that more clarity be added to the regulatory language of the credit clearance market.

Agency Response: ARB staff disagrees that the regulation, as originally proposed, was inadequate to define how the CCM will operate, and has proposed only minor clarifications via the 15-day change proposal. Additionally this comment is not directed to any change in the 15-day changes proposal, and as such needs no response.

1028. Comment: **LCFS FF43-34**

The commenter believes that the credit clearance market is a Last-In-First-Out (LIFO) accounting method.

Agency Response: The commenter appears to be misinterpreting the impact of the proposed change. The proposed change does not require a "Last-In-First-Out" accounting method.

1029. Comment: **LCFS FF43-35**

The commenter expresses uncertainty as to whether the immediately preceding year's unmet obligation will be included in the calculated interest.

Agency Response: ARB staff disagrees that the proposed changes are unclear. The interest is applied only to accumulated deficits, those that were outstanding at the end of the previous year's CCM. The interest charge does not apply to deficits that are part of the immediate previous year's compliance obligation.

1030. Comment: **LCFS FF43-36**

The commenter expresses uncertainty about the criteria and conditions for retiring deficit carryovers in paragraph 95485(c)(5)(C).

Agency Response: The CCM is designed to mitigate, to the greatest degree possible, deficit shortfalls that the regulated parties experienced in the most recent compliance year. Credits that have been procured through the CCM can only be used for that limited purpose. Regulated parties must acquire low carbon intensity fuels to self-generate or purchase credits from the regular LCFS credit market to procure credits needed to retire accumulated deficits.

1031. Comment: **LCFS FF43-37**

The commenter objects to ARB publishing a list of Credit Clearance Market participants and each participating party's pro-rata share of pledged credits, and feels ARB's decision to list this information without any explanation or basis is arbitrary and capricious.

Agency Response: This comment is not directed to any change in the 15-day changes proposal, and as such needs no response. We note that a similar comment and response can be found at **LCFS 40-69**.

1032. Comment: **LCFS FF43-38**

The commenter requests clarity on the prohibition of selling credits when the entity has a roll-over deficit.

Agency Response: This comment is not directed to any change in the 15-day changes proposal, and as such needs no response.

1033. Comment: **LCFS FF43-39**

The commenter requests that ARB modify the regulation to allow credit generation before the entities have reconciled with their business partners provided they make a "good faith effort."

Agency Response: As is the case under virtually every environmental regulatory scheme, regulated parties are strictly liable for any failure to comply with the law; good faith efforts are not sufficient, although such efforts can be considered as a mitigating factor in an enforcement context. With the extended period provided for report submission and a specific period for reconciliation, it should provide an ample amount of time to reconcile reports between business partners. It is a requirement that all regulated parties work with their business partners during the reconciliation process to resolve discrepancies.

1034. Comment: **LCFS FF43-40**

The commenter objects to the removal of language guaranteeing that credit transfer information submitted online would be treated as confidential business information (CBI).

Agency Response: ARB staff disagrees that the language was necessary. See response to comment **FF35-10**.

1035. Comment: **LCFS FF43-41**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

1036. Comment: **LCFS FF43-42**

The commenter expressed appreciation for staff's revision to allow potential criteria pollutant and toxics increases associated with candidate projects to be offset as provided in the applicable project permitting requirements.

Agency Response: ARB staff appreciates the support for the proposed changes.

1037. Comment: **LCFS FF43-43**

The commenter expressed agreement with staff's decision to remove the proposed 50% discount for any credits generated by "less efficient refiners".

Agency Response: ARB staff appreciates the support for the proposed changes.

1038. Comment: **LCFS FF43-44**

The commenter also expressed appreciation for staff's decision to reduce the 10% bio-feedstock minimum in the Hydrogen Co-processing provision which should make it more likely for such projects to move forward.

Agency Response: ARB staff appreciates the support for the proposed changes.

1039. Comment: **LCFS FF43-45**

The commenter requests that ARB lower the minimum threshold requirement of 0.1 gCO_2e/MJ minimum CI improvement for RIC project eligibility to a flat 5,000 metric ton of CO2e per year project impact threshold.

Agency Response: This comment is not directed to any change in the 15-day changes proposal, and as such needs no response. We note that a similar comment and response can be found at **LCFS 38-10**.

1040. Comment: **LCFS FF43-46**

The commenter requests staff should utilize January 1, 2015 as the associated date for eligibility and not January 1, 2016.

Agency Response: The purpose of the Refinery Investment Credit Provision is to incent marginal projects that might not have otherwise been economical without the provision. Projects that have undergone permitting have already been deemed economical and are not the target of this provision.

1041. Comment: **LCFS FF43-47**

The commenter states that there still is a lack of specificity of the proposed language that calls for identification of the primary purpose or intent of a candidate project. Staff should clarify that projects whose primary intent is increased energy efficiency but involve equipment shutdowns are not excluded.

Agency Response: The refinery investment provision allows for non-capital projects that offer sustained GHG improvements to qualify under the provision. The provision no longer requires capital projects only. Staff understands the commenter's concerns and considered modifying the regulation language to clarify which projects would qualify for the Refinery Investment Credit Provision. However, ARB staff found there were too many different types of projects to give guidance for in the regulation. Staff considered providing a list of qualifying projects. However, this approach might not include all potential projects. Staff instead decided to provide the maximum amount of flexibility. The intent of the shutdown language is to prevent refineries from generating credits for shutting down major units without upgrading or replacing them and from generating credits for equipment downtime during turnarounds. Equipment taken out of service to be upgraded or replaced is not the target of the shutdown language in the provision.

1042. Comment: **LCFS FF43-48**

The commenter states that staff has removed the ability to generate refinery investment credits from co-processing liquid bio-feed stocks at facilities, leaving Hydrogen co-processing as the only viable option available to some. While the opportunity to seek dedicated pathway approvals for such applications is still provided, staff's action eliminates substantial flexibility for parties' smaller scale projects/applications that may not warrant the dedication of time and resources to the rigors of the specified pathway approval processes.

Agency Response: The existing dedicated pathway approach is a vetted and proven process and is ideal for approving the co-processing of liquid bio-feedstocks at facilities. Including competing pathway approval processes in the regulation would be redundant.

1043. Comment: **LCFS FF43-49**

The commenter believes that adding the term “pilot program” to the title of the Refinery Investment Provision signals staff’s intention to make it a temporary provision.

Agency Response: Please see response to comment **LCFS FF43-8**.

1044. Comment: **LCFS FF43-50**

The commenter is opposed to putting a cap on the amount of refinery investment credits a facility can generate.

Agency Response: Staff imposed these caps to facilitate the learning period for these types of credits as described in **LCFS FF43-8**. The LCFS program could suffer if a large number of new, unestablished credits flooded the marketplace. Staff wishes to avoid this outcome in the LCFS, both by evaluating each credit application rigorously and by imposing the fixed usage limits through the 2020 timeframe. These limits could potentially be relaxed in future rulemakings if the experience with the pilot programs is positive.

1045. Comment: **LCFS FF43-51**

The commenter opposes the limitation on selling refinery investment credits.

Agency Response: See response to **LCFS FF43-52**.

1046. Comment: **LCFS FF43-52**

The commenter believes that this limitation on selling RICs may be simply be the result of limitations in staff’s ability to bring about the necessary LRT revisions in a timetable consistent with the LCFS re-adoption schedule.

Agency Response: The commenter is partially correct. The prohibition on the sale of credits generated from the refinery investment credit and the renewable hydrogen provisions is based, in part, on concerns about the timetable to bring about the necessary LRT revisions to handle limits imposed on the credits generated from the refinery investment credit and the renewable hydrogen provisions.

Additional reasons to limit, for the time being, the sale of these credits include the fact that these are new pilot credit options within the LCFS system. Staff would prefer to gauge the response of the refiners and better understand the types of projects that will be submitted prior to making these credits fully fungible with all other credits.

All eligible regulated parties generating these credits also generate large deficits. They may use the credits from these pilot programs to meet their compliance obligations, which would reduce their need to buy additional credits or free up credits from other sources for sale.

1047. Comment: **LCFS FF43-53**

Despite some improvements made by staff in the 15-day package, WSPA still believes that the current proposal substantively impedes valid credit generation in conflict with what ARB hopes to incentivize with the measure.

Agency Response: See response to comments **LCFS FF43-47**, **LCFS FF43-48**, **LCFS FF43-49**, **LCFS FF43-50**, and **LCFS FF43-52**.

1048. Comment: **LCFS FF43-60**

The commenter recommends that requirements for ARB in determining the Annual Crude Average CI be included in Table 12 of the regulation.

Agency Response: The regulation requirement for posting the Annual Crude Average carbon intensity calculation reads “Within 15 days of receiving the Annual Compliance reports, the Executive Officer shall post the Annual Crude Average carbon intensity calculation at the LCFS web site (http://www.arb.ca.gov/fuels/lcfs/lcfs.htm) for public comment.” Because the posting of the calculation is dependent on when the final Annual Compliance report is received, there is no set date by which the calculation must be posted. Therefore, ARB staff did not include the requirement for posting the calculation in Table 12.

1049. Comment: **LCFS FF43-61**

The commenter objects to the removal of annual reports from the section related to Correcting a Previously Submitted Report. There may be instances in which an annual report may also need to be reopened for corrective edits and resubmittal. The removal of annual reports from this section essentially dis-allows regulated parties to correct previously submitted annual reports.

Agency Response: Staff is striving to limit the amount of corrections requested to previously submitted reports and is ramping up efforts to consider appropriate enforcement action against parties that file incorrect information.

However, if corrections are still needed, the corresponding annual report(s) are automatically opened in the LRT-CBTS whenever a quarterly report is re-opened. The annual report is resubmitted by the regulated party once the quarterly corrections are approved. Therefore, a regulated party does not need to submit a separate request for opening an annual report for quarterly reports.

The other functional reasons to open an annual report in the LRT, other than for quarterly report corrections, are to modify the number of credits “Exported to” another program, which is not permitted. The second case is where a document was not uploaded with the annual report, as required.

Given the additional attention being placed on ensuring accurate reporting, this situation is expected to occur infrequently, not requiring a special process and will be handled by the LRT-CBTS administrator.

1050. Comment: **LCFS FF43-62**

The commenter approves of a change to clarify that penalties for unmatched deficits would be assessed on a per-deficit basis, rather than a per-day basis, but recommends a wording change to clarify that the penalty would not be per deficit, and then multiplied by some number of days.

Agency Response: ARB believes that the regulation as written is consistent with a “per-deficit” approach, not deficits multiplied by days. The wording in question – “each deficit . . . constitutes a separate day of violation” – simply accepts the Legislature’s invitation to “develop a method to convert a violation of any rule . . . into a number of days, where appropriate, for the purposes of the penalty provisions” in the Health & Safety Code – all of which state that each day is a separate violation. (*See* Health & Saf. Code §38580, subd. (b)(3).) ARB chose to equate one deficit with one day, rather than with five days or some other number of violations.

1051. Comment: **LCFS FF43-63**

ARB defined the "material information" which, if incorrect, can serve as a basis for revoking credits. The commenter believes that by defining material information ARB expanded the bases for revocation; the commenter suggests striking the definition.

Agency Response: ARB staff disagrees – a broad power to revoke has always been part of the proposal; the definition simply clarifies and defines that power without expanding it. Eliminating the definition could leave regulated parties to wonder exactly what "material [mis]information" could lead to revocation. The commenter objects to the potential for revocation, faulting ARB for not somehow insuring the validity of credits, citing to the "verifiable" emission reduction requirement in Health & Safety Code section 38562(d)(1). ARB staff disagrees that the credits are not verifiable; indeed the regulation includes a revocation provision on the very assumption that some credits will be verifiably fraudulent or otherwise unsupported. ARB expects that it will be in private parties' best interest (including the commenter's members) to take steps to verify the validity of credits before surrendering them for compliance. See also response to comment **LCFS 40-39**.

1052. Comment: **LCFS FF43-64**

This comment indicates support for the 2017 Progress Report concept.

Agency Response: ARB staff appreciates the support for the 2017 Progress Report concept.

RE: RPMG Comments on Proposed Re-adoption of the Low Carbon Fuel Standard

Dear Clerk of the Board,

Renewable Products Marketing Group (RPMG) is a biofuel marketing company currently representing 21 ethanol facilities located throughout the Midwest. Of those 21 facilities, RPMG actively markets ethanol and distiller's oil produced from various feedstock types from 10 facilities directly into the California fuels market. RPMG is a supporter of the Low Carbon Fuel Standard (LCFS), which diversifies transportation fuel supply, incentivizes innovative technology and advanced renewable fuel selection, creates jobs, stimulates the California economy, and, most importantly, improves the environment. The track record of the U.S. renewable fuel industry and the LCFS is a shining example of these activities being achieved through hard work and ingenuity. We are writing today to provide comment on the recent proposed re-adoption of the LCFS. Implementation of the re-adopted LCFS is going to take a lot of communication and joint effort between industry and CARB.

Below are our detailed comments and indications of areas needing additional clarification with regard to the proposed 15-day amendments published on June 4, 2015. We have broken down our comments into six subsection groupings for reference. We invite CARB staff to contact us with any questions or requests for additional information on any of the points raised. We sincerely appreciate the opportunity to provide these comments to you today, and we thank you for your thorough consideration of each.

Section 95488, Title 17, California Code of Regulations, "Obtaining and Using Fuel Pathways"

Section 95488(a)(3)

While RPMG acknowledges and supports the general intention to avoid creating artificial market barriers and competition for CARB resources with the proposed changes to 95488(a)(3), it remains largely unclear how this proposal would be carried out in practice. It is imperative that CARB provide guidance such that industry can adequately plan and implement the pursuit of pathway approvals. These are some areas of ambiguity and concern we have identified:

- Is each fuel type placed into a single batch for review with a predeclared deadline for application submission, or will there be multiple scheduled batches per fuel type such that applications received in the defined window will be batched and released by a defined date? LCFS FF44-1
- What is the trigger or signal that a batch is "closed" and ready to move on to the staff review stage (quantity of applications received, defined window of opportunity, etc.)? LCFS FF44-2
- Is staff proposing to wait to review any other fuel type application until ALL ethanol pathways are received and reviewed? LCFS FF44-3

- Has staff reviewed the potential credit losses to the whole program by delaying other fuel type pathways? LCFS FF44-4

- What are the anticipated deadlines and release dates of pathways? LCFS FF44-5

- When will CARB begin accepting pathway applications? LCFS FF44-6

- Has CARB consulted the limited number of pathway consultants and advisors available to industry for their input? What are the expressed and anticipated constraints on those resources available to industry? LCFS FF44-7

- What will be deemed the completeness date in the certification approval documents? LCFS FF44-8

- How are the parameters of completeness defined and/or determined? LCFS FF44-9

Through discussions with staff and knowledgeable industry parties, it has come to our awareness that a guidance document is being compiled by CARB staff. We support the development of this guidance document. It is imperative for industry to prepare for and timely obtain new fuel pathways. This will require the coordination and mobilization of both internal and external resources. Clear and definitive information will allow industry to adequately prepare. In turn this should assist CARB in its own preparation to receive and process those applications. However, we are concerned this document may be published without the opportunity for industry involvement or public input. We suggest that CARB provide a public forum for reviewing concepts of the guidance document and allow the opportunity to make recommendations. LCFS FF44-10

Section 95488(c)(5)(B) and (e)(5)(B)

RPMG sympathizes with the expressed concern of CARB staff in 95488(c)(5)(B) and (e)(5)(B) of "eliminating potentially unrealistic deadlines in various parts of the existing proposal." However, it has been the experience of RPMG and our associated producers throughout the four-year history of implementation of the LCFS that delays, extended review periods and uncertainty (specifically in pathway applications) have become the "status quo." It is essential for the program to provide industry with a means of assessing timely responses that will provide the basis for market certainty. This is not achieved through the imposed deadlines on industry participants while simultaneously proposing to remove a similar expectation of deadlines for CARB staff. RPMG would encourage CARB in the future to maintain clear expectations of deadlines on the part of both the regulated industry and CARB staff. By maintaining equitable treatment in this manner, CARB will ensure that it is sending a strong signal of reliability and accountability to the market. LCFS FF44-11

Section 95488(b)(3)

We appreciate staff's proposal to reduce confusion and clarify that the iLUC values referenced in the ISOR are a part of the proposal with the addition of Table 5 in section 95488(b)(3). We also appreciate the simplicity in having a table to reference in the regulations, which is a place where a regulated party can and should expect to find pertinent details of the program without having to consult multiple reference materials or guidance documents. Our concern is the addition of this table limits iLUC to just these values. Our understanding is once an item is codified in regulation it requires a formal rulemaking process to modify any part. If this is not the case, CARB should clarify further. As such, we caution against the formalization of such a table if it would impact or delay the addition or modification of new values, or the inclusion of new feedstock types. Without the means of modifying iLUC values administratively this table is a hindrance to the environmental and market incentive objectives of the program. Any such hindrance would not justify its codification in the regulations. If that is the case, we highly recommend CARB staff devise an administrative LCFS FF44-12 alternative to approving and incorporating iLUC values for the program.

Section 95488(c)(3) and (c)(4)(I)(2)

Adding the Tier Pathways to this section is problematic for a variety of reasons, including structure and implementation.

Throughout the regulations, we note evidence of establishing Tier 1 and Tier 2 pathways. With these revisions, we are noting a distinct shift to attempting to classify Tier 1 and Tier 2 facilities. By definition, Tier 1 and Tier 2 labels are applicable to pathways, not facilities. This is very simply demonstrated when you consider that a single facility may have the ability to co-process different tier fuels simultaneously, such as conventional corn ethanol and cellulosic ethanol from non-starch cellulosic material. Further, one should consider single facilities installing and utilizing innovative production methods. It is logical to assume that during the periods when relevant innovative technologies and equipment are utilized, the facility would be producing under a Tier 2 pathway, and conversely, when not utilizing that equipment, the fuel would qualify for a Tier 1 pathway. We wish to point out that "commercial operation" of a facility is materially different from "commercial operation" of a pathway or new fuel product stream.

LCFS FF44-13

Adding Tier 1 pathways to the provisional pathways section is concerning because new or expanding facilities are now disincentivized from entering the California fuel market for the requisite two-year "provisional" period. This disincentive will not only impact investments and liquidity of those operations, but it is also a major obstacle for innovative technologies to befit the LCFS program in any meaningful way. This provision creates a barrier to deploying innovative technologies and to supplying the California market with meaningful volumes of low carbon fuel from new sources and those new technologies. With this proposal, CARB is stifling innovation at the greater expense of the explicit goal of the LCFS: to reduce carbon emissions and improve the environment.

LCFS FF44-14

Deficit-generating industry parties have repeatedly indicated they are not interested in procuring "commercial" volumes of fuel without obligation. They do not desire to take on the risk of potentially not benefiting from the fuel or blendstock they procure in terms of credit generation for a two-year period. Further, by the time the two-year "provisional" period sunsets, the credit potential for that fuel has incrementally decreased at the predefined rate of the compliance schedule. Both of these factors are barriers to market entry. This is in direct conflict with the objectives of the LCFS.

LCFS FF44-15

Real-world implementation challenges and interpretation of this section from the perspective of a producer can be expressed in three case scenarios: newly operational commercial fuel producers in California, newly operational commercial fuel producers outside of California, and preexisting operational commercial fuel producers deploying capital investment projects in new and innovative technologies. We interpret fuel producers falling within these three categories would not be allowed to participate in the LCFS for provisional pathway fuels, until they reach one full calendar quarter of commercial operations. We understand this will restrict them from applying for a pathway until they achieve this milestone. If this is inaccurate, CARB should clarify. The potential market for those fuels becomes so small it is almost nonexistent, as regulated parties generating a deficit will be strongly inclined to procure fuel and credits elsewhere (citing regulatory risk, commercial risk, limitations in access to resources, uncertainty in viability of counterparty, etc.). This will place extreme limitations on producer liquidity. Out-of-state producers will not have sufficient incentive to opt in to the program, and all credit potential for those periods will be lost. Consider that the program incentivizes early credit generation and makes it harder to achieve meaningful credit generation over time. Not being allowed to transfer obligation with physical fuel will disincentivize refiners, blenders and other deficit-generating regulated parties from choosing to utilize these fuels, effectively blocking their access to the market and thereby limiting California's environmental benefit.

LCFS FF44-16

This section introduces many unintended consequences by CARB, and we strongly advise staff rework this section of the proposal, even if it means reopening this section after re-adoption of the rule as a whole. LCFS FF44-16 cont.

Section 95488(e)

RPMG supports the clarification by CARB in 95488(e) that existing physical pathway demonstrations that were approved under the previous regulation order will be accepted without any resubmittal requirements. This will ensure that CARB is meeting its objective in streamlining the pathway approval process. LCFS FF44-17

Section 95491, Title 17, California Code of Regulations, "Reporting and Recordkeeping"

Section 95491(a)(7)

RPMG notes that the addition of "for the current compliance period" in section 95491(a)(7) adds ambiguity while addressing end-of-year reporting responsibilities in the new year. Upon review, we are unclear how to interpret "current compliance period" during the old-year to new-year transitioning period affecting Q4 progress reporting and annual compliance reports. We request clarification on this part to ensure clear and understandable boundaries from the perspective of the reporting schedule. LCFS FF44-18

In closing, RPMG acknowledges this program is complex. Re-adoption is helpful and a worthwhile pursuit, but it does leave implementation questions. We encourage additional clarity and guidance. Further, we welcome the opportunity for a continued open dialogue with CARB staff to ensure the program moves forward with the proper foundation and clear expectations for industry to adhere to the program regulations.

Sincerely,

JWHoffmann

1053. Comment: **LCFS FF44-1**

The comment is related to batch processing to recertify pathways.

Agency Response: If the Board approves the proposed regulation, Staff will be conducting workshops post Board Hearing and will provide guidance surrounding the administrative process of recertifying pathways.

The deadline to request pathway recertification will be February 1, 2016 (see § 95488(a)(2)(A)).

1054. Comment: **LCFS FF44-2**

The comment is related to batch processing to recertify pathways.

Agency Response: See response to **LCFS FF18-1** and **LCFS FF44-1**.

1055. Comment: **LCFS FF44-3**

The comment is related to batch processing to recertify pathways.

Agency Response: See response to **LCFS FF18-1** and **LCFS FF44-1**.

1056. Comment: **LCFS FF44-4**

This comment is related to batch processing to recertify pathways and a question related to equitable treatment of the batches.

Agency Response: Pathways that are being recertified will be active until recertification. Therefore, it is not likely that credits will be lost due to pathways not being recertified earlier in the process compared to later. Staff will be conducting workshops post Board Hearing and will provide guidance surrounding the process of recertifying pathways.

1057. Comment: **LCFS FF44-5**

The comment is related to batch processing to recertify pathways.

Agency Response: See response to **LCFS FF18-1** and **LCFS FF44-1**.

1058. Comment: **LCFS FF44-6**

This comment is a question related to when staff will accepting pathway applications.

Agency Response: The comment does not make a recommendation or objection regarding the proposal, and needs no response.

1059. Comment: **LCFS FF44-7**

This comment is a question whether staff has knowledge of the constraints on resources to aid industry with pathway applications.

Agency Response: ARB staff views the recertification process as primarily an administrative action undertaken by ARB staff. Staff will attempt to process recertifications with existing data, but will request additional information from the applicant for recertification if needed.

Staff will be conducting workshops post Board Hearing and will provide guidance to assist industry with the process. ARB staff has also been actively receiving feedback prior to the release of the draft regulation from industry consultants. Staff will work with industry, consultants, and all stakeholders alike to enable fuel pathway applicants to receive the necessary information and guidance to help them apply for pathways. It is staff's belief that with the new Tier 1 process, the overall need for consultants and advisors will be reduced significantly.

1060. Comment: **LCFS FF44-8**

The comment is related to LCFS pathway applications being deemed complete.

Agency Response: Staff will be conducting workshops post Board Hearing and will provide guidance surrounding the process of applying for fuel pathways. Generally, an application that is deemed complete contains all relevant information that is required for staff to process the application. The date that all such information is received is the deemed complete date.

1061. Comment: **LCFS FF44-9**

The commenter requests clarification on how the parameters of the completeness of the application are determined.

Agency Response: The comment does not make a recommendation or objection regarding the 15-day modification, and needs no response. See response to **LCFS FF44-8**.

1062. Comment: **LCFS FF44-10**

This comment is related to the commenter being informed that staff will provide guidance to assist stakeholders with pathway application processing.

Agency Response: ARB staff notes that this comment is not directed to any change in the 15-day proposal. As a courtesy however, staff is providing a response to the comment.

Staff will be conducting workshops post Board approval and will provide guidance surrounding the process of applying for fuel pathways. All such workshops are open to the public and staff greatly appreciates stakeholder.

1063. Comment: **LCFS FF44-11**

This comment is related to deadlines being removed under § 95488(c)(5)(B) and § 95488(e)(5)(B).

Agency Response: Please see response to comment **LCFS FF35-7.**

1064. Comment: **LCFS FF44-12**

The commenter requests that ARB not include iLUC values in the regulation if it hinders updating the values frequently.

Agency Response: Updating indirect land use change (iLUC) values will require a formal rulemaking process. This is due to the complexity of updating the science and methodology to estimate iLUC values. The current iLUC values were developed by accounting for updates in land use change science and methodologies in economic modeling of such effects. It required significant effort (and resources) by staff, researchers and stakeholders to consider, evaluate, and include relevant updates for the current round of rulemaking. Updating iLUC frequently would also place an enormous burden on stakeholders required to modify their pathway CIs every time an iLUC value is updated to reflect the findings of a single report. At this time, staff is contemplating an update iLUC values once every three years as part of a rulemaking package.

1065. Comment: **LCFS FF44-13**

This comment is related to the language used when characterizing a fuel pathway as a Tier 1 or Tier 2 facility.

Agency Response: ARB staff appreciates the commenter's keen observation regarding the use of the term facility compared to pathway in the regulation, but does not believe an amendment is needed. Tier 1 and Tier 2 are only related to pathways, but may also apply to a facility that is only Tier 1 or Tier 2. Similarly, a facility may have multiple pathways for which some may be Tier 1 and others may be Tier 2. Furthermore, Tier 1 and Tier 2 do not refer to specific fuels, but to fuel pathways. It would not be possible to implement the regulation if the term facility (Tier 1 or Tier 2) was taken literally.

1066. Comment: **LCFS FF44-14**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

1067. Comment: **LCFS FF44-15**

The commenter believes that the 2-year barrier on sales of provisional credits is a market barrier.

Agency Response: In the second 15-day package, ARB changed the proposal to allow for the sale of credits generated through provisional pathways subject to certain conditions. The Executive Officer still maintains the authority to adjust the number of credits or reverse any provisional credit in the producer's account without a hearing.

1068. Comment: **LCFS FF44-16**

This comment is related to provisional pathways being able to generate credits as soon as commercial production begins. The commenter also suggests that staff can revisit this requirement and make modifications during implementation of the LCFS.

Agency Response: See response to **LCFS FF27-3**. ARB staff looks forward to helping to provide implementable solutions to concerns that the commenter presented.

1069. Comment: **LCFS FF44-17**

The commenter indicates support for the clarification that existing physical pathway demonstrations will not be required to be resubmitted.

Agency Response: ARB staff appreciates the support.

1070. Comment: **LCFS FF44-18**

The commenter is unclear how to interpret "current compliance period" during the old-year to new-year transitioning period affecting Q4 progress reporting and annual compliance reports.

Agency Response: An “Unlock Request” can be made online in the LRT-CBTs to request corrections to previously submitted quarterly reports "for the current compliance period." This applies to where the annual compliance reporting deadline has not yet passed. Regulated parties need to ensure that all corrections to their quarterly and annual reports are completed prior to the deadline for annual reporting.

Growth Energy's Comments on June 4, 2015, 15-Day Notice for the Proposed Revisions to the LCFS Regulation

On December 30, 2014, CARB circulated for public review an Initial Statement of Reasons (the "ISOR") and an Environmental Analysis ("EA") for CARB's proposed revisions to the Low Carbon Fuel Standard (the "LCFS regulation"). Following a February 19, 2015, public hearing on the LCFS regulation, the Board directed staff to consider modifications to the LCFS regulation, and respond to environmental comments.

CARB released proposed modifications to the LCFS regulation through its June 4, 2015, Notice of Public Availability of Modified Text and Availability of Additional Documents (the "15-Day Notice"). Due to various concerns regarding the LCFS regulation, including issues raised in the 15-Day Notice, Growth Energy submits the following comments on the proposed modifications to the LCFS regulation under the California Environmental Quality Act, the California Administrative Procedures Act, and the Health & Safety Code.

A. CARB's LUC Value for Corn Ethanol of 19.8 gCO_2e/MJ Is Not Supported By Substantial Evidence, and Would Result in Adverse Climate Change Impacts

CARB's proposed revisions to the LCFS regulation contemplate a land use change ("LUC") value for corn ethanol of 19.8 gCO_2e/MJ. This value, however, is not supported by substantial evidence. Specifically, to calculate the corn ethanol LUC, CARB staff used the average of five price-yield values [0.05, 0.10, 0.175, 0.25, and 0.35], which is 0.19. LCFS FF45-1

As explained in the accompanying declaration of Tom Darlington, a price-yield of 0.19 is contrary to the evidence, as the value recommended by Purdue is 0.25. (Decl. Darlington ¶ 5.) Lower price yields such as 0.05 and 0.10 are also inconsistent with CARB's own modeling. The research that could be read as supporting such low price-yields is based on short-term shock, while CARB's GTAP model uses medium- and long-term shock. (*Id.*)

Moreover, the only study relied upon by CARB to support a low price-yield value was prepared by David Rocke of UC Davis. The Rocke analysis is based on only one set of data – a 2012 dissertation by Juan Francisco Rosas Perez, who concluded that price-yield response was approximately 0.29. Despite the use of this data set, the Rocke study concluded – based on his own "statistical analysis" – that the price yield should be lower. (*Id.* ¶ 6.)

The rulemaking file does not contain an explanation as to how the Rocke study reached this conclusion or performed his statistical analysis. While commenting parties have requested this data, CARB staff has never supplied the data to the public. As a result, there is no evidentiary support for the lower price-yield values, and CARB should eliminate the lowest two values – 0.05 and 0.10 – due to a complete lack of evidentiary support for those values. (*Id.* ¶¶ 5-7.)

This failure is not merely academic. If the lowest two price yield values are eliminated, CARB's average price yield for corn ethanol would be 0.26. This would result in a

LUC value for corn ethanol of 15.53 gCO_2e/MJ, compared to 19.84 gCO_2e/MJ, (*id.* ¶ 7, Table 1), which would in turn lower the Carbon Intensity ("CI") Value for corn ethanol. LCFS FF45-1 cont.

In addition to the practical consequences on the use of corn ethanol in the marketplace, CARB's reliance on unsupported price-yields also has real environmental consequences. The LUC values are a component of the CI Value placed on a fuel by CARB. If CARB inaccurately calculates the LUC (and thus the CI value) of a fuel as being too high, it will incentivize the use of fuels that have a higher carbon intensity, creating an adverse climate change impact. In the rulemaking for the first LCFS regulation, CARB's consultants explained the importance of accurately calculating the CI Values in the Lookup Table: LCFS FF45-2

> [I]f we make a mistake in one direction in estimating these numbers, we'll use too much of a biofuel that's actually higher carbon [than] we thought and will therefore increase global warming. And if we use numbers that are too low, then we'll use too little of a biofuel that's lower carbon than we thought and will therefore increase global warming.

(Attachment "C" at 73-74 [excerpts from April 23, 2015, CARB Meeting].)

To avoid these potential adverse consequences, and to develop LUC Values (and thereby CI Values) that are based on scientific data, CARB should eliminate the lowest two values – 0.05 and 0.10 – for its average price-yield for corn ethanol.

B. CARB's LUC Value for Brazilian Cane Ethanol Is Not Supported By <u>Substantial Evidence, Due to Errors in the GREET Model</u>

LCFS FF45-3

The most recent version of the GREET model made available in June 2015 contains an error in its estimation of emissions resulting from ethanol produced from sugar cane in Brazil. Specifically, as explained in the accompanying declaration of Tom Darlington, an error in the GREET model results in cane ethanol plants with no mechanized harvesting having the same emissions as plants with 100% mechanized harvesting. (Decl. Darlington ¶ 10.) The correction of this error would obviously result in an increase in the CI Value for cane ethanol.

C. CARB Should Not Eliminate the Multimedia Evaluation Provisions <u>From the LCFS</u>

The 15-day Notice for the revised LCFS regulation suggests that CARB is proposing to eliminate the multimedia evaluation ("MME") provisions for new fuels contained in Sections 95490, 95481(a)(59), and 95488(c)(4)(G). As explained in the Declaration of Jim Lyons, the removal of the MME for new fuels has the potential to result in additional emissions and other adverse impacts. (Decl. Lyons ¶¶ 7-10.) Further, this change is not sufficiently related to the original text of the regulation such that a member of the directly affected public could have been put on notice that the changes had the potential to occur. Thus, CARB should reinstate the MME provisions and/or recirculate the proposed LCFS regulation for a full 45-day public review. LCFS FF45-4

1. The Elimination of the MME for New Fuels Could Result in <u>Additional Emissions</u>

The elimination of the MME requirement for new fuels will result in potentially significant environmental effects. First, the MME process provides important safeguards to help ensure new fuels will not result in increases in emissions. (See, e.g., Health & Saf., § 43830.8.) Without such safeguards, fuels can be allowed in California that result in additional emissions of criteria pollutants. LCFS FF45-5

For example, CARB permitted the introduction of biodiesels into the California market without requiring a MME under Section 43830.8. (Decl. Lyons ¶ 8.) "Based on CARB staff estimates, in 2014, biodiesel use for compliance with the LCFS regulation allowed by CARB without an approved [MME] . . . resulted in increased NOx emissions of 1.2 tons per day statewide." (*Id.*) Had CARB adopted fuel specifications, and required biodiesels to complete the MME process in 2009, these increased emissions could have been eliminated. (*Id.* ¶¶ 8-9.) CARB should learn from its past mistakes – not repeat them – and require new fuels to undergo the MME evaluation process.

2. The Elimination of the MME Requirement for New Fuels Is Not Sufficiently Related to the Original Text, and Requires Recirculation of the LCFS Regulation for a 45-Day Comment <u>Period</u>

California law provides that "[n]o state agency may adopt, amend or repeal a regulation which has been changed from that which was originally made available to the public . . . unless the change is . . . ***sufficiently related*** to the original text that the public was adequately placed on notice that the change could result from the originally proposed regulatory action." (Govt. Code, § 11346.8(c) [emphasis added].) To be "sufficiently related," changes must be such that "a reasonable member of the directly affected public could have determined from the [original text of the] notice that these changes to the regulation could have resulted." (1 Cal. Code Regs, § 42.)

LCFS FF45-6

California generally requires all new fuels to undergo the MME process under Section 43830.8 of the Health & Safety Code. Neither the original LCFS regulation nor the revised LCFS regulation circulated for a 45-day public review suggested that new fuels would be exempt from the MME process. Despite this, the 15-day notice now suggests many new fuels will be exempt from the MME requirement. Because Section 43830.8 is a preexisting requirement for new fuels that is unrelated to the LCFS regulation, the public could not have anticipated that the MME requirements would be eliminated by CARB. Thus, the elimination of the MME requirement for new fuels is not "sufficiently related" to the original text and, unless the MME requirement is reinstated, CARB must recirculate the revised LCFS regulation for a new 45-day public review period. (Govt. Code, § 11346.8(c); 1 Cal. Code Regs., § 42.)

D. CARB Failed to Include All Required Documents in the Rulemaking <u>File</u>

CARB recently added a series of email documents to the LCFS rulemaking file (see LCFS 15-Day Notice at 13), all of which date from 2013 or 2014. According to CARB, it is adding those materials to the rulemaking file, and inviting public comment on them, because the documents "might be characterized as containing non-privileged factual information submitted to ARB from ARB consultants." (*Id.* at 13.)

Those emails, likely along with many other documents from 2013 and 2014 submitted to CARB in connection with the proposed regulatory amendments, should have been included in the rulemaking file that CARB opened at the time of the notice of proposed rulemaking, which was dated December 16, 2014. CARB cannot cure this self-evident violation of section 11347.3 of the Government Code by adding those materials to the rulemaking file and inviting 15-day comments; CARB must cure this deficiency, along with numerous other violations of the governing statutes and regulations, by noticing the LCFS regulation for another public hearing after allowing 45-days for public comment.

The requirements of the Government Code are clear. Section 11347.3 of the Government Code requires CARB to maintain a "file of [the] rulemaking proceeding" for any proposed regulatory action subject to the APA, including the LCFS regulation." The rulemaking file must include, among other items, the following:

> (6) All *data and other factual information***,** any studies or reports, and written comments submitted to the agency in connection with the adoption, amendment, or repeal of the regulation. LCFS FF45-7
>
> (7) All data and other factual information, *technical*, *theoretical*, and *empirical studies or reports*, if any, on which the *agency is relying* in the adoption, amendment, or repeal of a regulation, including any cost impact estimates as required by Section 11346.3.

(Govt. Code, § 11347.3, subds. (b)(5), (b)(6) [emphasis added].) The entire rulemaking file, including the foregoing material, must be "available to the public for inspection" from the time when the first notice of the proposed rulemaking is published in the California Regulatory Notice Register, (*id.* at § 11347.3, subd. (a)), which in the case of the low-carbon fuel standards occurred on March 6, 2009. (See Cal. Reg. Notice Reg., Vo. 10-Z at 371.)

As the above-quoted text makes clear, rulemakings at ARB must include the creation of a rulemaking file that includes "*[a]ll* data and other factual information, any studies or reports, and written comments submitted to the agency" in connection with the proposal. (Govt. Code § 11347.3, subds. (a), (b)(6) [emphasis added].) To assure immediate public access to the supporting materials as soon as the 45-day materials are released, the APA requires that the 45-day notice include a statement that the agency on the date of the notice "has available *all* information upon which [the] proposal is based." (*Id.* § 11346.5, subd. (a)(16) [emphasis added].) A separate provision confirms that the agency must in fact make those records, and any other "public records, including reports, documentation, and other materials, related to the proposed action," available. (*Id.* § 11346.5, subd. (b).)

The "written comments" that must be placed in the record are not simply those submitted to the agency in a particular manner or at a particular time, such as during the period between publication of the notice of a public hearing and public hearing – an agency must put "all" it receives "in connection with" a regulatory proposal in the rulemaking file. The Legislature's choice of words to describe what comments must be placed in the file – "in connection with" – sweep with intentional breadth, and require inclusion of any comments that bear on the subject of the regulatory effort. In addition, the period of public availability must "[c]ommenc[e] *no later than* the date that the notice of the proposed action is published." (*Id.* § 11347.3, subd. (a) [emphasis added].) The use of the term "no later than" makes it clear that the Legislature expected written comments submitted in connection with a proposed regulatory action and received before publication of the required notice to be included in the rulemaking file.

LCFS FF45-7 cont.

In addition to failing to include these new, late-added documents in the rulemaking file, CARB has not properly construed or applied the relevant provisions of the Government Code. In particular, the rulemaking file is not to be limited to "factual information" that comes from "consultants" to CARB: Section 11347.3(b)(5) does not use the word "consultant," and it covers "any . . . written comments submitted to the agency in connection with" the adoption or amendment of a regulation. If "factual information" from sources that CARB defines as "consultants" received before CARB opened the rulemaking file for the current LCFS rulemaking warrant inclusion into the rulemaking file, so do any other written comment submitted to CARB in connection with the adoption or amendment of the LCFS regulation, or the adoption of the proposed alternative diesel fuels regulation. In addition, materials received from external sources, such as consultants, are presumptively not "privileged" and must be included in the rulemaking file.

LCFS FF45-8

Growth Energy therefore requests the following:

- An explanation of the reasons, if any, why CARB does not interpret section 11347.3 to require that all written comments received from any source in connection with the adoption or amendment of the LCFS regulation, or the adoption of the proposed alternative diesel fuels regulation, be included in the rulemaking file;

LCFS FF45-9

- An explanation of the reasons why the 2013-2014 documents that have now been added to the rulemaking file were not included in the rulemaking file at the time the file was first opened for public access; and

LCFS FF45-10

- An identification of each record from a consultant (or any person or entity retained by CARB) that would otherwise have been placed in the rulemaking file has not been placed in the file under color of privilege, so that compliance with section 11347.3 can be assessed by the public.

LCFS FF45-11

E. CARB Failed to Perform an Adequate External Scientific Peer Review for the Revised LCFS Regulation

This portion of Growth Energy's comments addresses the requirements of section 57004 of the Health and Safety Code, and CARB's failure substantially to comply with those requirements in the LCFS rulemaking.[1] LCFS FF45-12

1. Factual and Legal Background

Section 57004 of the Health and Safety Code creates several mandatory duties that must be fulfilled before CARB can take "any action" to adopt the proposed regulation to replace the current LCFS program. (Health & Saf. Code, § 57004, subd. (d).) Those duties include the following:

- CARB must submit "the scientific portion of the proposed rule" — in this instance, the regulation that the staff has proposed for final approval by the Board as a replacement for the current LCFS regulation — for review by an appropriate "external scientific peer review entity," along with "a statement of the scientific findings, conclusions, and assumptions on which the scientific portions of the proposed rule are based and the supporting scientific data, studies, and other appropriate materials." (*Id.*, § 57004, subd. (d) (1). LCFS FF45-13

- The "external scientific peer review entity" must then "prepare a written report." That report must "contain[] an evaluation of the scientific basis for the proposed rule." (*Id.*, § 57004, subd. (d)(2).) LCFS FF45-14

Memoranda sent by the CARB staff to the Manager of the Cal/EPA Scientific Peer Program dated November 19, 2014, and January 21, 2015, indicate an intent to comply to with section 57004. A letter from the Manager of the Cal/EPA Scientific Peer Program dated May 5, 2014, appears intended to convey the results of the external scientific peer review entity created for the proposed new LCFS rule. Neither the memoranda to the Manager of the Program nor the Manager's letter indicate that compliance with section 57004 in the current rulemaking was not mandatory, or that complete compliance with section 57004 was not required. Nor does the record indicate that there was insufficient time to permit CARB to ensure compliance with the requirements of section 57004. Those who were responsible for compliance with section 57004 had twice the time to complete their work than the public was provided to comment on the proposed regulation, the scientific portions of which were to receive review by the external scientific peer review entity.[2] LCFS FF45-15

---

[1] CARB posted some of the external scientific peer review materials for the new LCFS regulation on May 21, 2015, and additional materials on May 27, 2015 (*see* Attachment A), even though the peer review materials appear to have been completed weeks prior to May 21.

[2] There were 104 calendar days from January 21, 2105, to May 5, 2015. The rulemaking notice for the proposed regulation was dated December 16, 2014, but was not announced on the CARB website and made available to the public along with some supporting material until

Comment on the May 5, 2014 letter and its attachments is appropriate now, because the letter and its attachments comprise Reference 26 on the list of Additional References and Supplemental Documents in the staff's June 4, 2015, 15-Day Notice. Related materials also appear as References 27-29 on the same list.

Section 57004 of the Health and Safety Code defines the "scientific portions" of a proposed rule to include "those foundations of a rule that are premised upon, or derived from, ***empirical data*** or ***other scientific findings, conclusions, or assumptions*** establishing a regulatory level, standard, or other requirement for the protection of public health or the environment." (Health & Saf. Code, § 57004, subd. (a)(2) [emphasis added].) As indicated in the May 5 letter, the Manager of the Cal/EPA Scientific Peer Program intended that the "reviewers" selected for participation in the work would be "ultimately responsible for assessing the relevance and accuracy of ***all information*** upon which the staff report is based." (May 5 Letter at 2 [emphasis added].) While the May 5 letter is not clear about the identity of the "staff report" to which it refers, the reference may refer to the four summary documents that the CARB staff apparently prepared for consideration by the external scientific peer review entity; regardless, because those four documents are derived from the December 2014 Initial Statement of Reasons ("ISOR") for the proposed regulation, the external peer review entity was responsible for assessing the relevance and accuracy of all the information on which the ISOR was based. If CARB disagrees with that interpretation of the scope of the external scientific peer review entity's responsibilities in the current rulemaking, Growth Energy requests that CARB fully explain its reasons for disagreement in the response to these 15-day comments required by the California Administrative Procedures Act (the "APA"). LCFS FF45-16

Finally, it is important to be clear on one other point. The CARB staff memoranda to the Manager of the Cal/EPA Scientific Peer Program specified the number of reviewers whom the CARB staff considered necessary for various elements of the proposed LCFS regulation, and the required expertise for the reviewers who were to comprise the external scientific peer review entity. Nevertheless, Cal/EPA requires the "UC Project Director," following "careful consideration of the information" submitted by an agency, to determine the number of reviewers and the expertise required of the reviewers, presumably before the review gets under way.[3] Any such determination by a UC Project Director appears to be missing from the rulemaking file, and for all that appears, is mandatory in order for CARB substantially to comply with the provisions of the Health and Safety Code. LCFS FF45-17

Growth Energy requests an explanation for that omission in response to this comment as required by the APA.

December 30, 2014. There were 50 calendar days from December 30, 2014 to February 17, 2015, the deadline established by the Executive Officer for comment on the LCFS proposal, and 52 days from December 30, 2014 to the public hearing on February 19, 2015.

[3] G.W. Bowes, "Exhibit F -- Cal/EPA External Scientific Peer Review Guidelines" (Nov. 2008) at 8, *available at* http://www.arb.ca.gov/fuels/lcfs/peerreview/exhib_f.pdf.

2. CARB Has Failed to Comply With Section 57004 Because it Did Not Obtain an Evaluation of the "Scientific Portions" of the LCFS Regulation By an "Entity," as the Statute Requires, and Instead Has Provided Disaggregated Comments by Individual Reviewers

The text of Section 57004 makes plain that the evaluation of the scientific portions of a rule must be conducted by an "external scientific peer review entity," which must prepare "a written report," and that the entity must make certain findings. Individuals who participate in the work of that entity are not, acting themselves, the same as the "entity." (Health & Saf. Code, § 57004, subd. (d)(2).) When the statute refers to individual reviewers, who are called "person[s]," (*id.*, § 57004, subd. (c)), it does so explicitly, in establishing the minimum credentials for participation in the work of the external scientific review entity. (*Id.*, § 57004, subds. (b),(c).) The report and the findings of the "entity" are to come from the entity, as a singular being, and not separately from each individual reviewer: thus, if the "entity finds," (*id.*, § 57004, subd. (d)(2)), one or another conclusion to be true — and not what multiple reviewers might "find" — various consequences follow. The stature requires "a report," (*id.*, § 57004, subd. (d)(2)), not multiple reports.

A single, unitary "entity" must do what the statute requires, for any number of reasons (though no specific reasons need be identified, given the clarity of the statute). A report that reflects the evaluation of more than one external reviewer might, for example, have been expected to have greater balance and to reflect a collective and therefore more thoughtful insight and analysis that what could be expected from a single reviewer. If the Legislature had intended for individual reviewers to make the necessary report and findings, it would have used the term "reviewer" in subsection 57004(d)(2), as it was able to do in other portions of the statute, such as subsection 57004(c). If the words used by the Legislature are to have any real meaning, "reviewer[s]" are not the same as the "external scientific review entity" in section 57004. LCFS FF45-18

Against that statutory backdrop, CARB has not complied, substantially or otherwise, with the clear requirements of the statute. The collection of the separate reviews of the four individuals as attachments to the May 5 letter, which itself does not and cannot make any competent findings of the type required by the statute, do not constitute an "entity" of any type, much less the external scientific peer review entity that the statute requires, nor is the May 5 letter itself a "report" as the statute requires. The fact that CARB may not have complied with the statute in the past does not change the requirements of the statute: repeated noncompliance with section 57004 does not change that section's requirement. CARB cannot take "any action" to finally approve the proposed LCFS regulation until it has obtained the necessary report and findings from an external scientific peer review entity as the statute requires. Once that report and those findings have been obtained, CARB must permit at least the same opportunity for public review and comment that it has provided with respect to the materials for which comment was invited on June 4. There is time for CARB to undertake and complete this process consistent with its goal of completing consideration of amendments to the LCFS regulation this year.

3. The Individual Evaluations of the Four Separate Peer Reviews Do Not Each Demonstrate Full or Adequate Command of the "Scientific Portions" of the LCFS Proposal and Do Not, Alone or on a Consolidated Basis, Adequately Evaluate the Proposed Regulation's Lifecycle Emissions Analysis

Four individuals have provided written documents that appear intended to address various aspects of the scientific portions of the proposed LCFS regulation. Even if one could ignore the statutory text that requires a written report and certain findings from an entity, rather than from four separate reviewers, the four memoranda attached to the May 5 letter do not constitute competent and fully informed and considered reports that meet the purposes of the statute, which include providing a fully informed and well-considered external review of the CARB staff's scientific analysis.

Dr. Clarens' Memorandum. Starting with Dr. Clarens' memorandum, which is only two pages in length, it is apparent that Dr. Clarens did not have a basic understanding of some of the main features of the lifecycle analysis on which the proposed rule is based. Perhaps for reasons beyond his control, Dr. Clarens did not even know the indirect land-use change value being assigned in the proposed rule to corn ethanol. Thus, he states: "The report does not provide the actual value of the iLUC contribution that CARB is using but I found it online (30 g/MJ) . . . ." (Clarens memorandum page 2.) The proposed ILUC value for corn ethanol of 19.8 g/MJ appears on page ES-6 of the ISOR. Dr. Clarens was obliged to conduct an "online" search to ascertain the ILUC values for alternative fuels like corn ethanol, and thought it important enough to include what he found "online" in his report (which is only two pages). Nevertheless, his online research gave him an obsolete and incorrect value for the indirect land-use emission factor assigned to corn ethanol. It is unclear what, if any, indirect land-use change values, for other alternative fuels, Dr. Clarens assumed or applied in his analysis, whether he considered those emissions factors for any alternative fuels other than corn ethanol, or indeed if he understood that different alternative fuels have been assigned different ILUC values that he needed to evaluate. While Dr. Clarens may be "confident" that the "methods" reflected scientific portions of the proposed rule that he reviewed "are based on sound science and represents [*sic*] the state of the art in CI estimation," no one reading his report can have any confidence in Dr. Clarens' analysis.

LCFS FF45-19

In addition to his clear error concerning ILUC values, Dr. Clarens shows confusion about the treatment of coproducts in GREET in this portion of his brief memorandum:

> As written, the report states that the source must be directly consumed in the production process. But this is ambiguous in certain contexts such as those fuels that produce co-products. For example, if a corn feedstock were used to make ethanol and the stover were also used to make fuel (but was not consumed in the same production process) would that not trigger a switch from Tier 1 to Tier 2? It seems like it should but as written it might not. Clarifying this language is key for groups seeking to obtain co-product credit through the CA-LCFS.

In this statement, Dr. Clarens is referring to coproducts, corn feedstock, and stover. In his question, it is not clear whether he believes stover is a coproduct of the corn feedstock, or is a separate feedstock. If he believes stover is a coproduct of corn ethanol, clearly it is not. If he understands that both corn and stover are by themselves feedstocks, then it is not clear why he is mentioning the impact of coproducts the Tier 1/Tier 2 categories. In any event, Dr Clarens imagines a relevant confusion among "groups seeking to obtain co-product credit" that evades Growth Energy.

LCFS FF45-19 cont.

Insofar as Dr. Clarens is one of the reviewers expected to evaluate the OPGEE portions of the proposed rule, all he says is that the OPGEE model "goes into great detail" and that "the results are fascinating." Yet there is no indication that Dr. Clarens actually reviewed any models in order to prepare his evaluation: his memorandum refers only to "reviewing … three staff reports." The May 5 letter claims that it was the responsibility of individual reviewers to assess the "relevance and accuracy" of 'all information" on which the staff's reports are based. (See *supra*.) Dr. Clarens' memorandum raises serious questions about the staff's efforts to facilitate review of their proposal, or the process of selecting external reviewers and the standards applied in accepting materials from the reviewers for publication, or perhaps both. For the foregoing reasons, Dr. Clarens' memorandum cannot properly be used in order to comply with CARB's duties under section 57004.

Dr. Matthews' Memorandum. Turning next to Dr. Matthews' memorandum, there are also clear signs that Dr. Matthews lacked an adequate understanding of the scientific portions of the proposed rule, although his errors may seem not so blatant as those of Dr. Clarens'. Dr. Matthews's comment — which he calls his "first impression" — that "the net effect on a CO2e basis would be neutral between increasing VOC and decreasing CO emissions factors," to the extent his comment is intelligible, does not appear to be directed at what the CARB staff and Cal/EPA would call the "Big Picture." Conversely, Dr. Matthews (the reviewer with a background most heavily concentrated in economics) does not take account in his discussion of "the actual reduction in greenhouse gas emissions" of the fact that fuels to which higher CI values are assigned can and are produced and sold outside California regardless of the LCFS program. That effect, so-called "fuel shuffling," has been conceded by the CARB staff, and it should have been part of the scientific basis for the proposed regulation to be evaluated, insofar as what Dr, Matthews calls the "actual" impacts on greenhouse gas emissions are relevant, in his opinion, to the proposed rule.

LCFS FF45-20

Dr. Matthews then makes the following observations about the CA-GREET results in one of the documents supplied by the CARB staff:

> The CA-GREET results shown on pages 14-15 (Tables 1 and 2) are presented as 'CI lookup tables'. As presented, it was not clear what these were. However from reading the ISOR my understanding is that these are default values determined ex ante by staff for a generic production of a Tier 2 fuel used for Method 1 (as a default value that would apply for a particular supplier unless they wanted to show a lower value from other use of the methods like 2A or 2B). My lack of understanding has no effect on the scientific merit of the work.

In the above passage, and putting his point more directly, Dr. Matthews is stating that he did not really understand the values presented in the materials supplied to him in order for him to evaluate CA-GREET, but that those values must be acceptable because the CARB staff must have had some basis for using them, and that in any event his own "lack of understanding has no effect on the scientific merit of the work," so that he did not need to do anything further to address his lack of a complete understanding of the CA-GREET results.

With all due respect to Dr. Matthews, the approach to his assignment revealed in the quoted passage reflects substantial abdication of his responsibility as an external peer reviewer. Whether or not his ignorance about CA-GREET or the results of CA-GREET have any impact on the "scientific merit" of the CARB staff's work, if those results were significant enough to warrant the mention that he gives them in his memorandum, he had a duty to assess their scientific merit. Stated another way, the issue is not whether Dr. Matthews' ignorance affects the quality of the scientific portions of the proposed rule, but whether Dr. Matthews was equipped to review the model and the results of the model that he agreed to review, and that he was presumably paid to review. Dr. Matthews may or may not have understood his assignment, but there is no question that his evaluation of the CA-GREET model, such as it is, is incomplete if not useless, and cannot be relied upon in order to demonstrate compliance with section 57004. As with Dr. Clarens' work, Dr. Matthews' work either exhibits a level of ignorance concerning the scientific basis for the portions of the proposed rule for which he was a primary reviewer that requires CARB not to rely on his memorandum, or fails to demonstrate sufficient technical or scientific competence for his assignment to permit such reliance. By either standard, Dr. Matthews' work cannot properly be used to try to demonstrate compliance with section 57004 of the Health and Safety Code.

LCFS FF45-20 cont.

Further questions about whether Dr. Matthews possessed an orientation to his assignment making his work useful in an external review process comes at the end of his memorandum, where he adverts to GTAP:

> **Component 3 -- GTAP/Indirect Land Use Model**
>
> While my area of expertise is connected with the first two models, I did my best to read through the third modeling area. While I was unable to comprehend the model, data, or inputs at the same level of critical insight, I found nothing associated with that work that caused me to doubt its credibility. I thus agree with the staff's conclusion, have no big picture issues, and have no doubt that the work done was based on sound science.

LCFS FF45-21

Again putting Dr. Matthews' statement more simply: he has "no doubt" that the "work done" to assess indirect land-use change was based on sound science, even though, as he states, "I was unable to comprehend the model, data, or inputs" at the "same level of critical insight" as he displayed in his evaluation of CA-GREET. This begs the question: what is Dr. Matthews' reason for having "no doubt" about the scientific basis for the staff's indirect land-use analysis?[4] While the existence of bias is not necessary to demonstrate that Dr. Matthews'

[4] Dr. Matthews states at the outset of his memorandum that it was an "honor" to "look at" the CARB staff's work, and he calls the "work done by this evolving team over time "to have

analysis should not form a part of CARB's external peer review, Growth Energy has never read an external peer review for any CARB rulemaking that reflects bias in the same manner and to the same extent as Dr. Matthews' analysis. LCFS FF45-21 cont.

Dr. McCarl's Memorandum. Compared to the work by Dr. Clarens and Dr. Matthews, a more skeptical and informed analysis might have been expected from the memorandum provided by Dr. McCarl, who holds a Chair at Texas A&M University, and who has experience in econometric analysis of agricultural markets. At the outset, it should be noted that it is possible that the version of Dr. McCarl's memorandum published by CARB was not his final memorandum: on page 7 of the memorandum (which lacks page numbers), the memorandum refers to "G tab," obviously a phonetic version of GTAP, and a sure sign that the published document was dictated but not reviewed by Dr. McCarl (or by the Cal/EPA official in charge of collecting peer review materials, or by the CARB staff). Later, the draft memorandum attributed to Dr. McCarl states:

> In GTAP I believe that there also are increases in emissions from intensification (more irrigation or fertilization) so that the characterization of it only in terms of indirect land use change is not accurate. … In improving the indirect land use analysis when you're looking at corn ethanol byproducts there are also newer developments in terms of extracting corn oil from the DDGs.

LCFS FF45-22

There are no increases in emissions in GTAP attributed to intensification, and so the first quoted statement is untrue, as anyone who has rudimentary knowledge of GTAP would understand. The second statement reflects no understanding of, or consideration of, the fact that the amount of corn oil converted to biodiesel is unknown. As with Dr. Clarens' memorandum, though perhaps for different reasons (such as CARB's apparent failure to obtain from Dr. McCarl a final version of his evaluation), Dr. McCarl's memorandum raises questions about the process used by CARB and the reviewers to provide or obtain adequate understanding of the scientific portion of the proposed rule, the competence of the reviewer to perform the evaluation, or both. Putting those questions aside, the memorandum attributed to Dr. McCarl that has been placed in the public docket reveals that a lack of understanding of GTAP should prevent CARB from attempting to rely on that memorandum in order to demonstrate adequate external review of the scientific portion of the proposed rule.

---

been "one of the most impressive scholarly efforts I have seen in my career." Dr. Matthews, who from the preamble of his memorandum makes it clear that he is a strong supporter of the LCFS program, imagines on page 4 of his memorandum a distinction between "scientific credibility of the method" used in the regulatory proposal, on the one hand, and what he calls the "magnitude of the overall potential benefits of the program." How Dr. Matthews believes that he can separate the "scientific credibility of the method" from the assessment of the potential impacts of the proposed regulation is unclear, unless he considers a "method" that does not permit an assessment of the potential benefits of a proposed regulation to possess scientific credibility, despite that deficiency. The question presented for Dr. Matthews is therefore this: what is the purpose of scientific credibility in a rulemaking intended to establish or create environmental benefits?

One indication that the deficiencies originate at least in part with the CARB staff appears on page 11 of Attachment 1 to CARB's January 21, 2015, memo. There, the CARB staff claims that 2004 is the "most recent year for which a complete global land use database exists." That statement is not correct, and should have been known to the CARB staff not to be correct at the time when written. A report by Iowa State University ("ISU") researchers, which the CARB staff reviewed in the fall of 2014, and which was the subject of testimony at the February 2015 public hearing, used a more recent complete global land-use database, inter alia to impeach or challenge the credibility of CARB's use of the 2004-based GTAP system. It is unknown how and why the CARB staff could advise their reviewers that a data set more than a decade old is the "most recent" that exits. If the CARB staff's use of the word "complete" in the phrase, "complete global land use database" is studied, then the lack of candor and transparency of the CARB staff in presenting relevant information to their reviewers makes a mockery of the peer-review process required by the Health and Safety Code, and makes that process as applied to this rulemaking substantially noncompliant with the statute. To obtain an external review of the scientific basis for the proposed rule with respect to GTAP, CARB must provide the external reviewers with, at a minimum, the ISU study that was a subject of interest to the CARB staff last year, and that was included in the comments filed with the Board prior to the February public hearing.

LCFS FF45-22 cont.

Overall Issues Concerning the Selection of Peer Reviewers. Growth Energy also believes the process used to select the external reviewers for the proposed LCFS regulation did not provide for sufficient depth of review because none of the reviewers expressed, or could have been identified from prior work to have possessed, any skepticism about the scientific portions of the current LCFS regulation or the approach being taken in the new proposed rule. Publications and other work available to the CARB staff since the commencement of the first LCFS rulemaking reveal experts who are both skeptical of the LCFS regulation and not aligned with stakeholders. They include Dr. Valerie Thomas, of the Georgia Institute of Technology, who was an external reviewer for the 2009 rulemaking process. Dr. Thomas noted in her 2009 review that "the values used to quantify the carbon intensity due to land use change for ethanol from corn and sugarcane are not yet sufficiently developed to be scientifically confirmed" and that "refinement and validation of those quantities [are] needed." (*See* Attachment B.) As Dr. Thomas also stated in 2009, "ARB could develop a more data driven and less model-dependent approach by observing and tracking changes in land use patterns that have been observed to date and that will be observed over the next few years . . . ."

Dr. Thomas's earlier external review is significant and raises two questions. The first is why Dr. Thomas did not participate in the current peer review. The second is why, in light of the success in identifying someone with Dr. Thomas' level of skepticism and independence in 2009, Cal/EPA or another appropriate body did not include anyone in the current external review process who expressed a similar, or any, level of skepticism about the scientific portions of the proposed new rule.

LCFS FF45-23

Growth Energy also notes that none of CARB's four current external reviewers appear to have attempted any systematic review of the CA-GREET model for sugarcane ethanol from Brazil, or biodiesel and renewable diesel. Given the importance assigned to those alternative fuels in the compliance scenarios developed for the new proposed rule by the CARB staff, those omissions are significant and make the current external scientific review substantially

LCFS FF45-24

noncompliant with section 57004 of the Health and Safety Code, because CARB has failed to obtain meaningful external review of all the relevant and important CA-GREET models. LCFS FF45-24 cont.

4. Selected List of Specific Questions CARB Staff Must Address

Although the following list of questions does not cover all the comments presented above concerning CARB's LCFS external review, and should not be taken to limit the scope of issues that CARB must address in its response to the 15-day comments, this list includes some of the questions concerning the LCFS peer review that the CARB staff should address. If CARB does not consider itself obliged to respond in full to any of the following questions, Growth Energy requests that for each such question, CARB explain separately why it is taking such a position.

- Did the materials provided or made available to the external peer reviewers include all the "best available economic … information" available to the CARB staff in developing the scientific portions of the proposed rule? (Cal. Health & Safety Code § 38561(e).) Did those materials include all the "best available … scientific information" available to the CARB staff in developing the scientific portions of the proposed rule? (*Id.*) If not, why not? LCFS FF45-25
    - Why were the external peer reviewers not advised of, or given materials concerning, fuel shuffling? LCFS FF45-26
    - Why were the external reviewers not provided with the ISU report co-authored by Dr. Babcock that casts doubt on the use of GTAP in regulatory settings, which was supplied to CARB in the 45-day comment process? LCFS FF45-27
    - What is CARB's definition of a "complete global land use database," as that term is used in the materials provided to the external peer reviewers? Does (or do) the database or databases referenced in the ISU report noted above meet the standard or criteria for a "complete global land use database?" If not, how is the 2004 GTAP database more "complete" than the database or databases referenced in the ISU report? LCFS FF45-28
- Does CARB consider Dr. Clarens to be adequately informed concerning the scientific portion of the proposed rule, notwithstanding the errors in his memorandum noted above? If so, why? Has CARB considered or will CARB consider asking Dr. Clarens to revise his evaluation and address the issues presented here, and if not, why not? LCFS FF45-29
    - What is CARB's understanding of Dr. Clarens' knowledge of the ILUC value assigned to corn ethanol in the proposed rule? Upon receipt of Dr. Clarens' report, did CARB staff attempt to provide Dr. Clarens with additional information? If not, why not? LCFS FF45-30

- What is CARB's understanding of the portion of Dr. Clarens' report excerpted on page 4 of the comments above? If CARB does not agree with Growth Energy's interpretation of that portion of Dr. Clarens' report, or with the identified errors in that portion of Dr. Clarens' report, why not? LCFS FF45-31

- Does CARB have confidence that Dr. Clarens had an adequate understanding of the scientific portions of the proposed rule that he claimed to evaluate, and if so why? LCFS FF45-32

- Does CARB consider Dr. Matthews' comments on the indirect land-use change portions of the scientific basis for the proposed rule to be relevant or useful in the external review of the proposed rule? If so, why? LCFS FF45-33

- Does CARB consider the CA-GREET results to which Dr. Matthews refers in the excerpt from his memorandum on page 5 of the above comments to be part of the scientific portion of the proposed regulation? If not, why did CARB include it in the report provided to the external reviewers? Which external reviews understood completely and reviewed those results? LCFS FF45-34

- Does CA-GREET use the MOVES model? If so, in what respects? If not, did the CARB staff take any action to advise Dr. Matthews of the error postulated on page 5 of the above comments with respect to MOVES? LCFS FF45-35

- Does CARB believe that the "scientific credibility" of the "method" that it used in the proposed rule is not affected by or related to estimates of the "overall potential benefits" of the LCFS regulation, as those terms are used in Dr. Matthews' memorandum? LCFS FF45-36

- Does CARB consider Mr. McCarl to be qualified to evaluate GTAP, notwithstanding the apparent errors in his understanding of GTAP noted on page 7 of the above comments? If so, why? LCFS FF45-37

  - Does GTAP attribute emissions to intensification, as the latter term is used in Dr. McCarl's draft memorandum?

  - Did CARB consider whether to invite Dr. McCarl to review and revise his memorandum? If not, why not?

- How did the CARB staff determine the number of peer reviewers required for each portion of the scientific basis of the proposed regulation? If the evaluations by Dr. Clarens, Dr. Matthews or Dr. McCarl are excluded to any extent from the external review, based on the issues presented here, will CARB seek additional external review? If so, under what specific circumstances, and if not, why not? LCFS FF45-38

Stuart,

I'm attaching three documents and a cover page that were provided to the LCFS peer reviewers but that were not posted to the peer review page when it was set up. I'm told these files contain all of the content you are asking about. Staff will be adding these documents to the web page as well.

Thank you,
Steve

Stuart,

I wanted to make sure you're aware that separate peer reviews were conducted on biodiesel and renewable diesel as part of the multimedia evaluation on those two fuels. Those reviews are listed in the 15-day notice for the ADF regulation that went out Friday, and the peer review documents for those are at
http://www.arb.ca.gov/fuels/diesel/altdiesel/biodocs.htm

Stuart,

I'm going to ask staff to take a look at your questions and the documents posted as part of the peer review reports. You can expect to hear back from me, or as you suggest I might have staff communicate directly with one of your colleagues if that seems the simpler way to proceed.

Steve

Subject: LCFS -- External Review Materials

Steve --

Tom Darlington, Jim Lyons and I are having some trouble in readily locating some of the documents to which Dr. McCarl and Dr. Kumar, two of the LCFS external reviewers, refer in their April 29 and May 5 reports for the staff.   On behalf of Growth Energy, I wondered if your Office could help us locate those documents, or if they are not currently on the external-review page on CARB's website, if your Office could let us know if there are any plans to post them. If it is more efficient for someone on the technical side to get in touch directly with Tom Darlington and/or Jim Lyons, that's fine too -- maybe we have just overlooked something. It is not possible to understand the external reviews without the ability to look at the same documents that the reviewers did.

Here is an excerpt from the first page Dr. McCarl's report:

"As I understand it the peer review is intended to develop external review opinions on whether the CI methodology used by the ARB staff and supporting parties in calculating carbon intensity values and use of greenhouse gas emission models yields a valid scientific basis for the conclusions in the air resources Board staff reports.

"I also believe that while I was sent three reports and a plain English version that I am only supposed to review those within my field of expertise which limits me to comment on

"Calculating Lifecycle Carbon Intensity Values of Transportation Fuels in California, March 2015 (Staff Report 1)

"Calculating Carbon Intensity Values from Indirect Land Change of Crop-Based Biofuels (Staff Report 3)

"Additionally I will comment on the attachment entitled *Plain English summary of staff's methodology in calculating fuel carbon intensities*."

Page 1 of Dr. Kumar's report refers to "Staff Report 2." That report appears to address carbon intensity values for crude oil.

The "Plain English" summary appears to be a 15-page document attached to Mr. Aguila's Jan. 21, 2015, memo to Dr. Bowes at the Water Board, which is posted on the external review page of the CARB website as part of Mr. Aguila's memo. Mr. Aguila's memo refers to the three Staff Reports but they do not seem to be attached to his memo, and in any event I don't understand how a memo dated January 2015 could have included a report that according to Dr. McCarl is dated March 2015. Are the three referenced Staff Reports also on the CARB website, and if so where? Are there multiple versions of the Staff Reports?

I also wanted to ask if there is a later version of Dr. McCarl's report. On the seventh page, there is a reference to "G tab," which we assume is supposed to be "GTAP."

Here is the url for the external review page:

http://www.arb.ca.gov/fuels/lcfs/peerreview/peerreview.htm

Anil Prabhu is listed as the technical contact person on the website.

Thanks in advance for your help, and my apologies if this is something easy to find that we have just missed. Give me a call if you would like to discuss.

-- Stuart

Review of
Proposed Regulation to Implement the Low Carbon Fuel Standard
California Environmental Protection Agency
Air Resources Board

The Air Resources Board has made a great deal of progress in modeling and quantifying the greenhouse gas and other environmental impacts of fuels. This work provides a strong foundation for understanding the impacts of these fuels, and for further development of understanding as experience with alternative fuels increases.

The five issues identified by the ARB to be addressed by the peer reviewers are addressed below.

1. Greenhouse Gas Modeling

a. The description in the text of the greenhouse gas impacts of corn-derived and sugarcane-derive ethanol is solid, and could be emphasized more prominently: "Direct GHG emissions from the production and use of corn and sugarcane ethanol are less than the comparable emissions from gasoline. When land use change emissions are considered, however, the emissions-reduction benefit from corn and sugarcane ethanol is diminished." (p. IV-42)

b. The lookup table values for carbon intensity for the three gasoline fuels appear to be well justified.

c. The evaluation of carbon intensity for eleven different corn-derived ethanol is sound practice and provides a basis for encouraging low-carbon production of corn-derived ethanol. LCFS FF45-39

d. The numerical values assigned to the GHG emissions from production of corn-derived and sugarcane-derived ethanol have some uncertainties that could be reduced through revised analysis and further reduced when more data become available.

i. The calculation of the direct GHG emissions from production of corn-derived and sugarcane-derive ethanol is by-and-large solid and consistent with a well-developed body of scientific research. The calculation of the coproduct credits does, in my view, somewhat overvalue these credits, resulting in an understimate of the direct GHG impacts of corn-derived ethanol of perhaps 10%.

Attachment "B"

2. Land Use Modeling

The calculation of the indirect, land-use-change GHG emissions from production of corn-derived and cane-derived ethanol has significant uncertainties.

a. That observed data have not be used to validate the GTAP model findings is a significant weakness. The changes in corn production resulting from the federal renewable fuel standard, and the changes in Brazilian sugar production resulting from increased ethanol production should be measurable, and should be measured to validate the model assumptions. The ARB model should be adjusted to reflect data.

b. The lack of a time dimension in GTAP results in an awkward match with the question at hand. Corn yields have been increasing largely linearly for some time now in the United States, yet the model appears to use 2008 corn yields to determine land impacts of corn-derived ethanol. The projected steady increase in use of corn for ethanol in the US over the next few years suggests that land use change will be somewhat less than projected here.

c. The greenhouse gas impact of land use change occurs mainly at the time of land clearing. This suggests that the effect of increased use of corn for ethanol will depend on whether and when total global corn production increases. An increase in use of corn for ethanol in a year in which corn demand decreases or stays constant will have a different greenhouse gas effect than in a year in which total corn demand increases. The increased use of corn for ethanol in one year can result in land clearing in a future year, depending on overall global total corn production and production of other crops. The ARB staff has put a great deal of effort in to thinking about the time dimension of this problem. Nevertheless, time-related issues are still addressed in piecemeal way that makes some unjustified assumptions. A more comprehensive approach to the changes in corn production over time would be simpler and could be more accurate. ARB could develop a more data driven and less model-dependent approach by observing and tracking changes in land use patterns that have been observed to date and that will be observed over the next few years as corn-derived and cane-derived ethanol production increases.

d. The development of the land use change analysis for Brazilian sugarcane-derived ethanol appears to be less developed than the analysis of US corn-derived ethanol. The Brazilian analysis should be revised using up-to-date yield values, if they were not used in this analysis, and should reflect data on land use changes in Brazil.

3. Economic Impacts

LCFS FF45-39 cont.

The LCFS staff report predicts that the LCFS will result in an overall savings in the State of California. The economic impacts of the LCFS will depend on future prices of petroleum and the future production costs of alternative fuels and vehicle technologies, which cannot be definitively predicted in advance. Nevertheless, the economic assessment appears reasonable, and the projection that the net economic impact will not be large and may even be slightly positive appears sound.

4. Environmental and Multimedia Impacts

The LCFS staff report covers many of the environmental impacts well. An important set of environmental impacts that are not mentioned are the increased impacts of nitrogen, phosphorus, and other agricultural inputs from increased corn production. As mentioned in the report, the increase in corn production is not likely to take place in California. Nevertheless, the impacts may be significant at the national and international scale. Hypoxia in the Gulf of Mexico is linked to increased corn production.[1] The use of nitrogen fertilizers and other agricultural inputs have a range of other environmental impacts that should be included in the environmental assessment.

5. Credit Trading

The credit trading framework and details appear reasonable. Note that the credit trading provisions may help to reduce the actual land-use-change impacts of corn-derived and sugarcane-derived ethanol: When corn or sugar prices are high, regulated parties may choose to use less corn-derived or sugar-derived ethanol, which would help to moderate corn and sugar demand and reduce pressure to increase plantings of corn and sugarcane.

LCFS FF45-39 cont.

The Big Picture

a. Are there any additional scientific issues to be addressed?

No.

b. Taken as a whole, is the scientific portion of the proposed rule based upon sound scientific knowledge, methods, and practices?

Taken as a whole, the scientific portion of the proposed rule is based upon sound scientific knowledge, methods and practices. Use of a non-zero positive value for the carbon intensity due to land use change for ethanol from corn and sugarcane is sound. The direct emission values for ethanol from corn and sugarcane, and the differences in direct carbon intensity values for different ethanol production processes are sound. However, the values used to quantify the carbon intensity due to land use change for ethanol from corn and sugarcane are not yet sufficiently developed to be scientifically confirmed; refinement and validation of those quantities is needed.

Detailed comments:

[1] US EPA SAB. Hypoxia in the Northern Gulf of Mexico. December 2007. EPA-SAB-08-003 http://epa.gov/msbasin/pdf/sab_report_2007.pdf

Table IV-1, page IV-3. This table appropriately separates the direct emissions from the land use effects, and appropriately shows fewer significant figures for land use effects than for direct emissions. The direct emissions, however, should not be shown to four significant figures because the estimates are not that accurate; these results should be expressed to at most two significant figures.

p. IV-12. Coproduct allocation. Coproduct credits for corn ethanol are allocated in GREET by assuming that the use of coproducts as animal feed results in decreased production of the displaced feed in exactly the amount that is displaced. This effectively assumes completely inelastic demand for the displaced product. This is not consistent with the land use change calculations, which do assume demand elasticities. In other words, the coproduct calculation appears to be overestimated, resulting in a somewhat lower calculation of the direct GHG impact than is probably likely, and indicating uncertainty in the direct emissions results for corn ethanol of at least several percent.

p. IV-17. Among the choices to meet demand for biofuel feedstock, one option not mentioned is to convert existing agricultural lands from non-food crops – such as cotton or tobacco, for example.

p. IV-20. The GTAP model is not time dependent, whereas the land use change from biofuels is time-dependent. In particular, yields of corn and other feedstocks can be expected to increase in time. Although there is extensive discussion of this issue, particularly in Appendix C6, the expected increase in yield of corn beyond 2008 does not appear to be incorporated into the model.

LCFS FF45-39 cont.

p. IV-24. Of the three time accounting methods described, the first one is by far the most sensible. The Net Present Value calculation is not appropriate here. Net present value calculations are used for money because of the potential to invest money and receive a return over time. That is not true for greenhouse gas emissions. The Fuel Warming Potential also is not appropriate; the greenhouse gases will remain in the atmosphere beyond the project time horizon, and presumably the policy interest is to reduce climate change impacts over a longer time horizon than this project time horizon. Presenting the net present value approach and the fuel warming approach gives the impression that these are valid approaches that could be used. I suggest that discussion of these approaches be dropped from the main body of this report, although retained in the Appendices. Development of these ideas in the peer-reviewed literature would provide a basis for inclusion in future ARB analyses.

p. IV-26. ARB staff appropriately uses the annualized method.

p. IV-29. The results of the GTAP model are for a situation in which 13.25 billion gallons of increased ethanol production is produced in the year 2008. Yield will increase in subsequent years, requiring less land for a given amount of ethanol. If the increases in corn production occur after 2008, the land use impact will be less.

p. IV-31. It should be possible to validate with data the projections of land use change shown in Table IV-10, and especially the projections of US land use change.

p. IV-33, Table. IV-12. It should be possible to validate with data he projections of land use change resulting from cane-derived ethanol production in Brazil. The projections seem to be entirely model-derived, with no reference to studies of actual land use change in Brazil. The results should be validated with data. Also, cane yield in Brazil has increased significantly over time. The cane yield used in the GTAP model is not mentioned, but if the 2001 baseline is used, then the modeled land use change would be larger than if the 2006-08 sugarcane yield were used. And, as discussed elsewhere for corn, sugarcane yields can be expected to continue to increase, suggesting that land use change impacts will decrease over time.

p. IV-34. "As an initial estimate, we assumed a 75 percent coproduct credit for soy meal." ARB staff appropriately flags the uncertainty of this estimate.

p. IV-39. Comparison of GTAP results with Observed Market Behavior. The effects of corn ethanol on land use either are, or are not, large enough to be observable. As this section states, there are many factors that influence corn production and corn exports. If the effects of ethanol production are large enough to be measurable and identifiable, then this effect should certainly be taken into account in the assessment of corn-derived ethanol. Observation of the effect and validation of the model results is critical to validation of the greenhouse gas calculation for corn-dervied and cane-derived ethanol. This section indicates that the GTAP model results cannot be validated, or have not yet been validated. Surely there is some aspect of the calculation that could be validated. For example, the changes in US forest and pasture land due to the federal RFS should be measurable.

LCFS FF45-39 cont.

p. IV-41-IV-42. This entire section expresses more certainty than warranted. Some judicious editing would prevent it from being misinterpreted. For example, in the bulleted list on p. IV-42, the word "about" should also be used in the last two bullets – these numbers are very uncertain.

p. IV-42. This statement is solid: "Direct GHG emissions from the production and use of corn and sugarcane ethanol are less than the comparable emissions from gasoline. When land use change emissions are considered, however, the emissions-reduction benefit from corn and sugarcane ethanol is diminished."

pp. IV-46. Increases in crop yield with time. The adjustments made to convert GTAP results from 2001 yields to 2006-08 yields, as described in Appendix C, do appear to be reasonable. However, the time profile of the land use change implied by the LCFS may warrant additional scaling of the GTAP results. In particular, if the increase in corn-derived ethanol is assumed to scale with the federal RFS, then the amount of corn used for ethanol will increase over time; if corn yields also increase over time then the land use impact of the corn-derived ethanol will decrease over time, although it will still be postive. However, if the amount of corn-derived ethanol used to fulfill the LCFS is constant, as suggested by the scenarios presented in appendix E, then the land use change would all be concentrated in the very near future (or even recent past). The time scenario for corn-derived ethanol production (how much in which year, and the total change in demand in each year) will affect the actual land use change and the actual greenhouse gas impacts. The land use change impact will occur in the year that land use changes, which will not necessarily be the same as the year of the increased use of corn-derived ethanol.

p. IV-47. Uncertainties associated with time-accounting. As mentioned before, it would be feasible, and add clarity to the model, to do more explicit time-depedent modeling.

p. IV-48. The paragraph at the bottom of page IV-48 is solid. ARB should continue to refine its analysis and adjust the GHG emission values as the analysis develops, and data become available.

Appendices:
p. iii. The word "not" seems to be missing from lines 2.

p. C-5. Energy Economy Ratios. In Brazil, development of flex-fuel vehicle technologies with higher compression ratios has provided an opportunity to increase the efficiency of vehicles using ethanol fuels somewhat. ERB may not want to incorporate this potential into its LCFS EERs, but this potential may warrant at least a one-sentence mention.

LCFS FF45-39 cont.

p. C-27. A corn yield of 151.3 bushels per acre is mentioned here, but a corn yield of 160 bushels per acre is used in the derivation of the "110,000 acres of U. S. farmland" mentioned on p. IV-42 and derived on page C-41. The 160 bushels per acre may be taking into account future yield increases, as I have advocated above. The yield value assumptions, and the year to which each yield value is associated, should be clarified.

p. C-54. Co-product credit for DDGS. The decision of ARB to not adopt Wang's findings on this issue is solid. However, there is an additional co-product credit issue. In GREET, when a coproduct is used instead of the substitute product, the reduced use of the substitute is assumed to result in exactly that amount of decreased production of that product. This is surely an overestimate, resulting in a small underestimate of the direct GHG impacts of corn-derived ethanol.

p. C-54. "Staff will revisit this issue and make updates to the co-product credit, as appropriate." ARB's commitment to revising the analysis is important and will improve the assessment; increased production of biofuels will provide more data with which to refine the analysis.

CERTIFIED SHORTHAND REPORTER
LICENSE NUMBER 10063

We've been working in such close collaboration that we scientists merge.

CHAIRPERSON NICHOLS: -- forgotten his last name.

STATIONARY SOURCE DIVISION CHIEF FLETCHER: But Mike has been working with us very closely since the inception of this project, and he has a few comments that he would like to make.

CHAIRPERSON NICHOLS: Thank you.

MR. O'HARE: Oh, I guess we got that to work.

(Thereupon an overhead presentation was Presented as follows.)

MR. O'HARE: So I'd like to make a few remarks on I guess you could call a bigger picture look at the land use change issue especially.

And the general burden of these remarks is to regard the land use change estimates that the staff has given you as being -- I don't want to use the word "conservative," but I would say biofuel favorable in the competition between fuels to satisfy the LCFS requirements. LCFS FF45-40

I do want to say at the beginning that it's not clear what "conservative" means in this context because it is a low carbon fuel standard. And if we make a mistake in one direction in estimating these numbers, we'll use too much of a biofuel that's actually higher carbon than we thought and will therefore increase global warming. And if we use numbers that are too low, then we'll use too little of a biofuel that's lower carbon than we thought and will therefore increase global warming.

So the cost to the world of being wrong in both directions is fairly symmetrical. And there's no obvious conservative direction as there is, for example, in life and safety regulation.

Next slide please.

--o0o--

MR. O'HARE: I want to thank a large and growing group of collaborators, including one of your distinguished Board members, at this point, and also remember Alex who set us out on this path a couple of years ago. This has become quite a large group enterprise. And I think it's good for that reason.

Next slide please.

--o0o--

MR. O'HARE: So let me just quickly recall the history we'd been through and emphasize the policy is forcing the science quite rapidly.

The policy intentions of California and the nation and also other countries is pushing the science forward probably a lot faster than it would otherwise go. On the whole I think this is a good thing.

LCFS FF45-40 cont.

CALIFORNIA ENVIRONMENTAL PROTECTION AGENCY

CALIFORNIA AIR RESOURCES BOARD

DECLARATION OF THOMAS L. DARLINGTON

I, Thomas L. Darlington, declare as follows:

1. I am an engineer with training and expertise in lifecycle emissions analysis, the use of models to estimate lifecycle emissions and to attribute emissions to the production, distribution and use of various fuels, and use of regulations to control mobile-source emissions. My areas of expertise also include land-use change ("LUC") modeling and the application of econometric models to attributional and consequential lifecycle emissions analysis. Following my graduation from the University of Michigan in 1979, I served for eight years as a Project Manager at the United States Environmental Protection Agency's Motor Vehicle Emissions and Fuels Laboratory in Ann Arbor, Michigan. Thereafter I worked at Detroit Diesel Corporation and General Motors Corporation, and as the Director of Mobile Source Programs at Systems Application International. I am the President of Air Improvement Resource ("AIR"), a company formed in 1994 to provide mobile source emission modeling to government and industry. A copy of my CV is attached to this Declaration as Attachment A.

2. I have participated on behalf of renewable fuels producers in the public consultation and rulemaking processes at the California Air Resources Board ("ARB" or "the Board") to consider, adopt and revise the low-carbon fuel standard ("LCFS") regulation since 2008. I testified at the Board's February 2015 hearing concerning proposed amendments to the LCFS regulation. I am fully familiar with the models released by CARB to establish and implement the LCFS regulation, including the versions of the Global Trade Analysis Project ("GTAP") modeling systems used by CARB or proposed for use by the CARB staff as part of the current and proposed LCFS regulation.

3. I make this Declaration based upon my personal knowledge, my training and expertise, and my familiarity with the subjects that I address here. This Declaration is divided into four parts: (1) Access to the Database Used by ARB Consultant David Rocke, (2) Proposed Modification 18 in the 15-Day Notice, (3) Differences between the December and June versions of CA-GREET and (4) Memoranda from ARB's External Scientific Reviewers.

A. Access to the Database Used by ARB Consultant David Rocke

4. ARB's LUC emission factor for corn starch ethanol in the revised LCFS regulation is 19.8 grams of carbon dioxide equivalent emissions per megajoule of energy ("g/MJ"). That is 12.2 g/MJ lower than the 30 g/MJ used in the current LCFS rule. The CARB staff has declined to consider and to propose a different and lower LUC emission factor for corn starch ethanol, in reliance on an analysis of crop price-yield values by David Rocke, an ARB consultant. ARB used Dr. Rocke's work for ARB in selecting price-yield values in its analysis of LUC values for all ethanol feedstocks; that analysis was in turn used in the proposed new LCFS regulation that is now under consideration by the Board. As soon as it learned of the project assigned to Dr. Rocke by

LCFS FF45-41

ARB, in the fall of 2014, AIR requested the data used by Dr. Rocke. As explained below, although ARB staff agreed to provide to the public the data used by Dr. Rocke, but the data were never provided by ARB to me or other members of the public; the lack of timely access to that data has prevented effective public participation in the current LCFS rulemaking. LCFS FF45-41 cont.

5. The ARB analysis applied in the proposed regulation in reliance on the data used by Dr. Rocke and on Dr. Rocke's analysis employs five price-yield values: 0.05, 0.10, 0.175, 0.25, and 0.35. The average of these 5 values is 0.19. Those values are used in ARB's version of the GTAP model, originally developed at Purdue University. The Purdue recommended value is 0.25. CARB's Expert Working Group for the LCFS regulation also recommended 0.25. ARB sponsored research indicated that there was little or no price-yield response (i.e., 0.0). AIR recommended that ARB should drop the lower price yield values (0.05 and 0.10) because the research supporting these lower values was developed over the very short term (1-3 years of price and yield data), and the GTAP model is a longer-term model (5-10 years). [1] ARB utilizes an 11.59 billion gallon per year shock of corn ethanol in its corn ethanol modeling, clearly illustrating that ARB is exercising the model with a medium-term shock, and not a short-term shock. Thus, ARB's use of short term price yield responses with the medium or longer term GTAP model is clearly inconsistent. LCFS FF45-42

6. In the Initial Statement of Reasons ("ISOR") for the new LCFS regulation, ARB references a recent analysis by Dr. Rocke in support of using lower price-yield responses. [2] The Rocke analysis utilized one set of data from a 2012 dissertation by Juan Francisco Rosas Perez. [3] That dissertation indicated that the price-yield response was in the region of 0.29, very close to the Purdue default value. Dr. Rocke obtained the data from the dissertation, conducted his own statistical analysis, and concluded that the data did not support the 0.29 price yield value. LCFS FF45-43

7. Because of the differences between these two analyses (Perez and Rocke), which stakeholders clearly must understand fully, AIR requested from ARB staff the data that Dr. Rocke used for his analysis. While staff said they were trying to get the data for AIR, the data was never supplied by staff. Therefore, AIR was unable to replicate Dr. Rocke's analysis of the Perez data. There is insufficient information in Dr. Rocke's available written work to reject the Perez analysis. (Dr. Rocke's rebuttal is only three pages in length.). In addition, this is only one of two sources (according to Rocke) that were used to support the 0.25 price-yield value, Rocke did not attempt to critique the other source. Thus, because ARB never supplied Rocke's database, AIR was not able to replicate Rocke's sketchy analysis, and Rocke only critiqued one source. To my knowledge no other person or organization has been able further to understand or replicate this portion of the analysis used in the current regulatory proposal. Based on the standards for transparency and public participation that I have observed in other regulatory proceedings, ARB should not rely on the Rocke analysis for its use of low price-yield values, and should therefore eliminate the lowest two values (0.05 and 0.10). The impacts of eliminating the lowest two price-yield values on corn LCFS FF45-44

[1] "Discussion of the Yield Price Elasticity of GTAP", Taheripour and Tyner, Purdue University, April 2014. (See Attachment B.)

[2] "Statistical issues Related to the Low-Carbon Fuel Standard", October 31, 2014. (See Attachment C.)

[3] "Essays on the Environmental Effects of Agricultural Production", Dissertation, Perez, Juan Francisco Rosas, Iowa State University. (Copyright material, not included in public filing.)

ethanol LUC emissions are shown in Table 1 below. Without both 0.05 and 0.10, the LUC value is 15.53 gCO2e/MJ instead of 19.84. CARB's choice of the higher emissions factor creates an inefficient bias against the use of corn starch ethanol, by overstating the LUC emissions attributed to the use of corn starch ethanol. LCFS FF45-44 cont.

Table 1. Impact of the Low Price-Yield Values		
Average of ARB Scenarios	Average price-yield	LUC (gCO2e/MJ)
All (ARB value)	0.19	19.84
w/o 0.05, 0.1 price-yield	0.26	15.53

B. Proposed Modification 18 in the 15-Day Notice

8. Proposed Modification 18 in the June 4, 2015, 15-day notice discusses recertification of the approximately 270 existing fuel pathways. Staff is proposing a system for prioritizing that work and eliminating potentially unrealistic deadlines in various parts of the existing proposal. Staff proposes to review and approve fuel pathway applications in batches based on fuel type, so that providers of the same fuel compete on equal terms, obtaining the new carbon intensity score at the same time. The proposed prioritization of fuel types would be: ethanol, followed by biodiesel, renewable diesel, compressed natural gas, liquefied natural gas, and finally all others. This prioritization makes sense, but the record submitting requirements of the recertification process are unnecessary burdensome for ethanol plants. LCFS FF45-45

9. The relevant sections of the recordkeeping requirements for recertification in the proposed regulation order are shown below. Plants are to submit

> *Invoices and receipts for all forms of energy consumed in the fuel production process, all fuel sales, all feedstock purchases, and all co-products sold. Invoices shall be submitted in electronic form. Each set of invoices shall be accompanied by a spreadsheet summarizing the invoices. Every invoice submitted shall appear as a record in the summary. Each record shall, at a minimum, specify in a separate column the period covered by the purchase, the quantity of energy purchased during that period, the invoice amount, and any special information that applies to that record (the special information column need not be populated for every record). For each form of energy consumed, the two-year total and average consumption shall be reported in the spreadsheet. These two-year totals and averages shall be used to calculate the per-million-Btu and per-megajoule energy consumption inputs used to calculate the life cycle CI of the fuel pathway.* LCFS FF45-46
>
> *a. Period Covered. The period covered shall be the most recent two-year period of relatively typical operation.*
>
> *b. Production Processes Covered. The invoices submitted under this provision shall cover the energy consumed in all unit operations devoted to feedstock handling and pre-processing; fuel production; co-product handling and processing; waste handling, processing, and treatment; the handling, processing and use of chemicals, enzymes, and organisms; the generation of process energy, including the generation, handling and*

processing of combustion fuels; and all plant monitoring and control systems. If the fuel produced or any by-products or co-products receive additional processing after they leave site, such as additional distiller's grains drying or fuel distillation, invoices covering the energy consumed for those processes must also be submitted. If the fuel production facility is co-located with one or more unrelated facilities, and energy consumption invoices are not separately available for the fuel production process, the applicant shall obtain a third-party energy audit sufficient to establish the long-term, typical energy consumption patterns of the fuel production facility.

3. In lieu of receipts or invoices for fuel sales, feedstock purchases, or co-product sales, the applicant may seek Executive Officer approval to submit audit reports prepared by independent, third-party auditors that document fuel sales, feedstock purchases, or co-product sales.

LCFS FF45-46 cont.

Ethanol production plants can have dozens of invoices for feedstock every week from many different suppliers. It would not be unusual for plants to have 3000-5000 invoices, DDG sales receipts, ethanol sales receipts, and other information requested by CARB. All of this information would require not only scanning but also significant redacting of key information to protect business relationships. I believe this is unnecessarily burdensome, nor do I believe CARB staff will be able to adequately review all of this information for 270 biofuel plants in the time required. Therefore, I request staff to revise these requirements. I recommend that the requirements be revised to require only summary information of key plant inputs and outputs (feedstock used, natural gas and electricity used, ethanol produced, DDG produced, etc.) on a monthly basis. This would be far more manageable by plants, and would not need as much redacting. The information could be verified by staff through on-site auditing if necessary.

I note that ARB allows applicants to seek Executive Officer approval to submit audit reports prepared by independent, third-party auditors that document fuel sales, feedstock purchases, or co-product sales. I recommend that ARB allow 3rd party audits to be performed using generally accepted auditing standards which would allow for a sampling approach, and would not need to involve every transaction unless there was a significant deficiency in the sampled data.

C. Differences between the December and June versions of CA-GREET

10. The June version of the CA-GREET model differs from the version of the CA-GREET model provide with the ISOR. CA-GREET includes a feature for selecting the presence of, and percentage of, mechanized harvesting of sugarcane. Users may select whether mechanized harvesting is used, and if so, in what percentage of feedstock used by a cane ethanol plant. In both the December (ISOR) and June versions of CA-GREET, when mechanized harvesting is selected, the model reduces emissions from cane straw burning. If 100% mechanized harvesting is selected, the model eliminates emissions from straw burning. Of course, a producer claiming that credit, referred to in the model as the "mechanized harvesting credit," must attest to and demonstrate the use of mechanized harvesting

LCFS FF45-47

11. Unlike the December version of CA-GREET, the new, June versions of CA-GREET awards a producer a mechanized harvesting credit even if a user does not specify, and is not thereby

LCFS FF45-48

requited to attest to, mechanized harvesting. Thus, even if a producer's percent of mechanized harvesting is 0%, the newly proposed regulation still awards a mechanized harvesting credit of 100%. Whether by design or error, a Brazilian sugarcane ethanol plant that had no mechanized harvesting would be assumed to have the same emissions as a plant with 100% mechanized harvesting. LCFS FF45-48 cont.

D. Memoranda from ARB's external scientific reviewers.

12. In one of the memoranda attached to a May 2015 letter concerning the work of various external scientific reviewers retained by CARB, Dr. Clarens states as follows:

> *As written, the report states that the source must be directly consumed in the production process. But this is ambiguous in certain contexts such as those fuels that produce co-products. For example, if a corn feedstock were used to make ethanol and the stover were also used to make fuel (but was not consumed in the same production process) would that not trigger a switch from Tier 1 to Tier 2? It seems like it should but as written it might not. Clarifying this language is key for groups seeking to obtain co-product credit through the CA-LCFS.*

Despite my familiarity with the models to which Dr. Clarens is apparently referring, I am unable to determine whether Dr. Clarens believes stover is a coproduct of the corn feedstock or is a separate feedstock. Stover is not a coproduct of corn ethanol, clearly it is not. To the extent that Dr. Clarens recognizes that stover is a feedstock, I am unable to understand why or how he relates that fact to the impact of coproducts in relation to "trigger[ing] a switch from Tier 1 to Tier 2." In addition, I am unable to understand the point of confusion that Dr. Clarens perceives that would important to clarify for producers whose pathways include coproduct credits, even though I prepare pathway applications for some of those producers and am familiar with the newly proposed changes for registration and certification of ethanol pathways. I also note that Dr. Clarens appears not to know the LUC emissions factor that has been proposed for corn starch ethanol: he believes it to be 30 g/MJ, based on his memorandum. In my opinion, Dr. Clarens's memorandum demonstrates insufficient knowledge of the scientific portions of the proposed regulation to be given credibility in the scientific community as a reviewer of the LUC and CA-GREET portions of the proposed rule. LCFS FF45-49

13. In the memorandum from Dr. Matthews that is attached to the May 5 letter, Dr. Matthews comments on the potential interaction between GHG emissions and emissions of volatile organic compounds and carbon monoxide. Those who work in the fields of GHG regulation and of criteria or related pollutant regulation consider such potential interactions to be minor, compared with the limitations on the effectiveness of GHG emissions regulations that do not address net emissions impact, or "leakage." The phenomenon of "fuel shuffling" -- in whch fuels that are not sold for use in California are still produced for sale elsewhere, regardless of the LCFS regulation -- is well recognized, but is not discussed in Dr. Matthews' memorandum. LCFS FF45-50

14. In the draft memorandum from Dr. McCarl attached to the May 5 letter, Dr. McCarl states as follows: LCFS FF45-51

In GTAP I believe that there also are increases in emissions from intensification (more irrigation or fertilization) so that the characterization of it only in terms of indirect land use change is not accurate.

Dr. McCarl's belief about the contents of GTAP is not correct. There are no increases in emissions in GTAP attributed to intensification. Fertilization rates, for example are addressed in CA-GREET and not in GTAP, for purposes of ARB's lifecycle emissions analysis and standard-setting. I believe this error in Dr. McCarl's memorandum would be identified by anyone familiar with the relevant portions of the scientific basis of the proposed regulation. Although I believe Dr. McCarl to possess expertise in LUC modeling, the draft memorandum attributed to him does not demonstrate a level of familiarity with the scientific portions of the LCFS regulation on which he appears to be opining that can be considered to give the draft memorandum's opinion on those portions of the regulation credibility in the scientific community.

LCFS FF45-51 cont.

I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct.

Executed this 18th day of June, 2015 in Holland, Michigan.

Thomas L. Darlington
President, Air Improvement Resource Inc.

Profile

Thomas L. Darlington is President of Air Improvement Resource, a company formed in 1994 specializing in mobile source emission modeling. He is an internationally recognized expert in mobile source emissions modeling, lifecycle analysis, and land use modeling.

Professional Experience

1994-Present	President, Air Improvement Resource
1993-1994	Director, Mobile Source Programs, Systems Application International
1989-1994	Senior Engineer, General Motors Corporation, Environmental Activities
1988-1989	Senior Project Engineer, Detroit Diesel Corporation
1979-1988	Project Manager, U.S. EPA, Ann Arbor, Michigan

Recent Major Projects

- Developed Life Cycle reports and complete applications for 8 plants for the California Low Carbon Fuel Standard; six are currently registered, two plants are pending. Five plants were corn ethanol plants, one is sorghum and two are cellulose.
- Participated in and provided written comments on ARB's three 2014 iLUC workshops
- With Purdue and Don O'Connor, conducted study of iLUC emissions of rapeseed and other oilseeds in 2013 utilizing an updated version of GTAP
- Reviewed EPA's palm oil iLUC emissions in 2013
- Submitted comments on ARB's new GREET2.0 model
- Reviewed CARB's land use emissions for soybean biodiesel
- Reviewed the land use impacts of the RFS2 from EPA, including the notice of Proposed Rule, Regulatory Impact Analysis, and approximately one hundred documents in the rulemaking docket.
- Completed a land use study for Renewable Fuels Association and reviewed California Air Resource Board's Initial Statement of Reasons for the Low Carbon Fuel Standard
- Represented three stakeholders in the recent development of the ARB Predictive Model for reformulated gasoline in California (Alliance of Automobile Manufacturers, Renewable Fuels Association and Western States Petroleum Association)
- Represented two stakeholders in EPA's development of the MOVES on-highway emissions model (Alliance of Automobile Manufacturers and Engine Manufacturers Association)

Attachment "A"

- Developed the effects of ethanol permeation on on-highway and off-highway mobile sources in California and other states for the American Petroleum Institute
- Studied gasoline and diesel fuel options for Southeast Michigan (for SEMCOG, API and Alliance of Automobile Manufacturers)

Recent Publications

"Study of Transportation Fuel Life Cycle Analysis: Review of Economic Models Use to Assess Land Use Effects", CRC-E-88-3, July 2014.

"Land Use Change Greenhouse Gas Emissions of European Biofuel Policies Utilizing the Global Trade Analysis Project Model", Darlington, Kahlbaum, O'Connor, and Mueller, August 30, 2013.

"A Comparison of Corn Ethanol Lifecycle Analyses: California Low Carbon Fuels Standard (LCFS) Versus Renewable Fuels Standard (RFS2)", June 14, 2010. Renewable Fuels Association and Nebraska Corn Board. This study compared and contrasted the corn ethanol lifecycle analyses performed by both CARB (as a part of the LCFS) and the EPA (as a part of RFS2).

"Review of EPA's RFS2 Lifecycle Emissions Analysis for Corn Ethanol", September 25, 2009. Conducted for Renewable Fuels Association. This study reviewed EPA's land use GHG emissions assessment for corn ethanol, including the FASOM and FAPRI models and Winrock land-use types converted and emission factors by ecosystem type. The study made many recommendations for improving the land-use and emissions modeling.

"Review of CARB's Low Carbon Fuel Standard Proposal", April 15, 2009. Conducted for Renewable Fuels Association. This study reviewed CARB's analysis of land use emissions using GTAP6 and CARB's overall lifecycle emissions for corn ethanol. This study made many recommendations for improving the land use and lifecycle emissions of corn ethanol.

"Emission Benefits of a National Clean Gasoline", August 2008. Conducted for the Alliance of Automobile Manufacturers. This study evaluated the nationwide criteria pollutant emission reductions of a national clean gasoline standard.

"Land Use Effects of Corn-Based Ethanol", February 25, 2009. Conducted for Renewable Fuels Association. This study evaluates possible land use changes and GHG emissions associated with these land use changes as a result of the renewable fuel standard mandated 15 billion gallons of corn ethanol required by calendar year 2015. The study utilized projections of land use in the US and rest of world performed by Informa Economics, LLC, as well as newer estimates of the land use credits of co-products produced by ethanol plants to evaluate possible land use changes.

"On-Road NOx Emission Rates From 1994-2003 Heavy-Duty Trucks", SAE2008-01-1299, conducted for the Engine Manufacturers Association. This study examined

manufacturers consent decree emissions data to determine on-road NOx emission rates, and deterioration in emissions from heavy-duty vehicles. (Peer reviewed publication)

"Evaluation of California Greenhouse Gas Standards and Federal Energy Independence and Security Act - Part 2: CO2 and GHG Impacts", SAE2008-01-1853, conducted for the Alliance of Automobile Manufacturers. This paper evaluated the comparison of greenhouse gases from cars and light trucks in the US under both the Federal and California GHG policies. (Peer reviewed publication)

"Effectiveness of the California Light Duty Vehicle Regulations as Compared to Federal Regulations", June 15, 2007. Conducted with NERA Economic Consulting and Sierra Research for The Alliance of Automobile Manufacturers. This study compares the emission benefits of the California and Federal light duty vehicle regulations for HC, CO, NOx, PM, SOx, and Toxics taking into account the difference in emission standards, new vehicle costs and its effect on fleet turnover, new vehicle fuel economy and its effect on vehicle miles traveled, and other factors. Both the EPA MOBILE6 and ARB EMFAC on-road emissions models were used to estimate changes in emissions inventories.

"The Case for a Dual Tech 4 Model Within the California Predictive Model", May 20, 2007. Conducted with ICF International and Transportation Fuels Consulting for the Renewable Fuels Association (RFA). This study developed separate emissions vs fuel property models for lower and higher Tech 4 (1986-1995) vehicles, and showed that utilizing this alternative Predictive Model would result in a higher compliance margin for fuels containing higher volumes of ethanol. It was thought that this could lead to higher ethanol concentrations in the state, but even if the dual model is not used, it is a better representation of the 2015 inventory than the ARB single model.

"Updated Final Report, Effects of Gasoline Ethanol Blends on Permeation Emissions Contribution to VOC Inventory From On-Road and Off-Road Sources, Inclusion of E-65 Phase 3 Data and Other Updates", June 20, 2007. Conducted for the American Petroleum Institute. This report updates the earlier March 3, 2005 report for API utilizing data collected by CRC and others since of the time of the earlier report.

Final Report, Development of Technical Information for a Regional Fuels Strategy, February 28, 2006. Conducted for the Lake Air Directors Consortium (LADCO). This report provided guidance to the LADCO states (Midwestern states) concerning how to model different types of fuel control programs (in particular) using EPA mobile source models, and how to set up the baseline input files so that results are consistent between the different states.

"Emission Reductions from Changes to Gasoline and Diesel Specifications and Diesel Engine Retrofits in the Southeast Michigan Area", February 23, 2005. Conducted for the Southeast Michigan Council of Governments (SEMCOG), the Alliance of Automobile Manufacturers, and the American Petroleum Institute. This study examined the on-road and off-road emission benefits of many different possible gasoline and diesel fuel

specifications that the state could adopt to help meet the 8-hour ozone standards. This study formed the basis for the state's move to lower RVP summer gasoline.

"Examination of Temperature and RVP Effects on CO Emissions in EPA's Certification Database, Final Report", CRC Project No. E-74a, April 11, 2005. Conducted for the Coordinating Research Council. This study compared CO vs temperature results from the MOBILE6 model to the certification data, and recommended further testing, which is being conducted by the CRC at this time.

"Effects of Gasoline Ethanol Blends on Permeation Emissions Contribution to VOC Inventory From On-Road and Off-Road Sources" March 3, 2005. Conducted for the American Petroleum Institute (API). Using data from the CRC-E-65 program, and data collected by the California EPA and Federal EPA, this study estimated the impacts of ethanol use on increasing permeation VOC emissions from on-road vehicles, off-road equipment and vehicles, and from portable containers. Emission inventory estimates were made for a number of geographical areas including the state of California, and results showed that the permeation effect increases anthropogenic VOC inventories by 2-4%.

Review of EPA Report "A Comprehensive Analysis of Biodiesel Impacts on Exhaust Emissions", February 11, 2003. Conducted for the American Petroleum Institute. This study critically examined the methods that EPA used to develop the impacts of biodiesel fuels on HC, CO, NOx, and PM emissions.

"Well-To Wheels Analysis of Advanced Fuel/Vehicle Systems – A North American Study of Energy Use, Greenhouse Gas Emissions, and Criteria Pollutant Emissions", May 2005. Conducted for General Motors Corporation, with Argonne National Labs. This study examined many different well to wheels pathways for various fuels, and their impacts on GHG and criteria pollutant emissions.

"Potential Delaware Air Emission Impacts of Switching From MTBE to Ethanol in the Reformulated Gasoline Program", May 26, 2005. Conducted for Lyondell Chemical Company. This study examined the HC, CO, and NOx impacts of switching from MTBE to ethanol.

"Potential Massachusetts Air Emission Impacts of Switching From MTBE to Ethanol in the Reformulated Gasoline Program" June 17, 2005. Conducted for Lyondell Chemical Company. This study is similar to the Delaware study above.

"Potential Maryland Air Emission Impacts of a Ban on MTBE in the Reformulated Gasoline Program", October 18, 2005. Conducted for Lyondell Chemical Company. This study is similar to the Delaware study above.

"MOBILE6.2C with Ethanol Permeation and Ethanol NOx Effects", February 8, 2005. Conducted for Health Canada. This study modified the MOBILE6.2C model for ethanol permeation VOC and ethanol NOx effects.

Discussion of the Yield Price Elasticity in GTAP

Farzad Taheripour and Wallace E. Tyner
Purdue University

At the March 11, 2014 CARB meeting, there was considerable interest in the yield to price elasticity parameter in GTAP. There also seemed to be a good bit of confusion on what it does and does not do. The purpose of this note is to provide an explanation of the role of this parameter in GTAP, explain why it is there, and to explain other reasons why yields can change in GTAP.

First, the basic idea behind the parameter is that over the medium to long term (the time horizon of GTAP), one would expect the agricultural sector to respond to increases in net returns to crops with appropriate investments in improving yields of crops with growing returns. This investment is certainly not limited to on-farm investment. In fact, a major portion of it may occur off-farm. It could include investments by seed companies to produce higher yielding seeds, investments in chemical companies to produce better herbicides/pesticides, investments by farm equipment companies to produce more efficient machinery for cultivation and harvest, investments by farmers to improve drainage and other soil properties, and other productivity enhancing investments. In other words, this parameter attempts to capture responses throughout the agricultural sector to higher returns in given crops.

The yield to price elasticity does not measure changes over one crop year. In fact, any estimate done over one year would be totally inappropriate for GTAP and should be excluded from consideration in determining appropriate values for the parameter.

What is the precise definition of the yield to price elasticity (YDEL)? YDEL is the percentage change in intensive yield over the percentage changes in relative price of a crop over input prices. In other words it is the intensive yield change with respect to change in variable returns to a crop. If the YDEL value is 0.25, and the change in variable returns of a crop is 10%, then the change in intensive yield would be 2.5%. It is very important to emphasize that the parameter YDEL only governs changes in intensive yield due the changes in net return. Other factors can affect crop yields as well.

How else can yields change in GTAP? Yields are affected by changes on the intensive and extensive margins. As noted in Hertel et al. (2010), there are two important sources which affect the extensive margin of yields. The first source is due to shifting among crops. For example, shifting from corn-soybean rotation to corn-corn rotation could affect yield. The second source of change in extensive yield is due to land conversion from forest or pasture to cropland. In the first case, if there is a corn ethanol shock applied to the model, more corn will be demanded, and there likely will be both crop switching and land cover changes to accommodate the higher demand for corn. With crop switching, there will be more acres of corn and fewer acres of other lower yielding crops. Thus, when one calculates the weighted average yields after the shock, the average likely would be higher. For example, consider typical corn, soybean, and wheat yields of 4.5, 1.2, and 1.7 tons/ac respectively. If the post shock crop mix has more corn acreage, the post shock

Attachment "B"

weighted average yields can be higher even if YDEL were zero. That is simply because corn has a higher mass yield per acre.

Yields can also change when more or less productive acres come into corn from other uses. Crop switching can result in higher or lower productivity. However, land cover changes from pasture or forest typically tends to reduce yields because new land could be lower productivity. The productivity of converted land is affected by the ETA parameter.

Since GTAP is a CGE model, yields can also be influenced by a myriad of other changes such as changes in relative price of variable inputs. The bottom line is that while yields can be and are affected by many factors working in GTAP, the YDEL parameter is only designed to capture the incentive to invest over the medium term in crops with increasing returns.

It is not correct to divide the weighted average of percentage changes in crop yields by the weighted average of percent changes in crop prices as was done in the CARB presentation. This calculation incorporates area changes as well as yield changes. One must take into account percentage changes in variable costs of production as well. The calculated value from the CARB presentation of 0.39 for yield to price elasticity for US for the corn ethanol expansion is meaningless because it includes many factors. If we follow the CARB approach and calculate the same measure for Brazil due to the US corn ethanol shock, we get a yield to price elasticity of -0.16 for Brazil, which obviously does not make sense. Furthermore, CARB has ignored the fact that the yield to price ratio only cover the percentage change in intensive yield not total yield. In their calculations, percentage changes in total yield instead of intensive yield were used. LCFS FF45-52

Analysis of Simulations for ILUC

Two separate simulation methodologies were employed by CARB to help determine factors to which Indirect Land Use Change (iLUC) is sensitive. The iLUC impact of biofuels relates to the unintended increase of carbon emissions due to land-use changes around the world induced by the expansion of croplands for production of biofuels such as ethanol in response to the increased global demand for these fuels. If more biofuels are needed, in general the price of the feedstock would rise compared to other uses of the land. This in turn may result in forests or other uncropped land being converted to agricultural use. Because natural lands, such as rainforests and grasslands, store carbon in their soil and in biomass as plants grow each year, clearance of wilderness for new farms translates to a net increase in greenhouse gas emissions. Due to this change in the carbon stock of the soil and the biomass, indirect land use change has consequences in the greenhouse-gas emissions balance of a biofuel.

Both sets of simulations are based on the Global Trade Analysis Project (GTAP) database and the Agro-ecological Zone Emission Factor (AEZ-EF) Model. One method was to use varying specific values of some parameters as sensitivity analysis. For example, this could consist of YDEL, the price elasticity of yield, ETL1, the elasticity of transformation between forest, cropland, and pasture, ETL2, the elasticity of transformation among crops, PAEL_US, the yield elasticity for cropland/pasture in the US, and PAEL_Brazil, yield elasticity for cropland/pasture in Brazil. The other simulation method used the Monte Carlo methodology in which values for a large number of parameters were chosen at random repeatedly.

In order to determine the most influential factors, we conducted a statistical analysis of the iLUC factor for corn ethanol in terms of the input variables in a simulation with 600 variables and 3,000 trials. This was done using stepwise regression, but since all the parameters were chosen independently in the Monte Carlo (except CDGC and CDGS, which were highly correlated), the coefficient estimates were almost orthogonal, so the results of a single analysis of the 600 variable model would have been very similar, except for CDGC and CDGS. Table 1 gives the results of this analysis. The most influential factors in terms of contribution to the sum of squares were YDEL, the price elasticity of yield, the ESBV parameters, the elasticity of substitution between primary input factors in production, ETA, the elasticity of effective hectares with respect to harvested area, and ETL1, the elasticity of transformation among crops.

Table 1. Statistical Analysis of Corn Ethanol ILUC Factor in a Monte Carlo Simulation

Price Elasticity of Yield (YDEL)

In view of the importance of YDEL in the analysis, and in view of the conflicting results in the literature on its likely size, the next part of the project undertaken was to analyze one of the data sets upon which these estimates have been based. The data were used in a 2012 dissertation of Juan Francisco Rosas Pérez (also given as Juan Francisco Rosas in a 2014 paper by Rosas, Hayes, and Lence, apparently taken from the dissertation). In these works, the price elasticity of yield was estimated from data on corn (maize) in Iowa for 1960–2004, and was said to be in the range of 0.29. The data set was publicly available so it was used for a re-analysis. The analysis used by Rosas Pérez, was complex, and can be criticized for insufficiently handling autocorrelation in the series. Therefore, a simpler analysis was conducted that should have similar results to the more complex analysis if the latter is not flawed.

The data set used was the one supplied with the Rosas Pérez dissertation, though there is no good data dictionary and the meaning of some of the statistics was less than clear. The most clearly relevant variables were a corn price index series (here called corn.price) and a corn supply index series (corn.supply) and their natural logarithms (lcorn.price and lcorn.supply). There do not seem to be good data on land devoted to corn, or perhaps land at all, since the variable Z4 = Q Land is equal to 1 for all years, so this analysis was aimed at the price elasticity of supply not the price elasticity of yield; this would tend to overestimate the effect of price on supply given that land substitution is often an easier response to greater potential profit from a crop than is attempting to increase yield.

The quantity of interest then would be the ratio of the percentage change in supply to the percentage change in price. Roughly, the percentage change is equal to the actual change on the natural log scale. For example (110 – 100)/100 = 0.10 while log(110) – log(100) = 0.0953, so we will proceed to relate the change on the log scale of supply to the change on the log scale of price.

Without participating in debates about the proper functional form of multi-equation models of the agricultural economy, we can go back to statistical basics using the following principles:

1. All other things being equal, the price elasticity of supply can be estimated by regressing log(supply) on log(price).
2. In regressions with autocorrelated time series, it is important to account for the self-effects of the series being predicted before asking if another series has an effect. This is sometimes called Granger causality analysis.

In fact, both series are autocorrelated in a plausibly autoregressive way, with the ACF function declining slowly and the PACF function dropping of more quickly (see Figures 1 and 2 for the supply series later in the document). As can be seen from the output in Table 2, there is no significant relationship of supply to current or past prices after accounting for last year's supply. In fact, the estimated coefficients are not even positive.

While there may exist alternative explanations of these results with respect to omitted factors, it is hard to find such modeling aspects that provide effects in the direction of reducing the apparent response of supply to price and that themselves could explain a large elasticity that is so hidden. The best interpretation of these results is that

1. The price elasticity of yield implied by the Iowa corn data is likely close to 0 and very unlikely to be as large as 0.10 or 0.20.
2. The results obtained by Rosas Pérez showing an apparently higher elasticity is likely caused by mishandling the autocorrelation in the time series.

As documented in Berry (2011), Berry and Schlenker (2011), and Roberts and Schlenker (2013), much of the literature providing purported estimates of the price elasticity of yield is deeply methodologically flawed. In addition to the problems of endogeneity and autocorrelation that are badly handled, there are other important issues. In Goodwin, Michele Marra, Piggott, and Mueller (2012), for example, 15 years of data are multiplied into 405 data points by considering 27 different districts. But there are still only 15 price values and it is hard to believe that the strong relationships of weather, price, and technology within a given year can be handled by econometric tricks. The analyses, such as those in Roberts and Schlenker (2013), that are methodologically sound all show small to zero price elasticities of yield.

STATE OF CALIFORNIA

BEFORE THE AIR RESOURCES BOARD

Declaration of James M. Lyons

I, James Michael Lyons, declare as follows:

1. I make this Declaration based upon my own personal knowledge and my familiarity with the matters recited herein. It is based on my experience of nearly 30 years as a regulator, consultant, and professional in the field of emissions and air pollution control. A copy of my résumé can be found in Attachment A.

2. I am a Senior Partner of Sierra Research, Inc., an environmental consulting firm located at 1801 J Street, Sacramento, California owned by Trinity Consultants, Inc. Sierra specializes in research and regulatory matters pertaining to air pollution control, and does work for both governmental and private industry clients. I have been employed at Sierra Research since 1991. I received a B.S. degree in Chemistry from the University of California, Irvine, and a M.S. Degree in Chemical Engineering from the University of California, Los Angeles. Before joining Sierra in 1991, I was employed by the State of California at the Mobile Source Division of the California Air Resources Board (CARB).

3. During my career, I have worked on many projects related to the following areas: 1) the assessment of emissions from on- and non-road mobile sources, 2) assessment of the impacts of changes in fuel composition and alternative fuels on engine emissions including emissions of green-house gases, 3) analyses of the unintended consequences of regulatory actions, and 4) the feasibility of compliance with air quality regulations.

4. I have testified as an expert under state and federal court rules in cases involving CARB regulations for gasoline, Stage II vapor recovery systems and their design, factors affecting emissions from diesel vehicles, evaporative emission control system design and function, as well as combustion chamber system design. While at Sierra I have acted as a consultant on automobile air pollution control matters for CARB and for the United States Environmental Protection Agency. I am a member of the American Chemical Society and the Society of Automotive Engineers and have co-authored nine peer-reviewed monographs concerned with automotive emissions, including greenhouse gases and their control. In addition, over the course of my career, I have conducted peer-reviews of numerous papers related to a wide variety of issues associated with pollutant emissions and air quality.

5. This Declaration summarizes the results of my review of the CARB Notice of Public Availability of Modified Text and Availability of Additional Documents for the Proposed Re-Adoption of the Low Carbon Fuel Standard Regulation on the Commercialization of Alternative Diesel Fuels (the LCFS Regulation) dated June 4,

2015. I have performed this review as an independent expert for Growth Energy. If called upon to do so, I would testify in accord with the facts and opinions presented here.

6. Based on my review of the changes proposed to the LCFS regulation by CARB, the elimination of the multimedia evaluation provisions from the LCFS through the deletion of Section 95490 and related deletions in Sections 95481(a)(59) and 95488(c)(4)(G)6.d. creates the potential for significant adverse environmental impacts to occur as the result of the introduction of new lower carbon intensity fuels. I have participated in every aspect of the development of the LCFS regulation in which a member of the public was allowed by CARB to participate. This change to the proposed regulation could not reasonably have been anticipated, based on the notice of proposed rulemaking and the supporting materials made available in December 2014. LCFS FF45-53

7. The discussion of the need for the multimedia evaluation provisions that CARB staff is now proposing to delete is summarized in both the current Initial Statement of Reasons (ISOR) for re-adoption of the LCFS regulation as well as the ISOR prepared in 2009 for the original LCFS regulation. The language relevant to the multimedia evaluation provisions in both the current and 2009 ISOR is virtually identical. With respect to why the multimedia evaluation provisions were needed in the LCFS, both the ISOR for the re-adoption of the LCFS regulation[1] and the 2009 ISOR[2] state that:

> *The LCFS regulation incorporates this principle as a pre-sale prohibition applied to fuels that are subject to an ARB specification that is modified or adopted after adoption of the LCFS regulation. In such cases, regulated parties would be prohibited from selling the affected fuels in California to comply with the LCFS requirements until a multimedia evaluation is approved for those fuels pursuant to H&S §43830.8.*

LCFS FF45-54

Elimination of the multimedia evaluation provisions from the LCFS regulation as now proposed by CARB staff would permit fuel suppliers to sell new fuels in California in order to try to comply with the LCFS without ensuring that adverse environmental impacts associated with their use have been identified and properly mitigated. Such new fuels could include gasoline-butanol blends, alternative diesel fuels other than biodiesel and renewable diesel, and renewable natural gas fuels that fail to comply with CARB's existing natural gas fuel specifications. In addition, these potential impacts of the LCFS regulation were not considered in the Environmental Analysis prepared for the LCFS and ADF regulations.

8. There are several ways in which new fuels which could lead to adverse environmental impacts could be sold in California before the approval of a multimedia LCFS FF45-55

1. [1] Page III-64

[2] Page V-32

evaluation pursuant to H&S §43830.8. The first of these is if the California Division of Measurement Standards (CDMS) rather than CARB adopts fuel specifications allowing the use of the new fuel. In the past, new fuels have been allowed in California through specifications enacted by CDMS that have not been required to undergo multimedia evaluation pursuant to H&S §43830.8. Biodiesel is one such fuel that has created adverse environmental impacts. Based on CARB staff estimates, in 2014, biodiesel use for compliance with the LCFS regulation allowed by CARB[3] without an approved multimedia evaluation pursuant to H&S §43830.8 resulted in increased NOx emissions of 1.2 tons per day statewide.[4] Increased NOx emissions due to the use of biodiesel for purposes of LCFS compliance have occurred since the inception of the LCFS program as a result of CARB's failure to adopt fuel specifications and complete the multimedia evaluation required pursuant to H&S §43830.8 despite having committing to do so as early as 2009.[5] Elimination of the requirements for approval of a multimedia evaluation before allowing new fuels to be sold for purposes of LCFS approval would allow other new fuels to be sold in California that, like biodiesel, create adverse environmental impacts before those impacts have been identified through the multimedia evaluation process. These potential environmental impacts created by the LCFS as a result the elimination of the LCFS multimedia evaluation requirements were not considered in the Environmental Assessment.

LCFS FF45-55 cont.

9. That the increases in NOx emissions resulting from biodiesel use in California without an approved multimedia evaluation were significant can be seen through a comparison of the criteria used to assess air quality impacts in areas of California outside the South Coast and San Joaquin Air Basins and the increases in NOx emissions estimated to result from biodiesel use. Using the Sacramento Metropolitan Air Quality Management District as an example,[6] the significance threshold for NOx emissions projects subject to CEQA is 65 pounds per day or 0.0325 tons per day. The 0.0325 tons per day threshold can be compared to both the 1.2 ton per day increase in NOx emissions due to biodiesel use estimated by CARB staff for 2014 statewide. Clearly, elimination of the requirements for multimedia evaluation for new fuels sold for LCFS compliance could lead to similar, and therefore significant, unmitigated, increases in NOx emissions or significant and unmitigated increases in emissions of other pollutants.

LCFS FF45-56

10. Another way in which new fuels could create potential adverse environmental impacts if the multimedia evaluation requirements are deleted is through the

LCFS FF45-57

[3] See *http://www.arb.ca.gov/fuels/diesel/altdiesel/20111003biodiesel%20guidance.pdf*

[4] See Table 1 of *http://www.arb.ca.gov/regact/2015/adf2015/signedadfnotice.pdf*

[5] See page V-33 of *http://www.arb.ca.gov/regact/2009/lcfs09/lcfsisor1.pdf*

[6] See *http://airquality.org/ceqa/ceqaguideupdate.shtml*

Developmental Engine Fuel Variance Program operated by CDMS.[7] Again, the multimedia evaluation requirements of H&S §43830.8 that apply to fuels for which CARB adopts specifications would not apply in this case and adverse environmental impacts can occur. Allowing new fuels that are part of this program to be sold for purposes of LCFS compliance without having an approved multimedia evaluation would increase the likelihood that fuel producers would seek to use this program and the likelihood that new fuel that leads to unmitigated adverse environmental impacts would be used in California. These potential environmental impacts that the LCFS regulation could create as a result of the proposed elimination of the multimedia evaluation requirements were not considered in the Environmental Assessment. LCFS FF45-57 cont.

11. In addition, the Alternative Diesel Fuel regulation proposed by CARB staff creates another way by which new fuels with potential adverse environmental impacts could be sold in California for purposes of LCFS compliance should the multimedia evaluation requirements be eliminated. Currently, fuels involved in Stage 1 or Stage 2 of the LCFS regulation are not required to have completed a multimedia evaluation and therefore could not be sold for purposes of LCFS compliance until they reach Stage 3, at which point completion of a multimedia evaluation and adoption of fuel specifications by CARB are required. Elimination of the current multimedia evaluation requirements from the LCFS regulation as now proposed by CARB staff, would allow fuels in Stage 1 and Stage 2 to be sold for purposes of LCFS compliance before the potential adverse environmental consequences have been assessed or mitigated. Again, these potential environmental impacts due to the LCFS were not considered in the Environmental Assessment. LCFS FF45-58

12. In summary, retention of the current LCFS requirements that new fuels have received an approved multimedia evaluation pursuant to H&S §43830.8 before being allowed to be sold for purposes of LCFS compliance is the only way to ensure that the LCFS is not responsible for use of these new fuels creating potential adverse environmental impacts. LCFS FF45-59

I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct.

Executed this 19th day of June, 2015 at Sacramento, California.

1071. Comment: **LCFS FF45-2, LCFS FF45-4 through LCFS FF45-6, LCFS FF45-53 through LCFS FF45-59**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

1072. Comment: **LCFS FF45-1**

The commenter states that 1) ARB's LUC Value for corn ethanol of 19.8 gCO2e/MJ is not supported by substantial evidence and is equivalent to an average value of 0.19 for price-yield, 2) that staff used an inconsistent approach by including the lowest values (i.e., 0.05 and 0.10) of yield-price in the iLUC analysis, and 3) that they do not agree with David Rocke's conclusion related to the analysis of the work completed by Rosas Perez and request that the data used by David Rocke for his report be released to the public.

Agency Response: (1) See response to **LCFS 8-9**. ARB staff does not agree with commenter that the two lowest values of yield price elasticity be eliminated. The data used by David Rocke has been published as part of a 3rd 15-day package released on July 31, 2015. Staff does not consider modifying the current analysis to use of a lower iLUC value (e.g., 15.53 g/MJ) for corn ethanol as suggested by the commenter to be warranted.

In addition, ARB does not agree with commenter that an iLUC value estimated using 0.19 (average of five values as referenced by the commenter) is equivalent to an average iLUC value calculated using all YPE values independently. Each value of YPE results in a simultaneous solution of complex equations that govern the behavior of the GTAP model. Given the complexity of this model, it is unlikely that the output of the model using a single value of YPE (e.g. 0.19) would be equivalent to a calculated average of outputs from five independent runs. In addition, runs completed by staff did not consider only varying YPE but varied other parameters simultaneously (detailed in Appendix I of the ISOR.)

2) *Staff used an inconsistent approach by including the lowest values (i.e., 0.05 and 0.10) of yield-price in the iLUC analysis*.

It is true that in estimating YPE, some studies make a distinction between short-term and long-term yield responses to price but some do not. The studies used by ARB to develop the range of YPE values of 0.05 and 0.35 are all inclusive and presented in ISOR Appendix I, Attachment 1 Table I-2. It should be noted that among these studies only Goodwin, et al. make an explicit distinction between short and long-term price responses. It can be argued that Smith & Sumner also measure short term responses in an implicit way. None of the YPE estimates in the Keeney and Hertel (2009) or ARB's literature review can be characterized as a yield response to price after an exact number of years.

3) *The commenter does not agree with David Rocke's conclusion related to the analysis of the work completed by Rosas Perez and request that the data used by David Rocke for his report be released to the public.*

ARB released the data used by Rocke (3rd 15-day package to be released in August 2015) and does not agree with commenter that the two lowest values should be eliminated. As ARB informed the commenter, permission to release the data had not been provided by Dr. Perez. ARB's legal team was able to determine that this data could be published and accordingly made available the data as part of the 3rd 15-day package released on July 31, 2015. With reference to Rocke's analysis supporting low yield price elasticities, ARB's use of the entire range of values for YPE was not based on David Rocke's analysis. That analysis confirmed other studies in the academic literature which have found that the YPE value should be small. As detailed above, a comprehensive literature review of YPE revealed that there is a wide range of likely values based on econometric/statistical treatment applied to estimate yield price. This review was the basis for ARB to include the entire range of likely values for YPE in the analysis.

See also responses to **LCFS B12-6**, **LCFS 46-79**, **LCFS 46-103**, **LCFS 46-102**, **LCFS 46-107**, and **LCFS 8-9**.

1073. Comment: **LCFS FF45-3**

The comment points out a bug in the CA-GREETv2.0-Tier 1 Calculator that leads to an erroneous credit in the life cycle analysis of Brazilian sugarcane-based ethanol pathways.

Agency Response: ARB staff agrees with the commenter that sugar cane harvested mechanically should be treated differently than sugar cane harvested manually, after burning the cane field. ARB has consistently distinguished between mechanized and manually-harvested sugar cane feedstock since early development of the LCFS program in 2009, again in the Method 1 pathways that were part of the original LCFS, and in the ISOR and CA-GREETv2 model that were part of the proposed re-adoption. While adjusting a different part of CA-GREETv2 as part of the June 4, 2015 15-day modifications a pre-existing link between cells in the model was accidentally not preserved. The missing cross-reference between cells has been replaced. Staff thanks the commenter for notifying ARB of the error.

1074. Comment: **LCFS FF45-7**

The commenter takes exception to the addition of nine emails to the rulemaking record as part of a 15-day Notice, arguing that those nine emails and unidentified others should already have been included in the rulemaking file earlier.

Agency Response: ARB staff disagrees with the commenter's implicit characterization of the emails as either "factual information … submitted to the agency in connection with the adoption, amendment, or repeal of the regulation" or "factual information … on which the agency is relying in the adoption, amendment or repeal of a regulation." The emails are not "factual information;" ARB is not relying on them; and they were not "submitted to" ARB "in connection with the adoption amendment, or repeal of the regulation." Notably, the commenter does not assert otherwise and, indeed, omitted any substantive discussion of the content of the emails from its comment.

ARB also disagrees with the commenter's contention that the rulemaking file is incomplete. ARB complied with the legal requirements for the rulemaking file, and these emails do not suggest otherwise as noted above. The remainder of this comment reflects the commenter's abstract legal opinions and requires no response.

1075. Comment: **LCFS FF45-8**

The commenter believes that ARB has not properly construed or applied the relevant provisions of the Government Code.

Agency Response: See response to **LCFS FF45-7.**

1076. Comment: **LCFS FF45-9**

The commenter believes that ARB did not comply with section 11347.3 of the government code.

Agency Response: See response to **LCFS FF45-7.**

1077. Comment: **LCFS FF45-10**

The commenter wants to know why additional documents from 2013 and 2014 were added to the rulemaking file.

Agency Response: See response to **LCFS FF45-7.**

1078. Comment: **LCFS FF45-11**

The commenter requests a list of all the documents ARB did not include in the rulemaking file.

Agency Response: See response to **LCFS FF45-7.**

1079. Comment: **LCFS FF45-12**

The commenter believes that ARB failed to substantially comply with Health & Safety Code section 57004. The comment begins with quotations from that statute and a recitation setting out various dates together with the commenter's interpretation of correspondence in the record, none of which require a response. More legal quotations follow, then the commenter's application of the commenter's version of the law to the commenter's version of the facts. An interrogatory follows: "If CARB disagrees [with the previous confusing, self-contradicting prose] . . . [commenter] requests that CARB fully explain its reasons . . ."

Agency Response: ARB fully complied with section 57004 by submitting the LCFS and its scientific bases for peer review. Included in the materials submitted for peer review were three staff reports (provided as hard copies in one binder) and several electronic files (provided on CD), including software and program packages, bibliographical references, and supporting documents. The comment's confused, long sentences (e.g., 88 words) are difficult to interpret, but do not appear to include an objection or recommendation regarding the proposal See also response to **LCFS FF45-7**.

1080. Comment: **LCFS FF45-13**

The commenter states that ARB must comply with Health & Safety Code section 57004 subsection (D)(1).

Agency Response: See response to **LCFS FF45-12**.

1081. Comment: **LCFS FF45-14**

The commenter states that ARB must comply with Health & Safety Code section 57004 subsection (D)(2).

Agency Response: See response to **LCFS FF45-12**.

1082. Comment: **LCFS FF45-15**

The commenter states that the peer reviewers had twice the amount of time to review the proposal than the public did.

Agency Response: See response to **LCFS FF45-12**.

1083. Comment: **LCFS FF45-16**

The commenter states that the peer reviewers should have reviewed all documents that the proposal was based on.

Agency Response: See response to **LCFS FF45-12**.

1084. Comment: **LCFS FF45-17**

The commenter claims that a UC Project Director's determination regarding the number and expertise of peer reviewers is "missing from the rulemaking file."

Agency Response: ARB staff disagrees that administrative steps taken by independent outside bodies such as the University of California must be documented beyond what is in the rulemaking file. It is not clear that the desired document even exists. Clearly the determination was made because the review was indeed conducted, and the number of peer reviewers – four—is apparent from the reviews themselves.

1085. Comment: **LCFS FF45-18**

The commenter asserts that "[a] single, unitary 'entity' must do what [§57004] requires," hence the work by four academic experts to conduct and write the peer review failed to comply with the statute.

Agency Response: ARB disagrees. While it is true that section 57004(d)(1) requires evaluation by "the external scientific peer review entity," in section 57004(b) the Legislature provided that the external reviewer may be any of the following:

(1) "the National Academy of Sciences," which does not actually employ or control its approximately 2,250 members and nearly 440 foreign associates, who are dispersed at a wide variety of research, academic, and business settings;

(2) "the University of California," including 10 campuses, 30,835 full time academic staff, and 29,393 part time academic staff as of April 2015;

(3) "the California State University," including 23 campuses and 47,000 faculty and staff;

(4) "any similar scientific institution of higher learning";

(5) "any combination of those entities";

(6) "a scientist or group of scientists of comparable stature and qualifications that is recommended by the President of the University of California."

By definition, the entities listed by the Legislature work only through the individual thoughts and efforts of the human beings associated with the organization. In light of that simple fact, the commenter's complaint that the "four individuals" separately evaluated the proposal rather than an "entity" is merely literalism taken to an absurd extreme. Here, as expressly provided in the statute, the President of the University of California recommended four "scientists of comparable stature and qualifications."

Unsatisfied with the favorable evaluation that the LCFS proposal received, the commenter switches, in comments **LCFS FF45-19** through **LCFS FF45-22**, to *ad hominem* attacks on the reviewers

ARB does not agree with those attacks, or with the repeated implication that ARB staff, who had no contact with the reviewers, actively misled the reviewers and "lack[ed] candor."

1086. Comment: **LCFS FF45-19**

The commenter critiques Dr. Claren's review.

Agency Response: See response to **LCFS FF45-18**.

1087. Comment: **LCFS FF45-20**

The commenter critiques Dr. Matthews' review.

Agency Response: See response to **LCFS FF45-18**.

1088. Comment: **LCFS FF45-21**

The commenter critiques Dr. Matthews' review.

Agency Response: See response to **LCFS FF45-18**.

1089. Comment: **LCFS FF45-22**

The commenter critiques Dr. McCarl's review.

Agency Response: See response to **LCFS FF45-18**.

1090. Comment: **LCFS FF45-23**

The commenter objects that the reviewer selection process must have been improper because none of the peer reviewers had published skeptical reviews prior to being selected. The commenter attaches a review of the 2009 proposal, apparently to illustrate that individuals who are skeptical of the LCFS concept exist.

Agency Response: ARB staff disagrees that any particular reviewer or type of reviewer needed to be appointed, other than someone whom the University of California deemed to have the requisite knowledge and expertise. ARB does not choose the reviewers; the suggestion that the University of California should select reviewers who had pre-judged the merits of a proposal should be directed to the University.

1091. Comment: **LCFS FF45-24**

The commenter expresses dissatisfaction with what they believe is the apparent lack of "systematic" review of certain details residing in the CA-GREET model.

Agency Response: ARB does not agree that it is fair to assume that none of the four reviewers properly reviewed a model that was (1) assigned for review by the University of California and (2) evaluated in a written report by the reviewer.

None of the above comments reasonably suggest that ARB did not comply with section 57004.

1092. Comment: **LCFS FF45-25**

The commenter asks ARB if they provided the peer reviewers the best economic information.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-12**.

1093. Comment: **LCFS FF45-26**

The commenter asks if the peer reviewers were given material relating to fuel shuffling.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-12**.

1094. Comment: **LCFS FF45-27**

The commenter asks if the peer reviewers were given the ISU report.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-12**.

1095. Comment: **LCFS FF45-28**

The commenter asks for the definition of a "complete global land use database."

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-12**.

1096. Comment: **LCFS FF45-29**

The commenter asks for ARB's opinion on Dr. Clarens.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response.

1097. Comment: **LCFS FF45-30**

The commenter asks if ARB staff is aware of Dr. Clarens' knowledge of iLUC.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-12**.

1098. Comment: **LCFS FF45-31**

The commenter asks if ARB agrees with the commenter's critique of Dr. Clarens' peer review.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-12**.

1099. Comment: **LCFS FF45-32**

The commenter asks for ARB's opinion on Dr. Clarens' qualifications.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-18** and **LCFS 45-23**.

1100. Comment: **LCFS FF45-33**

The commenter asks if ARB finds Dr. Matthew's peer review useful.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-12**.

1101. Comment: **LCFS FF45-34**

The commenter asks ARB if they think any reviewer understood and reviewed CA-GREET.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-18** and **LCFS 45-23**.

1102. Comment: **LCFS FF45-35**

The commenter asks if ARB notified Dr. Matthew about his mistake on the MOVES model.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-12**.

1103. Comment: **LCFS FF45-36**

The commenter asks ARB if they agree with Dr. Matthew's memorandum.

Agency Response: The comment does not make a recommendation about the proposal or an objection, and needs no response. See response to **LCFS FF45-12**.

1104. Comment: **LCFS FF45-37**

The commenter asks if ARB believes that Dr. McCarl is qualified to review GTAP.

Agency Response: See response to **LCFS FF45-17, LCFS 45-17, LCFS 45-18,** and **LCFS 45-23**.

1105. Comment: **LCFS FF45-38**

The commenter asks how ARB determined the number of peer reviewers.

Agency Response: See response to **LCFS FF45-17** and **LCFS 45-18**.

1106. Comment: **LCFS FF45-39**

The commenter attaches Professor Valerie Thomas' review of the LCFS as it was proposed in 2009.

Agency Response: The review was prepared years ago, and does not contain objections or recommendations regarding the regulation considered by the Board in 2015. Prof. Thomas' review was attached to document the point raised in comment **LCFS FF45-23**, in essence that Prof. Thomas exists, had questions in 2009, and was not selected by the University of California to review the December 30, 2014 proposal. Please see response to **LCFS FF45-17, 45-18** and **LCFS 45-23** above.

1107. Comment: **LCFS FF45-40**

The comment is a copy of part of the transcript from the 2009 Board Hearing.

Agency Response: While this comment is outside the scope of the 15-day changes, ARB staff acknowledges this comment. Since then, the indirect land use change has been updated based on the latest science.

1108. Comment: **LCFS FF45-41**

The commenter states that ARB's LUC Value for corn ethanol of 19.8 gCO2e/MJ is not supported by substantial evidence and is equivalent to an average value of 0.19 for price-yield.

Agency Response: See response to **LCFS FF45-1**.

1109. Comment: **LCFS FF45-42**

The commenter states that staff used an inconsistent approach by including the lowest values.

Agency Response: See response to **LCFS FF45-1**.

1110. Comment: **LCFS FF45-43**

The commenter states that they do not agree with David Rocke's conclusion related to the analysis of the work completed by Rosas Perez and request that the data used by David Rocke for his report be released to the public.

Agency Response: See response to **LCFS FF45-1**.

1111. Comment: **LCFS FF45-44**

Agency Response: See response to **LCFS FF45-1.**

1112. Comment: **LCFS FF45-45**

These comments are related to recertification of fuel pathways and the records required for recertifying pathways.

Agency Response: ARB staff appreciates the commenter's concerns regarding record submittal requirements for fuel pathways during recertification. The commenter is first concerned that the records requirement for recertified pathways is burdensome. Staff has attempted to minimize this burden with the release of the revised regulation order on June 23, 2015. Specifically, § 95488(a)(2)(B) states,

> "Recertifications will be processed by the Executive Officer using information previously supplied to the Executive Officer under the provisions of the former LCFS regulation order,

provided such information was complete pursuant to the former LCFS regulation's requirements. The requirements of subsections 95488(c)(3)-(5) and subsection 95488(e) are not applicable to recertifications, unless the Executive Officer specifically requests such information from an applicant."

Staff believes that using existing data and some defaults will allow the process of recertification to go smoothly and rapidly. Staff will request additional information from pathway recertification applicants if needed. See response to **LCFS FF17-1** and **LCFS FF17-2**.

1113. Comment: **LCFS FF45-46**

These comments are related to recertification of fuel pathways and the records required for recertifying pathways.

Agency Response: See response to **LCFS FF17-2** and **LCFS FF45-45**.

1114. Comment: **LCFS FF45-47**

The comment points out a bug in the CA-GREETv2.0-Tier 1 Calculator that leads to an erroneous credit in the life cycle analysis of Brazilian sugarcane-based ethanol pathways

Agency Response: See response to **LCFS FF45-3**.

1115. Comment: **LCFS FF45-48**

The comment points out a bug in the CA-GREETv2.0-Tier 1 Calculator that leads to an erroneous credit in the life cycle analysis of Brazilian sugarcane-based ethanol pathways

Agency Response: See response to **LCFS FF45-3**.

1116. Comment: **LCFS FF45-49**

The commenter points out that (1) peer reviewer Dr. Clarens' report contained a question, (2) the commenter does not understand exactly what Dr. Clarens meant, and (3) the commenter does not have sufficient familiarity with the models reviewed.

Agency Response: ARB staff disagrees that the peer review process was not conducted as required by health & Safety Code section 57004. See responses to **LCFS FF45-1** through **LCFS FF45-51**.

1117. Comment: **LCFS FF45-50**

The commenter notes that peer reviewer Prof. Matthews did not discuss the phenomenon of “fuel shuffling.”

Agency Response: ARB staff disagrees with the implication that the peer review process was not conducted as required by health & Safety Code section 57004. See responses to **LCFS FF45-1** through **LCFS FF45-51**.

1118. Comment: **LCFS FF45-51**

The commenter believes that peer reviewer Dr. McCarl did not understand that GTAP does not attribute emissions to [crop] intensification. The commenter further believes that McCarl’s report might lack credibility in the ‘scientific community’ that is neither identified, quoted, nor cited by the commenter.

Agency Response: ARB staff disagrees with any implication that the peer review process was not conducted as required by health & Safety Code section 57004. See responses to **LCFS FF45-1** through **LCFS FF45-50**.

1119. Comment: **LCFS FF45-52**

The commenter states that ARB did not calculate the yield to price elasticity correctly.

Agency Response: ARB staff disagrees with the commenter about the interpretation of the results presented at the March 11, 2015 meeting. Also, the comment highlighting the incorrect approach used by ARB to develop a 0.39 value is irrelevant since no structural changes or other modifications were made to negate such effects after staff discovered this particular aspect of the GTAP model. It was the intent of staff to estimate 'net yield' when a specific input value was used for yield-price elasticity (YPE). In the analysis conducted by ARB, staff estimated that when a value of 0.25 was used for YPE, the 'net yield' was 0.39, reflecting a higher effective yield (e.g., in relation to the input value of 0.25). Staff recognizes that the GTAP model includes impacts from both intensive and extensive effects and also a myriad of other changes in determining an equilibrium solution to a given set of input conditions. The higher 'net yield' confirmed the effects of extensive and other factors in addition to intensive effects. Additionally, staff conducted simulations with a value of zero for YPE (~0.01) and observed 'net yields' that were non-zero. These tests served to provide ARB with improved understanding of the interactions of intensive, extensive, and other effects within the GTAP model. None of the GTAP modeling structure or other aspects was changed after staff observed this behavior. The comments are therefore not relevant to the analysis presented by staff as part of the re-adoption of the LCFS rulemaking process. As for the reported value of -0.16 for Brazil, ARB does not have details to replicate this value referenced by the commenter.

Subject: Comments on the 15 Day Regulatory package for the LCFS Regulation

I strongly support the Low Carbon Fuel Standard's (LCFS or regulation) provisions for Low Complexity – Low Energy Use Refiners (LCLE Refiners). These provisions recognize that not all refineries are the same. I believe that there is solid policy and technical justifications for this distinction to be codified in the LCFS. The Air Resources Board (CARB or Board), as well as, the U.S. Environmental Protection Agency have traditionally recognized in their regulatory programs the unique value small refiners (LCLE) occupy in both the oil and finished fuel markets, as well as, their unique configurations and operating constraints. Recognizing that difference is a very positive step.

However, I am disappointed that the proposed final regulatory provisions for the re-adoption of California's Low Carbon Fuel Standard (15-day changes) fails to recognize Alon's Bakersfield Refinery as a low carbon fuel producer (LCLE). The facility is configured and engineered to produce low CI base fuels. It is for this reason that I am disappointed that staff was unable to agree on a solution that would include all of California's truly LCLE refineries. The staff had an opportunity to make the LCFS's LCLE provisions work for all low carbon intensity refineries in California, but decided against various compromise proposals presented, including proposals to limit the benefit any single LCLE refiner could receive in an attempt to deal with staff's concerns for "regulatory creep" and "breaking the Bank"

In closing, I strongly urge the Board to direct staff to revisit this issue at the earliest opportunity. Should you have any questions or concerns, please contact me or my Chief of Staff, Yolanda Sandoval, at (916) 319-2032.

LCFS FF46-1

Sincerely,

Rudy Salas

**Re: Low Carbon Fuel Standard 2015 – Comment Period 15-1.
Marin Clean Energy's Comments on Proposed 15-Day Regulation Order for the Re-Adoption of the Low Carbon Fuel Standard**

I. Introduction

Marin Clean Energy ("MCE"), a joint powers agency which administers California's first operating Community Choice Aggregator ("CCA") program began serving retail generation customers on May 7, 2010. Since that time, MCE has significantly expanded with current membership including: City of Belvedere, City of Benicia, Town of Corte Madera, City of El Cerrito, Town of Fairfax, City of Larkspur, City of Mill Valley, County of Marin, County of Napa, City of Novato, City of Richmond, Town of Ross, Town of San Anselmo, City of San Pablo, City of San Rafael, City of Sausalito, Town of Tiburon. MCE now serves approximately 170,000 customer accounts. MCE's mission "is to address climate change by reducing energy related greenhouse gas emissions and securing energy supply, price stability, energy efficiency and local economic and workforce benefits."[1]

Electricity customers within these member communities are presently able to choose between four retail generation service options, including: 1) MCE Light Green service, which includes a minimum 50 percent renewable energy supply; 2) MCE Deep Green service, a voluntary service election which provides participating customers with 100 percent renewable energy supply; 3) MCE Local Sol, another voluntary service election which will provide participating customers with 100 percent locally produced photovoltaic solar electricity, beginning in late 2015; and 4) generation service provided by Pacific Gas & Electric Company ("PG&E"), the incumbent Investor-Owned Utility ("IOU"). The availability of these choices is fundamental to MCE's business model, as well as the CCA service model generally, providing residential and business customers within MCE's member communities with a variety of electric service options that are responsive to a broad range of customer preferences and priorities. Furthermore,

[1] *See* MCE's website: http://www.mcecleanenergy.org/about-us/.

customers may readily choose to move from MCE to PG&E service, "opting-out" of the CCA program, subject to applicable terms and conditions.

II. Background

MCE approximates it serves somewhere between 2,000 and 6,050 Electric Vehicles ("EVs") within its service territory based upon publically available county-level Clean Vehicle Rebate Program ("CVRP") data.[2] MCE is also actively collaborating with the local municipal governments and transportation planning authorities within its service territory to site and install publically accessible Electric Vehicle Service Equipment ("EVSE"). For these reasons MCE is very interested in engaging in the LCFS to leverage LCFS credit revenues to accelerate the adoption and usage of electricity-fueled vehicles. LCFS FF47-1

Additionally, two of MCE's communities, the Cities of Richmond and Benicia, have operational refineries located within them. MCE is actively pursuing opportunities to work with these refineries to reduce their greenhouse gas emissions through facilitating consumption of renewable electricity. For example MCE is leasing a brownfield site located at Chevron's Richmond facility and is in the process of building a 10.5 MW ground mounted solar photovoltaic array on this land.[3] This installation will leverage local labor, provide hands-on experience for new green job trainees from RichmondBUILD, and provide the community with local renewable energy for the next decade, at least. For these reasons, MCE supports the Air Resource Board's attempts to broaden the means through which oil refineries can reduce their greenhouse gas emissions through both *innovative fuel production methods* and *refinery investment credits.* LCFS FF47-2

III. CCAs Should Be Permitted to Serve as Regulated Parties for Electricity Within the LCFS

MCE believes the Air Resources Board ("CARB") should expand the eligibility requirements within the LCFS to allow CCAs to elect to serve as Regulated Parties for LCFS credit generation tied to electricity usage due to transportation within CCA service territories. Respectfully, it is MCE's opinion that the present LCFS regulation errs by associating the LCFS electricity credit generation process with the delivery functionality of utilities, rather than the generation and retail service functionalities of Load Serving Entities, including CCAs and IOUs. After all, the LCFS credit generation due to electricity consumption as a transportation fuel, is inherently linked to how that electricity is generated, *not* how that electricity is delivered to the customers. Put another way, it is a Load Serving Entity's retail electricity services – not the Electric Distribution Utility's distribution services – that have influence over the Carbon Intensity of the electricity. CCAs enable communities to source cleaner electricity to serve their usage needs, and the LCFS should recognize and reward these communities not only for using electricity to fuel transportation, but also for seeking out the cleanest electricity possible to serve as transportation fuel. The most direct way to allow this would be to enable CCAs to elect to participate as Regulated Parties under the LCFS regulation. LCFS FF47-3

Furthermore, because CCAs are local government entities governed by the same elected officials that serve on the boards for local government land use planning agencies, local and regional transit planning agencies, transportation planning agencies, and air quality management agencies, CCAs are inherently far more connected with the sphere of local government entities that are instrumental to effectively and efficiently promoting electric vehicle adoption and usage, as well as vendor agnostic charging infrastructure deployment, within their communites. Additionally, CCAs are already trusted and authorized by the legislature to administer ratepayer collected funds through Energy Efficiency programs. LCFS FF47-4

[2] *See* http://energycenter.org/clean-vehicle-rebate-project/rebate-statistics.
[3] *See* MCE Solar One at Richmond Brownfield: 10.5 MW: http://www.mcecleanenergy.org/local-projects/.

CCAs are the trusted local authority on electricity matters within their communities and are therefore better suited to effectively and efficiently administer the revenue from LCFS credit sales to directly return this value to the electric vehicle using populous. It is the intent of MCE to reinvest any LCFS revenue back into incentives for the deployment of electric vehicle charging infrastructure and electric vehicle adoption. Specific revisions to the draft regulation language that would enable CCAs to participate as Regulated Parties within the LCFS are provided in Attachment A. LCFS FF47-4 cont.

IV. MCE Supports the Creation of Additional Incentives Within the LCFS to Encourage Oil Refineries and Producers to Reduce Their Fuel and Facility Greenhouse Gas Emissions

As described above, CCAs are able to provide both refiners and the communities in which refineries are located with access to clean, renewable electricity generation. Furthermore, through collaborations like MCE's Solar One facility that is being built on degraded refinery land, CCAs are able to create new local green job and economic opportunities within historically disadvantaged communities through encouraging and facilitating the development of local renewable generation. As part of the Re-Adoption of the LCFS, the CARB has provided two new mechanisms through which oil refineries and producers can leverage on-site renewable generation to either reduce or meet their compliance obligations under the LCFS regulation: 1) § 95489(d) *Credits for Producing Crudes using Innovative Methods*; and 2) § 95489(f) *Refinery Investment Credit Pilot Program*. MCE is supportive of these new incentive mechanisms because MCE believes these incentives will result in further opportunities for collaborative efforts between CCAs and refineries within communities served by CCAs to significantly reduce greenhouse gas emissions and improve local economies. LCFS FF47-5

With that said, MCE believes there is still need to provide additional clarity regarding how these incentive mechanisms would interact with other state policies that address renewable development and climate change. In particular MCE wishes to better understand how Renewable Energy Credits ("RECs") would factor into on-site renewable generation used to by a refinery to participate in either of these two credit mechanisms under the LCFS. Based on its cursory review, it appears that the *Credits for Producing Crudes using Innovative Methods* would be sensitive to the renewable attributes associated with the on-site generation through the f_{renew} factor.[4] <u>CARB should clarify whether RECs associated with on-site generation under the *Credits for Producing Crudes using Innovative Methods*, would retain the California RPS PCC1 designation and count toward RPS compliance.</u> LCFS FF47-6

Alternatively, the *Refinery Investment Credit Pilot Program* appears to only be sensitive as to whether the electricity consumed by the refinery is imported or exported from the grid, as expressed in the *electricity* factor.[5] On-site generation could reduce a refinery's need to import electricity, while also presenting increased opportunities to export more electricity back onto the grid. Whether this on-site generation is coming from a greenhouse gas-emitting or greenhouse gas-free generation resource appears to not be considered within the calculations of this methodology. <u>CARB should also clarify whether RECs associated with on-site generation under the *Refinery Investment Credit Pilot Program*, would retain the California RPS PCC1 designation and count toward RPS compliance.</u> LCFS FF47-7

.

[5] *See* LCFS Regulation at 95489(f)(2)(A).

V. Conclusions and Recommendations of MCE.

MCE appreciates the opportunity to provide its comments on the Proposed 15-Day Regulation Order for the Re-Adoption of the Low Carbon Fuel Standard and urges the Air Resources Board to recognize and empower CCAs to facilitate greenhouse gas reductions under the LCFS program. LCFS FF47-8

Appendix A:
Revisions to LCFS Regulation

All edits marked in red text.
Additions noted by underlined text. Omissions noted by ~~crossed-through~~ text.

§ 95481. Definitions and Acronyms.

(29) "Retail Electricity Provider ~~Electrical Distribution Utility~~ (REP)" means an entity that provides retail electricity services to ratepayers ~~that owns or operates an electrical distribution system~~, including:

(A) a public utility as defined in the Public Utilities Code section 216 (referred to as an Investor Owned Utility, or IOU); or

(B) a local publicly-owned electric utility (POU) as defined in Public Utilities Code section 224.3; or

(C) an Electrical Cooperative (COOP) as defined in Public Utilities Code section 2776~~.~~; or

(D) a Community Choice Aggregator (CCA) as defined in Public Utilities Code section 366.2.

* * * * *

§ 95483. Regulated Parties.

(e) *Regulated Parties for Electricity.* For electricity used as transportation fuel, the party who is eligible to generate credits is determined as specified below:

(1) For all instances where electricity is utilized as a transportation fuel with the shared service territory of both a Community Choice Aggregator and an Investor Owned Utility, the CCA has priority over the IOU to opt in and serve as the Regulated Party for the electricity used as transportation fuel within its service territory.

(A) Upon submittal to and approval by the Executive Officer of the CCA's written acknowledgment that it will not opt in and generate credits as the Regulated Party for electricity used as transportation fuel within its service territory, the IOU may elect to serve as the Regulated Party for this load;

(B) If a CCA opts in to serve as the Regulated Party for electricity used as transportation fuel within its service territory, and the IOU has previously opted in to serve as the Regulated Party for this same electricity load, then at the start of the next annual reporting cycle the responsibility of reporting on this electricity load will shift to the CCA and the IOU will no longer serve as the Regulated Party on behalf of this load; and

(C) If a CCA that initially opted in to serve as the Regulated Party for electricity used as transportation fuel within its service territory, for whatever reasons, subsequently opts out of serving as the Regulated Party for this load by submitting to and being approved by the Executive Officer of the CCA's written acknowledgment that it will not no longer opt in and generate credits as the Regulated Party for electricity used as transportation fuel within its service territory, then the IOU may elect to serve as the Regulated Party for this load.

(2)~~(1)~~ For on-road transportation fuel supplied through electric vehicle (EV) charging in a single- or multi-family residence, the Retail Electricity Provider ~~Electrical Distribution Utility~~ is eligible to generate credits in its service territory. To receive such credits, the Retail Electricity Provider ~~Electrical Distribution Utility~~ must:

(A) Use all credit proceeds to benefit current or future EV customers;

(B) Educate the public on the benefits of EV transportation (including environmental benefits and costs of EV charging, or total cost of ownership, as compared to gasoline

(C) Provide rate options that encourage off-peak charging and minimize adverse impacts to the electrical grid; and

(D) Include in annual compliance reporting the following supplemental information: an itemized summary of efforts to meet requirements (A) through (C) above and costs associated with meeting the requirements. For investor owned utilities, this requirement may be satisfied by supplying a copy of the annual implementation report required under Order 4 of Public Utilities Commission of California (PUC) Decision 14-12-083, or any successor PUC Decisions.

(3)~~(2)~~ For on-road transportation fuel supplied through public access EV charging, the Retail Electricity Provider ~~Electrical Distribution Utility~~ is eligible to generate credits in its service territory. Upon submittal to and approval by the Executive Officer of its written request to opt in and generate the credits under this provision, the third-party non-utility Electric Vehicle Service Provider (EVSP) that has installed the equipment, or had an agent install the equipment, and who has a contract with the property owner or lessee where the equipment is located to maintain or otherwise service the charging equipment, is eligible to generate the credits for the electricity. To receive credit for transportation fuel supplied through public access EV charging equipment, the EVSP or Retail Electricity Provider ~~Electrical Distribution Utility~~ must meet the requirements set forth in section 95483(e)(1)(B) through (D).

(4)~~(3)~~ EV Fleets

(A) For on-road transportation fuel supplied to a fleet of EVs, the Retail Electricity Provider ~~Electrical Distribution Utility~~ is eligible to generate credits in its service territory, and must meet the requirements set forth in section 95483(e)(1)(B) through (D). Upon submittal to and approval by the Executive Officer of the fleet operator's written request to opt in and generate credits associated with a specified fleet, the fleet operator is eligible to generate the credits for the electricity. To receive credit for transportation fuel supplied to an EV fleet, an accounting of the number of

EVs in the fleet must be included as supplemental information in annual compliance reporting.

(B) For on-road transportation fuel supplied through the use of a battery switch station, the Retail Electricity Provider ~~Electrical Distribution Utility~~ is eligible to generate credits in its service territory, and must meet the requirements set forth in section 95483(e)(1)(B) through (D). Upon submittal to and approval by the Executive Officer of the station owner's written request to opt in and generate credits associated with a specific location or locations, the station owner is eligible to generate the credits for the electricity.

(5)~~(4)~~ For on-road transportation fuel supplied through private access EV charging equipment at a business or workplace, the Retail Electricity Provider ~~Electrical Distribution Utility~~ is eligible to generate credits in its service territory, and must meet the requirements set forth in section 95483(e)(1)(B) through (D). Upon submittal to and approval by the Executive Officer of the site host's written request to opt in and generate credits associated with a specific location or locations, the site host is eligible to generate the credits for the electricity. To receive credit for transportation fuel supplied through private access EV charging equipment at a business or workplace, the following requirements apply to a site host that opts in:

(A) Educate employees on the benefits of EV transportation (including environmental benefits and costs of EV charging, or total cost of ownership, as compared to gasoline) through outreach efforts directed to all employees, such as meetings, flyers, and preferred parking; and

(B) Include in annual compliance reporting the following supplemental information: a summary of efforts to meet the requirement in 95483(e)(4)(A), above, and an accounting of the number of EVs known to be charging at the business.

(6)~~(5)~~ In the event that there is measured on-road electricity as a transportation fuel that is not covered in subsections 95483(e)(2)~~(1)~~ through (5)~~(4)~~ above, the Retail Electricity Provider ~~Electrical Distribution Utility~~ is eligible to generate credits for the electricity with Executive Officer approval, and must meet the requirements set forth in section 95483(e)(2)~~(1)~~(B) through (D).

(7)~~(6)~~ For transportation fuel supplied to a fixed guideway system, the transit agency operating the system is eligible to generate credits for electricity used to propel the system. Upon submittal to and approval by the Executive Officer of the transit agency's written acknowledgment that it will not opt in and generate credits under this provision, the Retail Electricity Provider ~~Electrical Distribution Utility~~ is eligible to generate the credits for the electricity, and must meet the requirements set forth in section 95483(e)(2)~~(1)~~(B) through (D).

(8)~~(7)~~ For transportation fuel supplied to electric forklifts, the Retail Electricity Provider ~~Electrical Distribution Utility~~ is eligible to generate credits for the electricity, and must meet the requirements set forth in section 95483(e)(2)~~(1)~~(B) through (D).

* * * * *

Additional Universal Edits to LCFS Regulations

All additional references to “Electrical Distribution Utility” or “EDU” throughout the LCFS regulations should be replaced with reference to “Retail Electricity Provider” or “REP” as demonstrated above in sections 95483(e)(2) through (7).

47_FF_LCFS_CE

1121. Comment: **LCFS FF47-1**

The commenter states that it is very interested in engaging in the LCFS to leverage LCFS credit revenues to accelerate the adoption and usage of electricity-fueled vehicles.

Agency Response: Staff acknowledges Marin Clean Energy (MCE)'s interests in participating in the LCFS program.

1122. Comment: **LCFS FF47-2**

MCE supports the Air Resource Board's attempts to broaden the means through which oil refineries can reduce their greenhouse gas emissions through both innovative fuel production methods and refinery investment credits.

Agency Response: ARB staff appreciates the support for the refinery investment and the innovative crude oil provisions.

1123. Comment: **LCFS FF47-3**

The commenter states that ARB should allow Community Choice Aggregator (CCA) to serve as a regulated party for electricity under LCFS.

Agency Response: This comment is beyond the scope of the 15-day changes and, therefore, requires no further response. No CCA has previously suggested inclusion or requested the ability to participate as a regulated party under the LCFS. The level of interest is unknown (apart, perhaps, from the commenter's). To date ARB has not had occasion to explore the interplay between CCAs, public utilities, investor-owned utilities, and the regulatory contexts in which they operate in connection with possible LCFS participation. Absent thorough consideration and public debate, ARB will not amend the LCFS at this time to include CCAs. ARB is open to learning more and evaluating possible roles for CCAs in the future. ARB appreciates the commenter's interest in the LCFS.

1124. Comment: **LCFS FF47-4**

The commenter states that ARB should allow Community Choice Aggregator (CCA) to serve as a regulated party for electricity under LCFS.

Agency Response: See response to **LCFS FF47-3**.

1125. Comment: **LCFS FF47-5**

MCE is supportive because these incentives will result in further opportunities for collaborative efforts between CCAs and refineries within communities served by CCAs to significantly reduce greenhouse gas emissions and improve local economies.

Agency Response: ARB staff appreciates the support for the refinery investment provision. See also response to **LCFS FF47-3**.

1126. Comment: **LCFS FF47-6**

The commenter asks ARB to clarify whether RECs associated with on-site generation under the *Credits for Producing Crudes using Innovative Methods*, would retain the California RPS PCC1 designation and count toward RPS compliance.

Agency Response: These details of the RPS program are not covered under ARB's purview. As a result, ARB staff cannot comment on how on-site generation under the Innovative Crude Provision would affect California RPS PCC1 designation or RPS compliance.

1127. Comment: **LCFS FF47-7**

The commenter suggests ARB should clarify whether RECs associated with on-site generation under the Refinery Investment Credit Pilot Program, would retain the California RPS PCC1 designation and count toward RPS compliance.

Agency Response: See the response to **LCFS FF47-6**.

RE: LCFS Re-adoption

Dear Mary Nichols & Staff:

My question concerns the proposed regulation in 95488(d)(2) regarding provisional pathways and the restriction to sell or transfer credits generated under provisional pathways. It appears that the provisional pathway would now include Tier I pathways with innovative fuel technologies. We are evaluating options that would potentially allow us to produce ethanol at our existing facilities with an innovative fuel technology. If a facility has been in full commercial production for over two years but recently deploys an innovative technology to lower the carbon intensity of the fuel, will this facility receive a provisional pathway and also be subject to the restrictions for two years? If so, my concern is the marketability of fuel into California without being able to transfer the associated CI as well as the timing gap to realize any return on investment that is necessary to support investment in innovative technologies.

LCFS FF48-1

LCFS FF48-2

Please feel free to contact me to clarify the provisions or to discuss further. We want to work with ARB to ensure we are helping ARB to continue to improve and strengthen the LCFS program to not only help the state meet its increasing GHG targets, but also to provide a lower carbon intensity product for our customers.

Thank you for the opportunity to comment and provide feedback.

Sincerely,

Carol Tjiong

48_FF_LCFS_WE

1128. Comment: **LCFS FF48-1**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

1129. Comment: **LCFS FF48-2**

The commenter is questioning whether an existing facility/pathway could make a change that would result in the facility or pathway entering a new phase of commercial operation and being required to be in operation for two years.

Agency Response: An existing facility in commercial operation adopting an innovative technology will be eligible to apply for a new pathway for their facility and receive a new provisional CI after a quarter of operating the new technology. They must then provide the two years of data on a quarterly basis to substantiate their new fuel pathway. In the first quarter of operating the new technology they may continue to use their existing CI or, at their option, one of the temporary fuel pathway codes from Table 7 of the regulation.

VIA ELECTRONIC POSTING
Comment List: lcfs2015

Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento CA, 95814

Dear Chairman Nichols and Board Members:

Kern Oil & Refining Co. (Kern) is providing comments on the California Air Resources Board's (ARB) Proposed 15-Day Regulation Order (15-day Package) of the Low Carbon Fuel Standard (LCFS). Specifically, Kern is providing comments on the following: (1) Low-Complexity/Low-Energy Use (LC/LU) Refinery Adjustment Calculations; (2) Assignment of Default Crude Carbon Intensity within the Refinery-specific Incremental Deficit Option; (3) Inclusion of a De Minimum Threshold for Assessing Incremental Deficits; (4) Limits on the Use of Refinery Investment Credits; and (5) Changes to the Pathway Approval Process.

Kern is an independently owned, small refinery located in the Southern San Joaquin Valley, just outside Bakersfield, California. At a crude oil capacity of 26,000 barrels per day, Kern is literally the smallest refinery currently producing transportation fuels in California. In its comment letter dated February 17, 2015, Kern previously called attention to the potential detrimental impacts to certain refineries that result from methodologies adopted to effectuate program goals in a manageable manner for CARB. Kern gave recognition to the Board and Staff for not only acknowledging these circumstances and functional differences, but for taking action and incorporating provisions that recognize and mitigate the inequalities inherent in the broader LCFS "average refinery" implementation methodologies. Kern echoes that appreciation here, as ARB's continued support for these issues is evidenced within the 15-day Package.

Simplification of Low-Complexity/Low-Energy Use (LC/LU) Refinery Adjustment Calculation

LCFS FF49-1

Kern reiterates its strong support of ARB's inclusion of a provision issuing a carbon intensity adjustment for Low-Complexity/Low-Energy Use (LC/LU) refineries in recognition of the inherent lower carbon intensities (CI) of transportation fuels produced at these facilities. The credit helps address the unfair subsidization of higher than average energy-use refiners that results from the current regulation's reliance upon the "average refinery" in determining CI values for finished transportation fuels. Kern greatly appreciates the extensive work performed by CARB staff in calculating the demonstrable lower CI of the transportation fuels produced by LC/LU refineries, which serves as the strong scientific and technical basis for the credit consideration being given to those refineries.

Staff is proposing to credit the LC/LU refineries 5 gCO2e/MJ for CARBOB and diesel. The 15-day Package contains revisions to the calculations for quantifying the number of LC/LU refinery credits generated in a compliance year. Kern appreciates the added clarity and agrees with Staff's presentation that these revisions simplify the equations. Kern strongly supports the credit proposal and is grateful to staff for the years of work, analysis and stakeholder collaboration that have ultimately culminated in the current proposal.

Assignment of Default Crude CI within the Refinery-specific Incremental Deficit Option

Kern continues to be encouraged by ARB's acknowledgement that low volume refineries are disadvantaged by the current California Average Approach, in that they can be affected by the incremental deficit but cannot affect the sector-wide annual crude average CI. ARB is proposing a one-time opportunity for Low-Complexity/Low-Energy Use (LC/LU) refineries to opt out of the California Average Approach, and instead have their incremental deficits determined through a comparison of the facility's annual average crude CI and its 2010 baseline crude CI. Kern previously commented on the application of a default CI for crude oils that do not have a specific CI assigned in the regulation, noting that the use of the California average CI would have unnecessarily limited, or even prevented, LC/LU refineries from running new crude oils without incurring incremental deficits.

LCFS FF49-2

Kern appreciates Staff's consideration of comments made in Kern's February 17, 2015 letter. The 15-day Package includes revisions to use the individual LC/LU refinery baseline crude average CI as a default CI value for new crude oils until such time the specific CI value is added to the LCFS. This replaces the use of the California average crude CI as a default value which would have disadvantaged LC/LU refineries utilizing the option for individual compliance. Likewise, the 15-day Package incorporates the use of a three-year rolling average approach within the Refinery-specific Incremental Deficit Option, similar to the three-year rolling phase-in approach proposed in the California Average Approach for transitioning from the 2010 Crude CI Lookup Table to the 2012 Crude CI Lookup Table. Kern supports both of these proposed revisions.

Inclusion of a De Minimus Threshold for Assessing Incremental Deficits

LCFS FF49-3

Staff is proposing to include a de minimus value of 0.1 gCO2e/MJ as a minimum threshold prior to assessing incremental deficits resulting from increases to the crude oil CI three-year rolling average. The de minimus threshold would apply to all refineries, regardless of their decision to comply through the California Average Approach or the Refinery-specific Incremental Deficit option. Kern and other refiners have voiced concern for this issue throughout the rulemaking process. Kern is pleased to see this addition to the proposed regulation and supports the revision.

Limits on the Use of Refinery Investment Credits

Kern's previous comment letter expressed cautious optimism for ARB's proposal to reward refiners for projects resulting in demonstrable emission reductions at a stationary source facility by means of incorporating a Refinery Investment Credit provision within the LCFS. Specifically, Kern noted its understanding that Staff's intention is to allow for a project to be implemented in multiple phases over an approved period of time in order to achieve the threshold 0.1 gCO2e/MJ. Kern echoes its previous recommendation that additional language be added to the proposed regulatory text to clarify Staff's intent. As a small refinery, Kern has limited resources and must utilize its efforts, resources and investments with a high degree of efficiency. Allowing flexibility on the timing of a project is critical because it is not always financially feasible to carry out a substantial project all at once.

LCFS FF49-4

Staff has presented revisions within the 15-day Package that refers to the Refinery Investment Credit as a "Pilot Provision" and further has introduced language that will limit the use of credits generated from the provision to satisfaction of no more than 20% of a refinery's annual compliance obligation. Kern recognizes Staff's intent to avoid any unanticipated impacts to the credit market; however, Kern does not support the limited use of the credits, as proposed. Neither the regulatory text nor discussion within the 15-day Package address what is meant by "Pilot Program," what duration such a pilot testing is intended to span, or at what point the limitation expires and the credits then be available for unrestricted use. Similarly, the 15-day Package expresses Staff's concern that the volumes of these credits could outstrip the current expectations; however, there is no discussion of what these current expectations are and at what volumes this concern would actually be realized. Kern believes Staff should provide stakeholders with additional justification for this limitation.

Changes to the Pathway Approval Process

LCFS FF49-5

Staff is proposing revisions within the pathway application process, specifically the certification step of section 95488(c)(5), that would eliminate a 60-day limit within which the Executive Officer would be required to advise an applicant of whether their fuel pathway application is complete or incomplete. Rather, the current proposal leaves this duration open-ended, under the premise that numerous pathways will require recertification within a one-year period and that Staff could be faced with unrealistic deadlines. Coupled with the elimination of the 60-day limit, Staff is proposing to process fuel pathway applications in batches, where like fuels are grouped together for the purpose of review and approval.

Kern certainly appreciates the magnitude of work that will be faced in recertifying the hundreds of pathways and the need to prioritize that work appropriately. The proposal to review and approve pathway applications in batches of like-kind fuels should indeed add a necessary degree of efficiency to the process. However, Kern disagrees that leaving undefined the length of time ARB is granted in notifying an applicant of whether the application package is complete would add any further efficiency to the process. From the applicant's perspective, the effect of this revision is to the contrary; for applicants, this revision would add inefficiency by imposing unnecessary delay in compiling what information and/or data would complete the process. It seems reasonable that ARB would want to have a batch of applications for review and approval, already knowing that each application within the batch is complete. Kern urges Staff to revisit this proposed revision and incorporate a reasonable amount of time for deeming an application complete – one that is serving of both the agency and the applicant's needs.

In conclusion, Kern appreciates ARB's consideration of Kern's comments. As always, Kern is committed to working with Staff throughout this regulatory process.

Sincerely,

Melinda L. Hicks
Manager, Environmental Health and Safety

1130. Comment: **LCFS FF49-1**

The 15-day Package contains revisions to the calculations for quantifying the number of LC/LE refinery credits generated in a compliance year. Kern appreciates the added clarity and agrees with Staff s presentation that these revisions simplify the equations. Kern strongly supports the credit proposal and is grateful to staff for the years of work, analysis and stakeholder collaboration that have ultimately culminated in the current proposal.

Agency Response: ARB staff appreciates the support for the LC/LE provision.

1131. Comment: **LCFS FF49-2**

The commenter expresses support for the revised default crude oil Cis for the refinery-specific incremental deficit option.

Agency Response: ARB staff appreciates the support for the change made to the default CI under the LC/LEU refinery-specific incremental deficit option.

Staff would like to note, however, that the proposed 15-day changes for the refinery-specific option do not include a “three-year rolling phase in…for transitioning from the 2010 Crude CI Lookup Table to the 2012 Crude CI Lookup Table” as mentioned by the commenter.

1132. Comment: **LCFS FF49-3**

The commenter expresses support for the inclusion of a de minimus threshold for assessing incremental deficits.

Agency Response: ARB staff appreciates the support for the inclusion of a de minimus threshold for assessing incremental deficits.

1133. Comment: **LCFS FF49-4**

The commenter notes its understanding that staff’s intention is to allow for a project to be implemented in multiple phases over an approved period of time in order to achieve the threshold 0.1 $gC0_2e/MJ$. The commenter echoes their previous recommendation that additional language be added to the proposed regulatory text to clarify staff’s intent.

The commenter does not support the limited use of the credits, as proposed. Neither the regulatory text nor discussion within the 15-day Package address what is meant by "Pilot Program," what duration such a pilot testing is intended to span, or at what point the limitation expires and the credits then be available for unrestricted use. Kern believes staff should provide stakeholders with additional justification for this limitation.

Agency Response: ARB staff does not agree that additional language is necessary to address the concerns expressed by Kern. A refinery applying for a Refinery Investment Credit may define the length and scope of the project as appropriate in its application for the Refinery Investment Credit. However, the project cannot generate credits until it meets the 0.1 gCO_2e/MJ threshold from the comparison baseline.

See response to comment **LCFS FF43-8** and **LCFS FF43-50** in regards to the “Pilot Program” portion of the comment.

1134. Comment: **LCFS FF49-5**

This comment is related to the removal of the 60 calendar day period, under § 95488(c)(5) for the Executive Officer to notify the applicant if their fuel pathway application is complete.

Agency Response: Please see response to comment **LCFS FF35-7**.

Biotechnology Industry Organization
Comments to the California Air Resources Board

On the Notice of Public Availability of Modified Text and Availability of Additional Documents and Information for the Proposed Re-adoption of the Low Carbon Fuel Standard
June 19, 2015

The Biotechnology Industry Organization (BIO) appreciates the opportunity to submit comments on the modified text and additional documents and information for the proposed re-adoption of the Low Carbon Fuel Standard (LCFS).

BIO is the world's largest trade association representing biotechnology companies, academic institutions, state biotechnology centers and related organizations across the United States and in more than 30 other nations. BIO members are involved in the research and development of innovative healthcare, agricultural, industrial and environmental biotechnology products. BIO represents nearly 90 companies leading the development of new technologies for producing conventional and advanced biofuels that could be used in the California market. Through the application of industrial biotechnology, BIO members are improving conventional biofuel processes, enabling advanced and cellulosic biofuel production technologies and speeding development of new purpose grown energy crops.

BIO and its members support California's efforts to reduce the carbon intensity of transportation fuels through the LCFS regulation. Unfortunately, the proposed modifications to provisional pathways in sections 95488 (c) (3) and (c) (4) (1) (2) would create a serious barrier to entry for any new advanced biofuel coming to market. Indeed, these modifications would be an undue burden on the very fuels that California seeks to incentivize.

LCFS FF50-1

As CARB states on p. 53 in the provisional pathways section 95488, "*applicants are required to have been in full commercial production for at least one full calendar quarter before applying for a new pathway*".

BIO believes that requiring months of commercial production status just to apply for a new pathway seriously disadvantages new fuels and disincentivizes refiners from incorporating new feedstocks into their blending mix for a multitude of reasons, for example, the undue administrative burden placed on the refiner to test and qualify a new feedstock. Further, biofuel refiners use an array of feedstocks – from soy oil, cooking oil, tallow, etc. They also blend feedstock to produce biodiesel and renewable diesel. The way that feedstocks are processed at a facility in the span of three months would make it almost impossible to provide consistent data for a new feedstock in that timeframe. Moreover, the pre-qualification would significantly delay the timeframe to monetize credits --- it can take an operation one year before its pathway is secured from ARB --- and with the provisional credit proposal, there would be an even longer delay.

LCFS FF50-2

As CARB states on p. 54 in the provisional pathways section 95488, "*the applicant is provided only "provisional" credits and may not sell credits for 2 years"*.

BIO strongly urges CARB to allow credit trading for provisional pathway approvals as soon as provisional status is granted. CARB's current proposal would be extremely harmful to new entrants in the market since it would deny monetization of credits for two years. Without the ability to monetize, the economic incentive to sell new advanced biofuels in California is basically gone. In addition to the devastating economic impacts, new feedstock providers who partner with numerous refiners have to start the two year clock anew with each refining partner, which would create a proliferation of pathways for ARB to review.

LCFS FF50-3

To conclude, we strongly urge the Air Resources Board to reformulate the pathways section in a way that encourages new feedstocks and fuels to commercialize and contribute to a low carbon economy. If additional verification of carbon intensity data is needed, is it possible to set a requirement to submit operational data after two years and make the carbon intensity adjustment

LCFS FF50-4

at that point? Please do not hesitate to contact BIO for any additional data or information that may help to further the success of the LCFS. Thank you.

This page intentionally left blank.

50_FF_LCFS_BIO

1135. Comment: **LCFS FF50-1**

The commenter states that the proposed modifications to provisional pathways in sections 95488 (c) (3) and (c) (4) (1) (2) would create a serious barrier to entry for any new advanced biofuel coming to market. Indeed, these modifications would be an undue burden on the very fuels that California seeks to incentivize.

Agency Response: See responses to **LCFS FF31-1** and **LCFS FF56-2**.

1136. Comment: **LCFS FF50-2**

The comment is related to provisional pathways being able to generate credits as soon as commercial production begins, the quarter the provisional pathway is approved, and the prior quarter.

Agency Response: See responses to **LCFS FF31-1** and **LCFS FF56-2**.

1137. Comment: **LCFS FF50-3**

These comments are related to provisional pathways not being able to generate or sell LCFS credits during the two-year provisional period required under the first 15-day changes.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

1138. Comment: **LCFS FF50-4**

This commenter proposes that the requirement for pathways entering commercial production not be required to submit quarterly data.

Agency Response: Staff must review quarterly data during a provisional pathway period that is by definition from a facility that has not been in long-term commercial production. Many innovative fuel pathways that enter commercial production have data based upon demonstration facilities, pilot facilities or on modeling that perform differently at full production scale. In order to ensure that the new fuel pathway producing fuel in a new facility achieves the carbon intensity claimed the quarterly reporting is required. Staff will work with stakeholders at workshops after Board Hearing to consider these topics and ways to make these requirements less burdensome, but will likely be on a case-by-case basis. Staff will also work with stakeholders to develop guidance documents to help ease applicants through this process.

Mr. Sam Wade
Transportation Fuels Branch
California Air Resources Board
1001 I Street
Sacramento, CA
95814

Subject: LCFS 15 Day Changes

Dear Mr. Wade

On behalf of the undersigned organizations, we are writing to express our strong support for the re-adoption of the Low Carbon Fuel Standard in July, 2015 by the California Air Resources Board. We view the LCFS as critical to attaining California's health-protective climate and clean air goals, as well as supporting innovative California businesses and workers helping to bring more clean, low-carbon transportation solutions to market.

According to the American Lung Association's *State of the Air* 2015 report, California is home to the five most polluted American cities by unhealthy ozone and particle pollution days, and the seven cities most polluted by annual levels of particle pollution. Over 80 percent of smog-forming NOx emissions are associated with the manufacture, transportation and combustion of petroleum fuels. Petroleum is also responsible for nearly half of California's greenhouse gas pollution. The health burdens posed by unhealthy fuels can affect all residents, but especially those communities living near refineries and other major pollution sources. The LCFS provides an opportunity to reduce the overall impact of air pollution in California by encouraging cleaner investments by the fuels industry, including switching from high carbon, harmful fuels and inputs to healthier, lower carbon alternatives like electricity, hydrogen and advanced renewable, as well as incentivizing clean-up of existing petroleum refineries.

Our comments below focus on the 15 Day Change Package released on June 4, 2015:

Extending the use of Hydrogen in addition to the lift truck proposal: We support the inclusion of the hydrogen lift truck provision and encourage ARB to continue to explore opportunities to expand the market and opportunities to deploy electric-drive technologies, including those powered by low-carbon, renewable hydrogen fuel, within the context of the LCFS. The proposal to clarify the pathway for hydrogen forklifts is an appropriate provision for inclusion in the program to reduce reliance on higher-carbon fuels. In addition, we encourage ARB to ensure the program allows for reporting of hydrogen fuel use in other possible off-road applications (e.g., airport tugs, etc.) and for on-road applications in fuel cell transit buses or other light- medium- and heavy- duty fuel cell vehicle platforms. Like the proposed EER values for Heavy-Duty electricity-fueled vehicle platforms, the program should allow similar applications for fuel cell transit buses and other fuel cell vehicle platforms in the medium- and heavy- duty applications category. In extending provisions for the use of hydrogen as a transportation fuel we would ask CARB to further encourage the use of renewable hydrogen. LCFS FF51-1

Refinery Investment Credit Pilot Program: Our organizations support the intent of this provision, which is to encourage adoption of cleaner, lower carbon-intensity technologies at refineries that can reduce emissions of greenhouse gases, criteria air pollutants and toxic air contaminants that disproportionately impact residents living near refineries. We also agree with other stakeholders that the program can also encourage refinery investments that promote jobs. LCFS FF51-2

We believe that the structure of the application and public review process is appropriate in that refiners would be required to document any changes in criteria air pollutants or air toxics and that the applications for credits would be open to public review and comment. As the provision is implemented over the coming years, we encourage ARB to:

- Prioritize the evaluation of project applications that provide the greatest reductions in greenhouse gas, criteria air pollutants and toxic air contaminants on-site at refineries.
- Ensure adequate notice and public data is given to allow communities neighboring refineries and stakeholders to evaluate and comment on proposed pathways in an open and transparent process.
- Ensure adequate staffing and resources is provided to effectively implement the provisions in a manner that enables adequate monitoring and evaluation of the applications and pathways, identifies good projects that accomplish the above goals, and prevents gaming by regulated parties such as merely “shuffling” emissions associated with processing dirtier, higher carbon feedstocks and products into the “export” category, for example. LCFS FF51-3
- Only credit actual, net reductions across the refinery facilities while avoiding crediting projects in piecemeal fashion, whereby emissions in only one processing unit of the facility decrease while other units increase emissions. In implementing the provisions, ARB should require and ask that applicants provide a broad enough system boundary and data set to capture net emission changes across the refinery operation(s).
- Increase knowledge and information about technologies and trends that can improve environmental performance of the current petroleum supply chain, as well as shed light on technologies and trends that can worsen them. For example, clean investments in improved energy efficiency at refineries may be offset over time if refineries increase overall processing energy for dirtier, heavier crudes.

Our organizations look forward to working with the Board and staff to carefully implement these, and all provisions of the LCFS, to ensure that the program achieves its goals of providing healthier, cleaner fuel choices for all Californians.

Sincerely,

Will Barrett

1139. Comment: **LCFS FF51-1**

The commenter encourages ARB to ensure the program allows for reporting of hydrogen fuel use in other possible off-road applications, in addition to fuel cell forklifts.

Agency Response: See response to **LCFS FF33-1**.

1140. Comment: **LCFS FF51-2**

The commenter expresses support for the refinery investment provision.

Agency Response: ARB staff appreciates the support for the Refinery Investment provision.

1141. Comment: **LCFS FF51-3**

The commenter supports the refinery investment provision as written. The commenter suggests that ARB prioritize project reviews, ensure public access to application, ensure adequate staffing, credit only actual reductions, and continue to increase knowledge of technologies.

Agency Response: ARB staff appreciates the support for the Refinery Investment provision. Staff will continue to work with stakeholders to evaluate

Re: Low Carbon Fuel Standard Program Amendments for Regulated Parties for Suppliers of Electricity Used as a Fuel Substitute.

Dear Madam or Sir:

NRG EVgo ("EVgo") appreciates the opportunity to review and comment on the referenced amendments to the Low Carbon Fuel Standard Program as they affect suppliers of electricity used as a fuel supplement.

EVgo is a leading Electric Vehicle Services Provider ("EVSP") in the state of California seeking to grow the market for the future of California's EV drivers and the environment. EVgo has a multi-faceted business model engaged in expanding both private and public access EV charging infrastructure throughout California. As a company heavily engaged in the development of EV charging infrastructure, we believe the LCFS credit program can be beneficial to the continued expansion of our business operations and the growth of the EV market in California. The proposed amendments restrict the ability of EVSPs to generate credits to public access charging alone, which unnecessarily constrains incentives for EVSPs in expanding charging opportunities at multifamily dwellings and workplaces. The success of the EVSP industry hinges on the viability of a complete ecosystem of EV charging products covering: home, public access, workplace, and multifamily. EVgo would like to see the California Air Resources Board maximize credit generating opportunities for EVSPs across all public and private access chargers.

LCFS FF53-1

EVgo aims to enroll in the LCFS program shortly and looks forward to working closely with the California Air Resources Board to maximize EV adoption.

Generally, EVgo objects to the elimination of the general category "electricity services supplier" as a regulated party eligible for the full suite of credit generation opportunities.

LCFS FF53-2

The policy objectives supporting the use of electricity in the LCFS should incentivize all market participants to increase electrification and reduce carbon intensity. Restricting certain categories of LCFS eligibility to Electrical Distribution Utilities creates a skewed playing field that unfairly favors utilities over private market participants such as EVSPs. LCFS FF53-2 cont.

EVgo respectfully objects to the proposed language of § 95483(e)(1) for failing to include EVSPs as an eligible regulated party at single- or multi-family residences.

Expanding EV charging into multi-family residences is a critical component of EV adoption in California. EVgo's business model includes contracting with apartment communities to provide turnkey charging services to its residents. The ability to generate credits through these relationships would provide a significant incentive to increasing deployment. Owners of multi-family residences have generally been hesitant to invest in EV infrastructure and manage the authentication, networking, maintenance and billing activities needed to serve residents. Permitting EVSPs to generate credits through the provision of private access residential charging services would encourage further development and lead to more opportunities for EV drivers to charge their vehicles during off-peak hours. LCFS FF53-3

EVgo requests that § 95483(e)(1) be amended to include verbiage similar to § 95483(e)(2) or § 95483(e)(4) (assuming "site host" would include EVSPs) such that EVSPs who have contractual relationships with property owners or managers to provide charging services are permitted to generate credits at single- and multi-family residences.

EVgo respectfully supports the proposed language of § 95483(e)(2) including EVSPs as an eligible regulated party at public access EV charging stations.

EVgo is investing heavily in public access EV charging stations across the state of California. Generating credits through the LCFS will enable us to expand our offerings and increase the pace of deployment. Additionally, the public education requirements align closely with many of EVgo's current programs and its ultimate business objectives. LCFS FF53-4

EVgo respectfully requests clarification of the term "Site Host" in § 95483(e)(4) to include EVSPs in connection with business and workplace charging.

Workplace charging is an essential component of EV adoption in California. EVgo welcomes the opportunity to generate credits as the EVSP of private access charging stations at a business or workplace. The term "site host" should be clarified to include EVSPs who have contractual relationships with a business or property owner to provide charging services. LCFS FF53-5

53_FF_LCFS_NRG

1143. Comment: **LCFS FF53-1**

The commenter encourages ARB to maximize credit generating opportunities for EVSPs across all public and private access chargers.

Agency Response: ARB staff is open to meet with stakeholders such as NRG EVgo to discuss credit generating opportunities for EVSPs for public and private access charging.

1144. Comment: **LCFS FF53-2**

The commenter objects to the elimination of the general category "electricity services supplier" as a regulated party eligible for the full suite of credit generation opportunities.

Agency Response: The term "electricity service supplier" is broad and ambiguous and therefore was not included in the final proposal. The final proposal includes specific provisions for Electric Distribution Utilities, Electric Vehicle Service Provider, and Electric Vehicle Fleet Owner, etc. This does not create a skewed playing field that disadvantages EVSPs. Please see response to **LCFS FF41-2.**

1145. Comment: **LCFS FF53-3**

The commenter objects to the proposed language of § 95483(e)(1) for failing to include EVSPs as an eligible regulated party at single- or multi-family residences.

Agency Response: The proposed 15-day changes did not change the regulated parties for single- or multi-family residences. This comment is beyond the scope of the 15-day changes and, therefore, requires no further response.

1146. Comment: **LCFS FF53-4**

The commenter supports the proposed language of § 95483(e)(2) including EVSPs as an eligible regulated party at public access EV charging stations.

Agency Response: ARB staff appreciates the support from NRG EVgo.

1147. Comment: **LCFS FF53-5**

The commenter requests clarification of the term “Site Host” in § 95483(e)(4).

Agency Response: For private access EV charging equipment, Staff’s goal continues to be to provide the LCFS credit value to the entity that made the initial investment in (or for legacy facilities the entity that currently owns) the charging infrastructure. The term “site host” was chosen to replace the term “business owner” in an attempt to improve clarity. The prior term was ambiguous (i.e., could be read to include either the property owner or the lessee for business properties) and might not always supply the credit value to the entity that made the EV infrastructure investment.

In the case where two or more parties own EV charging infrastructure components at a given location, they should contractually agree as to which party is the site host before applying to ARB for LCFS credits.

Richard W. Corey
Executive Officer
Re: Suggested modifications Low Carbon Fuel Standard regulatory language
1001 I St
Sacramento, CA 95812-2815

Dear Mr. Corey and CARB LCFS staff:

The California Fuel Cell Partnership is pleased to provide input on the suggested modifications to the LCFS regulatory language[i] for 15-day comments. We appreciate the inclusion of hydrogen as a low carbon transportation fuel for credits, including those under the Renewable Hydrogen Refinery Credit Pilot Program. The monetary value of these credits will support the sustainability of hydrogen as a renewable fuel and energy storage medium. With the proposed LCFS language revision and CPUC requiring energy storage for renewable electricity, California is sending a vital signal and builds confidence among all early market participants.

Please consider the following comments for consistency across zero emission vehicle technology platforms and enabling transportation fuels:

a. Throughout the document, include stronger encouragement and support of renewable content based hydrogen as a fuel or energy storage medium. LCFS FF54-1

b. "Electric Vehicle (EV)" (30) (p7) definition should also include Fuel Cell Electric Vehicles. LCFS FF54-2

c. Include definitions for "Fuel Cell Electric Vehicle" and "Battery Electric Vehicle" as "Plug In Hybrid Electric Vehicle" is also defined, and "FCV" and "BEV" are included as Acronyms under (b) (p14). LCFS FF54-3

d. Consider including a definition for "Renewable Hydrogen", as this is used extensively on p93ff. LCFS FF54-4

e. *Add "Hydrogen fueling" as one of the "Transaction Types", this will cover all hydrogen fuel cell vehicle applications, including hydrogen fuel cell forklift fueling (p12-13).* LCFS FF54-5

f. An EER Value for electricity in forklifts and hydrogen in fuel cell forklifts is included, as well as light duty fuel cell vehicles, but no specific EER Values for fuel cell transit buses and a variety of different fuel cell vehicle platforms in the medium- and heavy duty applications category, like the variety of EER Values in the Heavy-Duty Electricity fueled vehicle platforms (Table 4, p32). LCFS FF54-6

The California Fuel Cell Partnership is a collaboration in which several companies and government entities are independent participants. It is not a joint venture, legal partnership or unincorporated association.

g. "Hydrogen for fuel cell electric forklifts" is mentioned as an option to report for to receive transportation fuel credits (p103), but not hydrogen for fuel cell transit buses, other light- medium- and heavy duty fuel cell vehicle platforms, and off-road applications. **LCFS FF54-7**

Thank you for your leadership in helping develop a sustainable market for fuel cell electric vehicles and hydrogen as a fuel, and for the opportunity to provide comments. Please do not hesitate to contact me at (916) 371-2396 or belrick@cafcp.org if you have any questions or require clarification.

Sincerely,

Bill Elrick
Executive Director

cc: Justin Ward, CaFCP Chair

[i] As posted at: http://www.arb.ca.gov/regact/2015/lcfs2015/regorderfinal.pdf

54_FF_LCFS_FCP

1148. Comment: **LCFS FF54-1**

The commenter encourages and supports renewable content based hydrogen as a fuel or energy storage medium.

Agency Response: ARB staff acknowledges the importance of hydrogen from renewable sources and has included one fuel pathway - compressed hydrogen from on-site reforming with renewable feedstocks into the regulation. Staff commits to continue working with stakeholders to develop more fuel pathways for hydrogen from renewable sources.

1149. Comment: **LCFS FF54-2**

The commenter states that the EV definition should also include “Fuel Cell Electric Vehicles”

Agency Response: Staff acknowledges that improvements could potentially be made to enhance clarity of definitions related to advanced vehicles and fuels. Staff commits to work with stakeholders to develop improved definitions in the next rule making. Because the vehicle population in this category is still small, the change is not urgent.

1150. Comment: **LCFS FF54-3**

The commenter states that the definitions should also include additional categories of advanced vehicles.

Agency Response: See response to **LCFS FF54-2**.

1151. Comment: **LCFS FF54-4**

The comment requests that ARB consider including a definition for “Renewable Hydrogen”.

Agency Response: See response to **LCFS FF54-2**.

1152. Comment: **LCFS FF54-5**

The commenter suggests adding “Hydrogen fueling” as one of the “Transaction Types”.

Agency Response: See response to **LCFS FF54-2**.

1153. Comment: **LCFS FF54-6**

The commenter states that no specific EER Values for fuel cell transit buses and a variety of different fuel cell vehicles has been provided as was done for electric vehicles.

Agency Response: See response to **LCFS FF21-1**.

1154. Comment: **LCFS FF54-7**

The commenter states that only fuel cell forklifts are mentioned in credits generation, not hydrogen for fuel cell transit buses, and other light/medium/heavy duty fuel cell vehicles.

Agency Response: See response to **LCFS FF21-1**.

June 19, 2015

Members of the Board
c/o Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Comments to Re-Adoption of the Low Carbon Fuel Standard – Proposed 15 Day Regulation Order

Members of the Board:

CR&R Environmental Services (CR&R) is pleased to provide the following comments and recommendations regarding the above referenced proposed regulation order. We appreciate the opportunity to provide our input to the modification of this extremely important set of regulations for the State of California.

As you may be aware, CR&R is a privately held integrated waste management company based in Southern California serving some 45 cities and jurisdictions, with 3 million residential and 5,000 commercial customers. CR&R has launched a renewable energy division where we have heavily invested in an anaerobic digestion (AD) project in the City of Perris (Riverside County). CR&R has chosen AD as our technology of choice to help our cities and customers meet the State's new organics recycling goals that are phasing in between now and the year 2020. From a feedstock of our collected green and food waste we will be generating approximately one million diesel gallon equivalents (dge) of renewable natural gas (RNG) per year per phase. We have four phases permitted in Perris that will collectively generate 4 million dge per year of RNG at full build out. The RNG we generate will initially fuel our own fleet of CNG trucks with subsequent phases planned to be further processed to be injected into the SoCal Gas pipeline per Rule 30 specifications.

We are grateful for the considerable financial investment the State has made in our Perris AD project. Namely, the California Energy Commission ($4.52 Million), South Coast AQMD ($500,000), and CalRecycle ($3 million) have made Phase 1 and 2 of our project possible. As you are well aware, leading edge technology is expensive and our approximately $60 million dollar investment in Phase 1 and 2 was made possible only with this type of public assistance. We anticipate completion of Phase 1 in November of this year.

On the operations side, when developing our operating budget for the Perris AD project, we relied on the availability of two key carbon incentives, RFS2 and LCFS, to enable us to generate an economic return. **We are concerned that the proposed LCFS amendments delay our ability to monetize LCFS credits which will significantly impact our project's economic viability.**

LCFS FF55-1

We have the following specific concerns with the proposed modifications:

1) **The requirement for 2 years of energy consumption data required under the registration process for Tier 2-LookUp Table Pathway CNG 005 listed in Table 6.**

LCFS FF55-2

11292 Western Ave.
P. O. Box 125
Stanton, CA 90680-2912

t: 800.826.9677
t: 714.826.9049
f: 714.890.6347

crrwasteservices.com

the face of a greener generation

LCFS FF55-2 cont.

The proposed amendments require that CR&R register the project under Tier2-LookUp Table Pathway CNG005 which, among other requirements, calls for the submission of energy invoices for a period no less than **2 years** per 95488(4)(D)(1). Once the registration is approved for that specific CI, the LCFS credits will be generated retroactively based on the fuel production since startup of operations. Furthermore, 95488(4)(E), states that to obtain final approval, the CI chosen has to be approved by the Executive Officer. However, there is no deadline set for the Executive Officer to make this determination. **Our interpretation is that applicants will not be able to sell the LCFS credits generated until at least 2 years after the registration of the project, causing a significant impact on the cash flow of the project.**

In order to resolve this we suggest two solutions:

1. *That CARB reduces the amount of required energy invoices that have to be submitted to one quarter.*
2. *That there is a limit of 30 days for the Executive Officer to make his determination once the energy invoices, and all the other required documentation, is submitted.*

2) The possibility that will have to halt LCFS credit generation when transitioning from the current regulation to the new regulation.

LCFS FF55-3

Our financial pro-forma was based on existing rules where producers start generating LCFS credits upon starting operations. As our plant is expected to come online in November 2015, we expect to register our project under Method 2 CNG005 and start generating credits soon after start-up under the existing regulations. The proposed regulations require that we re-register the facility under the Tier2-LookUp Table Pathway prior to the sunset date of December 2016. **Our interpretation is that at the time of re-registration, applicants will have to halt the generation of LCFS credits until the re-registration is approved. This will cause a hiatus in the planned income from LCFS credits as it was included in our pro-forma.**

In order to resolve this issue, we recommend:

When a project's registration is approved and is generating LCFS credits, the project's registration requirements are grandfathered in under the new regulations with the new respective CI index and therefore there would not be a hiatus in LCFS credit generation.

3) The CI Index for the Temporary FPCs for Indeterminate CI are very high. The production of CNG from an anaerobic digester is included in the Biomethane CNG pathway listed in Table 7.

If we were to be required to use a temporary pathway due to the LCFS cash flow implications of item 1 above, we would have to default to a CI that unrealistically high as compared to the published CARB pathways for anaerobic digester. While we understand that these values need to be conservative, there is no explanation of how these CI were created.

LCFS FF55-4

In order to resolve this issue, we suggest:

Isolate the CNG production from anaerobic digesters from this category. Furthermore, explain the determination of these values.

We very much appreciate the opportunity to comment. Please do not hesitate to contact us if you have any questions regarding these comments.

Sincerely,

P.P.

1155. Comment: **LCFS FF55-1**

The commenter expresses concerns that the proposed LCFS amendments delay their ability to monetize LCFS credits which will significantly impact their project's economic viability.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1.**

1156. Comment: **LCFS FF55-2**

The commenter expresses concerns about the requirement for two years of energy consumption data under the registration process for Tier 2 Lookup table pathway code CNG005 listed in Table 6.

Agency Response: Please see responses **LCFS FF15-1** and **LCFS FF31-1**. In order to encourage the development of innovative fuel technologies, applicants may submit New Pathway Request Forms covering Tier 1 and Tier 2 facilities that have been in full commercial operation for less than two years, provided they have been in full commercial production for at least one full calendar quarter. If that form is subsequently approved by the Executive Officer, the applicant shall submit operating records covering all period of full commercial operation, provided those records cover at least one full calendar quarter**.**

1157. Comment: **LCFS FF55-3**

The commenter expresses concern about the possibility that they will have to halt LCFS credit generation when transitioning from the current regulation to the new regulation.

Agency Response: ARB staff does not intend nor believe the recertification process will create any gap in credit generation. In order to ensure that all fuels sold under all certified pathways compete fairly in the California marketplace, all pathway CIs must be calculated using the same model. For this reason, the proposed regulation requires all pathways certified under the current regulation to be recertified with CIs calculated using CA-GREET 2.0. Recertification must occur within one year of the effective date of the proposed regulation. Since the proposed regulation is expected to take effect on January 1, 2016, holders of pathways with CA-GREET 1.8b-based CIs will have until January 1, 2017, to recertify those pathways as long as the data has not changed. As proposed in the proposed regulation, applications to recertify fuel pathway certifications, registrations that were approved under the current LCFS (and still in effect on the date this proposed regulation goes into effect) and new applications for fuel pathways in 2016 will, to the extent feasible, be processed in groups based on fuel type in the following order of priority: ethanol, biodiesel, renewable diesel, compressed natural gas, liquefied natural gas, and all others. For legacy pathways, the CIs will still be in effect until the pathways are recertified or until January 1, 2017. As soon as the recertification is approved, the new CI will be in effect while the previous CI will be deactivated. Therefore, the transition should cause no halt in the credit generation.

1158. Comment: **LCFS FF55-4**

The comment states that the temporary FPCs for fuels with indeterminate CIs are very high.

Agency Response: See response to **LCFS FF35-6**.

Re: The Proposed Re-Adoption of the Low Carbon Fuel Standard

COMMENTS OF SOLAZYME, INC. ("Solazyme")

Solazyme appreciates the opportunity to comment on the California Air Resources Board's (ARB's) proposal for the 2015 Re-Adoption of the Low Carbon Fuel Standard (LCFS), and we are supportive of the LCFS. Solazyme was founded in California over 12 years ago and is based in South San Francisco. We are in commercial production and already selling biofuel to private fleets in the US, and we are eager to supply advanced biofuels for the California market.

Solazyme understands that the ARB is trying to address concerns over Carbon Intensity (CI) data reporting compliance for new pathways Section 95488 (d)(2). Solazyme agrees that there needs to be a solution to this matter, although we feel that this proposal creates a serious barrier for any new advanced biofuel coming to market through onerous upfront requirements. In fact, the undue burdens created in this proposal are truly a show-stopper for advanced biofuels coming to market in California. Instead, the new requirements as written favor incumbents, such as first generation biofuels, who have legacy operations. Below we outline some areas of concern and look forward to ARB's consideration of these issues. LCFS FF56-1

Introduction to Solazyme

Solazyme has pioneered an industrial biotechnology platform that harnesses the prolific oil-producing ability of microalgae. Our platform is feedstock flexible and can utilize a wide variety of plant-based sugars such as sugarcane-based sucrose, corn-based dextrose, and sugar from other biomass sources including cellulosics. By growing our proprietary microalgae in the absence of light using fermentation tanks to convert photosynthetic plant sugars into oil, we are in effect utilizing "indirect photosynthesis." Solazyme develops and manufactures products for the food, skin-care, industrial chemical and lubricants, and industrial/military fuels sectors.

Solazyme is Currently Producing Advanced Biofuels

At Solazyme, we are creating clean, low carbon, renewable algae-derived advanced biofuels. The company's tailored oils are refined into cost-effective, high-quality, on-spec "drop-in" replacements for diesel and jet fuels. Solazyme's algae-derived fuels are compatible with existing infrastructure, meet industry specifications, and can be used with factory-standard engines, without modifications. The company has worked with Chevron, UOP Honeywell, and other industry leading refining partners, to produce Soladiesel$_{RD}$® renewable diesel, Soladiesel® renewable diesel for ships, and Solajet® renewable jet fuel for both military and commercial application testing.

- Soladiesel$_{BD}$® and Soladiesel$_{RD}$® are the first algae-derived fuels to be successfully road-tested in blended and unblended (B100) forms for thousands of miles in unmodified vehicles. Both fuels are compatible with existing infrastructures, meet current US and European fuel specifications, and may be used in factory-standard diesel engines without modification.
- Soladiesel$_{RD}$® (Renewable #2 Diesel) is ASTM D975 compliant and has demonstrated a cetane rating of over 74, which is more than 60 percent better than standard US diesel fuel. Also, Solazyme produces Soladiesel® that meets the HRD-76 military specifications for ships. It was used as the base fuel for testing and certification of renewable F-76.
- Solajet® is the world's first 100 percent algae-derived jet fuel, for both military and commercial applications. The fuel has been used in a US Navy testing and certification program. Solajet® meets all military specifications for HRJ-5 jet fuel and all non-petroleum commercial specifications for ASTM D 7566.

General Comments

Provisional Pathways

LCFS FF56-2

The language in Section 95488, and specifically 95488(d)(2), is greatly concerning to Solazyme because of the upfront requirements for a new pathway. For instance, the proposal requires applicants to have been in full commercial production for at least one full calendar quarter before applying for a new pathway. This timeline is not feasible for two reasons. First, biofuel refiners use or blend a broad array of feedstocks when making biodiesel or renewable diesel (e.g., cooking oil, tallow, soy oil, etc.). The dynamic nature of feedstocks processed at a facility over the course of one quarter would make it near impossible to generate consistent data for one new feedstock.

LCFS FF56-3

In addition, this timeline does not match the natural course of the commercialization process for a new biofuel. It is standard practice for biofuel refiners to take time to scale up a new feedstock while it is introduced. That means that the refiners will not generate a quarter's worth of consistent data on the new feedstock during its early adoption. This requirement will therefore significantly delay the opportunity for a new pathway and delay advanced biofuels from being introduced into California. It creates an undue administrative burden on the refiners to test and qualify new feedstocks and will greatly reduce their enthusiasm to incorporate new feedstocks. Instead, this requirement rewards incumbents.

LCFS FF56-4

Monetizing the LCFS credits are also delayed as the rule states that the applicant is provided only "provisional" credits and may not sell credits for two years. This is a stonewall barrier for innovative advanced biofuels producers and refiners alike. Without the ability to monetize credits for two years, the economic incentive to sell new advanced biofuels in California is basically gone. Once again, this requirement heavily favors incumbents.

LCFS FF56-5

Any new technology coming to market, and expanding, requires capital to build facilities. In the event that ARB requires a 2 year monetization hold, with the potential to withhold credits, this will also

LCFS FF56-5 cont.

impact the ability of new entrants to finance. Financiers will typically need to discount any credit until it is confirmed. Start-up, and the first years of operation, are also the most critical for a new plant in terms of cash flow. The current proposal makes that initial period worse, and thus increases the cost of commissioning significantly.

Furthermore, as new feedstock producers enter the California market, this will create a proliferation of pathways for ARB staff to handle. Most feedstock providers will partner with numerous refiners to produce the end product: biodiesel or renewable diesel. This means there will be a two year process for each refiner, as well as a new pathway application for each refiner, for the ARB to review.

LCFS FF56-6

California and the ARB have typically lead adoption for new technologies, and we hope this legacy continues, particularly at a time when so many technologies are poised to enter the market.

Table 7 Temporary FOCs for Fuels with Indeterminate CIs

LCFS FF56-7

Microalgae naturally make triglyceride oils, just like the oils made by any animal or plant-based sources. In fact, several types of microorganisms are used by many other companies as the basis for a new generation of advanced biofuels. Table 7. *Temporary FOCs for Fuels with Indeterminate CIs,* however, does not include a default pathway for fuels derived from these sources. Solazyme believes that the ARB should add a category for "Any feedstock *derived from microorganisms*" for Biodiesel and Renewable Diesel fuels. With this new generation of advanced biofuels coming into commercialization, this will allow for California to benefit from new and broad innovation.

LCFS FF56-8

Solazyme understands that lack of compliance for CI verification after two years is an important concern. However, it would seem that this can be addressed by withholding the right to sell credits until compliance is met rather than putting in place requirements for full operational data upfront for new advanced biofuel providers looking to enter the market. We believe this will significantly delay (or halt) the entry of advanced biofuels to the California market.

We appreciate this opportunity to provide comments. Please contact me if you have any questions or require additional information.

Sincerely,

p.p.

1159. Comment: **LCFS FF56-1**

The commenter is concerned that the requirements and restrictions in the proposed Modified Regulation Order create barriers for developers of newly constructed fuel production facilities or operations that apply for provisional pathways.

Agency Response: This comment introduces those that follow; ARB responds to those detailed comment in responses to **LCFS FF56-2** through **LCFS FF56-8**.

1160. Comment: **LCFS FF56-2**

The comment states that the regulation's requirement for one calendar quarter of operational data makes it difficult to generate data when multiple new feedstocks are processed.

Agency Response: One calendar quarter of operational data is sufficient to commence evaluation of a provisional pathway and verify fuel carbon intensity, providing a minimum amount of data on which to make a CI determination. One quarter of operational data also demonstrates that facility construction is complete and commercial production has commenced, thus precluding applicants with fuel production facility design plans that have not commenced construction from making frivolous applications that may never materialize into tangible fuel pathways. Such applications could lead to abuse of certified CIs, as well as occupy limited staff resources to process pathway applications.

1161. Comment: **LCFS FF56-3**

The comment states that the requirement for one calendar quarter of operational data poses an undue administrative burden on fuel developers and hinders the commercialization and scale-up of processes.

Agency Response: See response to **LCFS FF56-2.**

1162. Comment: **LCFS FF56-4**

The commenter also expresses concern that LCFS credits generated by new fuel producers who have been granted provisional pathways are not liquid for two years; thereby constricting their cash flows and operating capital demanded by advanced biofuel producers and refiners alike.

Agency Response: See response **LCFS FF31-1**. ARB modified that aspect of the proposal to allow generation and sale of provisional credits.

1163. Comment: **LCFS FF56-5**

The comment states that the 2-year hold on monetization will impact a fuel producer's ability to secure financing.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

1164. Comment: **LCFS FF56-6**

The comment states that each feedstock producer will partner with multiple refiners and that will mean multiple pathway applications for each refiner and feedstock combination for ARB staff to review.

Agency Response: See response to **LCFS FF56-2** and **FF56-4**.

1165. Comment: **LCFS FF56-7**

The commenter suggests that there is no specific Temporary Fuel Pathway Code (FPC) for Fuels with Intermediate CIs that caters to Renewable Diesel or Biodiesel derived from micro-organisms.

Agency Response: Temporary FPCs with CIs were created in broad categories so that regulated parties may be able to report purchased-fuel volumes. While an exact match of the Temporary FPC and the applicant's modeled estimate of the fuel CI may not exist, staff believes that the Temporary FPC categories are broad enough to place the applicant's CI in close proximity to the one of many Temporary FPCs. There are temporary FPCs that are reasonably close to CI expectations for renewable diesel and biodiesel derived from micro-organisms, (see Table 7 FPCs BIOD201, and RNWD301T, for example).

1166. Comment: **LCFS FF56-8**

The commenter also expresses concern that LCFS credits generated by new fuel producers who have been granted provisional pathways are not liquid for two years; thereby constricting their cash flows and operating capital demanded by advanced biofuel producers and refiners alike.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF20-1**.

Mary D. Nichols
Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95812

RE: SUPPORT FOR LCFS READOPTION: 15-Day Proposed Modifications to LCFS

Dear Chair Nichols:

I am very pleased to submit these comments in support of the 15-Day Proposed Modifications on behalf of the California Biodiesel Alliance (CBA) and to reiterate the strongest support for the re-adoption of California's Low Carbon Fuel Standard (LCFS). As California's not-for-profit biodiesel industry trade association, CBA works very closely with and fully supports all of the comments of the national trade association, the National Biodiesel Board (NBB).

We begin by highlighting a key issue, detailed by the NBB, and also requesting that ARB include Tier 1 pathways for integrated oil and biodiesel producers or that the Tier 2 GREET model be available to those integrated biodiesel producers who qualify. To that point, we strongly urge a reinstatement of the "uncooked" used cooking oil (UCO) pathway under Tier 1. We believe it's very important for our California-based biodiesel producers who make biodiesel from used restaurant grease and don't use a cooking process, to benefit from a CI score that has been as much as 4 or more points lower than the pathway in which "cooking" is involved. This is coupled with the request that, toward the goal of accuracy in determining CI values, Tier 1 pathways account for integrated operations by allowing for the input of specific feedstock processing values, not just default values. LCFS FF57-1

Also, while we understand the need for a period of review to determine accurate energy use for commercial-scale operations for provisional pathways, we are concerned about language suggesting a potential 2-year delay in the ability to monetize credits. LCFS FF57-2

In closing, let me reiterate our appreciation for ARB's work, especially the skill and dedication that ARB staff has brought to the difficult tasks involved in LCFS readoption. We can attest to the willingness of staff at all levels to engage and satisfactorily address issues raised by our industry experts. We are very excited about the future of the California biodiesel industry and the growing contributions we can make to the state's carbon and petroleum reduction and related goals.

Thank you for considering these comments. Please call me with questions at 760-398-0815.

Sincerely,

Curtis Wright
Chairman

Building Trades Council

Kern, Inyo, & Mono Counties of California AFL-CIO

June 18, 2015

Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Subject: Comments of the 15 Day Regulatory Package for the LCFS Regulation

The Kern, Inyo and Mono Counties Building and Construction Trades Council strongly supports the Low Carbon Fuel Standard's (LCFS or regulation) provisions for Low Complexity – Low Energy Use Refiners (LCLE Refiners). These provisions recognize that not all refineries are the same. We believe that there are solid policy and technical justifications for this distinction to be codified in the LCFS. The Air Resources Board (CARB or Board), as well as, the U.S. Environmental Protection Agency have traditionally recognized in their regulatory programs the unique value small refiners (LCLE) occupy in both the oil and finished fuel markets, as well as, their unique configurations and operating constraints. Recognizing that difference is a very positive step.

However, we are disappointed that the proposed final regulatory provisions for the re-adoption of California's Low Carbon Fuel Standard (15-day changes) fails to recognize Alon's Bakersfield Refinery as a low carbon fuel producer (LCLE). The facility is configured and engineered to produce low CI base fuels. It is for this reason that we are saddened that staff was unable to agree on a solution that would include all of California's truly LCLE refineries. The staff had an opportunity to make the LCF"s LCLE provisions work for all low carbon intensity refineries in California, but decided against various compromise proposals presented, including proposals to limit the benefit and single LCLE refiner could receive in an attempt to deal with staff's concerns for "regulatory creep" and "breaking the bank". LCFS FF58-1

We strongly urge the Board to direct staff to revisit this issue at the earliest opportunity.

Respectfully submitted,

John Spaulding
Executive Secretary

CalETC

California Electric Transportation Coalition

June 19, 2015

Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: SUPPORT for Re-Adoption of the Low-Carbon Fuels Standard as modified by the proposed 15-day Regulation Order

Dear Chairman Nichols and Honorable Board Members:

The California Electric Transportation Coalition (CalETC) appreciates the opportunity to comment in support of re-adoption of the Low Carbon Fuels Standard (LCFS) as modified by the proposed 15-day Regulation Order . CalETC is a non-profit association with a board of directors that includes: Los Angeles Department of Water and Power, Pacific Gas & Electric, Sacramento Municipal Utility District, San Diego Gas & Electric and Southern California Edison. Our membership also includes major auto makers and we work closely with our colleagues in the alternative fuels community.

First, we laud the California Air Resources Board (CARB) in the design and implementation of the LCFS. The regulation sets a standard for the regulated industry and allows the industry to determine how best to meet that standard, providing flexibility in an industry long constrained by the transportation sector's near-total dependence on only one fuel. The LCFS program has resulted in unanticipated innovation in both fuels and vehicles and expanded consumer choice. In the first years of implementation of the LCFS, industry is over-complying, credits are being generated from unanticipated and innovative sources, and consumers are responding to expanding choices in fuels and vehicles.

CalETC particularly appreciates CARB's recognition that electricity is a fundamentally different fuel option for consumers. The CARB approach to electricity supports consumer choice in fuels and fueling options and does not tie electricity to a liquid fuel paradigm that could restrict consumer options. The unanticipated innovations the LCFS has helped bring to market, including the proliferation of many vehicle and fueling options for electricity, present unique challenges for CARB. CARB staff has demonstrated an exceptional ability to develop and implement a regulation that allows consumer-driven free-market approaches to reducing the carbon content of our transportation fuels sector.

We respectfully submit the following comments on the proposed 15-day Regulation Order:

- CalETC appreciates the opportunities for utilities to earn LCFS credits for workplace, fleet and public-access locations, in those instances where the site host does not want to take on that role. LCFS FF59-1

- CalETC supports the increased transparency and specificity included for the residential charging LCFS credit estimation formula. CalETC will continue to support CARB and provide as much information as we have to ensure transparency and robustness. LCFS FF59-2
- We also support the other clarification modifications that were included in the electricity section. LCFS FF59-3
- CalETC supports the CARB staff recommended carbon intensity for electricity. LCFS FF59-4

In closing, CalETC supports re-adoption of this groundbreaking and essential regulation. Thank you for your consideration and ongoing leadership.

Regards

Eileen Wenger Tutt, Executive Director
California Electric Transportation Coalition

Subject: FW: Error in CA-GREET 2.0 Tier 1 Calculation of Ethanol CI

From: Logan Caldwell [mailto:lc@hbioc.net]
Sent: Tuesday, June 09, 2015 11:50 AM
To: Chowdhury, Hafizur@ARB
Cc: Pham, Chan@ARB
Subject: Error in CA-GREET 2.0 Tier 1 Calculation of Ethanol CI

In the recently released Tier 1 calculator there is an error in the calculation of denaturant CI. On the EtOH sheet, cell L436, a fixed amount is used for the feedstock CI. However, since this varies with the pathway, it should be linked to the feedstock CI that is manually entered in sheet “T1 Calculator”, cell c62, after the first step of the upstream/feedstock CI calculation.

LCFS FF17-1

As a result of this error, the denaturant calculation is in error because it does not reflect the CI of the upstream portion of the ethanol pathway.

Please confirm whether sending this to you all is sufficient for this issue to be considered, or whether it needs to be a formal comment.

Thanks!

1174. Comment: **LCFS FF60-1**

The commenter pointed out a broken link in the Tier 1 calculator. The cell in question, L436, is meant to link to a cell containing the applicant's ethanol feedstock CI, but due to a clerical error, in the June 4, 2015 version of CA-GREET2.0 cell L436 instead linked to the wrong place.

Agency Response: That error has been corrected as a nonsubstantial change in the model version provided to OAL "June 4, 2015 CA-GREET2.0 corrected.

From: Logan Caldwell [mailto:lc@hbioc.net]
Sent: Friday, June 26, 2015 10:31 AM
To: Chowdhury, Hafizur@ARB
Subject: Which "CI" is the reference for the 20% reduction Tier 2 requirement?

Hafizur:

In section 95488(b) (2)(F)(4) it is written:
"Production process innovations that improve production efficiency such that resulting CI is at least 20 percent lower due to the process innovation."

I have looked at the definition of "carbon intensity", and the acronym "CI" and it is not clear whether this section is referring to the total indirect and direct CI, the direct CI or the CI of the energy consumption in the process facility. LCFS SF1-1

In the definitions section of the proposed regulations, "day" is defined as meaning a calendar day unless specified otherwise. Perhaps "carbon intensity" should also be further specified in the definition to mean the total direct and indirect CI over the full lifecycle unless specified otherwise, or whatever specific definition want to have for the term "carbon intensity". The definition mentions lifecycle, but does not state full lifecycle. LCFS SF1-2

1_SF_LCFS_HBC Responses

1175. Comment: **LCFS SF1-1**

The commenter states that it is not clear whether section 95488(b)(2)(F)(4) is referring to the total indirect and direct CI, the direct CI or the CI of the energy consumption in the process facility.

Agency Response: Staff notes that this comment is not relevant to the changes made through the second 15-day notice. However, ARB staff appreciates the commenter raising this issue for clarification. The "source-to-tank" CI should be used to determine whether an innovative process sufficiently improves production efficiency to qualify a pathway for Tier 2. As defined in conjunction with the Method 2A substantiality requirement under Section § 95488(c)(4)(G)2:

> "Source-to-tank" means all the steps involved in feedstock production and transport, and finished fuel production, transport, and dispensing. A source-to-tank CI does not include the carbon intensity associated with the use of the fuel in a vehicle; "source-to-tank" is also referred to as "well-to-tank."

Staff suggests that the source-to-tank CI should not include the indirect land use change modifier. To demonstrate 20% reduction, the reference CI should be calculated using all the same inputs as would be appropriate for the proposed Tier 2 pathway, without the innovative process.

1176. Comment: **LCFS SF1-2**

The commenter states that in the definitions section of the proposed regulations, "day" is defined as meaning a calendar day unless specified otherwise. Perhaps "carbon intensity" should also be further specified in the definition to mean the total direct and indirect CI over the full lifecycle unless specified otherwise.

Agency Response: This comment is beyond the scope of the second 15-day changes and, therefore, requires no further response.

Subject: Assertion in 2nd Notice Summary that no data needed for many legacy pathways

In the summary of the changes in the 2nd 15-day Notice, regarding recertification of "legacy pathways" staff has written: "For many of these pathways ARB staff already has all of the information needed to conduct recertification without any submission of additional data by the applicant." (for convenient reference, I have copied below all of item #3 of the summary that contains this statement)

LCFS SF2-1

Does this mean that no data will be needed for chemical, enzyme and yeast use at fuel ethanol plants and that no transportation distances for feedstocks and ethanol will be needed? How will CARB calculate the CI using the Tier 1 calculator without this information? Has CARB decided to allow legacy pathways to use default values for these items?

Thank you for considering and commenting.

Copy of Item #3:

3. In section 95488, staff is proposing a streamlined recertification process by which "legacy pathways" certified under prior versions of the LCFS regulation could be recertified, pursuant to the proposed regulation, by ARB staff using the CA GREET 2.0 model. The goal of these changes is to minimize disruption of credit generation in the program due to the move from CA-GREET 1.8b to CA-GREET 2.0.

The program currently has over 270 Method 2 legacy pathways, including pathways posted as recently as May of 2015 . During the first 15-day comment

period stakeholders requested additional clarity on the fate of these existing pathways.

For many of these pathways ARB staff already has all of the information needed to conduct recertification without any submission of additional data by the applicant, and an abbreviated pathway re-certification process is appropriate.
Under the proposed changes, ARB staff could request additional information if required.

Regards,
Logan

1177. Comment: **LCFS SF2-1**

The commenter asks if ARB will allow legacy pathways to use default values for chemical, enzyme and yeast use at fuel ethanol plants.

Agency Response: Staff's current thinking is that CA-GREET2.0 default values for chemical and material input quantities will be used to recertify legacy pathways; however, staff may request additional information and documentation if necessary. Presuming the Board adopts the proposed rule, staff plans to include this item in the workshop and draft guidance document that will be discussed after the board hearing.

To: Chowdhury, Hafizur@ARB
Subject: What is the Executive Officer likely to request for Recertifications?

Hafizur:

The 2nd 15-day notice modifications provide that portions of the normal certification requirements may not be required for recertification of existing pathways. The problem is knowing which of the requirements are likely to be needed; otherwise, there will be inefficiencies involved in the process from either providing too much or too little with applications for certification. I have summarized for the Tier 1 pathways the items that may or may not be required. It seems to me that certain items will definitely be required, for example the CA-GREET 2.0 Tier 1 model with the Tier 1 sheet completed. Another example is the fuel producer attestation letter. If these are definitely going to be needed, I would suggest rewording the language in the regulations to say so. Then, the only unknown is has to do with the invoices.

LCFS SF3-1

The requirements of subsections 95488(c)(3)… are not applicable to recertifications, *unless the Executive Officer specifically requests such information from an applicant*.
95488(c)(3):

95488 (c) (3)(A) …submit the following information to the Executive Officer for processing and verification:

1. Calculation of CI with CA-GREET 2.0 T1 with T1 interface completed.

2. Invoices and receipts for all forms of energy consumed in the fuel production process, all fuel sales, all feedstock purchases, and all co-products sold. Each set of invoices shall be accompanied by a spreadsheet summarizing the invoices.

- In lieu of receipts or invoices for energy consumption, fuel sales, feedstock purchases, or co-product sales, the applicant may seek Executive Officer approval to submit audit reports prepared by independent, third-party auditors that document energy consumption, fuel sales, feedstock purchases, or co-product sales.

3. LCFS Fuel Producer Attestation Letter

Clarifying this point should make the process smoother for all concerned.

Regards,
Logan

1178. Comment: **LCFS SF3-1**

Regulation should be amended to clarify requirements for legacy pathway re-certification especially with respect to what additional information is needed.

Agency Response: ARB staff appreciates the commenter's suggestion for clarification of the regulation order. At this time we do not anticipate further changes to the regulation. Staff views recertification as largely an administrative process undertaken by ARB staff. Presuming the Board adopts the proposed rule, staff plans include this item in the workshop and draft guidance document that will be discussed after the board hearing. See response to **LCFS FF18-1**.

To: Chowdhury, Hafizur@ARB
Subject: Question regarding: Requirements to be Classified as a Tier 1 Pathway: Three Years seems excessive

The 2nd (and 1st) 15-day notice proposed language states the following at 95488(b)(1):

Tier 1. Conventionally-produced alternative fuels of a type that has been in full commercial production, excluding start-up or ramp-up phase, for at least three years, **and for which certified LCFS pathways have existed for at least three years** shall be classified into Tier 1.

The full commercial production for three years could be an issue for some plants that were out of service due to market conditions for a period of time.

LCFS SF4-1

The bigger question and issue is the requirement "and for which certified LCFS pathways have existed for at least three years." If I assume the reference date for determining three years is January 1, 2016, this means that only pathways that were certified and posted on the ARB web site by January 1, 2013 or earlier will qualify for Tier 1 status. This would eliminate from consideration as Tier 1 pathways approximately 86 of the 125 facility pathways (some facilities have more than one pathway) shown currently on the CARB website: http://www.arb.ca.gov/fuels/lcfs/2a2b/2a-2b-apps.htm . In addition there are a number of Internal ARB-Developed Fuel Pathways that were issued after January 1, 2013, that would be a problem too for any facilities that used them for Method 1 certification.

I think it would be helpful to reconsider or clarify these requirements. Otherwise CARB staff is going to be overwhelmed with Tier 2 applications and the whole LCFS program will obviously suffer.

LCFS SF4-2

1179. Comment: **LCFS SF4-1**

The commenter states that full commercial production for three years could be an issue for some plants that were out of service due to market conditions for a period of time.

Agency Response: This comment is beyond the scope of the second 15-day changes and, therefore, requires no further response. However, for the sake of clarity, ARB staff believes the commenter has misinterpreted the regulation language under section 95488(b)(1), which is meant to clarify "conventionally-produced." This provision does not apply to individual plants or individual LCFS-certified pathways, but rather "to fuels **of a type** that has been in commercial production...**and** for which certified LCFS pathways have existed for at least three years." Thus, a new producer who has been in operation for less than three years, but the same feedstock-fuel pathway has been LCFS certified for at least three years (for example, corn-ethanol), that applicant should apply for a Tier 1 pathway. Conversely, if a producer has been in operation for five years, but uses a feedstock-fuel combination which has not been a LCFS certified pathway for three years (for example, algae-biodiesel), that producer may apply for a Tier 2 pathway.

1180. Comment: **LCFS SF4-2**

The commenter requests clarification on the 3-year requirement for Tier 1 pathways.

Agency Response: See response to **LCFS SF4-1**.

RE: Low Carbon Fuel Standard
Proposed Fuel Pathway Registration Process

July 6, 2015

Dear Chairman Nichols and Board Members,

Thank you for the opportunity to provide comments regarding the readoption of the California Low Carbon Fuel Standard and, in particular, the proposed modifications to the fuel pathway registration process as proposed in the draft regulation released on June 4.

LCFS SF5-1

We comment today specifically about §95488(d)(2) subtitled "Provisional Pathways" wherein new biofuel facilities are granted only provisional status while waiting on two full years of operating data before being fully approved by ARB for unrestricted LCFS participation. While previous drafts of the new regulation applied this restriction only to new facilities producing novel and less proven Tier 2 biofuels, the June 4 draft captured new facilities producing established and well understood Tier 1 biofuels as well. Although the June 23 draft eased these restrictions to Tier 1 producers a small bit, they still allow for ARB to make unannounced changes to a new pathway and still retain a great deal of uncertainty to biofuel producers and investors. We believe that this is a serious miscalculation on the part of Staff that undermines the entire rationale for redesigning and streamlining the pathway application process.

LCFS SF5-2

GHI Energy urges ARB to modify this provision and to exclude new Tier 1 facilities from this provisional requirement completely, or, at the very least, **reduce the statutory provisional time period for new Tier 1 facilities to a much shorter duration (for example, three to six months)**. Given than the entire purpose of the new Tier 1 / Tier 2 designation is to "streamline" the application process based on Staff's familiarity with certain common types of biofuels, it would stand to reason that less operational data would be needed to ensure that a new Tier 1 facility is constructed and operating properly as compared to the more new and less proven types of facilities designated as Tier 2 that would logically require more operating data.

If ARB still believes that a two year provisional period is appropriate even for new Tier 1 facilities, then GHI would urge ARB to allow at least a portion of a new Tier 1 facility's' LCFS credits to be marketable and unrestricted, perhaps equal to a maximum "baseline" CI level (much like the Method 1 "Table" lookup in place today), and **make only the incremental portion of the pathway (i.e. CI reductions under the baseline) provisional instead.** LCFS SF5-3

Given that Staff's compliance scenarios are heavily reliant on the introduction of new types of biofuels and the increasing consumption of existing fuels such as biomethane and biodiesel, it would stand to reason that the credit transfer restrictions that come from such a long provisional status could in effect "lock out" the development of new biofuels facilities and prevent the LCFS from achieving its ultimate 2020 carbon reduction goal. Combined with the proposed cost containment mechanism in the new regulation, this provisional designation could further reduce the perceived payback to investors in new biofuel facilities – thus causing them to decline to fund new facilities – and further risk the success of the LCFS in the future. LCFS SF5-4

Sincerely,

John M Greene
President

5_SF_LCFS_GHI

1181. Comment: **LCFS SF5-1**

The commenter believes that the Provisional Pathway section of the regulation retains uncertainty for biofuel producers and investors.

Agency Response: Staff believes the proposed changes provide the appropriate balance of flexibility for low CI producers and the need for LCFS accuracy and reliability. See response to **LCFS FF20-1**.

1182. Comment: **LCFS SF5-2**

The commenter urges ARB to modify the provisional pathway provision to exclude new Tier 1 facilities or reduce the provisional time period for new Tier 1 facilities to a much shorter duration (for example, three to six months).

Agency Response: See response to **LCFS SF5-1** and **LCFS FF20-1**.

1183. Comment: **LCFS SF5-3**

The commenter urges ARB to allow at least a portion of a new Tier 1 facility's' LCFS credits to be marketable and unrestricted, perhaps equal to a maximum "baseline" CI level (much like the Method 1 "Table" lookup in place today), and make only the incremental portion of the pathway (i.e. CI reductions under the baseline) provisional instead.

Agency Response: See response to **LCFS FF20-1**.

1184. Comment: **LCFS SF5-4**

The commenter expresses concern that the 2-year provisional designation for new facilities could reduce the perceived payback to investors in new biofuel facilities.

Agency Response: See response to **LCFS FF20-1**.

ELECTRONIC SUBMITTAL (http://www.arb.ca.gov/lispub/comm/bclist.php)

July 8, 2015

Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Comments regarding proposed modified regulatory language with respect to the re-adoption of the Low Carbon Fuel Standard ("LCFS")

Dear Sir or Madam:

Ensyn Corporation ("Ensyn"), a privately owned U.S. company, is an experienced producer of cellulosic renewable fuels and renewable chemical products made from wood residues and other non-food cellulosic biomass. Ensyn appreciates the efforts of the Air Resources Board (the "Board" or "ARB") to reduce the carbon intensity ("CI") of transportation fuels used in California and the opportunity to provide comment on the above referenced regulations.

ENSYN'S TECHNOLOGY

Ensyn and its affiliated companies have been producing renewable fuels and chemicals commercially since 1989. Over this period, Ensyn's technology has produced over 37 million gallons of liquid product, a volume unmatched by any other cellulosic biofuels company. To date, Ensyn's cellulosic renewable fuel has been combusted in boilers to replace heating oil, and now Ensyn is focusing on expanding into the refinery market.

Ensyn's renewable fuel can be used as a secondary feedstock at a refinery in an application called "Refinery Coprocessing." In this application, a refiner purchases Ensyn's renewable fuel and coprocesses it with crude oil at a refinery to make ASTM-certified gasoline and diesel. In contrast, other biofuel companies produce a biofuel that must be blended downstream with finished gasoline or diesel. Refinery Coprocessing creates an untapped midstream biofuels market that is not subject to "blendwall" concerns and therefore can significantly expand the total quantity of low carbon intensity fuels in California and enable timely achievement of the LCFS CI reduction target.

Ensyn is currently developing production facilities in several regions across North America and globally, with world-class strategic partners, including UOP, a Honeywell Company; Chevron Technology Ventures; and Fibria Cellulose S.A, a Brazilian fiber company that is the world's largest market pulp producer. These projects include production facilities in the Pacific Northwest and California that would ultimately produce renewable fuel for use in California refineries.

Several key attributes contribute to our robust project development pipeline, including the following:

- Feedstock Partners – Ensyn is partnering with large timber management and forest products companies to provide abundant biomass residuals and waste for its projects.
- Offtake Partners – Ensyn is partnering with large global oil refiners, as well as smaller independent refiners, that would be offtake customers for our projects.
- Proven Technology – Ensyn's rapid thermal process (RTP™) technology has been proven in commercial operations for over 25 years. Our joint venture with UOP Honeywell provides commercial performance guarantees further supporting the technology.
- Powerful Economics - Cash production costs of approximately $50 per barrel provide significant downside protection and result in attractive economics for our projects.

Over the past year, Ensyn has spent considerable time and effort developing a life cycle analysis and is nearing completion of its LCFS pathway application. Ensyn considers the LCFS program to be an important policy driver for the expansion of low carbon fuel production. Based on extensive modeling and discussions with ARB staff, Ensyn anticipates that it will receive an extremely low CI score for its fuel pathway, well within the range of an ultra low carbon fuel.

PROVISIONS OF CONCERN

As an innovative producer of ultra low carbon fuel, Ensyn has commentary on the following provisions in the proposed regulations:

Provisional Pathways- Under Section 9588(d)(2) of the proposed regulations, applicants may not submit New Pathway Request Forms covering facilities that have not been in full commercial production for less than one full calendar quarter. At any time during the first two calendar years of the facility's commercial production, the Executive Officer of the Board or his or her designee (the "Executive Officer") may revise as appropriate the facility's actual operational CI based on the receipts for energy purchases submitted by the applicant of the fuel pathway application for the facility. During such two-year period, the applicant may only generate provisional credits and the Executive Officer may adjust the number of credits or reverse any provisional credit in the producer's account without a hearing.

Credit Invalidation- Under Section 95495(b)(1) of the proposed regulations, the Executive Officer may modify or delete an approved CI and invalidate credits or recalculate deficits. Under Section 95495(b)(4), in the event that the Executive Officer makes a final determination that invalidates credits and results in the creation of a deficit in a past compliance period, the deficit holder has 60 days from the date of final determination to purchase sufficient credits to eliminate the entire deficit.

RECOMMENDED CHANGES

We believe that the foregoing provisions would greatly hinder the value of LCFS credits in obtaining financing for any project utilizing an innovative fuel technology. Based on our experience, financial participants are extremely conservative in forecasting revenue streams for advanced biofuel projects. The current proposed language pertaining to provisional pathways and credit invalidation is likely to undermine financing for projects and thereby frustrate attainment of the Board's aggressive CI and petroleum reduction goals. However, relatively modest changes to the proposed language will preserve the Board's goal of ensuring verifiable greenhouse gas emission reductions while also supporting the development and expansion of low CI fuel production facilities.

LCFS SF6-1

Monetization of LCFS Credits- The first aspect of enabling financing of a biofuels facility is to facilitate the monetization of LCFS credits as early in the facility's commissioning as is feasible and consistent with the goals of the LCFS program. In our experience, there is a great deal of plant optimization that occurs as innovative production facilities are brought on line and ramped up to nameplate production capacity. Given the necessity of "proving" CI reductions to the Executive Officer through the submission of actual energy usage data at the specific production facility, the LCFS program is already structured to incentivize a new facility to delay its LCFS commissioning date until energy efficient performance has been achieved. Requiring a full calendar quarter of data is overly burdensome on plants which are being financed and constructed. For newly operational facilities, rather than relying on data from actual operations, third party validation of an applicant's provisional pathway should provide sufficient assurance of performance metrics to the Board. The validation process that has been successfully employed in the British Columbia Carbon Offset Protocol may be used as a template for this approach.

In any case, if the Board believes that operational data is required, a sixty (60) day period would be sufficient to validate the data and would enable much quicker monetizing of credits for project investors.

From a drafting perspective, this change could be achieved simply by changing the following sentence in Section 95488(d)(2) as indicated:

> *"In order to encourage the development of innovative fuel technologies, however, applicants may submit New Pathway Request Forms, as set forth in section 95488(c)(1),*
> *covering Tier 1 and Tier 2 facilities that have been in full commercial operation for less than two years, provided they have been in full commercial production for at least ~~one full calendar quarter~~ sixty (60) days."*

While the third party validation or sixty-day approach enables quicker LCFS credit monetization, the same subsection provides that based on operational data, "the Executive Officer may adjust the number of credits or reverse any provisional credit in the producer's account without a hearing…" This broad oversight power of the Executive

Officer ensures that the Board retains ample authority to ensure that actual CI reductions are being achieved. In addition, the Executive Officer's enhanced enforcement powers under Section 95495 further minimize any risk to LCFS program goals.

Minimizing the Period of Uncertainty- The second aspect of enabling financing is minimizing the period during which the production facility will be regarded by financiers as having an indefinite CI score. During the period in which the credits are provisional and may be adjusted without a hearing, the value of the credits will be considered an uncertainty. This uncertainty factor will adversely affect the facility's pro forma by discounting or nullifying the value of LCFS credits for the entire two-year period. Consequently, we would request that the Board reduce the provisional period to a maximum of six months. Once a facility has been commissioned and has commercially produced fuel for six months, its energy demands are stable so there is no significant risk to programmatic goals resulting from the adoption of a shorter provisional period. By contrast, a two-year provisional period undermines programmatic greenhouse gas and petroleum reduction goals by rendering it more difficult to obtain financing needed to establish innovative ultra low carbon production facilities.

Clarifying Provisional Credits- Regarding provisional credits, we would like to bring your attention to two sentences of Section 95486(a)(2) that could be interpreted inconsistently with the intent of the latest version of the proposed regulations. The clause states: LCFS SF6-2

> *"Where an application or demonstration pursuant to sections 95488 or 95489 has been completed but not yet approved, the applicant may report transactions in the LRT-CBTS. Such provisional credits may not be used for any purpose until fully recognized."*

The phrase "provisional credits" as used here appears to reference non-approved facilities that cannot yet generate credits. However, since the phrase "provisional credits" is used in Section 95488(d)(2) to specifically reference credits from facilities that have Executive Officer approval, we are concerned that this sentence could be interpreted as a lingering restriction on the use of provisional credits. Therefore, we would recommend striking the phrase "provisional credits" from Section 95486(a)(2) and replacing it with "reported transactions".

Remedying a Deficit- We believe that a period of sixty (60) days for a producer to remedy a deficit in a past compliance period caused by an invalidation of credits is an insufficient period and would cause undue economic burden on the producer. We suggest that the appropriate period to remedy the deficit should be one year. LCFS SF6-3

From a drafting perspective, this change could be achieved simply by changing the following sentence in Section 95495(b)(4) as indicated:

> *"Where such action creates a deficit in a past compliance period, the deficit holder has ~~60 days~~ one year from the date of the final determination to purchase sufficient credits to eliminate the entire deficit."*

CONCLUSION

We appreciate the opportunity to provide these comments and are available to work with the Board to assist it in achieving its environmental goals.

Respectfully submitted,

Robert A. Pirraglia
President

This page intentionally left blank.

6_SF_LCFS_Ensyn

1185. Comment: **LCFS SF6-1**

The comment is related to the monetization of the LCFS Credits, stabilization and optimization of processes after a newly-built facility has commenced commercial operations, operating contingency for new LCFS pathway applicants, third-party certification, and a proposed alternate approach to the LCFS regulation requirements.

Agency Response: We agree with the commenter that there is a great deal of plant optimization that occurs as innovative production facilities are brought on line and ramped up to nameplate production capacity, therefore we cannot issue a final certified CI until such issues are worked through. See response **LCFS SF12-5** and **LCFS SF8-22**.

Lastly, the Commenter's suggestion that ARB use third-party certification of pathways for newly-built facilities in operation has been entertained before. Staff will continue to evaluate the merits of such a proposal and find ways to assimilate such a process into the existing LCFS program, framework, and pathway certification process.

1186. Comment: **LCFS SF6-2**

The comment is related to the monetization of the LCFS Credits over the two-year provisional period over which the number of provisional credits generated could be lowered based on actual operating data submitted by the applicant. The commenter has asked the Board to reduce the provisional period from two years to six months citing that once a facility has been commissioned and has been commercially producing fuel for six months, its energy demands have stabilized, and there is no significant risk to programmatic goals resulting from a shorter provisional period.

Agency Response: ARB staff responds that fuel pathway CI certifications have always been based on the applicant's submittal of two years of actual operations data backed by energy invoices, production reports, and other forms of evidence. These requirements enhance accuracy and deter fraud and should remain in place. The commenter has cited the difficulty in procuring financing for construction of newer fuel production facilities with novel ultra-low carbon pathways as the reason for a requiring a shorter provisional period. Staff reiterates that the two-year operating data requirement is the standard we have based for producing fuel pathway CI certifications with lower uncertainty, thereby bringing more credibility to our LCFS program.

The commenter has suggested that “provisional credits” be stricken from Section 95486(a)(2) of the modified LCFS regulation order, and be replaced by “reported transactions.” That section was further modified in the third 15-day change striking the language that the commenter wanted to replace.

1187. Comment: **LCFS SF6-3**

The comment states that a period of sixty (60) days for a producer to remedy a deficit in a past compliance period caused by an invalidation of credits is an insufficient period and would cause undue economic burden on the producer. We suggest that the appropriate period to remedy the deficit should be one year.

Agency Response: Producers of low carbon intensity fuels who are careful to follow the actual operating condition limits in the CI certification would not be facing invalidation of any credits generated for fuel transactions reported. Similarly, importers and entities purchasing “with-obligation” fuels should ensure that the fuels being purchased are consistent with the relevant pathway. Finally, parties who knowingly generate bad credits will be subject to prompt enforcement and remediation.

Section 95495 includes a process and timeline for invalidation of a credit, deficit calculation, or approved CI pathway. These steps are systematic from discovery of the issue to notifying all parties and final determination in resolving the issue. We note that regulated or opt-in parties are free to withhold a small percentage of their credits to ensure that there are always LCFS credits on hand if needed.

Credits and deficits are generated by regulated and opt-in parties after each quarterly reporting period ends and fuel transaction data are submitted in the LCFS reporting tool. These credits are available for use on a quarterly basis. The amount of time in the schedule in this section from discovery to final determination, plus an additional 60-days, gives entities 110 days. Staff believes that this provides producers and regulated parties ample time to clear up any credit invalidation actions taken against them. Additionally, this approach ensures that the Program objectives are met within reasonable timeframes and that regulated and opt-in parties take responsibility and exercise due diligence when purchasing, importing or producing LCFS compliant fuels.

Enerkem

July 8, 2015

Clerk of the Board,
Air Resources Board
1001 I Street,
Sacramento, California 95814

Dear Sir/Madam,

Enerkem appreciates the opportunity to submit comments on the modified text for the proposed re-adoption of the Low Carbon Fuel Standard (LCFS).

Enerkem is a leading waste-to-biofuels and chemicals company. We produce clean fuels and green chemicals from non-recyclable municipal solid waste, thus helping diversify energy sources while offering a sustainable alternative to landfilling and incineration. Our facility in Edmonton, Alberta (Canada) is the world's first commercial biorefinery to use municipal solid waste to produce biomethanol and ethanol. We are currently developing biorefineries in North America and globally, based on our modular and standardized manufacturing approach and using our proprietary biofuels technology, developed in-house since 2000.

The LCFS makes California a very attractive market for the low carbon ethanol to be produced at our Edmonton biorefinery (currently beginning operations), and also an attractive investment environment for developing future Enerkem facilities in the state.

We would first like to thank the Air Resources Board for taking low carbon fuel producers' concerns into account following the first 15-Day Modified Regulation Order by removing the limitations on the sale and transfer of credits generated under provisional pathways. Dropping this limitation removes a significant barrier to financing of projects to develop new capacity for low carbon fuel production in California and for the California market. LCFS SF7-1

This change, while very important, does not resolve all issues relating to new low carbon fuel production facilities. The proposed rule still requires that facilities be in "full commercial production" for at least one full calendar quarter before even applying for a new pathway. The rule places new facilities in an extremely difficult commercial position, by effectively requiring facilities to be in commercial production but without possibility to sell the fuel produced. Considering the time from submission of a new pathway application to publishing of the CI, new facilities would, in effect, have to be in "full commercial production" for approximately one year before being able to sell fuel into the California market.

This places a significant damper on any plans to develop new low carbon fuel production facilities in California, as it is unclear how such facilities could sell fuel produced during the first year of commercial operations. The uncertainty concerning revenue streams following plant construction, and the barrier to selling fuel in the first year of operations, will undermine financing for projects utilizing innovative fuel technologies and thereby hinder attainment of the Air Resources Board's aggressive CI and petroleum reduction goals.

1130 Sherbrooke Street West
Suite 1500
Montréal QC H3A 2M8 CANADA
www.enerkem.com

The provision also creates a barrier for out-of-state new production facilities that could potentially supply low carbon fuel to the California market, as without a CI it is nearly impossible to secure off-take agreements for low carbon fuel.

Enerkem urges the Air Resources Board to remove the requirement to have been in full commercial production for one quarter prior to applying for a new pathway, in order to encourage the production and commercialization of new low carbon fuels such as municipal waste to ethanol. LCFS SF7-2

Enerkem believes that the power of the Executive Officer to adjust the number of credits or reverse any provisional credit in the producer's account, until the provisional CI has been successfully corroborated by operational records covering a full two years of commercial operation, is sufficient to enable verification of carbon intensity data from new production facilities. However, if the Air Resources Board considers it necessary to have operational data to verify the proposed carbon intensity of the new pathway at the time of application, greater flexibility could be afforded to companies by allowing some of this data to come from the company's existing pilot or demonstration facilities or from commissioning activities at the facility for which the pathway is being requested. LCFS SF7-3

If the Air Resources Board wishes to limit pathway applications to commercial facilities that are being built, rather than leave the door open to the creation of pathways for which commercial projects have not yet been developed, Air Resources Board could consider requiring an independent engineering review and a site visit to be included with the application for a new pathway. LCFS SF7-4

We thank the Air Resources Board for the opportunity to submit comments on the modified text for the proposed re-adoption of the Low Carbon Fuel Standard (LCFS), and hope that the Board will make the small changes necessary to enable low carbon fuel producers to secure the financing required to develop new production facilities, which will be needed to achieve the Board's greenhouse gas emissions reductions goals.

Sincerely,

MHLabrie

Marie-Helene Labrie
Senior Vice-President, Government Affairs and Communications

7_SF_LCFS_Enerkem

1188. Comment: **LCFS SF7-1**

The comment is expressing support for ARB staff's proposed changes for provisional pathways.

Agency Response: See response **LCFS FF56-2**, **LCFS SF12-5**, **LCFS SF8-22**, and **LCFS SF6-1**.

1189. Comment: **LCFS SF7-2**

The commenter has urged the Air Resources Board to remove the proposed requirement for new LCFS applicants to be in full commercial production for one quarter prior to applying for pathway certification.

Agency Response: See response to **LCFS FF56-2**.

1190. Comment: **LCFS SF7-3**

This comment is related to the adjustments of LCFS credits and deficits accrued by the fuel producer over the two-year provisional pathway period by the Executive Officer. The Commenter concurs with the proposed method to adjust the CI and further suggests use of pilot plant data.

Agency Response: The Commenter concurs with the proposed method used by the Executive Officer to adjust the CI or inform the producer that the provisional CI has been successfully corroborated by operational records covering a full two years of commercial operation, and further adjust the number of credits or reverse any provisional credit in the producer's account. The Commenter's suggestion to use pilot or demonstration plant data in lieu of actual operating data from the fuel production facility with provisional certification will not suffice (due to concerns of process scalability, and reliability) for staff to assess life cycle analysis of GHG impacts of the fuel pathway based on actual operational data. See also **LCFS FF56-2**.

1191. Comment: **LCFS SF7-4**

This Comment is related to third-party engineering evaluation and facility visit to corroborate plant design and operating conditions.

Agency Response: ARB staff agrees and has made 15-day changes to address the concern. See response to **LCFS FF15-1**.

The following letter was submitted to the LCFS Docket during the Second 15-day comment period.

This page intentionally left blank.

Growth Energy's Comments on June 23, 2015, 15-Day Notice for the Proposed Revisions to the LCFS Regulation

Growth Energy submits the following comments on the California Air Resources Board's ("CARB") June 23, 2015 Notice of Public Availability of Modified Text and Availability of Additional Documents (the "Second 15-Day Notice") for CARB's proposed revisions to the Low Carbon Fuel Standard (the "LCFS regulation").

The Second 15-Day Notice represents the second time CARB staff has performed substantive modifications to the proposed LCFS regulation since it initially circulated an Initial Statement of Reasons (the "ISOR") and an Environmental Analysis ("EA") for public review on December 30, 2014. The first 15-day notice was circulated for public review on June 4, 2015 (the "First 15-Day Notice").

Due to various concerns regarding the LCFS regulation, Growth Energy submitted comments on the ISOR and the EA during the first comment period, as well as the comment period for the First 15-Day Notice, under the California Environmental Quality Act, the California Administrative Procedures Act, and the Health & Safety Code. In addition to the issues raised previously, Growth Energy submits the following comments on the Second 15-Day Notice. Submitted with these comments are the declarations of James C. Lyons and Thomas L. Darlington, which are enclosed as Attachments "A" and "B," respectively.

A. CARB's LUC Value for Cane Ethanol of 11.8 gCO_2e/MJ Is Not Supported By Substantial Evidence, and Could Increase Greenhouse Gas Emissions

CARB's proposed revisions to the LCFS regulation contemplate a land use change ("LUC") value for cane ethanol of 11.8 gCO_2e/MJ, which is a significant departure from the 46 gCO_2e/MJ value stated in the original LCFS regulation. As explained in the Declaration of Thomas L. Darlington, which is provided as Attachment B, the substantial drop in LUC emissions for cane ethanol relates to CARB's estimate of the "perennial reversion GHG emissions" associated with cane. (Darlington ¶ 4.) "These emissions describe the carbon stored in a field when cane is planted after forest is removed for cane." (*Id.*)

Although CARB has produced a report describing the emissions released when various types of land are converted from one use to another, the report contains "no documentation or description for the perennial reversion emissions for various perennials, including cane" ethanol. (Decl. Darlington ¶ 5 [citing *Agro-Ecological Zone Emission Factor Model (v52)*, Plevin, Gibbs, Duffy, *et al.*, December 11, 2014.].) Appendix I of the ISOR likewise does not contain this information. (*Id.*) Because this information has not been provided, and is nowhere available in the public record, experts in the field are unable to "review how the cane LUC emissions were developed." (*Id.*) LCFS SF8-1

Growth Energy's expert, Thomas L. Darlington, has made several attempts to receive this information from CARB, to no avail. Among other things, Mr. Darlington has emailed CARB on several occasions to determine how ARB estimated these emissions. Yet, no substantive information regarding how CARB developed its estimate of the "perennial reversion GHG emissions" was provided. Thus, CARB has either failed to include documents in the rulemaking filed under Section 11347.3(b) of the Government Code, or CARB's LUC for cane ethanol is not based on any evidence, data, or study, and is thus arbitrary and capricious.

CARB's failure to support the 11.8 gCO_2e/MJ LUC value for cane ethanol also raises significant questions about the adequacy of CARB's environmental findings. Growth Energy considers the use of indirect LUC factors in the LCFS regulation to be generally unsound. Nevertheless, CARB has decided to include LUC factors as a component of the Carbon Intensity ("CI") Value placed on a fuel by CARB. If CARB inaccurately calculates the LUC (and thus the CI Value) of a fuel—such as sugarcane ethanol—as being too low, it will make more difficult the task of achieving reductions in greenhouse gas emissions, which is the purpose of the LCFS regulation. By reducing the CI value assigned to sugarcane ethanol below a level that is scientifically supportable relative to other renewable fuels, CARB is incentivizing the use of fuels that do not provide the maximum GHG reductions in a cost-effective manner. The LCFS regulation will create incorrect "market signals" contrary to the intended effect of the overall LCFS program.[1] LCFS SF8-1 cont.

To avoid these potential adverse consequences, and to develop LUC Values (and thereby CI Values) that are based on scientific data, CARB should produce the evidence, data, or study upon which its estimate of the "perennial reversion GHG emissions" for cane was based, (assuming such information exists), and recirculate the revised LCFS regulation for public comment.

B. CARB Staff Failed to Disclose Material Information Regarding the Proposed LCFS Regulation to the California Environmental Policy Council

Prior to the June 23, 2015, public hearing by the California Environmental Policy Council ("CEPC") on the LCFS regulation, Growth Energy and Western States Petroleum Association ("WSPA") submitted written comments on the multimedia evaluation ("MME") prepared for the LCFS regulation. Those written comments are included as Exhibits "F" and "G" to the Lyons Declaration, which is enclosed with these comments as Attachment B.[2] The comments specifically reference flaws in both CARB's proposed MME and the peer review process: (1) the failure ***of the MME*** to assess the environmental impacts of di-tertiary butyl peroxide (DTBP) at higher concentrations than the presently; (2) incorporation ***in the MME*** of an obsolete and incomplete analysis of air quality impacts associated with biodiesel that has been superseded by an analysis CARB staff performed for the ADF rulemaking; and (3) CARB staff's failure to provide ***the MME's peer reviewers*** with all of the relevant scientific information and data available to CARB staff related to air quality impacts associated with biodiesel. The LCFS SF8-2

1 See CARB, "Staff Report: Initial Statement of Reasons, Proposed Regulation to Implement the Low Carbon Fuel Standard," Vol. I at VI-20 (March 5, 2006), available at http://www.arb.ca.gov/fuels/lcfs/030409lcfs_isor_vol1.pdf.

2 The comments stated in Exhibits "F" and "G" to the Lyons Declaration are incorporated into this letter as if set forth fully herein.

comment letter submitted by Growth Energy also referenced a proposed alternative to CARB staff's proposed ADF regulation that would ensure no NOx increases would occur.

Although the comments submitted by Growth Energy and WSPA relate directly to the MME, CARB staff did not summarize those comments to the CEPC. Rather, CARB staff at the June 23, 2015 hearing represented to the CEPC that Growth Energy's and WSPA's comments were "not particularly relevant." After CARB's Assistant Chief Counsel subsequently corrected CARB staff's statements, and conceded that the comments "did pertain to the Multi-Media Evaluation," CARB staff then asserted the comments "did nothing to alter the CARB findings being presented to the CEPC." (Decl. Lyons ¶ 6.) Although CARB staff was asked at several points by CEPC Chair Matthew Rodriquez about the comments, CARB staff preempted a serious discussion of the concerned raised by Growth Energy and WSPA by the CEPC.

LCFS SF8-2 cont.

As a result of these flaws, CARB did not fully discharge its duty under Section 43830.8 of the Health and Safety Code. Among other things, Section 43830.8 requires a "multimedia evaluation" to be based on (i) "the best available scientific data," (ii) "written comments submitted by any interested person," and (iii) "information collected by the state board in preparation for rulemaking." As explained in the comments of Growth Energy and WSPA, CARB complied with none of these requirements, and instead chose to ignore the best available scientific data, concealed arguments submitted in written comments, and declined to disclose more recent information collected by the state board itself. Because CARB failed to comply with its procedural mandate under Section 43830.8, CARB cannot adopt the LCFS regulation at this time.

ATTACHMENT A

Declaration of James M. Lyons

STATE OF CALIFORNIA

BEFORE THE AIR RESOURCES BOARD

Declaration of James M. Lyons

I, James Michael Lyons, declare as follows:

1. I make this Declaration based upon my own personal knowledge and my familiarity with the matters recited herein. It is based on my experience of nearly 30 years as a regulator, consultant, and professional in the field of emissions and air pollution control. A copy of my résumé can be found in Exhibit "A."

2. I am a Senior Partner of Sierra Research, Inc., an environmental consulting firm located at 1801 J Street, Sacramento, California owned by Trinity Consultants, Inc. Sierra specializes in research and regulatory matters pertaining to air pollution control, and does work for both governmental and private industry clients. I have been employed at Sierra Research since 1991. I received a B.S. degree in Chemistry from the University of California, Irvine, and a M.S. Degree in Chemical Engineering from the University of California, Los Angeles. Before joining Sierra in 1991, I was employed by the State of California at the Mobile Source Division of the California Air Resources Board (CARB).

3. During my career, I have worked on many projects related to the following areas: (1) the assessment of emissions from on- and non-road mobile sources, (2) the assessment of the impacts of changes in fuel composition and alternative fuels on engine emissions including emissions of green-house gases, (3) analyses of the unintended consequences of regulatory actions, and (4) the feasibility of compliance with air quality regulations.

4. I have testified as an expert under state and federal court rules in cases involving CARB regulations for gasoline, Stage II vapor recovery systems and their design, factors affecting emissions from diesel vehicles, evaporative emission control system design and function, as well as combustion chamber system design. While at Sierra I have acted as a consultant on automobile air pollution control matters for CARB and for the United States Environmental Protection Agency. I am a member of the American Chemical Society and the Society of Automotive Engineers and have co-authored nine peer-reviewed monographs concerned with automotive emissions, including greenhouse gases and their control. In addition, over the course of my career, I have conducted peer-reviews of numerous papers related to a wide variety of issues associated with pollutant emissions and air quality.

5. This Declaration identifies significant omissions by CARB staff in providing relevant information to the California Environmental Policy Council (CEPC) during the Council's Public Meeting of June 23, 2015. These omissions include (1) the failure of LCFS SF8-3

CARB staff to accurately summarize written comments related to the Multi-Media Evaluation (MME) of biodiesel[1] submitted to the CEPC, and (2) the failure of CARB staff to make the CEPC aware during the meeting of alternatives that would be more environmentally protective than the proposed Alternative Diesel Fuel regulation and therefore the Low Carbon Fuel Standard (LCFS) regulation. A complete electronic video recording of the June 23, 2015 CEPC meeting, which I received from CEPC, has been submitted along with this Declaration and is referred to here as Exhibit "B." In addition, the briefing presentation,[2] staff presentation,[3] and draft resolution[4] that was ultimately approved by the CEPC on June 23, can be found in Exhibits "C," "D," and "E," respectively, to this Declaration. LCFS SF8-3 cont.

6. Both Growth Energy[5] and the Western States Petroleum Association (WSPA)[6] submitted written comments to the CEPC (see Exhibits "F" and "G," respectively, to this Declaration). The sole summary of the written comments submitted by Growth Energy can be found on page 90 of the staff presentation contained in Exhibit "D." As can be seen, there is no substantive summary of either the Growth Energy or WSPA comments. During a discussion of these comments[7] involving CEPC Chair, Matthew Rodriquez, and CARB staff member Jim Aguila, both sets of comments were deemed to be "not particularly relevant." However, later in the proceeding,[8] Stephen Adams, Assistant Chief Counsel of CARB, acknowledged that at least portions of the Growth Energy and WSPA comments "did pertain to the Multi-Media Evaluation" and provided two limited examples from the comments to illustrate that point. Mr. Rodriquez then returned to the issue of the relevance of the Growth Energy and WSPA comments[9] and, in response to his question, was told by CARB that they did nothing to alter the CARB findings being presented to the CEPC. LCFS SF8-4

[6] See http://www.calepa.ca.gov/cepc/2015/BoydWSPA.pdf

[7] This discussion takes place between about 1:44 and 1:46 of the runtime of the recording submitted as Exhibit "B."

[8] This discussion takes place between about 1:53 to 1:55 of the runtime of the recording submitted as Exhibit "B."

[9] This discussion takes place between about 1:57 and 1:58 of the runtime of the recording submitted as Exhibit "B."

7. As documented through the video recording of the June 23, 2015 CEPC public meeting, the CEPC was relying on CARB staff to summarize both the substance and import of the written comments received from Growth Energy and WSPA. As indicated by Mr. Adams, these comments did pertain to the biodiesel MME and, based on my expertise, should be considered by any entity claiming to have reached a conclusion "based on the best available scientific information and public comments received," as is stated in the CEPC resolution. More specifically, issues raised in the Growth Energy and WSPA comments and directly germane to the environmental impacts of biodiesel, but not presented to the CEPC by CARB, include the following:

- Failure of the MME to comprehensively assess the environmental impacts of the use of di-tertiary butyl peroxide (DTBP) at much higher concentrations than it is currently used; LCFS SF8-5
- Incorporation in the MME of an obsolete and incomplete analysis of the air quality impacts associated with the use of biodiesel, which was superseded by the analysis CARB staff actually performed for the ADF rulemaking; LCFS SF8-6
- Failure of CARB staff to provide the peer reviewers of the biodiesel MME with all of the relevant scientific information and data that were available to CARB staff and related to the air quality impacts associated with biodiesel; and that LCFS SF8-7
- Growth Energy has proposed an alternative to the staff's proposed ADF regulation that would ensure that increases in NOx emissions would not occur in California due to the use of biodiesel. LCFS SF8-8

12. In summary, in my opinion, the flaws in the biodiesel MME identified in the written comments supplied by Growth Energy and WSPA to the CEPC render it unsuitable to support a finding that there will be no significant adverse environmental impact from the use of biodiesel in California. Given that the CEPC has relied on the biodiesel MME, its findings regarding the environmental impact of biodiesel use in California are similarly flawed. LCFS SF8-9

I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct.

Executed this 8th day of July, 2015 at Sacramento, California.

JAMES M. LYONS

8_SF_LCFS_GE (Page 1 – 7)

1192. Comment: **LCFS SF8-1, LCFS SF8-2, LCFS SF8-5 through LCFS SF8-9**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

1193. Comment: **LCFS SF8-3**

Furthering its comment **SF8-2** [that ARB did not comply with section 43830.8 of the Health and Safety Code], the commenter attaches the Lyons declaration arguing that ARB failed to provide the CEPC with an accurate summary of written comments regarding the MME, and failed to inform the CEPC regarding alternatives the commenter claims would be more environmentally protective than the proposed ADF.

Agency Response: ARB staff disagrees; the ample record before the CEPC allowed the CEPC to fulfill its role under section 43830.8 of the Health and Safety Code. That record is too voluminous to include in this response, but it is publicly available, and the Board found that the MME process was regularly conducted and approved as required by section 43830.8 of the Health and Safety Code.

1194. Comment: **LCFS SF8-4**

The commenter asserts that the written comments to the CEPC were not adequately summarized in the staff's presentation to that body, and further assumes that the CEPC did not consider comments submitted to it.

Agency Response: This comment seems directed primarily at the actions of the CEPC, which is a separate body from ARB, and thus does not require response. However, as the comment itself shows, the written comments to the CEPC were discussed at the CEPC meeting. Further, the CEPC considered those comments and expressly indicated it had done so: "WHEREAS, the Council received and considered written comments submitted on June 22, 2015 by Growth Energy and by the Western States Petroleum Association, and also received and considered comments from interested parties at the June 23, 2015 meeting of the Council." The CEPC also "RESOLVED, that after review of the biodiesel multimedia evaluation and the proposed ADF regulation, and based on the best available scientific information and public comments received, the Council determines that the use of biodiesel in California consistent with the proposed ADF regulation will not pose a significant adverse impact on public health or the environment compared to CARB diesel fuel."

The CEPC meeting notice specifically requested that written comments be submitted in advance of the hearing precisely so the CEPC members had time to consider them prior to taking action. The written comments were in fact received before the day of the hearing and were provided to CEPC members for their consideration. Council members also listened to oral comments made at the hearing itself prior to taking action. There is no legal requirement that staff separately summarize written or oral comments submitted to the CEPC, and those submitting written comments could have appeared at the hearing to summarize their written comments if they chose to do so, but elected not to.

The commenter appears to ask ARB to disbelieve CEPC's assertion that it considered the written comments presented to it. Setting aside whether ARB could do so, the comment provides no basis to conclude that CEPC's clear findings are erroneous.

Résumé

James Michael Lyons

Education

1985, M.S., Chemical Engineering, University of California, Los Angeles

1983, B.S., Cum Laude, Chemistry, University of California, Irvine

Professional Experience

4/91 to present — Senior Engineer/Partner/Senior Partner
Sierra Research

Primary responsibilities include oversight and execution of complex analyses of the emission benefits, costs, and cost-effectiveness of mobile source air pollution control measures. Mr. Lyons has developed particular expertise with respect to the assessment of control measures involving fuel reformulation, fuel additives, and alternative fuels, as well as accelerated vehicle/engine retirement programs, the deployment of advanced emission control systems for on- and non-road gasoline- and Diesel-powered engines, on-vehicle evaporative and refueling emission control systems, and Stage I and Stage II service station vapor recovery systems. Additional duties include assessments of the activities of federal, state, and local regulatory agencies with respect to motor vehicle emissions and reports to clients regarding those activities. Mr. Lyons has extensive litigation experience related to air quality regulations, product liability, and intellectual property issues.

7/89 to 4/91 — Senior Air Pollution Specialist
California Air Resources Board

Supervised a staff of four professionals responsible for identifying and controlling emissions of toxic air contaminants from mobile sources and determining the effects of compositional changes to gasoline and diesel fuel on emissions of regulated and unregulated pollutants. Other responsibilities included development of new test procedures and emission standards for evaporative and running loss emissions of hydrocarbons from vehicles; overseeing the development of the state plan to control toxic emissions from motor vehicles; and reducing emissions of CFCs from motor vehicles.

4/89 to 7/89 — Air Pollution Research Specialist
California Air Resources Board

Responsibilities included identification of motor vehicle research needs; writing requests for proposals; preparation of technical papers and reports; as well as monitoring and overseeing research programs.

9/85 to 4/89 — Associate Engineer/Engineer
California Air Resources Board

Duties included analysis of vehicle emissions data for trends and determining the effectiveness of various types of emissions control systems for both regulated and toxic emissions; determining the impact of gasoline and diesel powered vehicles on ambient levels of toxic air contaminants; participation in the development of regulations for "gray market" vehicles; and preparation of technical papers and reports.

Multimedia Workgroup

Briefing for Council Members

Multimedia Evaluations of Biodiesel and Renewable Diesel

June 2015

Why is ARB Interested in Biodiesel and Renewable Diesel?

- Both are low carbon and renewable fuels
- Air quality benefits in toxics, PM, HC, CO_2
- Key strategies for Low Carbon Fuel Std.
- 2030 goal of 40% GHG reduction
- 2030 goal of 50% reduction in petroleum use
- Federal Renewable Fuel Standard 2

Multimedia Evaluation (MME)

- Definition – *Identification and evaluation of **any significant adverse impact** on public health or the environment, including air, water, or soil, that may result from the production, use, or disposal of the motor vehicle fuel that may be used to meet the state board's motor vehicle fuel specifications.* (HSC 43830.8)

- Requirements
  - ✓ MME required before motor vehicle fuel specifications are established
  - ✓ Must address:
    - – *Emissions of air pollutants*
    - – *Contamination of surface water, groundwater, and soil*
    - – *Disposal or use of byproducts and waste materials*
  - ✓ Summary of MME – Multimedia Working Group (MMWG) Staff Report
  - ✓ External Scientific Peer Review
  - ✓ CA Environmental Policy Council (CEPC) Review
  - ✓ CEPC determination of significant impact, less adverse alternatives

CEPC and MMWG

- CEPC
  - Established pursuant to Public Resources Code 71017
  - Council Members
    - *Matthew Rodriquez*, Agency Secretary
    - *Mary D. Nichols*, Chairman, ARB
    - *Lauren Ziese*, Acting Director, OEHHA
    - *Felicia Marcus*, Chairman, Waterboard
    - *Barbara A. Lee*, Director, DTSC
    - *Brian R. Leahy*, Director, DPR
    - *Caroll Mortensen*, Director, CalRecycle

- MMWG
  - Oversees MME process
  - Reviews reports; prepares MME Staff Report
  - Makes recommendations to CEPC
  - Members: ARB, DTSC, OEHHA, Waterboard, OSFM

California Environmental Policy Council Shall:

Determine whether proposed regulation will cause significant adverse impact on public health or environment, whether less-adverse alternatives exist

- No significant adverse impact and no less-adverse alternatives – No further action dictated
- Significant adverse impact or less harmful alternatives exist – Council recommends alternative measures to reduce impacts

ARB MMEs Considered by CEPC

- 2011 – Viscon-Treated Diesel Fuel as verified Diesel Emission Control strategy (vDECS)
- 2004 – PuriNOx-Treated Diesel Fuel as vDECS
- 2004 – Amendments to the California Diesel Fuel Regulations
- 1999 – Ethanol Used in California Reformulated Gasoline

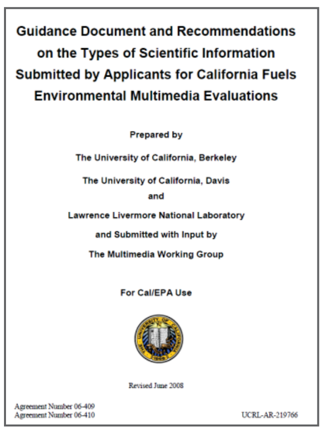
Procedural Requirements/Elements

- Bagley-Keene Act applies to EPC:
  - Agenda and notice must be published by June 12
  - Limits on discussions between EPC members
- CEQA does not apply:
  - Ultimate approval authority lies with ARB, not EPC
  - Impact analysis of MME varies from CEQA analysis
- Conduct of hearing:
  - Legal adviser to EPC (TBD)
  - Each BDO on MMWG will have a presentation
  - Staff will respond to questions from EPC members, but not directly to public comment unless EPC members asked for staff response

Multimedia Evaluation Process

Tier I
Work Plan

Work Plan
- Define framework and scope
- Identify key knowledge gaps
- Feedback provided



Guidance Document and Recommendations on the Types of Scientific Information Submitted by Applicants for California Fuels Environmental Multimedia Evaluations

Prepared by
The University of California, Berkeley
The University of California, Davis
and
Lawrence Livermore National Laboratory
and Submitted with Input by
The Multimedia Working Group

For Cal/EPA Use

Revised June 2008

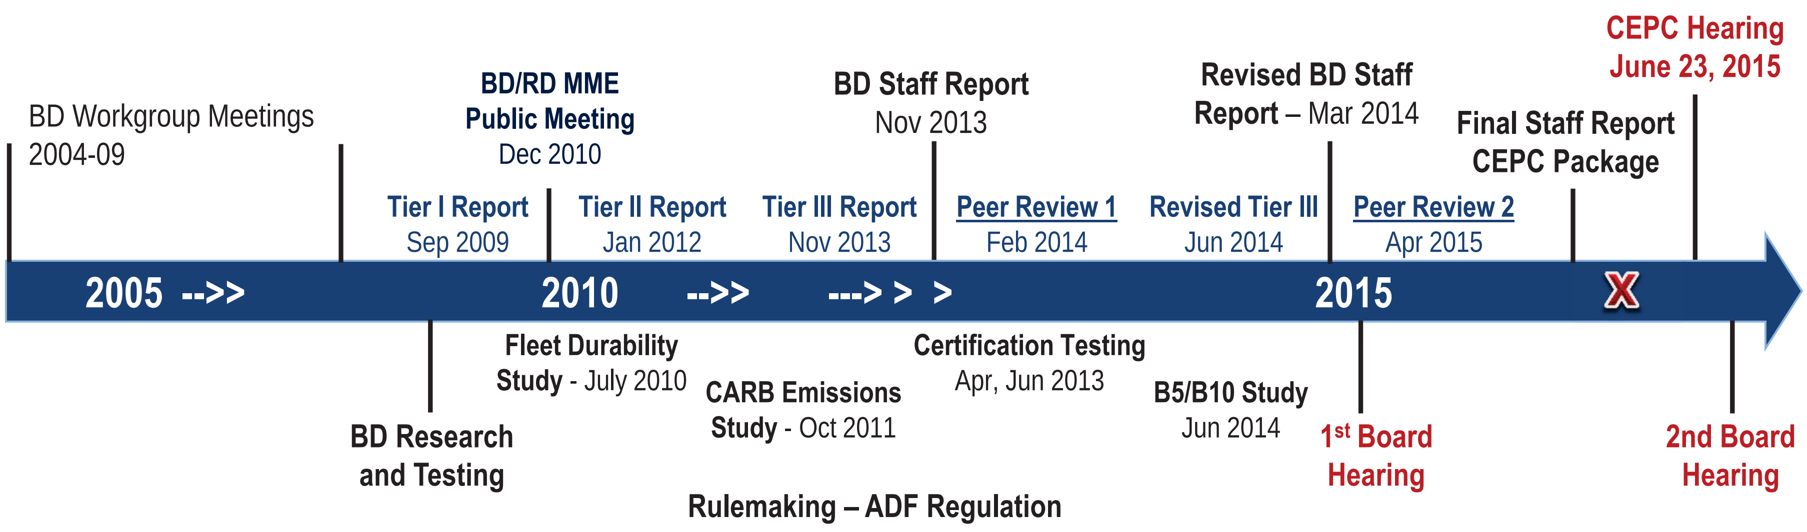
- Final report used as basis for MMWG recommendations

Tier III
Multimedia Risk Assessment Final Report

Multimedia Evaluation Guidance Document , June 2008

Biodiesel Overview



13 Contracts and Grants – Biodiesel Research Studies, Testing, and Multimedia Evaluation

- Contractors/Recipients – UCD, UCB, UCR
- Total Funding ~ $3 million

Biodiesel Peer Review Process

- Initial Peer Review: Nov 2013 - Feb 2014
  - 7 reviewers; 4 areas of expertise (air, water, soil, public health)
  - Support MMWG conclusions, which are based on sound scientific knowledge, methods, and practices
  - 2 reviewers provided emerging public health information on oxidative stress and inflammation
  - New B5/B10 Biodiesel Study published June 2014, ARB updated ADF Regulation
- Supplemental Peer Review: Dec 2014 - Apr 2015
  - 4 original reviewers; 2 areas of expertise (air, public health)
  - Limited to OEHHA public health evaluation (oxidative stress and inflammation) and new B5/B10 Biodiesel Study
  - Confirm support of MMWG conclusions

Biodiesel Conclusions

Air:

ARB concludes that with in-use requirements, BD, as specified in the MME and proposed regulation, does not pose a significant adverse impact on public health or the environment from potential air quality impacts.

Water:

Water Board concludes that given the information provided by the UC researchers, biodiesel presents minimal additional risks to beneficial uses of CA waters than that posed by CARB diesel. Water Board supports the MME of BD, which meets the ASTM specifications, and the finding of no significant adverse impact on public health or the environment.

Biodiesel Conclusions (*Continued*)

Public Health:

OEHHA concludes that the information currently available indicates a reduction in cancer risk from the use of biodiesel and a reduction in GHG emissions, which are associated with a myriad of environmental and public health impacts. It is difficult to state with certainty that the use of BD will decrease cardiovascular or respiratory health risks because of the uncertainty introduced by recent studies that provide some evidence for increased oxidative stress and inflammatory response to BD emissions relative to petroleum diesel particles on a mass basis. The reduction in PM and other emissions may offset this potential increased inflammatory response. CEPC may want to emphasize in its determination the continued importance of emissions controls for BD fueled engines, as has been the emphasis for petroleum diesel fuel engines.

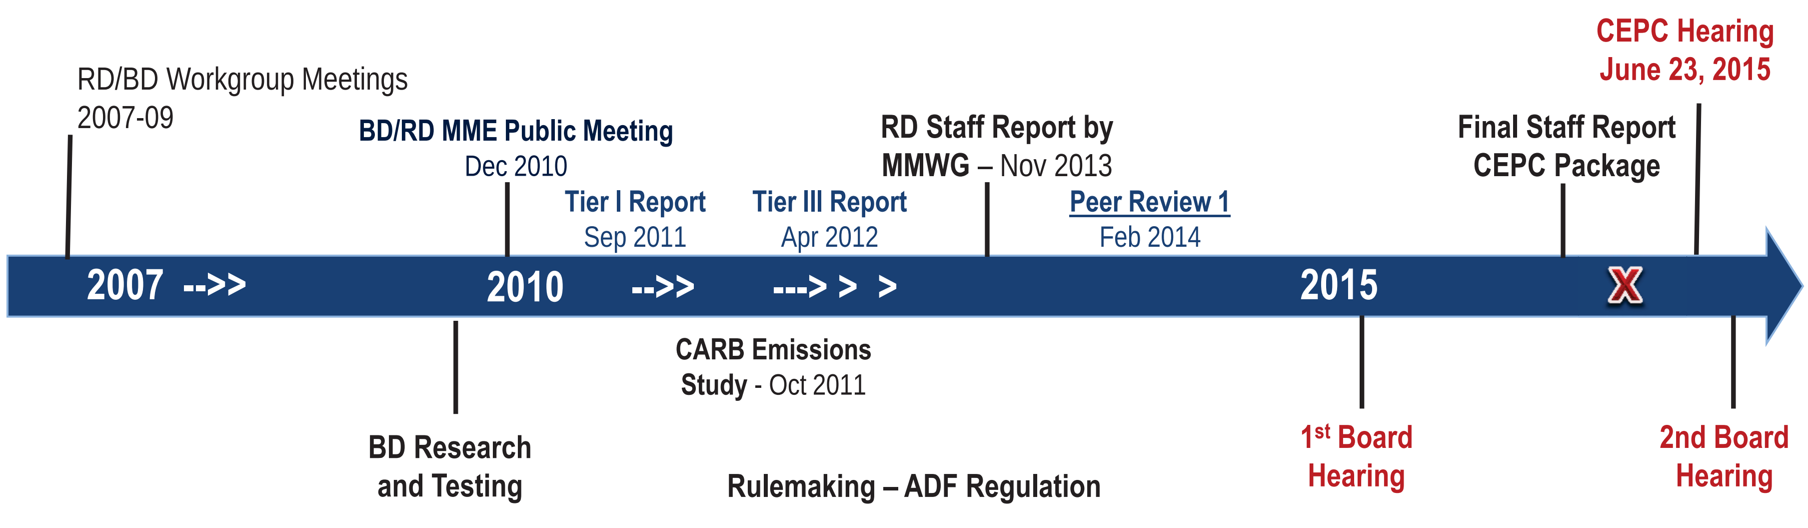
Soil and Hazardous Waste:

DTSC concludes that BD aerobically biodegrades more readily than CARB diesel. Also, some additized biodiesel preliminarily has a higher aquatic toxicity for a small subset of tested species, but further testing is needed to determine a causal relationship. In general, BD has no significant difference in vadose zone infiltration rate. BD's infiltration rate from animal fat appeared to be similar to CARB diesel. However, biodiesel left a noticeable increase in the residual's vertical dimension and spread less extensive horizontally.

Biodiesel Recommendations

- Use of biodiesel does not pose a significant adverse impact compared to CARB diesel fuel
- Conditions
  - Must meet ADF requirements
  - Review:
    - Any new BD formulations/additives
    - New oxidative stress and inflammation literature
    - BD use in light of emerging information

Renewable Diesel Overview



4 Contracts and Grants – RD Elements of BD Research Studies and Testing, and RD Multimedia Evaluation

- Contractors/Recipients – UCD, UCB, UCR
- Total Funding ~ $1 million

Renewable Diesel Peer Review

Peer Review: <u>Nov 2013 - Feb 2014</u>

- 7 reviewers; 4 areas of expertise (air, water, soil, public health)
- Support MMWG conclusions, which are based on sound scientific knowledge, methods, and practices
- No issues raised

Renewable Diesel Conclusions

Air:

Based on a relative comparison between CARB diesel and hydrotreated vegetable oil renewable diesel (HVORD), ARB staff concludes that the use of renewable diesel and the resulting air emissions do not pose a significant adverse impact on public health or the environment.

Water:

Waterboard staff concludes that given the information provided by the UC researchers, and the similarities of renewable diesel and CARB diesel, renewable diesel presents minimal additional risks to beneficial uses of California waters than that posed by CARB diesel alone. Waterboard staff supports the multimedia evaluation of renewable diesel that meets ASTM D975 and the finding of no significant adverse impacts on public health or the environment.

Renewable Diesel Conclusions

Public Health:

OEHHA scientists conclude that use of renewable diesel fuel produced by hydrotreating fatty acids from vegetable oil may reduce the amount of PM and aromatic organic chemicals that is released into the atmosphere in diesel engine exhaust.

Soil and Hazardous Waste:

In comparing renewable diesel with CARB diesel, DTSC's review concludes that the chemical compositions of renewable diesel are almost identical to that of CARB diesel. Therefore, the impacts on human health and the environment in the case of a spill to soil, groundwater, and surface waters would be expected to be similar to those of CARB diesel. Based on the current production, use, transportation, and storage of renewable diesel in California, renewable diesel will not increase the potential negative impacts to human health and the environment.

Renewable Diesel Recommendations

- Use of renewable diesel does not pose a significant adverse impact
- Conditions
  - Must meet CARB diesel specifications
  - Review:
    - New RD formulations/additives
    - RD use in light of emerging information

Proposed Alternative Diesel Fuel (ADF) Regulation

- Creates pathway for commercialization of emerging ADF
- Establishes Biodiesel specifications as ADF
- In-use requirements to preclude NOx increase from legacy fleet
- RD can be used to mitigate NOx from BD
- Exemption for advanced new technology diesel engines with selective catalytic reduction
- Sunset for in-use requirements in 2022 timeframe

Proposed Schedule

TASK	DATE
CEPC Briefings	Late May - Early June
Hearing Notice Released to Public	June 12
Final CEPC Hearing Documents Due to Cal/EPA	June 16
CEPC Hearing	**June 23, 2015**
ARB Hearing on Proposed ADF Regulation	**July 23, 2015**

This page intentionally left blank.

Exhibit D to Declaration of James M. Lyons

Public Meeting of the California Environmental Policy Council

MULTIMEDIA EVALUATION OF BIODIESEL AND RENEWABLE DIESEL

June 23, 2015

Agenda

- Fuels Multimedia Evaluation
- Biodiesel Fuel
  - Individual Agency Presentations: ARB, State Water Board, OEHHA, DTSC
  - Summary of External Peer Review
  - Recommendations
- Renewable Diesel Fuel
  - Individual Agency Presentations: ARB, State Water Board, OEHHA, DTSC
  - Summary of External Peer Review
  - Recommendations
- Proposed Alternative Diesel Fuel Regulation
- Public Comments
- Council Consideration

Multimedia Evaluation

Health & Safety Code 43830.8

- Definition – *Identification and evaluation of* ***any significant adverse impact*** *on public health or the environment, including air, water, or soil, that may result from the production, use, or disposal of the motor vehicle fuel that may be used to meet the state board's motor vehicle fuel specifications. (Health & Safety Code §43830.8(b))*

- Requirements
  - ✓ Required before ARB establishes motor vehicle fuel specifications
  - ✓ Must address:
    - *Emissions of air pollutants*
    - *Contamination of surface water, groundwater, and soil*
    - *Disposal or use of byproducts and waste materials*
  - ✓ Summary of Evaluation – Multimedia Working Group (MMWG) Staff Report
  - ✓ External Scientific Peer Review
  - ✓ CA Environmental Policy Council (CEPC) Review
  - ✓ CEPC determination of significant impact, less adverse alternatives

California Environmental Policy Council Shall:

Determine whether proposed regulation will cause significant adverse impact on public health or environment

- No significant adverse impact and no less-adverse alternatives – No further action dictated

- Significant adverse impact or less harmful alternatives exist – Council recommends alternative measures to reduce impacts

Multimedia Working Group (MMWG)

- Oversees multimedia evaluation process
- Makes recommendations to CEPC
- Members:
  - ARB
  - DTSC
  - OEHHA
  - State Water Board
  - Other agencies consulted as needed

MMWG Responsibilities

- **ARB** – Lead agency, Evaluate air quality impacts
- **State Water Board** – Assess surface water and ground water impacts
- **OEHHA** – Evaluate potential public health impacts
- **DTSC** – Evaluate potential soil and hazardous waste concerns

Evaluation Uses Rigorous Scientific Process

CEPC Action Needed

- MMWG prepares summary report
- Summary report and proposed ARB regulation subject to peer review
- CEPC reviews proposed regulation and summary report
- CEPC makes determination

Agenda

- Fuels Multimedia Evaluation
- Biodiesel Fuel
  - Individual Agency Presentations: ARB, State Water Board, OEHHA, DTSC
  - Summary of External Peer Review
  - Recommendations
- Renewable Diesel Fuel
  - Individual Agency Presentations: ARB, State Water Board, OEHHA, DTSC
  - Summary of External Peer Review
  - Recommendations
- Proposed Alternative Diesel Fuel Regulation
- Public Comments
- Council Consideration

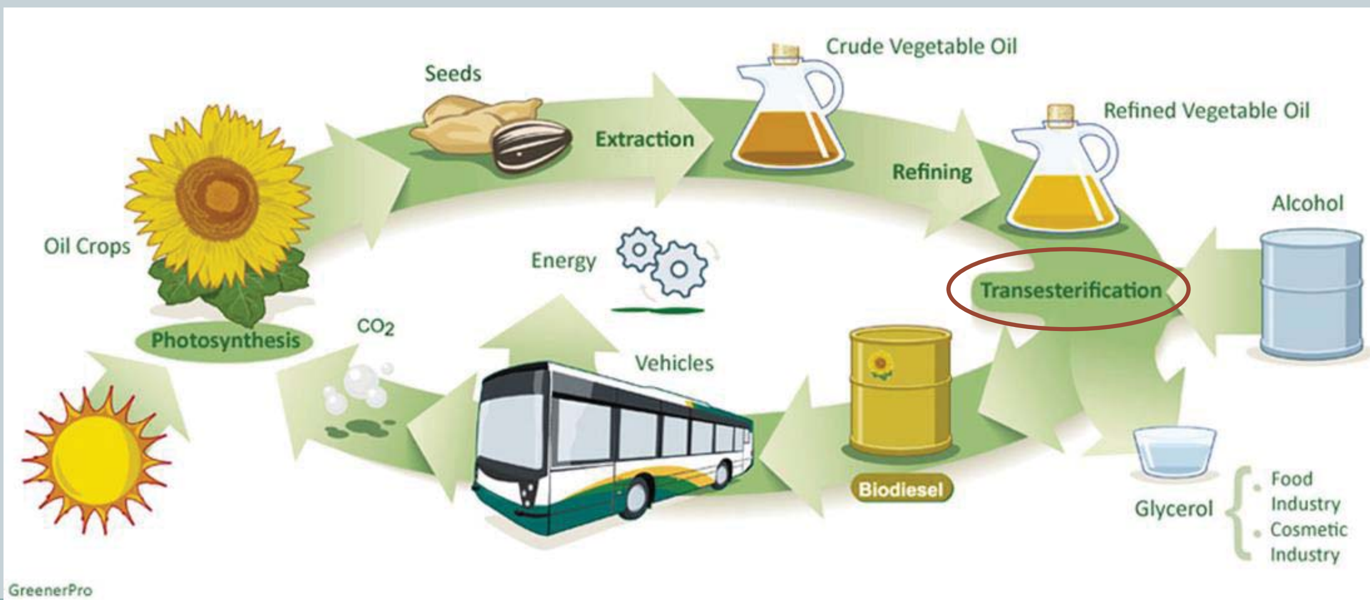
Biodiesel Fuel

- *What is Biodiesel?*
  - Fatty acid methyl ester

  - Derived from renewable feedstocks
    - Vegetable Oil – Soy, Palm, Corn, Canola, Safflower
    - Animal Fat – Tallow
  - Meets ASTM International Standards
    - D975 – B5
    - D7467 – B6 to B20
    - D6751 – B100

Biodiesel Fuel (*Continued*)

- *How is it Produced?*
  - Transesterifcation – Feedstock is reacted with alcohol in presence of a catalyst to produce glycerin and methyl esters (biodiesel)
  - Produced on relatively small scale



Biodiesel Fuel (*Continued*)

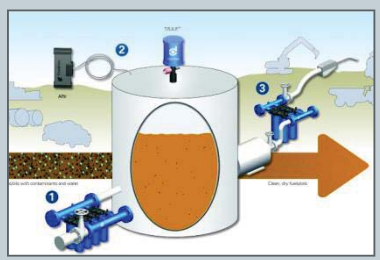
- *How is Biodiesel Transported and Distributed?*

Production Plant

Bulk Terminal

Refueling Station

- *How is Biodiesel Stored?*



Beneficial Aspects of Biodiesel

- Low carbon, renewable, alternative diesel fuel
- Reduces GHG – Supports 2030 and 2050 goals
- Reduces PM, CO, and air toxic emissions
- Key fuel supporting LCFS and Federal RFS2
- Reduces petroleum use – Supports 2030 goal
- Energy security – Feedstocks primarily sourced in U.S.

Air Quality Evaluation

Jim Aguila - ARB

Air Quality Evaluation

- Comparative analysis – Biodiesel compared to CARB diesel
- Criteria pollutants – PM, THC, CO, NO, NOx
- Air toxic emissions – Diesel PM, other Toxics
- Greenhouse gas emissions – CO_2, CH4, others

Air Quality Conclusions

- Reduces PM, THC, CO and some air toxics
- Non-statistically significant increase in 1,2-nanthroquinone, acrolein
- Reduces health risk from PM in diesel exhaust
- Biodiesel is considered low carbon fuel and supports GHG emissions reductions

Air Quality Conclusions (*Continued*)

- Studies found environmental benefits associated with biodiesel compared to CARB diesel
- Slight increased NOx emissions at certain blend levels in older vehicles & equipment
- With in-use requirements biodiesel, as specified in multimedia evaluation and proposed ADF regulation, does not pose a significant adverse impact

Water Evaluation

Laura Fisher- State Water Board

Background and Limitations

- Consistent with University of California, Davis and University of California, Berkeley, Tier I, Tier II, and Tier III Reports the State Water Board staff evaluation is specific to differential environmental impacts between biodiesel and CARB diesel

Background and Limitations (*Continued*)

- State Water Board staff conclusions and recommendations for biodiesel have limited application as they are based on:
  - Fuel additives used during testing (approved additives currently used in CARB diesel)
  - Fuels which meet ASTM fuel specifications

Biodiesel

- Aquatic toxicity screening with biodiesel blends during the Biodiesel Tier II study by UC Davis exhibited somewhat increased toxicity to subsets of screened species compared to CARB diesel
- Both B100 and B20 mixtures caused variable effects on algae cell growth, water flea survival and reproduction and abalone shell development
- However, the chemical analyses did not unambiguously reveal any causative compound for the toxicity

Biodiesel (*Continued*)

- Multimedia Evaluation identifies that unadditized biodiesel and biodiesel blends consistently show increased biodegradation as compared to CARB diesel, and additized biodiesel and biodiesel blends can result in some decreased biodegradation
- These biodegradability scenarios are influenced by additives used and biodiesel blend concentration

Biodiesel (*Continued*)

- Information provided by University of California, Davis and University of California, Berkeley and material compatibility testing has demonstrated that biodiesel and biodiesel blends are incompatible with various products commonly used in California's existing underground storage tank infrastructure

Biodiesel (*Continued*)

- Incompatibility can increases the risk of unauthorized releases, therefore material selection in underground storage tank (UST) equipment and leak detection technology is important
- Material selection resulting in proper compatibility is a statutory and regulatory requirement
- Material compatibility is reviewed and approved by local permitting agencies and implemented by UST owners/operators

Biodiesel (*Continued*)

- State Water Board recently revised UST regulations allow:
  - Biodiesel blends up to B5 may be stored in both single or double-walled USTs
  - Biodiesel blends above B5 may be stored in double-walled USTs

State Water Board Staff Conclusions and Recommendations

Given:

- Information provided by University of California, Davis and University of California, Berkeley
- Stringent design, construction and operational criteria for USTs
- Office of State Fire Marshal finding that aboveground storage tanks in compliance with APSA and SPCC that store biodiesel pose no additional risk to the environment
- UST spills/releases from USTs in California are 4 times lower than the national average, and number of new releases reported each year continues to decrease
- When spills/releases do happen they typically occur on the surface, in the subsurface soil, and/or groundwater and are detected fairly quickly

State Water Board staff concludes that there are minimal additional risks to beneficial uses of California waters posed by biodiesel than that posed by CARB diesel alone

State Water Board Staff Conclusions and Recommendations (*Continued*)

- State Water Board staff supports the Multimedia Evaluation of biodiesel which meets ASTM fuel specifications, and the finding of no significant adverse impacts on public health or environment with the recommendations provided in the Biodiesel Multimedia Evaluation Staff Report

State Water Board Staff Conclusions and Recommendations (*Continued*)

- As identified in the California Biodiesel Multimedia Evaluation Report, Tier III, the potential scope of any unanticipated impacts is difficult to determine due to the limited funding and time of the Multimedia Evaluation, therefore:
  - It is State Water Board staffs recommendation that any unanticipated risks that may have a significant impact on public health, safety or environment, as full scale production and use of biodiesel becomes common, be addressed as they occur by reconvening the Multimedia Working Group

Public Health Evaluation

Dr. Page Painter - OEHHA

Dr. John Budroe - OEHHA

OEHHA Evaluation of Potential Biodiesel Public Health Impacts

OEHHA staff evaluated the potential public health impacts from the use of biodiesel based on:

- A review of toxicity data from the UC Tier reports
- Additional relevant studies comparing toxicity of emissions from petroleum diesel and biodiesel

The evaluation focuses on the relative toxicity differences between biodiesel and petroleum diesel.

Biodiesel/CARB Diesel Exhaust Comparisons

- Substitution of biodiesel for CARB diesel appears to reduce:
  - The rate of addition of carbon dioxide to the atmosphere
  - The amount of carcinogenic PM, benzene, ethyl benzene, and PAHs released into the atmosphere
- Biodiesel use may increase NOx emissions for certain blends.

Biodiesel/CARB Diesel Exhaust Comparisons

- Biodiesel combustion may produce higher levels of some toxic constituents (e.g. 1,2-napthoquinone and acrolein)
- Biodiesel exhaust may contain a larger proportion of total particles as ultrafine particles relative to petroleum diesel exhaust

Biodiesel Exhaust and Oxidative Stress/Inflammation

- Some recent data suggest that exposure to biodiesel combustion emissions may induce enhanced inflammatory and oxidative stress responses relative to petroleum diesel when measured on a PM mass basis

Biodiesel Exhaust and Oxidative Stress/Inflammation (*Continued*)

Experimental data interpretation uncertainties :

- Unclear whether biodiesel combustion emissions would be more potent at inducing oxidative stress/inflammation than petroleum diesel combustion emissions if compared on the basis of PM emissions per mile or per horsepower hour

Biodiesel Exhaust and Oxidative Stress/Inflammation (*Continued)*

Experimental data interpretation uncertainties:

- Different studies used different test conditions. Factors that affect toxicity of diesel emissions:
  - Type of engine
  - Test cycle
  - Biodiesel source
  - Type of petroleum diesel (e.g., CARB diesel, low sulfur Euro diesel, high sulfur diesel, etc.)
- Difficult to compare different studies

Biodiesel Exhaust and Oxidative Stress/Inflammation (*Continued*)

Experimental data interpretation uncertainties:

- Several studies showed increased emissions of carbonyls (oxidative stress-inducers) with certain biodiesel fuels while a few showed decreases
- Differences in study design make comparisons of study results difficult

Biodiesel Exhaust and Oxidative Stress/Inflammation (*Continued*)

- Comparisons of oxidative stress, or other toxicity, needs to be placed in the context of decreased overall emissions

- Oxidative stress is probably just one of the mechanisms involved in the toxicity of diesel exhaust emissions, which include respiratory and cardiovascular health effects, immunotoxicity, and carcinogenicity

Biodiesel Exhaust and Oxidative Stress/Inflammation (*Continued*)

- Further research is warranted to determine if exposure to biodiesel exhaust emissions results in an increase in oxidative stress and/or inflammation compared to CARB diesel exhaust emissions
- Such research would be most useful if performed using test conditions optimized for California (e.g. engine types, test cycles, fuels)

Biodiesel Exhaust Public Health Impacts: Conclusion

OEHHA cannot determine with certainty whether replacing petroleum diesel by biodiesel or biodiesel-petroleum diesel blends for on-road motor vehicle use will reduce adverse human health impacts attributable to oxidative stress and inflammation from toxic chemicals in diesel-engine emissions.

Biodiesel Exhaust Public Health Impacts: Conclusion

However, the information currently available to OEHHA indicates:

- A reduction in cancer risk from use of biodiesel
- A reduction in PM and greenhouse gas emissions, which are associated with myriad environmental and public health impacts

Hazardous Waste and Soil Evaluation

Donn Diebert - DTSC

DTSC Role in Multimedia Fuel Evaluation

- Hazardous Waste Evaluation:
  - Production and Handling
  - Product Properties
- Soil Evaluation:
  - Environmental Fate and Transport in Soil if Spill Occurs
  - Effects on Soil Cleanup of Hazardous Waste Release

Biodiesel Hazardous Waste Evaluation (Production and Handling)

- Potential releases during the production of Biodiesel include:
  - Hexane or CO2 released to the air during seed extraction from feed stocks
  - Potential for odors associated with waste biomass

Biodiesel Hazardous Waste Evaluation (Production and Handling)

- Accidental releases during the production and handling of Biodiesel include spills or leaks of:
  - Bulk feedstock oil (non-hazardous)
  - Chemicals used during production such as methanol, hexane, acid, base
  - Approved additive packages for CARB Diesel such as antioxidants, biocides, cold flow enhancers, urea, etc.

Biodiesel Hazardous Waste Evaluation (Production and Handling)

- CARB Diesel vs. Biodiesel
  - Pure biodiesel aerobically biodegrades more readily than CARB diesel
  - Some additized biodiesel preliminarily has a higher aquatic toxicity for a small subset of tested species

Biodiesel Soil Evaluation (Fate/Transport and Soil Clean Up)

- CARB Diesel vs. Biodiesel
  - Based on the testing, no significant differences in infiltration rate into the soil
    - Some preliminary tests indicated that Biodiesel tended to move faster in the vertical than horizontal direction
  - Break down of CARB Diesel and Biodiesel have similar aerobic break down properties
  - Environment cleanup actions and remediation for soil would be similar

DTSC's Conclusions

- Hazardous waste evaluation:
  - Product Properties of CARB Diesel vs. Biodiesel **- No Significant Difference**
- Soil evaluation:
  - Environmental fate and transport in soil if spill occurs of CARB Diesel vs. Biodiesel **- No Significant Difference**
  - Effects on hazardous waste soil cleanup of CARB Diesel vs. Biodiesel **- No Significant Difference**

External Scientific Peer Review

- Initial Peer Review: <u>Nov 2013 - Feb 2014</u>
  - 7 reviewers; 4 areas of expertise (air, water, soil, public health)
  - Support MMWG conclusions – Based on sound scientific knowledge, methods, and practices
  - 2 reviewers provided emerging public health information on oxidative stress and inflammation
  - New B5/B10 Biodiesel Study published June 2014, Updated ADF Regulation

External Scientific Peer Review (*Continued*)

- Supplemental Peer Review: Dec 2014 - Apr 2015
  - 4 original reviewers; 2 areas of expertise (air, public health)
  - Limited to updated OEHHA public health evaluation (oxidative stress and inflammation) and ARB air quality evaluation (new B5/B10 Biodiesel Study and updated regulation)
  - Confirm support of MMWG conclusions

Recommendations

MMWG recommends that the CEPC:

- Find that the use of biodiesel fuel in California, as specified in this multimedia evaluation and the proposed regulation, does not pose a significant adverse impact on public health or the environment compared to CARB diesel fuel
- Condition the finding on the following
  - Biodiesel must meet the in-use requirements in the ADF regulation to preclude excess NOx emissions as applicable, or may qualify for an exemption

Recommendations (*Continued*)

- Any hazardous substances and hazardous waste used in production, storage, and transportation of biodiesel will be handled in compliance with applicable California laws and regulations
- Fuel formulations and additives not included within the scope of this multimedia evaluation must be reviewed by MMWG for consideration of appropriate action

Recommendations (*Continued*)

- Information regarding oxidative stress and inflammation will continue to be monitored by the MMWG. In event that information indicates potential significant risks to public due to exposure to biodiesel exhaust resulting from biodiesel use, the specific use of biodiesel will be reviewed by the MMWG for appropriate action

- In the event that any relevant available information indicate potential for significant risks to public health or the environment, the specific use of biodiesel will be reviewed by the MMWG for appropriate action

Agenda

- Fuels Multimedia Evaluation
- Biodiesel Fuel
  - Individual Agency Presentations: ARB, State Water Board, OEHHA, DTSC
  - Summary of External Peer Review
  - Recommendations
- <u>Renewable Diesel Fuel</u>
  - Individual Agency Presentations: ARB, State Water Board, OEHHA, DTSC
  - Summary of External Peer Review
  - Recommendations
- Proposed Alternative Diesel Fuel Regulation
- Public Comments
- Council Consideration

Renewable Diesel Fuel

- *What is Renewable Diesel?*
  - Aliphatic hydrocarbons, subset of CARB diesel (C11-C22 vs. CARB diesel C9-C45)
  - Derived from renewable feedstocks (same as biodiesel)
    - Vegetable Oil – Soy, Palm, Corn, Canola, Safflower
    - Animal Fat – Tallow
  - Meets ARB diesel fuel specifications and ASTM D975

- *How is it Produced?*
  - Hydrotreatment of feedstocks – Common refinery process
  - Produced on a relatively large scale

Renewable Diesel Fuel (*Continued*)

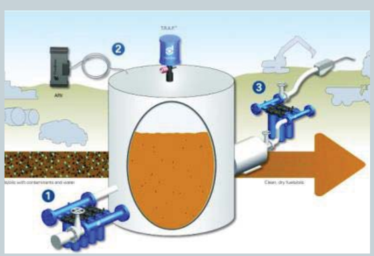
- *How is Renewable Diesel Transported and Distributed?*

Production Plant

Bulk Terminal

Refueling Station

- *How is Renewable Diesel Stored?*



Beneficial Aspects of Renewable Diesel

- Reduces PM, CO, and air toxic emissions
- Reduces NOx emissions
- Important fuel in LCFS and Federal RFS2
- Reduces petroleum use – Help achieve 2030 goal
- Energy security – Feedstocks sourced in U.S.
- Low carbon, renewable, alternative diesel fuel
- Reduces GHG – Help achieve 2030 and 2050 goals

Air Quality Evaluation

Jim Aguila - ARB

Air Quality Evaluation

- Comparative analysis - Hydrotreated vegetable oil renewable diesel compared to CARB diesel
- Criteria pollutants – PM, THC, CO, NO, NOx
- Air toxic emissions – Diesel PM, other Toxics
- Greenhouse gas emissions – CO_2

Air Quality Conclusions (*Continued*)

- Emits less PM, THC, CO, and NOx than CARB diesel
- Toxics results show reductions in most PAHs and VOCs
- Use and resulting air emissions do not pose a significant adverse impact of public health or environment

Water Evaluation

Laura Fisher - State Water Board

Background and Limitations

- Consistent with University of California, Davis and University of California, Berkeley, Tier I, Tier II, and Tier III Reports the State Water Board staff evaluation is specific to differential environmental impacts between renewable and CARB diesel

Background and Limitations (*Continued*)

- State Water Board staff conclusions and recommendations for renewable diesel have limited application as they are based on:
  - Fuel additives used during testing (approved additives currently used in CARB diesel)
  - Fuels that which meet ASTM fuel specifications

Renewable Diesel

- No significant changes in aquatic toxicity were identified by the University of California, Davis and University of California, Berkeley
- Based on data provided, impacts of fate and transport are not expected to be significantly different given similar chemical composition of renewable diesel and CARB diesel

Renewable Diesel (*Continued*)

- No significant impacts to UST material compatibility and leak detection functionality were raised within the Multimedia Evaluation

State Water Board Staff Conclusions and Recommendations

- State Water Board staff concludes that given the information provided by University of California, Davis and University of California, Berkeley there are minimal additional risks to beneficial uses of California waters posed by renewable diesel than that posed by CARB diesel alone

State Water Board Staff Conclusions and Recommendations (Continued)

- State Water Board staff supports the Multimedia Evaluation of renewable diesel which meets the ASTM fuel specifications, and the finding of no significant adverse impacts on public health or environment with recommendations provided in the Renewable Diesel Multimedia Evaluation Staff Report

State Water Board Staff Conclusions and Recommendations (Continued)

- As identified in the California Renewable Diesel Multimedia Evaluation Report, Tier III, the potential scope of any unanticipated impacts is difficult to determine due to the limited funding and time of the Multimedia Evaluation, therefore:
  - It is State Water Board staffs recommendation that any unanticipated risks that may have a significant impact on public health, safety or the environment, as full scale production and use of renewable diesel becomes common, be addressed as they occur by reconvening the Multimedia Working Group

Public Health Evaluation

Dr. Page Painter - OEHHA

Major Activities of OEHHA

- Identification of hazards from exposure to chemicals
- Dose-response assessment for toxic chemicals
- Calculation of health-based acceptable exposure levels for toxic chemicals

Major Activities of OEHHA Staff in the Multimedia Working Group

- Impact assessments of additives in reformulated fuels
- Comparative impact assessment of new fuels

Comparative assessment of a new or alternative diesel fuel requires:

- Comparing chemical concentrations in Combustion Emissions (CE) from a new diesel fuel to those from CARB diesel
- Comparing toxic impacts of CE from a new fuel to those from CARB diesel

Sources of Information Used for Comparative Fuel Impact Assessments

- Scientific studies published in peer-reviewed journals
- Reports submitted to government agencies

Renewable Diesel

- Produced by hydrotreating fatty acids from vegetable oil and is termed hydrotreated vegetable oil renewable diesel (HVORD)
- Composed of aliphatic hydrocarbons, chemicals of low toxicity

Data Sources for HVORD Assessment

- Report by Durbin et al. (2011)
- Four studies comparing CE from HVORD to CE from EN590 diesel

Comparative Evaluation of Particulate Matter (PM) and Toxic Chemicals in CE

- PM decreased in CE from HVORD
- NO_x decreased in CE from HVORD
- Benzene, ethyl benzene, toluene and xylene reduced in CE from HVORD
- Formaldehyde and acetaldehyde reduced in CE from HVORD
- Polycyclic aromatic hydrocarbon (PAH) content is reduced in CE from HVORD in most (but not all) tests

Conclusions

- Use of renewable diesel fuel produced by hydrotreating fatty acids from vegetable oil may reduce the amount of PM and aromatic organic chemicals released.
- OEHHA scientists do not find any evidence that these potential beneficial impacts are offset by adverse impacts on human health that might result from replacing some CARB ULSD use by HVORD use.

Hazardous Waste Evaluation

Donn Diebert - DTSC

Renewable Diesel Hazardous Waste Evaluation (Production and Handling)

- Potential releases during the production of Hydrotreated Renewable Diesel include:
  - n-hexane during the oil extraction process
  - Potential for odors associated with waste biomass

Renewable Diesel Hazardous Waste Evaluation (Production and Handling)

- Accidental releases during the production and handling:
  - Bulk feedstock oil (non-hazardous)
  - Chemicals used during production such as n-hexane
  - Approved additive packages for CARB Diesel such as antioxidants, biocides, cold flow enhancers, urea, etc.

Renewable Diesel Hazardous Waste Evaluation (Product Properties)

- CARB Diesel vs Renewable Diesel
  - The chemical composition and properties of Renewable Diesel are similar to CARB Diesel

Renewable Diesel Soil Evaluation (Fate/Transport and Soil Clean Up)

- CARB Diesel vs. Renewable Diesel
  - Migration of Renewable Diesel through soil is expected to be similar to CARB Diesel
  - Fate and transport of Renewable Diesel is expected to be similar to CARB Diesel
  - Break down of CARB Diesel and Renewable Diesel in the environment is expected to be similar, ultimate soil cleanup actions and remediation would be similar

DTSC's Conclusions

- Hazardous waste evaluation:
  - Product Properties of CARB Diesel vs. Renewable Diesel **- No Significant Difference**
- Soil evaluation:
  - Environmental fate and transport in soil if spill occurs of CARB Diesel vs. Renewable Diesel **- No Significant Difference**
  - Effects on hazardous waste soil cleanup of CARB Diesel vs. Renewable Diesel **- No Significant Difference**

External Scientific Peer Review

Renewable Diesel Peer Review: <u>Nov 2013 - Feb 2014</u>

- 7 reviewers; 4 areas of expertise (air, water, soil, public health)
- Support MMWG conclusions, based on sound scientific knowledge, methods, and practices
- No issues raised

Recommendations

MMWG recommends that the CEPC:

- Find that use of renewable diesel in California, as specified in this multimedia evaluation and proposed regulation, does not pose a significant adverse impact on public health or the environment compared to CARB diesel fuel
- Condition the finding on the following
  - Must meet definition in ADF regulation and California diesel fuel regulations under Title 13, California Code of Regulations, Section 2281-2285

Recommendations (*Continued*)

- Any hazardous substances and hazardous waste used in production, storage, and transportation of biodiesel will be handled in compliance with applicable California laws and regulations
- Fuel formulations and additives not included within scope of this multimedia evaluation must be reviewed by MMWG for consideration of appropriate action
- In the event any relevant available information indicates potential for significant risks to public health or environment, the specific use of biodiesel will be reviewed by the MMWG for appropriate action

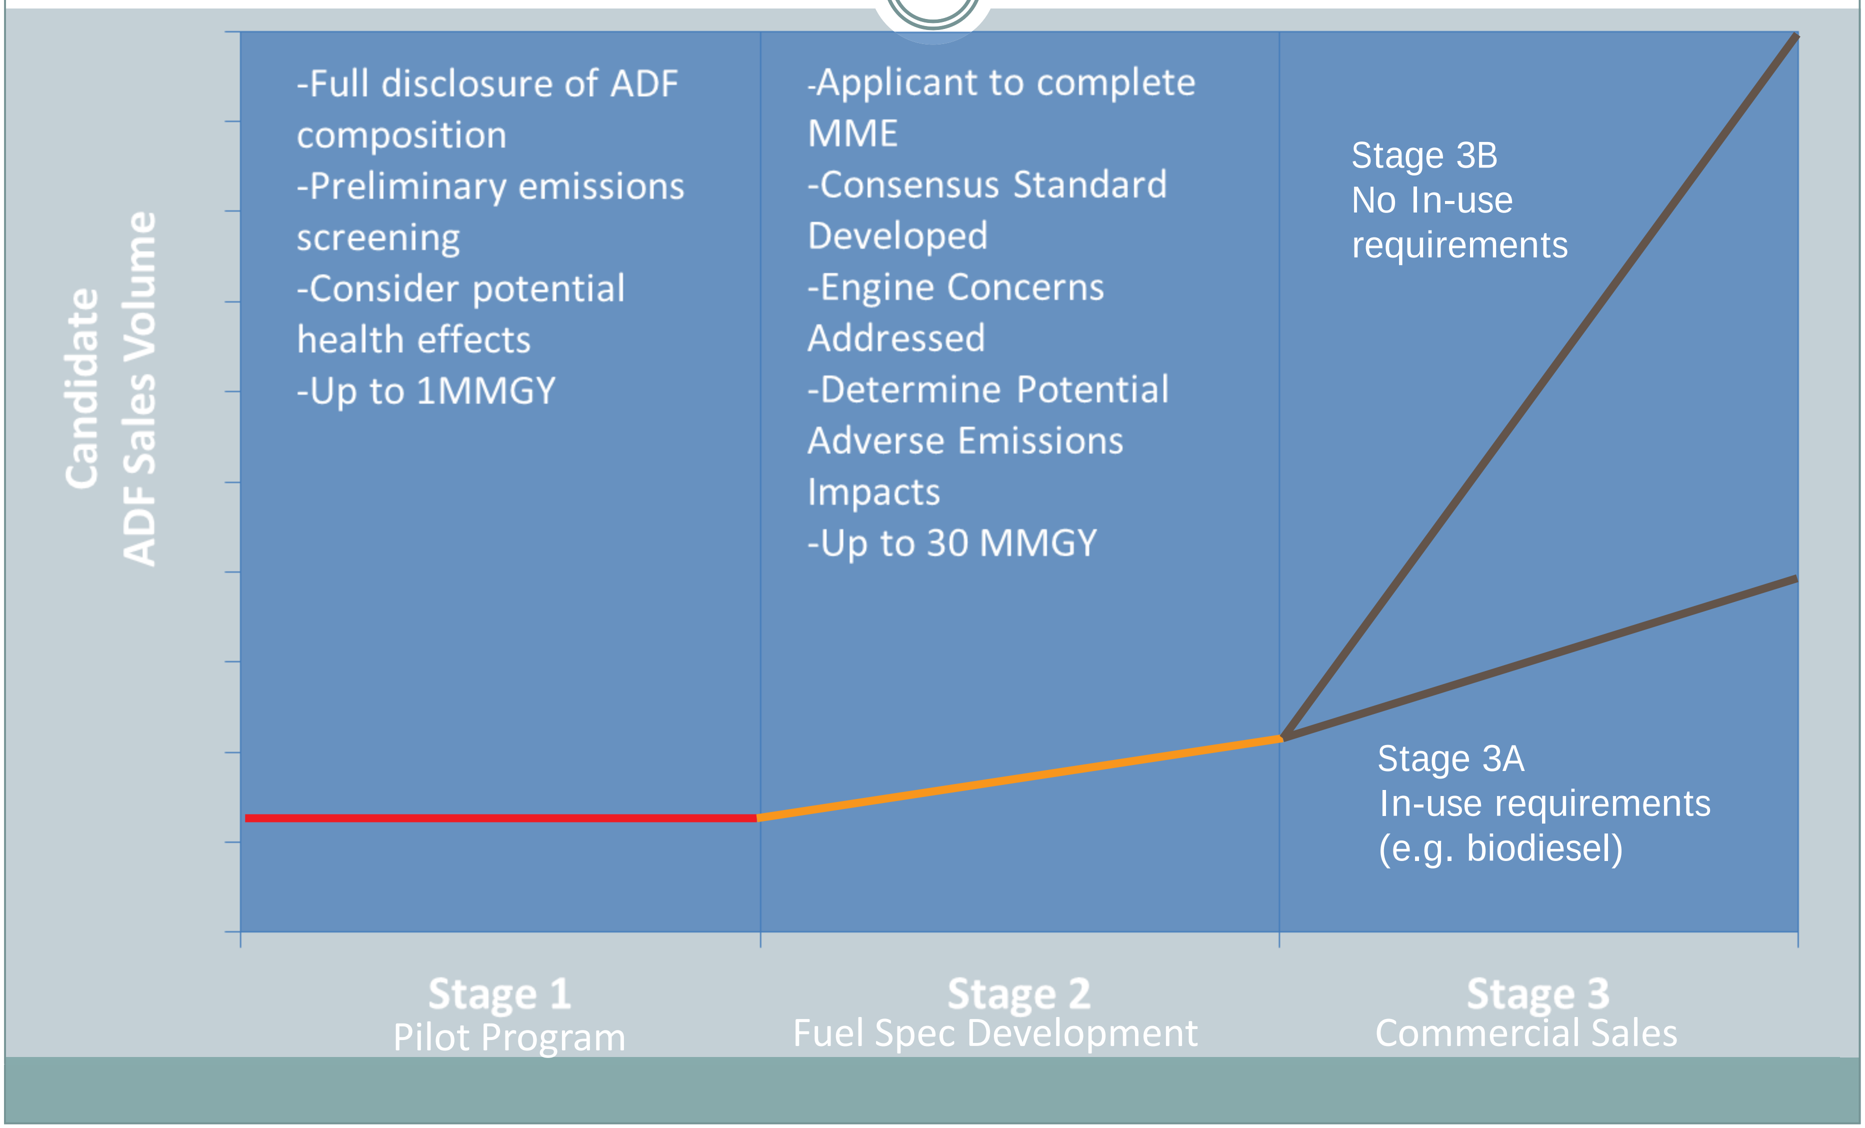
Agenda

- Fuels Multimedia Evaluation
- Biodiesel Fuel
  - Individual Agency Presentations: ARB, State Water Board, OEHHA, DTSC
  - Summary of External Peer Review
  - Recommendations
- Renewable Diesel Fuel
  - Individual Agency Presentations: ARB, State Water Board, OEHHA, DTSC
  - Summary of External Peer Review
  - Recommendations
- <u>Proposed Alternative Diesel Fuel Regulation</u>
- Public Comments
- Council Consideration

Alternative Diesel Fuel Regulation

- Subject to lengthy public process
- Support from both fuels industry and engine manufacturers
- Supports rapid deployment of low carbon diesel replacements
- Two major focuses
  - Three stage introduction of emerging ADFs into commerce
  - Establishes biodiesel as first ADF

Three-Stage Process for Emerging ADFs



Requirements for Biodiesel as First ADF

- Sets neat biodiesel fuel quality specifications
- Covers blends of biodiesel and conventional diesel (B5 to B20)
- Biodiesel blend limit: B10 or B5 depending on season and feedstock
- In-use requirements to preclude NOx increases from legacy fleet
- Exemptions for new technology diesel engines with selective catalytic reduction
- Program review by 2020

Public Comments

- Growth Energy
  - Received yesterday at noon
  - Re-submittal of comments submitted to ADF rulemaking
  - Generally pertain to environmental analysis in support of ADF rulemaking
- Western States Petroleum Association
  - Some comments outside of scope of multimedia evaluation
  - Some comments pertain to environmental analysis in support of ADF rulemaking

Agenda

- Fuels Multimedia Evaluation
- Biodiesel Fuel
  - Individual Agency Presentations: ARB, State Water Board, OEHHA, DTSC

Exhibit E to Declaration of James M. Lyons

California Environmental Protection Agency

State of California
ENVIRONMENTAL POLICY COUNCIL
Resolution
June 23, 2015

WHEREAS, California Health and Safety Code section 43830.8 provides that the Air Resources Board (ARB) may not adopt any regulation that establishes a specification for motor vehicle fuel unless that regulation, and a multimedia evaluation conducted by affected agencies and coordinated by ARB, are reviewed by the California Environmental Policy Council (Council);

WHEREAS, Public Resources Code section 71017 established the California Environmental Policy Council, consisting of the Secretary of Environmental Protection; the Chairpersons of ARB and State Water Resources Control Board (SWRCB); and the Directors of Office Environmental Health Hazard Assessment (OEHHA), Department of Toxic Substances Control (DTSC), Department of Pesticide Regulation (DPR), and Department of Resources Recycling and Recovery (CalRecycle) (formerly the California Integrated Waste Management Board, *see* Public Resources Code section 40400);

WHEREAS, Health and Safety Code section 43830.8(b) specifies that a multimedia evaluation shall include the identification and evaluation of any significant adverse impact on public health or the environment, including air, water, or soil, that may result from the production, use, or disposal of the motor vehicle fuel that may be used to meet ARB's motor vehicle fuel specification;

WHEREAS, Health and Safety Code section 43830.8(c) specifies that the multimedia evaluation shall be based on the best available scientific data, written comments submitted by any interested person, and information collected by ARB in preparation for the rulemaking, and address, at a minimum, an evaluation of the following:

- Emissions of air pollutants, including ozone forming compounds, particulate matter, toxic air contaminants, and greenhouse gases;
- Contamination of surface water, groundwater, and soil; and
- Disposal or use of the byproducts and waste materials from the production of the fuel;

WHEREAS, Health and Safety Code section 43830.8(g) specifies that ARB shall consult with other boards and departments within the California Environmental Protection Agency, the State Department of Public Health (formerly the State Department of Health Services, *see* Health and Safety Code section 20), the State Energy Resources

DRAFT

Conservation and Development Commission (Energy Commission), the Department of Forestry and Fire Protection (CAL FIRE), the Department of Food and Agriculture (CDFA), and other state agencies with responsibility for, or expertise regarding, impacts that could result from the production, use, or disposal of the motor vehicle fuel that may be used to meet the specification;

WHEREAS, Health and Safety Code section 43830.8(d) requires ARB to prepare a written summary of the multimedia evaluation, and submit it for external scientific peer review in accordance with Health and Safety Code section 57004, and to submit its written summary and results of the peer review to the Council;

WHEREAS, Health and Safety Code section 43830.8(e) specifies that if the Council determines that the proposed regulation will cause a significant adverse impact on public health or the environment, or that alternatives exist that would be less adverse, then the Council shall recommend alternative measures that the ARB or other State agencies may take to reduce the adverse impact on public health or the environment;

WHEREAS, Health and Safety Code section 43830.8(f) requires ARB, within 60 days of receiving notification from the Council of a determination of adverse impact, to make revisions to the proposed regulation to avoid or reduce the adverse impact, or the affected agencies are required to take appropriate action that will, to the extent feasible, mitigate the adverse impact so that, on balance, there is no adverse impact on public health or the environment;

WHEREAS, to address the ambient air toxic risk associated with exposure to diesel particulate matter (PM), ARB has adopted the Air Toxics Program, which establishes the process for the identification and control of toxic air contaminants, and includes provisions to make the public aware of significant toxic exposures and provisions for reducing such risks;

WHEREAS, ARB identified diesel PM as a toxic air contaminant with no safe threshold in 1998, and determined that diesel PM accounts for about 70 percent of the toxic risk from all identified toxic air contaminants;

WHEREAS, ARB plans to consider adopting an Alternative Diesel Fuel regulation (ADF regulation, or regulation) that contains a fuel specification and other requirements for biodiesel when used as a transportation fuel, and Council review of the biodiesel multimedia evaluation and the ADF regulation is required before ARB adopts the ADF regulation;

WHEREAS, ARB staff coordinated multimedia evaluations by the affected agencies of both biodiesel and renewable diesel;

WHEREAS, as part of the interagency collaboration through the Multimedia Working Group (MMWG), the ARB, SWRCB, OEHHA, and DTSC staff conducted the multimedia evaluations of both biodiesel and renewable diesel and submitted them for peer review in accordance with Health and Safety Code section 43830.8(d) and Health and Safety Code section 57004: (1) for biodiesel, the review was conducted in two parts, the first part of which was completed in February 2014, with a supplemental review completing the process in April 2015, and (2) for renewable diesel, the review was completed in February 2015;

WHEREAS, the May 2015 reports entitled "*Staff Report: Multimedia Evaluation of Biodiesel*" (Biodiesel Staff Report) and "*Staff Report: Multimedia Evaluation of Renewable Diesel*" (Renewable Diesel Staff Report) contain the results of the peer reviews required by Health and Safety Code sections 43830.8 and 57004;

WHEREAS, as part of the multimedia evaluations, the MMWG also consulted with the DPR, CalRecycle, the State Department of Public Health, the Energy Commission, CDFA, and CAL FIRE;

WHEREAS, the Council met in a duly noticed public meeting on June 23, 2015, and considered the Biodiesel Staff Report and the Renewable Diesel Staff Report, and the Alternative Diesel Fuel regulation proposed by ARB;

WHEREAS, the Council has also received and considered presentations from members of the MMWG, including ARB, SWRCB, OEHHA, and DTSC, summarizing the benefits and potential impacts of using biodiesel and renewable diesel in California;

WHEREAS, the Council received and considered written comments submitted on June 22, 2015 by Growth Energy and by the Western States Petroleum Association, and also received and considered comments from interested parties at the June 23, 2015 meeting of the Council;

WHEREAS, the Biodiesel Staff Report and Renewable Diesel Staff Report, along with other materials from the multimedia evaluations, have been made available for public comment;

WHEREAS, the multimedia evaluation for biodiesel concluded that:

- Biodiesel use must meet the in-use requirements in the proposed ADF regulation, and those requirements will preclude excess NOx emissions or other higher emissions relative to diesel motor fuel that meets current ARB specifications (CARB diesel) that could result in a significant adverse impact on public health or the environment from potential air quality impacts;

- Given the information provided by the UC researchers, there are minimal additional risks to beneficial uses of California waters posed by biodiesel than those posed by CARB diesel, and SWRCB staff supports the multimedia evaluation of biodiesel that meets the ASTM fuel specifications and the finding of no significant adverse impacts on public health or the environment;

- The substitution of biodiesel for CARB diesel appears to reduce the rate of addition of carbon dioxide to the atmosphere and the amount of PM, benzene, ethyl benzene, and polycyclic aromatic hydrocarbons (PAH) released into the atmosphere;

- A reduction in cancer risk is associated with use of biodiesel, as is a reduction in greenhouse gas emissions, which are themselves associated with myriad environmental and public health impacts; and

- Biodiesel aerobically biodegrades more readily than CARB diesel and preliminary testing of some additized biodiesel demonstrated higher aquatic toxicity for a small subset of tested species, but the results are not conclusive due to uncertainty; in general, biodiesel has no significant difference in vadose zone infiltration rate, and biodiesel's infiltration rate from animal fat appears to be similar to CARB diesel;

WHEREAS, testing results evaluated in the Renewable Diesel Staff Report show that the use of renewable diesel can reduce PM emissions by about 30 percent compared to CARB diesel;

WHEREAS, the multimedia evaluation for renewable diesel concluded that:

- In a relative comparison between CARB diesel and hydrotreated vegetable oil renewable diesel (HVORD), ARB staff concluded that the use of renewable diesel and the resulting air emissions do not pose a significant adverse impact on public health or the environment;

- Given the information provided by the UC researchers, and the similarities of renewable diesel and CARB diesel, there are minimal additional risks to beneficial uses of California waters posed by renewable diesel than that posed by CARB diesel alone; SWRCB staff supports the multimedia evaluation of renewable diesel that meets ASTM D975 and the finding of no significant adverse impacts on public health or the environment;

- PM, benzene, ethyl benzene and toluene in combustion emissions from diesel engines using HVORD are significantly lower than they are in combustion emissions from engines using CARB diesel; CO and NOx emissions are significantly lower in some tests using HVORD fuel; and variability between studies preclude drawing a conclusion as to differences in PAH exhaust output levels and PAH/PM exhaust ratios from engines equipped with a diesel oxidation catalyst (DOC)/particle oxidation catalyst (POC) between the two fuel types;

- Use of renewable diesel fuel produced by hydrotreating fatty acids from vegetable oil may reduce the amount of PM and aromatic organic chemicals that are released into the atmosphere in diesel engine exhaust, and OEHHA scientists do not find any evidence that these potential beneficial impacts are offset by adverse impacts on human health that might result from replacing CARB diesel with HVORD;

- In comparing renewable diesel with CARB diesel, diesel is free of the ester compounds found in fatty acid methyl ester biodiesel, has a lower aromatic hydrocarbon content, and the chemical compositions of renewable diesel are almost identical to that of CARB diesel;

- The relative environmental impact in case of a spill or leak of renewable diesel compared to a spill or leak from CARB diesel depends on the types, concentrations and use specifications of diesel additives used with renewable diesel, as well as the different production processes; and

- Based on the current production, use, transportation, and storage of renewable diesel in California, renewable diesel will not increase the potential negative impacts to human health and the environment;

WHEREAS, the Office of the State Fire Marshal (Office) concluded that:

- Since renewable diesel and biodiesel blends are subject to regulation under the Aboveground Petroleum Storage Act and the federal Spill Prevention, Control, and Countermeasure rule, sufficient controls are currently in place to prevent spills and releases to the environment and that aboveground storage of these fuels therefore poses no additional risk to the environment;

- There are no significant fire and panic safety impacts from renewable diesel, based on information in the renewable diesel multimedia evaluation; and

- There are minimal additional risks to public safety posed by biodiesel than posed by CARB diesel alone, and the Office supports the multimedia evaluation of biodiesel, and also supports the finding of no significant adverse impacts on fire and panic safety for biodiesel, related to the authorities of the Office;

WHEREAS, CalRecycle has stated that based on the multimedia evaluations provided by the MMWG, the agency is currently unaware of any significant adverse public health or environmental impacts from the use of biodiesel and renewable diesel;

WHEREAS, the Department of Pesticide Regulation (DPR) has reviewed the Staff Reports on Biodiesel and Renewable Diesel and found that the fuels are not registered as pesticidal active ingredients in California and are unlikely to be a major inert ingredient in pesticide products and, therefore, DPR is unaware of any adverse public health or environmental impacts that may occur.

WHEREAS, any hazardous substances and hazardous waste used in the production, storage, and transportation of biodiesel or renewable diesel is required to be handled in compliance with applicable California laws and regulations;

WHEREAS, renewable diesel must meet the requirements of CARB diesel fuel regulations under California Code of Regulations, title 13, sections 2281-2285;

WHEREAS, all other applicable local and State laws and regulations, including fuel storage requirements, will remain in effect;

WHEREAS, new fuel formulations and new additives that may be introduced into commerce in the future to comply with the ADF regulation, and were not included within the scope of these multimedia evaluations, will be reviewed by the MMWG to determine whether further multimedia evaluation is warranted, and if so, to make recommendations regarding any further action by the Council;

WHEREAS, information regarding oxidative stress and inflammation will continue to be monitored by the MMWG and in the event that new information indicates the potential for a significant adverse impact to public health from exposure to biodiesel exhaust resulting from biodiesel use, the use of biodiesel will be reviewed by the MMWG to determine whether further multimedia evaluation is warranted, and if so, to make recommendations regarding any further action by the Council; and

WHEREAS, in the event that any other new information indicates the potential for a significant adverse impact on public health or the environment from biodiesel use, the use of biodiesel will be reviewed by the MMWG to determine whether further multimedia evaluation is warranted, and if so, to make recommendations regarding any further action by the Council;

NOW, THEREFORE BE IT RESOLVED, that after review of the biodiesel multimedia evaluation and the proposed ADF regulation, and based on the best available scientific information and public comments received, the Council determines that the use of biodiesel in California consistent with the proposed ADF regulation will not pose a significant adverse impact on public health or the environment compared to CARB diesel fuel;

BE IT FURTHER RESOLVED, that after review of the renewable diesel multimedia evaluation and the proposed ADF regulation, and based on the best available scientific information and public comments received, the Council determines that the use of renewable diesel in California consistent with the proposed ADF regulation will not pose a significant adverse impact on public health or the environment compared to CARB diesel fuel;

BE IT FURTHER RESOLVED, that based on its determinations of no significant adverse impact from biodiesel and renewable diesel use, the Council does not identify any alternatives that would be less adverse than the use of biodiesel and renewable diesel as contemplated by the proposed ADF regulation; and

BE IT FURTHER RESOLVED, that the MMWG is instructed to continue to monitor issues relating to the use of renewable diesel or biodiesel, including but not limited to the use of new fuel formulations and additives and potential oxidative stress and inflammation impacts of biodiesel, and in the event that any new information indicates the potential for a significant adverse impact to public health or the environment from the use of renewable diesel or biodiesel, the MMWG is directed to determine whether further multimedia evaluation is warranted, and if so, to make recommendations regarding any further action by the Council to protect the public health or the environment.

Secretary Matthew Rodriquez, Chair
Environmental Policy Council
1011 I Street
P.O. Box 2815
Sacramento, California 95812

Re: Comments of Growth Energy on Multimedia Evaluations of Biodiesel and Renewable Diesel

Dear Mr. Rodriquez:

I am writing on behalf of Growth Energy to provide comments on the Multimedia Evaluation of Biodiesel (the "MME"), which Growth Energy understands will be discussed at the California Environmental Policy Council's June 23, 2015, public hearing.

First, as explained in the declarations submitted by James M. Lyons on February 17, 2015, June 8, 2015, and June 19, 2015, concerning the Alternative Diesel Fuel regulation (the "ADF regulation"), and Low Carbon Fuel Standard (the "LCFS regulation"), the air quality analysis prepared by CARB staff is fatally flawed. (See, e.g., February 17, 2015, Decl. Lyons ¶¶ 12-15; *id.*, Attachment F; June 8, 2015, Decl. Lyons ¶¶ 6-12.) LCFS SF8-10

Mr. Lyons' declarations also explain that the air quality analysis prepared by CARB staff in its Environmental Assessment for the ADF regulation and the LCFS regulation is different from that contained in the MME in several material respects. (See June 8, 2015, Decl. Lyons ¶¶ 13-15.) LCFS SF8-11

Further, CARB did not provide several important documents, including analyses raising questions regarding the air quality analysis underlying the ADF regulation, to either the persons working on the MME, or the MME peer reviewers. Without these documents, the preparers of the MME, and the MME peer reviewers, are provided only a one-sided view of the regulations, LCFS SF8-12 and insufficient information to fully analyze the potential air quality impacts of the regulations. The documents CARB failed to disclose include, but are not limited to, (1) *NOx Emission Impacts of Biodiesel Blends*, Robert Crawford, Rincon Ranch Consulting (February 10, 2015); and (2) February 17, 2015, Declaration of James M. Lyons, with attachments, both of which are enclosed.

LCFS SF8-12 cont.

Due to the above issues, the Environmental Policy Council should not approve the MME at this time, and should instead require CARB to revise its air quality analysis to correct the existing flaws. The Environmental Policy Council should also require CARB to make all relevant analyses – not just those supporting CARB's position – available to both the preparers of the MME and the MME peer reviewers, prior to the Environmental Policy Council's consideration of the MME.

LCFS SF8-13

Respectfully submitted,

John P. Kinsey

Enclosures:

1. Declaration of James M. Lyons (June 19, 2015)

2. Declaration of James M. Lyons (June 8, 2015)

3. Declaration of James M. Lyons (February 17, 2015)

4. *NOx Emission Impacts of Biodiesel Blends*, Robert Crawford, Rincon Ranch Consulting (February 10, 2015)

5. *NOx Emissions Impact of Soy- and Animal-based Biodiesel Fuels: A Re-Analysis*, Robert Crawford, Rincon Ranch Consulting (December 10, 2013)

6. California Air Resources Board, Initial Statement of Reasons, ADF Regulation , Main Text (January 2, 2015)

7. California Air Resources Board, Initial Statement of Reasons, ADF Regulation, Appendix B [Technical Supporting Information] (January 2, 2015)

8_SF_LCFS_GE (Page 142 - 144)

1200. Comment: **LCFS SF8-10 through LCFS SF8-12**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

1201. Comment: **LCFS SF8-13**

The commenter attaches a letter addressed to the CEPC in which the commenter's attorneys ask that the regulatory process be delayed, and suggests that the CEPC should require ARB to make additional "relevant analyses" available to the people who prepared and reviewed the MME.

Agency Response: The comment does not identify specific "relevant analyses" that were not provided; it is not clear from the comments whether additional analyses even exist. ARB staff cannot respond to such a vague suggestion, although we note that the MME process was conducted according to law, and duly approved by the CEPC on June 23, 2015.

STATE OF CALIFORNIA

BEFORE THE AIR RESOURCES BOARD

Declaration of James M. Lyons

I, James Michael Lyons, declare as follows:

1. I make this Declaration based upon my own personal knowledge and my familiarity with the matters recited herein. It is based on my experience of nearly 30 years as a regulator, consultant, and professional in the field of emissions and air pollution control. A copy of my résumé can be found in Attachment A.

2. I am a Senior Partner of Sierra Research, Inc., an environmental consulting firm located at 1801 J Street, Sacramento, California owned by Trinity Consultants, Inc. Sierra specializes in research and regulatory matters pertaining to air pollution control, and does work for both governmental and private industry clients. I have been employed at Sierra Research since 1991. I received a B.S. degree in Chemistry from the University of California, Irvine, and a M.S. Degree in Chemical Engineering from the University of California, Los Angeles. Before joining Sierra in 1991, I was employed by the State of California at the Mobile Source Division of the California Air Resources Board (CARB).

3. During my career, I have worked on many projects related to the following areas: 1) the assessment of emissions from on- and non-road mobile sources, 2) assessment of the impacts of changes in fuel composition and alternative fuels on engine emissions including emissions of green-house gases, 3) analyses of the unintended consequences of regulatory actions, and 4) the feasibility of compliance with air quality regulations.

4. I have testified as an expert under state and federal court rules in cases involving CARB regulations for gasoline, Stage II vapor recovery systems and their design, factors affecting emissions from diesel vehicles, evaporative emission control system design and function, as well as combustion chamber system design. While at Sierra I have acted as a consultant on automobile air pollution control matters for CARB and for the United States Environmental Protection Agency. I am a member of the American Chemical Society and the Society of Automotive Engineers and have co-authored nine peer-reviewed monographs concerned with automotive emissions, including greenhouse gases and their control. In addition, over the course of my career, I have conducted peer-reviews of numerous papers related to a wide variety of issues associated with pollutant emissions and air quality.

5. This Declaration summarizes the results of my review of the CARB Notice of Public Availability of Modified Text and Availability of Additional Documents for the Proposed Re-Adoption of the Low Carbon Fuel Standard Regulation on the Commercialization of Alternative Diesel Fuels (the LCFS Regulation) dated June 4,

Reproduction of Pages 58 - 61 of Comment Letter 45_FF_LCFS_GE Consisting of Comments LCFS FF45-53 through LCFS FF45-59

2015. I have performed this review as an independent expert for Growth Energy. If called upon to do so, I would testify in accord with the facts and opinions presented here.

6. Based on my review of the changes proposed to the LCFS regulation by CARB, the elimination of the multimedia evaluation provisions from the LCFS through the deletion of Section 95490 and related deletions in Sections 95481(a)(59) and 95488(c)(4)(G)6.d. creates the potential for significant adverse environmental impacts to occur as the result of the introduction of new lower carbon intensity fuels. I have participated in every aspect of the development of the LCFS regulation in which a member of the public was allowed by CARB to participate. This change to the proposed regulation could not reasonably have been anticipated, based on the notice of proposed rulemaking and the supporting materials made available in December 2014.

7. The discussion of the need for the multimedia evaluation provisions that CARB staff is now proposing to delete is summarized in both the current Initial Statement of Reasons (ISOR) for re-adoption of the LCFS regulation as well as the ISOR prepared in 2009 for the original LCFS regulation. The language relevant to the multimedia evaluation provisions in both the current and 2009 ISOR is virtually identical. With respect to why the multimedia evaluation provisions were needed in the LCFS, both the ISOR for the re-adoption of the LCFS regulation[1] and the 2009 ISOR[2] state that:

> *The LCFS regulation incorporates this principle as a pre-sale prohibition applied to fuels that are subject to an ARB specification that is modified or adopted after adoption of the LCFS regulation. In such cases, regulated parties would be prohibited from selling the affected fuels in California to comply with the LCFS requirements until a multimedia evaluation is approved for those fuels pursuant to H&S §43830.8.*

Elimination of the multimedia evaluation provisions from the LCFS regulation as now proposed by CARB staff would permit fuel suppliers to sell new fuels in California in order to try to comply with the LCFS without ensuring that adverse environmental impacts associated with their use have been identified and properly mitigated. Such new fuels could include gasoline-butanol blends, alternative diesel fuels other than biodiesel and renewable diesel, and renewable natural gas fuels that fail to comply with CARB's existing natural gas fuel specifications. In addition, these potential impacts of the LCFS regulation were not considered in the Environmental Analysis prepared for the LCFS and ADF regulations.

8. There are several ways in which new fuels which could lead to adverse environmental impacts could be sold in California before the approval of a multimedia

Reproduction of Pages 58 - 61 of Comment Letter 45_FF_LCFS_GE Consisting of Comments LCFS FF45-53 through LCFS FF45-59

1. [1] Page III-64

[2] Page V-32

evaluation pursuant to H&S §43830.8. The first of these is if the California Division of Measurement Standards (CDMS) rather than CARB adopts fuel specifications allowing the use of the new fuel. In the past, new fuels have been allowed in California through specifications enacted by CDMS that have not been required to undergo multimedia evaluation pursuant to H&S §43830.8. Biodiesel is one such fuel that has created adverse environmental impacts. Based on CARB staff estimates, in 2014, biodiesel use for compliance with the LCFS regulation allowed by CARB[3] without an approved multimedia evaluation pursuant to H&S §43830.8 resulted in increased NOx emissions of 1.2 tons per day statewide.[4] Increased NOx emissions due to the use of biodiesel for purposes of LCFS compliance have occurred since the inception of the LCFS program as a result of CARB's failure to adopt fuel specifications and complete the multimedia evaluation required pursuant to H&S §43830.8 despite having committing to do so as early as 2009.[5] Elimination of the requirements for approval of a multimedia evaluation before allowing new fuels to be sold for purposes of LCFS approval would allow other new fuels to be sold in California that, like biodiesel, create adverse environmental impacts before those impacts have been identified through the multimedia evaluation process. These potential environmental impacts created by the LCFS as a result the elimination of the LCFS multimedia evaluation requirements were not considered in the Environmental Assessment.

9. That the increases in NOx emissions resulting from biodiesel use in California without an approved multimedia evaluation were significant can be seen through a comparison of the criteria used to assess air quality impacts in areas of California outside the South Coast and San Joaquin Air Basins and the increases in NOx emissions estimated to result from biodiesel use. Using the Sacramento Metropolitan Air Quality Management District as an example,[6] the significance threshold for NOx emissions projects subject to CEQA is 65 pounds per day or 0.0325 tons per day. The 0.0325 tons per day threshold can be compared to both the 1.2 ton per day increase in NOx emissions due to biodiesel use estimated by CARB staff for 2014 statewide. Clearly, elimination of the requirements for multimedia evaluation for new fuels sold for LCFS compliance could lead to similar, and therefore significant, unmitigated, increases in NOx emissions or significant and unmitigated increases in emissions of other pollutants.

10. Another way in which new fuels could create potential adverse environmental impacts if the multimedia evaluation requirements are deleted is through the

Reproduction of Pages 58 - 61 of Comment Letter 45_FF_LCFS_GE Consisting of Comments LCFS FF45-53 through LCFS FF45-59

[3] See *http://www.arb.ca.gov/fuels/diesel/altdiesel/20111003biodiesel%20guidance.pdf*

[4] See Table 1 of *http://www.arb.ca.gov/regact/2015/adf2015/signedadfnotice.pdf*

[5] See page V-33 of *http://www.arb.ca.gov/regact/2009/lcfs09/lcfsisor1.pdf*

[6] See *http://airquality.org/ceqa/ceqaguideupdate.shtml*

Developmental Engine Fuel Variance Program operated by CDMS.[7] Again, the multimedia evaluation requirements of H&S §43830.8 that apply to fuels for which CARB adopts specifications would not apply in this case and adverse environmental impacts can occur. Allowing new fuels that are part of this program to be sold for purposes of LCFS compliance without having an approved multimedia evaluation would increase the likelihood that fuel producers would seek to use this program and the likelihood that new fuel that leads to unmitigated adverse environmental impacts would be used in California. These potential environmental impacts that the LCFS regulation could create as a result of the proposed elimination of the multimedia evaluation requirements were not considered in the Environmental Assessment.

11. In addition, the Alternative Diesel Fuel regulation proposed by CARB staff creates another way by which new fuels with potential adverse environmental impacts could be sold in California for purposes of LCFS compliance should the multimedia evaluation requirements be eliminated. Currently, fuels involved in Stage 1 or Stage 2 of the LCFS regulation are not required to have completed a multimedia evaluation and therefore could not be sold for purposes of LCFS compliance until they reach Stage 3, at which point completion of a multimedia evaluation and adoption of fuel specifications by CARB are required. Elimination of the current multimedia evaluation requirements from the LCFS regulation as now proposed by CARB staff, would allow fuels in Stage 1 and Stage 2 to be sold for purposes of LCFS compliance before the potential adverse environmental consequences have been assessed or mitigated. Again, these potential environmental impacts due to the LCFS were not considered in the Environmental Assessment.

12. In summary, retention of the current LCFS requirements that new fuels have received an approved multimedia evaluation pursuant to H&S §43830.8 before being allowed to be sold for purposes of LCFS compliance is the only way to ensure that the LCFS is not responsible for use of these new fuels creating potential adverse environmental impacts.

STATE OF CALIFORNIA

BEFORE THE AIR RESOURCES BOARD

Declaration of James M. Lyons

I, James Michael Lyons, declare as follows:

1. I make this Declaration based upon my own personal knowledge and my familiarity with the matters recited herein. It is based on my experience of nearly 30 years as a regulator, consultant, and professional in the field of emissions and air pollution control. A copy of my résumé can be found in Attachment A.

2. I am a Senior Partner of Sierra Research, Inc., an environmental consulting firm located at 1801 J Street, Sacramento, California owned by Trinity Consultants, Inc. Sierra specializes in research and regulatory matters pertaining to air pollution control, and does work for both governmental and private industry clients. I have been employed at Sierra Research since 1991. I received a B.S. degree in Chemistry from the University of California, Irvine, and a M.S. Degree in Chemical Engineering from the University of California, Los Angeles. Before joining Sierra in 1991, I was employed by the State of California at the Mobile Source Division of the California Air Resources Board (CARB).

Reproduction of Pages 11 - 16 of Comment Letter 5_F_ADF_POET Consisting of Comments ADF F5-15 through ADF F5-22

3. During my career, I have worked on many projects related to the following areas: 1) the assessment of emissions from on- and non-road mobile sources, 2) assessment of the impacts of changes in fuel composition and alternative fuels on engine emissions including emissions of green-house gases, 3) analyses of the unintended consequences of regulatory actions, and 4) the feasibility of compliance with air quality regulations.

4. I have testified as an expert under state and federal court rules in cases involving CARB regulations for gasoline, Stage II vapor recovery systems and their design, factors affecting emissions from diesel vehicles, evaporative emission control system design and function, as well as combustion chamber system design. While at Sierra I have acted as a consultant on automobile air pollution control matters for CARB and for the United States Environmental Protection Agency. I am a member of the American Chemical Society and the Society of Automotive Engineers and have co-authored nine peer-reviewed monographs concerned with automotive emissions, including greenhouse gases and their control. In addition, over the course of my career, I have conducted peer-reviews of numerous papers related to a wide variety of issues associated with pollutant emissions and air quality.

5. This Declaration summarizes the results of my review of the CARB Notice of Public Availability of Modified Text and Availability of Additional Documents for the Proposed Regulation on the Commercialization of Alternative Diesel Fuels (the ADF Regulation) dated May 22, 2015, and the California Environmental Protection Agency's Staff Report, Multi-Media Evaluation of Biodiesel, Prepared by the Multimedia Working

Group and dated May 2015, which has been added by CARB to the ADF rulemaking file. I have performed this critical review as an independent expert for Growth Energy. If called upon to do so, I would testify in accord with the facts and opinions presented here.

6. Based on my review of the changes proposed to the ADF regulation by CARB, the new exemption from mitigation requirements for B6 to B20 fuels provided through Section 2293(a)(5)(C) creates the potential for significant increases in NOx emissions from vehicles operating in areas outside the South Coast or San Joaquin Valley Air Basins. I have participated in every aspect of the development of the ADF regulation in which a member of the public was allowed by CARB to participate. The new exemption could not reasonably have been anticipated, based on the notice of proposed rulemaking and the supporting materials made available in December 2014.

7. CARB staff agrees on page 11 of the notice that the new exemption could result in increased NOx emissions. However, CARB staff claims on pages 11 to 13 of the notice that the agency has conducted "additional analysis" of NOx emissions related to a number of new issues, including the new exemption that will be added to the ADF Regulation record, and concluded that the overall impact of the ADF regulation on NOx emissions will be smaller than it originally estimated. Unfortunately, CARB has failed to provide the detailed information required for public review and comment. As a result, it was not possible for me to review the data and assumptions used by CARB staff, nor to reach a conclusion about the accuracy of the analysis that was purported to have been performed or the conclusions drawn from the analysis by CARB.

Reproduction of Pages 11 - 16 of Comment Letter 5_F_ADF_POET Consisting of Comments ADF F5-15 through ADF F5-22

8. The notice claims, based on undisclosed "additional analysis," that increased emissions due to the new exemption will be mitigated on a statewide basis averaged over an entire year. Even assuming the "additional analysis" is correct, higher NOx emissions could occur due to the new exemption in areas outside the South Coast or San Joaquin Valley Air Basins which are not in attainment with federal and state ambient air quality standards for ozone. Although the South Coast and San Joaquin Valley Air Basins experience the highest ozone levels in the state, there are many other areas in non-attainment of the federal[1] and state[2] standards where increased NOx emissions could create adverse impacts on air quality.

9. CARB should be required to provide the necessary data to perform a careful assessment. Increased NOx emissions resulting from the new exemption could potentially be significant. This can be seen through a comparison of the criteria used to assess air quality impacts in areas of California outside the South Coast and San Joaquin Air Basins and the increases in NOx emissions estimated to result from biodiesel use. Using the Sacramento Metropolitan Air Quality Management District as an example,[3] the significance threshold for NOx emissions projects subject to CEQA is 65 pounds per day

[1] See http://www.arb.ca.gov/desig/adm/2013/fed_o3.pdf

[2] See http://www.arb.ca.gov/desig/adm/2013/state_o3.pdf

[3] See http://airquality.org/ceqa/ceqaguideupdate.shtml

or 0.0325 tons per day. Using the data in the row labeled "Emission Inventory (Diesel TPD)" in Table 1 of the CARB Notice, 0.0325 tons per day can be compared to both the 0.95 ton per day estimate for 2016 statewide increases in NOx due to the ADF regulation in Table 1 of the notice, and also the difference between that value and the 1.27 ton per day value that was CARB's original estimate. Clearly, if the new exemption results in the use of even a small amount of biodiesel in the Sacramento area without mitigation, the increase in NOx emissions could be significant. Further, similar situations where significant increases in NOx emissions occur in other ozone non-attainment areas outside of the South Coast and San Joaquin Air Basins can be expected.

10. The only way to ensure that increased NOx emissions due to the new exemption would not potentially lead to adverse air quality impacts in areas where it is allowed, and thus mitigate impacts to NOx caused by the exemption, would be to require that appropriate amounts of renewable diesel biodiesel are used in the same location and at the same time as the biodiesel provided for under the new exemption. The only way to ensure this would happen would be to require blending of renewable diesel into the biodiesel blends allowed under the new exemption. There is no such requirement in the ADF regulation.

Reproduction of Pages 11 - 16 of Comment Letter 5_F_ADF_POET Consisting of Comments ADF F5-15 through ADF F5-22

11. Another major problem with CARB's "Updated ADF NOx Analysis" presented in Table 1 of the Notice is that CARB has failed to address a key flaw in its analysis of the adverse environmental impacts of biodiesel. This flaw relates to using a baseline for determining the significance of increased NOx emissions from biodiesel use where 65 million gallons of biodiesel are already in-use to conclude, as stated on page 47 of the Initial Statement of Reasons for the ADF regulation, that:

> *The net impacts of the proposal reduce NOx impacts from biodiesel, even assuming increased biodiesel volumes over the subsequent years. Estimated impacts under the proposal are less than the baseline (current year) and will continue to decrease as NTDE use increases in California.*

The correct baseline that is used everywhere else in the ISOR, as well as in the Multi-Media Evaluation and by the Peer Reviewers of that evaluation, is CARB diesel fuel containing **no** biodiesel. Given that the purpose of the ADF regulation is to establish specifications for fuels like biodiesel while identifying and ensuring mitigation of adverse environmental impacts, the no biodiesel baseline is clearly the correct baseline. Based on CARB's own "Updated ADF NOx Analysis," use of this baseline shows unmitigated NOx increases of about one ton per day statewide in California in 2015, 2016, and 2017, and at lower levels through 2020, despite its flaws. Further, as shown in my previous declaration, submitted to CARB prior to the ADF and LCFS public hearings in February 2015, the likely increases in NOx emissions are much larger and can be expected to continue indefinitely into the future.

When viewed in the context of the proper baseline, the data presented in Table 1 of the notice show that the proposed ADF regulation, even after CARB's update of its analysis, fails to mitigate increased NOx emissions due to biodiesel use. That CARB has erred in establishing the baseline for analysis of biodiesel NOx impacts is support by the ADF regulation itself, as sections 2293.5(a)(3)(C), 2293.5(b)(3)(C), 2293.5(b)(5)(B), 2293.5(b)(5)(D), and 2293.5(b)(6)(B), make it clear that increased emissions from an ADF will not be included in baseline. Rather, the baseline required to be used has to reflect conditions in place before the use of the ADF.

12. Notwithstanding the above, CARB's "additional analysis" is also fatally flawed for all of the other reasons set forth in my previous declaration and its attachments dated February 17th 2015, which was filed as part of Growth Energy's comments during the original 45 day comment period on the ADF regulation.

13. Turning to the Staff Report on the Multimedia Evaluation of Biodiesel that has only recently become available for public comment and is now being included in the ADF regulation record, I have reviewed the air quality assessment that is reported to have been prepared by CARB staff, and have found it to be both inconsistent with the analysis presented in the ADF ISOR as well as fatally flawed in that it fails to consider all of the available information regarding the impact of biodiesel on NOx emissions from what CARB refers to as New Technology Diesel Engines (NTDEs). As a direct result, the Supplemental External Scientific Peer Review of the air quality impacts of biodiesel is also flawed.

Reproduction of Pages 11 - 16 of Comment Letter 5_F_ADF_POET Consisting of Comments ADF F5-15 through ADF F5-22

14. The primary conclusion of the Multimedia Evaluation of Biodiesel with respect to air quality is:

> *Based on a relative comparison between biodiesel and CARB diesel (containing no biodiesel), ARB staff concludes that with in-use requirements biodiesel, as specified in the multimedia evaluation and proposed regulation, does not pose a significant adverse impact on public health or the environment from potential air quality impacts.*

This statement clearly highlights the fundamental inconsistency between the baseline used in the ISOR analysis of air quality impacts, where the baseline included biodiesel use, and the baseline identified in the Multimedia Evaluation Staff Report which included no biodiesel. As noted above, the appropriate baseline is the one identified in the Multimedia Evaluation Staff Report.

15. Another major inconsistency between the Multimedia Evaluation and the ISOR is the fact that CARB failed to include much of the information found in Chapters 6 and 7, and in Appendices B and G of the ISOR, all of which addresses the impact of biodiesel on emissions and air quality in the Multimedia Evaluation. Key information omitted includes:

- The finding that NOx emission increases due to soy biodiesel are statistically significant based on all data considered on page 40 of the ISOR;

- The ton per day increases in NOx emissions due to the ADF shown in Tables 7.1 and B-1 of the ISOR;

- The Supplemental Statistical Analysis presented in Appendix G of the ISOR; and

- The following peer reviewed technical papers listed as references 21 through 24 for Chapter 6 of the ISOR, which contradict CARB's claims regarding the impact of biodiesel on NOx emissions from NTDEs:

    - Gysel, Nicholas et al., *Emissions and Redox Activity of Biodiesel Blends Obtained from Different Feedstocks from a Heavy-Duty Vehicle Equipped with DPF/SCR Aftertreatment and a Heavy-Duty Vehicle without Control Aftertreatment*, SAE 2014-01-1400, Published 04/01/2014.

    - McWilliam, Lyn and Zimmermann, Anton, *Emission and Performance Implications of Biodiesel Use in an SCR-equipped Caterpillar C6.6*, SAE 2010-012157 Published, 10/25/2010.

    - Mizushima, Norifumi and Nurata, Yutaka, *Effect of Biodiesel on NOx Reduction Performance of Urea-SCR system*, SAE 2010-01-2278, Published 10/25/2010.

    - Walkowicz, Kevin et al., *On-Road and In-Laboratory Testing to Demonstrate Effects of ULSD, B20, and B99 on a Retrofit Urea-SCR Aftertreatment System*, SAE 2009-01-2733.

Reproduction of Pages 11 - 16 of Comment Letter 5_F_ADF_POET Consisting of Comments ADF F5-15 through ADF F5-22

CARB's failure to include and fully to address the foregoing information and analysis made it impossible for any external reviewers, who were relying upon CARB for full disclosure of all relevant data and information, to perform a credible scientific review of the emissions and air quality evaluation and the conclusions reached by CARB.

16. Similarly, CARB failed to include data and information directly relevant to the issues of biodiesel impacts on emissions and air quality provided during the public comment period on the ADF regulation in the materials considered in the Multimedia Evaluation Staff Report, and therefore by the external reviewers. Data and information provided during the public comment period that contradict CARB's findings regarding biodiesel NOx impacts on NTDEs that was not made part of the Multimedia Evaluation includes:

- "NOx Emission Impacts of Biodiesel Blends," Robert Crawford, Rincon Ranch Consulting, February 17, 2015; and

- Declaration of James M. Lyons, February 17, 2015, with attachments.

Again, CARB's failure to include this information also made it impossible for the Peer Reviewers, who were relying upon CARB for full disclosure of all relevant data and information, to perform a credible scientific review of the emissions and air quality evaluation and the conclusions reached by CARB.

I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct.

Executed this 8th day of June, 2015 at Sacramento, California.

Résumé

James Michael Lyons

Education

1985, M.S., Chemical Engineering, University of California, Los Angeles

1983, B.S., Cum Laude, Chemistry, University of California, Irvine

Professional Experience

4/91 to present	Senior Engineer/Partner/Senior Partner Sierra Research

Primary responsibilities include oversight and execution of complex analyses of the emission benefits, costs, and cost-effectiveness of mobile source air pollution control measures. Mr. Lyons has developed particular expertise with respect to the assessment of control measures involving fuel reformulation, fuel additives, and alternative fuels, as well as accelerated vehicle/engine retirement programs, the deployment of advanced emission control systems for on- and non-road gasoline- and Diesel-powered engines, on-vehicle evaporative and refueling emission control systems, and Stage I and Stage II service station vapor recovery systems. Additional duties include assessments of the activities of federal, state, and local regulatory agencies with respect to motor vehicle emissions and reports to clients regarding those activities. Mr. Lyons has extensive litigation experience related to air quality regulations, product liability, and intellectual property issues.

7/89 to 4/91	Senior Air Pollution Specialist California Air Resources Board

Supervised a staff of four professionals responsible for identifying and controlling emissions of toxic air contaminants from mobile sources and determining the effects of compositional changes to gasoline and diesel fuel on emissions of regulated and unregulated pollutants. Other responsibilities included development of new test procedures and emission standards for evaporative and running loss emissions of hydrocarbons from vehicles; overseeing the development of the state plan to control toxic emissions from motor vehicles; and reducing emissions of CFCs from motor vehicles.

4/89 to 7/89 — Air Pollution Research Specialist
California Air Resources Board

Responsibilities included identification of motor vehicle research needs; writing requests for proposals; preparation of technical papers and reports; as well as monitoring and overseeing research programs.

9/85 to 4/89 — Associate Engineer/Engineer
California Air Resources Board

Duties included analysis of vehicle emissions data for trends and determining the effectiveness of various types of emissions control systems for both regulated and toxic emissions; determining the impact of gasoline and diesel powered vehicles on ambient levels of toxic air contaminants; participation in the development of regulations for "gray market" vehicles; and preparation of technical papers and reports.

Attachment 3

STATE OF CALIFORNIA
BEFORE THE AIR RESOURCES BOARD
Declaration of James M. Lyons

I, James Michael Lyons, declare as follows:

1. I make this Declaration based upon my own personal knowledge and my familiarity with the matters recited herein. It is based on my experience of nearly 30 years as a regulator, consultant, and professional in the field of emissions and air pollution control. A copy of my résumé can be found in Attachment A.

2. I am a Senior Partner of Sierra Research, Inc., an environmental consulting firm located at 1801 J Street, Sacramento, California owned by Trinity Consultants, Inc. Sierra specializes in research and regulatory matters pertaining to air pollution control, and does work for both governmental and private industry clients. I have been employed at Sierra Research since 1991. I received a B.S. degree in Chemistry from the University of California, Irvine, and a M.S. Degree in Chemical Engineering from the University of California, Los Angeles. Before joining Sierra in 1991, I was employed by the State of California at the Mobile Source Division of the California Air Resources Board (CARB).

3. During my career, I have worked on many projects related to the following areas: 1) the assessment of emissions from on- and non-road mobile sources, 2) assessment of the impacts of changes in fuel composition and alternative fuels on engine emissions including emissions of green-house gases, 3) analyses of the unintended consequences of regulatory actions, and 4) the feasibility of compliance with air quality regulations.

4. I have testified as an expert under state and federal court rules in cases involving CARB regulations for gasoline, Stage II vapor recovery systems and their design, factors affecting emissions from diesel vehicles, evaporative emission control system design and function, as well as combustion chamber system design. While at Sierra I have acted as a consultant on automobile air pollution control matters for CARB and for the United States Environmental Protection Agency. I am a member of the American Chemical Society and the Society of Automotive Engineers and have co-authored nine peer-reviewed monographs concerned with automotive emissions including greenhouse gases and their control. In addition, over the course of my career, I have conducted peer-reviews of numerous papers related to a wide variety of issues associated with pollutant emissions and air quality.

5. This Declaration summarizes the results of analyses I have performed regarding CARB staff's analysis of different aspects of the re-adoption of the Low Carbon Fuel Standard (LCFS) Regulation and Regulation on the Commercialization of Alternative Diesel Fuels (ADFs) as an independent expert for Growth Energy. If called upon to do so, I would testify in accord with the facts and opinions presented here.

Reproduction of Pages 230 - 242 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-235 through LCFS 46-238 and ADF 17-18 through ADF 17-23

6. Based on a review of the Initial Statement of Reasons (ISOR) for the LCFS regulation and the associated appendices, including the draft Environmental Analysis, it is clear that CARB staff failed to quantify the GHG emission reductions associated with the LCFS regulation itself. Rather, staff notes that the GHG reduction estimates provide are inflated as the result of the "double counting" of GHG reductions due to other regulatory programs.

7. Further, this review shows that CARB staff failed to perform a complete analysis of the potential air quality impacts associated with the LCFS regulation. More specifically, CARB staff's air quality analysis fails to quantitatively assess the impact of the LCFS and ADF on all emission sources that could be affected nor does it consider all of the pollutants for which emission changes might occur. A summary of the review is Attachment B to this declaration.

8. CARB staff rejected a proposed alternative to the LCFS regulation submitted by Growth Energy claiming that it will likely result in the same environmental benefits, but not ensure a transition to lower carbon intensity fuels that CARB staff claims is the main goal of the LCFS regulation. As discussed in detail in Attachment C to this declaration, CARB staff failed to perform any analysis of the Growth Energy Alternative and has provided no support for this finding. Because the Growth Energy Alternative provides greater environmental benefits and is expected to cost less than the LCFS regulation, it must be adopted by CARB instead of the LCFS regulation.

9. As part of the development of the ADF regulation, CARB staff examined the impacts of the proposed regulation on emissions of pollutants including oxides of nitrogen (NOx) emitted from heavy-duty diesel engines operating on blends of diesel fuel and biodiesel.

10. NOx emissions directly affect atmospheric levels of nitrogen dioxide, a compound for which a National Ambient Air Quality Standards (NAAQS) has been established. NOx emissions are also precursors to the formation of ozone and particulate matter, which are also pollutants for which NAAQS have been established. Areas of the South Coast and San Joaquin Valley air basins are in extreme and moderate non-attainment of the most recent ozone and fine particulate standards, respectively.

11. In the Initial Statement of Reasons (ISOR) for the ADF regulation and its' appendices, CARB staff summarized its analysis of increases in NOx emissions from heavy-duty diesel vehicles over the period from 2014 through 2023. The results of the staff's analysis are most clearly summarized in Table B-1 of Appendix B of the ISOR. This table shows that staff estimate that biodiesel use allowed under the ADF regulation will increase NOx emissions by 1.35 tons per day in 2014 and that the magnitude of this emission increase will drop to 0.01 ton per day by 2023.

12. I have performed a review of the staff's assessment of the NOx emission impacts of biodiesel use allowed under the ADF regulation presented in ISOR and its' appendices and find it to be fundamentally flawed such that it is not reliable. First, the bases for total diesel NOx emissions inventory is not described in the ISOR or in other

Reproduction of Pages 230 - 242 of Comment Letter 46_OP_LCFS_GE/17_OP_ADF_GE Consisting of Comments LCFS 46-235 through LCFS 46-238 and ADF 17-18 through ADF 17-23 documents in the record. Second, CARB staff incorrectly assumes that the use of biodiesel in "New Technology Diesel Engines (NTDEs)" equipped with exhaust aftertreatment devices to lower NOx emissions will not lead to increased NOx emissions. Third, CARB staff incorrectly apply ratios of on-road vehicle travel by NTDEs from the now obsolete EMFAC2011 model to account for the amount of biodiesel used in all NTDEs including those found in non-road equipment. Fourth, to assess the overall impact of the ADF regulation on NOx emissions, CARB incorrectly subtracts NOx reductions resulting from the use of "renewable diesel fuel" from increases in NOx emissions resulting from the use of biodiesel.

13. In addition, I have performed a very conservative assessment of the NOx emission impacts of biodiesel use under the ADF that uses the latest CARB emissions models and corrects the flaws in the staff analysis, a summary of which is attached. The results of this assessment indicate that NOx increases from biodiesel will be much larger than those estimated by CARB staff and that the magnitude of the impacts will not decline over time as forecast by CARB staff. In addition, the analysis shows that the ADF regulation will lead to significant increases in NOx emissions in the South Coast and San Joaquin Valley air basins which are already in extreme non-attainment of the federal ozone NAAQS and moderate non-attainment of the federal fine particulate NAAQS. The details of both the review and revised emissions estimates are presented in Attachment D to this declaration.

Reproduction of Pages 230 - 242 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-235 through LCFS 46-238 and ADF 17-18 through ADF 17-23

14. In addition to identifying a fundamentally flawed analysis of the increases in NOx emissions from biodiesel use under the ADF, my review indicates that other elements of the staff's air quality and environmental analyses are also fundamentally flawed. These include incorrectly selecting 2014 as the baseline year for the environmental analysis, lacking documentation and using unsupported assumptions in determination of the NOx control level for biodiesel, and unnecessarily delaying the effective date for the implementation of mitigation requirements under the ADF regulation. All of these issues, which are discussed in detail in Attachment E, cause the adverse environmental impacts of the ADF regulation to be greater than purported by CARB staff.

15. Another important issue that I have identified with the ADF regulation is that it and the related LCFS and California Diesel regulations contain inconsistent and conflicting definitions and lack provisions requiring the determination, through testing, of the biodiesel content of commercial blendstocks. As a result, there is a clear potential for biodiesel blends to actually contain as much as 5% more biodiesel by volume than will be reported to CARB under the ADF regulation. A detailed discussion of the flaws in the ADF regulation that could allow this to occur is provided in Attachment F. Actual biodiesel levels above those reported under the ADF will lead to larger unmitigated increases in NOx emissions than have been estimated by either CARB staff or me.

16. CARB staff has rejected a proposed alternative to the ADF regulation submitted by Growth Energy, claiming that it will result in the same environmental benefits but be more costly than the staff proposal. As discussed in detail in Attachment G to this declaration, this finding is based on the same fundamentally flawed emissions

analysis performed by CARB staff that is discussed above. Given that the Growth Energy alternative is designed to mitigate all potential increases in NOx emissions (when assessed in light of a proper emissions analysis) due to biodiesel use under the ADF as soon as the regulation becomes effective, it yields greater and more timely environmental benefits than the staff proposal. In addition, the Growth Energy alternative would require the same mitigation techniques as the ADF regulation, but simply expands the circumstances under which they must be applied, and has an estimated cost-effectiveness equal to that of ADF regulation. Because the Growth Energy Alternative provides greater environmental benefits as cost-effectively as the ADF regulation, it must be adopted by CARB instead of the ADF regulation.

Reproduction of Pages 230 - 242 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-235 through LCFS 46-238 and ADF 17-18 through ADF 17-23

I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct.

Executed this 17th day of February, 2015 at Sacramento, California.

Résumé

James Michael Lyons

Education

1985, M.S., Chemical Engineering, University of California, Los Angeles

1983, B.S., Cum Laude, Chemistry, University of California, Irvine

Professional Experience

4/91 to present	Senior Engineer/Partner/Senior Partner Sierra Research

Primary responsibilities include oversight and execution of complex analyses of the emission benefits, costs, and cost-effectiveness of mobile source air pollution control measures. Mr. Lyons has developed particular expertise with respect to the assessment of control measures involving fuel reformulation, fuel additives, and alternative fuels, as well as accelerated vehicle/engine retirement programs, the deployment of advanced emission control systems for on- and non-road gasoline- and Diesel-powered engines, on-vehicle evaporative and refueling emission control systems, and Stage I and Stage II service station vapor recovery systems. Additional duties include assessments of the activities of federal, state, and local regulatory agencies with respect to motor vehicle emissions and reports to clients regarding those activities. Mr. Lyons has extensive litigation experience related to air quality regulations, product liability, and intellectual property issues.

7/89 to 4/91	Senior Air Pollution Specialist California Air Resources Board

Supervised a staff of four professionals responsible for identifying and controlling emissions of toxic air contaminants from mobile sources and determining the effects of compositional changes to gasoline and diesel fuel on emissions of regulated and unregulated pollutants. Other responsibilities included development of new test procedures and emission standards for evaporative and running loss emissions of hydrocarbons from vehicles; overseeing the development of the state plan to control toxic emissions from motor vehicles; and reducing emissions of CFCs from motor vehicles.

4/89 to 7/89 — Air Pollution Research Specialist
California Air Resources Board

Responsibilities included identification of motor vehicle research needs; writing requests for proposals; preparation of technical papers and reports; as well as monitoring and overseeing research programs.

9/85 to 4/89 — Associate Engineer/Engineer
California Air Resources Board

Duties included analysis of vehicle emissions data for trends and determining the effectiveness of various types of emissions control systems for both regulated and toxic emissions; determining the impact of gasoline and diesel powered vehicles on ambient levels of toxic air contaminants; participation in the development of regulations for "gray market" vehicles; and preparation of technical papers and reports.

Review of CARB Staff's Analysis of the GHG and Air Quality Impacts of the LCFS Regulation

In developing the proposed Low Carbon Fuel Standard (LCFS) regulation for re-adoption, CARB staff purports to have performed an analysis of the impacts that the regulation will have on emissions of both greenhouse gases and air pollutants. However, as is documented below, a review the CARB analysis demonstrates that the staff's analysis is incomplete and unsuitable for use in determining whether or not all adverse impacts have been identified and properly quantified, and all mitigation measures have been appropriately considered.

Reproduction of Pages 243 - 247 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-239 through LCFS 46-255

Summary of the CARB Staff Air Quality Analysis

On December 30, 2014, CARB staff released the proposed LCFS regulation language and the accompanying Initial Statement of Reasons (ISOR), Draft Environmental Analysis, and other supporting documents. Staff's analysis of the impact of the LCFS proposed for re-adoption is contained in Chapter IV of the ISOR as well as in Chapter 4.3. of the Draft Environmental Analysis.

In Table IV-2 of Chapter IV of the ISOR, CARB staff provides unsupported estimates of the reduction in GHG emissions associated with the LCFS regulation proposed for re-adoption. However, by CARB staff's own admission, the estimates presented in Table IV-2:

> *…do not include a reduction to eliminate the double counting of the Zero Emission Vehicle mandate, the federal Renewable Fuels Standard program, the Pavley standards, or the federal Corporate Average Fuel Economy program.*

Given that CARB staff has failed to estimate and report the GHG reduction benefits of the LCFS regulation proposed for re-adoption separately from other regulations that also seek to reduce GHG emissions from mobile sources, the Board and the public do not know the actual benefits expected to result from the regulation nor can alternatives to the LCFS regulation be properly evaluated by CARB staff.

Turning to the air quality analysis in Chapter IV of the ISOR, CARB staff provides a general discussion of emissions associated with transportation fuel production at California refineries, as well as ethanol, biodiesel, renewable diesel, and potential cellulosic ethanol facilities. Emission factors in, terms of pollutant emissions per year per million gallons of fuel produced, are provided for some facilities. CARB staff also provides an undocumented analysis of NOx and $PM_{2.5}$ emissions associated with "*...the movement of fuel and feedstock in heavy-duty diesel trucks and railcars*" with and without the LCFS and ADF regulations in place. No other assessment of the air quality impacts associated with the LCFS is provided in the LCFS ISOR.

As noted above, the draft Environmental Analysis (EA) for the LCFS and ADF, which is Appendix D to both the LCFS and ADF ISORs, also addresses air quality in Chapter 4.3. Here, short term air quality impacts related to the construction of projects of various types related to the production and distribution of lower carbon intensity fuels under the LCFS are presented. There is, however, no analysis that indicates where these projects will be located within California, nor any quantitative assessment of the emission and environmental impacts beyond the following:

> *Based on typical emission rates and other parameters for abovementioned equipment and activities, construction activities could result in hundreds of pounds of daily NO_x and PM emissions, which may exceed general mass emissions limits of a local or regional air quality management district depending on the location of generation. Thus, implementation of new regulations and/or incentives could generate levels that conflict with applicable air quality plans, exceed or contribute substantially to an existing or projected exceedance of State or national ambient air quality standards, or expose sensitive receptors to substantial pollutant concentrations.*

There is also a general discussion of potential approaches to mitigation, which CARB staff concludes are outside of the agency's authority to adopt. Ultimately, the draft EA concludes that the "short-term construction-related air quality impacts…associated with the proposed LCFS and ADF regulations would be potentially significant and unavoidable."

The draft EA also purports to assess the long-term impacts of the LCFS and ADF regulations, but addresses and attempts to quantify only potential increases in NOx emissions due to the use of biodiesel fuels, and concludes with CARB staff ultimately claiming that the long term impacts of the LCFS and ADF on air quality will be "beneficial."

Review of the CARB Staff Air Quality Analysis

As summarized above, the air quality related analyses performed by CARB staff regarding the proposed LCFS regulation are both limited and cursory. In order to demonstrate that this is in fact the case, one has to look no further than the air quality analysis CARB staff performed in 2009 to support the original LCFS rulemaking.[1]

[1] California Air Resources Board, Proposed Regulation to Implement the Low Carbon Fuel Standard, Volume I: Staff Report: Initial Statement of Reasons, March 5, 2009 and Volume II: Appendices, March 5, 2009. See in particular, Chapter VII of the ISOR and Appendix F.

The first point of note is that in the 2009 ISOR, CARB staff presents quantification of the GHG reductions expected from the LCFS occurring both in California and worldwide in Tables VII-1 and VII-2. While, those estimates have no relevance to the current rulemaking given the differences in the two regulations, fundamental changes in CARB's expectations with respect to how fuel producers will comply with a LCFS regulations, as well as the evolution of methodologies for estimating GHG emissions, provide clear evidence that the GHG emission benefits of the proposed LCFS can and should be explicitly quantified without any "double counting" of the benefits due to other regulatory programs. It should also be noted that in the 2009 ISOR, CARB staff also breaks down the GHG emission benefits expected from specific substitutes for gasoline and diesel fuel.

Turning to the air quality analysis itself, the lack of documentation provided precludes any detailed review of the accuracy of the assumptions and methodologies underlying the analysis or any effort to attempt to reproduce the staff's results. Given this lack of documentation, additional information was requested from CARB. As part of this request, Sierra Research pointed out that pursuant to the requirements of AB 1085, the agency had provided far more detailed information for other recent major rulemakings, including the Advanced Clean Cars program, than it released regarding the LCFS and ADF proposals. Unfortunately, CARB staff choose not to provide any additional information related to the analyses underlying the proposed LCFS and ADF regulations.

Another striking contrast which highlights the superficiality of the air quality analysis performed for the re-adoption of the LCFS can be seen in the treatment of potential emission impacts associated with the development of biofuel production facilities in California. These impacts are particularly important because the form of the LCFS regulation provides incentives to build biofuel production facilities in areas of California that violate federal National Ambient Air Quality standards, rather than in other states that are in compliance with those standards. The incentive for locating biofuel plants in California is to avoid GHG emissions from fuel and/or feed stock transportation which result in higher carbon intensity values.

As noted above, the air quality analysis for the re-adoption of the LCFS presented in section IV of the ISOR provides only estimates for existing California biofuel production facilities and the potential emissions of NO_x, PM_{10}, and volatile organic compounds (VOCs) associated with a hypothetical "northern California" cellulosic ethanol plant. In contrast, in the 2009 ISOR, staff provides a quantitative estimate of the overall number and types of new biofuel production facilities expected to be built in California (Table VII-6 of the 2009 ISOR) as well as a distribution of the number and type of plants expected to be built in eight of the state's air basins and a map showing expected locations. The increases in emissions of not only NO_x, PM_{10}, and VOC, but also carbon monoxide (CO) and $PM_{2.5}$ associated with these biodiesel production facilities were quantified by CARB staff (Table V11-10 of the 2009 ISOR). Again, although the data presented in the 2009 LCFS ISOR are irrelevant with respect to the current re-adoption of the LCFS regulation, the same level of detail and scope of the analysis performed by CARB staff in 2009 should have at a minimum been applied to the current LCFS air quality analysis.

Another issue noted with the air quality analysis performed for the re-adoption of the LCFS is related to emission impacts associated with "fuel and feedstock transportation and distribution."

Reproduction of Pages 243 - 247 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-239 through LCFS 46-255

The total impact of the LCFS and ADF on NOx and $PM_{2.5}$ emissions from these activities, which constitute a long term operational impact on air quality, are quantified in Table IV-16 of the ISOR. However, the documentation provided describing how the staff's analysis was performed is insufficient to allow one to either review or reproduce it. Further, these emissions are not addressed in the appropriate section of the draft EA. Given that staff estimates that the LCFS/ADF will increase these emissions, they should be identified and assessed as part of the draft EA, particularly given that staff has concluded that the LCFS/ADF impacts on long term air quality are beneficial without considering fuel and feedstock transportation and distribution emissions. The current analysis of these emissions also falls far short of the level of detail shown in the analysis of the same issue performed by CARB staff in the 2009 ISOR, as can be seen in Table VII-11 where impacts on VOC, CO, PM_{10}, and oxides of sulfur (SO_x) were reported by low CI fuel type.

Reproduction of Pages 243 - 247 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-239 through LCFS 46-255

Again, as noted above, the only issue addressed with respect to long term LCFS/ADF air quality impacts in the draft EA are potential NOx emission increases due to the use of biodiesel blends. As discussed in detail elsewhere,[2] the analysis upon which the draft EA and its conclusions are based is fundamentally flawed. However, the air quality analysis in the draft EA is also incomplete in that it fails to address long term changes in motor vehicle emissions beyond those associated with biodiesel and renewable diesel. That such impacts should have been addressed for the current rulemaking can be seen from the CARB staff air quality analysis included in the 2009 ISOR and presentation, which included detailed estimates of motor vehicle impacts on VOC, CO, NOx, SOx, PM_{10}, and $PM_{2.5}$ (rather than just NOx and $PM_{2.5}$) as a function of vehicle and fuel type in Table VII-12.

In addition to the above, two other important issues are: 1) CARB staff's failure to even attempt to quantify construction emissions associated with biofuel production facilities in California after finding them to be potentially significant and unavoidable; and 2) to identify and quantify potential emission increases associated with an increase in the number of tanker visits to California ports as the result of the ADF and LCFS regulations. With respect to the former, a California specific tool, CalEEmod,[3] is readily available that could have been used by CARB staff in estimating construction impacts form biofuel plants located in California.

With respect to the latter, it should be noted that although CARB staff concluded in the 2009 LCFS air quality analysis that there would be "little to no change to emissions at ports," that analysis predates the current proposal[4] regarding the assignment of CI to crude oil which are likely to encourage crude oil shuffling; as well as CARB staff assumptions regarding increases in assumed volumes of renewable diesel fuel potentially coming to California from production facilities in Asia, and the potential for direct importation of cane ethanol into California from Brazil. These factors will undoubtedly result in increased tanker operations in California waters the emission impacts of which can be estimated using the Emissions Estimation Methodology for Ocean-Going Vessels available on CARB's emission inventory website. According to this source, 1,919 visits by crude oil and petroleum product tankers are forecast for 2015 with roughly 50% percent of those trips involving southern California ports that are part of the South

Coast air basin. The emissions estimated by CARB to be associated with one tanker visit to California are presented in Table 1. As shown, the tanker emissions associated with a single new visit far exceed the NOx, $PM_{2.5}$ and SOx significance thresholds. Given that multiple new tanker visits are likely to result from the LCFS and ADF regulations, these values demonstrate that CARB staff has failed to identify a potentially significant source that will created adverse air quality impacts in its draft EA.

Attachment C

The Growth Energy Alternative to the Proposed LCFS Regulation is the Least-Burdensome Approach that Best Achieves the Project Objectives at the Least Cost That Must be Adopted

As part of the rulemaking process leading to CARB staff's proposed re-adoption of the LCFS regulation, staff was required to solicit and consider alternatives to the proposed regulation. Growth Energy submitted such an alternative. While CARB staff acknowledged that the Growth Energy alternative could provide equivalent reductions in GHG emissions, the agency rejected it from further consideration or analysis by stating only that it was insufficient to transition California to alternative, lower carbon intensity fuels. As discussed below, CARB staff's premise for rejecting the Growth Energy alternative is incorrect. Further, given that the Growth Energy Alternative achieves the same environmental benefits through reductions in GHG emissions as the LCFS regulation, likely at the same or lower cost, it should have been analyzed by CARB staff, in which case it would have to be adopted as the least-burdensome approach the best achieves the project objectives at the least cost.

Reproduction of Pages 248 - 252 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-256 through LCFS 46-260

<u>Background</u>

On May 23, 2014, CARB published a "Solicitation of Alternatives for Analysis in the LCFS Standardized Regulatory Impact Assessment" which is attached. On June 5, CARB published a response to a request from Growth Energy extending the deadline for the submission of alternatives from June 5, 2014 to June 23, 2014. On June 23, 2014, Growth Energy submitted an alternative regulatory proposal for the LCFS regulation (which is attached) to CARB in response to the agency's solicitation. On December 30, 2014, CARB staff published both the ISOR for the LCFS regulation as well as a document entitled "Summary of DOF Comments to the Combined LCFS/ADF SRIA and ARB Responses," which is Appendix E to the LCFS ISOR. Appendix E discusses the Growth Energy LCFS alternative and CARB's reason for its rejection.

The staff's assessment of the Growth Energy (GE) Alternative published in Appendix E of the LCFS ISOR is as follows (emphasis added):

> *The proposed alternative assumes that the exclusive goal of the LCFS proposal is to achieve GHG emissions reductions without regard to source. If that were the case, this would be a viable alternative to the LCFS and would be assessed in this analysis. It is likely true that the estimated GHG emissions reductions appearing in the 2009 LCFS Initial Statement of Reasons (California Air Resources Board, 2009) could be achieved by the AB 32 Cap-and-Trade Program, along with the other programs cited by Sierra Research and Growth Energy. The LCFS proposal, however, was designed to address the carbon intensity of transportation*

fuels. Transportation in California was powered almost completely by petroleum fuels in 2010. Those fuels were extracted, refined, and distributed through an extensive and mature infrastructure. Transitioning California to alternative, lower-carbon fuels requires a very focused and sustained regulatory program tailored to that goal. The other regulatory schemes the alternative would rely on are comparatively "blunt instruments" less likely to yield the innovations fostered by the LCFS proposal. In the absence of such a program, post-2020 emissions reductions would have to come from a transportation sector that would, in all likelihood, have emerged from the 2010-2020 decade relatively unchanged.

In the absence of an LCFS designed to begin the process of transitioning the California transportation sector to lower-carbon fuels starting in 2010, post-2020 reductions would be difficult and costly to achieve. This is why the primary goals of the LCFS are to reduce the carbon intensity of California fuels, and to diversify the fuel pool. A transportation sector that achieves these goals by 2020 will be much better positioned to achieve significant GHG emissions reductions post 2020.

ARB is required to analyze only those alternatives that are reasonable and that meet the goals of the program as required by statute. An initial assessment of the program indicates the goals of the LCFS proposal can be achieved by keeping the program "…separate of the AB 32 Cap-and-Trade system initially (at least first 10 years) in order to stimulate innovation and investment in low-GWI [global warming intensity] fuel (or transportation) technologies."[16] Due to the strong justifications that the Cap-and-Trade program alone generates neither the CI reductions nor fuel in the transportation sector, this alternative will not be assessed in this document.

Discussion

Given that there is no analysis or other support provided by CARB staff for the assertions it makes in rejecting the Growth Energy alternative other than the one reference, which dates to 2007—before either the original LCFS or Cap-and-Trade regulation were adopted was reviewed. The discussion of interactions between a LCFS program with AB32 regulations from the reference is provided below. As can be determined by the reader, the discussion was written before the AB32 regulations were adopted, and the basic concern expressed is that the lower cost of achieving the same GHG reductions from a broader program will be lower than the cost of doing the same from the LCFS program. Further, the concern expressed regarding lifecycle emission under the LCFS was explicitly addressed in the Growth Energy alternative.

5.2 Interactions with AB32 regulations

RECOMMENDATION 16: The design of both the LCFS and AB32 polices must be coordinated and it is not possible to specify one without the other. However, it is clear that if the AB32 program includes a hard cap, the intensity-based LCFS must be separate or the cap will be meaningless. Including the transport sector in both the AB32 regulatory program and LCFS will provide complementary incentives and is feasible. CARB will soon be developing regulations under AB32 to control GHG emissions broadly across the economy, most likely through a cap-and-trade system plus a set of regulatory policies. Thus, emissions from electricity generation, oil production, refining, and biofuel production are likely to be regulated directly under AB32. These energy production emissions are "upstream" in a fuel's life cycle (while emissions from a vehicle are "downstream"). The recent Market Advisory Committee report recommends including all CO2 emissions from transportation, including tailpipe emissions.

The LCFS regulates consumption emissions—the full life cycle emissions associated with products consumed in California, while it is expected that sector-specific emission caps will be imposed by AB 32 on production emissions—the emissions that are directly emitted within the borders of the state. The different types of boundaries used by these regulations causes certain upstream emissions to be double regulated under the LCFS and AB32. However, the potential for double regulation only applies to fuel production processes in the state of California or other jurisdictions where legislation similar to AB 32 also applies. We agree with the Market Advisory Committee that the LCFS and AB32 regulations will provide complementary incentives and that transportation emissions of GHGs should be included in the AB32 program.

There is no inherent conflict between the LCFS and AB32 caps; both are aimed at reducing GHG emissions and stimulating innovation in low-carbon technologies and processes. However, there are some differences. Most importantly, the LCFS is designed to stimulate technological innovation in the transportation sector specifically, while the broader AB32 program will stimulate technological innovation more broadly. The concerns associated with market failures and other barriers to technological change in the transportation sector (discussed in Section 1.3 of Part 1 and Section 2.3 of Part 2) are the motivation for adopting the sector-specific LCFS. These concerns suggest separating the LCFS from the AB32 emission caps.

The second key difference is that as a product standard using a lifecycle approach, the LCFS includes emissions that occur outside of the state such as

Reproduction of Pages 248 - 252 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-256 through LCFS 46-260

those associated with biofuel feedstock production and the production of imported crude oil. These emissions will not be included in the AB32 regulations.

The third difference is in expected costs. In the absence of transaction costs and other market imperfections, economic theory suggests that a broader cap-and-trade program will be less costly than a narrower one. By allowing more sectors and more firms to participate in a market for emission reductions, one reduces the cost to achieve a given level of emission reductions -- suggesting that the LCFS be linked to the broader AB 32 regulatory system. In addition, commercially available low-carbon options exist in the electricity and other sectors, but not in transportation fuels (see Part 1 of this study, Section 1.3).

The specific regulations and market mechanisms used to implement AB32 are not yet determined, so it is not possible at this time to specify how the LCFS should interact with them. The ARB should carefully consider the differences in incentives and constraints that the combination of rules will create.

Reproduction of Pages 248 - 252 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments LCFS 46-256 through LCFS 46-260

Returning to the issue of diversification of the transportation fuel sector, CARB concerns are directly refuted by Growth Energy's submission. As noted on pages 9 and 10, ethanol will be added to California gasoline, and renewable diesel and biodiesel will be blended into California diesel fuel as the result of the federal RFS program. The range of fuels and feedstocks from which they are produced under the RFS will be diverse. For example, the following fuel/feedstock pathways, among others, are currently recognized by U.S. EPA under the RFS:[1,2,3,4,5]

- Ethanol from
  - Corn
  - Sugar cane
  - Grain sorghum
  - Celluosic materials

- Biodiesel from
  - Camelina oil
  - Soy bean oil
  - Waste oils, fats and greases
  - Corn oil
  - Canola/rapseed oil

- Renewable diesel from
  - Waste oils, fats and greases

[1] EPA-420-F-13-014
[2] EPA-420-F-14-045
[3] EPA-420-F-12-078
[4] EPA-420-F-11-043
[5] EPA-420-F-10-007

- Renewable gasoline from
  - Crop residue and municipal solid waste

- Renewable natural gas from
  - Landfills
  - Digesters

As can be seen from Appendix B to the LCFS ISOR, these are many of the fuels that CARB staff also expects to be used in California under the LCFS. Similarly, electricity and hydrogen will be used as transportation fuels in California given the states regulatory mandates for the production of vehicles that operate on these fuels under the Advanced Clean Cars program. Further, in later years these fuels are expected to be required in heavy-duty vehicles as CARB adopts regulations under its proposed Sustainable Freight Transport Initiative, the purpose of which is stated by CARB staff as follows:

> *The purpose of the Strategy is to identify and prioritize actions to move California towards a sustainable freight transport system that is characterized by improved efficiency, zero or near-zero emissions, and increased competitiveness of the logistics system.*

It should also be noted that fuel providers in California will still be incentivized to provide these fuels in California under the Growth Energy alternative in order to reduce the number of GHG credits they will be required to retire under cap-and-trade program.

Finally, on pages 15 and 16, Growth Energy's proposal for addressing the loss of upstream emission benefits from the LCFS regulation is explicitly discussed.

Given that the Growth Energy alternative:

1. Provides, as determined by CARB staff, the same GHG reductions as the LCFS regulation; and

2. Is expected to result in lower costs of compliance than the LCFS.

CARB must adopt the Growth Energy alternative as it better achieves the stated project objectives in an equally cost-effective manner.

Attachment D

Review of CARB Staff Estimates of NOx Emission Increases Associated with the Use of Biodiesel in California Under the Proposed ADF Regulation

In developing the proposed Alternative Diesel Fuel (ADF) regulation, CARB staff has performed a statewide analysis of the increase in NOx emissions that is currently occurring in California due to the use of biodiesel, as well as the increases in NOx emissions that can be expected in the future due to the continued use of biodiesel in California under the proposed ADF regulation. As documented below, a review of the CARB staff analysis performed by Sierra Research demonstrates that the staff's analysis is fatally flawed and cannot be relied upon. Given this, Sierra Research has performed an analysis, also documented below, that demonstrates there will be substantial increases in NOx emissions if the ADF regulation is implemented as proposed. The significance in the NOx emissions increase associated with the use of biodiesel under the proposed ADF is clear given the dramatic reductions which CARB, the South Coast Air Quality Management District, and the San Joaquin Air Pollution Control District are seeking given their "extreme" non-compliance status with respect to the federal National Ambient Air Quality Standard for ozone.[1] This significance is also reinforced by a comparison of the estimated increase in NOx emissions from biodiesel under the proposed ADF regulation with the benefits of proposed and adopted NOx control measures intended for implementation on a statewide basis as well as in the South Coast and San Joaquin Valley air basins, respectively.

Reproduction of Pages 253 - 270 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-24 through ADF 17-35

Review of the CARB Staff Analysis

On December 30, 2014, CARB staff released the proposed ADF regulation language and the accompanying Initial Statement of Reasons (ISOR), technical and economic support information, and draft environmental analysis. Staff's analysis of the impact of the proposed ADF regulation on NOx emissions and supporting information and assumptions are contained in Chapters 6 and 7 of the ISOR, as well as Appendix B entitled "Technical Supporting Information."

The first issue that was identified with the staff's emissions analysis is that the information and data supplied by CARB staff are insufficient to determine exactly how the analysis was performed. Specifically, CARB staff provides no source for the values in Table B-1 labeled "Emission Inventory (Diesel TPD)," which are key to the analysis. As illustrated below, a clear understanding of what diesel sources (e.g., on-road heavy-duty, non-road, marine, locomotives, etc.) are included in the "inventory" is critical to assessing the accuracy of the staff's analysis.

[1] It should be noted that the CARB statewide analysis fails to provide any estimate of the impacts of increased NOx emissions from the ADF regulation in these air basins, where the agency has stated that massive reductions in NOx emissions are required to achieve compliance with federal air quality standards.

Given the lack of documentation regarding the source of the diesel emission inventory values, additional information regarding this analysis as well as other analyses associated with the ADF and Low Carbon Fuel Standard (LCFS) rulemakings was requested. As part of this request, Sierra Research pointed out that pursuant to the requirements of AB 1085, the agency had provided far more detailed information for other recent major rulemakings, including the Advanced Clean Cars program, than it released regarding the LCFS and ADF proposals. Unfortunately, CARB staff choose not to provide any additional information related to the analyses underlying the proposed LCFS and ADF regulations.[2]

Reproduction of Pages 253 - 270 of Comment Letter 46_OP_LCFS_GE/17_OP_ADF_GE Consisting of Comments ADF 17-24 through ADF 17-35

Despite the lack of all the information necessary to fully review the CARB staff analysis, it was possible to discern some key assumptions and the general methodology that was applied. The following key assumptions were identified:

1. Actual biodiesel use and the total demand for diesel fuel and substitutes in California will exactly match that forecast by CARB staff in the "illustrative compliance scenarios" developed as part the LCFS rulemaking;[3]

2. Actual renewable diesel use in California will exactly match that forecast by CARB staff in the "illustrative compliance scenarios" developed as part the LCFS rulemaking;[2]

3. Forty percent of renewable diesel delivered to California will be used directly by refiners to comply with the requirements of CARB's existing diesel fuel regulations[4] while the remaining 60% will be blended into fuel that complies with the diesel fuel regulations downstream of refineries;

4. The use of biodiesel up to the B20 level in New Technology Diesel Engines[5] (NTDEs, which employ exhaust aftertreatment systems to reduce NOx emissions) will not result in any increase in NOx emissions;

5. The use of biodiesel in heavy-duty diesel engines other than NTDEs—which are referred to by CARB staff as "legacy vehicles"—will increase NOx linearly with increasing biodiesel blend content, up to a 20% increase for B100;

---

[2] See attached emails from Jim Lyons of Sierra to Lex Mitchel and other CARB staff from January 2015.
[3] These are presented in Appendix B to the LCFS ISOR.
[4] Sections 2281 to 2284, Title 13, California Code of Regulations.
[5] Proposed section 2293.3 Title 13 CCR (see Appendix A to the LCFS ISOR) defines a New Technology Diesel Engines as:

a diesel engine that meets at least one of the following criteria:

(A) Meets 2010 ARB emission standards for on-road heavy duty diesel engines under section 1956.8.

(B) Meets Tier 4 emission standards for non-road compression ignition engines under sections 2421, 2423, 2424, 2425, 2425.1, 2426, and 2427.

(C) Is equipped with or employs a Diesel Emissions Control Strategy (DECS), verified by ARB pursuant to section 2700 et seq., which uses selective catalytic reduction to control Oxides of Nitrogen (NOx).

6. The blending of renewable diesel downstream of refineries will reduce NOx emissions from legacy vehicles, with each 2.75 gallons of renewable diesel blended offsetting the emissions increase associated with each gallon of biodiesel used; and

7. During the period from 2018 to 2020, 30 million gallons of biodiesel will be blended to the B20 level for use in legacy vehicles each year, and will therefore be subject to the mitigation requirements of the proposed ADF regulation and will not cause an increase in NOx emissions. Furthermore, this volume will increase to 35 million gallons per year from 2021 to 2023.

Reproduction of Pages 253 - 270 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-24 through ADF 17-35

Based on the above assumptions, CARB staff followed the methodology steps outlined below for estimating biodiesel impacts.

1. The fraction of legacy vehicles in a given year is determined by subtracting the percentage of vehicle miles traveled by on-road heavy-duty vehicles with NTDEs from 100%.

2. The fraction of legacy vehicles from Step 1 is multiplied by the total volume of biodiesel assumed to be consumed in a given year to yield the number of gallons of biodiesel used in legacy vehicles in that year.

3. For years 2018 and later, the amount of biodiesel assumed to be sold as emissions-mitigated B20 in a given year is subtracted from the total volume of biodiesel used in legacy vehicles in that year.

4. The total volume of renewable diesel assumed to be sold in a given year is multiplied by the percentage of legacy vehicles in that year and then multiplied by 0.6 to account for renewable diesel used in refineries to yield the amount of renewable diesel creating reductions in NOx emissions from legacy vehicles in that year.

5. The amount of renewable diesel used in legacy vehicles is then divided by 2.75 to determine the number of gallons of biodiesel for which NOx emissions have been offset for that year.

6. The number of gallons of biodiesel for which NOx emissions have been offset, as determined in Step 5, is then subtracted from the amount of biodiesel used in legacy vehicles, as determined in Step 3, to yield the total number of gallons of biodiesel used in legacy vehicles that cause increased NOx emissions for that given year.

7. The biodiesel volume from Step 6 is multiplied by the assumed NOx increase of 20% for B100 and then divided by the total volume of diesel fuel forecast to be used in that year to get the percentage increase in diesel emissions for that year.

8. The value from Step 7 is multiplied by the assumed Diesel Emissions inventory for that year to yield the final estimate of increased NOx emissions due to biodiesel in units of tons per day for the entire state of California.

Using the above methodology, CARB staff estimates that use of biodiesel in California led to a 1.36 ton per day increase in NOx emissions in 2014, and that the proposed ADF regulation will reduce the magnitude of that increase through 2023 down to 0.01 ton per day.[6]

The review of the staff's emission analysis identified two major issues in addition to the lack of documentation regarding how the diesel "Emission Inventory" values used by staff were developed:

1. Assuming that biodiesel use in NTDEs at levels up to B20 will not increase NOx emissions; and

2. Assuming that biodiesel NOx emissions are offset by the use of renewable diesel fuel.

Beginning with NTDEs, it has been demonstrated[7] that the available data indicate not only that NOx emissions from NTDEs will increase with the use of biodiesel in proportion to the amount of biodiesel present in the blend, but also that the magnitude of the increase on a percentage basis will be much greater than that observed for "legacy vehicles." At the B20 level where CARB staff assumed that there will be no NOx increase, the best current estimate is that NTDE NOx emissions will be increased by between 18% and 22%. CARB staff's failure to account for increased NOx emissions from NTDEs renders the staff's emission analysis meaningless in terms of assessing the adverse environmental impacts of the proposed ADF regulation. Another problem with CARB staff's treatment of NTDEs is that they have incorrectly assumed that the penetration of NTDEs into the on-road fleet is equal to that in the non-road fleet. NTDE penetration rates into the non-road fleet will be delayed due to the later effective date of the Tier 4 Final standards, relative to the 2010 on-road standards, and by the fact that while newer trucks dominate on-road heavy-duty vehicle operation, that effect does not occur in the non-road vehicle population.

Similarly, there are fundamental flaws with CARB staff's assumption that the use of renewable diesel will offset increased NOx emissions due to the use of biodiesel. First, it must be noted that there is nothing in either the proposed ADF regulation or the proposed LCFS regulation that mandates the use of any volume of biodiesel in California, much less the use of the exact ratio of renewable diesel to biodiesel assumed by CARB staff in its emissions analysis. Second, based on a review of the ADF and LCFS ISORs and supporting materials, there is no apparent basis for the staff's assumption that 40% of renewable diesel used in California will be used by refiners to aid in compliance with CARB's existing diesel fuel regulations, and that 60% will be blended downstream of refineries. To the extent that fuel producers choose to blend renewable diesel in California, one would expect them to do so by purchasing renewable diesel for use at their

Reproduction of Pages 253 - 270 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-24 through ADF 17-35

[6] Table B-1, Appendix B of the ADF ISOR.
[7] "NOx Emission Impacts of Biodiesel Blends," Rincon Ranch Consulting, February 17, 2015.

refineries where they can benefit from the other desirable properties of this fuel beyond its low carbon intensity (CI) value (e.g., high cetane number and fungibility with diesel fuel at all blend levels), rather than by purchasing LCFS credits generated by downstream blenders of renewable diesel fuel.

To illustrate the magnitude of the significance of CARB's flawed assumptions regarding NTDEs and renewable diesel, if one simply and extremely conservatively assumes that NTDE NOx increases will be the same on a percentage basis as legacy vehicles and eliminates the NOx offsets assumed from renewable diesel, the NOx increases expected from biodiesel increase from 1.35 tons per day statewide in 2014 to approximately 3.44 tons per day—a factor of about 2.65. For 2023, estimated NOx emission increases due to biodiesel rise to about 0.87 tons per day, or about 100 times more than the 0.01 tons per day CARB staff estimated. However, as documented below, a more rigorous analysis indicates that far greater increases in NOx emissions are likely.

Reproduction of Pages 253 - 270 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-24 through ADF 17-35

Detailed Analysis of Increases in NOx Emissions from Biodiesel Use

Given the flawed assumptions and undocumented sources of data associated with CARB staff's analysis of the emission impacts associated with biodiesel under the proposed ADF, Sierra Research undertook a detailed analysis of the same issue. The first step in this analysis was identifying the most current methods and tools for estimating NOx emissions from on- and non-road diesel engines operating in California for which biodiesel use is expected to increase NOx emissions.

On-Road Heavy-Duty Diesel Vehicles – On December 30, 2014, CARB officially released the final version of the EMFAC2014 model for estimating on-road emissions in California, which has replaced the now obsolete EMFAC2011 model that CARB staff relied upon for certain elements of its emission analysis. In releasing EMFAC2014, CARB staff noted a number of changes intended to improve the accuracy of the model relative to EMFAC2011. First, EMFAC2014 accounts for CARB's adoption of recent mobile source rules and regulations that lower future NOx emission estimates, including the Advanced Clean Cars program and the 2014 Amendments to the Truck and Bus Regulation. In addition, EMFAC2014 now estimates off-cycle emissions of SCR-equipped vehicles (i.e., NTDEs) by reflecting higher NOx emissions during low speed operation and cold starts.[8]

Given the above, Sierra selected EMFAC2014 for estimating NTDE emissions directly in this assessment. It was used to generate annual average NOx emissions, in tons per day, for the South Coast and San Joaquin Valley Air Basins, and the entire state for the years 2015, 2020, and 2023. Emission estimates were obtained for light-heavy-duty, medium-heavy-duty, and heavy-heavy-duty trucks, as well as school, urban, and transit buses. Output by "model year" was used to differentiate NOx emissions of legacy vehicles from those of NTDEs, which were defined as 2010 and later model-year vehicles consistent with the definition in proposed section 2293.2 Title 13, CCR (see Appendix A to the LCFS ISOR).

[8] Email from ARB EMFAC2014 Team, November 26, 2014.

<u>Off-Road Diesel Equipment and Engines</u> – The process of estimating emissions from off-road equipment and engines in California is much less straightforward than for on-road vehicles, as the most recent CARB models have been separated by equipment type and updated at various points in time as part of the rulemaking process associated with the development of regulations for different source categories.

In addition to having been developed and last updated at different points in time, some of the methodologies do not output data with sufficient detail (e.g., emissions by engine model year) to differentiate between "legacy vehicles" and NTDEs, which, in the case of off-road sources, are defined by CARB staff in proposed section 2293.2 Title 13 CCR as being compliant with Tier 4 final emission standards for non-road compression ignition (i.e., diesel) engines under sections 2421, 2423, 2424, 2425, 2425.1, 2426, and 2427 Title 13 CCR.[9] The effective dates of these standards vary as a function of engine power rating, as shown in Table 1. It should be noted that compliance with the Tier 4 Final standards by engines below 50 horsepower in general does not require the use of the SCR technology[10] that CARB has used to define "NTDEs." Therefore, all engines in this category were assumed to respond to biodiesel in the same way as legacy vehicles, despite the fact that they meet Tier 4 final standards and are technically classified as NTDEs by CARB under the ADF regulation. As discussed below, this again reduced the magnitude of the biodiesel NOx impact.

Reproduction of Pages 253 - 270 of Comment Letter 46_OP_LCFS_GE/17_OP_ADF_GE Consisting of Comments ADF 17-24 through ADF 17-35

Table 1
Effective Dates of Tier 4 Final Standards

Horsepower Range	Model Year
50-75	2013
76-175	2015
176-750	2014
Over 751	2015

Table 2 summarizes current state of CARB inventory models and methodologies for off-road diesel emission sources by equipment/engine sector[11] and indicates which outputs have sufficient detail to differentiate between emissions from legacy vehicles and NTDEs. As shown, only the general off-road equipment (construction, industrial, ground support, and oil drilling equipment), cargo handling equipment, and agricultural equipment sectors could be included in the Sierra analyses for the South Coast and San Joaquin Valley Air Basins. For the statewide inventory, it was possible to include transportation refrigeration units (TRUs) as well. Given that all diesel emission categories could not be included in the Sierra analysis, it should be noted that the results of the analysis presented below are conservative in that they do not account for the full magnitude of the increase in NOx emissions related to biodiesel use in California.

The CARB off-road emissions inventory tools were configured to include the impacts of the most recent regulatory actions in each sector, and were executed to provide estimates of annual average day NOx emissions for both legacy and NTDE vehicles for calendar years 2015, 2020, and 2023 occurring in the South Coast and San Joaquin Valley Air Basins, as well as the entire state.

Key Assumptions: The Sierra analysis of the emission impacts of biodiesel use in California relies on the following two key assumptions:

1. B5 will be in use on a statewide basis in 2015, 2020, and 2023;
2. At the B5 level, NOx emissions from legacy vehicles will be increased by 1%, and by 5% from NTDEs.

Reproduction of Pages 253 - 270 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-24 through ADF 17-35

Table 2
Summary of Current California Off-Road Diesel Emission Inventory Methodologies

Category	CARB Model/Database Tool	Capable of Differentiating Legacy Vehicle and NDTE Emissions
In-Use Off-Road Equipment	2011 Inventory Model	Yes
Cargo Handling Equipment	2011 Inventory Model	Yes
Transportation Refrigeration Units	2011 TRU Emissions Inventory	Yes – but not capable of estimating emissions by air basin
Agricultural Equipment	OFFROAD2007	Yes
Stationary Engines	2010 StaComm Inventory Model	No
Locomotives	NA	No
Commercial Harborcraft	2011 CHC/CA Crew and Supply Vessel/CA Barge and Dredge Inventory Databases	No
Ocean-Going Vessels	2011 Marine Emissions Model	No

The assumption regarding B5 was based on the fact that it represents the highest blend allowed under the ADF without mitigation, at least during the summer months. That this assumption is reasonable can be seen by comparing CARB's current and previous assumptions of biodiesel use: in the current LCFS compliance scenario,[3] the staff assumes a range from about B3 in 2015 to about B4 in 2020; in 2009,[12] the staff assumed approximately B1 in 2015 and B5 in 2020; and

[12] CARB, Proposed Regulation to Implement the Low Carbon Fuel Standard, Volume II, Appendices, March 5, 2009.

in 2011,[13] approximately B10 in 2015 and B20 in 2020 were assumed. Furthermore, the Sierra results can be scaled to reflect lower or higher non-mitigated biodiesel levels by multiplying them by the ratio of the assumed biodiesel level to B5.

The assumptions of a 1% and 5% increase at B5 for legacy vehicles and NTDEs, respectively, are based on the analysis of Rincon Ranch Consulting,[7] where 5% represents the mid-point of the range of estimates.

Diesel Emission Inventory and Biodiesel Impacts

The results of the Sierra analysis for the statewide diesel inventory for 2015, 2020, and 2023 are presented in Table 3 along with the undocumented values published by CARB staff.[6] As shown, the Sierra values are lower than those used by CARB staff. This is expected to some degree given that the Sierra analysis does not include, as explained above, some diesel source categories; however, the difference cannot be reconciled given the lack of information made available by CARB staff regarding its analysis.

Reproduction of Pages 253 - 270 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-24 through ADF 17-35

Table 3
Statewide Diesel Emissions tons/day

	2015	2020	2023
Sierra Analysis	621	436	277
CARB Table B-1, Appendix B ADF ISOR	863	634	496

Table 4 compares the results of Sierra's analysis with the results of the CARB staff's analysis. As shown, the differences are large and are due primarily to two factors: 1) the staff's assumption regarding biodiesel impacts on NTDE NOx emissions, which is contradicted by the available data; and 2) the differences in the assumed levels of biodiesel use. The impact of the latter difference can also be seen in the results presented in Table 4, where results from the Sierra analysis scaled to reflect the lower biodiesel use rates assumed by CARB staff are presented. Again, even with this adjustment, the results of the Sierra analysis indicate much greater NOx impacts under the proposed ADF. Finally, it should be recalled that because of limitations with CARB's emission inventory methods for off-road sources, not all sources of diesel emissions that could be impacted by biodiesel use under the ADF have been accounted for, and the actual impacts will be greater than those shown in Table 4.

[13] CARB, Low Carbon Fuel Standard 2011 Program Review Report, December 8, 2011.

Table 4 Statewide Increase in NOx Emissions Due to Biodiesel tons/day			
	2015	2020	2023
Sierra Analysis – B5	9.18	9.73	8.75
Sierra Analysis at CARB Assumed Biodiesel Levels from Table B-1	4.70	7.15	6.15
CARB Table B-1, Appendix B ADF ISOR	1.29	0.39	0.01

The results of the Sierra analysis are shown graphically in Figures 1a through c for the entire state as well as the South Coast and San Joaquin air basins, respectively. These figures also show the relative contributions of legacy vehicles and NTDEs to the total estimated for each area and year. As shown, the contributions of NTDEs to increased NOx emissions are substantial in 2015, and dominate the impacts in 2020 and 2023. Further data supporting these results are provided in Tables 6 through 8 at the end of this attachment.

As indicated above, the Sierra analysis uses the results from an assessment of existing data regarding biodiesel impacts on NOx emissions from NTDEs performed by Rincon Ranch Consulting. The key findings of that analysis are shown in Figure 2 (reproduced with permission), which establishes that the available data for biodiesel impacts on NTDE NOx emissions follow a linear relationship just as they do for legacy vehicles.

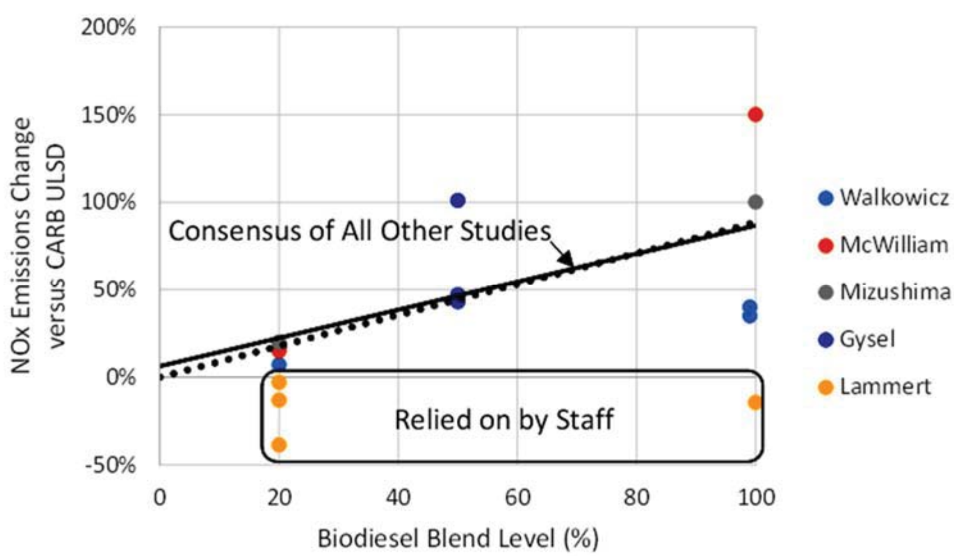
In contrast to the data upon which the Sierra analysis rests, the basis of CARB staff's assumption regarding biodiesel impacts on NTDE emissions rests on the following excerpts from the ADF ISOR:

> *Research also indicates that the use of biodiesel up to blends of B20 in NTDEs results in no detrimental NOx impacts. Therefore, the proposed regulation also includes a process for fleets and fueling stations to become exempted from the in-use requirements for biodiesel blends up to B20 as long as they can demonstrate to the satisfaction of the Executive Officer that they are fueling at least 90 percent light or medium duty vehicles or NTDEs.*
>
> *Staff proposes to take a precautionary approach and in the light of data showing there may be a NOx impact at higher biodiesel blends but not at lower biodiesel blends, staff is limiting the conclusion of no detrimental NOx impacts in NTDEs to blends of B20 and below.*

Reproduction of Pages 253 - 270 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-24 through ADF 17-35

Clearly, if CARB staff were truly taking a "precautionary approach" to the issue of biodiesel impacts on NTDE NOx emissions, they would also rely on the results of the analysis summarized in Figure 2.

Figure 2
The Impact of Biodiesel on NTDE NOx Emissions



The assumption made by CARB staff regarding biodiesel impacts on NDTE NOx emissions has additional ramifications beyond those shown above by the results of the Sierra analysis. As set forth in proposed section 2293.6, Title 13 CCR (see ISOR Appendix A), the mitigation requirements for biodiesel up to the B20 level will be dropped when NTDEs account for 90% of heavy-duty vehicle miles travelled in California (expected by staff to be 2023) and use of B20 without mitigation will be allowed in all fleets of centrally fueled vehicles comprised of more than 90% NTDEs. Given this, use of unmitigated biodiesel blends of up to B20 in NTDEs may be common under the proposed ADF regulation. The potential significance of these provisions of the staff proposal with respect to the potential for NOx increases is shown in Figures 3a through 3c, which illustrate the estimated increases in NDTE NOx emissions as a function of biodiesel content up to B20 for the state, the South Coast air basin, and the San Joaquin Valley air basins, respectively, for the years 2015, 2020, and 2023.

As shown, the potential NOx increases from extensive use of higher level biodiesel blends in NTDEs is quite large. Furthermore, although the results shown in Figures 3a through 3c are maximum potential impacts, they can again be simply scaled for other cases. For example, in order to estimate statewide NOx increases from B20 use in 50% rather than 100% of NTDEs, one would simply multiply the value of 30 tons per day by 0.5 (50/100) to arrive at a 15 ton per day increase. Finally, it should be noted that the values in Figures 3a through 3c reflect both on- and off-road NTDEs as described above for the Sierra analysis of B5 impacts.

Significance of Increases in NOx Emissions Caused by Biodiesel

As illustrated above, the proposed ADF regulations are likely to lead to substantial increases in NOx emissions for the state as a whole, as well as in the South Coast and San Joaquin Valley air basins, which are in extreme nonattainment of the federal standard for ozone and experience the state's highest levels of ozone and other pollutants. The significance of the NOx increases from biodiesel can be seen by comparing those increases with air quality planning documents.

Perhaps the best initial point of reference comes from CARB's "Vision for Clean Air"[14] prepared in conjunction with the South Coast Air Quality Management District and the San Joaquin Valley Unified Air Pollution Control District. This report addresses potential control strategies that will be required to bring these extreme ozone nonattainment areas into compliance. According to the Vision report, NOx emissions will have to be reduced by 80% to 90% from 2010 levels in both the South Coast and San Joaquin Valley areas in order to achieve ozone compliance. Furthermore, in working to identify potential control strategies, the three regulatory agencies chose to focus **only** on ways to reduce NOx emissions (and not hydrocarbon emissions) because, in their words, *"NOx is the most critical pollutant for reducing regional ozone and fine particulate matter."* Given this, CARB staff's proposal to allow any NOx emission increases from the use of biodiesel is difficult to understand.

Reproduction of Pages 253 - 270 of Comment Letter 46_OP_LCFS_GE/17_OP_ADF_GE Consisting of Comments ADF 17-24 through ADF 17-35

CARB staff's proposal becomes even more difficult to understand when the emission increases from biodiesel are compared to the emission benefits from adopted and proposed control measures. As an illustration, the NOx reductions expected from transportation control measures in the South Coast Basin that are part of the district's Air Quality Plan[15] are compared in Table 5 to estimated NOx emission increases under the ADF based on Sierra's analysis of B5. As shown, the increases due to biodiesel are far larger than the reductions from transportation control measures and completely offset the benefits of those measures that must be implemented as the result of their being included in the Air Quality Plan.

Table 5
Comparison of NOx Reductions from South Coast Transportation Control Measures (TCMs) and Estimated NOx Increases from Biodiesel Under the Proposed ADF Regulation

Calendar Year	NOx Reduction from TCMs, tons/day	NOx Increase due to Biodiesel tons/day
2014/2015	-0.7	2.72
2019/2020	-1.4	3.00
2023	-1.5	2.70

Similarly, the approximately two ton per day NOx increase estimated from the use of biodiesel in the San Joaquin Valley under the ADF can be compared to planned and implemented NOx control measures,[16,17] many of which have emission benefits on the order of two tons per day or less. Again, it should also be noted that the potential NOx emission increases allowed under the proposed ADF from extensive use of B20 in NDTEs without mitigation are far greater than the fleetwide impacts associated with the use of B5.

Attachment E

Assessment of CARB's Environmental Analysis and ADF Mitigation Requirements

In developing the proposed Alternative Diesel Fuel (ADF) regulation, CARB staff has performed an environmental analysis and included mitigation requirements intended to eliminate the adverse environmental impacts associated with increased NOx emissions resulting from the use of biodiesel under the ADF.

The environmental analysis is fundamentally flawed in that staff incorrectly selected 2014 as the baseline year and performed the analysis in light of biodiesel usage levels in that year. As documented below, CARB staff has long been aware that biodiesel use leads to increases in NOx emissions, and promised but failed to act to address those emissions through enactment of an ADF regulation as early as 2009. There is no basis for an agency to use its failure to promptly act to address an environmental issue of which it was clearly aware as grounds to change the baseline for assessing its' proposed effort to address that issue. This is even more apparent given that CARB staff acknowledges that a key function of the LCFS regulation is to incent low carbon intensity fuels including biodiesel which has to date generated 13% of all credits issued by CARB under the LCFS.[1] Given this, the proper baseline for assessing the ADF regulation should be 2009 when CARB first stated it would regulate biodiesel use and when, by CARB staff's own admission, little biodiesel was used in California and NOx emissions were minimal.

The mitigation requirements of the ADF regulation are equally flawed. First, they are based on CARB's staff's fundamentally flawed emission analysis, and second their implementation is unreasonably delayed until 2018—more than ten years after CARB staff was aware that biodiesel use in California would lead to increased NOx emissions.

Reproduction of Pages 271 - 277 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-36 through ADF 17-44

History of the ADF Regulation

Although the U.S. Environmental Protection Agency (EPA) published a report in 2002 showing that biodiesel use increases NOx emissions linearly with increasing biodiesel content,[2] the earliest document found on the CARB website indicates that agency discussions regarding the need to adopt regulations addressing NOx began at least as early as February 2004.[3] This led to the first meeting of the Biodiesel Work Group in April 2004.[4] A summary of that discussion

[1] See Page III-2 of the LCFS ISOR.

[2] See EPA, A Comprehensive Analysis of Biodiesel Impacts on Exhaust Emissions (available at http://www.epa.gov/otaq/models/analysis/biodsl/p02001.pdf).

[3] See CARB, Public Consultation Meeting Regulatory and Non-Regulatory Fuels Activities at 26-29 (Feb. 25, 2004) (available at http://www.arb.ca.gov/fuels/diesel/022504arb.pdf).

[4] See CARB Ltr. (Mar. 18, 2004) (available at http://www.arb.ca.gov/fuels/diesel/altdiesel/041204altdslwsh.pdf).

published at the time[5] it occurred indicates that topics discussed included ways to mitigate NOx emission increases associated with biodiesel use.

In 2006, CARB published a draft guidance document regarding the use of biodiesel in California,[6] at which time the agency simply decided not to address increased NOx emissions until biodiesel use became more widespread.[7] At that time, CARB instead could have ensured that there would be no NOx increases from biodiesel use by simply requiring those interested in selling biodiesel in California to demonstrate that they could formulate biodiesel blends in a way that did not increase NOx emissions, which is one of the approaches CARB is now considering.[8]

The first time CARB was scheduled to adopt regulations addressing this issue was in November 2009; this is indicated on page 12 of CARB's 2009 Rulemaking Calendar,[9] which includes the following summary:

> *Staff will propose motor vehicle fuel specifications for biodiesel and renewable diesel. These specifications are necessary for the implementation of the Low Carbon Fuel Standard regulation (to be considered at the March 2009 Hearing).*

No action was taken by CARB in 2009 and the planned adoption date was moved to June 2010; this is evidenced by CARB's 2010 Rulemaking Calendar,[10] which lists the regulatory item on page 11. This time the summary reads:

> *The staff will propose adoption of new motor vehicle fuel specifications for biodiesel and renewable diesel. These specifications are necessary to ensure that the use of these fuels will not increase emissions of criteria and toxic air pollutants when used as a motor vehicle fuel.*

Again, no action was taken by CARB in 2010 and the planned adoption date was moved to November 2011; this is evidenced by CARB's 2011 Rulemaking Calendar,[11] which lists the regulatory item on page 14. This time the summary reads:

[10] See CARB, 2010 Rulemaking Calendar Schedule (available at http://www.arb.ca.gov/regact/2010rulemakingcalendar.pdf).
[11] See CARB, 2011 Rulemaking Calendar Schedule (available at http://www.arb.ca.gov/regact/2011rulemakingcalendar.pdf).

The Low Carbon Fuel Standard incents the use of biodiesel and renewable diesel, for which there are no current emissions–based fuel specifications. Staff will propose fuel specifications for both of these diesel blendstocks.

Yet again, no action was taken by CARB in 2011 and the planned adoption date was moved to November 2012; this is evidenced by CARB's 2012 Rulemaking Calendar,[12] which lists the regulatory item on page 14. This time the summary reads:

Rulemaking to establish commercial fuel specifications for blends of commercial diesel fuel and neat biodiesel in amounts greater than five volume percent.

Yet again, no action was taken by CARB in 2012 and, for the fourth consecutive year, the item was scheduled to be presented to the Board—the CARB Rulemaking Calendar for 2013[13] indicates on page 8 that the Board is currently scheduled to consider adoption of amendments to the agency's Alternative Diesel Fuel Regulations in September 2013. This time the summary reads:

Proposed new motor vehicle alternative diesel fuel specifications and commensurate amendments to the diesel fuel regulations.

Unlike the previous years, during 2013 CARB staff did begin to take action to actually develop a regulation that it purported would address increases in NOx emissions resulting from biodiesel use. The hearing notice[14] and Initial Statement of Reasons[15] for the proposed ADF regulation were published in October 2013, in advance of a Board hearing to be held on December 12-13, 2013. However, that hearing was postponed to until March 20, 2014,[16] and then the entire rulemaking was abandoned prior to the March 2014 hearing.[17]

History of Biodiesel Use

Although CARB does not disclose the amounts of biodiesel used in California prior to 72 million gallons estimated in 2014 in the ADF rulemaking documents (see ISOR Appendix B), data for 2005 to 2012 are available from the California Energy Commission.[18] These data are shown in Figure 1 below. As shown, biodiesel use in California increased dramatically in 2006 when CARB staff indicated that it would not regulate biodiesel, and then decreased until the LCFS

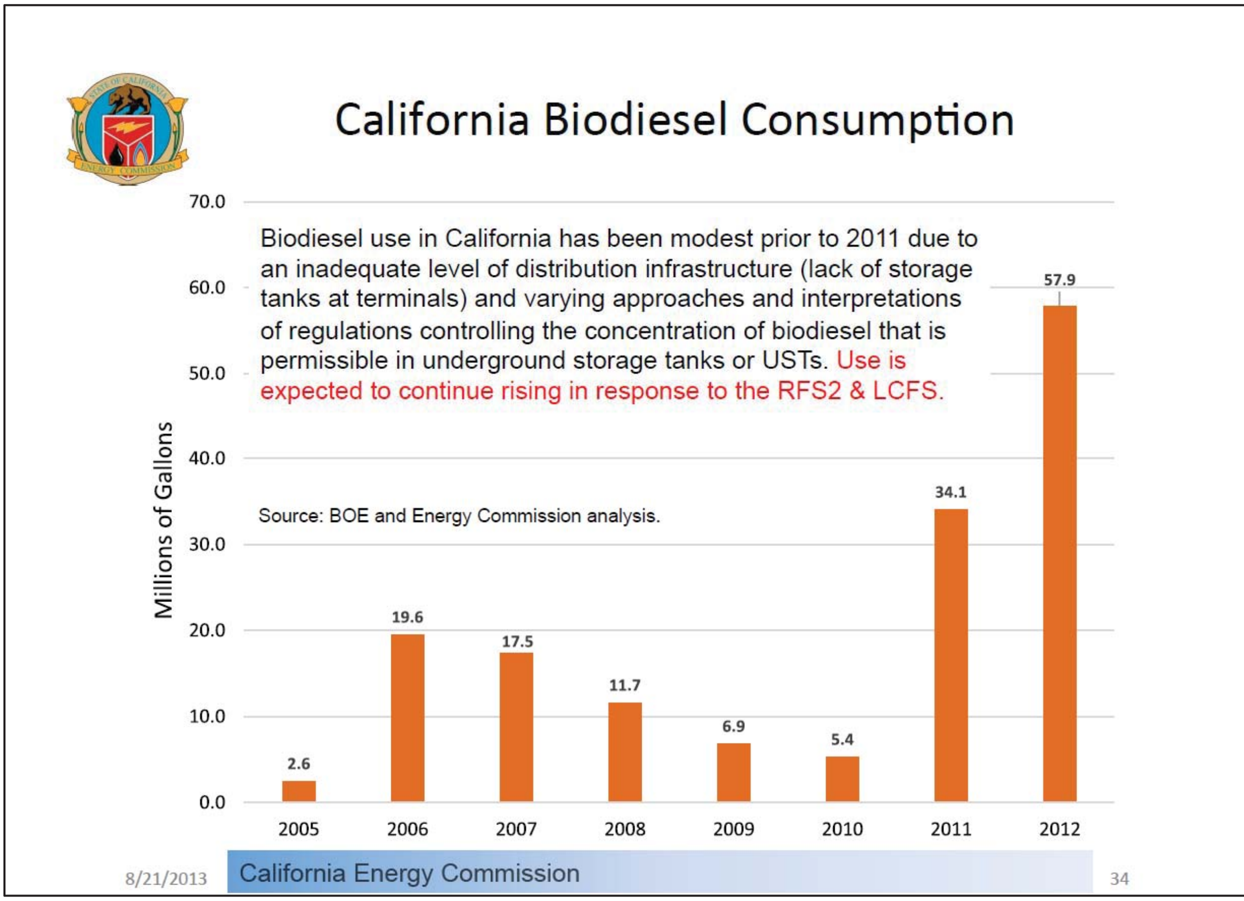
took effect in 2011 at which point it again increased dramatically. Clearly, the appropriate baseline year for analysis of the ADF regulation is 2009 or 2010 when CARB first committed to adopting a regulation to address biodiesel NOx impacts, not any later year after which substantial increases in biodiesel use occurred in response to the LCFS.

Figure 1
Biodiesel Consumption in California as Reported by the California Energy Commission



Reproduction of Pages 271 - 277 of Comment Letter 46_OP_LCFS_GE / 17_OP_ADF_GE Consisting of Comments ADF 17-36 through ADF 17-44

The NOx increases resulting from CARB's failure to regulate biodiesel during the period from 2005 to 2014 are summarized in Table 1. The values presented are approximate and are based on the Sierra Research methodology for 2015 adjusted to account for differences in biodiesel use as well as the absence of NTDE engines in years prior to 2010. Biodiesel use for 2014 is taken from Appendix B of the ADF ISOR, and the estimated use for 2013 assumed linear growth in biodiesel use from 2012 to 2014. Significant increases in NOx emissions from 2011 to 2014 can be seen from a comparison of the values presented in Table 1 with the values presented in Table B-1 of Appendix B to the ADF ISOR. These increased NOx emissions from 2011 to 2014 total 782, 1032, and 3,463 tons for the San Joaquin Valley, South Coast, and entire state, respectively.

Table 1 Estimated Increases in NOx Emissions Due to Biodiesel Use in California from 2005 to 2014 (tons per year)			
Calendar Year	Statewide	South Coast	San Joaquin Valley
2005	31	9	7
2006	234	70	50
2007	209	63	45
2008	140	42	30
2009	82	25	18
2010	65	19	14
2011	447	134	98
2012	825	246	184
2013	1000	298	227
2014	1191	354	273
Total	4225	1260	945

Proposed ADF Mitigation Requirements

Under the proposed ADF regulation,[19] mitigation is generally required for "low-saturation" biodiesel blends with diesel fuel above B5 (e.g., B6 and higher) during the summer, and above B10 (e.g., B11 and higher) during the winter, unless the fuels are used in vehicles with new technology diesel engines in which case mitigation is not required for levels up to B20. For "high-saturation" biodiesel blends with diesel fuel, mitigation is required year-round above B10 (e.g., B11 and higher) again, unless the fuels are used in vehicles with new technology diesel engines in which case mitigation is not required for levels up to B20. However, no mitigation is required for any biodiesel blend sold in California prior to January 1, 2018.

According to the ADF ISOR,[20] CARB staff selected these levels based on an "analysis" for which no detail or documentation has been provided, and that reportedly included consideration of the impacts of new technology diesel engines (NTDEs) and the use of renewable diesel as "offsetting factors." Although it is impossible to thoroughly review an analysis which is not described in detail, in this case it can still be demonstrated to be fundamentally flawed. As discussed elsewhere, CARB incorrectly assumes that NOx emissions from NTDEs are unaffected by biodiesel despite the fact that available data show statistically significant increases in NOx emissions. Further, CARB cannot rely on the use of renewable diesel as mitigation for NOx increases from biodiesel as there is nothing in the ADF or the LCFS regulation that mandates the use of any volume of renewable diesel in California, nor which links the amount of renewable diesel used to the amount of biodiesel used. Further, neither the ADF nor LCFS regulations ensure that fuel producers will use biodiesel in a manner that provides surplus

Reproduction of Pages 271 - 277 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-36 through ADF 17-44

[19] Proposed section 2293.6 Title 13, CCR in ISOR Appendix A.
[20] Chapter 6, Part H.

reductions[21] in NOx emissions. Given that CARB's reliance on "offsetting factors" is fundamentally flawed, the agency's "Determination of NOx Control Level for Biodiesel" is also fundamentally flawed. Another problem with the "determination" is that CARB staff claims to have performed an "analysis" for which no detail or documentation is provided, indicating that the higher blend level threshold for mitigation that applies to "low-saturation" blends during the winter months will not result in adverse air quality impacts. Again, it is not possible to critically review an analysis which is not described in detail; further, the information provided in this analysis is so insufficient that it is not even possible to develop an appropriate set of comments.

In addition to the flaws in CARB staff's analysis of what mitigation should be applied to address the increased NOx emissions associated with biodiesel use, CARB staff is arbitrarily delaying the date on which mitigation is required by two years from the expected effective date of the ADF regulation. According to ADF ISOR, CARB staff claim the reason for this delay is:

> *ARB is also proposing the in-use requirements come into effect on January 1, 2018, as time is needed to overcome logistical and other issues in implementation of in-use requirements. For example, use of the additive Di-tert-butyl peroxide (DTBP) will require replacement of steel tanks with stainless steel tanks, permitting of hazardous substance storage, approval by local fire agencies, additional additization infrastructure, and logistical business changes to acquire the additive. All of this is expected to take around 2 years to complete. Another method of compliance is re-routing higher blends to NTDEs. Research shows that the use of biodiesel in blends up to B20 in NTDEs results in no detrimental NOx impacts. This and other methods of complying with the in-use requirements, such as certification of additional options are also expected to take 2 years or more. Because compliance with the in-use options would be infeasible during initial implementation on January 1, 2016, only recordkeeping and reporting provisions will be implemented initially. The in-use requirements are proposed to come into effect on January 1, 2018.*

It is not clear why CARB staff believes that a two year delay in the implementation of mitigation requirements is required under the ADF regulation when the maximum delay in the implementation of new requirements under the LCFS regulation, which will much more dramatically impact fuel producers than the ADF requirements, is only one year, until January 1, 2017. Further, as the biodiesel industry has been on notice that CARB intended to impose NOx mitigation requirements for over ten years, it is not clear why such measures cannot be required from the expected January 1, 2016 effective date of the proposed regulation.

The impact of the failure to immediately require Biodiesel mitigation under the ADF regulation is shown in Table 2. These values are based on the Sierra Research emissions methodology which assumes statewide use of B5. As discussed elsewhere, these impacts

Reproduction of Pages 271 - 277 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-36 through ADF 17-44

[21] In order to generate surplus reductions in NOx, renewable diesel would have to be blended into diesel fuel downstream of refineries, and although CARB staff has assumed that this will occur they have provided no basis for that assumption.

are significant in that the increases are as large or larger than those sought from emission control measures implemented of under consideration by CARB and local air pollution control agencies in the South Coast and San Joaquin Valley air basins.

Attachment F

Potential for Actual Biodiesel Blend Levels to Exceed Levels Purported Under the Proposed ADF Regulation

In order to properly understand and mitigate the adverse environmental impacts of biodiesel blends sold in California, it is critical that the actual amount of biodiesel present in a blend be accurately known. Despite this, the proposed ADF regulation fails to adequately ensure that the actual biodiesel content of biodiesel blends—and therefore their adverse environmental impacts—will be accurately known or appropriately mitigated. As discussed below, significant changes are required to definitions used in the proposed LCFS and ADF regulations, and new testing, recordkeeping, and reporting requirements need to be added to the ADF regulation to prevent the blending of biodiesel with fuels that already contain undisclosed amounts of biodiesel.

Reproduction of Pages 278 - 282 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-45 through ADF 17-46

<u>Background</u>

CARB regulations at §2281 and §2282, Title 13, California Code of Regulations apply to vehicular diesel fuel sold in California and define "diesel fuel" as follows:

> *"Diesel fuel" means any fuel that is commonly or commercially known, sold or represented as diesel fuel, including any mixture of primarily liquid hydrocarbons – organic compounds consisting exclusively of the elements carbon and hydrogen – that is sold or represented as suitable for use in an internal combustion, compression-ignition engine."*[1]

The proposed LCFS regulation contains the following definitions that are relevant to biodiesel blends (See ISOR Appendix A):[2]

> *"B100" means biodiesel meeting ASTM D6751-14 (2014) (Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels), which is incorporated herein by reference.*

> *"Biodiesel" means a diesel fuel substitute produced from nonpetroleum renewable resources that meet the registration requirements for fuels and fuel additives established by the Environmental Protection Agency under section 211 of the Clean Air Act. It includes biodiesel meeting all the following:*

[1] 13 CCR §2281(b)(1) and §2282(b)(3)
[2] See proposed §95481, Title 17, California Code of Regulations

(A) Registered as a motor vehicle fuel or fuel additive under 40 Code of Federal Regulations (CFR) part 79;
(B) A mono-alkyl ester;
(C) Meets ASTM D6751-08 (2014), Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels, which is incorporated herein by reference;
(D) Intended for use in engines that are designed to run on conventional diesel fuel; and
(E) Derived from nonpetroleum renewable resources.

"Biodiesel Blend" means a blend of biodiesel and diesel fuel containing 6 percent (B6) to 20 percent (B20) biodiesel and meeting ASTM D7467-13 (2013), Specification for Diesel Fuel Oil, Biodiesel Blend (B6 to B20), which is incorporated herein by reference.

"Diesel Fuel" (also called conventional diesel fuel) has the same meaning as specified in California Code of Regulations, title 13, section 2281(b).

"Diesel Fuel Blend" means a blend of diesel fuel and biodiesel containing no more than 5 percent (B5) biodiesel by weight and meeting ASTM D975-14a, (2014), Standard Specification for Diesel Fuel Oils, which is incorporated herein by reference.

Reproduction of Pages 278 - 282 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-45 through ADF 17-46

Finally, the proposed ADF regulation contains the following definitions that are relevant to biodiesel blends:[3]

"Alternative diesel fuel" or "ADF" means any fuel used in a compression ignition engine that is not petroleum-based, does not consist solely of hydrocarbons, and is not subject to a specification under subarticle 1 of this article.

"Biodiesel" means a fuel comprised of mono-alkyl esters of long chain fatty acids derived from vegetable oils or animal fats that is 99-100 percent biodiesel by volume (B100 or B99) and meets the specifications set forth by ASTM International in the latest version of Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels D6751 contained in the ASTM publication entitled: Annual Book of ASTM Standards, Section 5, as defined in California Code of Regulations, title 4, section 4140(a), which is hereby incorporated by reference.

"Biodiesel Blend" means biodiesel blended with petroleum-based CARB diesel fuel or non-ester renewable diesel.

[3] See proposed §2293.2(a), Title 13, California Code of Regulations

"Blend Level" means the ratio of an ADF to the CARB diesel it is blended with, expressed as a percent by volume. The blend level may also be expressed as "AXX," where "A" represents the particular ADF and "XX" represents the percent by volume that ADF is present in the blend with CARB diesel (e.g., a 20 percent by volume biodiesel/CARB diesel blend is denoted as "B20").

"B5" means a biodiesel blend containing no more than five percent biodiesel by volume.

"B20" means a biodiesel blend containing more than five and no more than 20 percent biodiesel by volume.

"CARB diesel" means a light or middle distillate fuel that may be comingled with up to five (5) volume percent biodiesel and meets the definition and requirements for "diesel fuel" or "California nonvehicular diesel fuel" as specified in California Code of Regulations, title 13, section 2281 et seq. "CARB diesel" may include: non-ester renewable diesel; gas-to-liquid fuels; Fischer-Tropsch diesel; diesel fuel produced from renewable crude; CARB diesel blended with additives specifically formulated to reduce emissions of one or more criteria or toxic air contaminants relative to reference CARB diesel; and CARB diesel specifically formulated to reduce emissions of one or more criteria or toxic air contaminants relative to reference CARB diesel.

Reproduction of Pages 278 - 282 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-45 through ADF 17-46

Discussion

The first issue related to the potential for uncertainty and inaccuracy in actual biodiesel content of fuels sold in California involves the different definitions that have been proposed for the term "biodiesel" under the proposed LCFS and ADF regulations. Although the two definitions may be functionally equivalent, they should be made the same under both the LCFS and ADF regulations unless CARB staff can articulate a compelling need for the use of different definitions to describe the same thing.

More importantly, the term "Biodiesel Blend" in the proposed LCFS regulation directly conflicts with the use of the same exact term in the proposed ADF regulation: a "Biodiesel Blend" under the LCFS regulations contains at least 6% biodiesel, while a "Biodiesel Blend" under the ADF is a diesel fuel containing any biodiesel. Furthermore, the LCFS regulation defines "Diesel Fuel Blend" as a blend of diesel fuel and up to 5% biodiesel, while such a fuel would be considered "CARB diesel" under the ADF regulation. Again, this haphazard use of the same term to describe fundamentally different fuels and different terms to describe the same fuel will assuredly lead to confusion in practice regarding the actual content of biodiesel available in California.

Further confusion is created by the definitions of "Biodiesel Blend" and "Blend Level" under the proposed ADF regulation. "Biodiesel Blend" is defined as a mixture of biodiesel and an undefined fuel referred to as "petroleum-based CARB diesel." "Blend

Level" applies to blends of all fuels subject to the ADF regulation, including biodiesel, and is defined as the ratio of an "Alternative diesel fuel" mixed with "CARB diesel." However, as noted above, "CARB diesel" may already contain as much as 5% biodiesel under the proposed ADF regulation. Furthermore, the definition of "Blend Level" includes no reference to the fuel termed "petroleum-based CARB diesel" that appears in the definition of "Biodiesel Blend" under the ADF—instead, it refers to "CARB diesel," which, as noted above, may contain as much as 5% biodiesel. Obviously, the addition of biodiesel to a fuel already containing some amount of biodiesel up to 5% will cause the actual biodiesel content to be higher than the blender expects; this, in turn, will lead to more significant adverse environmental impacts than expected. It is also clear that CARB staff mean for the definition of "Blend Level" to apply to "Biodiesel Blends," as that definition uses an example based on biodiesel (B20) to demonstrate the practical meaning of "Blend Level."

Finally, under the proposed ADF regulation, "B20" is nonsensically defined as a fuel that contains between 6% and 20% biodiesel, which directly contradicts the definition of "Blend Level" in same regulation. There appears to be no need for this definition or the definition of B5 in the proposed ADF regulation.

Reproduction of Pages 278 - 282 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-45 through ADF 17-46

As outlined above, the proposed CARB LCFS and ADF regulations fail completely in clearly defining the four fuels that are of fundamental importance to ensuring that the biodiesel content of a fuels sold in California—and hence the adverse environmental impacts associated with their use—is accurately known. Instead, the proposed regulations make it likely that biodiesel blenders will unknowingly use fuels that already contain an unknown amount of biodiesel (up to 5%) in blending and that the actual biodiesel content of biodiesel blends may be as much as 5% greater than that represented by the blender and reported to CARB under the ADF regulation. This is significant because, as discussed in other attachments to this declaration, the increases in NOx emissions and associated adverse environmental impacts caused by biodiesel blends become larger in direct proportion to the amount of biodiesel present.

Both the LCFS and the ADF regulation must clearly define the four fuels described below.

1. ***"Diesel fuel"* –** This should defined as under 13 CCR §2281(b)(1) and §2282(b)(3).

2. ***"Biodiesel"*** or "***B100"* –** It appears that this could be properly defined through changes to the definitions currently proposed in the LCFS and ADF regulations; this is what should be blended only with "diesel fuel" to create a "Biodiesel Blend."

3. ***"CARB diesel"* –** This is accurately defined under the proposed ADF regulation, but under no circumstances should it be allowed to be blended with biodiesel or any other ADF. It should be renamed to clearly differentiate it from "diesel fuel" such that no reasonable person would understand that it could be legally mixed with any ADF.

4. ***“Biodiesel Blend”*** **–** This should refer to the “Blend Level” and must correspond to the actual amount of “Biodiesel” or “B100” in terms of percentage by volume in the final blend with “diesel fuel.”

In addition to modifying the definitions as described above, the ADF regulation must also be modified to ensure that biodiesel blenders do not intentionally or unintentionally blend biodiesel into fuels that already contain biodiesel. This can easily be achieved by adding requirements to proposed §2293.8 Title 13, CCR, to require that any “diesel fuel” to be used in blending with biodiesel be tested for the presence of biodiesel prior to blending. Similarly, that section should be modified to include reporting and record keeping requirements for biodiesel blenders that document that they have used only biodiesel-free “diesel fuel” in all of their blending operations.

Attachment G

The Growth Energy Alternative to Proposed ADF Regulation is the Least-Burdensome Approach that Best Achieves the Project Objectives at the Least Cost That Must be Adopted

As part of the rulemaking process leading to CARB staff's proposed ADF regulation, staff was required to solicit and consider alternatives to the proposed regulation. Growth Energy submitted such an alternative which CARB staff acknowledged provided equivalent or superior reductions in NOx emissions from biodiesel use but rejected as being more costly. However, as is documented in detail below, CARB staff made fundamental errors in its' assessment of the Growth Energy Alternative, which will in fact provide greater reductions in NOx emissions from biodiesel use than the staff's proposed ADF regulation but do so with equal cost-effectiveness. (Equal cost-effectiveness means that the dollars spent per unit mass of NOx emissions eliminated will be the same.) Given that the Growth Energy alternative provides greater environmental benefits, which in turn substantially lessen the ADF's significant impacts, and is equally cost-effective as the staff's proposed ADF regulation, the Growth Energy Alternative rather than the staff proposal should be adopted by CARB.

Reproduction of Pages 283 - 285 of Comment Letter 46_OP_LCFS_GE / 17_OP_ADF_GE Consisting of Comments ADF 17-47 through ADF 17-50

Background

On July 29, 2014, CARB published a "Solicitation of Alternatives for Analysis in the Alternative Diesel Fuel Standardized Regulatory Impact Assessment" which is attached. On August 15, 2014, Growth Energy submitted an alternative regulatory proposal for the ADF regulation (which is attached) to CARB in response to the agency's solicitation. On December 30, 2014, CARB staff published both the ISOR for the ADF regulation as well as a document entitled "Summary of DOF Comments to the Combined LCFS/ADF SRIA and ARB Responses" which is Appendix E to the ADF ISOR, both of which include information related to staff's decision to reject the alternative to the ADF regulation proposed by Growth Energy.

The staff's assessment of the Growth Energy (GE) Alternative published in Appendix E of the ADF ISOR is as follows (emphasis added):

> ***Benefits:***
>
> ***ARB finds that the GE alternative would meet the emissions goals of the ADF proposal and achieve roughly the same emissions benefits as the ADF proposal. The GE alternative may achieve marginally more emissions benefits if biodiesel were to be widely used as an additive under the ADF proposal. Although the GE alternative is simpler than the ADF proposal, the GE alternative is unnecessarily strict; ARB's analysis of the science does not find that there are NO_X increases with B5 animal biodiesel or biodiesel used in NTDEs, so***

requiring mitigation for these does not achieve any additional emissions benefit versus the ADF proposal.

Costs:

The GE alternative would require mitigation of more fuel than the ADF proposal; regulated parties would incur more costs to mitigate non-animal- and animal-based biodiesel similarly and setting the significance level for both at one percent. Additionally, the NTDE exemption would increase the volumes of fuels to be mitigated, further increasing the direct costs on regulated parties.

Economic Impacts:

The REMI results also indicate that the combined LCFS/ADF proposal has no discernible difference from the GE alternative. Employment, GSP, and output differ only slightly and represent a difference of less than one tenth of one percent. Given that the GE alternative has higher direct costs, the combined LCFS/ADF alternative is preferred.

Cost-Effectiveness:

The GE alternative costs more than the ADF proposal, because it requires mitigation of more biodiesel than the ADF proposal. The GE alternative does not result in any more emissions reductions than the ADF proposal and as such is less cost effective than the ADF proposal.

Reason for Rejection:

ARB rejects the GE alternative because it costs more than the ADF proposal and does not achieve additional emissions benefits*.*

The reason for rejection of the Growth Energy (GE) alternative presented in the ADF ISOR itself is as follows:

This alternative proposal retains the same biodiesel NOx mitigation options as the ADF proposal*. However, under the GE alternative, animal and non-animal biodiesel would be treated equally and require NOx mitigation for all biodiesel blends, including blends below B5.* ***ARB rejects this alternative because the costs are significantly higher than the ADF proposal and do not achieve additional emissions benefits.*** *During the development of this regulation, staff considered alternatives to the proposal and determined that the proposal represents the least-burdensome approach that best achieves the objectives at the least cost.*

Finally, it should be noted that the stated intention of the ADF regulation according to CARB staff in the ADF ISOR is as follows (emphasis added):

Reproduction of Pages 283 - 285 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-47 through ADF 17-50

*The ADF regulation is intended to create a framework for these low carbon diesel fuel substitutes to enter the commercial market in California, **while mitigating any potential environmental or public health impacts**.*

Discussion

As indicated above, the stated reason why CARB staff rejected the Growth Energy alternative to the proposed ADF regulation is because CARB staff believed it would require that actions be taken to mitigate increased NOx emissions from biodiesel under circumstances where CARB staff incorrectly assumed there would no increased emissions due to biodiesel use on under the ADF. However, as is clearly demonstrated in another attachment to the declaration of James M. Lyons,[1] CARB staff's analysis and assumptions of the increases in NOx emissions that will result for the ADF regulation is fatally flawed as is CARB's basis for rejection of the Growth Energy Alternative.

Reproduction of Pages 283 - 285 of Comment Letter 46_OP_LCFS_GE/ 17_OP_ADF_GE Consisting of Comments ADF 17-47 through ADF 17-50

As shown by the Sierra emissions analysis, once the flaws in the CARB emissions analysis are corrected, it becomes clear that the ADF regulation will allow significant and unmitigated increases in NOx emissions to occur throughout California including areas such as the South Coast and San Joaquin air basins which experience the worst air quality in the state. As CARB staff itself admits, the Growth Energy alternative would require mitigation in exactly those areas where CARB staff was lead to believe it was not required based on its flawed emissions analysis. CARB staff also admits the Growth Energy alternative is based on the same mitigation options contained in the ADF regulation, which CARB staff has already determined to be technically feasible and cost-effective. However, the Growth Energy Alternative is superior to the ADF regulation because it expands the conditions under which this mitigation has to be applied in order to eliminate the potential for any increase in NOx emissions due to biodiesel use to a less-than-significant level. The Growth Energy Alternative therefore precludes any adverse environmental impacts due to increased NOx emissions, which is exactly what CARB staff has asserted the ADF regulation is intended to do.

Given that the Growth Energy alternative:

1. Provides complete mitigation of potential NOx emission increases due to biodiesel use under the ADF and any associated adverse environmental impacts; and

2. Relies on the same mitigation strategies proposed by CARB staff which staff has found to be technically feasible and cost-effective,

CARB must adopt the Growth Energy alternative as it better achieves the stated project objectives in an equally cost-effective manner.

NOx EMISSION IMPACTS OF BIODIESEL BLENDS

1. EXECUTIVE SUMMARY

The purpose of the Alternative Diesel Fuels (ADF) rulemaking, according to the Air Resources Board (ARB), is to create a regulatory framework that will permit biodiesel and other low-carbon, alternative diesel fuels to "enter the commercial market in California, while mitigating any potential environmental or public health impacts." [1]

The work presented in this report assesses the impacts of biodiesel use on NOx emissions from conventional and new technology diesel engines. It was performed by Rincon Ranch Consulting under subcontract to Sierra Research at the request of Growth Energy.

At present, most diesel fuel and biodiesel is consumed in conventional diesel engines that do not have exhaust gas after-treatment to reduce NOx emissions. The consensus of the literature is that biodiesel will increase NOx emissions by amounts that depend on the blending percentage (how much biodiesel is present in the diesel fuel) and the type of biodiesel feedstock (soy versus animal sources). NOx increases of 1-2% are expected from soy biodiesel at blend levels of B5 to B10 with smaller increases expected, in general, from animal biodiesel at the B5 to B10 level.

Over time, new technology diesel engines (NTDEs) equipped with exhaust gas after-treatment controls for NOx will increasingly make up the heavy duty fleet in response to other ARB programs. While baseline emissions from these engines will be reduced compared to conventional engines, the consensus of the literature available today is that use of biodiesel will still increase NOx emissions above the reduced baseline. At the B20 level, the NOx increase appears to be greater on a percentage basis than would be expected in conventional diesel engines.

The results of this work indicate the following with respect to conventional diesel engines:

- Soy biodiesels will increase NOx emissions at the B5 and B10 levels by approximately 1% and 2%, respectively. This work and Staff's analysis concur in both the conclusion and the estimated levels of NOx increase at B5 and B10. Soy biodiesels in this blend range require NOx mitigation on a per-gallon basis in order to prevent increases in NOx emissions.
- The consensus of the research community is that the effect of soy biodiesel on NOx emissions is continuous and linear with respect to the blending percentage. NOx

[1] "Proposed Regulation on the Commercialization of New Alternative Diesel Fuels. Staff Report: Initial Statement of Reason." California Air Resources Board, Stationary Source Division, Alternative Fuels Branch. January 2, 2015. http://www.arb.ca.gov/regact/2015/adf2015/adf15isor.pdf. Page 11.

increases have been observed at levels as low as B1.[2] The statistical analysis performed for ARB by Rocke supports this conclusion and estimates that soy biodiesel will increase NOx emissions by about 0.2% for each 1% biodiesel in the blend (0.99% for each 5% biodiesel).

In spite of this consensus, the Staff proposal requires NOx mitigation for soy-based biodiesel only above the B5 level in summer months and above the B10 level in winter months. Soy biodiesel blended at the B5 and lower levels would not require mitigation in any circumstance. The ADF regulatory framework must require mitigation of soy-based biodiesels at all blend levels if it is to ensure that such fuels do not increase NOx emissions.

- The effect of animal-based biodiesel on NOx emissions is more complicated than for soy-based blends. As the available literature demonstrates, some animal-based biodiesels will increase NOx emissions while other animal biodiesels will not. While Staff's proposal would establish B10 as the control level for animal-based biodiesel (e.g., mitigation would be required year-round for blends above B10), the available data do not support Staff's conclusion that there will not be increases in NOx emissions from B10 and lower blends. Given the Staff proposal, the only way to ensure that animal-based biodiesel does not increase NOx emissions is to require mitigation at all blend levels.

- Staff presents information indicating that animal biodiesels decrease NOx by 0.2% on average and that the emissions change in comparison to CARB diesel fuel is not statistically significant. The average and the test for statistical significance are both flawed by the failure to consider the varying effects that animal feedstocks have on Cetane Number (CN). The absence of CN as a variable in Staff's analysis leads Staff to wrongly conclude that animal biodiesels will not increase NOx below the B10 level.

- It is well established that increasing CN will reduce NOx emissions from diesel engines. Whether an animal biodiesel will increase NOx depends primarily on the extent to which the feedstock blending increases the CN of the blended fuel. Soy and animal biodiesel blends are not categorically different fuels once the differing effect of soy- and animal-feedstocks on CN is taken into account.

With respect to new technology diesel engines (NTDEs):

- Staff is incorrect in concluding that biodiesel use will not increase NOx in NTDEs. This conclusion is based on a highly selective reading of the technical literature (choosing one of four available studies) and relies on the one study in which the laboratory was not well equipped to measure the low levels of tailpipe NOx emissions from NTDEs.

- A fair reading of the technical literature indicates that B20 biodiesel will increase NOx emissions by about 20% in NTDEs. The four best studies estimate that B20 biodiesel

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

---

[2] McCormick 2002 tested a Fisher-Tropsch (FT) base fuel blended at the B1, B20, and B80 levels. Although the very high FT cetane number (≥75) takes it out of the range of commercial diesel fuels, the study nevertheless measured higher NOx emissions at the B1 level than it did on the FT base fuel.

increases NOx by 18-22% in NTDEs and that the increase is statistically significant. This is a greater percentage NOx increase in proportion to blend level than the increase caused by soy biodiesel in conventional diesel engines (1% at B5, 2% at B10 and ~4% at B20).

- The technical literature also indicates that one should expect NOx emissions to increase at blend levels below B20, with the size of the NOx increase being proportionate to blend level. At the B5 level, NOx emissions from NTDEs are expected to increase by about 5%.

- Staff makes no mention of the concern that use of biodiesel fuels in NTDEs may lead to the loss of NOx conversion efficiency in urea-SCR systems by shifting the NO_2/NOx ratio to lower values. Staff's proposal to allow B20 biodiesel to be used in NTDEs without mitigation potentially places at risk the investment in NOx after-treatment systems to meet the stringent NOx certification levels now in effect.

This analysis demonstrates that the proposed regulations will not "ensure that the use of biodiesel due to LCFS will not result in increases in NOx emissions in California." In fact, the regulations will result in increased NOx emissions in California from the following:

- B5 and lower soy biodiesels year round;
- B6 to B10 soy biodiesels in winter;
- At least some B10 and lower animal biodiesels year-round; and
- B20 and lower biodiesels of all types in NTDEs.

To our knowledge, ARB has not formulated a position on the level of NOx increase from alternative diesel fuel that is too small to warrant concern. A point of comparison for the NOx increases permitted by the proposed ADF regulations is the ARB program for Reformulated Gasoline (RFG). The RFG program permits alternative gasoline formulations to be sold in the California market provided they are demonstrated to be emissions equivalent to a reference gasoline using the Predictive Model for RFG. The emissions analysis differs somewhat for winter and summer gasoline, but in no instance may the alternative formulation increase emissions of the pollutants considered by more than 0.05%.

The biodiesel NOx emission increases permitted under the proposed ADF regulations dwarf the 0.05% threshold applied to RFG. Soy biodiesel will increase NOx by more than 0.05% at blend levels above 0.25% biodiesel (B0.25). Some animal biodiesels will increase NOx by 0.05% or more at blend levels twice as high (B0.5). The NOx emissions increase in NTDEs appears to be substantially greater on a percentage basis, so that biodiesels will exceed the 0.05% threshold at much lower blend levels.

In the ISOR, Staff uses the term "low saturation" to refer to soy and other feedstocks with CN < 56 and "high saturation" to refer to feedstocks, including animal sources, with CN ≥ 56. Classification based on saturation is useful because of its association with CN. By itself, however, it does not alleviate the concerns regarding NOx increases from unmitigated fuels.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

The analysis presented here indicates that CN changes induced by biodiesel blending have a large influence on the size of the NOx increase that is observed. Soy (low saturation) biodiesels adversely affect CN leading to larger NOx increases; animal (high saturation) biodiesels increase CN leading to smaller NOx increases. In fact, soy and animal biodiesels are not categorically different fuels once their differing effect on blend CN is taken into account.

It is strongly recommended that ARB consider as part of the ADF rulemaking a regulatory structure in which the NOx impacts of soy and animal biodiesel are accounted for using a statistical model analogous to the Predictive Model for RFG. The analysis documented in this report provides a possible form for a biodiesel predictive model.

2. NOX EMISSIONS FROM CONVENTIONAL DIESEL ENGINES

2.1 ARB Analysis in Support of the Proposed Regulations

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

In support of the proposed regulations, ARB commissioned an analysis of the available NOx emissions data by David M. Rocke, PhD. The results of the analysis are reported in Appendix G: Supplemental Statistical Analysis[3] to the ISOR. The analysis used NOx emission measurements on ULSD, B5, and B10 fuels in conventional diesel engines from five studies. The dataset is substantially the same as that used by Rincon Ranch Consulting in the analysis presented later in this section.

The Rocke analysis formulated a series of statistical models involving log(NOx) as the dependent variable and used a statistical approach termed Mixed Effects modeling to estimate the coefficient values. The Mixed Effects approach has statistical advantages over more commonly used methods when dealing with unbalanced datasets, as is the case here. A number of different models were specified, estimated, and the results compared in order to ensure that conclusions drawn from the analysis do not depend upon the model specifications.

For soy-based biodiesel, the Rocke study concludes that soy fuels increase NOx by 1% at B5 and by 2% at B10. The study also demonstrated that the NOx increase is linearly related to the blend level. The slope was estimated to be 0.99% for each 5% biodiesel in a blend and was highly significant statistically ($p \ll 0.001$). These results agree with the Rincon Ranch analysis presented later in this report. <u>There is no controversy with regard to the NOx impact of soy-based biodiesel.</u> Soy biodiesel will increase NOx emissions at all blend levels by about 0.2% for each 1% biodiesel in the blend.

With respect to animal biodiesel, the Rocke study concludes that animal biodiesel does not increase NOx emissions at B5 or B10. The emission changes that are observed are not statistically significant. <u>There is controversy here because the Rocke analysis did not account for the effect of feedstock blending on the CN of the tested fuels</u>. The CN change compared to ULSD is a fixed effect that must be accounted for because the four animal feedstocks that have been used in the technical literature show substantially different cetane behavior in blending.

[3] http://www.arb.ca.gov/regact/2015/adf2015/adf15appg.pdf.

The case for cetane as an explanatory variable for NOx emissions in animal blends is made in Section 2.2.4 of this report. It is well established that increasing CN will reduce NOx emissions from diesel engines. For example, ARB has shown that the additive DTBP can be used to raise CN and mitigate NOx increases caused by biodiesel blending. Whether an animal biodiesel will increase NOx depends primarily on the extent to which the feedstock blending increases CN of the blended fuel. The two animal blends that showed the smallest CN gain over ULSD caused statistically significant NOx increases in the engines tested. The one animal blend that showed the largest CN gain was certified to be NOx neutral, while the animal blend with the next largest CN gain may or may not be NOx neutral. Cetane appears to blend linearly when using soy feedstocks, so that the CN gain over ULSD is highly correlated with blend level. The same is not true for animal feedstocks, where highly non-linear blending behavior has been observed.

The Rocke analysis used a Mixed Effects model to estimate the NOx emissions change at B5 and B10. For animal blends, it concluded that the observed emission changes are not statistically significant. Implicit in the approach is the assumption that the fuels being tested are different, individual realizations from a homogenous population. In this instance, the residual variation not accounted for by the blend level is a random effect representing the scatter in test results due to a variety of factors. The statistical significance of the blend level effect (a fixed effect) is judged in comparison to the residual variation. When the residual variation is large in comparison to the fixed effect, the latter is said to be not statistically significant.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

The assumption of a homogenous population is appropriate for soy-based biodiesels. One soybean is much like the next, and the only appreciable differences among soy fuels will result from the methods of preparation. However, the assumption of homogeneity is not appropriate for animal-based biodiesels, which can be drawn from a variety of animal sources and prepared in different ways. The non-homogeneity is seen most readily in the greatly different cetane responses of biodiesel fuels:

- In the McCormick 2005 and Durbin 2011 studies, the animal feedstocks increased the CN of the biodiesel blends by small amounts. These fuels led to statistically significant increases in NOx.
- In the Durbin 2013A study, blending at the B5 level was sufficient to raise the CN of the blend by 8 numbers to reach the cetane level of the feedstock itself. This fuel was certified as NOx neutral at B5.
- The animal feedstock used in the Karavalakis 2014 study was intermediate in its CN effect and also intermediate in its NOx effect.

Because the ARB and Rocke studies have not included cetane as an explanatory variable for animal-based biodiesels, the residual variation term has been enlarged since a portion of it could be accounted for by including a fixed-effects term for cetane. With an enlarged estimate of the residual variance, the studies more easily find that the fixed effect of blend level is not statistically significant.

The absence of cetane as an explanatory variable also affects other methods of analysis used by Rocke. In a t-test comparison of emission differences between biodiesel and ULSD, Rocke finds two cases in which animal B5 changes NOx by statistically significant amounts (one increasing NOx and the other decreasing NOx) and one such case in animal B10 (decreasing NOx), while the other cases show no statistically significant change compared to the base fuel. The study wrongly concludes that these results demonstrate no or little systematic evidence for B5 or B10 animal to increase NOx emissions. In fact, these cases are systematically related to the CN gain of the animal blends in comparison to the base fuel.

The Rocke analysis was well planned and executed, and we concur with the conclusions drawn for soy-based blends. Because the analysis for animal-based blends is flawed by omission of a cetane variable, it should be revised to address CN gain. We expect that a revised analysis will shed further light on the circumstances in which animal-based biodiesels will and will not increase NOx emissions.

2.2 Rincon Ranch Analysis of ARB NOx Emissions Data

In July 2014, ARB released two datasets that represent the fruit of its efforts to compile the available biodiesel NOx emissions test data on conventional heavy-duty truck (HDT) engines. This report and the companion file *"Biodiesel Emissions Analysis Technical Summary 102014.pdf,"* which is attached to and incorporated in this report, present the results of a statistical analysis of the data sets released by ARB that was performed by Rincon Ranch Consulting at the request of Growth Energy.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

The analysis presented below focused on whether soy and animal blends will increase NOx at low blend levels in conventional diesel engines. The following issues were examined:

- The NOx impacts of soy and animal blends at B5 and B10;
- The NOx emission differences observed among animal feedstocks and blends;
- For animal blends, the effect on NOx emissions of the CN change relative to base fuel that is caused by blending of the animal feedstock; and
- The development of a cetane-based model of the biodiesel NOx impacts of soy and animal blends.

2.2.1 Data Used in the Analysis

As noted above, in July 2014, ARB released two datasets of NOx emissions data from testing of biodiesel blends in HDT engines. One file ("B5 & B10 Raw NOx Data") contains the subset of testing for B5 and B10 blends (soy and animal). The test data generated in the four ARB-sponsored UCR studies are present in the form of the individual test run measurements. Because test run information was not reported in their publications, the B5 soy data from Nikanjam 2010 and the B10 soy data from Thompson 2010 are present in the form of emission averages. No animal blends have been tested at the B5 or B10 levels except in the ARB-sponsored emissions testing. A second file ("2014 Biodiesel Literature Search Database") contains all of the biodiesel testing available in the literature through the B20 level (soy and animal), including ARB-sponsored testing and the literature search. The data are in the form of emission averages by engine, test cycle, feedstock type, and blend level.

For purposes of this analysis, the following information was added to the ARB datasets:

- The number of test replications for emissions averages for each study (estimated when the source did not report the number);
- The CN for CARB diesel, the biodiesel blends, and the biodiesel feedstocks; and
- Additional NOx emissions testing at the B50 and B100 levels (where available).

Appendix Table A presents a list of the studies included in the dataset and the author references used in citations here.

2.2.2 NOx Emissions from Soy Biodiesel Blends

Most past research on biodiesel emissions has focused on soy blends. As a result, the literature is relatively large and diverse. The dataset assembled by ARB is derived from 10 different studies, covers 13 different vegetable feedstocks (10 soy, 2 used cooking oil [UCO], 1 canola), and was conducted using 7 different test cycles on a wide variety of engines in different labs. Most of the data, in terms of number of data points, are derived from the three UCR studies (Durbin 2011, Durbin 2013B, and Karavalakis 2014) sponsored by ARB.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

We subjected the soy dataset to a number of different analyses using different statistical techniques and selections of the data to ensure that the conclusions we drew were robust. The statistical analyses included the t-test for the difference in mean values (e.g., between B5 and CARB diesel) and linear regression analysis using several different models. The data subsets were selected to use either individual test runs or emission averages and to contain testing through maximum blend levels of B5, B10, B20, B50, and B100.

Our analyses show that there is a consensus among the studies on the NOx impact of soy biodiesel without regard to the specific analytical methods or data used. Soy biodiesel increases NOx emissions by amounts that can be estimated with good statistical confidence because of the large size of the available dataset. The key conclusions are as follows:

- Soy biodiesel increases NOx emissions by ~1% at B5 and ~2% at B10;
- NOx emissions increase in a linear fashion with increasing blend level to reach ~4% at B20 and proportionately larger values at higher blend levels; and
- There is no evidence in the data for a threshold level below which soy biodiesel does not increase NOx.

These conclusions are supported by all of the available studies and data. None of the studies disagree substantially, and while the results for individual blends, engines, and test cycles will vary to some extent, the evidence across a wide range of engines and test cycles is clear. NOx increases can be expected for UCO, canola, and other vegetable biodiesels, but the data are very limited and it is not possible to draw definitive conclusions for these blends.

2.2.3 NOx Emissions from Animal Biodiesel Blends

The literature on NOx emissions from animal blends is much smaller—it consists of only four studies, three of which (Durbin 2011, Durbin 2013A, and Karavalakis 2014) were sponsored by ARB. Except for the McCormick 2005 study, the emissions testing was conducted at the UCR CE-CERT lab. A variety of test cycles were used, but most of the testing was conducted on the hot-start FTP cycle. Table 1 presents a summary of the emissions studies for animal biodiesel.

Table 1. Scope of Emissions Testing for Animal Biodiesel

	McCormick 2005	Durbin 2011	Durbin 2013A	Karavalakis 2014
Biodiesel Feedstock	Animal #1	Animal #2	Animal #3	Animal #4
Blend Levels Tested	B20	B5, B20, B50, B100	B5	B5, B10
Engines Tested	2 on-road	3 on-road, 1 off-road	1 on-road	1 on-road
Test Cycles	FTP	FTP, UDDS, 50 mph, ISO 8178	FTP	FTP, SET, UDDS
Test Replications on Biodiesel	6	126	26	80
Is NOx Increase Observed?				
At / Below B10	–	Yes	No	No
Above B10	Yes	Yes	–	–

It is important to understand the limitations of this small dataset. Without the ARB-sponsored testing, we would have only the six test replications (individual runs) conducted in the McCormick 2005 study. While the three UCR studies accumulated 232 test replications, the work involved only three different animal feedstocks. Including the McCormick 2005 study, the entire literature on NOx emissions from animal biodiesel is based on only four different animal feedstocks. The small number is an important limitation because animal feedstocks are much less homogenous than soy due the greater variety possible in animal sources and compositions. Further, there are notable differences among the four studies as to whether animal biodiesel increases NOx at the B5 and B10 levels (as indicated by the red circles in the table).

As in the soy analysis, we subjected the animal biodiesel data to a number of different analyses using different statistical techniques and selections of the data to ensure that the conclusions we drew were robust. The t-test is the most direct method to assess whether NOx emissions are higher at B5 compared to CARB diesel. Using the individual test run data available from the three UCR studies, we find the following for animal biodiesel at the B5 blend level:

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

- The animal feedstock used in Durbin 2011 increases NOx in 2 of 3 engines. The increase is highly significant[4] statistically for one engine.

- The animal feedstock used in Durbin 2013A decreases NOx in one engine. The decrease is statistically significant at the p=0.05 level, and the blend was certified as NOx neutral at B5.

- The animal feedstock used in Karavalakis 2014 increases NOx in three of six cases and decreases NOx in the other three cases. None of the changes are statistically significant. The blend may or may not change NOx.

Contrary to Staff's assertion that no NOx increase occurs in B5 animal blends, it is clear that some animal blends will significantly increase NOx emissions, while other animal blends will not. The fundamental issue is then understanding what the NOx impact of a particular animal biodiesel blend will be.

The effect of feedstock blending on the CN of the resulting animal blend is the reason for the apparently discordant results among the studies. Figure 1 plots the four series of animal blends used in the studies, with blend level on the horizontal axis and the change in blend CN (relative to CARB diesel) on the vertical axis. CN blended linearly to B20 for the McCormick feedstock, which showed a much smaller CN benefit than the feedstocks used by UCR—only three numbers at B20 (0.6 numbers at B5). In contrast, all three UCR animal blends achieve a large CN boost at low blending levels in which most or all of the CN benefit of the feedstock is achieved at B5.

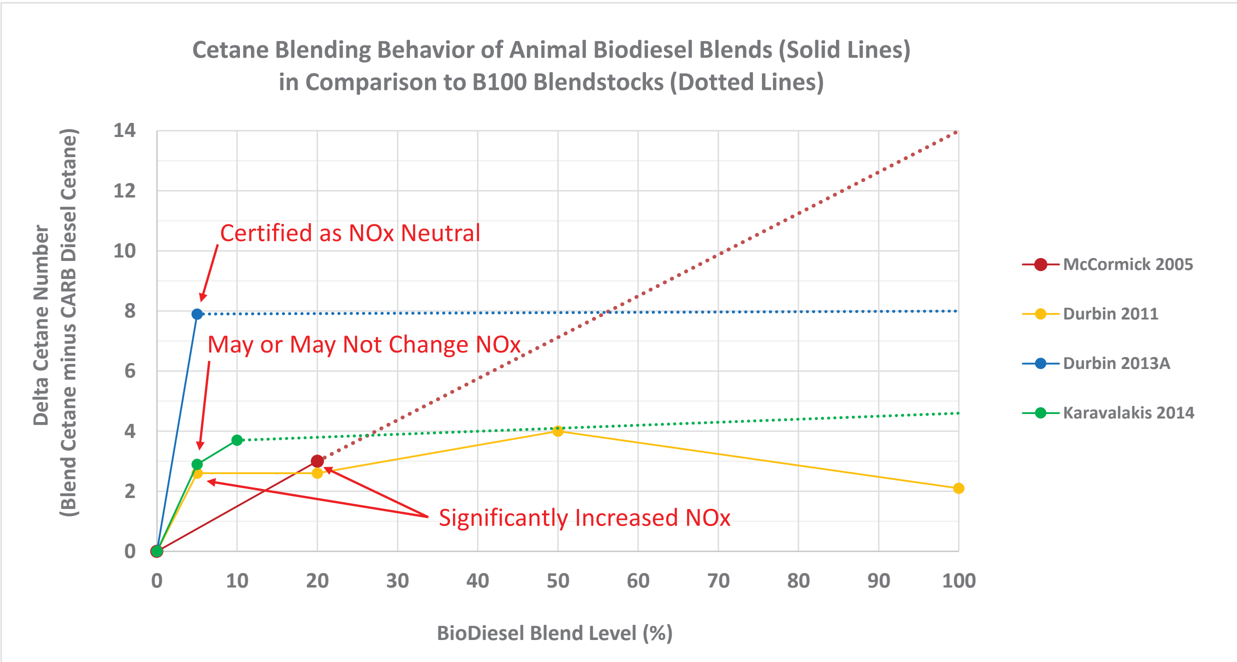
In Durbin 2011, the CNs for the blends are above that of the B100 feedstock. This result is probably caused by lab-to-lab differences (blend CN was determined at CE-CERT, while CN for CARB diesel and the B100 feedstock were determined by an outside lab). The actual CN changes are surely lower than shown here—at or below +2 CNs.

The two animal feedstocks that caused statistically significant NOx increases have the smallest CN benefits: McCormick 2005 (red) at B20 and Durbin 2011 (yellow) at B5. The animal B5 blend that passed certification testing as NOx neutral in Durbin 2013A (blue) has the highest CN benefit, where it achieved the entire B100 CN at just 5% blending. The Karavalakis 2014 B5 blend (green) had an intermediate CN benefit and may or may not change NOx.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

[4] The term "significant" is used in this report only to refer to statistical significance. When a result reaches the p=0.05 level, we can be 95 percent confident that it is real. In such case, and at smaller p values, the result is said to be statistically significant.

Figure 1. Cetane Blending Behavior of Animal Blends (Solid Lines) Compared to B100 Feedstocks (Dotted Lines)



The blending behavior of the UCR blends is surprising in comparison to the McCormick study, and we find relatively little research on the CN blending behavior of animal feedstocks. All conclusions from this dataset will be influenced by the CN blending behavior of the specific animal feedstocks involved. For such conclusions to be reliable, we must be confident that the large CN boost reported for the UCR blends is both real and representative of all animal feedstocks in California. Also, only limited information is available on the sources and characteristics of the animal feedstocks.

To permit all parties to better understand the animal feedstocks that were tested, ARB should release all information that it has on the following:

- CNs (methods of determination and measured values) for the Durbin 2011 and other UCR studies;
- Physical and chemical properties of the animal feedstocks and biodiesel blends tested;
- The distribution of sources, characteristics, and properties in the population of animal feedstocks that are available for use in the California market; and
- How the specific animal feedstocks tested at UCR were selected, including any information that would demonstrate that the feedstock properties and their CN blending behavior are representative of the animal feedstock population available for use in California.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

Staff's use of the terms low saturation (for soy) and high saturation (for animal) to classify biodiesel is useful to differentiate between feedstocks that will tend to decrease CN and those that will tend to increase it. However, it is not a sufficient step in that the CN change at each blend level is the determinative factor for NOx emissions, not the CN of the feedstock itself. Soy feedstocks appear to blend linearly with respect to cetane; however, animal feedstocks often lead to a highly non-linear CN response, as shown in Figure 1.

2.2.4 Development of a Cetane-based Model of NOx Impacts from Soy and Animal Biodiesel

The results presented above indicate the important role that CN plays in determining the NOx response for animal blends. Animal feedstocks tend to increase the CN of the blend above that of the CARB diesel and the CN change can be large at low blend levels. Soy feedstocks generally decrease the CN of the blend below that of the CARB diesel; for soy, the CN change at low blend levels can be smaller than the uncertainty in determining CN. The result of our work on a cetane-based model demonstrates that soy and animal blends are not categorically different fuels once their differing effect on CN is taken into accounted. Their NOx impacts can be represented by the same model as a function of blend level and the change in CN compared to CARB diesel.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

The document that accompanies this report explains the development of the cetane-based model in some detail. In brief, it was developed using conventional linear regression analysis with log(NOx) emissions as the dependent variable. Intercept terms were included to represent the varying emission levels on CARB diesel for each combination of study, feedstock type, engine, and test cycle. A *b* coefficient was included to represent the change in NOx emissions for each one percent biodiesel in a blend at constant CN. A *c* coefficient was included to represent the change in NOx emissions for each one number change in CN compared to CARB diesel at constant blend level. Both soy and animal blends were included in the estimation, along with the small number of canola and UCO data points, at blend levels up to (and including) B20.

The model estimation shows that the *b* and *c* coefficients are highly significant statistically ($p < 0.0001$). The estimation results also show the following:

- The *b* coefficient has a value of +0.00156, which estimates that soy and animal biodiesel will increase NOx emissions by 0.16% for each one percent biodiesel at constant CN or by 0.8% at B5.
- The *c* coefficient estimates that +5 CNs will decrease NOx emissions by 1.5% at constant blend level. This result is completely consistent with earlier work[5] on the relationship between CN and NOx emissions in HDT engines, which also found that +5 CNs will decrease NOx emissions by 1.5% in base fuels with CN ~50.

[5] The Effect of Cetane Number Increase Due to Additives on NOx Emissions from Heavy-Duty Highway Engines. EPA420-R-03-002. February 2004. Figure IV.A-1.

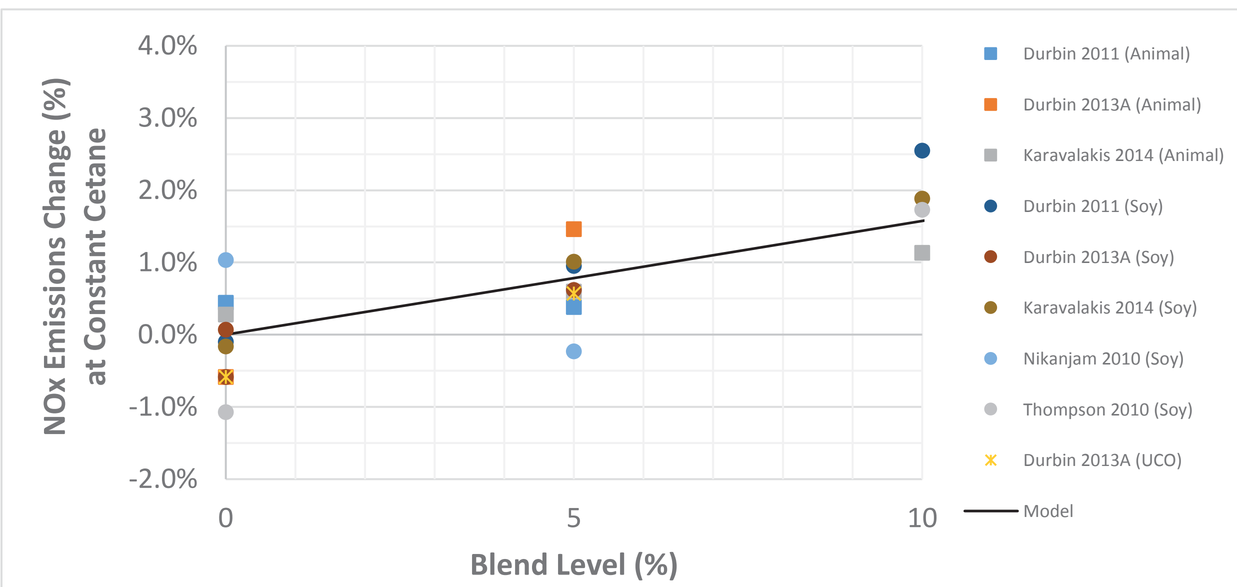
- An increase of -b/c = 0.5 CNs is needed to offset the NOx increase expected from each 1% biodiesel added. For B5, an increase of 2.5 CNs is required to offset the expected NOx increase.

The results explain why soy and animal blends appear to be different fuels. Soy blends have an additional, adverse CN effect that increases their NOx impact to ~1% at B5. Animal blends will generally increase CN and that reduces their NOx impact to about one-half the soy level or less, depending on the CN change caused by blending. The results also explain why some animal blends do not increase NOx emissions. If an animal feedstock increases CN by more than ~0.5 numbers for each 1% biodiesel blended, then the resulting fuel may not increase NOx emissions.

To demonstrate these conclusions, Figure 2 presents NOx emissions as a function of blend level for all fuels used to estimate the model once NOx emissions are adjusted for the CN change observed for each blend. For example, if an animal blend increased CN, then its NOx impact is <u>increased</u> as we return it to the base fuel CN. If a soy blend decreases CN, then its NOx impact is <u>decreased</u> as we return it to the base fuel CN. Once adjusted, percent changes in emissions are calculated. As seen in the figure, there is no discernable difference among feedstock types once CN changes are taken into account. Animal and soy blends scatter on both sides of the regression line, indicating that they obey the same blend level model.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

Figure 2. There Are No Detectable Differences Among Feedstock Types Once NOx Emissions Are Adjusted to Constant CN



Note: Animal blends are plotted as squares, soy blends as circles, and the non-soy vegetable blends as asterisks.

Note the scatter of points around the regression line (which gives the "average" response). Some of the scatter is due simply to emissions measurement error; however, other factors may be involved in determining the NOx impact for a given feedstock, including differences in the

FAME (fatty acid methyl ester) composition and uncertainty in determining CN for the blends. If ARB were to adopt a predictive model to determine the CN improvement needed to mitigate NOx, it should use the model to evaluate a "worst case" feedstock, meaning a point near the upper end of the range at each blend level.

The most important conclusion of this work is that soy and animal biodiesel blends are not categorically different fuels. Their emissions effects are similar, but they show different NOx impacts because they have different effects on CN. Furthermore, this work provides a potential answer to the problem that some animal blends will significantly increase NOx emissions, while other blends will not, by indicating what individual blends may do.

3. NOX EMISSIONS IN NEW TECHNOLOGY DIESEL ENGINES

Staff's position is that biodiesel will not increase NOx emissions in NTDEs at levels up to and including B20. Its assessment is stated in the ISOR as follows:

> *Engines that meet the latest emission standards through the use of Selective Catalytic Reduction (SCR) have been shown to have no significant difference in NOx emissions based on the fuel used. A study conducted by the NREL looked at two Cummins ISL engines that were equipped with SCR, and found that NOx emissions control eliminates fuel effects on NOx, even for B100 and even in fuels compared against a CARB diesel baseline.*[20] *However, a recent study at UC Riverside tested B50 blends and found a NOx increase with a 2010 Cummins ISX.*[21] *The UC Riverside study did not look at blends below B50. Staff proposes to take a precautionary approach and in the light of data showing there may be a NOx impact at higher biodiesel blends but not at lower biodiesel blends, Staff is limiting the conclusion of no detrimental NOx impacts in NTDEs to blends of B20 and below. Additional studies on NTDEs have been completed, however since they included either retrofit engines or non-commercial engines Staff did not include their results in this analysis*.[22,23,24] (Page 24)

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

Staff's reliance on Lammert 2012 (Ref. 20) is misplaced because the NREL lab was not equipped to measure the low NOx emission levels of the test vehicles, as the abstract of the Lammert paper clearly notes.[6] In fact, none of the emission changes observed in the study (with one exception) were statistically significant due to the high standard errors that necessarily exist when measurements are made close to the level of detection. In this instance, the failure to observe statistically significant NOx emissions increases from biodiesel at the B20 level is not a demonstration that such increases do not exist.

This specific shortcoming of the Lammert study is why its negative results are in conflict with the finding of the UC Riverside study (Gysel 2014) cited by Staff and the three other studies (Walkowicz 2009, McWilliam 2010, Mizushima 2010) that Staff dismissed. With respect to the

[6] "SCR systems proved effective at reducing NOx to near the detection limit on all duty cycles and fuels, including B100." Lammert 2012, Abstract.

three other studies, we see no reason why they should be dismissed. It is not the case that factory-designed NOx after-treatment systems will reduce NOx levels to below the detection limit of well-equipped labs (see Gysel 2014 and engine certification testing). Testing conducted using retrofit NOx after-treatment systems that achieve representative levels of NOx control, as in these studies, is entirely suitable for determining whether biodiesel increases tailpipe NOx emissions on a percentage basis. Having a different absolute level of emissions does not preclude reliable measurement of a percentage change.

When all available studies are included, a consensus of the literature is that biodiesel at the B20 level will increase NOx emissions from NTDEs in most, if not all cases. Lammert 2012 is the one study at odds with the rest of the literature. A range of biodiesel types were used in the studies. NOx increases should be expected at the B20 level for all biodiesel types until such time as additional research indicates differential impacts for biodiesels derived from different sources

3.1 Review of the NTDE Literature

The following sections briefly summarize the NTDE testing conducted in the studies and the conclusions drawn on the NOx emissions impact of biodiesel fuels. Testing of conventional diesel engines without NOx after-treatment is not considered, nor is testing on non-California fuels (low aromatics ULSD was considered equivalent to CARB ULSD). Appendix Table B presents a list of the studies included in the NTDE dataset and the author references used in citations here.

Walkowicz 2009. Chassis dynamometer testing was conducted using a 2005 International 9200i tractor equipped with and without a retrofit diesel oxidation catalyst (DOC) and urea-SCR NOx after-treatment system. On-road emissions measurements also were made using a RAVEM portable emissions measurement system. A ULSD base fuel was tested, as were B20 and B99 biodiesel blends. The type of biodiesel (soy or animal) was not specified, but was mostly likely soy-based as this is the feedstock most common in the market and in engine research.

- Under loaded, on-road conditions, biodiesel increased NOx by 17% at B20 and by about 40% at B99. At B20, the increase was marginally significant ($p=0.10$); at B99, the increase was statistically significant ($p=0.05$).
- Chassis dyno testing was done 24 months later at an ARB lab. The vehicle was determined to have high oil consumption, and lubricating oil was likely present in the exhaust stream. On the UDDS cycle, biodiesel increased NOx by 7% at B20 (marginally significant at $p=0.07$) and by 35% at B99 (highly significant, $p<0.01$).

The authors concluded "The use of biodiesel did result in higher NOx emissions than the use of ULSD (in tests with statistical significance)." The B20 test results did not reach the usual $p=0.05$ level for statistical significance, but were marginally significant ($0.05 < p \leq 0.10$).

McWilliam 2010. A Caterpillar 6.61 engine equipped with DOC and urea-SCR NOx after-treatment was tested using the European non-road transient cycle (NRTC). The fuels used were ULSD plus B20 and B100 biodiesels blended from a rapeseed methyl ester. Figure 9 of the paper shows tailpipe NOx emissions of the vehicle in g/kWh units. Reading from the graph because numerical emission values were not given, tailpipe NOx emissions increase ~15% at B20 and ~150% at B100. Based on the narrow error bars shown in the figure, both of these increases are statistically significant.

This study was conducted by Caterpillar because previous work had highlighted the potential for biodiesel to have an adverse impact on the NOx conversion efficiency of urea-SCR after-treatment systems. Thus, reductions in conversion efficiency have the potential to increase NOx emissions by amounts that exceed that caused by the biodiesel itself. At B20, only a 1% loss of conversion efficiency was noted, but a substantial 6% loss was observed at B100.

The authors of this paper concluded "Additional control strategies will be necessary to correct for NOx increases during biodiesel operation on installations requiring compliance regardless of fuel used."

Mizushima 2010. An inline 4-cylinder diesel engine equipped with DOC, diesel particulate trap (DPT), and urea-SCR NOx after-treatment system was tested using the JE-05 exhaust emissions test cycle used for heavy-duty vehicles in Japan. The fuels used were ULSD plus B20 and B100 blended from waste vegetable oil (WVO). Figure 4 of the paper shows tailpipe NOx emissions of the engine in g/kWh units. NOx emissions are highly linear with biodiesel blending level. Reading from the graph because numerical emission values were not given, tailpipe emissions increase ~20% at B20 and ~100% at B100. The paper does not address the statistical significance of these results.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

With respect to NOx conversion efficiency, the study noted a drop from 76% on ULSD to 47% at B100, with a smaller but still measurable drop at B20. The impact on NOx conversion efficiency was linked to the effect of biodiesel in lowering the overall NO_2/NOx ratio at the SCR inlet leading to reduced conversion efficiency.

The authors drew no conclusions regarding the NOx emissions effects of B20 biodiesel as the focus of their research was on the B100 fuel.

Lammert 2012. The NREL study examined NOx emissions from transit buses on both EPA and CARB diesel fuels, B20 soy blends of each, and B100 soy. Chassis dynamometer testing was conducted using the Manhattan Bus (MAN), Orange County Transit Authority (OCTA) and UDDS test cycles. Two of the buses were NTDEs, including a 2010 Cummins ISL and 2011 Gillig/Cummins ISL. Only the 2010 Cummins was tested using the CARB ULSD base fuel and the biodiesel fuels.

NOx emission results for the 2010 Cummins bus are shown in Figure 10 of the paper. For B20, NOx emissions decreased compared to CARB ULSD on all three cycles (MAN, OCTA, and UDDS), and for B100 on the MAN cycle (OCTA and UDDS were not tested). None of the differences were statistically significant except for B20 on the UDDS cycle, and the standard errors plotted in the figure are large in comparison to the emission averages.

The authors explain the non-significance of their results as follows:

> *For much of the cycle NOx would be at or near the detection limit of the laboratory equipment, which resulted in a 95% confidence interval error that was high relative to the value of the cycle emissions.* (Page 6)

One of the authors' conclusions is that SCR NOx after-treatment appears to nearly negate the effect of fuels on NOx emissions. Another conclusion is that SCR NOx after-treatment also negates any duty cycle effect on NOx. (Page 8) For buses without NOx after-treatment, NOx emissions are strongly related to the kinetic intensity (load) of the test cycle. This result is consistent with all past vehicle and engine research studies, which show that NOx emissions are increased when a diesel engine is operated under increased load. However, no such relationship is observed for SCR-equipped buses. Increased load will increase engine-out NOx levels in an SCR-equipped bus. Unless this is accompanied by an increase in NOx conversion efficiency, tailpipe NOx emissions should also increase. Neither conclusion is reliable because of the study's problems in measuring NOx emissions even on ULSD fuel.

Gysel 2014. A 2010 Cummins ISX-15 equipped with DOC, DPF and urea-SCR NOx after-treatment was tested on CARB ULSD and B50 biodiesel blended from soy, waste cooking oil (WCO) and animal fat feedstocks. Chassis dynamometer testing was performed at CE-CERT using the UDDS test cycle.

Figure 7 of the paper shows the NOx emissions measured on ULSD and the three B50 biodiesel blends. The soy and WCO B50 blends increased NOx by 43% and 101%, respectively, with both increases being highly statistically significant ($p<0.01$). The animal B50 blend increased NOx by 47%, which was marginally significant ($p=0.065$). The authors' conclude that "Overall, NOx emissions exhibited increases with biodiesel for both vehicles with the differences in NOx emissions relative to CARB ULSD being statistically significant for the new Cummins ISX-15 engine." (Page 6)

The authors note the negative results reported by Lammert 2012 as being in contrast to those of their study, "which shows that there is a relatively strong fuel effect with the B50 blends compared to CARB ULSD from the Cummins ISX-15 engine with SCR." (Page 6). They also note the following:

> *The NOx increase with biodiesel for SCR-equipped engines is usually attributed by a reduction of exhaust temperature and the change of NO_2/NO ratio in NOx emissions [38]. In general, the lower exhaust temperatures with biodiesel will lower the oxidation rates of NO to NO_2 from the DOC. It has been shown that a NO_2/NOx ratio below 0.5 significantly changes SCR reaction chemistry lowering the SCR removal efficiency of NOx [39]. Walkowicz et al. [40] found increases in NOx emissions of 7% with B20 and 26% with B99 compared to ULSD for a heavy-duty diesel vehicle equipped with a 2004 Caterpillar 400 hp C13 engine. For the same vehicle equipped with a urea-based SCR system, NOx increases were very similar on a percentage basis, with B20 and B99 having 7% and 27%, respectively, higher NOx than ULSD.* (Page 6)

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

The authors continue to say:

> *The trend of increasing NOx emissions for biodiesel blends is consistent with a wide range of studies found in the literature. Comprehensive investigations conducted by Mueller et al. [41] and Sun et al. [42] confirmed that biodiesel promotes a combustion process that is shorter and more advanced than conventional diesel, which contributes to the formation of thermal NOx. The higher NOx emissions with biodiesel for both vehicles could also be a consequence of the higher oxygen content in biodiesel, which enhances the formation of NOx. The lower volatility of biodiesel compared to diesel fuel could also contribute to decreased fractions of premixed burn, as a result of fewer evaporated droplets during the ignition delay period [43]. Another contributing factor for NOx emissions increase could be the engine control module (ECM), which may dictate a different injection strategy based on the lower volumetric energy content of biodiesel. Eckerle et al. [44] suggested that a higher fuel flow is required with biodiesel compared to diesel fuel for an engine to achieve the same power. The ECM interprets this higher fuel flow as an indicator of higher torque, and therefore makes adjustments to engine operating parameters that, under certain operating conditions, increase NOx emissions.* (Page 6).

The engineering mechanisms described by the authors indicate that <u>biodiesel should be expected to increase NOx emissions in NTDEs at blend levels below the B50 examined in the study</u>. There is no basis in these mechanisms to believe that biodiesel <u>will not</u> increase NOx emissions at B20 but <u>will</u> increase NOx emissions at B50.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

3.2 Consensus on Biodiesel NOx Impacts

Table 2 presents a summary of the available literature on the NOx emissions impact of biodiesel at the B20 blend level. Four of the five studies tested B20 fuels on NTDEs. Staff choose to rely on the one study in which NOx emissions were at or near the detection limit of the laboratory equipment for much of the test cycle on each fuel and to dismiss the other three studies "… since they included either retrofit engines or non-commercial engines …". The study that was retained did not observe a NOx increase because it had trouble measuring NOx emissions from the NTDE tested. The studies that were dismissed showed consistent NOx emission increases in the range of 10-20% at B20.

Staff notes the Gysel study, which found significantly increased NOx emissions at B50 compared to CARB ULSD, as its reason for setting the biodiesel control level at B20 for NTDEs. However, Staff did not note the study's discussion indicating that the Lammert results were in contrast to their results and to the results of other studies in the literature. Nor did Staff note the discussion of mechanisms by which biodiesel is believed to increase NOx emissions in NTDEs. These mechanisms include a reduction of the NO_2/NOx ratio that leads to loss of NOx conversion efficiency in urea-SCR systems, promotion of a combustion process that contributes to increased formation of thermal NOx, higher NOx emissions due to the oxygen content of biodiesel, and the lower volatility and lower volumetric energy content of biodiesel. <u>These mechanisms indicate that biodiesel can be expected to increase NOx emissions in NTDEs at blend levels below the B50 examined in the study</u>.

Table 2. Summary of NTDE Literature on NOx Emissions Impact of B20

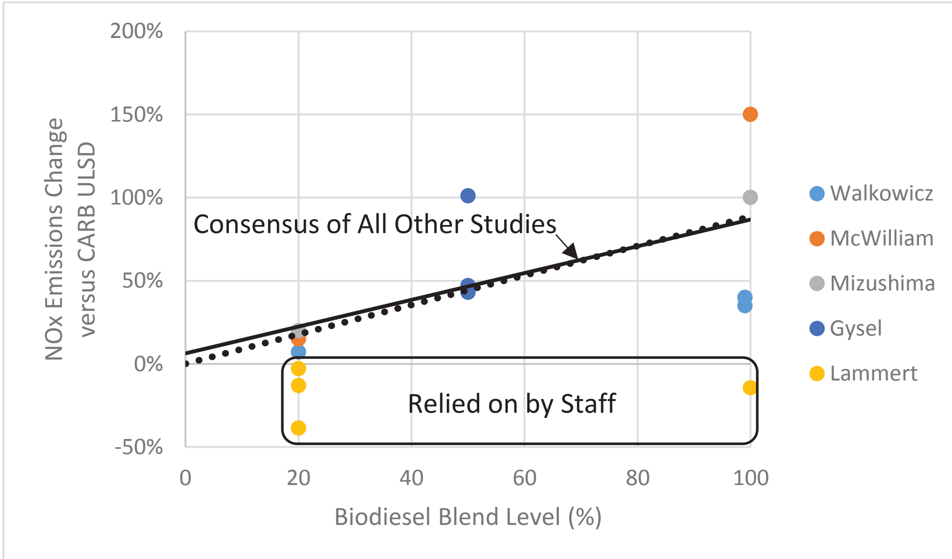
	B20 NOx Emissions Change (%) versus CARB ULSD	Comments
Studies Relied on by Staff		
Lammert 2012	NOx emissions decrease on three cycles	UDDS cycle decrease is statistically significant. NOx emissions on all fuels were at or near the detection limit of the laboratory equipment.
Gysel 2014	B20 not tested	The paper discusses how biodiesel effects NOx emissions. These mechanisms suggest that biodiesel <u>should</u> increase NOx emissions at levels below B50.
Studies Dismissed by Staff		
Walkowicz 2009	+17% on-road + 7% chassis dyno	Both results are marginally significant ($0.10 \leq p < 0.05$)
McWilliam 2010	~15% increase	European transient cycle
Mizushima 2010	~20% increase	Japanese heavy-duty test cycle

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

Figure 3 summarizes the impact of biodiesel on NTDE NOx emissions at all blend levels. The four studies (excluding Lammert 2012) establish a linear relationship between NOx emissions and blend level. The first trend line (solid black) passes very nearly through the origin without being constrained to do so. The second trend line (dotted black) is constrained to pass through the origin. While there is substantial scatter around the trend lines, the consensus of the four studies is that biodiesel increases NOx by 18-22% at B20, by 45-50% at B50, and by 90-100% at B100.

In spite of this consensus, Staff chose to rely only on the Lammert 2012 study, which shows that biodiesel <u>decreases</u> NOx emissions at both the B20 and B100 blend levels. This is the study that had difficulty measuring NOx emissions because NOx was at or near the detection limit of the laboratory equipment for much of the test cycle on all fuels.

Figure 3. The Impact of Biodiesel on NTDE NOx Emissions



To test the statistical significance of the trend lines shown in the figure, conventional regression analysis was conducted using the data reported by four of the studies (Lammert 2012 excluded) as summarized in Table 3. Regression A corresponds to the figure's solid trend line and is not constrained to pass through the origin. Its slope is +0.80% increase per 1% biodiesel in the blend; it is statistically significant at the $p=0.035$ level. Regression B corresponds to the dotted trend line and is constrained to pass through the origin. Its slope is +0.89% increase per 1% biodiesel, and it is statistically significant at the $p<0.001$ level. The two regression models predict a 22% and 18% increase, respectively, in NOx emissions at B20 in NTDEs.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

Table 3. Statistical Significance of Biodiesel NOx Effect in NTDEs

	Intercept	Significance	Slope (% NOx Increase per 1% biodiesel)	Significance	Predicted NOx Increase at B20
Regression A	6.4	p = 0.80	+0.80% (±0.32%)	p = 0.035	22%
Regression B	None	n/a	+0.89% (±0.16%)	p <0.001	18%

A fair reading of the technical literature would lead Staff to expect that biodiesel will increase NOx emissions in NTDEs by about 20% at B20 and by proportionately smaller amounts at blend levels below B20. At the B5 level, the impact is expected to be an increase in NOx emissions of about 5%. At the B20 level, the NOx increase appears to be greater on a percentage basis than would be expected in conventional diesel engines (1% at B5, 2% at B10, and ~4% at B20). The loss of NOx conversion efficiency when biodiesel fuels are used is one likely reason for the greater impact.

4. SUMMARY AND CONCLUSIONS

The key conclusions of this study are summarized below with respect to conventional diesel engines and new technology diesel engines.

Conventional Diesel Engines

- Soy and animal blends are not categorically different fuels once their differing effect on blend CN is taken into account.
- There is no evidence in the data of a threshold level below which biodiesel fuels as a group do not increase NOx, whether soy or animal. As shown here, the magnitude of the NOx impact observed depends on both the blend level and the change in CN that results from blending of the biodiesel feedstock.
- Soy blends clearly and significantly increase NOx by ~1% at B5 and by ~2% at B10. The effect is continuous and linear with respect to the blend level at all levels above ULSD. Soy blends require mitigation at all levels to offset increased NOx emissions.
- Staff's proposal requires NOx mitigation in summer months for soy fuels at blend levels greater than B5. Because soy fuels increase NOx at all blend levels, mitigation should be required for B5 and lower blends to prevent increased NOx emissions.
- Animal blends are more complicated. The current research is limited, and the evidence is mixed. At least one B5 animal blend significantly increased NOx, while another has been certified as NOx neutral. Other B5 animal blends may or may not increase NOx depending on their CN effect (and possibly other factors).
- Staff's assertion that no NOx increase occurs at B5 in animal blends is incorrect: some animal blends will significantly increase NOx emissions, while other animal blends will not.
- Animal blends cannot be assumed to have no impact on NOx emissions without a demonstration that feedstock blending raises CN enough to offset potential NOx increases.

New Technology Diesel Engines

- Staff is incorrect in concluding that biodiesels will not increase NOx in NTDEs. The Staff conclusion is based on a highly selective reading of the technical literature that relies on the one study in which the laboratory was not well equipped to measure the low levels of tailpipe NOx emissions from NTDEs.

Reproduction of Pages 531 -558 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-153 through ADF B3-197

- There is greater reason to exclude the study Staff relied on than the three studies that Staff excluded. If that is done, there are no test data at the B20 level or below in NTDEs and no basis whatsoever to permit biodiesel fuels in NTDEs in California.

- While the available data are limited, the four best studies (excluding Lammert 2012) support the conclusion that biodiesel increases NOx by 18-22% at B20 and that the increase is statistically significant. Staff has no basis to claim that no NOx impacts are associated with biodiesel at the B20 level and below in NTDEs.

- A fair reading of the technical literature would lead Staff to expect that biodiesel will increase NOx emissions by about 20% at B20 and by proportionately smaller amounts at lower blend levels. This is a greater percentage NOx increase in proportion to blend level than the increase caused by soy biodiesel in conventional diesel engines (1% at B5, 2% at B10, and ~4% at B20).

- Staff makes no mention of the concern that the use of biodiesel fuels may lead to the loss of NOx conversion efficiency in urea-SCR after-treatment systems by shifting the NO_2/NOx ratio to lower values. Conversion losses were observed at B20 in two of the studies.

Based on the results summarized above, it is strongly recommended that ARB consider as part of the ADF rulemaking a regulatory structure in which the NOx impacts of soy and animal biodiesel are accounted for using a statistical model analogous to the Predictive Model for RFG. We see the cetane-based model presented here as a possible draft for a biodiesel predictive model, but substantial additional work is needed to:

- Demonstrate that blends mitigated using DTBP obey the same model; and

- Further assess the impacts of biodiesel produced from animal feedstocks on both CN gain in blends as well as NOx emissions.

Further, more advanced statistical techniques should be used as was done in developing the Predictive Model for California Reformulated gasoline. The dataset used here is unbalanced, meaning that there are varying numbers of data points for each combination of study, feedstock type, engine, and test cycle. In fact, only a fraction of all possible study/feedstock/engine/test cycle cells are represented by one or more data points. Mixed Effects modeling is appropriate in such cases and its use will assure that coefficient estimates are not biased by the unbalanced distribution of the data.

1.ĀEXECUTIVE SUMMARY

1.1ĀBackground on the Proposed Rule

The California Air Resources Board (CARB) has proposed regulations on the commercialization of alternative diesel fuel (ADF) that were to be heard at the December 2013 meeting of the Board. The proposed regulations seek to "… create a streamlined legal framework that protects California's residents and environment while allowing innovative ADFs to enter the commercial market as efficiently is possible."[1] In this context ADF refers to biodiesel fuel blends. Biodiesel fuels are generally recognized to have the potential to decrease emissions of several pollutants, including hydrocarbons (HC), carbon monoxide (CO), and particulate matter (PM), but are also recognized to have the potential to increase oxides of nitrogen (NOx) unless mitigated in some way. NOx emissions are an important precursor to smog and have historically been subject to stringent emission standards and mitigation programs to prevent growth in emissions over time. A crucial issue with respect to biodiesel is how to "… safeguard against potential increases in oxides of nitrogen (NOx) emissions."[2]

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

The proposed regulations are presented in the Staff Report: Initial Statement of Reasons (ISOR) for the Proposed Regulation on the Commercialization of New Alternative Diesel Fuels[3] (referenced as ISOR). Chapter 5 of the document describes the proposed regulations, which exempt diesel blends with less than 10 percent biodiesel (B10) from requirements to mitigate NOx emissions:

> *There are two distinct blend levels relative to biodiesel that have been identified as important for this analysis. Based on our analysis to date, we have found that diesel blends with less than 10 percent biodiesel by volume (<B10) have no significant increase in any of the pollutants of concern and therefore will be regulated at Stage 3B (Commercial Sales not Subject to Mitigation). However, we have found that biodiesel blends of 10 percent and above (≥B10) have potentially significant increases in NOx emissions, in the absence of any mitigating factors, and therefore those higher blend levels will be regulated under Stage 3A (Commercial Sales Subject to Mitigation).*[4]

[1] "Notice of Public Hearing to Consider Proposed Regulation on the Commercialization of New Alternative Diesel Fuels." California Air Resources Board, p. 3. *http://www.arb.ca.gov/regact/2013/adf2013/adf2013notice.pdf*.
[2] Ibid. p. 3.

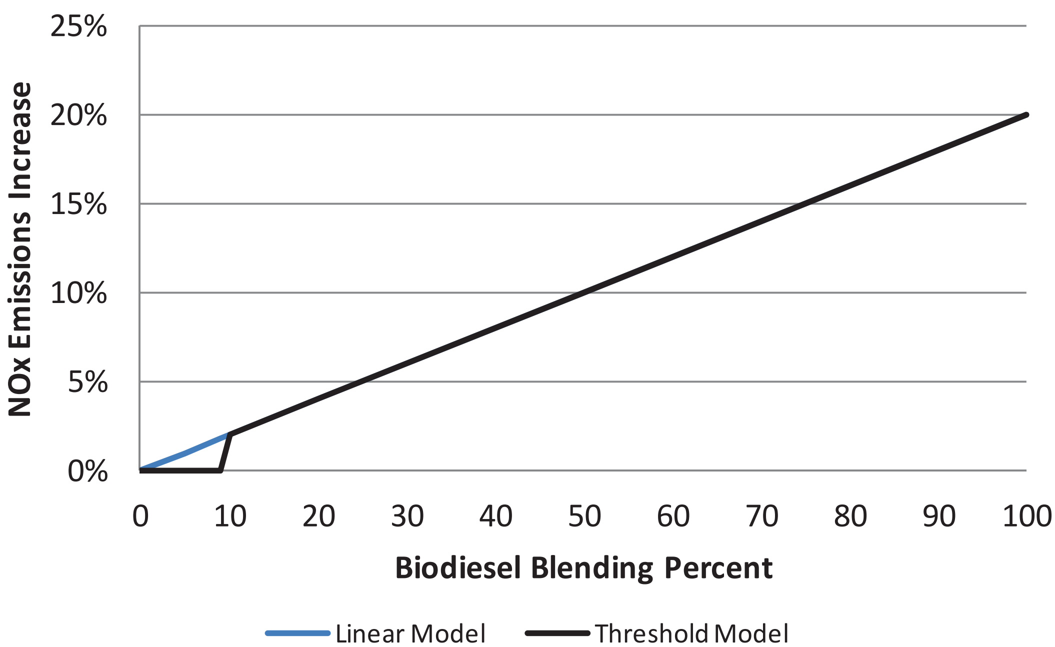
[4] Ibid, p. 22.

Existing research on the NOx emission effects of biodiesel has consistently been conducted under the hypothesis that the emission effect will be linearly proportional to the blending percent of neat biodiesel (B100) with the base diesel fuel. The Linear Model that has been accepted by researchers is shown as the blue line in Figure 1-1. The Staff position cited above is that biodiesel fuels do not increase NOx emissions until the fuel blend reaches 10% biodiesel. This so-called Staff Threshold Model departs from the Linear Model that underlies past and current biodiesel research by claiming that NOx emissions do not increase until the biodiesel content reaches 10 percent.

Figure 1-1
Linear and Staff Threshold Models for Biodiesel NOx Impacts



The Staff Threshold model is justified by the statement: "*Based on our analysis to date, we have found that diesel blends with less than 10 percent biodiesel by volume (<B10) have no significant increase in any of the pollutants of concern.*" Other portions of the ISOR state that Staff will track "… the effective blend level on an annual statewide average basis until the effective blend level reaches 9.5 percent. At that point, the biodiesel producers, importers, blenders, and other suppliers are put on notice that the effective blend-level trigger of 9.5 percent is approaching and mitigation measures will be required once the trigger is reached."[5] Until such time, NOx emission increases from biodiesel blends below B10 will not require mitigation.

Section 6 of the ISOR presents a Technology Assessment that includes a literature search the Staff conducted to obtain past studies on the NOx impact of biodiesel in heavy-duty

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

[5] Ibid, p. 24.

engines using California diesel (or other high-cetane diesel) as a base fuel. Section 6.d presents the results of the literature search with additional technical information provided in Appendix B. The past studies include the Biodiesel Characterization and NOx Mitigation Study[6] sponsored by CARB (referenced as Durbin 2011).

The results of the Staff literature search are summarized in Table 1-1, which has been reproduced from Table 6.1 of the ISOR. For B5 and B20, the data represent averages for a mix of soy- and animal-based biodiesels, which tend to have different impacts on NOx emissions (animal-based biodiesels increase NOx to a lesser extent). For B10, the data represent an average for soy-based biodiesels only. Staff uses the +0.3% average NOx increase at B5 in comparison to the 1.3% standard deviation to conclude:

> *Overall, the testing indicates different NOx impacts at different biodiesel percentages. Staff analysis shows there is a wide statistical variance in NOx emissions at biodiesel levels of B5, providing no demonstrable NOx emissions impact at this level and below. At biodiesel levels of B10 and above, multiple studies demonstrate statistically significant NOx increases, without additional mitigation.*[7]

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

Table 1-1
Results of Literature Search Analysis

Biodiesel Blend Level	NOx Difference	Standard Deviation
B5	0.3%	1.3%
B10[a]	2.7%	0.2%
B20	3.2%	2.3%

Source: Table 6.1 of Durbin 2011
Notes:
[a] Represents data using biodiesel from soy feedstocks.

<u>The Staff conclusion is erroneous because it relies upon an apples-to-oranges comparison among the blending levels</u>. Each of the B5, B10, and B20 levels include data from a different mix of studies, involving different fuels (soy- and/or animal-based), different test engines, and different test cycles. The B5 values come solely from the CARB Biodiesel Characterization study, while the B10 values come solely from other studies. The B20 values are a mix of data from the CARB and other studies. The results seen in the table above are the product of the uncontrolled aggregation of different studies that produces incomparable estimates of the NOx emission impact at the three blending levels.

[6] "CARB Assessment of the Emissions from the Use of Biodiesel as a Motor Vehicle Fuel in California: Biodiesel Characterization and NOx Mitigation Study." Prepared by Thomas D. Durbin, J. Wayne Miller and others. Prepared for Robert Okamoto and Alexander Mitchell, California Air Resources Board. October 2011.
[7] ISOR, p. 32.

As will be demonstrated in this report, the Staff conclusion drawn from the data in Table 1-1 is not supported by past or current biodiesel research, including the recent testing program sponsored by CARB. In fact, past and current studies indicate that biodiesel blends at any level will increase NOx emissions in proportion to the blending percent unless specifically mitigated by additives or other measures.

1.2 Summary and Conclusions

The following sections of this report examine the studies cited by CARB one-by-one. As evidenced from this review, it is clear that the data do not support the Staff conclusion and, indeed, the data refute the Staff conclusion in some instances. Specifically:

- There is no evidence supporting the Staff conclusion that NOx emissions do not increase until the B10 level is reached. Instead, there is consistent and strong evidence that biodiesel increases NOx emissions in proportion to the biodiesel blending percent.

- There is clear and statistically significant evidence that biodiesel increases NOx emissions at the B5 level in at least some engines for both soy- and animal-based biodiesels.

Considering each of the six past studies obtained from the technical literature and their data on high-cetane biodiesels comparable to California fuels, we find the following:

1. None of the six studies measured the NOx emissions impact from biodiesel at blending levels below B10. Only two studies tested a fuel at the B10 level. All other testing was at the B20 level or higher. Because none tested a B5 (or similar) fuel, none of them *can* provide direct evidence that NOx emissions are not increased at B5 or other blending levels below B10.

2. These studies provide no data or evidence supporting the validity of the Staff's Threshold Model that biodiesel below B10 does not increase NOx emissions. In fact, all of the studies are consistent with the contention that biodiesel increases NOx emissions in proportion to the blending percent.

3. Two of the studies present evidence and arguments that the NOx impact from biodiesel is a continuous effect that is present even at very low blending levels and will increase at higher levels in proportion to the blending percentage.

Considering the CARB Biodiesel Characterization report, we find that:

4. For the three engines where CARB has published the emission values measured in engine dynamometer testing, all of the data demonstrate that biodiesel fuels significantly increase NOx emissions for both soy- and animal-based fuels by amounts that are proportional to the blending percent. This is true for on-road and off-road engines and for a range of test cycles.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

5. Where B5 fuels were tested for these engines, NOx emissions were observed to increase. NOx emission increases are smaller at B5 than at higher blending levels and the observed increases for two engines were not statistically significant by themselves based on the pair-wise t-test employed in Durbin 2011.[8] However, the testing for one of the engines (the 2007 MBE4000) showed statistically significant NOx emission increases at the B5 level for both soy- and animal-based blends.

By itself, the latter result is sufficient to disprove the Staff's contention that biodiesel blends at the B5 level will not increase NOx emissions.

Based on examination of all of the studies cited by CARB as the basis for its proposal to exempt biodiesels below B10 from mitigation, it is clear that the available research points to the expectation that both soy- and animal-based biodiesel blends will increase NOx emissions in proportion to their biodiesel content, including at the B5 level. CARB's own test data demonstrate that B5 will significantly increase NOx emissions in at least some engines.

Based on data in the CARB Biodiesel Characterization report, soy-based biodiesels will increase NOx emissions by about 1% at B5 (and 2% at B10), while animal-based biodiesels will increase NOx emissions by about one-half as much: 0.45% at B5 (and 0.9% at B10). All of the available research says that the NOx increases are real and implementation of mitigation measures will be required to prevent increases in NOx emissions due to biodiesel use at blending levels below B10.

Finally, we note that CARB has not published fully the biodiesel testing data that it relied on in support of the Proposed Rule and thereby has failed to adequately serve the interest of full public disclosure in this matter. The CARB-sponsored testing reported in Durbin 2011 is the sole source of B5 testing cited by CARB as support for the Proposed Rule. Durbin 2011 publishes only portions of the measured emissions data in a form that permits re-analysis; it does not publish any of the B5 data in such a form. It has not been possible to obtain the remaining data through a personal request to Durbin or an official public records request to CARB and, to the best of our knowledge, the data are not otherwise available online or through another source.

CARB should publish all of the testing presented in Durbin 2011 and any future testing that it sponsors in a complete format that allows for re-analysis. Such a format would be (a) the measured emission values for each individual test replication; or (b) averages across all test replications, along with the number of replications and the standard error of the individual tests. The first format (individual test replications) is preferable because that would permit a full examination of the data including effects such as test cell drift over time. Such publication is necessary to assure that full public disclosure is achieved and that future proposed rules are fully and adequately informed by the data.

---

[8]As discussed in Section 3.3, the pair-wise t-test is not the preferred method for demonstrating statistical significance.

1.3Ā Review of 2013 CARB B5 Emission Testing

In December 2013, after the release of the ISOR and in response to an earlier Public Records Act request, CARB released a copy of new CARB-sponsored emission testing conducted by Durbin and others at the University of California CE-CERT[9]. The purpose of the study was "*... to evaluate different B5 blends as potential emissions equivalent biodiesel fuel formulations for California.*"[10] Three B5 blends derived from soy, waste vegetable oil (WVO), and animal biodiesel stocks were tested on one 2006 Cummins ISM 370 engine using the hot-start EPA heavy-duty engine dynamometer cycle. A preliminary round of testing was conducted for all three fuels followed by emissions-equivalent certification testing per 13 CCR 2282(g) for two of the fuels. As noted by Durbin: "*[t]he emissions equivalent diesel certification procedure is robust in that it requires at least twenty replicate tests on the reference and candidate fuels, providing the ability to differentiate small differences in emissions.*"[11]

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

Soy and WVO B5 Biodiesel

The B5-soy and B5-WVO fuels were blended from biodiesel stocks that were generally similar to the soy-based stock used in the earlier CARB Biodiesel Characterization Study (Durbin 2011) with respect to API gravity and cetane number. In the preliminary testing, the two fuels "*...showed 1.2-1.3% statistically significant [NOx emissions] increases with the B5-soy and B5-WVO biodiesel blends compared to the CARB reference fuel.*"[12] The B5-WVO fuel caused the smaller NOx increase (1.2%) and was selected for the certification phase of the testing. There, it "*... showed a statistically significant 1.0% increase in NOx compared to the CARB reference fuel*"[13] and failed the emissions-equivalent certification due to NOx emissions.

Animal B5 Biodiesel

The B5-animal derived fuel was blended from an animal tallow derived biodiesel that was substantially different from the animal based biodiesel used in the earlier Durbin study, and was higher in both API gravity and cetane number. The blending response for cetane number was also surprising, in that blending 5 percent by volume of a B100 stock (cetane number 61.1) with 95% of CARB ULSD (cetane number 53.1) produced a B5 fuel blend with cetane number 61.

In preliminary testing, the B5-animal fuel showed a small NOx increase which was not statistically significant, causing it to be judged the best candidate for emissions-equivalent certification. In the certification testing, it "*...showed a statistically*

[9] "*CARB B5 Biodiesel Preliminary and Certification Testing*." Prepared by Thomas D. Durbin, G. Karavalakis and others. Prepared for Alexander Mitchell, California Air Resources Board. July 2013. This study is not referenced in the ISOR, nor was it included in the rule making file when the hearing notice for the ADF regulation was published in October 2013.

[12] Ibid, p. 8.
[13] Ibid, p. 9.

significant 0.5% reduction in NOx compared to the CARB reference fuel"[13] and passed the emissions-equivalent certification. The NOx emission reduction for this fuel blend appears to be real for this engine, but given the differences between the blendstock and the animal based biodiesel blendstock used in the earlier Durbin study it is unclear that it is representative for animal-based biodiesels in general..

Summary

The conclusions drawn in the preceding section are not changed by the consideration of these new emission testing results. For plant-based biodiesels (soy- and WVO-based), the new testing provides additional and statistically significant evidence that B5 blends ***will*** increase NOx emissions at the B5 level. The result of decreased NOx for the B5 animal-based blend stands out from the general trend of research results reviewed in this report. However:

- The same result – reduced NOx emissions for some fuels and engines – has sometimes been observed in past research, as evidenced by the emissions data considered by CARB staff in ISOR Figure B.3 (reproduced in Figure 2.1 below). As shown, some animal-based B5 and B20 fuels reduced NOx emissions while others increased NOx emissions with the overall conclusion being that NOx emissions increase in direct proportion to biodiesel content of the blends and that there is no emissions threshold.

- Increasing cetane is known to generally reduce NOx emissions and has already been proposed by CARB as a mitigation strategy for increased NOx emissions from biodiesel[14]. The unusual cetane number response in the blending and the high cetane number of the B5-animal fuel may account for the results presented in the recently released study.

Considering the broad range of plant- and animal-based biodiesel stocks that will be used in biodiesel fuels, we conclude that the available research (including the recently released CARB test results) indicates that unrestricted biodiesel use at the B5 level will cause real increases in NOx emissions and that countermeasures may be required to prevent increases in NOx emissions due to biodiesel use at blending levels below B10.

[14] For example, see Durbin 2011 Section 7.0 for a discussion of NOx mitigation results through blending of cetane improvers and other measures.

2.Ā CARB LITERATURE REVIEW

The Staff ISOR explains that the Appendix B Technology Assessment is the basis for CARB's conclusion that biodiesels below B10 have no significant impact on NOx emissions. The assessment is based on data from seven studies (identified in Table 2-1) that tested high-cetane diesel fuels. The first study (Durbin 2011) is the Biodiesel Characterization Study that was conducted for CARB, while the others were obtained through a literature search.

Table 2-1

Source: Figures B.2 and B.3 of Appendix B: Technology Assessment

soy-based biodiesels are shown to increase NOx emissions by approximately 1% at B5, 2% at B10, and 4% at B20. Animal-based biodiesels are shown to increase NOx emissions by about one-half as much: 0.45% at B5, 0.9% at B10, and 1.8% at B20. Although there is substantial scatter in the results, these data do not appear to support the Staff Threshold Model that biodiesel does not increase NOx emissions at B5 but does so at B10.

We will examine the Durbin 2011 study at some length in Section 3. In this section, we look at each of the other studies cited by the Staff to find out what the studies say about NOx emissions impacts at and below B10.

2.1 Review of Literature Cited in the ISOR

The Staff literature search sought and selected testing that used fuels with cetane levels comparable to California diesel fuels; the Staff does not, however, list those fuels or provide the data that support the tables and figures in Appendix B of the ISOR. Therefore, we have necessarily made our own selection of high-cetane fuels in the course of reviewing the studies. The key testing and findings of each study are summarized below, with a specific focus on what they tell us about NOx emission impacts at B10 and below.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

2.1.1 Clark 1999

This study tested a variety of fuels on a 1994 7.3L Navistar T444E engine. Of the high-cetane base fuels, one base fuel (Diesel A, off-road LSD) was blended and tested at levels of B20, B50, and B100. NOx emissions were significantly increased for all of the blends. The other base fuel (CA Diesel) was tested only as a base fuel. Its NOx emissions were 12% below that of Diesel A, making it is unclear whether Diesel A is representative of fuels in CA. <u>This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below</u>.

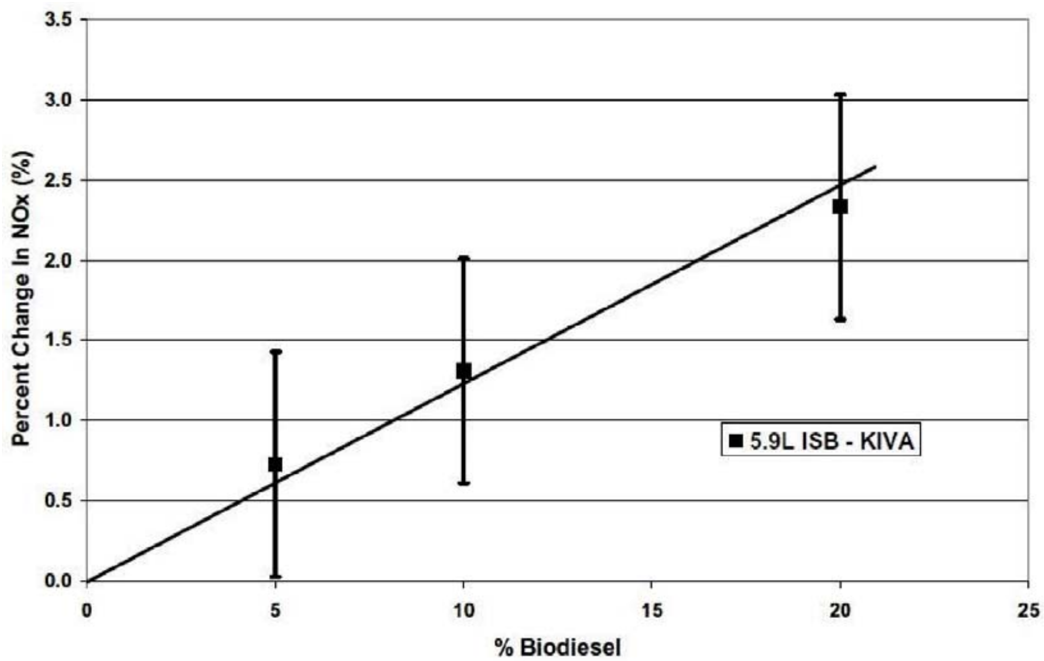
2.1.2 Eckerle 2008

This study tested low and mid/high-cetane base fuels alone and blended with soy-based biodiesel at the B20 level. The Cummins single-cylinder test engine facility was used in a configuration representative of modern diesel technology, including cooled EGR. Testing was conducted under a variety of engine speed and load conditions. FTP cycle emissions were then calculated from the speed/load data points. The test results show that B20 blends increase NOx emissions compared to both low- and high-cetane base fuels. <u>This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below</u>.

The study notes that two other studies "show that NOx emissions increase nearly linearly with the increase in the percentage of biodiesel added to diesel fuel." Eckerle's Figure 21 (reproduced below as Figure 2-2) indicates a NOx emissions increase at B5, which is the basis for the statement in the abstract that "Results also show that for biodiesel blends containing less than 20% biodiesel, the NOx impact over the FTP cycle is proportional to

the blend percentage of biodiesel." The authors clearly believe that biodiesel fuels have NOx emission impacts proportional to the blending percent at all levels including B5.

Figure 2-2
Impact of Biodiesel Blends on Percent NOx Change for the 5.9L ISB Engine Operation Over the FTP Cycle



Source: Figure 21 of Eckerle 2008

2.1.3 <u>McCormick 2002</u>

This study tested low- and mid-cetane base fuels alone and blended with soy- and animal-based biodiesel at the B20 level. The testing was conducted on a 1991 DDC Series 60 engine using the hot-start U.S. heavy-duty FTP. NOx emission increases were observed for both fuels at the B20 level. Mitigation of NOx impacts was investigated by blending a Fisher-Tropsch fuel, a 10% aromatics fuel and fuel additives. <u>This study conducted no testing of the NOx emissions impact from commercial biodiesels at the B10 level or below</u>.

This study also tested a Fisher-Tropsch (FT) base fuel blended at the B1, B20, and B80 levels. Although the very high cetane number (≥75) takes it out of the range of commercial diesel fuels, it is interesting to note that the study measured higher NOx emissions at the B1 level than it did on the FT base fuel and substantially higher NOx emissions at the B20 and B80 levels. While the B1 increase was not statistically significant given the uncertainties in the emission measurements (averages of three test runs), <u>it is clear that increased NOx emissions have been observed at very low blending levels</u>.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

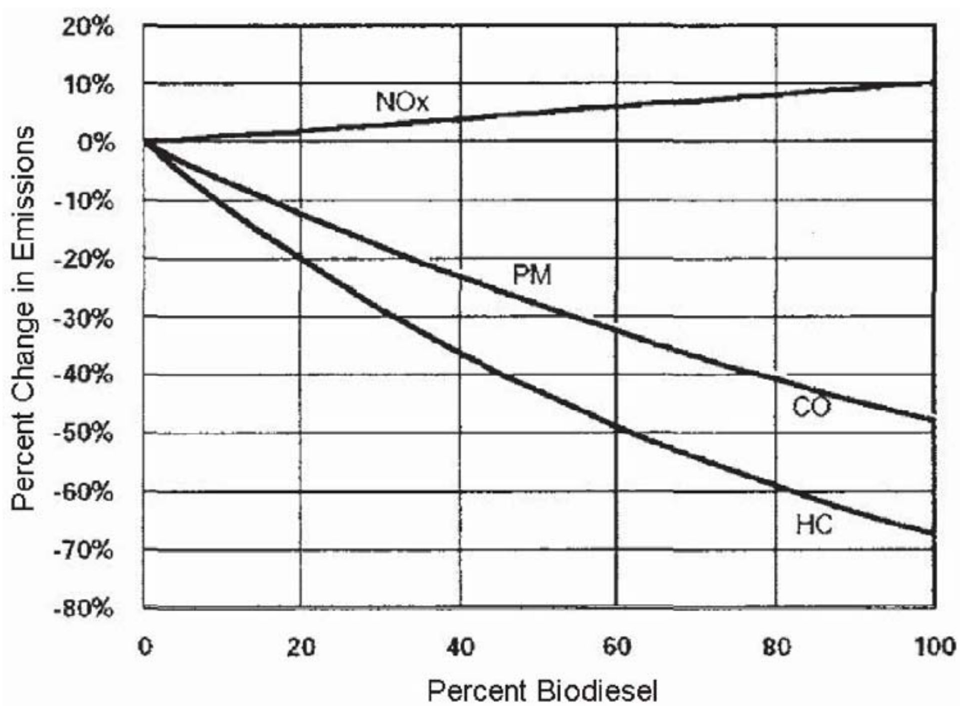
2.1.4 McCormick 2005

This study tested blends of soy- and animal-based biodiesels with a high-cetane ULSD base fuel at B10 levels and higher. Two engines were tested – a 2002 Cummins ISB and a 2003 DDC Series 60, both with cooled EGR. The hot-start U.S. heavy-duty FTP test cycle was used. The majority of testing was at the B20 level with additional testing at the B50 and B100 levels. One soy-based fuel was tested at B10. The study showed NOx emission increases at B10, B20, and higher levels. The study also investigated mitigation of NOx increases. This study conducted no testing of the NOx emissions impact from biodiesels below the B10 level.

The authors present a figure (reproduced as Figure 2-3) in their introduction that shows their summary of biodiesel emission impacts based on an EPA review of heavy-duty engine testing. It shows NOx emissions increasing linearly with the biodiesel blend percentage.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

Figure 2-3
Trend in HC, CO, NOx and PM Emissions with Biodiesel Percent



Source: McCormick 2005

2.1.5 Nuszkowski 2009

This study tested five different diesel engines: one 1991 DDC Series 60, two 1992 DDC Series 60, one 1999 Cummins ISM, and one 2004 Cummins ISM. Only the 2004 Cummins ISM was equipped with EGR. All testing was done using the hot-start U.S. heavy-duty FTP test cycle. The testing was designed to test emissions from fuels with and without cetane-improving additives. Although a total of five engines were tested, the base diesel and B20 fuels were tested on only two engines (one Cummins and one DDC Series 60) because there was a limited supply of fuel available. NOx emissions increased on the B20 fuel for both engines. A third engine (Cummins) was tested on B20 and B20 blended with cetane improvers to examine mitigation of NOx emissions. This study conducted no testing of the NOx emissions impact from biodiesels at the B10 level or below.

2.1.6 Thompson 2010

This study examined the emissions impacts of soy-based biodiesel at the B10 and B20 levels relative to low-cetane (42), mid-cetane (49), and high-cetane (63) base fuels using one 1992 DDC Series 60 engine. The emissions results were measured on the hot-start U.S. heavy-duty FTP cycle. The study found that NOx emissions were unchanged (observed differences were not statistically significant) at B10 and B20 levels for the low- and mid-cetane fuels. NOx emissions increased significantly at B10 and B20 levels for the high-cetane fuels. This study conducted no testing of the NOx emissions impact from biodiesels at levels below B10.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

2.2 Conclusions Based on Studies Obtained in Literature Search

From the foregoing summary of the studies cited by Staff, we reach the conclusions given below.

1. None of the six studies measured the NOx emissions impact from commercial-grade biodiesel at blending levels below B10, and only two studies tested a fuel at the B10 level. All other testing was at the B20 level or higher. Because none tested a B5 (or similar) fuel, none is capable of providing direct evidence regarding NOx emissions at B5 or other blending levels below B10.

2. These studies provide no data or evidence supporting the validity of Staff's Threshold Model that biodiesel below B10 does not increase NOx emissions. In fact, all of the studies are consistent with the contention that biodiesel increases NOx emissions in proportion to the blending percent.

3. Two of the studies present evidence and arguments that the NOx impact from biodiesel is a continuous effect that is present even at very low blending levels and will increase at higher levels in proportion to the blending percentage. One study tested a Fischer-Tropsch biodiesel blend at B1 and observed NOx emissions to increase (but not by a statistically significant amount).

###

3. CARB BIODIESEL CHARACTERIZATION STUDY

3.1 Background

CARB sponsored a comprehensive study of biodiesel and other alternative diesel blends in order "… to better characterize the emissions impacts of renewable fuels under a variety of conditions."[15] The study was designed to test eight different heavy- duty engines or vehicles, including both highway and off-road engines using engine or chassis dynamometer testing. Five different test cycles were used: the Urban Dynamometer Driving Schedule (UDDS), the Federal Test Procedure (FTP), and 40 mph and 50 mph CARB heavy-heavy-duty diesel truck (HHDDT) cruise cycles, and the ISO 8178 (8 mode) cycle. Table 3-1 (reproduced from Table ES-1 of Durbin 2011) documents the scope of the test program. Because the Staff relied only on engine dynamometer testing in its Technology Assessment, only the data for the first four engines (shaded) are considered here.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

Source: Table ES-1 of Durbin 2011, page xxvi
Notes:
[a] Data for the first four engines (shaded) are considered in this report.

[15] Durbin 2011, p. xxiv.

The original goal of this report was to subject all of the NOx emission testing in Durbin 2011 to a fresh re-analysis. However, it was discovered that Durbin 2011 did not report all of the data that were obtained during the program and are discussed in the report. The chassis dynamometer testing was conducted at the CARB Los Angeles facility. Emission results for the chassis dynamometer testing are presented in tabular and graphical form, but the report does not contain the actual emissions test data. For the engine dynamometer testing, some of the measured emission values are not reported even though the emission results are reported in tabulated or graphical form. Requests for the missing data were directed to Durbin in a personal request and to CARB through an official records request. No information has been provided in response and we have not been able to obtain the missing data from online or other sources.

For this report, we have worked with the data in the forms that are provided in Durbin 2011 as being the best-available record of the results of the CARB study. Because Staff used only data obtained in engine dynamometer testing, the analysis presented in this report has done the same. Nevertheless, the results of the chassis dynamometer testing are generally supportive of the results and conclusions presented here. Durbin 2011 notes:

> *"… The NOx emissions showed a consistent trend of increasing emissions with increasing biodiesel blend level. These differences were statistically significant or marginally significant for nearly all of the test sequences for the B50 and B100 fuels, and for a subset of the tests on the B20 blends."*[16]

Durbin notes that emissions variability was greater in the chassis dynamometer testing, which leads to the sometimes lower levels of statistical significance. There was also a noticeable drift over time in NOx emissions that complicated the results for one engine.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

3.2 Data and Methodology

Table 3-2 compiles descriptive information on the engine dynamometer testing performed in Durbin 2011. The experimental matrix involves four engines, two types of biodiesel fuels (soy- and animal-based), and up to four test cycles per engine. However, the matrix is not completely filled with all fuels tested on all engines on all applicable test cycles. The most complete testing is for the ULSD base fuel and B20, B50, and B100 blends. There is less testing for the B5 blend, and B5 is tested using only a subset of cycles. For this reason, we first examine the testing for ULSD, B20, B50, and B100 fuels to determine the overall impact of biodiesels on NOx emissions. We then examine the more limited testing for B5 to determine the extent to which it impacts NOx emissions.

This examination is limited by the form in which emissions test information is reported in Durbin 2011. A complete statistical analysis can be conducted only for the two on-road engines for which Appendices G and H of Durbin 2011 provide measured emissions, and for a portion of the testing of the Kubota off-road engine for which Appendix I provides

[16] Durbin 2011, p. 126.

Table 3-2
Experimental Matrix for Heavy-Duty Engine Dynamometer Testing Reported in Durbin 2011

Engine	Biodiesel Type	Fuels Tested	Test Cycles	Notes
On-Road Engines

measured emissions. The data needed to support a full re-analysis consist of measured emissions on each fuel in gm/hp-hr terms, which are stated in Durbin 2011 as averages across all test replications along with the number of replications and the standard error of the individual tests. With this information, the dependence of NOx emissions on biodiesel blending percent can be determined as accurately as if the individual test values had been reported and the appropriate statistical tests for the significance of results can be performed.

Regression analysis is used as the primary method of analysis. For each engine and test cycle, the emission averages for each fuel are regressed against the biodiesel blending percent to determine a straight line. The regression weights each data point in inverse proportion to the square of its standard error to account for differences in the number and reliability of emission measurements that make up each average. The resulting regression line will pass through the mean value estimated from the data (i.e., the average NOx emission level at the average blending percent), while the emission averages for each fuel may scatter above and below the regression line due to uncertainties in their measurement. The slope of the line estimates the dependence of NOx emissions on the blending percentage.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

Where the data points closely follow a straight line and the slope is determined to be statistically significant, one can conclude that blending biodiesel with a base fuel will increase NOx emissions in proportion to the blending percent. The regression line can then be used to estimate the predicted emissions increase for a given blending percent. The predicted emissions increase is the value one would expect on average over many measurements and is comparable to the average emissions increase one would expect in a fleet of vehicles.

The same level of analysis is not possible for the testing on B5 fuel, which is reported as a simple average for the on-road engines and is not reported at all for the off-road engines. For the B5 fuel, Durbin 2011 presents emission test results in a tabulated form where the percentage change in NOx emissions has been computed compared to ULSD base fuel. This form supports the presentation of results graphically, but it does not permit a proper statistical analysis to be performed. Specifically, the computation of percentage emission changes will perturb the error distribution of the data, by mixing the uncertainty in measured emissions on the base fuel with the uncertainties in measured emissions on each biodiesel blend, and it can introduce bias as a result of the mixing. Further statistical analysis of the computed percent values should be avoided because of these problems. Therefore, a more limited trend analysis of the NOx emissions data for B5 and the John Deere engine is conducted.

3.3Ā2006 Cummins Engine (Engine Dynamometer Testing)

Table 3-3 shows the NOx emission results for the 2006 model-year Cummins heavy-duty diesel engine based on a re-analysis of the data for this report. As indicated by highlighting in the table, the relationship between increasing biodiesel content and increased NOx emissions for soy-based biodiesel is statistically significant at >95% confidence level[17] in all cases. For the animal-based biodiesel, the relationship is statistically significant at the 92% confidence level for the UDDS cycle, the 94% confidence level for the 50 mph cruise, and the >99% confidence level for the FTP cycle.

For the soy-based fuels, the R^2 statistics show that the emissions effect of biodiesel is almost perfectly linear with increasing biodiesel content over the range B20, B50, and B100. Although not as high for the animal-based fuels (because the emissions effect is smaller and measurement errors are relatively larger in comparison to the trend), the R^2 statistics nevertheless establish a linear increase in NOx emissions with increasing biodiesel content over the same range. The linearity of the response with blending percent is well supported by the many NOx emissions graphs contained in Durbin 2011.

The table also gives the estimated NOx emission increases for B5 and B10 as predicted by the regression lines. For soy-based fuels, the values are 1% for B5 (range 0.8% to 1.3% depending on the cycle) and 2% for B10 (range 1.6% to 2.6% depending on cycle).

[17] A result is said to be statistically significant at the 95% confidence level when the p value is reported as $p \leq 0.05$. At the $p \leq 0.01$ level, a result is said to be statistically significant at the 99% confidence level, and so forth.

Table 3-3
Re-Analysis for 2006 Cummins Engine (Engine Dynamometer Testing)
Model: NOx = A + B · BioPct
Using ULSD, B20, B50, and B100 fuels

Biodiesel Type	Test Cycle	R^2	Intercept A	BioPct Slope B		Predicted NOx Increase for B5	Predicted NOx Increase for B10
			Value	Value	p value	Pct Change	Pct Change
Soy-based							
	UDDS	0.997	5.896	0.0100 [a]	0.001	0.8%	1.7%
	FTP	0.995	2.024	0.0052	0.003	1.3%	2.6%
	40 mph	1.000	2.030	0.0037	<0.0001	0.9%	1.8%
	50 mph	0.969	1.733	0.0028	0.016	0.8%	1.6%
Animal-based							
	UDDS	0.847	5.911	0.0021 [b]	0.080	0.2%	0.4%
	FTP	0.981	2.067	0.0031	0.001	0.7%	1.4%
	50 mph	0.887	1.768	0.0011	0.058	0.3%	0.6%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.
[b] Orange highlight indicates result is statistically significant at the 90% confidence level or better.

For animal-based fuels, the values are approximately one-half as large: 0.4% for B5 (range 0.2% to 0.7%) and 0.8% for B10 (range 0.4% to 1.4%). These predicted increases are statistically significant to the same degree as the slope of the regression line from which they are estimated. That is, the NOx increases predicted by the regression line for soy-based fuels are statistically significant at the 95% confidence level (or better) on all cycles and the predicted NOx increases for animal-based fuels are statistically significant at the 90% confidence level (or better) on all cycles and at the >99% confidence level for the FTP.

Because the limited data on B5 were not used to develop the regression lines for each cycle, and no test data on B10 are available, use of the lines to make predictions for B5 and B10 depends on their linearity over the range between ULSD and B20. Based on the R^2 statistics and the graphs in Durbin 2011, the slopes observed between ULSD and B20 are the same as the slopes observed between B20 and B100 for each of the test cycles. We believe that the linearity of the response with blending percent for values over the range ULSD to B100 would be accepted by the large majority of researchers in the field, as would the use of regression analysis to make predictions for B5 and B10.

The Durbin 2011 report takes a different approach for determining the statistical significance of NOx emission increases for each fuel. For each fuel tested, it computes a percentage change in emissions for NOx (and other pollutants) relative to the ULSD base fuel. It then determines the statistical significance of each observed change using a conventional t-test for the difference of two mean values (2-tailed, 2 sample equal

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

variance t-test). The t-test is conducted on the measured emission values before the percentage emission change is computed.

The t-test would be the appropriate approach for determining statistical significance if only two fuels were tested. However, it is a simplistic approach when three or more fuels are tested because it is applied on a pair-wise basis (B5 vs. ULSD, B20 vs. ULSD, etc.) and does not make use of all of the data that is available. It will have less power than the regression approach to detect emission changes that are real. This limitation is in one direction, however, in that the test is too weak when 3 or more data points are available, but a finding of statistical significance is valid when it occurs. As long as the linear hypothesis is valid, the regression approach should be the preferred method for analysis and for the determination of whether biodiesel blending significantly increases NOx emissions.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

Because emission changes will be smallest for B5 (because of the low blending volume), the pair-wise t-test is most likely to fail to find statistical significance at the B5 level. In cases where the pair-wise t-test for B5 says that the emission change vs. ULSD is not statistically significant – but slope of the regression line <u>is</u> statistically significant – the proper conclusion is that additional B5 testing (to improve the precision of the emission averages) would likely lead to the detection of a statistically significant B5 emissions change using the t-test. In this case, <u>the failure to find statistical significance using the t-test is not evidence that B5 does not increase NOx emissions</u>.

For this engine, soy-based B5 was tested on the 40 mph and 50 mph cruise cycles and animal-based B5 was tested on the FTP. To examine this matter further, Table 3-4 reproduces NOx emission results reported in Tables ES-2 and ES-3 of Durbin 2011. Soy-based B5 was shown to increase NOx emissions on the 40 mph cruise cycle, but not on the 50 mph cruise cycle. Animal-based B5 was shown to increase NOx emissions on the FTP. Durbin 2011 noted (p. xxxii) that "[t]he 50 mph cruise results were obscured, however, by changes in the engine operation and control strategy that occurred over a segment of this cycle." Therefore, we discount the 50 mph cruise results and do not consider them further. Neither of the remaining B5 NOx emission increases (for the 40 mph Cruise and FTP cycles) were found to be statistically significant using the t-test, although the 40 mph cruise result for soy-based fuels comes close to being marginally significant (it would be statistically significant at an 86.5% level). The NOx emission increases at higher blending levels were found have high statistical significance (>99% confidence level).

This format, used throughout Durbin 2011 to report emission test data and to show the effect of biodiesel on emissions, is subject to an important statistical caveat. The percent changes are computed by dividing the biodiesel emission values by the emissions measured for the ULSD base fuel. Therefore, measurement errors in the ULSD measurement are blended with the measurement errors for each of the biodiesel fuels. The blending of errors in each computed percent change can bias the apparent trend of emissions with increasing biodiesel content. As will be shown in Section 3.3.2, we can see this problem in the animal-based B5 test data for this engine.

Table 3-4 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 2006 Cummins Engine (Engine Dynamometer Testing)						
	Soy-based Biodiesel				Animal-based Biodiesel	
	40 mph Cruise		50 mph Cruise		FTP	
	NOx % Diff	p value	NOx % Diff	p value	NOx % Diff	p value
B5	1.7%	0.135	-1.1%	0.588	0.3%	0.298
B20	3.9% [a]	0.000	0.5%	0.800	1.5%	0.000
B50	9.1%	0.000	6.3%	0.001	6.4%	0.000
B100	20.9%	0.000	18.3%	0.000	14.1%	0.000

3.3.1 NOx Impact of Soy-based Biodiesel at the B5 Level

Figures 3-1a and 3-1b display the trend of NOx emissions with blending percent for the soy-based biodiesel on the 40 mph cruise cycle. Figure 3-1a plots the percentage increases as reported by Durbin 2011 in contrast to two different analytical models for the relationship:

- Ā The Linear Model shown by the blue line; and
- Ā The Staff Threshold model (black line), in which the NOx emission change is zero through B9 and then increases abruptly to join the linear model.

In Figure 3-1a, the linear model is an Excel trendline for the computed percent changes. While the data violate a key assumption for the proper use of regression analysis, this approach is the only way to establish a trendline given the form in which Durbin 2011 tabulates the data and presents the results of its testing.

Figure 3-1b plots the actual measured emission values in g/bhp-hr terms in contrast to the same two analytical models. Here, the linear model line is determined through a proper use of regression analysis, in which each emission average in g/bhp-hr terms is weighted inversely by the square of its standard error, using the data for ULSD, B20, B50 and B100 (i.e., excluding the B5 data point). In the case of this engine and biodiesel fuel, both forms of assessment show generally the same trend for NOx emissions as a function of blending percent. Although the NOx emission increases for B5 may fail the t-test for significance, emissions are increased at B5 and the B5 data point is fully consistent with the Linear Model. The Threshold model is clearly a less-satisfactory representation of the test data.

Figure 3-1a
Durbin 2011 Assessment: 40 mph Cruise Cycle NOx Emissions Increases for Soy-Biodiesel Blends (2006 Cummins Engine)

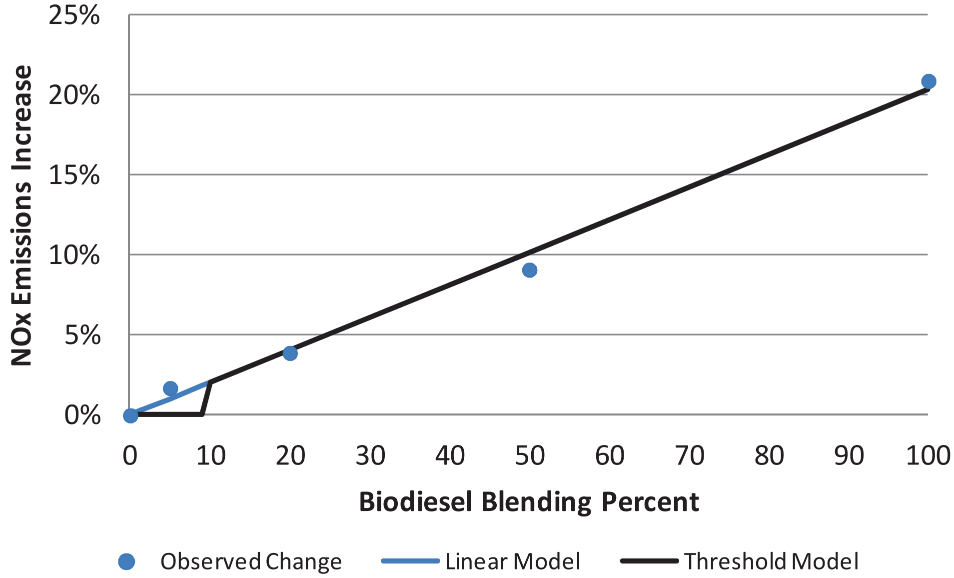

Figure 3-1b
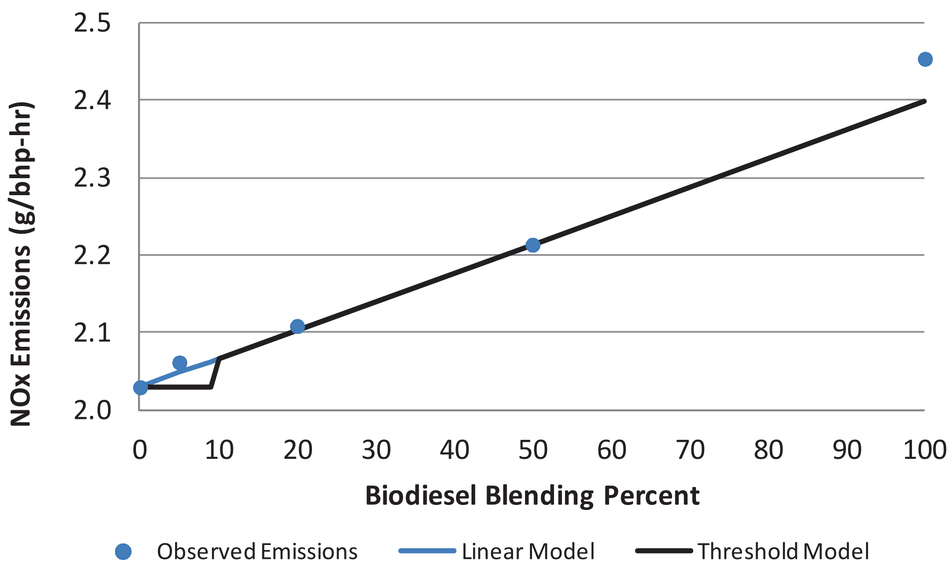
Re-assessment of 40 mph Cruise Cycle NOx Emissions Increases for Soy-Biodiesel Blends (2006 Cummins Engine)



Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

Note that the slope of the trendline (Figure 3-1a) is greater than the slope of the regression line (Figure 3-1b). In the latter figure, the B100 data point stands above the regression line, which passes below it. The regression line (but not the trendline) is fit in

a manner that accounts for the uncertainties in each data point, so that the line will pass closer to points that have smaller uncertainties and farther from points that have greater uncertainties. For these data, the B100 data point has the largest uncertainty (±0.026 g/bhp-hr) followed by the B20 data point (±0.025 g/bhp-hr). The other three data points (ULSD, B5, and B50) have uncertainties less than ±0.001 g/bhp-hr. The B20 data point happens to fall on the line, but the B100 data point is found to diverge above. Because the regression analysis can account for the relative uncertainties of the data points, it provides a more accurate and reliable assessment of the impact on NOx emissions.

3.3.2 NOx Impact of Animal-based Biodiesel at the B5 level

Figures 3-2a and 3-2b display the trend of NOx emissions with blending percent for the animal-based biodiesel on the FTP test cycle as reported by Durbin 2011 and as re-assessed in this report using regression analysis, respectively. As Figure 3-2a shows, the NOx percent change values reported by Durbin 2011 appear to follow the Staff Threshold model in that NOx emissions are not materially increased at B5, but are increased significantly at B20 and above. As a result, the blue trendline in the figure (fit from the B20, B50 and B100 data points) has a negative intercept.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

Figure 3-2b paints a very different picture from the data. Here, the ULSD and B5 data points stand above the weighted regression line (blue) developed from the data for ULSD, B20, B50 and B100. In the data used to fit the regression line, the ULSD data point has the largest uncertainty (±0.013 g/bhp-hr) while the other three data points (B20, B50, and B100) have uncertainties of ±0.002 g/bhp-hr (one case) and ±0.001 g/bhp-hr (two cases). Considering all of the data, the B5 data point has the second highest uncertainty (±0.007 g/bhp-hr). The regression line closely follows a linear model with a high R^2 (0.981) considering the weighted errors, while the ULSD and B5 points lie above it.

Because the ULSD data point is subject to more uncertainty and appears to be biased high compared to the regression line, the NOx percent changes computed by Durbin 2011 are themselves biased. The trendline result in Figure 3-2a that appeared to be supportive of the Staff Threshold model now appears to be the result of biases in the ULSD and B5 emission averages.

Two important conclusions can be drawn from the foregoing:

1. Accurate and reliable conclusions regarding the impact of B5 on NOx emissions cannot be drawn from the computed percent changes that are reported in Durbin 2011. Nor can accurate and reliable conclusions be drawn from visual inspection of graphs that present such data. Weighted regression analysis of the measured emission values (g/bhp-hr terms) must be performed so that the uncertainties in emissions measurements can be fully accounted for.

2. When a weighted regression analysis is performed using the testing for this engine, there is no evidence that supports the conclusion that B5 blends will not increase NOx emissions. In fact, the data are consistent with the conclusion that biodiesel increases NOx emissions in proportion to the blending percent.

3.4 2007 MBE4000 Engine (Engine Dynamometer Testing)

To analyze the data for the 2007 MBE4000 engine, it has proved necessary to remove two data points, one for the soy-based B20 fuel on the 50 mpg cruise cycle and one for the animal-based B50 fuel on the FTP test cycle:

- Appendix H reports the 50 mph cruise emission average for soy-based B20 to be 0.014 ± 0.020 g/bhp-hr. This value is implausible and wholly inconsistent with the NOx emission change of +6.9% reported in Table ES-4 of Durbin 2011, which would imply a NOx emission average of 1.21*1.069 = 1.30 g/bhp-hr.

- Appendix H reports the FTP emission average for the animal-based B50 fuel to be 2.592 ± 0.028 g/bhp-hr, which stands well above the other test data on animal-based biodiesel. This value is also inconsistent with the NOx emission change of +12.1% reported in Table ES-4 of Durbin 2011, which would imply a NOx emission average of 1.29*1.121 = 1.45 g/bhp-hr.

We believe these reported values are affected by typographical errors and have deleted them from the dataset used here.

With these corrections, Table 3-5 shows the results of the NOx emissions analysis for the 2007 model-year MBE4000 heavy-duty diesel engine. As indicated by highlighting in the table, the relationship between increasing biodiesel content and increased NOx emissions is statistically significant at >99% confidence level in two cases for soy-based biodiesel (the UDDS and FTP cycles) and at the 90% confidence level in one case (the 50 mph cycle). For the animal-based biodiesel, the relationship is statistically significant at the 96% confidence level for the UDDS cycle, the 98% confidence level for the FTP cycle, and >99% confidence level for the 50 mph cycle.

Durbin 2011 again notes a problem with the 50 mph cruise test results, saying (p. xxxii) that "[the NOx] trend was obscured, however, by the differences in engine operation that were observed for the 50 mph cruise cycle." Therefore, we will focus the discussion on the UDDS and FTP results.

For the soy-based fuels, the R^2 statistics show that the emissions effect of biodiesel is almost perfectly linear with increasing biodiesel content over the range from ULSD to B20, B50, and B100 for all cycles (including the 50 mph cruise). That is, the NOx emissions increase between ULSD and B20 shares the same slope as the NOx emissions increase between B20 and B100. For the animal-based biodiesel, the R^2 statistics also establish a linear increase in NOx emissions with increasing biodiesel content over the same range. The linearity of the response with blending percent is also well supported by the many NOx emissions graphs contained in Durbin 2011.

Table 3-5 **Re-Analysis for 2007 MBE4000 Engine (Engine Dynamometer Testing)** Model: NOx = A + B · BioPct Using ULSD, B20, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A	BioPct Slope B		Predicted NOx Increase for B5	Predicted NOx Increase for B10
			Value	Value	p value	Pct Change	Pct Change
Soy-based							
	UDDS	0.989	2.319	0.0090 [a]	0.005	4.6%	9.1%
	FTP	0.998	1.268	0.0049	0.006	2.5%	5.0%
	50 mph	0.979	1.198	0.0054 [b]	0.092	2.7%	5.5%
Animal-based							
	UDDS	0.913	2.441	0.0036	0.044	2.0%	4.0%
	FTP	0.999	1.288	0.0038	0.020	2.5%	5.0%
	50 mph	0.994	1.205	0.0049	0.003	2.5%	5.0%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.
[b] Orange highlight indicates result is statistically significant at the 90% confidence level or better.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

The table also gives the estimated NOx emission increases for B5 and B10 as predicted by the regression lines. For soy-based fuels, the values are ~3.5% for B5 (range 2.5% to 4.6% depending on the cycle) and ~7.5% for B10 (range 5.0% to 9.1% depending on cycle). For animal-based fuels, the values are approximately two-thirds as large: ~2.3% for B5 (range 2.0% to 2.5%) and ~4.5% for B10 (range 4.0% to 5.0%). The predicted increases are statistically significant to the same degree as the slope of the regression line from which they are estimated. That is, the predicted NOx increases are statistically significant at the >99% confidence level for soy-based fuels on the UDDS and FTP cycles and at the >95% confidence level for animal-based fuels on all cycles. The predicted NOx increase is statistically significant at the 90% confidence level for soy-based fuels on the 50 mph cruise cycle.

For this engine, soy- and animal-based B5 were tested on the FTP. Table 3-6 reproduces the NOx emission results reported in Tables ES-4 and ES-5 of Durbin 2011. While there are caveats on use of the pair-wise t-test, the FTP test data for this engine show NOx emissions at the B5 level for both soy- and animal-based fuels that are statistically significant at the 99% confidence level (or better) in this case. That is, <u>the test data for this engine as reported by Durbin 2011 refute the Staff Threshold Model that biodiesel blends below B10 do not increase NOx emissions</u>.

Table 3-6 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 2007 MBE4000 Engine (Engine Dynamometer Testing)				
	Soy-Based Biodiesel FTP		Animal-Based Biodiesel FTP	
	NOx % Diff	p value	NOx % Diff	p value
B5	0.9% [a]	0.007	1.3%	0.000
B20	5.9%	0.000	5%	0.000
B50	15.3%	0.000	12.1	0.000
B100	38.1%	0.000	29%	0.000

Source: Table ES-4/5 of Durbin 2011, p. xxix
Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on pair-wise t-test.

Figures 3-3a and 3-3b below compare the FTP data for this engine to the regression line representing the linear model (blue) and the Staff Threshold model (black) for both soy- and animal-based biodiesel. In both cases, the regression line was developed using the data for ULSD, B20, B50, and B100 (i.e., excluding the B5 data point). For both soy- and animal-based biodiesels, the data point for B5 falls on the established line, while the Staff Threshold model is inconsistent with the data. For this engine, it is clear that soy- and animal-based biodiesels increase NOx emissions at all blending levels.

3.5Ā1998 Kubota TRU Engine (Engine Dynamometer Testing)

The 1998 Kubota V2203-DIB off-road engine was tested on the base fuel (ULSD) and soy-based biodiesel at four blending levels (B5, B20, B50, B100) in two different series using the ISO 8178 (8-mode) test cycle. Appendix I reports the measured emissions data only for the first series (ULSD, B50, B100). Using this subset of data, Table 3-7 summarizes the results of the re-analysis for this engine.

As for the other engines, the results of the analysis demonstrate the following:

- Ā The high R^2 statistic shows that the emissions effect of biodiesel is almost perfectly linear over the range B50 and B100. That is, the slope from ULSD to B50 is the same as the slope from B50 to B100. The slope of the regression line is statistically significant at the 99% confidence level.

- Ā NOx emissions are estimated to increase by 1.0% at the B5 level and by 2.1% at the B10 level. These estimated NOx emission increases are statistically significant to the same high degree as the regression slope on which they are based.

Table 3-7 Re-Analysis for 1998 Kubota V2203-DIB Engine (Engine Dynamometer Testing) Model: NOx = A + B · BioPct Using ULSD, B50, and B100 fuels							
Biodiesel Type	Test Cycle	R^2	Intercept A	BioPct Slope B		Predicted NOx Increase for B5	Predicted NOx Increase for B10
			Value	Value	p value	Pct Change	Pct Change
Soy-based	ISO 8178	0.999	12.19	0.0256 [a]	0.01	1.0%	2.1%

Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better.

The second test series involved ULSD, B5, B20, and B100 fuels. Measured emissions data are not given in Appendix I, so we must work with the calculated percent changes in NOx emissions tabulated in Durbin 2011. Table 3-8 reproduces the NOx emission results reported in Table ES-8 of Durbin 2011 for the two test series. For the second test series, biodiesel at the B5 level increased NOx emissions, but the result fails the pair-wise t-test for statistical significance. The NOx emission increase at the B20 level was statistically significant at the 90% confidence level, and the increase at the B100 level was statistically significant at the >99% confidence level. The significance determinations use the pair-wise t-test, which is subject to caveats, but this is the only method available to gauge significance because re-analysis of the computed percentage changes is not possible.

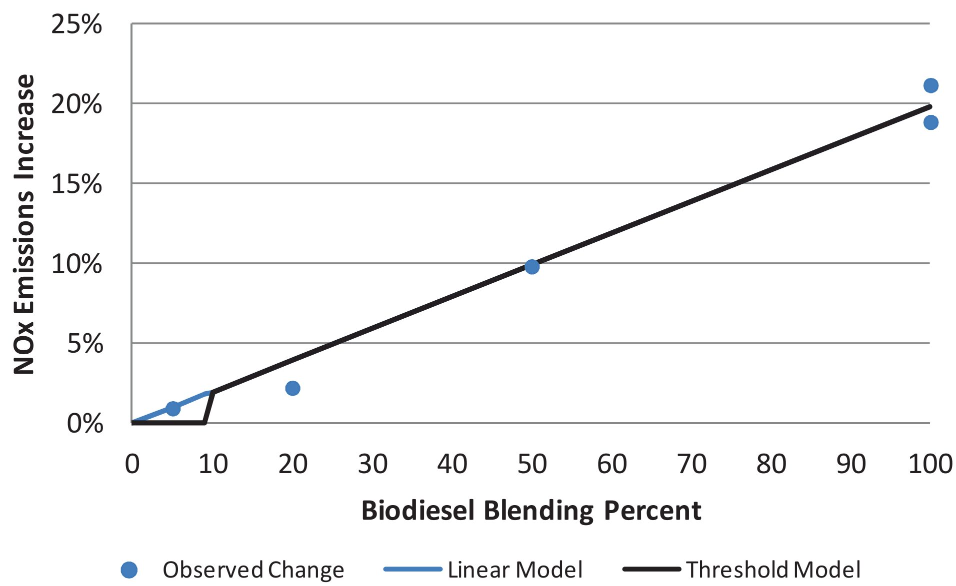
Table 3-8 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 1998 Kubota TRU Engine (Engine Dynamometer Testing)				
	Soy-Based Biodiesel Series 1 ISO 8178		Soy-Based Biodiesel Series 2 ISO 8178	
	NOx % Diff	p value	NOx % Diff	p value
B5	Not tested		0.97%	0.412
B20	Not tested		2.25% [a]	0.086
B50	7.63% [b]	0.000	Not tested	
B100	13.76%	0.000	18.89%	0.000

Source: Table ES-8 of Durbin 2011, p. xxxviii
Notes:
[a] Orange highlight indicates result is statistically significant at the 90% confidence level or better based on pair-wise t-test.
[b] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on pair-wise t-test

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

Figure 3-4 displays the trend of NOx emissions with blending percent for the first and second test series combined. As the figure shows, the available data points scatter around the trendline determined from the emission change percentages (not from regression analysis). The B20 data point falls below the trend line while the two B100 data points bracket the trend line. It is not possible to explain the divergence of the B20 data point

Figure 3-4
Durbin 2011 Assessment: ISO 8178 Cycle NOx Emissions Increases for Soy-based Biodiesel Blends (1998 Kubota Engine, Test Series 1 and 2 Combined)



because the emissions data for the second test series are not published in Durbin 2011. The B5 data point clearly supports the Linear Model and is inconsistent with the Staff Threshold Model.

3.6Ā2009 John Deere Off-Road Engine (Engine Dynamometer Testing)

The only information on the 2009 John Deere off-road engine comes from the tabulation of calculated percentage emission changes. Table 3-9 reproduces these data from Table ES-7 of Durbin 2011. For the soy-based biodiesel, NOx emissions are significantly increased at the B20 and higher blend levels. The increase for B20 is statistically significant at the 90% confidence level and the increases for B50 and B100 are statistically significant at the >99% confidence level based on the pair-wise t-test. A soy-based B5 fuel was not tested.

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

Table 3-9 Percentage Change in NOx Emissions for Biodiesel Blends Relative to ULSD: 2009 John Deere Engine (Engine Dynamometer Testing)				
	Soy-Based Biodiesel ISO 8178		Animal-Based Biodiesel ISO 8178	
	NOx % Diff	p value	NOx % Diff	p value
B5	Not tested		-3.82	0.318
B20	2.82% [a]	0.021	-2.20	0.528
B50	7.63%	0.000	Not tested	
B100	13.76%	0.000	4.57	0.000

Source: Table ES-7 of Durbin 2011, p. xxxviii
Notes:
[a] Blue highlight indicates result is statistically significant at the 95% confidence level or better based on pair-wise t-test.

For animal-based biodiesel, the testing shows the unusual result that B5 and B20 appear to decrease NOx emissions, while B100 increases NOx. The B5 and B20 decreases are not statistically significant, while the B100 increase is statistically significant at the >99% confidence level. Durbin 2011 concludes:

> *The animal-based biodiesel also did not show as great a tendency to increase NOx emissions compared to the soy-based biodiesel for the John Deere engine, with only the B100 animal-based biodiesel showing statistically significant increases in NOx emissions.*[18]

Durbin 2011 does not discuss these results further and does not note any problems in the testing, making further interpretation of the results difficult. Figure 8-1 of Durbin 2011 presents the NOx results for this engine with error bars. First, we note that the figure appears to suggest that NOx emissions were increased on the B20 fuel in contradiction to the table above. Second, it is clear that the error bars are large enough that no difference in NOx emissions can be detected among ULSD, B5, and B20 fuels. Overall, this result could be consistent with the Staff Threshold Model through B5, but the failure to detect a NOx emission increase at B20 is not. Without further information, it is not possible to determine whether the result seen here is a unique response of the John Deere engine to animal-based biodiesel or is the result of a statistical fluctuation or an artifact in the emissions data.

3.7 Conclusions

The Biodiesel Characterization report prepared by Durbin et al. for CARB is an important source of information on the NOx emissions impact of biodiesel fuels in heavy-duty engines. It is the sole source of information on the NOx impact of B5 blends cited in the ISOR. When the engine dynamometer test data are examined for

Reproduction of Pages 168 -209 of Comment Letter 12_B_LCFS_GE/ 3_B_ADF_GE Consisting of Comments ADF B3-46 through ADF B3-92

[18] Durbin 2011, p. xx.

the three engines for which emissions test data have been published, we find clear evidence that biodiesel increases NOx emissions in proportion to the blending percent. Where B5 fuels were tested for these engines, NOx emissions are found to increase above ULSD for both soy- and animal-based blends in all three engines and by statistically significant amounts in one engine.

Specifically, a re-analysis of the NOx emissions test data demonstrates the following:

1. For the 2006 Cummins engine, biodiesel fuels are found to significantly increase NOx emissions for both soy- and animal-based blends by amounts that are proportional to the blending percent. This result indicates that biodiesels will increase NOx emissions at blending levels below B10. When B5 fuels were tested, NOx emissions were observed to increase but by amounts that fail to reach statistical significance according to the pair-wise test.[19] Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

2. For the 2007 MBD4000 engine, biodiesel fuels are found to significantly increase NOx emissions for both soy- and animal-based blends by amounts that are proportional to the blending percent. This result indicates that biodiesels will increase NOx emissions at blending levels below B10. When B5 fuels were tested, NOx emissions were observed to increase and by amounts that are found to be statistically significant using the pair-wise t-test.[13] This result alone is sufficient to disprove the Staff Threshold Model. Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

3. For the 1998 Kubota TRU (off-road) engine, soy-based biodiesel fuels are found to significantly increase NOx missions. Animal-based biodiesel was not tested. When a soy-based B5 fuel was tested, NOx emissions were observed to increase but by amounts that fail to reach statistical significance according to the pair-wise test.[13] Graphical analysis demonstrates that NOx emissions measured for B5 fuels are consistent with the Linear Model, but not the Staff Threshold Model.

The measured emissions test data for the other off-road engine (2009 John Deere) are not contained in the Durbin 2011 report and CARB has not made them publicly available. Thus, a re-analysis was not possible. Based on the tables and figures in Durbin 2011, soy-based biodiesel fuels were shown to significantly increase NOx emissions at B20 levels and higher, but B5 was not tested. Testing of animal-based blends shows no change in NOx emissions at B5 and B20 levels, but B100 is shown to significantly increase NOx emissions. Durbin 2011 discusses this result only briefly, and it is unclear what conclusions can be drawn from it.

APPENDIX AĀ

RESUME OF ROBERT W. CRAWFORD

Education

1978 Doctoral Candidate, ScM. Physics, Brown University, Providence, Rhode Island
1976 B.A. Physics, Pomona College, Claremont, California

Professional Experience

1998-Present Independent Consultant

Individual consulting practice emphasizing the statistical analysis of environment and energy data with an emphasis on how data and statistics are properly used to make scientific inferences. Mr. Crawford provides support on statistical, data analysis, and modeling problems related to ambient air quality data and emissions from mobile and stationary sources.

Ambient Air Quality and Mobile Source Emissions – Mr. Crawford has worked with Sierra Research on elevated ambient CO and PM concentrations in Fairbanks AK and Phoenix AZ, including the effect of meteorological conditions on ambient concentrations, the relationship of concentrations to source inventories, and the use of non-parametric techniques to infer source location from wind speed and direction data. Ongoing work is employing Principal Components Analysis to elucidate the relationship between meteorology and $PM_{2.5}$ concentrations in Fairbanks. In the past year, this work led to creation of the AQ Alert System, a tool used by air quality staff to track $PM_{2.5}$ monitor concentrations during the day and to prepare AQ alerts over the next 3 days based on the meteorological forecast.

In past work for Sierra, he has also conducted studies of fuel effects on motor vehicle emissions for Sierra. For CRC, he determined the relationship between gasoline volatility and oxygen content on tailpipe emissions of late model vehicles at FTP and cold-ambient temperatures. For SEMPRA, he determined the relationship between CNG formulation and tailpipe emissions of criteria pollutants and a range of air toxics. Other work has included the design of vehicle surveillance surveys and determination of sample sizes, development of screening techniques similar to discriminant functions to improve the efficiency of vehicle recruitment, the analysis of vehicle failure rates measured in inspection & maintenance programs, and the statistical evaluation of data collected on freeway speeds using automated sensors.

Stationary Source Emissions – Over the past 5 years, Mr. Crawford has worked with AEMS, LLC on EPA's MACT and CISWI rulemakings for Portland Cement plants, in which significant issues related to data quality, data reliability, and emissions variability are evident. Key issues include the need to properly account for uncertainty and emissions variability in setting emission standards. He also supported AEMS in the

current EPA rulemaking on reporting of greenhouse gas emissions from semiconductor facilities, where the proper characterization of emission control device performance was a key issue. He is currently supporting AEMS in a regulatory process to re-determine emission standards for an industrial facility where the new standard will be enforced by continuous emissions monitoring (CEMS). At issue is how to set the standard in such a way that there will be no more than a small, defined risk that 30-day emission averages will exceed the limitations while emissions remain well-controlled .

Advanced Combustion Research – In recent work for Oak Ridge National Laboratory, Mr. Crawford conducted a series of statistical studies on the fuel consumption and emissions performance of Homogenous Charge Compression Ignition (HCCI) engines. One of these studies was for CRC, in which fuel chemistry impacts were examined in gasoline HCCI. In HCCI, the fuel is atomized and fully-mixed with the intake air charge outside the cylinder, inducted during the intake stroke, and then compressed to the point of spontaneous combustion. The timing of combustion is controlled by heating of the intake air. If R&D work can demonstrate a sufficient understanding of how fuel properties influence engine performance, the HCCI combustion strategy potentially offers the fuel economy benefit of a diesel engine with inherently lower emissions.

1979-1997 Energy and Environmental Analysis, Inc., Arlington, VA. Director & Partner (from 1989).

<u>Primary work areas</u>: Studies of U.S. energy industries for private and institutional clients emphasizing statistical analysis, business planning and computer modeling/forecasting. Responsible for the EEA practice area that provided strategic planning and forecasting services to major energy companies. Primary topical areas included: U.S. energy market analysis and strategic planning; gas utility operations; and natural gas supply planning.

<u>U.S. Energy Market Analysis</u>

During 1995-1997, Mr. Crawford directed EEA’s program to provide comprehensive energy supply and demand forecasting for the Gas Research Institute (GRI) in its annual *Baseline Projection of U.S. Energy Supply and Demand*. Services included: development of U.S. energy supply, demand, and price forecasts; sector-specific analyses covering energy end-use (residential, commercial, industrial, transportation), electricity supply, and natural gas supply and transportation; and the preparation of a range of publications on the forecasts and energy sector trends.

From 1989 through 1997, he directed the use of EEA's Energy Overview Model in strategic planning and long-term market analysis for a client base of major energy producers, pipelines, and distributors in both the United States and Canada. The Energy Overview Model was used under his direction as the primary analytical basis for the 1992 National Petroleum Council study *The Potential for Natural Gas in the United States*. Mr. Crawford also provided analysis for clients on a wide range of other energy market issues, including negotiations related to an LNG import project intended to serve U.S. East Coast markets. This work assessed the utilization and economic value of seasonal

gas deliverability in order to develop LNG pricing formulas and evaluate the project's viability.

Other topical areas of work during his period of employment with EEA include:

Gas Load Analysis and Utility Operations – Principal investigator in a multi-year research program for the Gas Research Institute (GRI) that examined seasonal gas loads, utility operations, and the implications for transmission and storage system reliability and capacity planning.

Gas Transmission and Storage – Principal investigator for a study of industry plans for expansion of underground gas storage capacity in the post-Order 636 environment, including additions of depleted-reservoir and salt-formation storage, an engineering analysis of capital and operating costs for the projects, and unbundled rates for new storage services.

Natural Gas Supply Planning – Mr. Crawford was EEA's senior manager and lead analyst on gas supply planning issues for both pipeline and distribution companies, which included technical and analytic support in development and justification of gas supply strategies; and identification of optimal seasonal supply portfolios for Integrated Resource Planning proceedings.

Transportation Systems Research

Mr. Crawford also had extensive experience in motor vehicle fuel economy and emissions while at EEA. He participated for five years in a DOE research program on fuel economy, with emphasis on the evaluation of differences between laboratory and on-road fuel economy. His work included analysis of vehicle use databases to understand how driving patterns and ambient (environmental) conditions influence actual on-road fuel economy. He also developed a software system to link vehicle certification data systems to vehicle inspection and testing programs and participated in a range of studies on vehicle technology, fuel economy, and emissions for DOE, EPA, and other governmental agencies.

EXECUTIVE SUMMARY

The staff of the Air Resources Board (ARB or Board) is proposing a regulation to govern the commercialization of motor vehicle alternative diesel fuels (ADF) in California. Through California's fuel policies, consumers are beginning to see increasingly cleaner fuels as well as more options for fueling their motor vehicles. The ADF regulation is intended to create a framework for these low carbon diesel fuel substitutes to enter the commercial market in California, while mitigating any potential environmental or public health impacts. ADFs are those alternative diesel fuels that do not have an established ARB fuel specification in effect prior to January 1, 2016. The proposed regulation consists of two major parts:

1) A three stage process for ADFs to be introduced into the California market including, if necessary, a determination of mitigation measures to ensure no degradation in air quality.
2) In-use requirements for biodiesel as the first ADF

Although this will be a new regulation, the proposal consolidates many current administrative and regulatory practices into one regulation that provides a clear framework for commercialization of ADFs. The formal framework is necessary for two primary reasons. First, programs such as California's Low Carbon Fuel Standard (LCFS) and the federal Renewable Fuels Standard (RFS) are expected to incentivize the rapid development of ADFs. Many of these fuels provide criteria pollutant and toxic air contaminant emission reductions in addition to their greenhouse gas (GHG) benefit. Second, some ADFs may have adverse effects under certain circumstances. For these reasons, ARB is proposing the regulation to ensure that ADFs are commercialized in California under specific requirements and conditions that avoid potential adverse impacts while realizing the benefits that ADFs can provide.

The first ADF that will be subject to in-use requirements under this framework is biodiesel. Fuel specifications and other requirements for future ADFs will be incorporated into this regulation through additional rulemakings. Biodiesel has particulate matter (PM) and GHG benefits, however testing by ARB and others show that biodiesel can increase oxides of nitrogen (or NOx) under certain circumstances and without considering offsetting factors. These effects are only observed in older (pre-2010) vehicles. As new technology diesel engines are phased in through other ARB programs such as the Truck and Bus Regulation, the NOx impacts will be reduced until they are negligible. ARB expects the in-use specifications to sunset around 2023. Until that time, the in-use specifications will reduce NOx from current levels and Californians will continue to experience the PM and GHG benefits.

There has been confusion between biodiesel and renewable diesel; however, these are two distinct fuels. Renewable diesel and biodiesel are both biomass based diesel fuel replacements and can be confused with each other, but the distinctions are important. Although the two fuels use the same feedstocks (e.g. animal tallow, used cooking oil, soybean oil), they are produced using different production processes with resulting products having different chemical properties and environmental attributes. Renewable diesel is not considered an ADF as it consists solely of hydrocarbons and is chemically indistinguishable from conventional diesel. Renewable diesel has been shown to decrease emissions of GHGs, PM, hydrocarbons, and carbon monoxide and, in contrast to biodiesel, renewable diesel has also been shown to reduce NOx. Because renewable diesel is not an ADF, it would not be subject to in-use requirements and is expected to increase significantly over time, with associated co-benefits of reduced air pollutants.

The availability of both renewable diesel and biodiesel will help fulfill our climate goals, provide fuel diversity, contribute PM emission reduction benefits, and, with the implementation of this regulation, have no degradation of air quality from current levels.

What are we proposing?

The proposed regulation would require an ADF to proceed through a three-stage process that evaluates the fuel for environmental impacts prior to use above a minimum threshold amount in California. As part of that evaluation process, the regulation establishes measures that apply to maintain current air quality protections. Many of the provisions in this regulation are already required under existing State law. The three stages of this process are described below.

Stage 1: Pilot Program. In this stage, an ADF applicant(s) would apply to ARB for a pilot program under which no more than 1 million gallons total of the ADF could be used in the State in well-defined fleets within a year. During that time, the applicant would conduct required testing and emissions evaluations. The application process includes disclosure of the chemical composition of the ADF, as well as other important information, which would enable staff to conduct a screening analysis. This screening analysis is intended to help staff determine whether use of the ADF presents a potential adverse impact to the public health or environment. Advancement to Stage 2 requires the ADF applicant to fulfill the Stage 1 requirements and enter into an agreement with the Executive Officer (EO) to complete and satisfy specified terms and conditions, such as additional emissions testing, which will apply during the second stage.

Stage 2: Fuel Specification Development. In this stage, an ADF proponent(s) would apply for a broader, but still limited, agreement allowing use of up to 30 million gallons of that ADF per year in a larger fleet. The larger volume and sample fleet would allow for more comprehensive testing and analyses that would inform a multimedia evaluation; help develop consensus standards for the ADF; identify what circumstances, if any, could result in an adverse impact on public health or the environment; and, if necessary, determine appropriate mitigation options. During this stage, ARB staff would determine, if necessary, a pollutant control level for a particular pollutant of concern.

Stage 3: Commercial Sales. This stage is split into Stage 3A and Stage 3B. Stage 3A is applicable to ADFs for which ARB staff has identified a pollutant control level. An ADF sold in California under this stage would be subject to potential sales conditions and mitigation measures that are based on the pollutant control level(s) determined in

Stage 2. By contrast, Stage 3B is applicable to ADFs for which no pollutant control level is necessary. Accordingly, ADFs in Stage 3B can be used at any blend level and without any conditions of use or mitigation measures.

An ADF subject to Stage 3A is subject to enhanced monitoring and recordkeeping. The ARB staff would use such monitoring and records, along with other market and fleet data, to determine whether the pollutant control level has been reached.

Staff has determined that certain blends of biodiesel, the first ADF to be subject to the proposed regulation, can increase NOx under certain circumstances and in the absence of offsetting factors. However, ARB staff has also determined that NOx associated with these biodiesel blends are offset by a number of factors. Accordingly, ARB staff has designed the proposed regulation to ensure that biodiesel can be commercialized without an increase in NOx. The proposed regulation provides for a proper accounting of offsetting factors already occurring in the California market and the appropriate application of in-use requirements.

Accounting for feedstock saturation and offsetting factors such as renewable diesel usage and fuel use by newer heavy duty trucks, biodiesel can be used in lower blends levels without triggering in-use specifications. In-use specifications are necessary above a five percent blend level (B5) for low saturation biodiesel and a B10 level for high saturation biodiesel during ozone season and above B10 for all biodiesel in low ozone season.

Why are we taking this action?

Consumption of ADFs, such as biodiesel, is expected to increase in the coming years due to a variety of policy incentives including the RFS, LCFS, and potentially the continuance of federal blending tax credits. These fuels will help California meet its climate and petroleum reduction goals, provide fuel diversity, and contribute PM benefits. As such, it is important to ensure that the full commercialization of these fuels do not increase air pollution or cause other environmental concerns. The proposed regulation will ensure this by subjecting new ADFs to a rigorous, phased environmental review with specific terms and conditions. As part of the environmental review, staff will determine whether the ADF has a “pollutant control level” for the pollutant of concern, which is defined to be that level of ADF use which could lead to an increase in the pollutant of concern. In that case, staff will identify the terms of the pollutant control level and define the specific in-use requirements, when conditions warrant mitigation. This regulation will ensure that ADFs avoid potential adverse impacts while realizing the benefits that ADFs can provide in terms of reductions in GHGs and PM and increase in fuel diversity in the state.

Who is affected by this proposed regulation?

The regulation applies primarily to producers and importers of alternative diesel fuels. If necessary, the applicant producer or importer would be responsible for applying any mitigation measures that may be required under a Stage 3A scenario. Retail marketers and distributors of alternative diesel fuels are generally not affected by the in-use requirements unless they are also conducting fuel blending. Retailers and distributors may be required to do some of the required recordkeeping and monitoring, but these generally would apply to the higher blends of an ADF (e.g., for marketers of biodiesel in blends above B10).

What are the costs of this proposed regulation?

Staff expects the costs directly attributable to this proposed regulation to be minimal. Regulatory costs are primarily due to some increases in reporting, recordkeeping and testing of ADFs, as well as costs for in-use requirements affecting some biodiesel blends. Many of the requirements of this regulation already exist under other State law, and, as such, are not an additional cost of this regulation. For example, much of the reporting associated with this regulation is already required to comply with the LCFS regulation or other State or federal programs. The requirement for a multimedia evaluation of new ADFs is already required by ARB pursuant to Health and Safety Code (H&SC) section 43830.8, and development of consensus standards is already required by existing regulations implemented by the California Department of Food and Agriculture. The differences between existing law and this proposed regulation is primarily the enhanced monitoring required and a more streamlined route to the commercial market.

Staff also estimated potential costs of in-use control for biodiesel use. Staff's analysis shows that with full implementation of the in-use requirements in 2018, biodiesel used in B5 blends incur no in-use requirement costs, only minimal recordkeeping costs. Higher blends above B5 may have a small cost per gallon. For 2018, the projected costs for complying with the in-use requirements are about $3 million on 180 million gallons of biodiesel, or less than two cents per gallon. Beyond 2018, the cost for biodiesel blends above B5 is projected to decrease to zero because the in-use requirement will sunset upon near full fleet penetration of new technology diesel engines in California.

CHAPTER 1. INTRODUCTION

A. Air Quality

Due to its unique geography, California has unique air pollution challenges. Ambient air quality standards designed to protect public health have been established for several pollutants in the State. Although California has made substantial progress, in many parts of the State air pollution exceeds these ambient air quality standards. To attain the ambient air quality standards, the California Air Resources Board (ARB or Board) has designed a multi-faceted strategy, including emission reductions from mobile sources and motor vehicle fuels. The ARB uses its legal authority to regulate emissions from motor vehicle fuels in the State when appropriate to reduce air pollution. To date, ARB has developed fuel quality standards for gasoline, diesel and several alternative motor vehicle fuels.

In anticipation of increasing biodiesel use and additional alternative motor vehicle fuels in California, ARB staff recognizes the need for a new regulation to maintain air quality benefits for future commercial substitute diesel fuels.

B. Alternative Motor Vehicle Fuels

There is a trend in California toward increasing consumption of alternative motor vehicle fuels in place of conventional petroleum-based gasoline and diesel fuels. This trend is primarily due to economic incentives and policies at the State and national level that incent the use of lower polluting, less toxic, and lower carbon intensity fuels in the commercial market. A more detailed discussion of these new fuels is presented in Chapters 2 through 4. As a result of this diversification, some diesel fuel substitutes have started to enter commerce in California without clear regulatory requirements to ensure there are no detrimental impacts to air pollution as a result of their use. In response to this, ARB staff is proposing a new Alternative Diesel Fuel (ADF) regulation that will put the proper regulatory structure into place to ensure no detrimental impacts to air quality as California moves toward increased alternative motor vehicle fuels consumption.

C. Alternative Diesel Fuels Overview

In general, alternative diesel fuels are a category of motor vehicle fuels that are not conventional diesel and do not solely consist of hydrocarbons. While there are a few alternative diesel fuels in existence today, biodiesel is by far the most prevalent. While renewable diesel is also an innovative diesel fuel replacement, it consists solely of hydrocarbons and is virtually indistinguishable from conventional diesel; therefore, renewable diesel is not considered an alternative diesel fuel under this proposed regulation.

Biodiesel and renewable diesel are both low carbon fuels that can be produced domestically. Using conventional feed stocks, these fuels provide carbon intensities about 25 percent lower than petroleum diesel fuel. Using waste feedstocks, the carbon intensity can be as much as 80 percent lower than petroleum diesel fuel. Biodiesel and renewable diesel also decrease emissions of harmful air pollutants. Blends of biodiesel and renewable diesel have been shown to decrease the emission rates of particulate matter, hydrocarbons and carbon monoxide. Renewable diesel has also been shown to reduce NOx.

1. Biodiesel

Biodiesel has already been in use in California for several decades. Waste restaurant grease is frequently confused with biodiesel. Grease is referred to as straight vegetable oil (SVO), which has a long history of use in diesel engines. Peanut oil, a type of SVO, was the fuel that powered Rudolph Diesel's original compression ignition engine at the 1911 World Fair.

Although SVO can be used in most diesel engines, its use leads to durability issues, such as clogging of fuel injectors and fatty engine deposits. To create a fuel that is more appropriate for the modern diesel engine, SVO must be chemically converted to a form that has improved combustion properties through a process called transesterifcation. In order to accomplish this conversion, the SVO, or other feed stock, is chemically converted to fatty acid methyl esters (FAME) by reacting the SVO with methanol and a catalyst. The resulting FAME biodiesel is much cleaner burning and less viscous, reducing or eliminating many of the problems caused by SVO.

Biodiesel feed stocks such as animal tallow and waste vegetable oil contain high concentrations of triglycerides, which is the main component of fats and oils. These feed stocks can be processed into biodiesel and depending upon the specific feed stock, there may be a range of emissions effects. For example, soybean oils tend to produce higher NOx emitting biodiesel than animal tallow.

2. Renewable Diesel

In addition to biodiesel, ARB considered renewable diesel during this rulemaking. Renewable diesel uses essentially the same feed stocks that are used to make biodiesel, but instead of the transesterification reaction, renewable diesel is produced by hydroprocessing, which results in a fuel containing pure hydrocarbons, paraffinic compounds and nearly no aromatics. Renewable diesel has few of the disadvantages normally associated with biodiesel such as poor cold weather performance, biological degradation or oxidation stability. However, renewable diesel exhibits poor lubricity and generally must be used in a lubricated mixture or have a lubricity additive incorporated in the fuel. Finally, renewable diesel is generally more homogeneous and does not exhibit the chemical variability of biodiesel made from different production feedstocks.

D. Low Carbon Fuel Standard Litigation

On July 15, 2013, the State of California Court of Appeal, Fifth Appellate District (Court) issued its opinion in POET, LLC versus California Air Resources Board (2013) 218 Cal.App.4th 681. Among the issues in the lawsuit was the treatment of biodiesel in the original LCFS regulation. The judge's opinion was that ARB did not adequately address biodiesel NOx emissions that could potentially result from implementation of the LCFS. The Court held that the LCFS would remain in effect and that ARB can continue to implement and enforce the 2013 regulatory standards while it takes steps to cure California Environmental Quality Act and Administrative Procedure Act issues associated with the original adoption of the regulation. In addition to the general impetus of this regulation to protect air quality, it is also designed to fulfill the court's requirements and to remedy issues with NOx emissions from biodiesel. Implementation of this regulation will ensure that the use of biodiesel due to LCFS will not result in increases in NOx emissions in California.

E. Development Process for the Proposed Regulation

Staff evaluation of ADFs and biodiesel began in the early 2000s. During the informal rulemaking process, ARB staff conducted numerous meetings of the Multimedia Working Group (MMWG), multiple public workshops, and numerous meetings with individual stakeholders to discuss a proposed regulation. The MMWG is an inter-agency group responsible for oversight of multimedia evaluations. Below is a timeline of the public actions taken leading up to this proposal, each of the meetings below included opportunities for public comment, which were considered when developing the proposed ADF regulation.

Table 1.1: ADF Regulatory Development Timeline

Date	**Meeting**
2004-2005	Two Biodiesel Work Group Meetings
2006-2007	Five Meetings of the Biodiesel Work Group
2008-2009	Six Meetings of the Biodiesel Work Group
2010	Two Biodiesel Rulemaking Workshops
December 8, 2010	Multimedia Evaluation Meeting
October 4, 2011	Released Biodiesel Guidance Document
February 15, 2013	ADF Concept Paper
April 23, 2013	ADF Rulemaking Workshop
June 13, 2013	ADF Rulemaking Workshop
September 5, 2013	ADF Rulemaking Workshop
February 13, 2014	ADF Rulemaking Workshop
April 17, 2014	ADF Rulemaking Workshop
July 1, 2014	Webinar/Biodiesel Emissions Characteristic Study
October 20, 2014	ADF Rulemaking Workshop
November 21, 2014	Final ADF Rulemaking Workshop and Proposed Draft Regulatory Language

For each of the rulemaking meetings above, over 7,000 individuals or companies were notified and invited to participate. Each of these meetings was well attended by a variety of stakeholders including refiners, oil marketers, alternative fuel producers, non-governmental organizations, academia, and other State agencies. Notices for the workshops, and associated materials, were posted to ARB's biodiesel and renewable diesel webpage at: http://www.arb.ca.gov/fuels/diesel/altdiesel/biodiesel.htm, and emailed to subscribers of our "altdiesel" listserve. Rulemaking workshops were made available to remote attendees by either webcast or webinar in all cases.

In addition to the public meetings, staff had many meetings with stakeholders, attended trade meetings, and exchanged technical information on a regular basis with staff from other State agencies, academia, industry groups, and non-governmental organizations. As a result of this extensive communication with the affected entities, the proposal contained herein is based upon feedback from nearly every corner of the regulated industry as well as other impacted organizations and individuals that are affected by actions concerning or regulate the fuels industry.

Staff also conducted a Standardized Regulatory Impact Assessment (SRIA) in combination with the LCFS. As required by Senate Bill 617 (Chapter 496, Status of 2011), ARB conducted a SRIA and received public feedback and comments from the Department of Finance.

As part of the SRIA process, ARB solicited public input on alternative ADF approaches, including any approach that may yield the same or greater benefits than those associated with the proposed regulation, or that may achieve the goals at lower cost. Alternative approaches submitted to ARB were considered as staff prepared a SRIA. The combined SRIA of Low Carbon Fuel Standard and ADF summary is posted at: http://www.dof.ca.gov/research/economic_research_unit/SB617_regulation/2014_Major_Regulations/documents/ADF_DF_131_SUMMARY.PDF

F. Organization of This Report

This report is organized into twelve chapters with five appendices. We start with four chapters of background and introduction followed by chapters for description of the proposed regulation, alternatives considered, technology assessment, environmental assessment, multimedia assessment, economic impacts analysis of this proposed regulation and concluding with a summary and rationale for the regulation as well as a references chapter. The five appendices include Proposed Regulation Order, Technology Assessment, Economic Assessment, Standardized Regulatory Impact Assessment and California Environmental Quality analysis.

CHAPTER 2. CALIFORNIA MANDATES ON AIR QUALITY

A. Ambient Air Quality Standards

Ambient air quality standards (AAQS) are established to protect even the most sensitive individuals in our communities. An air quality standard defines the maximum amount of a pollutant that can be present in outdoor air without harm to the public's health. Both the ARB and the U.S. Environmental Protection Agency (U.S. EPA) are authorized to and have set ambient air quality standards. California has established AAQS standards for certain pollutants such as fine particulate matter (PM_{10}), ozone, carbon monoxide and sulfur dioxide, which are more protective of public health than federal ambient air quality standards. California has also set standards for some pollutants that are not addressed by federal standards in addition to six criteria pollutants that are on National AAQS list.

Air pollution harms the health of California residents, damages agricultural crops, forests and other plants, and creates the haze that reduces visibility. A large body of scientific evidence associates air pollution exposure with a variety of harmful health effects. To address air pollution, both the California ARB and the U.S. EPA have adopted ambient (outdoor) air quality standards. These legal limits on outdoor air pollution are designed to protect the health and welfare of Californians.

B. Greenhouse Gases and Climate Change

California Global Warming Solutions Act of 2006 (AB 32) outlined the process by which the Board would reduce GHG emissions in California to 1990 levels by 2020 - a reduction of approximately 30 percent by 2020, and then an 80 percent reduction below 1990 levels by 2050. Required actions are codified in H&SC section 38500 through 38599, and Executive Orders S-3-05 and B-16-2012. Some specific provisions of AB 32 included the following responsibilities of ARB:

- Prepare and approve a scoping plan for achieving the maximum technologically feasible and cost-effective reductions in GHG emissions from sources or categories of sources of GHG by 2020 (H&SC §38561); and
- Identify the statewide level of GHG emissions in 1990 to serve as the emissions limit to be achieved by 2020 (H&SC §38550); and
- Adopt a regulation requiring the mandatory reporting of GHG emissions (H&SC §38530); and
- Identify and adopt regulations for discrete early actions that could be enforceable on or before January 1, 2010 (H&SC §38560.5).

AB 32 also requires ARB to develop a Scoping Plan (H&SC §38561) which lays out California's strategy for meeting the GHG reduction goals. The Scoping Plan must be updated every five years and in December 2008, the Board approved the initial Scoping Plan, which included a suite of measures to sharply cut GHG emissions. In May 2014, ARB approved the First Update to the Climate Change Scoping Plan (Update), which builds upon the initial Scoping Plan with new strategies and recommendations. The Update highlights California's progress toward meeting the near-term 2020 GHG emission reduction goals, highlights the latest climate change science and provides direction on how to achieve long-term emission reduction goal described in Executive Order S-3-05. Low Carbon Fuel Standard Program was one of the discrete early actions identified by ARB pursuant to AB 32.

CHAPTER 3. CALIFORNIA MOTOR VEHICLE DIESEL FUEL POLICIES

This chapter provides a summary of various State policies that affect motor vehicle diesel fuel and specifically the development of the ADF regulation. These policies broadly include statutes, regulations, or initiatives that impact the development of the ADF regulation.

A. California Health and Safety Code

California Senate and Assembly bills pertinent to motor vehicle diesel fuels are codified in the California Health and Safety Code (H&SC). These statutes are then administered as rules and regulations in the California Code of Regulations (CCR). The relevant statutes and regulations are provided below but are primarily contained in H&SC Division 26, Parts 1, 2, and 5; and CCR Division 3, Titles 13 and 17.

1. Development of Diesel Fuel Regulations

H&SC Sections 39600, 39601, 43013, 43018, 43101, and 43833 authorize the Board to adopt motor vehicle diesel fuel regulations. Section 43013 is the primary source of ARB's legal authority to adopt and implement motor vehicle fuel specifications, motor vehicle emission standards, and in-use performance standards for the control of air contaminants and sources of air pollution which the Board has found to be necessary, cost effective, and technologically feasible.

Section 43018 expands ARB's authority to adopt whatever control measures pertaining to fuels that are technologically feasible, cost-effective, and necessary to attain the state AAQS by the earliest practicable date.

2. Fuels Multimedia Evaluation

H&SC section 43830.8 requires the state Board to conduct a multimedia evaluation before adopting any regulation that establishes motor vehicle fuel specifications. Section 43830.8(b) defines "multimedia evaluation" as "the identification and evaluation of any significant adverse impact on public health or the environment, including air, water, or soil, that may result from the production, use, or disposal of the motor vehicle fuel that may be used to meet the state board's motor vehicle fuel specification."

Section 43830.8 also requires the California Environmental Policy Council (CEPC or Council) to review the multimedia evaluation and determine if any significant adverse impact on public health or the environment may result from a proposed regulation. If the Council determines that the proposed regulation will cause a significant adverse impact on public health or the environment, or that alternatives exist that would be less adverse, the Council shall recommend alternative or mitigating measures to reduce the adverse impact on public health and the environment.

B. Low Carbon Fuel Standard

In January 2007, Executive Order S-01-07 called for a low carbon fuel standard for transportation fuels to be established for California. The Executive Order specifies a reduction of at least 10 percent in the average carbon intensity of the State's transportation fuels by 2020.

The Executive Order instructed the California Environmental Protection Agency to coordinate activities between the University of California (UC), the California Energy Commission (CEC), and other state agencies to develop and propose a draft compliance schedule to meet the 2020 target. Furthermore, it directed ARB to consider initiating regulatory proceedings to establish and implement the LCFS. The ARB identified the LCFS as a discrete early action measure and approved it on April 23, 2009. The LCFS regulation reduces the carbon intensity of transportation fuels used in the State by an average of 10 percent by the year 2020 to be in line with Executive Order S-01-07.

California's LCFS is expected to reduce GHG emissions from the transportation sector in California by about 16 million metric tons (MMT) in 2020. These reductions account for almost 20 percent of the total GHG emission reductions needed to achieve the State's mandate of reducing GHG emissions to 1990 levels by 2020. In addition, the LCFS is designed to reduce California's dependence on petroleum, create a lasting market for clean transportation technology, and stimulate the production and use of alternative, low carbon fuels in California.

The LCFS is designed to provide a framework that uses market mechanisms, based on carbon intensity – a full lifecycle accounting of a fuel's carbon emissions relative to its energy potential, to spur the steady introduction of lower carbon fuels. The framework establishes performance standards that fuel producers and importers must meet each year beginning in 2011. Since the regulation went into effect, regulated parties have operated under the LCFS program with no significant compliance issues.

To date, the LCFS is working as designed and intended. Fuel producers are innovating and achieving reductions in their fuel pathway carbon intensities, an effect the LCFS regulation is expressly designed to encourage.

The LCFS, as well as other policies and incentives, are prompting the development and use of new ADFs in the State. As such, it is important to ensure that the full commercialization of these fuels do not adversely affect air quality or cause other environmental concerns. The proposed ADF regulation helps ensure this by subjecting new ADFs to rigorous environmental review and a comprehensive multimedia evaluation. In response to the LCFS, biodiesel production is projected to increase. As the LCFS and other policies continue to incentivize the use of ADFs, the proposed regulation will maintain air quality protections and address potential environmental and public health impacts.

Under the LCFS, biodiesel and emerging ADFs represent an important strategy for meeting annual compliance standards and will continue to be an essential part of California's fuel pool. The ADF regulation not only provides regulatory certainty for biodiesel and biodiesel blends, but also provides a clear pathway to streamline the commercialization of new ADFs in the future.

1. ADF Role within the Low Carbon Fuel Standard Program

The proposed ADF regulation is separate and not a part of the LCFS regulation, however the two are interconnected. The LCFS (among other policies and regulations) is expected to drive demand for biodiesel, renewable diesel, and other low carbon fuels. As a result of the increased use of biodiesel in recent years, interest has developed on the impacts of these fuels, especially as it relates to NOx emissions which had been identified as a potential concern. As such the proposed ADF regulation is a response in part to the LCFS and increased demand for biodiesel, as well as potential future demand for other ADFs.

2. Low Carbon Fuel Standard Litigation

Since the initial adoption of the LCFS in 2009, ARB has been involved with two separate lawsuits. The first, Rocky Mountain Farmers Union vs. Corey, relates to a federal lawsuit that challenges the LCFS on the grounds that the regulations were preempted by the federal Clean Air Act and the federal Energy Independence and Security Act and violated the dormant Commerce Clause. On December 29, 2011, the District Court granted Rocky Mountain Farmers Union's request for a preliminary injunction and American Fuels & Petrochemical Manufacturers Association's partial motion for summary judgment, concluding that the LCFS violated the dormant Commerce Clause of the U.S. Constitution. On September 18, 2013, the Ninth Court of Appeals reversed the District Court's opinion that held that the LCFS violated the dormant Commerce Clause and remanded the case for trial. The Ninth Circuit reversed on all but the Clean Air Act preemption claims and remanded for entry of partial summary judgment in favor of ARB.

A second lawsuit, POET, LLC vs. CARB was initiated on December 23, 2009, on the grounds that ARB violated the Administrative Procedure Act (APA) and California Environmental Quality Act (CEQA) during the adoption process. On July 15, 2013, the State of California Court of Appeal, Fifth Appellate District (Court) issued its opinion in POET, LLC v. California Air Resources Board (2013) 218 Cal.App.4th 681. The Court held that the LCFS would remain in effect and that ARB can continue to implement and enforce the 2013 regulatory standards while it takes steps to comply with APA and CEQA statutes.

Among the issues in the POET, LLC vs. CARB lawsuit was the treatment of biodiesel in the original LCFS regulation. The Court concluded that ARB violated CEQA by deferring the formulation of mitigation measures for NOx emissions from biodiesel without committing to specific performance criteria for judging the efficacy of the future mitigation measures. In addition to the general impetus of this ADF regulation to protect air quality, it is also designed to fulfill the court's requirements and to address issues with NOx emissions from biodiesel. Implementation of this proposed regulation will ensure that the use of biodiesel subject to LCFS will not result in increases in NOx emissions in California relative to current conditions.

Also, in response to the Court's directive, ARB staff will propose re-adoption of the LCFS regulation in 2015. This will allow ARB to comply with all procedural requirements imposed by CEQA and the APA. As stated earlier, the Court held the 2013 regulatory standards in place until the LCFS regulation can be re-adopted. Since the LCFS is scheduled to be presented to the Board in early 2015, the new LCFS requirements are schedule to go into effect January 1, 2016. As part of the LCFS re-adoption effort, new elements and amendments are also being considered.

C. California Diesel Fuel Programs

Diesel and biodiesel are regulated by multiple state agencies in California. This section gives an overview of major state regulations affecting ADF use in California.

1. ARB Regulations

As the state air pollution agency, ARB is authorized to adopt standards, rules, and regulations to achieve the maximum degree of emission reduction possible from vehicular and other mobile sources in order to accomplish the attainment of the State ambient air quality standards at the earliest practicable date. ARB regulations can be found under California Code of Regulations (CCR) Division 3, Titles 13 and 17.

a. California Reformulated Diesel Fuel

In November 1988, the Board approved regulations limiting the aromatic hydrocarbon content to 10 percent by volume with a 20 percent limit for small refiners. These diesel fuel regulations, which became effective in 1993, are a necessary part of the State's strategy to reduce air pollution through the use of clean fuels, lower-emitting motor vehicles, and off-road equipment. The regulation includes provisions that enable diesel fuel producers and importers to comply through alternative diesel formulations that may cost less. The alternative specifications must result in the same emission benefits as the 10 percent aromatic standard (or in the case of small refiners, the 20 percent standard).

On July 24, 2003, the Board approved amendments to the California diesel fuel regulations. The amendments reduced the sulfur content limit from 500 ppmw to 15 ppmw for diesel fuel sold for use in California in on-road and off-road motor vehicles starting in mid-2006. The lower sulfur limit aligned the California requirement with the on-road diesel sulfur limit adopted by the U.S. EPA, but expanded the limit to include off-road motor vehicle diesel fuel. The new sulfur standard enabled the use of the emissions control technology, such as particulate filters, used for 2007 and subsequent model-year heavy-duty engines and vehicles.

In 2005, the Board also adopted a measure that applied the diesel fuel standards to harborcraft and intrastate locomotives.

b. Alternative Fuels

"Alternative fuel" generally means any motor vehicle transportation fuel that is not gasoline or diesel fuel. This includes, but is not limited to, those fuels that are commonly or commercially known or sold as one of the following: M-100 fuel methanol, M-85 fuel methanol, E-100 fuel ethanol, E-85 fuel ethanol, biodiesel, compressed natural gas (CNG), liquefied natural gas (LNG), liquefied petroleum gas (LPG), or hydrogen.

The quality of alternative motor vehicle fuels is subject to ARB-approved composition specifications under Title 13, California Code of Regulations, Sections 2292.1 through 2292.6, as follows:

- M-100 fuel methanol (13 CCR §2292.1),
- M-85 fuel methanol (13 CCR §2292.2),
- E-100 fuel ethanol (13 CCR §2292.3),
- E-85 fuel ethanol (13 CCR §2292.4),
- compressed natural gas (13 CCR §2292.5), and
- liquefied petroleum gas (13 CCR §2292.6).

Biodiesel is considered to be an alternative diesel fuel, but there are currently no ARB standards for biodiesel fuel.

2. SWRCB Regulations

The California State Water Resources Control Board (SWRCB) regulates the storage of diesel and biodiesel in Underground Storage Tanks (UST). These tanks must undergo compatibility testing by an independent certification lab, such as Underwriters Laboratory, for any new fuel that may be stored in them. B5 has undergone such a certification. Fuels above B6 have not undergone independent certification and there is no current activity to obtain certification, as such B6-B20 blends of biodiesel are generally stored above ground.

3. CDFA Regulations

The Division of Measurement Standards (DMS) of the California Department of Food and Agriculture (CDFA) regulates diesel and biodiesel for compliance with California specifications and measurement. DMS is statutorily obligated to adopt specifications for new fuels when an independent specification organization, such as ASTM, sets specifications for that fuel.

In 2008, ASTM international developed three biodiesel specifications. First, ASTM updated its specifications for B-100 blendstock, D6751-08, “Standard Specification for Biodiesel Fuel Blend Stock (B100) for Middle Distillate Fuels.” Second, ASTM approved revisions to D975-08, “Standard Specification for Diesel Fuel Oils,” which would subject biodiesel blends from B1 to B5 to the same specification as regulation diesel fuel. Finally, ASTM adopted new fuel specifications for B-6 to B-20 in D7467-08, “Standard Specification for Diesel Fuel Oil Biodiesel Blend (B6 to B20).”

DMS conducted a rulemaking to adopt ASTM D6751 Standard Specification for Biodiesel fuel Blend Stock (B100) for use in Middle Distillate Fuels. DMS has also adopted ASTM D7467 Standard Specification for Diesel Fuel Oil, Biodiesel Blends (B6-B20). ASTM D975, Standard Specification for Diesel Fuel Oils, allows up to B5 to be used and has also been adopted by ASTM.

4. OSFM Regulations

The Office of the State Fire Marshal regulates diesel and biodiesel storage, dispensing, and vapor recovery. All diesel and biodiesel facilities must follow California building and fire code and adhere to the specific provisions regarding diesel and biodiesel.

5. Air Quality Improvement Program (AB 118)

The *California Alternative and Renewable Fuel, Vehicle Technology, Clean Air, and Carbon Reduction Act of 2007* (Assembly Bill (AB) 118) establishes two funding programs for alternative fuels and vehicle technologies.[1] The Air Quality Improvement Program (AQIP) is a voluntary incentive program administered by the ARB. Through AQIP, ARB invests in clean vehicle and equipment projects that reduce criteria pollutant and air toxic emissions, often with concurrent climate change benefits. For current information on annual funding plans and guidelines, please visit ARB’s Air Quality Improvement Program website at http://www.arb.ca.gov/msprog/aqip/aqip.htm.
The Alternative and Renewable Fuel and Vehicle Technology Program (ARFVTP), administered by the CEC, is a competitive grant program that provides as much as $100 million annually towards innovative transportation and fuel technologies. The CEC’s program is governed by its AB 118 Investment Plan, through which the CEC has provided nearly $415 million to date in funding for production and infrastructure projects involving diesel substitutes, including biodiesel and renewable diesel.[2] For more information on total funding amounts and clean transportation projects to date, please visit the CEC’s ARFVTP website at http://www.energy.ca.gov/drive/index.html.

CHAPTER 4. FEDERAL POLICIES AFFECTING MOTOR VEHICLE DIESEL FUEL

This chapter summarizes various Federal policies that affect motor vehicle diesel fuel and may specifically impact the ADF regulation. The policies covered in this chapter include pertinent federal fuel regulations, standards, and requirements.

A. Federal Fuel Registration

U.S. EPA regulations establish fuel registration and formulation requirements.
U.S. EPA requires that all diesel fuels and fuel additives for on-road motor vehicle use be registered in accordance with 40 Code of Federal Regulation (CFR) Part 79. To become registered, a new fuel must apply for registration and meet “substantially similar” requirements as either conventional gasoline or diesel fuel. The “substantially similar” requirement means that the fuel must be of mostly the same composition as the fuel it is displacing, which in the cases depicted under this regulatory proposal would be diesel fuel. Any biodiesel used in California must also be registered as a fuel with U.S. EPA.

The registration requirements for diesel fuels apply to fuels composed of more than 50 percent diesel fuel by volume, and their associated fuel additives. Manufacturers may enroll a fuel or fuel additive in a group of similar fuels and fuel additives through submission of jointly-sponsored testing and analysis conducted on a specific product, for which additives would be measured in parts per million (ppm). In addition, the regulation requires a cetane index of at least 40 or an aromatic hydrocarbon content of no greater than 35 volume percent. All on-road motor vehicle diesel fuel sold or supplied in the United States, except in Alaska, must comply with representative specifications for all products in that group.

B. Federal Regulations Affecting Diesel Fuel Quality

U.S. EPA motor vehicle diesel fuel standards, contained in 40 CFR Part 80 Subpart I, requires on-road motor vehicles diesel fuel to have a sulfur content of no greater than 15 ppmv.

The diesel fuel sulfur regulations require refiners, importers, distributors, and retailers who produce, import, sell, store, or transport diesel fuel to meet the standards specified in the diesel regulations. Sulfur standards were phased in from 2006 to 2010, and were designed to ensure widespread availability of highway diesel fuel containing 15 ppm sulfur or less.

C. Federal Renewable Fuels Standard

Congress adopted the Renewable Fuels Standard (RFS) in 2005 and strengthened it (RFS2) in December 2007 as part of the Energy Independence and Security Act of 2007 (EISA). The RFS2 contains, among other provisions, requirements for increasing volumes of biofuels every year, up to a required volume of 36 billion gallons by 2022. New categories of renewable fuel were also established with separate volume requirements for each category.

Successful implementation of the RFS2 will result in significant quantities of low carbon intensity biofuels that could be used toward compliance with California's LCFS. In addition, successful implementation would also signal that the necessary technological breakthroughs to produce second and third generation biofuels have occurred.

1. Renewable Fuel Volume Requirements

The RFS2 requires fuel producers to use a progressively increasing amount of biofuel, culminating in at least 36 billion gallons of biofuel by 2022[3]. The U.S. EPA must establish regulations to ensure that the transportation fuel sold in, or imported into, the United States contains a minimum volume of renewable fuels as required under the EISA of 2007. Responsible parties under the U.S. EPA regulations relating to biofuels include refiners, blenders, and importers of transportation fuels.[4] RFS2 differentiates between "conventional biofuel" (corn-based ethanol) and "advanced biofuel." Advanced biofuel is renewable fuel, other than corn-based ethanol, with lifecycle greenhouse gas emissions that are at least 50 percent less than greenhouse gas emissions produced by gasoline or diesel. Starting in 2009, a progressively increasing portion of renewable fuels must be advanced biofuels, such as cellulosic ethanol.

2. Renewable Fuels GHG Requirements

The RFS2 requires GHG reductions for the various categories of renewable fuels, but only in discrete "bins" (e.g., both advanced biofuel and biomass-based diesel must achieve a life-cycle GHG emission-reduction threshold of 50 percent).[5] This federal program does not use a carbon intensity standard like the LCFS. As noted, there are specific requirements for the different classifications of renewable fuels. In general, these specifications are set relative to the baseline lifecycle GHG emissions for gasoline and diesel fuel sold or distributed in 2005. The lifecycle GHG emissions are specifically defined as:

> *"The term 'lifecycle greenhouse gas emissions' means the aggregate quantity of greenhouse gas emissions (including direct emissions and significant indirect emissions such as significant emissions from land use changes), as determined by the Administrator, related to the full fuel lifecycle, including all stages of fuel and feedstock production and distribution, from feedstock generation or extraction through the distribution and delivery and use of the finished fuel to the ultimate*

consumer, where the mass values for all greenhouse gases are adjusted to account for their relative global warming potential."[6]

There are four general classifications of renewable fuels defined in RFS2: renewable fuels, advanced biofuels, cellulosic biofuels, and biomass-based diesel.

3. Renewable Biomass Definition

The RFS2 defines renewable fuel as fuel that is produced from renewable biomass. Renewable biomass is then defined as each of the following[7]:

- Planted crops and crop residue harvested from agricultural land cleared or cultivated at any time prior to the enactment of this sentence that is either actively managed or fallow, and nonforested.
- Planted trees and tree residue from actively managed tree plantations on non-federal land cleared at any time prior to enactment of this sentence, including land belonging to an Indian tribe or an Indian individual, that is held in trust by the United States or subject to a restriction against alienation imposed by the United States.
- Animal waste material and animal byproducts.
- Slash and pre-commercial thinnings that are from non-federal forestlands, including forestlands belonging to an Indian tribe or an Indian individual, that are held in trust by the United States or subject to a restriction against alienation imposed by the United States, but not forests or forestlands that are ecological communities with a global or State ranking of critically imperiled, imperiled, or rare pursuant to a State Natural Heritage Program, old growth forest, or late successional forest.
- Biomass obtained from the immediate vicinity of buildings and other areas regularly occupied by people, or of public infrastructure, at risk from wildfire.
- Algae.
- Separated yard waste or food waste, including recycled cooking and trap grease

One aspect of the definition of renewable biomass is that there are significant federal incentive funds for producing advanced biofuels. To qualify for these incentives, the renewable fuels must be produced from renewable biomass.

4. U.S. EPA Rulemakings Implementing the RFS2

U.S. EPA is responsible for implementing the volume requirements in the RFS2. Section 211(o) of the Clean Air Act (CAA or the Act), as amended, requires the

[6] *Energy Independence and Security Act of 2007*, Title II-Energy Security Through Increased Production of Biofuels; Subtitle A Section 201 (1)(H).
[7] *Energy Independence and Security Act of 2007*, Title II-Energy Security Through Increased Production of Biofuels; Subtitle A Section 201 (1)(I).

U.S. EPA Administrator to annually determine a renewable fuel standard and publish the standard in the Federal Register. Based on this standard, each obligated party determines the volume of renewable fuel that it must ensure is consumed as motor vehicle fuel. This standard is calculated as a percentage, by dividing the amount of renewable fuel that the Act requires to be blended into gasoline for a given year by the amount of gasoline expected to be used during that year, including certain adjustments specified by the Act.

a. RFS2 Volume Requirement - 2013

In August 2013, U.S. EPA finalized the 2013 renewable fuel standards which established the 2013 annual percentage standards for cellulosic biofuel, biomass-based diesel, advanced biofuel, and total renewable fuel.[8]: Note that the 16.55 billion gallons of renewable fuel required in 2013 was projected to include approximately 1.7 billion gallons of biodiesel and renewable diesel. In April 2014, U.S. EPA took direct final action to revise the 2013 cellulosic biofuel standard. The final 2013 volumes are shown in Table 4.1 below.

Table 4.1: Volumes Used to Determine the Final 2013 Percentage Standards

Category	Volume*
Cellulosic Biofuel	810,185 gal
Biomass-based Diesel	1.28 billion gal
Advanced Biofuel	2.75 billion gal
Renewable Fuel	16.55 billion gal

*All volumes are ethanol-equivalent, except for biomass-based diesel which is actual.

The U.S. EPA also used the applicable volumes that are specified in the statute to set the percentage standards for advanced biofuel and total renewable fuel for 2013.[9] The percentage standards required under the RFS program represent the ratio of renewable fuel volume to non-renewable gasoline and diesel volume. The 2013 standards are shown in Table 4.2 below.

Table 4.2: Final Percentage Standards for 2013

Category	Percent
Cellulosic Biofuel	0.0005%
Biomass-based Diesel	1.13%
Advanced Biofuel	1.62%
Renewable Fuel	9.74%

b. RFS2 Volume Requirements - 2014

[8] U.S. Environmental Protection Agency, Office of Transportation and Quality. *EPA Finalizes 2013 Renewable Fuel Standards,* EPA-420-F-13-042. August 2013
[9] U.S. Environmental Protection Agency, Office of Transportation and Quality. *EPA Issues Direct Final Rule for 2013 Cellulosic Standard,* EPA-420-F-14-018. April 2014

In November 2013, U.S. EPA proposed 2014 percentage standards for cellulosic biofuel, biomass-based diesel, advanced biofuel, and renewable fuels.[10] The projected 2014 volumes used to determine the proposed percentage standards are shown in Table 4.5 below:

Table 4.3: Volumes Used to Determine the Proposed 2014 Percentage Standards

Category	Proposed Volume*	Projected Range
Cellulosic Biofuel	17 million gal	8-30 million gallons
Biomass-based Diesel	1.28 billion gal	1.28 billion gallons**
Advanced Biofuel	2.20 billion gal	2.0-2.51 billion gallons
Renewable Fuel	15.21 billion gal	15.00-15.52 billion gallons

* All volumes are ethanol-equivalent, except for biomass-based diesel which is actual
** U.S. EPA is requesting comment on alternative approaches and higher volumes

The percentage standards represent the ratio of renewable fuel volume to non-renewable gasoline and diesel volume. The proposed 2014 standards are shown in Table 4.6 below.

Table 4.4: Proposed Percentage Standards for 2014

Category	Percent
Cellulosic Biofuel	0.010%
Biomass-based Diesel	1.16%
Advanced Biofuel	1.33%
Renewable Fuel	9.20%

The proposed 2014 standards were submitted to the Office of Management and Budget of interagency review in August 2014. However, in November 2014, the U.S. EPA announced that it will not be finalizing the 2014 standards until 2015.

D. Federal Trade Commission Labeling Requirements

The EISA of 2007 required Federal Trade Commission (FTC) to adopt regulations pertaining to the labeling of biodiesel and biomass-based diesel at retail dispensing outlets. This regulation was enacted under Title 16, Code of Federal Regulations, Part 306.12. The regulation requires labeling of biodiesel and biomass-based diesel if the blend level is above 5 percent. Specifically it requires labeling of blend B6 to B20 and blends above B20 are required to be labeled by the exact amount of biodiesel for example B63. Biomass-based diesel labeling requirements are parallel but independent of biodiesel volume.

[10] U.S. Environmental Protection Agency. *2014 Standards for the Renewable Fuel Standard Program; Proposed Rule.* Federal Register. Volume 78, No. 230. Part II. 40 CFR 80. November 29, 2013

CHAPTER 5. DESCRIPTION OF PROPOSED REGULATION

A. Overview of Proposed Regulation

The primary purpose of the proposed regulation is to create a framework that allows for innovation and diversity in the California diesel fuel pool while ensuring the introduction of ADFs is managed responsibly by setting up a three stage process to evaluate environmental impacts of ADFs. Additionally, this rulemaking will establish in-use specifications for biodiesel as part of Stage 3A requirements of the proposed regulation.

B. Applicability

The proposed regulation will apply to all producers, importers, blenders and distributors of ADFs in the State of California. Fuel that meets a specification under the alternative fuels regulation 13 CCR 2292 are not considered ADFs and are thus not subject to this regulation. It is ARB's intention that this proposed regulation be in effect at all points of sale, offer, or supply in the California fuel distribution infrastructure.

C. Definitions

For the purposes of sections 2293 through 2293.9, the definitions in H&SC sections 39010 through 39060 shall apply, except as otherwise specified in subarticle 1:

Section (a) covers the definitions in the proposed regulation.

Section (b) is a glossary of acronyms used in the proposed regulation.

D. Applicable Requirements for Alternative Diesel Fuels

It is the goal of this proposed regulation to ensure that there are no adverse environmental impacts of ADFs as they are introduced into California. This proposed regulation relies on a three-stage introduction of ADFs, through which the environmental impacts will be determined and, if necessary, any adverse impacts minimized.

1. Stage 1 (Pilot Program)

The first stage of this proposed regulation is referred to as a pilot program. Any new ADF proponent may apply to setup a pilot program in order to begin testing of their fuel in California. The pilot program will limit the amount of a new ADF, not to exceed the energy equivalent of one million gallons of diesel fuel, used in well-defined fleets. The pilot program will last for one year, with three opportunities to renew for six months each. The application for a pilot program includes public disclosure of many properties of the fuel that may affect its impact to the environment (e.g., density, distillation curve, and water-octanol partition coefficient). The EO will use this information to conduct a preliminary review of the fuel to determine whether it is appropriate for use in California and if any potential risks resulting from the use of the fuel in a pilot program are outweighed by any potential benefits of the fuel. The EO will issue an Executive Order if the pilot program application is approved. The Executive Order will contain the necessary terms and conditions of additional testing based on the properties of the fuel. Completion of the terms of the Executive Order will be required prior to advancing to Stage 2. Applicants under a Stage 1 Executive Order will also be required to submit quarterly reports on how much fuel is being used.

2. Stage 2 (Fuel Specification Development)

Once an ADF applicant completes the terms of a Stage 1 Executive Order, they may apply for an updated Executive Order to move to Stage 2. The Stage 2 Executive Order will include a limit on the amount of that fuel that may be sold in California, to be determined by the EO but not to exceed the energy equivalent of 30 million gallons of diesel.

During Stage 2, an ADF applicant would be required to: (1) complete a multimedia evaluation, (2) achieve adoption of consensus standards, (3) obtain approval for use from 75 percent of engine manufacturers who produce engines in which the ADF is expected to be used, and (4) identify appropriate specifications for the fuel.

During Stage 2, ARB would make a determination of potential adverse emissions impacts from use of the ADF in question, using emissions data assembled during a multimedia evaluation. If it is determined that an ADF has been shown to have no potential adverse emissions impacts, the ADF would then be eligible to apply to advance to Stage 3B. If, however, it has determined there are potential adverse emissions impacts for the ADF or ADF blends, the ADF would be eligible to apply to advance to Stage 3A.

3. Stage 3 (Commercial Sales)

After completing the requirements of Stage 2, an ADF proponent may apply to the EO to move their fuel to Stage 3. If a determination of potential adverse emissions impacts was made under Stage 2, the EO may declare intent to advance the fuel to Stage 3A where an evaluation to determine whether there are adverse emissions impacts considering the effects of offsetting factors will commence. If the EO determines there are adverse emissions impacts the appropriate specifications and/or in-use requirements will be established by rulemaking. Throughout the course of a Stage 3A rulemaking, the volume limits from Stage 2 shall apply. In a Stage 3A rulemaking the EO shall consider, at a minimum, the offsetting effects of feedstocks, other fuel use, and vehicle effects when determining the appropriateness of establishing specifications and/or in-use requirements.

If the ADF was found to have no potential adverse emissions impacts, the EO may advance the ADF to Stage 3B by issuing an Executive Order with the specific provisions of the no potential adverse impacts determination. In Stage 3B, there are no limits on the fuel volume a proponent may sell or supply for use in California. Stage 3B consists of reporting and recordkeeping for an ADF.

E. Biodiesel as an Alternative Diesel Fuel

Biodiesel will have completed all of the relevant steps that are outlined in Stage 2 of the proposed regulation by the time this proposed regulation is in full effect. Potential adverse impacts have been identified. As such, ARB is proposing to regulate biodiesel at stage 3A. Because of the potential adverse emissions impacts identified for NOx emissions, ARB is proposing to establish specifications and in-use requirements for biodiesel and its blends.

ARB is also proposing the in-use requirements come into effect on January 1, 2018, as time is needed to overcome logistical and other issues in implementation of in-use requirements. For example, use of the additive Di-tert-butyl peroxide (DTBP) will require replacement of steel tanks with stainless steel tanks, permitting of hazardous substance storage, approval by local fire agencies, additional additization infrastructure, and logistical business changes to acquire the additive. All of this is expected to take around 2 years to complete. Another method of compliance is re-routing higher blends to NTDEs. Research shows that the use of biodiesel in blends up to B20 in NTDEs results in no detrimental NOx impacts. This and other methods of complying with the in-use requirements, such as certification of additional options are also expected to take 2 years or more. Because compliance with the in-use options would be infeasible during initial implementation on January 1, 2016, only recordkeeping and reporting provisions will be implemented initially. The in-use requirements are proposed to come into effect on January 1, 2018.

Staff's statistical analysis found that for certain vehicles biodiesel has potential adverse emissions impacts on NOx in any blends of low saturation biodiesel (un-additized CN <56) but not in blends of high saturation biodiesel (un-additized CN ≥56) up to B10. Staff has also found that there exist offsetting factors, in the form of renewable diesel and NTDEs that are expected to reduce and eventually eliminate any NOx increase from low level blends (B5 or less) of low saturation biodiesel. In order to ensure that the use of higher blends of biodiesel do not increase NOx emissions, staff is proposing NOx control levels above which per gallon in-use requirements would be instituted. Table 5.1 below shows the proposed NOx control levels based on feedstock and time of year.

Table 5.1: NOx Control Levels

	Control Level (April 1 to October 31)	Control Level (November 1 to March 31)
Low Saturation BD	B5	B10
High Saturation BD	B10	B10

In the period between November 1 and March 31, NOx control for reduction of ozone is less necessary. In order to maximize the PM reductions from biodiesel and allow increased flexibility for the biodiesel industry, ARB is proposing a control level of B10 for all biodiesel during this period.

Staff expects increasing use of NTDEs to eliminate biodiesel's NOx impact over time, thus the proposed biodiesel provisions include a sunset provision. ARB is proposing that the NOx control levels would sunset when EMFAC 2011 (ARB's model for estimating emissions from California on-road vehicles) shows more than 90 percent of Vehicle Miles Travelled (VMT) by NTDEs. The sunset provision is expected to trigger in 2023. However, staff has also proposed a review to be completed by December 31, 2019 in order to make sure that the offsetting factors are on track and that the in-use requirements for biodiesel are operating as expected.

Research indicates that the use of biodiesel in light- or medium-duty vehicles results in no detrimental NOx impacts. Research also indicates that the use of biodiesel up to blends of B20 in NTDEs results in no detrimental NOx impacts. Therefore, the proposed regulation also includes a process for fleets and fueling stations to become exempted from the in-use requirements for biodiesel blends up to B20 as long as they can demonstrate to the satisfaction of the Executive Officer that they are fueling at least 90 percent light or medium duty vehicles, or NTDEs.

CHAPTER 6. TECHNOLOGY ASSESSMENT

A. Introduction

This chapter summarizes the process by which ARB developed the conclusions on the NOx impacts of the use of biodiesel. This process includes the studies that ARB has sponsored, the additional studies upon which we based our analysis, as well as the statistical methods and study selection criteria that we used.

B. Emissions Studies Literature Review

Multiple studies have looked at the impact of biodiesel on heavy-duty diesel vehicle NOx emissions. The National Renewable Energy Lab (NREL) and the U.S. EPA have both examined the literature to determine these effects. Neither of these databases focused primarily on the effects of using CARB diesel as the base fuel. To fill this knowledge gap, ARB staff conducted a literature search that addresses the impacts of biodiesel use on NOx emissions in heavy duty engines using California diesel as the base fuel. It is important to focus on studies which use CARB diesel as the baseline, since multiple studies, such as the NREL and EPA studies referenced above, have found that base fuel impacts the presence and magnitude of a biodiesel NOx impact.

1. Criteria for Choosing Relevant Studies

The literature search focused on biodiesel blends B20 and below and characterized studies by their baseline fuel properties. Studies looking at B20 and below were chosen as the focus, since these are the fuels which are currently legal commercially. Studies that used either explicitly CARB diesel or a diesel fuel that was tested to have a cetane number of at least 49 were included in the analysis. Non-CARB diesel that had a cetane number of at least 49 was determined by staff to be similar enough to CARB diesel in NOx emissions to treat as CARB diesel for the purposes of this analysis, including showing similar emissions result when testing biodiesel blends derived from these fuels.

The studies included in this analysis were all performed using an engine dynamometer with commercially available engines, and no engine modifications. Engine dynamometer data were chosen over chassis dynamometer data because they eliminate some variability and as such are able to get a more accurate representation of true fuel to fuel variances. For example, since chassis dynamometer requires a person driving who would attempt to match an acceleration curve and engine dynamometer curves are performed by a computer, driver to driver variability is eliminated. Studies using test cycles based on a single speed and mode were excluded from this analysis because their results do not transfer well to real world emissions. Instead studies that used test cycles such as the Federal Test Procedure (FTP) or Urban Dynamometer Drive Schedule (UDDS) were selected because these cycles vary load and engine speed over the cycle in order to approximate real world operation.

2. Major Studies

Below is a list of the studies that met the stated criteria for inclusion in this analysis from our literature search.

Table 6.1: Major Studies from Literature Search

In order to better understand emissions from biodiesel, ARB considered NOx data from literature studies as well as ARB studies from a wide range of vehicles feedstocks and test cycles. Table 6.2 below summarizes the testing matrix that was completed in studies included in the literature search.

Table 6.2: Summary of Testing Included in Literature Search

Application	Engine	Feedstocks	Test Cycles
On-road chassis	Caterpillar C15 Cummins ISM DDC MBE4000 Cummins ISX	Animal Soy Renewable diesel GTL	UDDS FTP 40mph Cruise 50mph Cruise
On-road HD engine	Cummins ISM DDC MBE4000 DDC Series 60	Animal Soy	UDDS FTP SET
Non-road engine	John Deere 4084 Kubota TRU	Animal Soy	ISO 8178-4

These studies found that most of the emissions from biodiesel are reduced from the CARB diesel baseline, including PM, CO, HC, and most toxic species. However, NOx was found to increase for certain biodiesel blend levels and feedstocks. Generally, it was found that soy based biodiesel blends had greater NOx emissions than those derived from animal based biodiesel. The results of these studies apply specifically to heavy-duty vehicles that do not use post-exhaust NOx emissions control, therefore the results of this study should not be extended to NTDEs or Light-duty and Medium-duty vehicles.

3. Effect of Base Fuel on Emissions

EPA 2002[11] examined the effect that base fuel has on the emissions results of biodiesel blends and found that using clean base diesel, such as CARB diesel, may impact the results in NOx emissions from biodiesel. As a result of this conclusion, ARB staff began looking into the effect that biodiesel might have on blends used within the State of California specifically. California's diesel fuel tends to be lower in aromatic hydrocarbon content and higher in cetane number than federal diesel. These two properties are important in the formation of NOx. After extensive testing and review, staff confirms EPA's original analysis and finds that the effects of biodiesel on NOx with CARB diesel as a base fuel are greater than the effects using federal diesel as a base fuel. As an example, EPA 2002 found NOx increases of about two percent in B20 derived from soy when federal diesel is the base fuel, whereas ARB's literature review finds NOx increases of about four percent in B20 derived from soy when CARB diesel is the base fuel. These results are discussed more in section C of this chapter.

C. NOx Emissions Data Analysis

ARB staff re-analyzed original data from three engine dynamometer studies that look at B5 to examine whether biodiesel blends yield different NOx emissions from conventional diesel fuel.[12,13,14] Staff chose to focus on engine studies because the

[11] U.S. Environmental Protection Agency, *A Comprehensive Analysis of Biodiesel Impacts on Exhaust Emissions*, 2002
[12] Durbin et al., *Biodiesel Characterization and NOx Mitigation Study,* October 2011

variability in emission measurements is smaller than for vehicles. A small change in emissions due to biodiesel would require a larger sample size to detect if vehicle data were used.

Our analysis focused primarily on soy B5, since soy is expected to be the dominant feed stock, and the existence of a significant effect at the 5% blend level would imply the existence of an effect at higher blend levels. Staff analyzed each blend level separately, and did not make any assumptions about whether the relationship between blend level and NOx emissions is linear or not.

Engine type and drive cycle have a significant impact on NOx emissions, and differences from one study to another can lead to large variations in emissions. We therefore controlled for these three variables in the statistical model. Out of several possible ways to reflect this in the model, we chose a simple approach: we treated the combination of engine type, drive cycle and study as a single categorical variable which we called the "experiment", and considered each experiment as yielding an independent estimate of the difference in NOx emissions between soy B5 and conventional diesel.

Past experience with emissions data suggests that transforming emissions by taking logarithms (or equivalently, working with percent differences instead of absolute differences) is appropriate. Staff confirmed this with model diagnostics.

Staff used a linear mixed effects model, with experiment as a random effect, fuel type as a fixed effect, and the natural logarithm of NOx emissions as the response, to estimate the difference in NOx emissions from soy B5 relative to CARB diesel.[15,16] Staff used R statistical software, specifically the `lmer` model fitting routine from R's `lme4` package.[17,18] The result: B5 yields approximately 1% higher NOx emissions than CARB diesel, and the increase is highly statistically significant (confidence level > 99.9999%).

Staff performed numerous sensitivity checks on the results. Staff tried several different formulations of the mixed model, as well as other statistical models. Staff also experimented with including other data sets that were not used for the final analysis. In each case soy B5 yielded around 1% higher NOx emissions than CARB diesel, and in each case the result was statistically significant.

[18] Bates et al., (2014). lme4: Linear mixed-effects models using Eigen and S4. R package version 1.1-7 http://CRAN.R-project.org/package=lme4

As a further check against ARB staff's results, ARB contracted with Prof. David Rocke of U.C.Davis to analyze the same data set and derive independent conclusions. Prof. Rocke's analysis is attached as Appendix F. His results matched ARB staff's: soy B5 yielded approximately 1% higher NOx emissions than CARB diesel. The increase was highly statistically significant (confidence level > 99.9999%).

Further analysis of other biodiesel blends yielded the following results:

Soy B10	approximately 2% higher than CARB diesel
Animal B5	no statistical difference
Animal B10	no statistical difference

These results are consistent with a linear relationship between blend level and NOx emissions for soy blends in the 5-10% range. However, no data were available for blend levels below 5%, and it is not possible to establish whether the relationship is linear in the 0-5% range.

It should be noted that this testing demonstrates the results of a specific fuel formulation on specific engines in controlled laboratory conditions. To translate this to any potential real-world emission impact requires consideration of many factors (e.g., number of NTDE engines, amount of renewable and other low-NOx diesel, amount of low saturation vs high saturation biodiesel, and any NOx-reducing additives).

The complex mechanisms creating NOx increases at different biodiesel levels are not completely understood. The NOx emissions appear to be affected primarily through thermodynamic interactions, yet other factors have also been proposed. For example, Bunce et. al.,[19] looked at engine factors such as air to fuel ratio, EGR fraction, rail pressure and start of injection, as well as cetane number, soot radiation, bulk modulus, Engine Control Module feedback, and adiabatic flame temperature as factors that could serve to control engine NOx emissions. The complex interactions created by the fuel and engine system demonstrate the uncertainty inherent in translating the results of laboratory testing to real world emissions effects. The consistent and highly significant findings for NOx give certainty that there is an effect compared to CARB diesel.

D. Biodiesel Emissions in Heavy-Duty Diesel Engines

Below staff presents emissions effects of biodiesel based on the literature search described in section B of this chapter. The average data below are based on averages of the data found in the literature search and are not weighted as they were in the statistical analysis above. These results should thus be used as estimates of the effect of biodiesel as no attempt was made to weight them according to representativeness of the engines tested in the California Heavy duty vehicle fleet. For the rest of this chapter staff refers to soy biodiesel as low saturation biodiesel, and animal biodiesel as high saturation biodiesel. This is explained more fully in section 4.

---

[19] Bunce et al, *Stock and Optimized Performance and Emissions with 5% and 20% Soy Biodiesel Blends in a Modern Common Rail Turbo-Diesel Engine,* Energy Fuels, 2010, *24* (2), pp 928–939

1. NOx Emissions

Biodiesel blend level was found to be directly related to NOx emissions level. Additionally, the NOx emissions from biodiesel were found to be dependent upon the saturation level of the biodiesel feedstock: high saturation feedstocks (animal in the studies) had less NOx emissions than low saturation feedstocks (soy and other lower cetane number feedstocks). Engine and duty cycle did not have substantial impacts on the NOx emissions. Table 6.3 below shows NOx emissions based on biodiesel blend levels and feedstock saturation.

Table 6.3: Biodiesel NOx Emissions by Blend Level and Feedstock Saturation

(ΔNOx Emissions)	**B5**	**B10**	**B20**
Low Saturation	1.1%	1.8%	4.0%
High Saturation	-0.2%	0.1%	1.5%

2. PM Emissions

Biodiesel blend level was found to be inversely correlated to PM emissions. Biodiesel feedstock or test method did not seem to substantively affect PM emissions. In 2007 and later engines equipped with PM filters, it was difficult to identify any meaningful differences in PM emissions between CARB diesel and biodiesel. Table 6.4 below shows PM emissions results by blend level.

Table 6.4: PM Reductions by Biodiesel Blend Level in pre-2007 Engines

(ΔPM Emissions)	**B5**	**B10**	**B20**
Pre-2007 Engines	-4.7%	-8.9%	-19.0%

3. VOC Emissions

Biodiesel blends generally had lower VOC emissions than CARB diesel, however in 2007 and later engines with PM filters it was difficult to identify any trends, likely because PM filters generally also include diesel oxidation catalysts which are designed to reduce VOCs. Effects of feedstocks and test cycles were not clear. Table 6.5 below shows VOC emissions in pre-2007 engines.

Table 6.5: VOC Emissions by Biodiesel Blend Level in pre-2007 Engines

(ΔVOC Emissions)	**B5**	**B10**	**B20**
Pre-2007 Engines	-2.2%	-3.1%	-10.1%

4. Effect of Biodiesel Properties on Emissions

NOx emissions from biodiesel are influenced by the feedstock from which the biodiesel is produced. Chemically the main properties of the biodiesel that are related to NOx appear to be the level of saturation and the chain length. Biodiesel is produced in such a way that several properties of the feedstock (e.g., saturation level, chain length) are retained in the biodiesel product. These chemical properties influence physical properties in fuel delivery and combustion that are important to the way the engine operates and thus relate to NOx emissions. The physical properties of interest include modulus of incompressibility, fuel atomization, and ignition delay; these properties are intercorrelated.

Rather than specifying feedstocks and their specific relationship with NOx emissions, which can pose technical and logistical difficulties for determination and tracking, it is preferable to separate biodiesel feedstocks and their NOx emissions potential using performance based properties. Staff is aware of two performance properties that have been shown to be reasonably well correlated to NOx emissions differences between feedstocks: Cetane number and iodine value. Neither of these properties are direct indicators of NOx emissions, but are surrogate values for predicting the chemical and physical properties which are related to NOx emissions. Cetane number has been shown to be a better indicator of NOx emissions differences than iodine number, but has problems when the fuels are additized with cetane enhancing additives.

Durbin 2011 showed that use of the cetane enhancing additive DTBP mitigated the NOx increases from a soy biodiesel. That same study showed that another cetane enhancing additive, 2-ethylhexyl nitrate (2-EHN), did not mitigate the NOx increases from a soy biodiesel. In fact, there were no differences between unnaditized biodiesel blends and additized biodiesel blends using 2-EHN. This result shows that the difference in NOx emissions from biodiesel is not based solely on cetane number of the mixture but on the properties of the biodiesel. Therefore, if cetane is used as an indicator of the NOx differences between biodiesel feedstocks, it should be measured prior to addition of cetane enhancing additives.

Alternatively, iodine number may be used to predict NOx differences between biodiesel feedstocks since it is not sensitive to cetane enhancing additives and is a measure of saturation of a fuel. Iodine number also has potential issues since it only addresses biodiesel saturation, and does not include the important effects of biodiesel chain length. However, this may not be an issue as the currently most frequently used feedstocks are very similar in chain length (primarily C16 and C18), and is not likely to become a problem unless more exotic feedstocks such as coconut oil (primarily C12) become popular. Staff proposes to use unadditized cetane number as the determinant of saturation level, since it is more frequently tested for by biodiesel producers and is more closely correlated to NOx emissions than iodine number.

5. Comparison of Vehicle Chassis to Engine Data

Vehicle chassis dynamometer and engine dynamometer are two popular methods of measuring the work exerted during emissions testing. In both cases, the goal is to relate the amount of emissions to some relevant value, generally grams/mile for chassis dynamometer and gram/brake horsepower hour for engine dynamometer. While chassis dynamometer certainly has its place and is able to better distinguish vehicle to vehicle differences, due to the use of the whole vehicle in testing, it adds greatly to the variability of testing, due to the driver, transmission and other sources of variability not present in engine testing. Therefore, when testing for fuel specific effects it is most appropriate to use engine dynamometer testing. As such, staff's analysis of specific numeric quantification of biodiesel emissions testing relies upon engine dynamometer studies.

It should be noted that although chassis dynamometer studies were not relied upon for quantification of emissions effects of biodiesel, staff examined several studies that included results using chassis dynamometer and they were directionally similar to the results staff got using engine data.

6. Emissions in New Technology Diesel Engines

Engines that meet the latest emission standards through the use of Selective Catalytic Reduction (SCR) have been shown to have no significant difference in NOx emissions based on the fuel used. A study conducted by the NREL looked at two Cummins ISL engines that were equipped with SCR, and found that NOx emissions control eliminates fuel effects on NOx, even for B100 and even in fuels compared against a CARB diesel baseline.[20] However, a recent study at UC Riverside tested B50 blends and found a NOx increase with a 2010 Cummins ISX.[21] The UC Riverside study did not look at blends below B50. Staff proposes to take a precautionary approach and in the light of data showing there may be a NOx impact at higher biodiesel blends but not at lower biodiesel blends, staff is limiting the conclusion of no detrimental NOx impacts in NTDEs to blends of B20 and below. Additional studies on NTDEs have been completed, however since they included either retrofit engines or non-commercial engines staff did not include their results in this analysis.[22,23,24]

7. Renewable Diesel NOx Emissions

Renewable diesel (as well as Gas-to-liquid diesel) has been found to decrease NOx emissions relative to CARB diesel. Durbin 2011 found that use of pure renewable diesel or GTL fuel reduced NOx emissions by about 10 percent relative to CARB diesel, and was found to be fairly linear according to blend level. Additionally as part of the

mitigation testing in that study, it was found that blends containing at least 2.75 gallons of renewable diesel per gallon of biodiesel were NOx neutral compared to CARB diesel.

E. Biodiesel Effects in Light and Medium Duty Vehicles

Light-duty and medium-duty vehicles have been found not to experience increases in NOx due to the use of biodiesel. For example, a study performed on three light-duty vehicles using different biodiesel blends found no significant and consistent pattern in NOx emissions based on blend levels across the different engines, blends and cycles.[25,26]

F. Biodiesel Effects in Non-road and Stationary Engines

1. Emissions from Non-road Engines

Durbin 2011 included two non-road engines in its test matrix, a John Deere 4084 and a Kubota TRU engine. Generally, the trends and magnitude of emissions for these engines were similar to those for the study as a whole. In general, NOx emissions increased, PM and HC emissions decreased with increasing biodiesel blend levels. The table below shows selected emissions for the John Deere and Kubota TRU engines, from a soy feedstock.

Table 6.6. Emissions from non-road engines on soy biodiesel

Engine	Blend Level	NOx	p-value	PM	p-value	HC	p-value
John Deere	B20	2.82%	0.021	-23.25%	0.028	-5.22%	0.498
	B50	7.63%	0.000	-31.75%	0.013	-15.12%	0.104
	B100	13.76%	0.000	-55.93%	0.000	-27.54%	0.001
Kubota TRU	B20	2.25%	0.086	-6.91%	0.011	-5.68%	0.153
	B100	18.89%	0.000	-40.30	0.000	-58.53%	0.000

2. Emissions from Stationary Engines

Stationary engines were not tested as part of staff's studies on biodiesel and no data were found on them during the literature search. As a conservative measure staff assumes that biodiesel also increases NOx at similar rates in stationary engines as in on-road and non-road engines.

G. NOx Emission Control Techniques

As a result of the Mitigation Study completed by UC Riverside and ARB, several technically feasible options were identified that would ensure no NOx increase as a

[25] Nikanjam et al, *Performance and Emissions of Diesel and Alternative Diesel Fuels in Modern Light-Duty Vehicles*, SAE 2011-24-0198, 2011
[26] Durbin et al., *Regulated Emissions from Biodiesel Fuels from On/Off-road Applications*, Atmospheric Environment, Volume 41, p. 5647-5658, 2007

result of biodiesel use. The options that were identified reduce NOx to parity with conventional CARB diesel by using additives or altering the baseline fuel.

The Mitigation study found that a blend of 1 percent di-tert butyl peroxide in B20 yielded NOx emissions that were equivalent to the CARB diesel baseline. Additionally, the Mitigation Study found that a blend of 55 percent renewable diesel, 25 percent CARB diesel and 20 percent biodiesel was equivalent to the CARB diesel baseline. Additionally, 2-ethylhexyl nitrate (2-EHN) was tested to determine whether it would also be able to mitigate the NOx from biodiesel blends since it is also a cetane improver. However, the fuels containing 2-EHN had essentially the same NOx emissions as those without additives. The difference between the NOx emissions of these blends compared to baseline CARB diesel is shown in the Table 6.3 below.

Table 6.7: NOx Emissions of Mitigation Measures

Fuel Blend	NOx Diff % from CARB diesel	p-value
B20 1%DTBP	0.0 %	0.959
C25 R55 B20	-0.8 %	0.029
B20 1% 2-EHN	6.3 %	0.000

In addition to the use of additives, staff is including certification procedures to allow for innovation and to allow the market to determine the best option for mitigation while ensuring no increase in NOx from the use of biodiesel. The certification option is based on the CARB diesel certification procedures under title 13 CCR section 2282(g). The certification requires a minimum of 20 tests each on a CARB diesel reference fuel and a candidate fuel. This number of replicates ensures that any emissions differences between the candidate fuel and the reference diesel are detected if they exist.

H. Determination of NOx Control Level for Biodiesel

Staff considered several factors in the analysis of what level of NOx control would be appropriate for biodiesel, primarily:

- NOx increase associated with biodiesel,
- Effects of high vs low saturation feedstocks,
- NOx reducing impacts of renewable diesel,
- Penetration rate of NTDEs,
- Reductions in emissions of pollutants other than NOx, and
- Feasibility of control methods.

When considering the impacts of biodiesel by feedstock, ARB determined that most of the biodiesel used in California would be low saturation biodiesel, which was found to have NOx increases at B5 with no clear point of NOx neutrality with CARB diesel. To be conservative, ARB has assumed that all blends containing low saturation biodiesel caused NOx increase.

ARB considered the range of factors which affect NOx emissions from diesel engines in the commercial market. NTDEs, which are increasing in number in California, do not show increased NOx from biodiesel use up to B20. Additionally, renewable diesel, which is increasing in California in response to the LCFS, reduces NOx. Given their impact on NOx emissions, renewable diesel and NTDEs are considered offsetting factors. Staff's analysis was designed to determine the appropriate blend level considering the Nox controls achieved by the above offsetting factors. Staff's analysis concluded that existing trends regarding use of NTDEs and renewable diesel as well as other factors supports a NOx control level of B5 for low saturation and B10 for high saturation biodiesel from April 1st to October 31st, and B10 for low and high saturation biodiesel from November 1st to March 31st.

For biodiesel blends below the NOx control level no in-use requirements are proposed because their use would not increase NOx emissions in the environment above current conditions after considering offsetting factors. In-use requirements will, under staff's proposal, be required for use of blends higher than NOx control level. These requirements could be met through the use of the additive DTBP, targeting exempt fleets, or certification of alternative options. The proposal addresses the seasonality of potential detrimental air quality impacts primarily related to summer-time ozone, and therefore allows a higher B10 blend for both low and high-saturation biodiesel during the low ozone season. Staff's analysis suggests that there will likely be no secondary PM detriment from the higher blends allowed in the low ozone season and may be benefits due to the direct PM reductions from biodiesel.

The net impacts of the proposal reduce NOx impacts from biodiesel, even assuming increased biodiesel volumes over the subsequent years. Estimated impacts under the proposal are less than the baseline (current year) and will continue to decrease as NTDE use increases in California. This proposal provides the maximum feasible level of mitigation while still achieving GHG and PM emission reductions.

CHAPTER 7. AIR QUALITY AND ENVIRONMENTAL JUSTICE

A. Introduction

This chapter outlines the expected air quality impacts of the proposed regulation as well as an analysis of potential effects of the ADF regulation on environmental justice and local communities. The CEQA related requirements and findings are discussed in Chapter 8 as well as the attached Environmental Analysis document attached in Appendix D.

B. Air Quality

One of the primary goals of the ADF regulation is to ensure no significant environmental impacts as a result of the use of ADFs. As such ARB is proposing an environmental review process through the three stage evaluation of ADFs, as well as provisions for biodiesel as the first commercial ADF. Biodiesel provides important air quality benefits, primarily in the form of PM and GHG emissions reductions. Use of biodiesel is expected to contribute to ARB's short and long term air quality and climate goals.

Biodiesel has been found to increase NOx emissions in some circumstances, depending on feedstock, blend level, and vehicle technology. Staff anticipates that over the long term offsetting factors, such as NTDEs and renewable diesel, will grow as a result of other ARB regulations and will eliminate any adverse NOx impacts associated with the use of biodiesel. However, until the offsetting factors reach a critical point (90 percent of on-road heavy-duty VMTs operated by NTDE) there is a risk that use of higher blends of biodiesel (greater than B5) could result in NOx emissions higher than the current levels in 2014. In order to eliminate this risk, ARB is proposing a NOx control level that varies depending on the saturation level of the biodiesel feedstock and the time of year.

In 2014, staff estimates that approximately 72 million gallons of biodiesel and 120 million gallons of renewable diesel were consumed in California. These volumes combined with the use of NTDEs resulted in an increase in NOx of about 1.3 tons per day (TPD) and a decrease in PM of about 0.8 TPD statewide compared to use of CARB diesel alone. Once the proposed ADF and LCFS regulations are adopted staff anticipates that NOx emissions will decrease from current levels. As a result of the in-use requirements on biodiesel, staff expects that use of biodiesel above B5 will not result in NOx impacts. Table 7.1 shows the expected NOx impacts of biodiesel compared to 2014, including offsetting factors.

Table 7.1: Fuel Volumes and Resulting NOx emissions relative to 2014 levels

Million gallons	2014	2015	2016	2017	2018	2019	2020	2021	2022
Low Saturation B5	72	97	129	160	150	150	150	150	150
RD	120	180	250	300	320	360	400	500	550
NTDE VMT %	40%	51%	60%	66%	71%	75%	80%	85%	89%
Net NOx TPD	0.0	-0.06	-0.08	-0.09	-0.51	-0.75	-0.9	-1.17	-1.26

The result of staff's analysis concludes that the proposed LCFS and ADF regulations will have long term air quality benefits with reductions in NOx expected as well as reductions in PM and GHG emissions.

C. Environmental Justice and Local Communities

Government Code section 65040.12(e) defines environmental justice as the fair treatment of people of all races, cultures, and incomes with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies. ARB is committed to supporting the achievement of environmental justice. In 2001, the Board adopted a framework for incorporating environmental justice into the ARB's programs consistent with the directives of State law. [27] Although ARB's environmental justice policies apply to all communities in California, they recognize that environmental justice issues have been raised more often in the context of low-income and minority communities.

As a result of ARB's work with the public, the business sector, local government, and air districts, California's ambient air is the cleanest since air quality measurements have been recorded.[28] Whereas the Los Angeles area experienced 148 smog alerts in 1970, by the year 2000, there was not a single smog alert.[29] However, large numbers of Californians live in areas that continue to experience episodes of unhealthy concentrations of ozone and PM2.5.

For this analysis, we note as an initial matter that any community in proximity to operations involving diesel fueled vehicles is already experiencing incremental risks from exposure to diesel particulate matter (PM). In 1998, ARB identified diesel PM as a toxic air contaminant with no safe threshold of exposure, which means that any diesel PM exposure may increase lifetime cancer risk for affected communities. Consequently, ARB embarked on a comprehensive diesel risk reduction program in the

[27] California Air Resources Board, Report, *Policies and Actions for Environmental Justice*, 2001
[28] California Air Resources Board, *History of Air Resources Board*, Website, http://www.arb.ca.gov/knowzone/history.htm, November 16, 20120 (accessed October 4, 2013)
[29] California Air Resources Board, Video file, *Clearing California Skies Updated*, http://www.arb.ca.gov/videos/clskies.htm (accessed October 4, 2013)

early 2000s, implementing a number of stationary, mobile, and portable diesel engine standards; fleet emission controls; and diesel fuel requirements designed to address such risks.

This proposed rulemaking is designed to maintain the air quality protections already in place under ARB's existing diesel fuel regulations. This includes, but is not limited to, maintaining protections in the only two areas nationwide whose air quality nonattainment status has been classified as "extreme," the San Joaquin Valley Air Basin and the South Coast Air Basin. Both areas have active environmental justice groups that have lobbied ARB to take aggressive action in pursuit of reduced toxic emission releases and attainment of ambient standards to ease air quality-related health burdens on their communities.

The air quality impacts of this regulatory proposal promote environmental justice by maintaining current protections for California's air quality in areas that are simultaneously the most adversely affected with respect to ground level ozone and home to many minority and low-income groups. At the same time, the proposed rulemaking provides a clear legal pathway to the commercialization of innovative, lower carbon diesel fuel substitutes. These innovative substitutes will reduce GHG emissions, and many of them also provide benefits in the form of additional reductions in PM, CO, NOx, toxic air contaminants, and other air pollutants.

As noted in Chapter 6, ADFs have the potential to reduce exposure to pollutants when used as a replacement for conventional diesel. To the extent that the proposed regulation expedites the introduction of ADFs as replacements for conventional diesel, all communities will benefit from improved air quality. In general, staff anticipates that any impacts resulting from the proposed regulation will be beneficial in nature, as a result of introducing new, lower-emitting ADFs.

To further ensure maintenance of air quality protections at the community level, the proposed regulation contains provisions that require a new ADF proponent to disclose comprehensive information about the ADF and the proponent's plan for limited fleet testing of that fuel. This comprehensive and detailed level of information required to be submitted before testing begins will permit ARB staff to assess the potential impacts such vehicle fleet studies could have on the most sensitive communities. Pertinent to the sensitive communities is a provision in the proposal that requires disclosure, in the Stage 1 and Stage 2 phases, of the ZIP codes in which the applicant proposes to conduct the limited vehicle fleet testing. The ARB staff will consider the proposed ZIP codes, along with the feasibility of conducting the fleet tests in alternative locations, as part of the Stage 1 and Stage 2 approval process. Depending on a number of factors, including the nature of the candidate ADFs and the extent of the fleet test, ARB staff may suggest or require a different location for the study as appropriate and feasible.

Based on staff's assessment of current and future ADFs, such as biodiesel and dimethyl ether, it is likely that new ADFs will exhibit less PM emissions relative to conventional diesel. In such cases, communities will benefit from lower cancer risk associated with the replacement of diesel fuel with ADFs. Likewise, communities will also benefit from any reductions in other criteria and toxic air pollutants associated with ADF use. The State mandated multimedia assessment will determine whether future ADFs will exhibit any increases in other toxic compounds, which may warrant additional controls. Moreover, since the proposed regulation provides for a more orderly process than currently exists towards commercialization, ARB would have more oversight over the approval of any ADF use in local communities and can ascertain whether additional requirements should apply to safeguard against any adverse impacts.

In addition to governing the approval and use of future ADFs, the proposed regulation would also explicitly identify biodiesel as the first ADF commercialized under this regulation. Biodiesel has an extensive history of environmental evaluation and consensus standard development. Indeed, much of the proposed regulation is modeled on ARB staff's experience in evaluating biodiesel over the years. As a result, the proposed regulation would explicitly identify biodiesel as a Stage 3A ADF, "Commercial Sales Subject to Mitigation," in recognition of the fact that biodiesel already has effectively undergone the requirements in Stage 1 and 2.

As discussed in Chapter 6 and the multimedia evaluation, biodiesel has been shown to reduce PM, HC, CO and greenhouse gases from diesel engines. Therefore, replacing diesel with biodiesel provides an immediate reduction in toxic cancer risk that is proportional to the percent reduction in PM emissions. Likewise, reductions in HC and CO also help communities by lowering near source and regional concentrations of ozone and CO.

Being the first commercially recognized ADF under the proposed regulation, biodiesel will have positive long term overall air quality impacts and benefits for all communities, and near term benefits to PM and GHG emissions. Staff expects that in the longer term (post 2022) no NOx mitigation will be necessary for biodiesel blends up to B20 due to the adoption of NTDEs.

In conclusion, the proposed ADF regulation is designed to ensure that the introduction and use of innovative ADFs in California, including biodiesel, will have no significant adverse environmental or public health impacts, as the heavy duty diesel fleet transitions to NTDEs. This conclusion applies at the State level as a whole, at the various air basin and regional levels, and at the local community level. As a result, the proposed regulation maintains the environmental and human health protections that are already provided under the existing diesel fuel regulations.

CHAPTER 8. ENVIRONMENTAL ANALYSIS

The Air Resources Board (ARB), as the lead agency for the proposed regulation, has prepared an environmental analysis under its certified regulatory program (17 CCR 60000 – 60008) to comply with the requirements of the California Environmental Quality Act (CEQA). ARB's regulatory program, which involves the adoption, approval, amendment, or repeal of standards, rules, regulations, or plans for the protection and enhancement of the State's ambient air quality has been certified by the California Secretary for Natural Resources under Public Resources Code section 21080.5 of CEQA (14 CCR 15251(d)). ARB, as a lead agency, prepares a substitute environmental document (referred to as an "Environmental Analysis" or "EA") as part of the Staff Report to comply with CEQA (17 CCR 60005).

The Draft Environmental Analysis (EA) for the proposed regulation is included in Appendix D to this Staff Report.   The Draft EA provides a single coordinated programmatic environmental analysis of an illustrative, reasonably foreseeable compliance scenario that could result from implementation of the proposed Alternative Diesel Fuel (ADF) regulation and the proposed re-adoption of the Low Carbon Fuel Standard (LCFS) regulation. The proposed ADF and LCFS regulations have two separate regulatory notices and staff reports and will be considered by the Board in separate proceedings. This approach is consistent with CEQA's requirement that an agency consider the whole of an action when it assesses a project's environmental effects, even if the project consists of separate approvals (14 CCR 15378(a)).

The Draft EA states that implementation of the proposed regulations could result in beneficial impacts to GHGs through substantial reductions in emissions from transportation fuels in California from 2016 through 2020 and beyond, long-term beneficial impacts to air quality through reductions in criteria pollutants, and beneficial impacts to energy demand. The Draft EA also states the proposed regulations could result in less than significant or no impacts to mineral resources, population and housing, public services, and recreation; and potentially significant and unavoidable adverse impacts to aesthetics, agriculture resources, biological resources, cultural resources, geology and soils, hazards and hazardous materials, hydrology and water quality, land use and planning, noise, transportation and traffic, and utilities, and short-term construction-related air quality impacts primarily related to the construction projects and minor expansions to existing operations that are reasonably foreseeable as a result of the proposed regulations.

Written comments on the Draft EA will be accepted starting January 2, 2015 through 5 p.m. on February 17, 2015. The Board will consider the Final EA and responses to comments received on the Draft EA before taking action to adopt an ADF regulation.

This page intentionally left blank

CHAPTER 9. MULTIMEDIA EVALUATION

H&SC section 43830.8 prohibits ARB from adopting any regulation that establishes motor vehicle fuel specifications unless that regulation is subject to a multimedia evaluation and reviewed by the CEPC. Pursuant to Public Resources Code section 71017(b), the CEPC was established as a seven-member body comprised of the Secretary for Environmental Protection; the Chairpersons of the ARB and SWRCB; and the Directors of the Office of Environmental Health Hazard Assessment (OEHHA), the Department of Toxic Substances Control (DTSC), the Department of Pesticide Regulation (DPR), and the Department of Resources Recycling and Recovery (CalRecycle). Key components of the evaluation process are the identification and evaluation of significant adverse impacts on public health or the environment and the use of best available scientific data.

A. General Overview

"Multimedia evaluation" means the identification and evaluation of any significant adverse impact in public health or the environment, including air, water, and soil, that may result from the production, use, and disposal of a motor vehicle fuel that may be used to meet the state board's motor vehicle fuel specifications (H&SC §43830.8(b)).

1. Multimedia Working Group

The California Environmental Protection Agency (Cal/EPA) formed the interagency multimedia working group (MMWG) to oversee the multimedia evaluation process. The MMWG includes representatives from the ARB, SWRCB, OEHHA, and DTSC. The MMWG also consults with other Cal/EPA agencies and experts as needed.

During a multimedia evaluation, ARB staff are responsible for the air quality impact assessment and overall coordination of the MMWG. SWRCB staff are responsible for the evaluation of surface water and groundwater quality and potential impacts. OEHHA staff are responsible for evaluating potential public health impacts. DTSC staff are responsible for evaluating potential hazardous waste and soil impacts.

2. California Environmental Policy Council

Before ARB adopts a regulation that establishes new fuel specifications, the CEPC must determine if the proposed fuel specification poses a significant adverse impact on public health or the environment. In making its determination, the CEPC must consider the following:

- emissions of air pollutants, including ozone-forming compounds, particulate matter, toxic air contaminants, and greenhouse gases,
- contamination of surface water, groundwater, and soil,
- disposal of waste materials, including agricultural residue, forest biomass, and municipal solid waste, and

- MMWG staff report and peer review comments.

The CEPC must complete its review of the evaluation within 90 calendar days following notice from ARB that it intends to adopt the regulation. If the CPEC determines that the proposed regulation will cause a significant adverse impact on public health or the environment, or that alternatives exist that would be less adverse, the CEPC shall recommend alternative measures to reduce the impact.

3. External Scientific Peer Review

H&SC section 43830.8(d) requires an external scientific peer review to be conducted on the multimedia evaluation in accordance with H&SC section 57004. The purpose of the peer review is to determine whether the scientific portions of the staff report are based upon "sound scientific knowledge, methods, and practices (HSC section 57004(d)(2))."

B. Summary of the Biodiesel and Renewable Diesel Multimedia Evaluation

As part of the ADF regulation, staff intends to establish fuel quality specifications for biodiesel. Therefore, a multimedia evaluation of biodiesel and renewable diesel fuel was conducted pursuant to H&SC section 43830.8 and the *Guidance Document and Recommendations on the Types of Scientific Information Submitted by Applicants for California Fuels Environmental Multimedia Evaluations,* ("Multimedia Evaluation Guidance Document").[30]

The MMWG prepared two staff reports entitled, "*Draft Staff Report: Multimedia Evaluation of Biodiesel*" (Biodiesel Staff Report)[31] and "*Draft Staff Report: Multimedia Evaluation of Renewable Diesel*" (Renewable Diesel Staff Report).[32] The draft staff reports consist of the MMWG's assessment of the biodiesel and renewable diesel multimedia evaluations conducted by the UC Berkeley and UC Davis, and the MMWG's analysis of potential significant adverse impacts on public health and the environment.

The MMWG's conclusions and recommendations are based on the results of the multimedia evaluation and the information provided in the UC final reports entitled, "*California Biodiesel Multimedia Evaluation Final Tier III Report*" (Biodiesel Final Report)[33] and "*California Renewable Diesel Multimedia Evaluation Final Tier III Report*" (Renewable Diesel Final Report).[34]

[33] U.C. Berkeley, U.C. Davis, *California Biodiesel Multimedia Evaluation Final Tier III Report*, May 2013
[34] U.C. Berkeley, U.C. Davis, *California Renewable Diesel Multimedia Evaluation Final Tier III Report*, April 2012

1. Biodiesel Multimedia Evaluation

The MMWG completed their assessment of the biodiesel multimedia evaluation and potential impacts on public health and the environment. The evaluation is a relative comparison between biodiesel and CARB diesel.

The MMWG concludes that the use of biodiesel fuel in California, as specified in the biodiesel multimedia evaluation, does not pose a significant adverse impact on public health or the environment relative to CARB diesel.

Each agency's individual assessments and conclusions are summarized below:

- Air Emissions Evaluation. ARB staff assessed potential air quality impacts and made conclusions based on their assessment of various emissions test results and air quality data, including criteria pollutants, toxic air contaminants, and greenhouse gas emissions data. ARB staff concludes that biodiesel reduces PM, CO, and HC emissions and may increase NOx emissions in some blends.

- Water Evaluation. SWRCB staff assessed potential surface water and groundwater impacts and made conclusions based on their assessment of potential water impacts and materials compatibility, functionality, and fate and transport information. SWRCB staff concludes that there are minimal additional risks to beneficial uses of California waters posed by biodiesel than that posed by CARB diesel.

- Public Health Evaluation. OEHHA staff assessed potential public health impacts and made conclusions based on their assessment of potential impacts on atmospheric carbon dioxide and combustion emissions results. OEHHA staff concludes that the substitution of biodiesel for CARB diesel reduces the rate of addition of carbon dioxide to the atmosphere and reduces the amount of PM, benzene, ethyl benzene, and polycyclic aromatic hydrocarbons (PAHs) released into the atmosphere, but may increase emissions of NOx for certain blends. Limited emission testing resulted in a non-statistical increase in acrolein for a higher B50 biodiesel blend level (i.e., confidence interval less than 95%). Furthermore, the statistical analysis for acrolein emission results was compared to only one data point for the control sample.

- Soil and Hazardous Waste Evaluation. DTSC staff assessed soil and hazardous waste impacts and made conclusions based on their evaluation of hazardous waste generation and potential impacts on the fate and transport of biodiesel fuel in the subsurface soil from unauthorized spills or releases. DTSC concludes that biodiesel aerobically biodegrades more readily than CARB diesel, has potentially higher aquatic toxicity for a small subset of tested species, and generally has no significant difference in vadose zone infiltration rates.

2. Renewable Diesel Multimedia Evaluation

The MMWG completed their assessment of the renewable diesel multimedia evaluation in support of low NOx standard. The evaluation is a relative comparison between renewable diesel and CARB diesel.

The MMWG concludes that the use of renewable diesel fuel in California, as specified in the renewable diesel multimedia evaluation, does not pose a significant adverse impact on public health or the environment relative to CARB diesel.

Each agency's individual assessments and conclusions are summarized below:

- Air Emissions Evaluation. ARB staff assessed potential air quality impacts and made conclusions based on their assessment of various emissions test results and air quality data, including criteria pollutants, toxic air contaminants, and greenhouse gas emissions data. ARB staff concludes that renewable diesel does not pose a significant adverse impact on public health or the environment from potential air quality impacts.

- Water Evaluation. SWRCB staff assessed potential surface water and groundwater impacts and made conclusions based on their assessment of potential water impacts and materials compatibility, functionality, and fate and transport information. SWRCB staff concludes that there are minimal additional risks to beneficial uses of California waters posed by renewable diesel than that posed by CARB diesel.

- Public Health Evaluation. OEHHA staff assessed potential public health impacts and made conclusions based on their analysis of toxicity testing data and combustion emissions results. OEHHA staff concludes that PM, benzene, ethyl benzene, and toluene in combustion emissions from diesel engines using hydrotreated vegetable oil renewable diesel are significantly lower than CARB diesel.

- Soil and Hazardous Waste Evaluation. DTSC staff assessed soil and hazardous waste impacts and made conclusions based on their evaluation of hazardous waste generation and potential impacts on the fate and transport of biodiesel fuel in the subsurface soil from unauthorized spills or releases. DTSC concludes that renewable diesel is free of ester compounds and has low aromatic content. The chemical compositions of renewable diesel are almost identical to that of CARB diesel. Therefore, the impacts on human health and the environment in case of a spill to soil, groundwater, and surface waters would be expected to be similar to those of CARB diesel.

C. Biodiesel and Renewable Diesel Peer Review

The peer review process was initiated by submittal of a request memorandum to the manager of the Cal/EPA Scientific Peer Review Program. The memorandum was prepared by ARB as the lead agency of the MMWG and included a summary of the nature and scope of the requested review, descriptions of the scientific issues to be addressed, and a list of recommended expertise. Upon approval, the University of California, through an interagency agreement with Cal/EPA, identified seven reviewers to complete the review of the biodiesel and renewable diesel multimedia evaluations.

The MMWG requested reviewers to address the Biodiesel and Renewable Diesel Staff Reports separately. Therefore, each reviewer completed two separate reviews, accordingly, for a total of 14 reviews.

In general, the peer reviewers determined that the conclusions and recommendations made by the MMWG were based upon sound scientific knowledge, methods, and practices, including the overall finding that the use of biodiesel and renewable diesel fuel in California, as specified in the biodiesel and renewable diesel multimedia evaluation, respectively, do not pose a significant adverse impact on public health or the environment relative to CARB diesel.

The complete set of peer review comments are posted on the *Fuels Multimedia Evaluation Meetings and Documents* webpage.[35] Individual peer review comments are categorized under the following general topics:

- Air quality
- Public health
- Water quality
- Soil and hazardous waste
- Multimedia evaluation
- Staff report
- Source reports
- Proposed regulation

The MMWG are preparing written responses to each of the comments. The complete set of peer review comments and MMWG responses will be included in the staff reports as new chapters, including any revisions to the staff reports that were made to address comments, where appropriate.

D. Current Status and Next Steps

The Biodiesel Staff Report is currently undergoing supplemental external peer review and internal MMWG analysis. Upon completion of the MMWG's review and

[35] Air Resources Board. *Fuels Multimedia Evaluation Meetings and Documents* webpage: http://www.arb.ca.gov/fuels/multimedia/meetings/meetings.htm

assessment of additional biodiesel studies and comments from the initial peer review, ARB intends to update and modify the Biodiesel Staff Report.

The supplemental external peer review of biodiesel will focus on the modifications to the MMWG's assessment of the biodiesel multimedia evaluation and the scientific basis for which the proposed modifications are based.

The supplemental peer review is currently scheduled from January to February 2015. Once all peer review comments are received, the MMWG will prepare written responses and make any revisions to the staff report, as needed. After all comments have been addressed, the MMWG will finalize the staff reports for submittal to the CEPC. The Cal/EPA will then convene a public meeting of the CEPC to consider the results of the peer reviews and the overall multimedia evaluation of biodiesel and renewable diesel fuel. Based on the evaluation and public comments, the CEPC will determine if the proposed regulation will cause a significant adverse impact on public health or the environment.

CHAPTER 10. ECONOMIC IMPACTS ASSESSMENT

A. Summary of Economic Impacts

In preparing this economic analysis, staff considered the costs of complying with the general provisions prescribed for Stage 1, Stage 2, and Stage 3 (as described in Chapter 5) of the proposed regulation. The compliance costs are determined on a fuel-by-fuel basis and will depend on whether a new ADF achieves full commercial development and successfully completes all three stages. Full commercialization of new ADFs in California will depend on successful resolution of a myriad of technical issues including, but not limited to, vehicle performance, fuel infrastructure compatibility, public health and environmental issues. If a new ADF completes all three prescribed stages, then only minimal recordkeeping and reporting above and beyond requirements that are already required under other State and Federal mandates will be the costs attributable to this regulation. These reporting requirements would be satisfied with reporting currently done through the Low Carbon Fuel Standard Reporting Tool (LRT) used to claim LCFS credits.

Because the majority of the provisions in all three stages are already required under existing State and Federal programs, staff estimates that the overall cost of the regulation to commercialize a future ADF will be minimal for the majority of ADF producers or distributors and would mainly account for additional, or “enhanced,” recordkeeping. Other than biodiesel, no other ADF has undergone more than a preliminary analysis akin to Stage 1 of this proposal. The environmental impacts of those potential fuels are unknown, as that is determined in Stage 2 during the multimedia evaluation. For an ADF under Stage 3B, there will be minimal costs attributable to the proposed regulation because those ADFs would be subject to the same reporting requirements as all other commercial motor vehicle fuels, and no costs if reporting is done via the LRT. Without knowing the type of ADF and associated volumes that may come to market in the future, pollutant control costs cannot be estimated for those fuels commercialized under Stage 3A. Since biodiesel is the first commercialized ADF to be regulated under this proposal, the cost for biodiesel suppliers to comply with the regulation is addressed in this chapter as the costs of the regulation.

As noted, biodiesel has already undergone the equivalent of the proposal’s Stages 1 and 2. Accordingly, biodiesel would be sold in the California market under Stage 3A upon this proposed regulation becoming effective. Staff propose to incorporate certain provisions in Stage 3A to ensure NOx emissions from biodiesel use do not cause any significant adverse impacts. These include per gallon NOx emission control requirements from April 1st through October 31st, for low saturation biodiesel blends above B5, as well as for blends above B10 for high saturation biodiesel. From November 1st through March 31st, the in-use requirements are relaxed and permit both low and high saturation biodiesel blends up to B10 for use without these in-use requirements. The current California biodiesel market currently uses and is projected to continue using the majority of the biodiesel produced in the state to create blends below B5, and therefore, we project limited costs due to NOx control requirements.

Biodiesel and biodiesel blends are being currently sold in California without regulatory oversight to safeguard against potential adverse emissions impacts, including NO_x. As such, the biodiesel industry has not invested in the additive blending infrastructure required for NO_x emissions controls, nor have they pursued certifications of low NO_x emissions biodiesel formulas. This absence of any NOx emissions controls infrastructure was brought up in the National Biodiesel Board's (NBB) submittal of an alternative to the proposed regulation, which also recommended a lead-in period. Given the current lack of NO_x emissions controls infrastructure, staff proposes that the in-use requirements not take effect until 2018, or two years after the implementation date of the regulation. Staff believes that two years is sufficient to provide the biodiesel industry with time to invest in the infrastructure necessary for additive handling and blending; to develop and pursue certifications for new NOx reduction options; and to adopt potential commercial changes such as focusing on exempted NTDE fleets. Also, this two year period is in keeping with established ARB policy, as many other ARB regulations have also provided similar grace periods to their affected industries; allowing them time to adjust their business practices and minimize adverse fiscal impacts, especially in cases where no regulatory oversight existed before.

The proposed regulation is not expected to have a significant adverse economic impact on California businesses or their competitiveness. However, the proposed ADF regulation will have some minimal economic costs to ADF fuel providers, including producers, distributors, and possibly retailers. In addition, consumers and government agencies that opt to fuel their fleets with biodiesel blends requiring NO_x emissions controls may experience an increase in fuel costs provided their fleets consist of heavy duty vehicles without NTDEs, though these costs are small. ARB determined that the regulation does not pose any requirements that will have an adverse economic impact. The highest cost year of the regulation is 2018 with a cost of $3,071,000 to produce both B10 and B20 blends. This represents less than one-one hundredth of the economic activity in California in 2018. Additionally, the direct costs to the industry are a small portion of the industry revenues and can likely be absorbed by either the ADF business or passed along to consumers. Finally, these additional costs will likely be offset by the revenue from credit generation in the LCFS program and therefore not impact the regulated entities significantly.

B. Major Regulations

ARB is subject to two separate major regulation requirements, identified below:

For a major regulation proposed on or after November 1, 2013, a standardized regulatory impact assessment (SRIA) is required. A major regulation is one "that will have an economic impact on California business enterprises and individuals in an amount exceeding fifty million dollars ($50,000,000) in any 12-month period between the date the major regulation is filed with the Secretary of State through 12 months after the major regulation is estimated to be fully implemented, as estimated by the agency." (Govt. Code Section 11342.548). This requirement is triggered if either the direct, indirect and induced costs, or taken separately, the benefits exceed $50 million. The economic impacts of this regulation may exceed $50 million, and therefore the regulation is treated as major according to the Government Code. In response, ARB prepared and submitted a SRIA to the Department of Finance[36].

For purposes of Health and Safety Code Section 57005(b), “major regulation” means any regulation that will have an economic impact (compliance cost) on the state’s business enterprises in an amount exceeding ten million dollars ($10,000,000), as estimated by the board, department, or office within the agency proposing to adopt the regulation in the assessment required by subdivision (a) of Section 11346.3 of the Govt. Code. This regulation may impose compliance costs that exceed $10 million and therefore the regulation is treated as major for the Health and Safety Code.

C. Economic Impacts Assessment

As discussed in Chapter 5, biodiesel is currently the only ADF identified as subject to the proposed regulation. Given the fact that biodiesel currently has consensus standards, is completing a multimedia assessment, and has an identified NOx emissions impact and in-use pollutant control strategies, staff proposes to recognize biodiesel as a Stage 3A commercial ADF subject to in-use requirements under specified conditions.

Therefore, only the cost of biodiesel compliance in Stage 3A would be attributable to the proposed regulation, and drives all the actual costs of the regulation. This means that the cost of biodiesel as the first commercial ADF will be primarily the cost of enhanced monitoring with minor costs due to in-use requirements. As staff discussed in Chapter 6, in-use requirements for NO_x control are unlikely to be utilized for most of the biodiesel sold in the state. In the unlikely scenario of blends requiring NO_x controls reaching wide scale market share in the future, the cost of these controls would also be attributable to the proposed regulation. NO_x control costs are presented in Appendix C.

Staff projects the same overall volumes of pure biodiesel (B100) will be produced as in business as usual. However, the blend levels will be adjusted downward to meet the provisions outlined in this regulation. Staff identified the following options that may occur in reaction to the ADF regulation:

Option 1: Businesses will use NO_x emissions controls and continue selling at the same level. Staff believes the majority of businesses will not opt to use NO_x emissions controls given that other options are less costly and therefore more feasible. These businesses will have an option to sell biodiesel blends up to B10 in the winter months.

Option 2: Businesses will continue selling blends with in-use requirements such as B20 at existing volumes by targeting NTDE fleets with exemptions from the in-use requirements. Many of the existing retailers (and therefore distributors), are already working with functionally exempt fleets. For example, staff discovered that many B20

[36] SRIA: http://www.dof.ca.gov/research/economic_research_unit/SB617_regulation/2014_Major_Regulations/

fueling pumps cannot accommodate HDVs because of low ceiling clearance and inaccessible facilities. As such, these retailers could seek exemptions that allow them to continue selling B20 to the medium and light duty vehicles, which these retail pumps are designed to accommodate. For the retailers that can accommodate HDVs, some change in their business practices will have to occur, such as establishing a dedicated lane for NTDEs that wish to use biodiesel blends such as B20. These business will also the option to sell biodiesel blends up to B10 in the winter months

Option 3: Businesses will stop selling B20 and only offer lower blends. For the retailers they may lose some business, which is likely negligible as the consumers of these fuels will likely transition from B20 to lower blends. The distributors will be able to stay in business, but have to change their business practices to accommodate a change to lower blends. For instance: they will likely have to distribute lower blends by truck, potentially leading to increased truckloads. These business also will have an option to sell biodiesel blends up to B10 in the winter months

Staff believes the reality will be a mix of these options. This chapter assumes the following scenario, which is evaluated in detail in this chapter:

Staff estimates that in 2018 the market share of biodiesel blends requiring NO_x controls will be around 17 percent (30 million gallons out of 180 of the total biodiesel volumes sold in the state), with volumes projected to remain steady until 2021 when total biodiesel volumes increase to 185 million gallons. These volumes then remain at 185 million gallons until 2023 when NTDE VMT exceeds 90 percent of total VMT in EmFAC 2011. At that point the in-use requirements will sunset and use of B20 will be allowed without in-use requirements.

- For all seasons, high saturation biodiesel has a NOx emissions control requirement at the level of B10. Staff assumes high saturation biodiesel will be sold at B10 with only the cost of testing to verify the high saturation exemption to the requirement for NOx emissions controls at the B5 level.
- The projection of VMT by NDTEs is 71 percent in 2018. Assuming some portion of these vehicles will be targeted by the B20 industry, coupled with additional B20 use in light and medium-duty vehicles, staff calculates 8 million gallons of B100 used in B20 will be exempted for all seasons in 2018. The VMT by NTDE's increases in the subsequent years from 75 percent in 2019 to 98 percent in 2023. As the VMT of the NTDE fleets increases, so will the proportion of biodiesel volumes with exemptions to the in-use requirements.
- The final 9 million gallons of low saturation biodiesel will be divided between winter and summer. Assuming slightly less biodiesel is used in the winter; staff assumes 4 million gallons in winter and 5 million in summer. The summer use will require a NOx emissions control of 5 percent DTBP per gallon of B100. The remaining 4 million will be used in winter as B10 without any in-use requirements.

This scenario is summarized in the table below, using volumes projected for 2018:

Table 10.1 Summary of Costs for 2018

Million Gallons of biodiesel blended above B5	**Category of Use**	**Requirement**	**Cost in 2018**
5	High-saturation use in summer as B10	Testing to verify high saturation*	$215,000
8	Low-saturation used in exempted fleets and vehicles in all seasons	Use in exempted fleets such as NTDEs, medium and light duty vehicles	Recordkeeping (included as part of $56,000.00)
5	Low-saturation use in summer as B20	5% DTBP per gallon of B100	$2,800,000
12	Low-saturation use in winter as B10	No NOx controls in winter for B10 and below (Nov 1-March 31)	Recordkeeping (included as part of $56,000.00)
Total: 30 million gallons			Total: $3,071,000**

* See Appendix C for testing costs methodology

** Includes reporting and recordkeeping costs for 150 million gallons of B100 used for blends below

As mentioned earlier, staff assumes the volumes of biodiesel with NO_x controls to decrease as the volumes of biodiesel used in exempted fleets such as NTDEs, medium and light duty vehicles increase each year. The table below reflects the changing scenario on increased NTDEs and the subsequent reduction in costs. Table 10.2 demonstrates how the volumes, and associated costs, of high saturation biodiesel for summer use and NO_x controls for low saturation biodiesel decreased while the volumes of low saturation biodiesel blends in exempted fleets increased; when compared to table 10.1. In 2023, only the cost of recordkeeping and reporting would apply due to the sunset provision.

In addition to the in-use requirement costs listed in Tables 10.1 and 10.2, the industry will face additional recordkeeping costs, which are outlined below. Following this discussion, this chapter will identify the costs as indicated in the table above.

Table 10.2 Summary of Costs for 2021

Million Gallons of biodiesel blended above B5	Category of Use	Requirement	Cost in 2021
2	High-saturation use in summer as B10	Testing to verify high saturation*	$86,000
14	Low-saturation used in exempted fleets and vehicles in all seasons	Use in exempted fleets such as NTDEs, medium and light duty vehicles	Recordkeeping (included as part of $56,000.00)
2	Low-saturation use in summer as B20	5% DTBP per gallon of B100	$1,120,000
12	Low-saturation use in winter as B10	No NOx controls in winter for B10 and below (Nov 1-March 31)	Recordkeeping (included as part of $56,000.00)
30			$1,262,000**

* See Appendix C for testing costs methodology
** Includes reporting and recordkeeping costs for 150 million gallons of B100 used for blends below

1. Cost of Enhanced Recordkeeping

Because staff is proposing to allow commercialization of biodiesel under Stage 3A with in-use requirements for low and high saturation biodiesel blends, detailed market sales and related information would be required from biodiesel producers to track blend levels and compliance with the in-use requirements. We anticipate similar compliance costs if pollutant controls are identified for future ADFs that are approved for commercialization under this regulation. For an ADF with no such controls identified, there will be no costs attributable to the proposed regulation because those ADFs would be subject to the same reporting requirements as all other commercial motor vehicle fuels. Biodiesel retailers will not experience any quantifiable costs for enhanced recordkeeping once a transition from Stage 3A to Stage 3B occurs.

As shown in Table 10.3, staff estimates that a typical cost for enhanced recordkeeping for each producer will be about $1,600 annually. For the 12 producers and 23 blender distributors we are aware of, we estimate the total cost for recordkeeping to be $56,000 per year. This number was reached using the prevailing wage for an environmental engineer of $40.00 an hour and an estimate of 40 hours needed to comply with the enhanced recordkeeping.

Table 10.3: Estimate of Annual Cost of Enhanced Recordkeeping*

Increased Annual Recordkeeping Hrs.	Cost per Hr**	Annual Cost per Producer and Blender/Distributor	Total Annual Cost for all Recordkeeping
40	$40.00	$1,600	$56,000

* Enhanced monitoring consists of: monthly biodiesel sales volumes by blend (B5, B10, B20, B100); geographic location of respective biodiesel blend sales; Sales of biodiesel produced from animal tallow feedstocks

** Prevailing wage for environmental engineer (source: http://www.bls.gov/ooh/architecture-and-engineering/environmental-engineers.htm)

2. Cost of NOx Emissions Controls for Biodiesel

a. High-saturation for use in all seasons

The 2018 projected biodiesel volumes of 180 million gallons consist of 150 million B100 gallons dedicated to biodiesel blends below the blend levels requiring NO_x emissions controls and 30 million B100 gallons used to create blends above that level. Of these 30 million gallons, 5 million gallons are potential high saturation biodiesel due to their marketability as B10 with only the cost of testing required (cost of testing is laid out in Appendix B). Staff expects most of this high saturation biodiesel to be sold as B10, which does not require more expensive NOx controls. So the resultant cost would be:

5 million gallons * $0.043/ gallon = $215,000

b. Low-Saturation Use in Summer

This will require DTBP additization at the cost of $0.112 per gallon of B20 (see Appendix C for the per gallon calculation). Staff assumes, that in 2018, 5 million gallons of low saturation B100 will be used in the summer and require NOx emissions controls. This means that 5 million gallons of B100, or 25 million gallons of B20 will cost the industry:

$0.112 per gallon. (B20 * 25 million gallons = $2,800,000)

Based on the analysis presented in Chapter 6, staff concludes that using additives such as DTBP is the least likely compliance option for blends with NOx emissions control requirements, due to the high cost of additives and infrastructure needed for additization blending. However, due to demand for these blends by certain government agencies and companies with policies that encourage “green” fuels, some additization will occur. A detailed cost analysis of the NOx control option using additive, as well as the certification option, can be found in Appendix C and is summarized in Table 10.4. The cost of ADF certification is not included as a direct cost because biodiesel producers are not required to pursue that option. It would be a producer’s decision to develop a certified low-NOx formula under a research and development protocol, which can be viewed as the cost of doing business.

c. Low-Saturation Use in Winter

Because the requirement for the winter allows a higher blend, the producers would likely not use additives for NOx controls but instead sell at the B10 blend level. Therefore, no additional costs above the recordkeeping would be incurred in the winter. Due to cloud point issues with biodiesel in cold weather, business as usual is typically the use of blends with a lower percentage than 20 percent by volume. However, because California has a fairly mild climate, blends of B10 in areas such as Southern California and the San Francisco Bay Area would not be expected to decrease in the winter. These areas also happen to be where the majority of biodiesel is consumed.

3. Potential Adverse Economic Impacts Directly Affecting Business

Biodiesel industries downstream from the producers such as blenders or jobbers, distributors, and retailers, are not expected to experience any costs during the first two years of the regulation. However, in 2018, when in-use requirements for certain biodiesel blends take effect, businesses that did not modify their business practices or seek exemptions to in-use requirements for blends above B5 for low saturation biodiesel, or B10 for high saturation biodiesel, can be expected to incur costs and/or losses. These costs or losses may include: costs of additizing the blends they sell, the costs of adopting new business practices, and the loss of business from not offering B20.

In addition to the measures businesses can take to reduce any adverse economic impacts resulting from the 2018 requirements of the proposal, others may find increased opportunities. Staff does not expect total biodiesel volumes in the State to decrease as a result of the regulation, but rather to be diverted from blends with in-use requirements to blends below B5, or to exempt fleets.

4. Impacts on Small Business

Tables 10.4 and 10.5 on the next page list several businesses that support biodiesel use in California, including 12 biodiesel producers and 23 biodiesel distributor/blenders operating in the State. Twenty-two of these are small businesses, seven are not, and six are unknown, based on the definition for small businesses (GC 11342.610). The list of producers and distributors was derived from Biodiesel magazine[37] and National Biodiesel Board's lists of biodiesel producers[38] and distributors[39].

[39] National Biodiesel Board, *Biodiesel Distributor Listings*, http://www.biodiesel.org/using-biodiesel/finding-biodiesel/locate-distributors-in-the-us/biodiesel-distributor-listings (accessed November 4 , 2014)

Many of the biodiesel fuel providers will take advantage of the two-year grace period to change business practices and thus incur minimal costs from recordkeeping. For instance, retail fuel providers that sell B20 at fueling stations that only accommodate light duty vehicles could work with a biodiesel producer to target customers of light duty vehicle fleets. This would allow the fuel producers and fuel providers to continue selling blends up to B20 at said stations.

5. Total Cost of Biodiesel Under Proposed Regulation

The total cost of the biodiesel regulation is identified for two time periods. The first time period addresses costs in 2016 and 2017 which are the years before the in-use requirement provisions take effect. The second time period is from 2018 through 2023 when provisions for in-use requirements, including NOx emissions controls, take effect until the sun setting of the regulation.

Based on the estimates above, we expect the total cost of biodiesel as the first commercial ADF regulation to be the cost of enhanced monitoring at $1,600 per year per producer and blender/distributor, or $56,000 total cost per year for all producers and distributors, and the cost of using NOx controls. Upon implementation of the ADF regulation in 2016, the annual biodiesel production is projected to be 129 million gallons (see Appendix B, Table B1) for an incremental biodiesel cost of less than one cent per gallon. These costs would remain steady through 2017.

In 2018, the projected volume increases to 180 million gallons for an incremental cost of less than one cent per gallon for recordkeeping. However, in 2018, in-use requirements take effect for NOx emissions control on certain biodiesel blends. From 2019 through 2020, projected volumes remain steady at 180 million gallons and from 2021 until the sunset provision in 2023, the volumes remain steady at 185 million gallons. However, it should be noted that from 2019 through 2023, the VMT of NTDEs is projected to increase considerably, due to other CARB regulations, which will allow for more biodiesel blends to be sold to exempted fleets with costs for in-use requirements. This would reduce the overall costs of NOx controls. The total cost of the regulation in 2018 is expected to reach $3,071,000. Each year thereafter, starting in 2019 will result in a reduction in costs from the previous year because of the increasing exemptions from NTDE fleets.

6. Potential Economic Costs to Consumers

As noted, we expect individual consumers would incur minimal or no costs as a result of the proposed regulation. Fuel suppliers already blend up to five percent biodiesel by volume in the CARB diesel that is offered throughout the state. Higher blends of biodiesel are currently sold at a price premium relative to CARB diesel, but such premiums exist in the absence of the proposed regulation. Therefore, the proposal should not adversely affect retail prices for biodiesel blends based on the anticipated minimal costs discussed above. Consumers that own either light or medium duty vehicles will not likely experience an increase in cost for biodiesel blends up to B20, because these fleets qualify for exemptions from in-use requirements.

D. Cost Effectiveness

Cost effectiveness is typically defined as the dollars spent to reduce a unit mass of a specified pollutant. Because the proposal is designed to maintain current environmental protections rather than achieve additional air pollution reductions, the concept of cost-effectiveness does not apply to the proposal. Nevertheless, upon implementation of the proposed ADF regulation in 2016, the regulatory costs of compliance (up to the low tens of thousands of dollars per year), if passed on to the consumer, would yield a per-gallon impact that is small (e.g., $56,000 per year /129 million gallons per year or less than one cent per gallon with full pass-through).

In 2018, when in-use requirements take effect the cost on a per gallon basis would increase, then go back down in subsequent years (e.g., $3,071,000 per year /180 million gallons per year or less than 2 cents per gallon increase if full pass-through).

No alternative considered by the agency would be more effective in carrying out the purpose for which the regulation is proposed or would be as effective as or less burdensome to affected private persons than the proposed regulation.

F. Reasons for Adopting Regulations Different from Federal Regulations

A main objective of the proposed ADF regulation is to consolidate existing requirements, supplemented with minor additional data requirements and enhanced recordkeeping provisions, to provide a clear, legal pathway to commercialization for new ADFs. As noted, many of the proposed regulatory requirements already exist in various State and federal programs.

Table 10.6 shows the existing applicable mandates, which require the same information required under the proposed regulation. However, under the proposed regulation, information generally would be required early in the phase-in process and before the ADF is commercialized in California to allow for screening of environmental and public health impacts. For purposes of this cost analysis, staff did not consider the costs of meeting the existing applicable mandates that overlap with the requirements under the proposal.

For example, H&SC section 43830.8 currently requires a multimedia evaluation to be conducted for any fuel before the ARB can establish motor vehicle fuel specifications for any particular fuel. Thus, while a multimedia evaluation is required under Stage 2 of the proposed regulation, the cost of that evaluation is not attributable to this rulemaking.

Table 10.6: Applicable Requirements from Various State and Federal Mandates

	Proposed Regulation	FTC[1] Labeling	DMS Fuels[2] Authority	DMS Fuel[3] Variance	H&S Code 43830.8[4]
Test Program Application	x			x	
- Test Plan (vehicle ID, fuels, duration, etc.)	x			x	
- Fuel Chemical Properties	x			x	
- U.S.EPA Registration[5]	x				
- Reporting & Recordkeeping	x	x	x	x	
Consensus Fuel Specification Development	x			x	
Enforcement of ASTM Stds.			x		
Fuel Quality Testing	x		x	x	
Pump Labeling (biodiesel blends)		x			
Multimedia Evaluation[6]	x				x
Determination of Pollution Control Levels	x				x
Enhanced Reporting	x				

1. Federal Trade Commission regulation on biodiesel pump labeling under 16 CFR Part 306.
2. CA Dept. of Food & Ag.-Div. of Measurement Stds. authority to enforce ASTM fuel quality stds. under CCR, title 4, §§ 4140, 4148, 4200, 4202-4205.
3. CDFA-DMS administration of developmental fuel variance program under CCR, title 4, §§4144, 4147 - 4148.
4. Multimedia evaluation requirements under Health & Safety Code §43830.8.
5. USEPA fuels and additives registration program under 40 CFR Part 79.
6. Also requires lifecycle analysis, release scenarios & emissions testing.

Another set of State mandates affecting the enforcement of potential ADFs pertains to regulatory requirements promulgated by the California Department of Food and Agriculture, Division of Measurement Standards (DMS). Under California Code of Regulations (CCR), Title 4, sections 4140-4149 and 4200-4205, DMS has the responsibility to enforce the consensus (ASTM) standards for the fuels listed therein, including biodiesel. Therefore, costs for meeting the ASTM standards or developing consensus standards for future ADFs are attributable to the DMS regulations.

The DMS also administers a program that is similar to the proposed Stage 1 requirements. Known as the developmental fuel variance (DFV), this program is authorized under Title 4 CCR, Sections 4144, 4147 and 4148. The DFV program allows unconventional motor vehicle fuels to be used in limited quantities to develop data in support of the development of consensus standards for those fuels. Stage 1 of the proposed regulation requires the same information as that required under the DFV, as well as some additional information. Thus, staff's analysis for the proposal does not consider the portion of the costs that would already be incurred under the DFV program.

Two federal programs also apply to ADFs that would be subject to the proposal. First, U.S. EPA requires a gasoline, diesel, or additive supplier to register under 40 CFR 79 prior to the sale or supply of such fuel products in California. Similarly, the proposed regulation would require U.S. EPA registration before an ADF could be sold or supplied in California under Stage 1. Second, the FTC specifies particular labeling requirements on individual pumps that dispense B6-B20 and blends above B20 (no labeling requirements for B5 and below). For enforcement purposes, fuel marketers are required to maintain volume sales and other fuel content records for these labeled pumps. The proposed regulation contains recordkeeping, testing, and reporting requirements that would piggyback on these existing federal requirements.

Alternative diesel fuels that meet the criterion for a Stage 3A will be required to conduct enhanced recordkeeping to monitor progress towards meeting any pollutant emissions levels that would require pollutant controls. The level of enhanced recordkeeping, and the cost of the pollutant controls (when applicable), will be a case-by-case determination because different ADFs have different chemistries.

G. Impacts to California State or Local Agencies

Several state agencies operate large fleets, often with many alternative fuel vehicles included in their fleet. Staff contacted several State agencies to determine biodiesel usage and received responses from some, but not all of the agencies contacted. Those that did respond did not indicate any usage of biodiesel blends with in-use requirements, and thus higher cost. During this period, staff became aware that Caltrans was the State agency using the most biodiesel. According to a 2013 report, "Caltrans Activities to Address Climate Change[40]", Caltrans is the biggest user of biodiesel in the State and is only using B5 blends currently; although they've used B20 blends in the past. As such, Caltrans would not incur any additional costs due to this regulation. In addition, the University of California system was contacted and staff was informed that the majority of their biodiesel use was B5, and that the majority of their fleet was vehicles eligible for an exemption to in-use requirements.

[40] Department of Transportation *Caltrans Activities to Address Climate Change Reducing Greenhouse Gas Emissions and Adapting to Impacts*, April 2013

Staff also contacted local municipalities and found that with the exception of San Francisco, all of the municipalities that responded did not use biodiesel blends above B5. Anecdotal evidence suggests that some school districts may be using biodiesel blends with in-use requirements. Therefore only those few agencies opting to use biodiesel blends with in-use requirements may incur some minor costs; though these can likely be absorbed in existing budgets. If these same agencies opt to use CARB diesel or lower blends of biodiesel, they could incur a costs savings.

CHAPTER 11. ANALYSIS OF REGULATORY ALTERNATIVES

As required by Senate Bill 617 (Chapter 496, Status of 2011), State agencies must conduct a Standardized Regulatory Impact Assessment (SRIA) when a proposed regulation has an economic impact exceeding $50 million in any 12-month period between the date the major regulation is estimated to be filed with the Secretary of State through12 months after the regulation is estimated to be fully implemented. The Department of Finance is required to review the completed SRIA submitted by agencies and provide comment(s) to the agency on the extent to which the assessment adheres to the regulations adopted by Finance. Rules implementing these requirements are found at title 1, sections 2000-2004 of the California Code of Regulations.

As part of the SRIA process, ARB solicited public input on alternative ADF approaches, including any approach that may yield the same or greater benefits than those associated with the proposed regulation, or that may achieve the goals at lower cost. Alternative approaches submitted to ARB were considered as staff prepared a SRIA. The combined SRIA of Low Carbon Fuel Standard and ADF summary is posted at: http://www.dof.ca.gov/research/economic_research_unit/SB617_regulation/2014_Major_Regulations/documents/ADF_DF_131_SUMMARY.PDF

Staff solicited public input and received two alternatives to the proposal that were considered as part of the SRIA process. The full analysis and comparison is located in Appendix D. The alternatives are summarized below:

A. Alternative Submitted by Growth Energy

The first alternative considered was submitted by Growth Energy (GE). Key provisions are listed below, along with the reason for rejecting this alternative in the following paragraphs.

- Treating animal- and non-animal-based biodiesel the same: setting the significance level for both at zero percent, as compared to the ADF proposal, which sets the significance level at B5 for non-animal-based biodiesel and B10 for animal-based biodiesel; and
- Eliminating the provisions for exemptions based on the use of NTDEs, as compared to the ADF proposal, which provides exemptions for biodiesel used in NTDEs; and
- Eliminating the sunset provision of the ADF proposal, whereas the ADF proposal would likely end mitigation for biodiesel in 2024.

This alternative proposal retains the same biodiesel NOx mitigation options as the ADF proposal. However, under the GE alternative, animal and non-animal biodiesel would be treated equally and require NOx mitigation for all biodiesel blends, including blends below B5. ARB rejects this alternative because the costs are significantly higher than the ADF proposal and do not achieve additional emissions benefits. During the development of this regulation, staff considered alternatives to the proposal and determined that the proposal represents the least-burdensome approach that best achieves the objectives at the least cost.

B. Alternative Submitted by National Biodiesel Board

The second alternative considered was submitted by the National Biodiesel Board (NBB). Key provisions are listed below, along with the reason for rejecting this alternative in the following paragraphs.

- Setting a significance level threshold for biodiesel at 10% biodiesel blend (B10) for all biodiesel feedstocks;
- Establishing an effective blend level that accounts for the impact of NTDEs, RD, and animal biodiesel, vs per-gallon mitigation in the ADF proposal; and
- Including a three-year phase-in period for the regulation.

This alternative would treat animal- and non-animal-based biodiesel the same by setting a significance level for both at 10 percent annually by volume. The alternative also includes a three-year phase-in period; accordingly, there are no costs for biodiesel mitigation in the first three years. For this alternative, mitigation would not be necessary until the statewide biodiesel content is up to 10 percent; after which the 10 percent any additional biodiesel would be mitigated using the same options available in the ADF proposal.

Because this alternative achieves substantially fewer emissions benefits than the ADF proposal, it does not meet the goals of the ADF proposal and ARB rejects the NBB alternative.

C. Conclusions

No alternatives were presented that would achieve the same emissions benefits and lessen any adverse impact on small businesses that may occur due to the regulation. However, the phase-in period suggested in the NBB proposal was modified to two years and included in the regulation to ensure ample time for small businesses to prepare and alter their business models to minimize their costs.

CHAPTER 12. SUMMARY AND RATIONALE

The Proposed ADF regulation is designed to allow a streamlined path to commercialization for alternative diesel fuels, while ensuring no increase in air pollution from those fuels. This section discusses the requirements and rationale for each provision of the proposed regulation.

Subarticle 1. Specifications for Alternative Motor Vehicle Fuels

Summary and Rationale for Subarticle 1
Article 1 is being renamed Subarticle 1 as part of splitting the article for clarity. Additionally, minor changes were made to accommodate the subarticle renaming and authority cited was added for clarity.

Subarticle 2. Commercialization of Alternative Diesel Fuels

Section 2293 Purpose
Summary of section 2293
Section 2293 states the purpose of the proposed regulation.

Rationale for section 2293
This section is needed to inform the regulated public and other market participants of the proposed regulation’s intent.

Section 2293.1 Applicability
Summary of section 2293.1
Subsection(a) establishes January 1, 2016, as the effective date of the proposed regulation, as well as laying out general requirements for alternative diesel fuels (ADFs) in California.

Rationale for section 2293.1
This section is needed to establish the implementation date, and general requirements that will apply to ADFs in California.

Section 2293.2 Definitions
Summary of section 2293.2
This section introduces definitions to the terms used in the regulation as well as the acronyms used in the proposed regulation.

Rationale for section 2293.2
It is necessary that ARB defines terms as applicable to the Alternative Diesel Fuels regulation. Several of these terms are used in the same manner as other articles and titles in the California Code of Regulations, Government Code sections or statutes. It is necessary for ARB to be consistent with existing definitions to the extent that they apply to this regulation.

Section 2293.3 Exemptions

<u>Summary of section 2293.3</u>
Section 2293.3 introduces the list of exemptions that apply to this proposed regulation.

<u>Rationale for section 2293.3</u>
This section is necessary for clarity of which fuels or additives are not subject to the regulation. The exempted fuels are already regulated elsewhere.

Section 2293.4 General Requirements Applicable to All ADFs

<u>Summary of section 2293.4</u>
This section outlines the provisions that apply to all ADFs in California

<u>Rationale for section 2293.4</u>
This section is necessary to ensure that it is clear that other applicable local, State, and federal requirements, including some specifically listed requirements, apply in addition to the provisions outlined in the proposed regulation.

Section 2293.5 Phase-In Requirements

<u>Summary of section 2293.5</u>
Section 2293.5 states that ADFs intended for use in motor vehicles that do not meet the requirements of this regulation by having a fuel specification or approved Executive Order in place cannot be sold without being in violation of this regulation.

<u>Rationale for section 2293.5</u>
This section is necessary to introduce the different stages of the regulation and the Executive Order requirements in Stage 1. The goal of this comprehensive process is to foster the introduction of new, lower polluting ADF fuels by allowing the limited sales of innovative ADFs in stages while emissions, performance, and environmental impacts testing is conducted. This testing is intended to develop the necessary real-world information to quantify the environmental and human health benefits from using new ADFs, determine whether these fuels have adverse environmental impacts relative to conventional CARB diesel, and identify any vehicle/engine performance issues such fuels may have.

<u>Summary of section 2293.5(a)</u>
Subsection (a) outlines the requirements of Stage 1: Pilot Program. This is the first in a series of 3 stages leading to potential commercialization of ADFs, and includes an initial analysis, submittal of relevant data, and a limited use of ADF allowed.

<u>Rationale for section 2293.5(a)</u>
This section is needed to communicate clearly the requirements for application, acceptance, and completion of Stage 1 for ADF proponents who are initially proposing an ADF for use. The purpose of this stage is to allow limited, small fleet use of innovative fuels while requiring screening tests and assessments to quickly determine whether there will be unreasonable potential impacts on air quality, the environment and vehicular performance. Such data will help inform more extensive testing and analysis

to be conducted in Stage 2. This Stage 1 is modeled after the existing ARB regulation that provides limited, fuel test program exemptions under 13 CCR 2259. The required submittals allow ARB and the public to evaluate the rigor of any proposed testing plan.

Summary of section 2293.5(b)
Subsection (b) outlines the requirements of Stage 2: Development of Fuel Specification. This is the second in a series of 3 stages leading to potential commercialization of ADFs, and includes rigorous environmental testing, development of standards, determination of environmental impacts, and increased use of ADF allowed.

Rationale for section 2293.5(b)
Subsection (b) is needed to communicate clearly the requirements for application, acceptance, and completion of Stage 2 for ADF proponents who are getting closer to commercial operation. The purpose of this stage is to allow limited but expanded fleet use of an ADF that has successfully undergone the Stage 1 pilot program. Stage 2 candidate ADFs undergo additional emissions and performance testing to better characterize potential impacts on air quality, the environment and vehicular performance. This testing and assessment will be conducted pursuant to a formal multimedia evaluation leading to the development of a fuel specification, as appropriate. Further, the multimedia evaluation will be the basis for determining whether the candidate ADF has potential adverse emissions impacts. The determination of potential adverse emissions impacts determines whether the candidate ADF can proceed to Stage 3A or Stage 3B. The required submittals will allow ARB and the public to evaluate the rigor of the proposed testing.

Summary of section 2293.5(c)
Subsection 2293.5(c) outlines the requirements of Stage 3A: Commercial Sales Subject to in-use Requirements. This is the culminating stage for ADFs that have been found to have potential adverse emissions impacts, and includes provisions for determination of in-use requirements and or fuel specifications if they are determined to be necessary.

Rationale for section 2293.5(c)
Subsection (c) is needed to communicate clearly the requirements for full commercialization of ADFs that have been found to have potential adverse emissions impacts.

Summary of section 2293.5(d)
Subsection 2293.5(d) outlines the requirements of Stage 3B: Commercial Sales Not Subject to In-use Requirements. This is the culminating stage for ADFs that have either been found to have no potential adverse emissions impacts or that have been found in Stage 3A to have no adverse emissions impacts. ADFs subject to this stage have limited reporting requirements.

Rationale for section 2293.5(d)
Subsection (d) is needed to communicate clearly the requirements for full commercialization of ADFs that will have no adverse emissions impacts relative to conventional CARB diesel. The provision makes the reporting consistent with reporting requirements in place for existing motor vehicle fuels.

Section 2293.6 In-use Requirements for Specific ADFs Subject to Stage 3A
Summary of section 2293.6
Section 2293.6 includes provisions for any ADF that has undergone the 3-stage process for commercialization and has been determined to be in Stage 3A with in-use requirements.

Rationale for section 2293.6
This section is needed to implement the provisions of Stage 3A once an ADF has completed the 3-stage commercialization process.

Summary of section 2293.6(a)
Subsection 2293.6 (a) contains the in-use requirements that apply to biodiesel as the first commercial ADF. This subsection includes a phase-in period, pollutant control levels, provisions for feedstock differences, a sunset provision, a process for exemption from the in-use requirements for biodiesel, and a mid-term review of the biodiesel provisions.

Rationale for section 2293.6(a)
Subsection (d) is needed to implement the solutions to the adverse emissions impacts associated with biodiesel. These adverse emissions impacts vary based on feedstock and engines, as such specific provisions for each of these are included.

Section 2293.7 Specifications for Alternative Diesel Fuels
Summary of section 2293.7
Section 2293.7 is a lead sentence to be completed in subsections 2293.7(a) and (b) that provide the specifications that must be met by ADFs, if not under a mitigation strategy in effect.

Rationale for section 2293.7
This section is needed to provide a framework for subsequent subsections.

Summary of section 2293.7(a)
Section 2293.7(a) is a title line for biodiesel the specification subsection.

Rationale for section 2293.7(a)
This section is needed to provide a framework for subsequent subsections.

Section 2293.8 Reporting and Recordkeeping

Summary of section 2293.8

Section 2293.8 (a) states that the applicable sampling methodology set forth in 13 CCR section 2296 shall be used for sampling of fuel properties as required by the Executive Order.

Rationale for section 2293.8

This subsection is needed to provide the applicant with guidance regarding their sampling requirements.

Section 2293.9 Severability

Summary of section 2293.9

Section 2293.8 states that each part of this subarticle shall be deemed severable, and in the event that any part of this subarticle is held to be invalid, the remainder of this subarticle shall continue in full force and effect.

Rationale for section 2293.9

This subsection is needed to inform the applicant of their responsibility to adhere to all applicable requirements of this regulation, in the event that any part of this subarticle shall be deemed severable.

Subarticle 3. Ancillary Provisions

Section 2294. Equivalent Test Methods

Summary of and Rationale for section 2294

This is former section 2293 renumbered to section 2294 and grouped under new subarticle 3 for consistency and ease of reading.

Section 2295. Exemptions for Alternative Motor Vehicle Used in Test Programs

Summary of and Rationale for section 2295

This is former section 2293.5 renumbered to section 2295 and grouped under new subarticle 3 for consistency and ease of reading.   This section facilitates innovation and testing for new fuels.

Appendix 1 In-use Requirements for Pollutant Emissions Control

Summary of Appendix 1

Appendix 1 outlines the in-use requirements that apply to ADFs operating under Stage 3A.

Rationale for Appendix 1

Appendix 1 is needed to identify the options that are available for complying with the provisions of Stage 3A

Summary of Appendix 1 (a)

This section includes the in-use requirement options that are available to biodiesel, currently additive blending and certification procedures.

Rationale for Appendix 1 (a)

This section is needed to convey the amount of additive needed to comply with in-use requirements for biodiesel based on time of year, feedstock, and blend level. The certification procedures are needed to provide flexibility for new in-use options that can be rigorously demonstrated to be effective.

APPENDIX B

TECHNICAL SUPPORTING INFORMATION

This Page Left Intentionally Blank

1. Biodiesel NOx Emissions Calculation

As part of staff's determination of the effect of biodiesel on NOx emissions a methodology was developed that takes into account varying factors including offsetting effects. As part of this analysis staff takes the illustrative fuel volumes from the LCFS re-adoption and the projected Vehicle Miles Travelled (VMT) of NTDEs in EmFAC 2011. The renewable diesel volumes are adjusted by the amount expected to be consumed by refineries. These factors are used to determine the total NOx emissions impacts of biodiesel compared to the use of CARB diesel, as shown in the table below.

After January 1, 2018, biodiesel used above B5 (assumed to be B20) is controlled by in-use requirements and does not cause NOx. Thus this volume is subtracted from total biodiesel to determine the amount of biodiesel (BD) potentially causing NOx. The next step is to determine the amount of biodiesel used in legacy vehicles (non-NTDE). This is important because the NOx increase is seen in legacy vehicles not NTDE vehicles. The proportion of legacy vehicles is determined by subtracting the percentage of NTDEs from 100% to determine the percentage of legacy vehicles. The amount of fuel used in legacy vehicles is then determined by multiplying the percentage of legacy vehicles by the volume of biodiesel potentially causing NOx. The same calculation is then completed for RD. Staff assumed that 40 percent of renewable diesel is used in refineries, and as such does not reduce NOx since refineries may use the NOx benefit of RD in their CARB diesel formulations. The calculated RD used in legacy vehicles is divided by 2.75 to get the amount of RD offsetting BD. As discussed earlier, renewable diesel decreases NOx and the NOx increase from one gallon of biodiesel is offset by the NOx decrease from 2.75 gallons of renewable diesel. The amount of biodiesel offset by legacy RD is then subtracted from the BD amount used in legacy to result in the amount of biodiesel causing NOx. That total is divided by the liquid diesel demand and multiplied by the NOx increase of B100 to determine a %NOx increase from BD. The total change is then multiplied by the diesel portion of the emissions inventory to get NOx increase from biodiesel.

Table B-1: Biodiesel NOx Emissions Calculations

(Million gallons)	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023
Total Biodiesel	72	97	129	160	180	180	180	185	185	185
B20 (No NOx post 2018)					30	30	30	35	35	35
BD Potentially causing NOx	72	97	129	160	150	150	150	150	150	150
RD Volume	120	180	250	300	320	360	400	500	550	600
Liquid Diesel Demand	3732	3788	3845	3903	3961	4021	4081	4142	4204	4267
	NOx emissions Calculations									
%NTDE (EmFAC 2011) (VMT)	40.09%	50.86%	59.87%	66.35%	71.26%	75.00%	79.78%	85.03%	88.74%	98.44%
BD used in legacy vehicles	43.1	47.7	51.8	53.8	43.1	37.5	30.3	22.5	16.9	2.3
%NOx increase (B100)	20%	20%	20%	20%	20%	20%	20%	20%	20%	20%

Legacy RD not used in refineries	43	53	60	61	55	54	49	45	37	6
Legacy BD offset by Legacy RD	16	19	22	22	20	20	18	16	14	2
%NOx increase from BD	0.15%	0.15%	0.16%	0.16%	0.12%	0.09%	0.06%	0.03%	0.02%	0.00%
Emissions Inventory (Diesel TPD)	916	863	818	772	726	680	634	588	542	496
NOx increase from BD (TPD)	1.35	1.29	1.27	1.26	0.84	0.60	0.39	0.17	0.09	0.01
Net NOx increase (from 2014)	0.00	-0.05	-0.08	-0.09	-0.50	-0.74	-0.95	-1.17	-1.26	-1.34
NOx increase from BD (TPY)	492	472	464	459	308	221	144	63	32	3

2. Biodiesel Emissions B5 and B10 Testing Results

As part of staff's determination of biodiesel impacts of low biodiesel blends, we released a spreadsheet of data gathered from all testing we were aware of from B5 and B10 biodiesel blends using a CARB diesel baseline. Those emissions results are included in Table B-2. These data are also available at: http://www.arb.ca.gov/fuels/diesel/altdiesel/20140725B5&B10studies_raw_all_pollutants_%20data.xlsx

Table B-2: Biodiesel B5 and B10 Blends Emissions Testing Results

Exhibit G to Declaration of James M. Lyons

Western States Petroleum Association
Credible Solutions • Responsive Service • Since 1907

Catherine H. Reheis-Boyd
President

June 22, 2015

Secretary Matthew Rodriquez, Chair
Environmental Policy Council
1001 I Street, P.O. Box 2815
Sacramento, CA 95812
Via electronic mail: cepc@calepa.ca.gov

Dear Secretary Rodriguez:

Re. Western States Petroleum Association Comments for June 23, 2015 CEPC Meeting Consideration of the Multi-Media Working Group staff reports - Multi-Media Evaluation of Biodiesel and Staff Report: Multi-Media Evaluation of Renewable Diesel

The Western States Petroleum Association (WSPA) is a non-profit trade association representing twenty-five companies that explore for, produce, refine, transport and market petroleum, petroleum products, natural gas and other energy supplies in California and 5 western states.

WSPA appreciates the opportunity to provide our comments and requests for CEPC action in the attached set of comments.

If there are any questions or a need for additional clarification of our comments, please contact Gina Grey of my staff (ggrey@wspa.org) to arrange for further dialogue with WSPA.

Sincerely,

c.c. Alex Mitchell, CARB

1415 L Street, Suite 600, Sacramento, California 95814

cathy@wspa.org ▪ www.wspa.org

Summary

WSPA supports the use of full Multi-Media Evaluations (MME) to assess the environmental impacts of fuels and fuel additives prior to their introduction. However, the current MME for biodiesel blends is not complete since it did not consider: LCFS SF8-14

- The use of di-tertiary butyl peroxide (DTBP), the sole additive proposed for mitigating NOx increases in biodiesel blends, at the concentrations required in the proposed Alternative Diesel Fuel (ADF) regulation, which can be 10 times those envisioned for DTBP use as a diesel cetane improver.
    - Concerns include the fate and transport of DTBP (soil, surface and ground water), potential toxicological impacts, safety (e.g., peroxide stability), and materials compatibility (e.g., metallurgy, engine compatibility). LCFS SF8-15

  The auto manufacturers are normally concerned about any fuel additives and the potential impact on vehicle systems, and in this case fuel stability impacts associated the higher dosage of DTBP. Testing should be completed at the higher concentration levels proposed in the ADF which has not been fully evaluated in the current MME.

- Water demands in biofuel production for the Low Carbon Fuel Standard (LCFS).
    - As Fulton and Cooley[1] state in a 2015 publication: "Although early LCFS policy assessments raised the issue of water demands and impacts from increased biofuel production, any subsequent efforts to track or address those impacts through policy have been lacking."

The allocation of water resource analysis proposed here is not within the traditional scope of California's MME process. However, we feel the scope of the MME segment should be broader given the scarcity of California's water resources to include water use/consumption/allocation consideration and, more particularly, the shifts in those brought about by regulatory action such as LCFS. Thus, we respectfully request that these two items be addressed by the Multimedia Working Group (MMWG) and the California Environmental Policy Council (CEPC) prior to the approval of this MME. LCFS SF8-16

Di-Tertiary Butyl Peroxide

WSPA is concerned that an adequate MME has not been performed with regard to the use of DTBP at the concentrations currently required for mitigation in the proposed Alternative Diesel Fuel (ADF) regulations. A review of the "STAFF REPORT - Multimedia Evaluation of Biodiesel" dated May 2015, only includes an evaluation of combustion air emissions impact (i.e. NOx reduction) due to the use of the DTBP additive. LCFS SF8-15 cont.

[1] Cooley, H., Fulton, J. The Water Footprint of California's Energy System, 1990–2012. Environmental Science and Technology. 2015. 49. 3314–3321.

The MMWG recommendations include a provision/condition that fuel formulations and additives that were not included within the scope of this multimedia evaluation must be reviewed by the MMWG for consideration of appropriate action. However, it is not clear the MMWG has adequately considered what the environmental impacts of those additives may be, and whether the types, concentrations, and use specifications differ from those used in conventional diesel.

The significance of these caveats involving the use of additives in the MME reports is particularly noteworthy for WSPA members who have previously pointed out to Air Resources Board (ARB) staff that a thorough assessment of DTBP, the sole additive included as a NOx mitigation measure in the proposed ADF regulation, has yet to be conducted. While air emissions impacts were considered for the use of DTBP, there is no documentation in the MME that other potential impacts of DTBP were evaluated, including, but not limited to: LCFS SF8-15 cont.

- Full multimedia evaluation of environmental impacts (e.g. fate and transport including soil, surface water & ground water and non-combustion air emissions),
- Toxicological impacts,
- Safety impacts (e.g. peroxide stability and interactions with other additives such as antioxidants), and,
- Materials compatibility impacts (e.g. OEM approval, metallurgical compatibility in distribution storage, piping, and fueling equipment).

We note that the State Water Resources Control Board's (SWRCB) review was limited to the differences between biodiesel and CARB diesel[2]. In addition, the Department of Toxic Substance Control (DTSC) performed fate and transport studies with biodiesel, CARB diesel, and biodiesel blends, and with two additives (a biocide and antioxidant). However, they did not test a biodiesel blend with DTBP. The DTSC also noted:

"If new or different additives from those tested are proposed for use, appropriate evaluation through the MMWG process should occur."

While DTBP is clearly being proposed for use, it does not appear that either a SWRCB or DTSC review of biodiesel blends containing DTBP was performed as part of the MME. Both agencies clearly indicated that newly proposed additives would need further evaluation, but there is no discussion in the MME as to why DTBP was not included in their reviews. LCFS SF8-17

Review of the MMWG response to Peer Review comments, indicates that the SWRCB evaluation assumed that the additives used in biodiesel and biodiesel blends will employ the same additives currently used in CARB diesel, and recommended that other additives used be evaluated separately by the MMWG[3]. However, DTBP, as proposed in the ADF, will be used for a purpose other than the one it was originally intended for (which was cetane enhancement)

---

[2] 2015 Biodiesel MME (page 12, Section B).
[3] 2015 Biodiesel MME (Appendix J, Page 31, Response to Comment E-9).

and at levels (0.25-1.00 volume percent) substantially higher than the range that it is typically used for cetane enhancement (0.1-0.3 volume percent – Society of Automotive Engineers Technical Series Paper No. 982574). The DTSC's response to Peer Review comments indicate that it is important to understand the real life fate and transport behaviors associated with additive packages relevant to biodiesel/CARB diesel blends[4], which was not done here.

LCFS SF8-17 cont.

In addition, a review of the MSDS for DTBP from two manufacturers[5,6] indicates there are specific issues regarding DTBP that are not discussed in ARB's MME. We feel the MME should include an evaluation of the DTBP specific issues listed below prior to approving the use of DTBP at the recommended concentrations:

- DTBP decomposes at approximately 80°C; recommended maximum storage temperature 40°C[4,5]
- Flash point of 6°C, highly flammable at room temperature[4,5];
- Precautions are needed to guard against electrostatic discharge[4,5]
- Control of vapor space, such as nitrogen blanketing, may be required or recommended[5]
- Segregation of DTBP from accelerators, stabilizers, acids, bases, and heavy metals is highly recommended[4,5]
- Use only stainless steel 316, polypropylene, polyethylene, or glass lined equipment for storage[5]
- Must avoid contact with rust, iron and copper[5]

LCFS SF8-18

We request that the CEPC recommend the MMWG fully re-examine the use of DTBP as proposed, to ensure all potential impacts associated with its use are reviewed and evaluated, and feel this request is consistent with the recommendations included in the MME.

LCFS SF8-19

Other Water Impacts

In addition to the DTBP evaluation included above, we have concerns that the MMWG has not sufficiently evaluated potential impacts to water in the US and the State of California.

- In the MME Conclusions of Water Impacts[7], SWRCB staff concludes there are minimal additional risks to use of California waters posed by biodiesel.
- Given the severe drought conditions California currently faces, the MME must take into account the significant water demands associated with the use of biofuels, which are outlined in in the recently published peer-reviewed study by Julian Fulton of the Energy and Resources Group at U.C. Berkeley and Heather Cooley of the Pacific Institute[8].

LCFS SF8-20

[4] 2015 Biodiesel MME (Appendix J, Page 23, Response to Comment D-1).
[5] United Initiators MSDS for DTBP from: http://www.united-initiators.com/products/details/di-tert-butyl-peroxide/
[6] Azko Nobel TRIGONOX B MSDS from: https://www.akzonobel.com/polymer/msds/
[7] 2015 Biodiesel MME (III.B, page 17).
[8] Cooley, H., Fulton, J. The Water Footprint of California's Energy System, 1990–2012. Environmental Science and Technology. 2015. 49. 3314–3321.

- We feel the SWCRB MME conclusion of minimal additional risks should be further evaluated relative to the conclusions drawn by Fulton and Cooley: "Although early LCFS policy assessments raised the issue of water demands and impacts from increased biofuel production, any subsequent efforts to track or address those impacts through policy have been lacking." **LCFS SF8-20 cont.**

8_SF_LCFS_GE (Page 405 - 410)

The commenter attaches a comment letter that was written by WSPA and submitted by WSPA to the CEPC public hearing. Although this document was not submitted as an objection or suggestion on the proposal, ARB staff responded where appropriate.

1217. Comment: **LCFS SF8-15 through LCFS SF8-17, LCFS SF8-19, and LCFS SF8-20**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

1218. Comment: **LCFS SF8-14**

The comment states that the multimedia evaluation is not complete and continues to list specific topics not considered.

Agency Response: Please see responses **LCFS SF8-15** and **LCFS SF8-16** in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

1219. Comment: **LCFS SF8-18**

The comment states that the multimedia evaluation should include an evaluation of specific issues regarding DTBP prior to approval.

Agency Response: Please see response **ADF F1-4** in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

This page intentionally left blank.

ATTACHMENT B

Declaration of Thomas L. Darlington

CALIFORNIA ENVIRONMENTAL PROTECTION AGENCY

CALIFORNIA AIR RESOURCES BOARD

DECLARATION OF THOMAS L. DARLINGTON

I, Thomas L. Darlington, declare as follows:

1. I am an engineer with training and expertise in lifecycle emissions analysis; the use of models to estimate lifecycle emissions and to attribute emissions to the production, distribution and use of various fuels; and the use of regulations to control mobile-source emissions. My areas of expertise also include land-use change ("LUC") modeling and the application of econometric models to attributional and consequential lifecycle emissions analysis. Following my graduation from the University of Michigan in 1979, I served for eight years as an Engineer and Project Manager at the United States Environmental Protection Agency's Motor Vehicle Emissions and Fuels Laboratory in Ann Arbor, Michigan. Thereafter I worked at Detroit Diesel Corporation and General Motors Corporation, and as the Director of Mobile Source Programs at Systems Application International. I am the President of Air Improvement Resource ("AIR"), a company formed in 1994 to provide mobile source emission modeling to government and industry. A copy of my CV is attached to this Declaration as Exhibit "B."

2. I have participated on behalf of renewable fuels producers in the public consultation and rulemaking processes at the California Air Resources Board ("ARB" or "the Board") to consider, adopt and revise the low-carbon fuel standard ("LCFS") regulation since 2008. I testified at the Board's February 2015 hearing concerning proposed amendments to the LCFS regulation. I am fully familiar with the models released by CARB to establish and implement the LCFS regulation, including the versions of the Global Trade Analysis Project ("GTAP") modeling systems used by CARB or proposed for use by the CARB staff as part of the current and proposed LCFS regulation.

3. I make this Declaration based upon my personal knowledge, my training and expertise, and my familiarity with the subjects that I address here.

A. Documentation for Perennial Reversion GHG Emissions for Sugarcane

4. The land use change emissions (LUC) for sugarcane have decreased from 46 gCO2e/MJ in the current LCFS to 11.8 gCO2e/MJ in the proposed LCFS. A factor that is important in this drop in LUC emissions for cane is the "perennial reversion GHG emissions" for cane. These emissions describe the carbon stored in a field when cane is planted after forest is removed for cane.

5. ARB has a report that describes the emissions released when various types of land are converted from one use to another.[1] AIR reviewed this report but there is no documentation or description for the perennial reversion emissions for various perennials, LCFS SF8-21

[1] *Agro-Ecological Zone Emission Factor Model (v52)*, Plevin, Gibbs, Duffy, et al, December 11, 2014.

including cane. AIR also reviewed Appendix I of the ISOR, which also contains details on the LUC estimates for various feedstocks.[2] This document also did not describe the perennial reversion emissions for various perennials. Finally, AIR emailed ARB on several occasions to determine how ARB estimated these emissions.[3] However, the information on how ARB developed these important emissions was not provided, so AIR was unable to satisfactorily review how the cane LUC emissions were developed. (See Exhibit "A," which provides copies of the text of email exchanges I had on this issue with CARB staff.)

LCFS SF8-21 cont.

B. Requirement for One Quarter's Plant Operating Data For Prospective LCFS Applications

6. For Provisional Pathways, ARB in its proposal requires one calendar quarter of plant operating data to be submitted with the application.

> As set forth in sections 95488 (c)(3) and (c)(4)(l)(2), LCFS pathways are generally developed for fuels that have been in full commercial production for at least two years. In order to encourage the development of innovative fuel technologies, however, applicants may submit New Pathway Forms, as set forth in section 95488(c)(1), covering Tier 2 facilities that have been in full commercial operation for less than two years, provided they have been in full commercial operation for at least one full calendar quarter.

7. In the current LCFS rule, ARB accepts engineering estimates for inputs that are based on pilot data. Under either regulation, plants must produce biofuels at CIs that are at or below their assigned value; therefore, requiring one calendar quarter of data is an unnecessary requirement in the current proposal. I believe the current proposal should be amended to allow the use of engineering estimates for process fuel use, ethanol and coproduct production, and other inputs needed to estimate the CI using CaGREET2.0.

LCFS SF8-22

I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct.

Executed this 8th day of July, 2015 in Holland, Michigan.

Thomas L. Darlington

Thomas L. Darlington

2 Appendix I of Initial Statement of Reasons.

3 See Exhibit A for email string.

Exhibit A to Declaration of Thomas L. Darlington

Exhibit "A"
Emails Concerning LUC of Cane

1. Text of Darlington's inquiry on February 6, 2015

Tom, I'm forwarding your request to Anil. Jim Duffy 916-599-9364 -----Original Message----- From: Tom Darlington [mailto:tdarlington@airimprovement.com] Sent: Friday, February 06, 2015 1:06 PM To: Duffy, James@ARB Subject: aez-ef model Jim - how were the forest-to-perennial and cropland pasture-to-perennial emission factors developed in the worksheet "EF" in the AEZ-EF model? I did not see a description of that in the AEZ-EF report. Tom

2. Email Received By Darlington on February 6, 2015 from Anil Prabhu

Tom, Please see below responses to your questions: For forest-to-perennial, the emissions: deforested_fraction_GHG * (biomass_loss_GHG + foregone_seq_GHG) + (1 - deforested_fraction) * -1 * perennialReversion_GHG We assume no change in soil carbon. For pasture-to-perennial, emissions: biomass_loss_GHG + foregone_seq_GHG Again, no change in SOC, and in this case, not weighted by deforestation vs afforestation. Hope this helps. Regards, Anil

3. Darlington's follow-up email on April 29, 2015

From: Tom Darlington [mailto:tdarlington@airimprovement.com]
Sent: Wednesday, April 29, 2015 9:12 AM
To: Prabhu, Anil@ARB
Cc: Sahay, Shailesh
Subject: Fwd: Re: aez-ef model

Anil - I still cannot find where the perennial reversion GHG emissions are discussed for sugar cane. Can you direct me to the proper documentation for that? Thanks.

Tom

4. Response Received By Darlington from Anil on April 30, 2015

Tom,

This is what we have. Hope it helps.

Regards,

Anil

There is no specific treatment for sugarcane: both oil palm and sugarcane are treated the same. The difference between perennials and annuals is that perennial-to-forest is assumed to not gain soil C, whereas crop-to-forest does gain soil C.

Reversion to forest by perennials is assumed to result in a gain of the "biomass regrowth C" minus the understory and deadwood and a portion of the litter for forest in the given AEZ-Region, as these pools would take more time to accumulate.

8_SF_LCFS_GE (Page 411 – 415)

1220. Comment: **LCFS SF8-21**

The commenter believes there is no documentation or description for the perennial reversion emissions for various perennials.

Agency Response: See response to **LCFS SF8-1** in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

1221. Comment: **LCFS SF8-22**

The commenter believes that requiring one calendar quarter of data is an unnecessary requirement in the current proposal.

Agency Response: Please see response to **LCFS FF56-2**.

This page intentionally left blank.

Exhibit B to Declaration of Thomas L. Darlington

Thomas L. Darlington

President, Air Improvement Resource Inc.

Profile

Thomas L. Darlington is President of Air Improvement Resource, a company formed in 1994 specializing in mobile source emission modeling. He is an internationally recognized expert in mobile source emissions modeling, lifecycle analysis, and land use modeling.

Professional Experience

1994-Present	President, Air Improvement Resource
1993-1994	Director, Mobile Source Programs, Systems Application International
1989-1994	Senior Engineer, General Motors Corporation, Environmental Activities
1988-1989	Senior Project Engineer, Detroit Diesel Corporation
1979-1988	Project Manager, U.S. EPA, Ann Arbor, Michigan

Recent Major Projects

- Developed Life Cycle reports and complete applications for 8 plants for the California Low Carbon Fuel Standard; six are currently registered, two plants are pending. Five plants were corn ethanol plants, one is sorghum and two are cellulose.
- Participated in and provided written comments on ARB's three 2014 iLUC workshops
- With Purdue and Don O'Connor, conducted study of iLUC emissions of rapeseed and other oilseeds in 2013 utilizing an updated version of GTAP
- Reviewed EPA's palm oil iLUC emissions in 2013
- Submitted comments on ARB's new GREET2.0 model
- Reviewed CARB's land use emissions for soybean biodiesel
- Reviewed the land use impacts of the RFS2 from EPA, including the notice of Proposed Rule, Regulatory Impact Analysis, and approximately one hundred documents in the rulemaking docket.
- Completed a land use study for Renewable Fuels Association and reviewed California Air Resource Board's Initial Statement of Reasons for the Low Carbon Fuel Standard
- Represented three stakeholders in the recent development of the ARB Predictive Model for reformulated gasoline in California (Alliance of Automobile Manufacturers, Renewable Fuels Association and Western States Petroleum Association)
- Represented two stakeholders in EPA's development of the MOVES on-highway emissions model (Alliance of Automobile Manufacturers and Engine Manufacturers Association)

- Developed the effects of ethanol permeation on on-highway and off-highway mobile sources in California and other states for the American Petroleum Institute
- Studied gasoline and diesel fuel options for Southeast Michigan (for SEMCOG, API and Alliance of Automobile Manufacturers)

Recent Publications

"Study of Transportation Fuel Life Cycle Analysis: Review of Economic Models Use to Assess Land Use Effects", CRC-E-88-3, July 2014.

"Land Use Change Greenhouse Gas Emissions of European Biofuel Policies Utilizing the Global Trade Analysis Project Model", Darlington, Kahlbaum, O'Connor, and Mueller, August 30, 2013.

"A Comparison of Corn Ethanol Lifecycle Analyses: California Low Carbon Fuels Standard (LCFS) Versus Renewable Fuels Standard (RFS2)", June 14, 2010. Renewable Fuels Association and Nebraska Corn Board. This study compared and contrasted the corn ethanol lifecycle analyses performed by both CARB (as a part of the LCFS) and the EPA (as a part of RFS2).

"Review of EPA's RFS2 Lifecycle Emissions Analysis for Corn Ethanol", September 25, 2009. Conducted for Renewable Fuels Association. This study reviewed EPA's land use GHG emissions assessment for corn ethanol, including the FASOM and FAPRI models and Winrock land-use types converted and emission factors by ecosystem type. The study made many recommendations for improving the land-use and emissions modeling.

"Review of CARB's Low Carbon Fuel Standard Proposal", April 15, 2009. Conducted for Renewable Fuels Association. This study reviewed CARB's analysis of land use emissions using GTAP6 and CARB's overall lifecycle emissions for corn ethanol. This study made many recommendations for improving the land use and lifecycle emissions of corn ethanol.

"Emission Benefits of a National Clean Gasoline", August 2008. Conducted for the Alliance of Automobile Manufacturers. This study evaluated the nationwide criteria pollutant emission reductions of a national clean gasoline standard.

"Land Use Effects of Corn-Based Ethanol", February 25, 2009. Conducted for Renewable Fuels Association. This study evaluates possible land use changes and GHG emissions associated with these land use changes as a result of the renewable fuel standard mandated 15 billion gallons of corn ethanol required by calendar year 2015. The study utilized projections of land use in the US and rest of world performed by Informa Economics, LLC, as well as newer estimates of the land use credits of co-products produced by ethanol plants to evaluate possible land use changes.

"On-Road NOx Emission Rates From 1994-2003 Heavy-Duty Trucks", SAE2008-01-1299, conducted for the Engine Manufacturers Association. This study examined

manufacturers consent decree emissions data to determine on-road NOx emission rates, and deterioration in emissions from heavy-duty vehicles. (Peer reviewed publication)

"Evaluation of California Greenhouse Gas Standards and Federal Energy Independence and Security Act - Part 2: CO2 and GHG Impacts", SAE2008-01-1853, conducted for the Alliance of Automobile Manufacturers. This paper evaluated the comparison of greenhouse gases from cars and light trucks in the US under both the Federal and California GHG policies. (Peer reviewed publication)

"Effectiveness of the California Light Duty Vehicle Regulations as Compared to Federal Regulations", June 15, 2007. Conducted with NERA Economic Consulting and Sierra Research for The Alliance of Automobile Manufacturers. This study compares the emission benefits of the California and Federal light duty vehicle regulations for HC, CO, NOx, PM, SOx, and Toxics taking into account the difference in emission standards, new vehicle costs and its effect on fleet turnover, new vehicle fuel economy and its effect on vehicle miles traveled, and other factors. Both the EPA MOBILE6 and ARB EMFAC on-road emissions models were used to estimate changes in emissions inventories.

"The Case for a Dual Tech 4 Model Within the California Predictive Model", May 20, 2007. Conducted with ICF International and Transportation Fuels Consulting for the Renewable Fuels Association (RFA). This study developed separate emissions vs fuel property models for lower and higher Tech 4 (1986-1995) vehicles, and showed that utilizing this alternative Predictive Model would result in a higher compliance margin for fuels containing higher volumes of ethanol. It was thought that this could lead to higher ethanol concentrations in the state, but even if the dual model is not used, it is a better representation of the 2015 inventory than the ARB single model.

"Updated Final Report, Effects of Gasoline Ethanol Blends on Permeation Emissions Contribution to VOC Inventory From On-Road and Off-Road Sources, Inclusion of E-65 Phase 3 Data and Other Updates", June 20, 2007. Conducted for the American Petroleum Institute. This report updates the earlier March 3, 2005 report for API utilizing data collected by CRC and others since of the time of the earlier report.

Final Report, Development of Technical Information for a Regional Fuels Strategy, February 28, 2006. Conducted for the Lake Air Directors Consortium (LADCO). This report provided guidance to the LADCO states (Midwestern states) concerning how to model different types of fuel control programs (in particular) using EPA mobile source models, and how to set up the baseline input files so that results are consistent between the different states.

"Emission Reductions from Changes to Gasoline and Diesel Specifications and Diesel Engine Retrofits in the Southeast Michigan Area", February 23, 2005. Conducted for the Southeast Michigan Council of Governments (SEMCOG), the Alliance of Automobile Manufacturers, and the American Petroleum Institute. This study examined the on-road and off-road emission benefits of many different possible gasoline and diesel fuel

specifications that the state could adopt to help meet the 8-hour ozone standards. This study formed the basis for the state's move to lower RVP summer gasoline.

"Examination of Temperature and RVP Effects on CO Emissions in EPA's Certification Database, Final Report", CRC Project No. E-74a, April 11, 2005. Conducted for the Coordinating Research Council. This study compared CO vs temperature results from the MOBILE6 model to the certification data, and recommended further testing, which is being conducted by the CRC at this time.

"Effects of Gasoline Ethanol Blends on Permeation Emissions Contribution to VOC Inventory From On-Road and Off-Road Sources" March 3, 2005. Conducted for the American Petroleum Institute (API). Using data from the CRC-E-65 program, and data collected by the California EPA and Federal EPA, this study estimated the impacts of ethanol use on increasing permeation VOC emissions from on-road vehicles, off-road equipment and vehicles, and from portable containers. Emission inventory estimates were made for a number of geographical areas including the state of California, and results showed that the permeation effect increases anthropogenic VOC inventories by 2-4%.

Review of EPA Report "A Comprehensive Analysis of Biodiesel Impacts on Exhaust Emissions", February 11, 2003. Conducted for the American Petroleum Institute. This study critically examined the methods that EPA used to develop the impacts of biodiesel fuels on HC, CO, NOx, and PM emissions.

"Well-To Wheels Analysis of Advanced Fuel/Vehicle Systems – A North American Study of Energy Use, Greenhouse Gas Emissions, and Criteria Pollutant Emissions", May 2005. Conducted for General Motors Corporation, with Argonne National Labs. This study examined many different well to wheels pathways for various fuels, and their impacts on GHG and criteria pollutant emissions.

"Potential Delaware Air Emission Impacts of Switching From MTBE to Ethanol in the Reformulated Gasoline Program", May 26, 2005. Conducted for Lyondell Chemical Company. This study examined the HC, CO, and NOx impacts of switching from MTBE to ethanol.

"Potential Massachusetts Air Emission Impacts of Switching From MTBE to Ethanol in the Reformulated Gasoline Program" June 17, 2005. Conducted for Lyondell Chemical Company. This study is similar to the Delaware study above.

"Potential Maryland Air Emission Impacts of a Ban on MTBE in the Reformulated Gasoline Program", October 18, 2005. Conducted for Lyondell Chemical Company. This study is similar to the Delaware study above.

"MOBILE6.2C with Ethanol Permeation and Ethanol NOx Effects", February 8, 2005. Conducted for Health Canada. This study modified the MOBILE6.2C model for ethanol permeation VOC and ethanol NOx effects.

Re: Comments on ARB's "Attachment A: Second 15-Day Modified Regulation Order" (LCFS)

Dear Executive Officer Corey:

The California Natural Gas Vehicle Coalition (CNGVC), NGVAmerica (NGVA), and the Coalition for Renewable Natural Gas (RNGC)[1] are pleased to provide these joint comments regarding ARB's proposed re-adoption of the Low Carbon Fuel Standard (LCFS) regulation. Specifically, this letter provides our detailed joint comments on ARB's "Attachment A: Second 15-Day Modified Regulation Order," which was released for public comment on June 23, 2015.

Below, we present our joint, detailed comments and recommendations. Many of these comments reiterate issues that were raised in our June 19th letter regarding the previous 15-day comment period. While ARB has addressed the critical issue of "provisional credits," we remain concerned about many issues that were not addressed in the most recent Modified Regulation Order.

We want to be clear that our three organizations continue to support ARB's proposed re-adoption of the LCFS regulation. We greatly appreciate the time and effort put forth by ARB staff over the last several months to meet with our representatives and address our specific concerns. ARB has made several changes that corrected erroneous information and updated obsolete inputs in early drafts of the proposed CA-GREET model revision (version 2.0). We remain committed to continue working closely with ARB staff, right up until the LCFS program re-adoption is anticipated at the Board's July 23, 2015 meeting.

A. Comments on Proposed LCFS Regulatory Changes

Our detailed comments regarding ARB's proposed LCFS regulatory changes are presented below, in six specific areas.

1. Provisional Pathway Process

We would like to thank Staff for addressing the concerns of many stakeholders by allowing the credits generated under the Provisional Pathway process to be immediately and fully tradeable. This change is crucial to support the continued development of low carbon fuels in the California marketplace. LCFS SF9-1

[1] For more information about our three organizations and respective memberships, please refer to the many previous formal comment letters that we uploaded over the last nine months to the ARB LCFS comments website.

2. Temporary FPC Values

Table 7 of the regulation proposes temporary carbon intensities for fuels where a specific fuel pathway cannot be identified. These may also potentially be used as "default" values for facilities awaiting application approval or in the beginning stages of the Provisional Pathway process. Hence, the values in Table 7 have a material impact on the credits and deficits generated under the LCFS. Despite the importance of these values, ARB staff have not provided information regarding the underlying assumptions used to determine most of the values in Table 7 (excluding the CIs for diesel and CARBOB, which are clearly documented elsewhere). We believe that the values in Table 7 are not consistent with typical values expected for natural gas pathways providing fuel to California. In fact, values for LNG from North American natural gas, and CNG or LNG derived from landfill gas are significantly higher than the illustrative values provided by ARB staff at the April 3rd workshop at which updates to CA-GREET 2.0 were extensively discussed.

LCFS SF9-2

In sum, the currently proposed revisions to Table 7 further increase the CIs for natural gas pathways above values previously proposed by staff, and these increases do not appear to be explainable by documented revisions to the CA-GREET model. We believe that it is inappropriate to further increase the values in Table 7 without providing details on the assumptions underlying these changes. Consequently, we request that ARB staff not modify the values in Table 7 from the values proposed in February. At the very least, we believe that any modifications to the values in Table 7 should be clearly linked to documented changes and updates to the CA-GREET model.

3. Application Review Timeline

Section 95488(c)(5)(B) proposes to eliminate the 60-day deadline for ARB staff to review an application and notify the applicant about its completeness. However, Staff is not proposing to modify the 180-day deadline for an applicant to provide a complete application. Staff notes that this change is being proposed to eliminate "unrealistic deadlines" during times when Staff will be working to recertify hundreds of existing pathways.

This removal of the 60-day deadline may be acceptable for applications covered by an existing pathway and able to generate credits as late as December 31, 2016. However, the proposed change <u>is not acceptable for new applications</u>. It is crucial that ARB continue to provide timely feedback to applicants regarding the completeness of their applications and any deficiencies that must be addressed. Delays in the review process can translate directly into lost credit generation, the associated revenue, and verified carbon reductions.

LCFS SF9-3

Further, we note that the removal of the 60-day requirement is not limited to the 2016 timeframe. It is inappropriate to establish a regulation in which Staff have no obligation to complete a timely review of an application but where the applicant is simultaneously constrained to a fixed deadline and dependent on Staff's review of the application.

Similarly, Staff propose to remove the 15-day deadline for review and notification of completeness of a fuel transport mode as defined in Section 95488(e)(5). We have similar concerns and objections to the removal of this requirement for timely review of the fuel transport mode application as we do for the pathway application review process in Section 95488(c)(5).

We urge Staff to retain the 60-day and 15-day deadlines in Sections 95488(c)(5)(B) and 95488(e)(5), respectively, and to provide the LCFS program the necessary resources to conduct timely review of applications during the 2016 timeframe. It is critically important that industry has a process for application review that includes firm deadlines for ARB's actions. LCFS SF9-3 cont.

4. Treatment of Business Confidential Information

Staff are proposing to eliminate language providing protection of credit transaction data as Business Confidential information. Section 95487(c)(1)(B) currently requires ARB to treat all data reported in Credit Transfer Forms as business confidential, with limited exceptions for reporting of aggregated data described in Section 95487(d).

Credit Transfer Forms contain a number of sensitive pieces of information including, but not limited to:

- Names and contact information of individuals at companies involved in the transaction;
- Parties to specific transactions;
- Price and number of credits involved with a specific transaction. LCFS SF9-4

There is no basis for broad public disclosure of the names and contact information of private persons, particularly when they are acting simply in an administrative role for a private organization. Further, the disclosure of the parties, pricing, types of credits, and number of credits associated with a particular transaction can be damaging to the business interests of regulated parties. The disclosure of such sensitive information is not consistent with other regulatory programs including the US EPA's Renewable Fuel Standard.

It should also be noted that, while the regulation allows brokers to facilitate "blind transactions," the disclosure of data in the Credit Transfer Forms would undermine blind transactions for any transactions where the broker does not first aggregate the credits from multiple buyers or sellers.

We urge Staff to retain the Business Confidential protection language in Section 95487(c)(1)(B). Confidentiality provisions are the industry standard for commodity transactions. However, we can support providing information for the sole purpose of calculating a published index.

5. Definition of L-CNG and Bio-L-CNG

The proposed regulatory text currently defines L-CNG as "LNG that has been liquefied and transported to a dispensing station where it was then re-gasified and compressed to a pressure greater than ambient pressure."

Similarly, Bio-L-CNG is defined as "biogas-derived biomethane which has been compressed, liquefied, re-gasified, and re-compressed into L-CNG, and has performance characteristics at least equivalent to fossil L-CNG." LCFS SF9-5

In both definitions, it is assumed that L-CNG is created by gasifying LNG and then compressing the resulting gas to pressures suitable for CNG, typically 3,600 psi. This is not an accurate description for most L-CNG and Bio-L-CNG facilities. The pumping of liquids to high pressures is much less energy intensive than the compression of gas. Most L-CNG facilities take advantage of this fact by first pumping LNG to high pressures and then re-gasifying the LNG at pressure, ultimately producing CNG without the need for a gas compression process. Such a distinction is important because it has a meaningful impact on the carbon intensity for L-CNG fuels. We note that this issue was raised in our comments submitted to ARB on December 15, 2014. Following that submission, Staff updated the CA-GREET model to reflect the typical operation of L-CNG stations. LCFS SF9-5 cont.

We recommend that Staff modify the definition of L-CNG and Bio-L-CNG to be consistent with the processes modeled in CA-GREET 2.0. Specifically, by eliminating the text asserting that L-CNG and Bio-L-CNG necessarily involve "compression" or "re-compression" of natural gas at the station.

6. Retroactivity

Section 95486(a)(2) limits the generation of retroactive credits to a maximum of two quarters; the quarter in which the complete application was submitted and the quarter in which the Executive Officer approves the application. Exceptions are made for provisional credits generated during the period that the applicant is accruing two years of operational data.

While the two-quarter limit on retroactive credit generation appears reasonable, it is predicated on the assumption that the Executive Officer will approve a complete application by the end of the quarter following submission of the application. Considering that Staff acknowledge the likelihood of significant delays in application processing during 2016, and in light of the proposed elimination of the 60-day and 15-day review deadlines discussed in item 3 above, we believe that retroactivity should not be constrained by a two-quarter limit. Specifically, we propose that retroactive credit generation should apply from the quarter the applicant submits a completed application or demonstration to the quarter in which the Executive Officer approves the application or demonstration. Hence, if the approval of the application or demonstration by the Executive Officer requires more than one quarter, the applicant does not lose credits due to delays outside the applicant's control. LCFS SF9-6

This proposed change is both reasonable and important. However, we do not believe it is worth delaying the adoption of the LCFS, provided that Staff ensures the timely review of applications as noted in our comments under Item 3, above. Instead, we strongly urge Staff to consider making this change in a future update to the LCFS, retain the 60-day and 15-day deadlines for review in the current rulemaking (or alternative reasonable timeline with a firm deadline), and ensure that the LCFS program has sufficient resources to provide timely review of applications.

B. Comments on CA-GREET Model Update

We would like to thank Staff for their efforts to address our concerns related to the draft CA-GREET 2.0 model over the last nine months. These interactions have resulted in important improvements to the model.

In the latest draft of CA-GREET, Staff incorporated estimates of Tank to Wheels (TTW) methane and nitrous oxide emissions from natural gas vehicles, based on a recent whitepaper from Argonne National Laboratory

(ANL).[2] The whitepaper provides estimated emissions for various vehicle types and applications, including combination long haul trucks, combination short haul trucks, refuse trucks, buses, heavy duty trucks and vans, and medium duty vehicles. Staff rely on the emissions rates in the ANL report, combined with estimates of the composition of the natural gas vehicle fleet, to calculate fleet-averaged TTW emissions rates for CNG and LNG.

The emissions rates calculated by ARB staff are not insignificant. As shown in Table 1, ARB assumes that the fleet-averaged emissions of methane and nitrous oxide for CNG and LNG vehicles are 4.90-4.91 gCO2e/MJ. This represents a 6% increase in pathway emissions for CNG and LNG from fossil sources, and potentially more than 25% of emissions from renewable natural gas pathways. However, as shown, emissions from some vehicle types are much lower than the calculated fleet average.

Table 1. Non-CO2 GHG emissions assumptions for natural gas vehicles

Vehicle Type	Non-CO2 vehicle emissions
ARB CNG Fleet Average	4.90 gCO2e/MJ
Light-Duty/Medium Duty	0.99 gCO2e/MJ
Heavy-Duty Class 8b	2.42 gCO2e/MJ
ARB LNG Fleet Average	4.91 gCO2e/MJ

Both heavy-duty class 8b vehicles and light/medium duty vehicles are estimated to have much lower TTW emissions than the fleet-average. Because of such wide variation in the emissions from vehicle types, the fleet-averaged emissions are very sensitive to the assumed fleet composition. Overestimating the fraction of the fleet in higher emitting applications raises the fleet average and potentially penalizes lower emitting applications.

We raise two specific concerns here, as described below.

1. Basis for the Current Fleet Mix

Staff calculates the current mix of applications consuming CNG and LNG based on data from the US Energy Information Administration's (EIA) Alternative Fuel User Database. The latest year for available data is 2011. We note that the data are both out of date, and inconsistent with other industry specific data sources. As an example, we note that ARB staff estimate that transit buses consume 60% of the 55 million gallons of LNG sold in 2014. This equates to nearly 22 million GGE, or 150% more LNG for transit buses than reported by EIA. The National Transportation Database (NTDB) reports that California transit fleets consumed only 7 million gallons of LNG, or approximately 4.6 million GGE in 2011; roughly half of the fuel consumption reported by EIA. Finally, it is unclear to what extent reported LNG consumption actually reflects LNG delivered to an LCNG station.

LCFS
SF9-7

The dominant purchasers of LNG in California for transit applications are Orange County Transportation Authority (OCTA) and Santa Monica's Big Blue Bus (BBB). These two agencies represent almost 95% of LNG purchased in 2011, according to the NTDB. Examination of a recent LNG purchase contract from OCTA reveals

[2] Cai, H. et al, The GREET Model Expansion for Well-to-Wheels Analysis of Heavy-Duty Vehicles, 2015

that the agency consumes roughly 22,000 gallons of LNG per weekday, or approximately 5.5 million LNG gallons per year.[3] A city council report on the BBB LNG fuel procurement for 2010-2011 reported that BBB purchases roughly 200,000 LNG gallons per month to serve a mix of BBB vehicles as well as city vehicles and the Santa Monica Unified School District.[4] BBB operates a mix of CNG and LNG buses, supplying the CNG buses through their LCNG station. Consequently, only a fraction of the BBB LNG purchases are actually used in transit applications. In total, the two largest purchasers of LNG for transit applications only represented less than 7.7 million LNG gallons in 2011. Again, this value is much lower than that reported by EIA.

Such disparities between EIA and other data sources make it clear that EIA is not a reliable basis upon which to develop a fleet-average emissions rates.

2. Evolving Fleet Mix

EIA's last available estimate of the population of NGVs in the US is 121,650 vehicles in 2011. Based on industry sales data, NGVA estimates that the current population of NGVs is in excess of 155,000 and growing. New deployments show growth in sales of Class 8 trucks in addition to sales in more traditional transit and refuse applications. It is clear that the mix of NGVs is changing and that it is not possible to accurate predict the future fleet mix. Further, because of the relatively small number of NGVs in the state (relative to traditional petroleum fueled vehicles), modest growth in any application could significantly alter the fleet mix.

LCFS SF9-7 cont.

Recommendations Regarding CA-GREET Update

Based on the two concerns described above – and the fact that the TTW emissions rates employed by ARB have non-trivial variations based on the vehicle type/application – we request that ARB allow fuel producers the option to adjust their pathway carbon intensities based on the vehicle type receiving the fuel. For example, a CNG or LNG station owner that documents the volume of fuel dispensed to Class 8b trucks would adjust their pathway CI based on non-CO2 TTW emissions of 2.42 gCO2e/MJ, rather than the fleet average of 4.90 or 4.91 gCO2e/MJ.

This option would help incentivize the deployment of NGVs in the lowest emitting categories by recognizing their specific emissions profiles and would require minimal changes to the data tracked in the LRT. Currently light and medium-duty natural gas consumption is tracked separately from heavy-duty natural gas fuel consumption in the LRT. Implementing the proposed recommendation would only require the separation of Class 8b fuel consumption from the remaining heavy-duty vehicle applications. Where the vehicle type cannot be determined or is not documented, the credit generator would continue to use the fleet-averaged TTW emissions rates.

Closing Comment

Our three organizations support re-adoption of the LCFS regulation. We genuinely appreciate the cooperation that ARB staff have shown in working with our industry representatives to improve the program, especially the critically important CA-GREET model. Leading up to the July 23 Board meeting, we urge you to expeditiously address the issues identified in this letter. LCFS SF9-8

Thank you for the opportunity to comment. If we can provide additional information, please contact any of us.

Sincerely yours,

1223. Comment: **LCFS SF9-1**

The commenter supports the regulatory language modifications in the second 15-day comments which effectively remove the restriction on the sale of LCFS credits based on the provisional pathway. The commenter thanked the Air Resources Board staff for regulatory language modifications in the second 15-day comments which effectively remove the restriction on the sale of LCFS credits based on the provisional pathway. They believe that the change is crucial to support the continued development of low carbon transportation fuels in California.

Agency Response: ARB staff appreciates the support for the modification of the provisional pathways.

1224. Comment: **LCFS SF9-2**

The commenter believes that the values in Table 7 are not consistent with typical values expected for natural gas pathways providing fuel to California.

Agency Response: This comment was submitted July 8, 2015 during the comment period for the Second 15-Day Modified Regulation Order, but relates to a change proposed in the First 15-Day Modified Regulation Order proposed on June 4, 2015. The comment duplicates a comment submitted during the first comment period; Staff believes that the response to CNGVC's comment **LCFS FF35-6** sufficiently addresses this comment.

1225. Comment: **LCFS SF9-3**

The commenter states that the elimination of 60-day deadline for staff to advise the applicant that application is complete or incomplete is not acceptable for new pathways.

Agency Response: This comment was submitted July 8, 2015 during the comment period for the Second 15-Day Modified Regulation Order, but relates to a change proposed in the First 15-Day Modified Regulation Order proposed on June 4, 2015. The comment duplicates a comment submitted during the first comment period; Staff believes that the response to CNGVC's comment **LCFS FF35-7** sufficiently addresses this comment.

1226. Comment: **LCFS SF9-4**

The commenter recommends retaining language in section 95487 that deems data in credit transaction forms confidential.

Agency Response: See response to comment **LCFS FF35-10**.

1227. Comment: **LCFS SF9-5**

The commenter recommends that staff modify the definition of L-CNG and Bio-L-CNG to be consistent with the processes modeled in CA-GREET 2.0. Specifically, by eliminating the text asserting that L-CNG and Bio-L-CNG necessarily involve “compression” or “re-compression” of natural gas at the station.

Agency Response: Because CA-GREET 2.0 correctly reflects the processing described by the comment, no further change is needed; the fuels in question will receive a correct CI.

1228. Comment: **LCFS SF9-6**

The commenter proposes that retroactive credit generation should apply from the quarter the applicant submits a completed application or demonstration to the quarter in which the Executive Officer approves the application or demonstration.

Agency Response: See response to comment **LCFS FF35-12**.

1229. Comment: **LCFS SF9-7**

The commenter states that disparities between EIA and other data sources make EIA an unreliable basis upon which to develop fleet-average emissions rates.

Agency Response: See responses to **LCFS FF35-13**, **LCFS FF35-14**, and **LCFS FF35-15**.

1230. Comment: **LCFS SF9-8**

The commenter supports the re-adoption of the LCFS regulation and urges staff to expeditiously address the issues identified in their letter.

Agency Response: ARB staff appreciates the support of the commenters. After the Board Hearing, staff will continue conducting workshops, providing guidance, and seeking stakeholder feedback regarding pathway processing.

RE: LCFS Re-adoption, 2nd 15-day notice

Dear Mary Nichols & Staff:

Thank you for the Second 15-Day Modified Regulation Order posted June 23, 2015. We are submitting comments for which we would appreciate ARB's consideration.

Our comment involves the proposed regulation regarding provisional pathways. We greatly appreciate ARB's proposed modification to Section 95488(d)(2) to allow the sale or transfer of credits generated under provisional pathways. However, if the regulations intend that these provisional credits (which we'd appreciate making a defined term for purposes of clarity) may not be utilized for compliance purposes by a regulated party [95486(a)(2)], such a prohibition may create hesitancy in customer acceptance of a fuel with a new fuel technology, and thus reduce feasibility, marketability, and potential benefit under LCFS to drive investment. We acknowledge ARB's need to adjust a provisional CI and appreciate ARB's willingness to allow provisional CIs, but if ARB intents to also adjust a provisional CI outside of a producer's account, we would prefer an alternate method to account for any adjustment necessary for any potential negative differences of CI upon the completion of the full two years of commercial operation. For example, if a provisional CI is changed to a higher operational CI, then any provisional credits *still in our account as producer* would be adjusted to the operational CI but the *accumulated difference* between the provisional CI and the operational CI for *any provisional CI already transferred to a third party* would be debited to our account, for which we would be obligated to clear (perhaps through purchasing credits on the open market or via any other credit balance in our account). LCFS SF10-1

Please feel free to contact me to clarify the provisions or to discuss further. We are excited to work with ARB to help meet its increasing GHG targets and provide a lower carbon intensity product for our customers. Thank you for the opportunity to comment and provide feedback.

Sincerely,

Carol Tjiong

Re: Second Notice of Proposed 15-day Regulation Order containing Modified Text and Availability of Additional Documents and Information for the Proposed Re-Adoption of the Low Carbon Fuel Standard

Dear Samuel Wade:

On behalf of DuPont, thank you for the opportunity to comment on the Second Notice of Proposed Modified Text for the LCFS. DuPont has significant investments in advanced biofuels that meet the specified greenhouse gas reduction threshold. These fuels will make transformative contributions to our nation's energy security, reduce greenhouse gas emissions and strengthen rural economies. These fuels represent a tremendous shift in how we energize our planet and are being commercialized due in large part to visionary state fuels programs like the CA Low Carbon Fuel Standard.

We look forward to doing business in California; however, DuPont has remaining concerns with the Second Notice of proposed modification to Obtaining and Using Fuel Pathways in Section 95488(d). The current proposed text is an improvement over the previous version which would have required a provisional status for new fuel producers for two years without the ability to transfer credits. In Section 95488 (d)(1)(D), the updated version appears to allow assigning a temporary fuel production code carbon intensity (CI) that could apply for two quarters. The issue with this approach is that the temporary CI could expire prior to a fuel pathway being approved. A new fuel producer must have 3 months of operational data before submitting a new pathway request pursuant to Section 95488 (d)(2). Completing and submitting an application form after the first 3 months of operation will take several weeks. We are concerned that the fuel pathway approval process could extend beyond the period of time covered by the temporary fuel production code. It is incredibly important for new advanced biofuel producers to be able to sell into the CA market from the first day of operation and continue without a lapse in valid carbon credits. In addition, DuPont recognizes the importance of accurate CI values and believes the Air Resources Board should develop a mechanism to compensate fuel producers or regulated parties when a fuel's CI value is adjusted upwards or downwards to include any change from the temporary fuel production code CI.

LCFS SF11-1

LCFS SF11-2

Therefore, DuPont recommends that the regulations be modified to: (1) allow the Air Resources Board flexibility to extend the period of time for temporary fuel production codes as long as a new fuel producer is actively seeking a fuel pathway approval; and (2) provide for an audit mechanism to debit or credit for adjusting CI values to fuel producers and regulated parties as needed to accurately account for changing CI values.

LCFS SF11-1 cont.

LCFS SF11-2 cont.

Introduction

DuPont is an industry leader in providing products for agricultural energy crops, feedstock processing, animal nutrition, and biofuels. Our three-part approach to biofuels includes: (1) improving existing ethanol production through differentiated agriculture seed products, crop protection chemicals, as well as enzymes and other processing aids; (2) developing and supplying new technologies to allow conversion of cellulose to ethanol; and (3) developing and supplying next generation biofuels with cellulosic ethanol and biobutanol.

We bring the perspective of a company deeply involved in the agricultural and biofuels industries. Our seed business DuPont Pioneer sells corn seed to farmers growing for a variety of end-use markets, including grain ethanol production. Our intimate relationship with our farmer customers and our extensive research provides us significant insight into the agronomics of the harvest and management of corn stover as a cellulosic feedstock. We provide a variety of products for the grain ethanol business as well, including saccharification enzymes and fermentation processing aids, and so have an intimate knowledge of the operation of these relevant sugar fermentation operations.

DuPont began its research into cellulosic technology a decade ago. What started as a lab scouting project grew into a full scale commercialization effort. In 2009, DuPont opened a demonstration facility in eastern Tennessee producing cellulosic ethanol from both corn stover and switchgrass. For the past four years, we have brought together growers, academia, public institutions like the USDA and custom equipment makers to conduct harvest trials on corn stover. All this work culminated in the groundbreaking of a 30 million gallon per year facility in December of 2012 in Nevada, Iowa, located approximately 40 miles north of Des Moines. I am happy to report that we are in the very final stages of construction, commissioning has been initiated and we will be open for business later this year. We anticipate that a number of other companies in addition to DuPont will bring cellulosic volumes to the market. Multiple companies are constructing, starting up or operating facilities producing renewable fuels from a wide variety of cellulosic feedstocks including corn stover, switchgrass, wheat straw, municipal solid waste and wood fiber. Many of these are large, well-capitalized, sophisticated companies with long track records in designing, constructing and operating manufacturing facilities. This diversity of operations provides a high level of confidence for multiple technologies succeeding at commercial scale.

In addition to cellulosic ethanol, DuPont is pursuing another advanced renewable fuel with our partner BP in a 50/50 joint venture called Butamax™. The joint venture has developed and extensively tested bio-butanol, a higher alcohol fuel produced by fermenting biomass. Biobutanol has excellent fuel properties, with higher energy density than ethanol and the ability to be distributed via the existing gasoline infrastructure, including pipelines. It also reduces volatility, allowing butanol gasoline blends to be used in the summer in regions that currently require waivers from air quality regulation for the use of ethanol-gasoline blends. Because butanol has less affinity for water and is a weaker solvent than ethanol, it will be more compatible with existing equipment, including small engines.

The proposed modification to Provisional Pathways

In the Proposed 15-day Regulation Order containing the Second Notice of Modified Text and Availability of Additional Documents and Information for the Proposed Re-Adoption of the Low Carbon Fuel Standard, the Air Resources Board proposes the following in Section 95488 (d)(1)(D) and (d)(2):

DUPONT

(D) A temporary FPC approved for use by the Executive Officer will be permitted for LRT-CBTS reporting purposes for up to two quarters. Reporting will be granted only for the quarter during which a temporary FPC is approved for use and the subsequent full quarter.

* * *

(2) Provisional Pathways. As set forth in sections 95488(c)(3) and (c)(4)(I)2., LCFS fuel pathways are generally developed for fuels that have been in full commercial production for at least two years. In order to encourage the development of innovative fuel technologies, however, applicants may submit New Pathway Request Forms, as set forth in section 95488(c)(1), covering Tier 1 and Tier 2 facilities that have been in full commercial operation for less than two years, provided they have been in full commercial production for at least one full calendar quarter. If that form is subsequently approved by the Executive Officer, as set forth in section 95488(c)(2), the applicant shall submit operating records covering all prior periods of full commercial operation, provided those records cover at least one full calendar quarter. The following subsections govern the development, evaluation, and post-certification monitoring of such provisional pathways.

Analysis and Recommendations

The proposed text is overly restrictive and burdensome for both California and biofuels interests that are set to bring new technologies and fuels to market in California. DuPont fully appreciates the need for accurate CI values for fuel that is sold pursuant to the LCFS while also encouraging production and growth for the advanced biofuels sector. For this reason, we are highlighting the following concerns with the Second Notice of proposed modified text from above:

1. The current proposed text would by default assign a temporary, conservative CI value to these fuels that can only be applied for two quarters. This means that the temporary CI credits could lapse before the fuel pathway is approved. Any waiting period that prevents these fuels from receiving CI credit is fundamentally unfair and is not based on principles of sound science.

2. Any waiting period that prevents a biofuels producer from receiving CI credits will prevent and delay fuel from being sold in California. DuPont's cellulosic ethanol is being manufactured in Iowa. Without the benefit of the CI credit, it would be unreasonable for us to make special arrangements to ship our fuel to California. In addition, obligated parties in California would have no reason to purchase fuel without CI credits. Given their obligations under the LCFS, they would need to purchase fuel with CI credits.

3. Any waiting period that prevents a biofuels producer from receiving CI credits would create an unfair competitive advantage for existing fuel producers. These producers would not be required to wait to receive CI credits thereby rewarding current producers.

LCFS SF11-1 cont.

4. New facilities need to be able to sell fuel for full market value from initial production and on a continuous basis in order to survive. Biofuels facilities do not have storage capacity beyond one or two days of fuel production. In addition, encouraging growth in the cellulosic and advance biofuels sector can only be achieved with supportive federal and state biofuels policies. A waiting period for CI credits would discourage rather than encourage growth. LCFS SF11-1 cont.

5. The temporary fuel production code CI for cellulosic ethanol is 41.05 as set forth in Table 7 in Section 95488. There is a very high probability that after one quarter of production and subsequent quarters of energy data submitted, that the CI value for this fuel will be reduced significantly. Therefore, we respectfully request a process for which any documented change in the CI value, in either the positive or negative direction, enables fuel producers to receive credit or require a debit for the change in CI value. LCFS SF11-2 cont.

Given the concerns above, DuPont recommends that the regulations be modified to provide the Air Resources Board the requisite flexibility to extend the assigned temporary fuel production code CI value as long as necessary while the new producer is actively pursuing a new pathway approval. LCFS SF11-1 cont. New producers should then be able to revise the CI value as quarterly energy collection data warrants with a debit or credit applied that reflects the change in CI value. LCFS SF11-2 cont.

Thank you for the opportunity to comment on the Second Notice of the Proposed 15-day Regulation Order for the Proposed Re-Adoption of the Low Carbon Fuel Standard as this is an important issue for DuPont's biofuels business. Please contact me at Jan.Koninckx@dupont.com if you have any questions about the comments provided.

Sincerely,

Jan Koninckx

DuPont Industrial Biosciences

11_SF_LCFS_DuPont

1232. Comment: **LCFS SF11-1**

The commenter believes that the fuel pathway certification process could extend beyond the period of time covered by the temporary fuel pathway codes (FPC).

Agency Response: The burden to furnish complete applications rests on the applicant. The time-limited availability of the FPC serves to limit the applicant from "application grid-lock" where requested missing information is not furnished by the applicant, nor can staff proceed further with processing the application without the missing information.

1233. Comment: **LCFS SF11-2**

This comment is related to compensating the fuel producers or regulated parties as a result of provisional CIs being determined to be higher or lower than the values assigned by the temporary Fuel Pathway Code (FPC).

Agency Response: The temporary FPCs have been conservatively estimated, are deemed to be valid, and final. To the extent that they are viewed as too high, that is meant to motivate a prompt application for an individualized CI. Allowing downward adjustments could result in endless and numerous requests for adjusted CI's – a workload that ARB staff could not keep up with.

RFA RENEWABLE FUELS ASSOCIATION

July 8, 2015

Mary Nichols
Chairwoman
California Air Resources Board
1001 "I" Street
Sacramento, CA 95812

Dear Chairwoman Nichols,

The Renewable Fuels Association (RFA) appreciates the opportunity to comment on proposed regulatory changes associated with the re-adoption of the Low Carbon Fuels Standard (LCFS) (Second Notice of Public Availability of Modified Text, June 23, 2015).

We are encouraged that the Air Resources Board (ARB) is revising several problematic elements of the first 15-day notice (released June 4, 2015) based on feedback from RFA and other interested stakeholders. A number of provisions in the first 15-day notice regarding establishment of fuel pathways were simply unworkable and we commend ARB for taking steps to address stakeholder concerns.

However, while the second 15-day notice represents a marked improvement over the initial proposed modified text, RFA believes ARB must make additional changes to ensure the pathway approval process is efficient and presents minimal administrative burden for both low carbon fuel producers and ARB staff. In addition, RFA again urges ARB to revise its indirect land use change (ILUC) analysis to reflect the best available science and data. Our comments and concerns on the second 15-day notice are detailed below.

1. **We support the new language added to section 95488(a)(2) allowing fuel producers to request re-certification of "legacy pathways" that were certified under prior versions of the LCFS.**

Under the first 15-day notice, the requirement that all low carbon fuel producers with existing certified pathways must entirely re-apply for those pathways was unnecessarily burdensome and duplicative. Thus, we welcome ARB's proposed modifications to section 95488 to streamline the re-certification process by allowing fuel producers to request re-certification of existing pathways by ARB staff using CA-GREET 2.0. We agree that, in most cases, ARB staff "already has all of the information needed to conduct recertification without any submission of additional data by the applicant…", and we support the use of a simple, straightforward electronic form through the LRT system to request re-certification. We assume that the key variables that influenced an individual ethanol producer's existing pathway carbon intensity (CI) score (e.g., natural gas use, transportation distances, ethanol yield, etc.) will be retained by ARB staff for the re-certification using CA-GREET 2.0. However, it is somewhat unclear how LCFS SF12-1

ARB will handle producer-specific inputs in CA-GREET 2.0 that were not included in approved pathway petitions based on CA-GREET 1.8 (e.g., yeast and enzymes). We encourage CARB to include fields for any additional information needed for re-certification on the online form. LCFS SF12-1 cont.

2. **RFA supports the proposed prioritization of fuel pathway re-certifications for "batch processing."**

LCFS SF12-2

Based on the volumes of distinct renewable fuels delivered to the California market, and the different roles certain fuels have played in helping regulated parties achieve compliance, we agree with ARB's proposed prioritization of fuel types for "batch processing" of re-certification requests.

3. **The description of "Tier 1" fuels in section 95488(b)(1) remains somewhat confusing and ambiguous. ARB should clarify that the "Tier 1" classification applies to specific *fuels* not specific *facilities* or *individual pathways*.**

ARB describes Tier 1 fuels as being "[c]onventionally-produced alternative fuels of a type that has been in full commercial production, excluding start-up or ramp-up phase, for at least three years, and for which certified LCFS pathways have existed for at least three years shall be classified into Tier 1." This language has caused much confusion amongst conventional ethanol producers. Many producers have interpreted this description as applying to individual facilities or specific Method 2 pathways; and some producers who have had an approved Method 2 pathway for fewer than three years have interpreted this language as meaning their fuel cannot be classified as "Tier 1." ARB should clarify that the "Tier 1" classification applies to specific *fuels*—not specific facilities—that have existed commercially for at least three years. In other words, ARB should clarify that all starch-based ethanol produced using conventional methods is "Tier 1" fuel. LCFS SF12-3

4. **"Tier 1" fuels should be excluded from the "Provisional Pathways" requirements described in section 95488(d)(2).**

For unexplained reasons, the second 15-day notice inserted Tier 1 fuels into the section governing provisional pathways. Because ARB is highly familiar with the feedstocks and production technologies associated with Tier 1 fuels, it is completely unnecessary to apply the same provisional pathway conditions to new Tier 1 fuel producers that are applied to new Tier 2 fuels. New facilities producing Tier 1 fuels should receive final approval of their CI scores by the Executive Officer based on one quarter of operational records, as facility operations and the fuel CI would not be expected to change following start-up. LCFS SF12-4

5. **Investment in the development of new "Tier 2" fuels is discouraged by the "Provisional Pathway" requirements described in 95488(d)(2). ARB should allow provisional CI scores to be based on pilot-scale data, rather than requiring operational data for a full quarter of commercial production.**

LCFS SF12-5

Developers of new and innovative low-carbon fuels will likely find it difficult to attract financing for scale-up due to ARB's requirement that new "Tier 2" facilities must have operational data for one full quarter of commercial production before even submitting a new pathway petition.

Developers of “Tier 2” fuel facilities are unlikely to raise the necessary capital for construction of commercial-scale facilities without the ability to show potential investors or lenders a provisional CI score that has been approved by ARB.

We agree that ARB can and should verify provisional CI scores using actual operational data once the Tier 2 facility is up and running. Further, if actual operational data indicates that the actual CI of the fuel is higher than the provisional CI score, we agree that the Executive Officer should “adjust the number of credits or reverse any provisional credit in the producer’s account without a hearing.” However, we strongly believe provisional CI scores should be approved on the basis of pilot-scale data provided by Tier 2 fuel developers so that the LCFS regulation encourages—rather than discourages—investment in new and innovative low-carbon fuels. LCFS SF12-5 cont.

6. **RFA again urges ARB to revise its indirect land use change (ILUC) analysis to reflect the best available science and data.**

RFA continues to strongly dispute the analyses underlying the ILUC values in ARB’s re-adoption proposal (Table 5). We have commented numerous times on ARB’s most recent ILUC analysis and provided volumes of new information and data from independent sources that support much lower ILUC values for corn ethanol. To that end, we are re-attaching our recent comments to ARB on the staff’s flawed ILUC analysis. LCFS SF12-6

RENEWABLE
FUELS
ASSOCIATION

February 16, 2015

Mary Nichols
Chairwoman
California Air Resources Board
1001 "I" Street
Sacramento, CA 95812

Dear Chairwoman Nichols,

The Renewable Fuels Association (RFA) appreciates the opportunity to provide comment on the California Air Resources Board's (CARB) Initial Statement of Reasons (ISOR) regarding re-adoption of the Low Carbon Fuel Standard (LCFS). While the proposal for re-adoption marks a slight improvement over the current regulation, we remain deeply concerned by several aspects of the proposal and believe it threatens the long-term durability of the LCFS program. Thus, RFA believes the ISOR needs significant revision before it can be presented to the Board for approval.

Grain-based ethanol has made a substantial contribution to LCFS compliance in the first four years of the program. Indeed, ethanol has accounted for **59% of total credits** generated from 2011Q1 through 2014Q3, and 95% of the ethanol used for compliance has been grain-based ethanol, according to CARB reporting data. If not for the LCFS credits generated by grain-based ethanol, deficit generation would have certainly outpaced credits by now, and compliance with the program would be extremely difficult, if not impossible. Thus, it is not an exaggeration to state that the LCFS has endured so far **only because of the contributions of grain ethanol**. Yet, the ISOR proposes to continue punitive carbon intensity (CI) penalties for grain ethanol and other crop-based biofuels based on purported indirect land use change (ILUC) emissions. If finalized, the proposed re-adoption regulation will make the use of most grain ethanol infeasible for compliance as early as 2016. Why would CARB use flawed and prejudicial analysis to purposely diminish the compliance viability of the low-carbon fuel that has provided the largest volume of credits to date?

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

As the attached comments show, CARB's ILUC analysis remains technically and methodologically flawed, and grossly overstates the land use impacts associated with biofuels expansion. A November publication by the Center for Agricultural and Rural Development (CARD) at Iowa State University makes a remarkably important contribution to the debate over ILUC modeling. The report marks the first time that actual land use changes over the past decade (i.e., the period in which commodity crop prices rose to record levels) have been quantified and discussed in the context of CARB's ILUC modeling results. The CARD/ISU paper, which is discussed in detail in the attached comments, found that "[t]he pattern of recent land use changes suggests that **existing estimates of greenhouse gas emissions caused by**

land conversions due to biofuel production are too high because they are based on models that do not allow for increases in non-yield intensification of land use." In essence, the authors found that the primary response of the world's farmers to higher crop prices "…**has been to use available land resources more efficiently rather than to expand the amount of land brought into production**."

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

The CARD/ISU research was submitted to CARB in early December. However, CARB's ISOR fails to even mention or acknowledge the work in any way. For the first time, we have real-world data that provides important insight into actual market responses to increased biofuels demand and higher crop prices. As described in the attached comments, we believe CARB must take into account the new CARD/ISU research and use it to immediately re-calibrate the GTAP model.

We appreciate CARB's consideration of our attached comments, which also address CA-GREET model revisions and assumptions used in CARB's illustrative compliance scenarios. We welcome further dialog on this subject and look forward to responses to any of the comments offered in the attached document.

Sincerely,

Geoff Cooper

Geoff Cooper
Senior Vice President

RENEWABLE FUELS ASSOCIATION

COMMENTS OF
THE RENEWABLE FUELS ASSOCIATION
IN RESPONSE TO THE CALIFORNIA AIR RESOURCES BOARD
STAFF REPORT: INITIAL STATEMENT OF REASONS
TO CONSIDER
RE-ADOPTION OF THE LOW CARBON FUEL STANDARD (LCFS)

The Renewable Fuels Association (RFA) offers the following comments in response to the California Air Resources Board's (CARB) release of its Initial Statement of Reasons (ISOR) proposing re-adoption of the Low Carbon Fuel Standard (LCFS)

I. Indirect Land Use Change Analysis

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

CARB continues to rely on a fundamentally flawed approach to predicting indirect land use change (ILUC) that favors hypothetical modeling results over empirical data, real-world observations, and improved assessment methods.

Nearly six years have passed since CARB originally adopted the LCFS, which included carbon intensity (CI) penalties for certain biofuels for predicted ILUC. In the intervening years since the program was adopted, the scientific understanding of land use change has significantly progressed. Retrospective analyses of global agricultural land use have been conducted, actual market responses to increased demand and higher commodity prices have been observed and characterized, the reliability of predictive economic models has been improved, and new data has emerged to better guide certain modeling assumptions.

Yet, in spite of these advances in the science, CARB continues to rely on the narrow—and completely unsubstantiated—view that "[a] sufficiently large increase in biofuel demand in the U.S. would cause non-agricultural land to be converted to cropland both in the U.S. and in countries with agricultural trade relations with the U.S."

CARB's entire approach to ILUC is founded on the notion that farmers are limited to only two responses to increased demand for crops. While CARB recognizes four potential market responses to heightened demand for crops, its predictive modeling framework essentially allows only two of these responses to play out. The four potential market responses acknowledged by CARB are shown below.

- **Response 1**: "Grow more biofuel feedstock crops on existing crop land by reducing or eliminating crop rotations, fallow periods, and other practices which improve soil conditions";
- **Response 2**: "Convert existing agricultural lands from food to fuel crop production";
- **Response 3**: "Convert lands in non-agricultural uses to fuel crop production"; or
- **Response 4**: "Take steps to increase yields beyond that which would otherwise occur."

CARB theorizes that there is essentially no crop yield response to increased demand (Response 4 above), and an artificially low elasticity value is used to reflect this belief in CARB's economic model. Further, the CARB modeling framework does not allow double-cropping or reduction of fallow/idle cropland; thus, Response 1 above is also eliminated. *As a result, CARB assumes increased demand for crops can only be met through displacement of animal feed and conversion of non-agricultural lands to crop production (Responses 2 and 3 above).* Not coincidentally, Responses 2 and 3 have the most significant GHG impacts.

CARB has produced no evidence whatsoever that such land conversions have actually occurred on a meaningful scale in response to the LCFS or growth in U.S. biofuels demand. Indeed, empirical evidence suggests that demand growth has been primarily met through Responses 1 and 4 above, which are effectively excluded from CARB's modeling framework.

Instead of tuning the modeling framework to reflect these observed market responses, CARB continues to rely on conjectural assumptions and model predictions to penalize biofuels for hypothetical market outcomes. In essence, CARB is using the exact same approach to estimating ILUC emissions that it used six years ago, making only minor adjustments to certain model parameters based on "judgment calls."

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

RFA believes the principles of sound policymaking and regulation demand that CARB recognize and incorporate the best available science and data in the LCFS process, particularly when empirical data is available to fill important knowledge gaps.

a. A New Publication by Babcock & Iqbal Has Important Implications for CARB's ILUC Analysis. CARB Should Give Serious Consideration to the Findings of the Paper, and Adjust its ILUC Estimation Methodology Accordingly

In mid-November, Babcock & Iqbal at the Center for Agricultural and Rural Development (CARD) published Staff Report 14-SR 109, "Using Recent Land Use Changes to Validate Land Use Change Models."[1] The paper (Attachment 1) makes a remarkably important contribution to the debate over ILUC modeling. The report marks the first time that actual global land use changes over the past decade (i.e., the period in which commodity crop prices rose to record levels) have been quantified and discussed in the context of CARB's ILUC modeling results. <u>The report was submitted to CARB staff in early December 2014, yet there is not a single mention of the paper (nor is there a response to its findings) in the ISOR.</u>

Babcock & Iqbal examined historical global land use changes from 2004-2006 to 2010-2012 and determined that "…the primary land use change response of the world's farmers from 2004

[1] Babcock, B.A. and Z. Iqbal (2014), Using Recent Land Use Changes to Validate Land Use Change Models. Center for Agricultural and Rural Development Iowa State University Staff Report 14-SR 109. Available at: http://www.card.iastate.edu/publications/synopsis.aspx?id=1230

to 2012 has been to use available land resources more efficiently rather than to expand the amount of land brought into production."[2] Among other important revelations, the paper shows that key regions where CARB's GTAP analysis predicts biofuels-induced conversion of forest and grassland have actually experienced substantial *losses* of cropland.

Unfortunately, CARB's GTAP analysis does not take into account the methods of intensification (e.g., double-cropping, increases in the share of planted area that is harvested, return of fallowed land to production) that have been observed in the real world over the past decade. According to Babcock & Iqbal, GTAP and other models "…do not capture intensive margin land use changes so they will tend to ***overstate land use change at the extensive margin and resulting emissions***."[3] This finding is corroborated by Langeveld et al (2013) (Attachment 2), who found GTAP and other models have "…limited ability to incorporate changes in land use, ***notably cropping intensity***," and "[t]he increases in multiple cropping have often been overlooked and should be considered more fully in calculations of (indirect) land-use change (iLUC)."[4]

Ultimately, the Babcock & Iqbal work calls into question the plausibility of CARB's GTAP results and demonstrates that CARB's ILUC results are directionally inconsistent with real-world data and observed market behaviors in many regions. The data and discussion presented in the paper challenge the very underpinnings of CARB's analysis and are simply too important for the agency to ignore. Thus, as described more fully in the comments below, we believe CARB should move immediately to calibrate its GTAP model using the real-world land use data made available by Babcock & Iqbal.

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

b. Countries and regions where cropland has decreased and/or forestland and grassland have increased over the past decade should be presumed to not have converted pasture or forest to crops in response to biofuel-induced higher prices. CARB should calibrate its GTAP model to reflect the absence of extensive land use change in these countries and regions.

At the outset, it is important to note that the lack of a "counterfactual case" to compare to the real-world data (i.e., the *ceteris paribus* principle) is not sufficient reason to ignore the Babcock & Iqbal results. CARB has stated that comparing GTAP results to real-world data is "not productive," because it is not possible to compare real-world data to a counterfactual case in which biofuel expansion did not occur. Appendix I to the ISOR further states:

> GTAP-BIO is not predicting the *overall aggregate* market trend—only the incremental contribution of a single factor to that trend. If GTAP-BIO projects reduced exports, for example, this should be understood to mean that exports will be lower than what they would have been in

[2] *Id,* Executive Summary.
[3] *Id,* Executive Summary. (emphasis added)
[4] Langeveld, J. W.A., Dixon, J., van Keulen, H. and Quist-Wessel, P.M. F. (2014), Analyzing the effect of biofuel expansion on land use in major producing countries: evidence of increased multiple cropping. Biofuels, Bioprod. Bioref., 8: 49–58. doi: 10.1002/bbb.1432. (emphasis added)

> the absence of the effect being modeled (increased ethanol production, in this case). It is the difference between predicting an absolute change and a relative change.[5]

This statement by CARB seems to misunderstand the recommendation from stakeholders to consider and integrate empirical data and observed outcomes into CARB's modeling work. *RFA and other stakeholders fully understand that CARB's GTAP modeling exercise is meant to isolate only the impacts of biofuels expansion on land use.* However, empirical data can be useful for checking the directional consistency and general reasonableness of model predictions. According to the Babcock & Iqbal, "…the historical record of land use changes can be used to provide insight into the types of land that were converted…"[6]

Comparing empirical land use data to GTAP predictions is particularly useful in regions where cropland has contracted over the past decade. That is, if cropland in a certain region *decreased* according to historical data, then there is no justification for asserting—as GTAP does—that biofuel expansion caused extensive margin conversion of natural forest and grassland in that region. In other words, if there was no cropland expansion resulting from biofuels expansion *and all other factors combined* (i.e., in aggregate), then there certainly is no rationale for arguing that biofuels expansion in isolation of other factors led to cropland expansion.

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

That is not to say, however, that biofuels expansion did not have an impact on land use in the region. Indeed, cropland may have contracted *even more* in a "world without biofuels" (i.e., the counterfactual case). In other words, some additional cropland might have gone out of production in the absence of biofuels, and the function of biofuels demand may have been to keep that cropland engaged in production. Thus, the appropriate question for regions that have experienced cropland *contraction* over the past decade is whether there was foregone sequestration because of biofuels—***not*** whether there was extensive conversion of forest and grassland and soil carbon loss because of biofuels. According to Babcock & Iqbal:

> The countries in Figure 8 that either had negligible or negative extensive land use changes **should be presumed to not have converted pasture or forest to crops in response to biofuel-induced higher prices**. Rather, the presumption should be that **any predicted change in land used in agriculture came from cropland that did not go out of production**.[7]

Figure 8 from Babcock & Iqbal is embedded below. Note that many countries and regions for which CARB's latest GTAP analysis predicts extensive change from forest and grassland to crops actually showed cropland losses or no change. This includes Canada, EU, Japan, China, India, Russia, the U.S., and Oceania. Further, the amount of corn ethanol-induced conversion of

[7] *Id*. at 26.

forest and grassland in the U.S. predicted by CARB's GTAP model is two to four times larger than the actual extensive land use change in the U.S. driven by ***all factors in aggregate***.

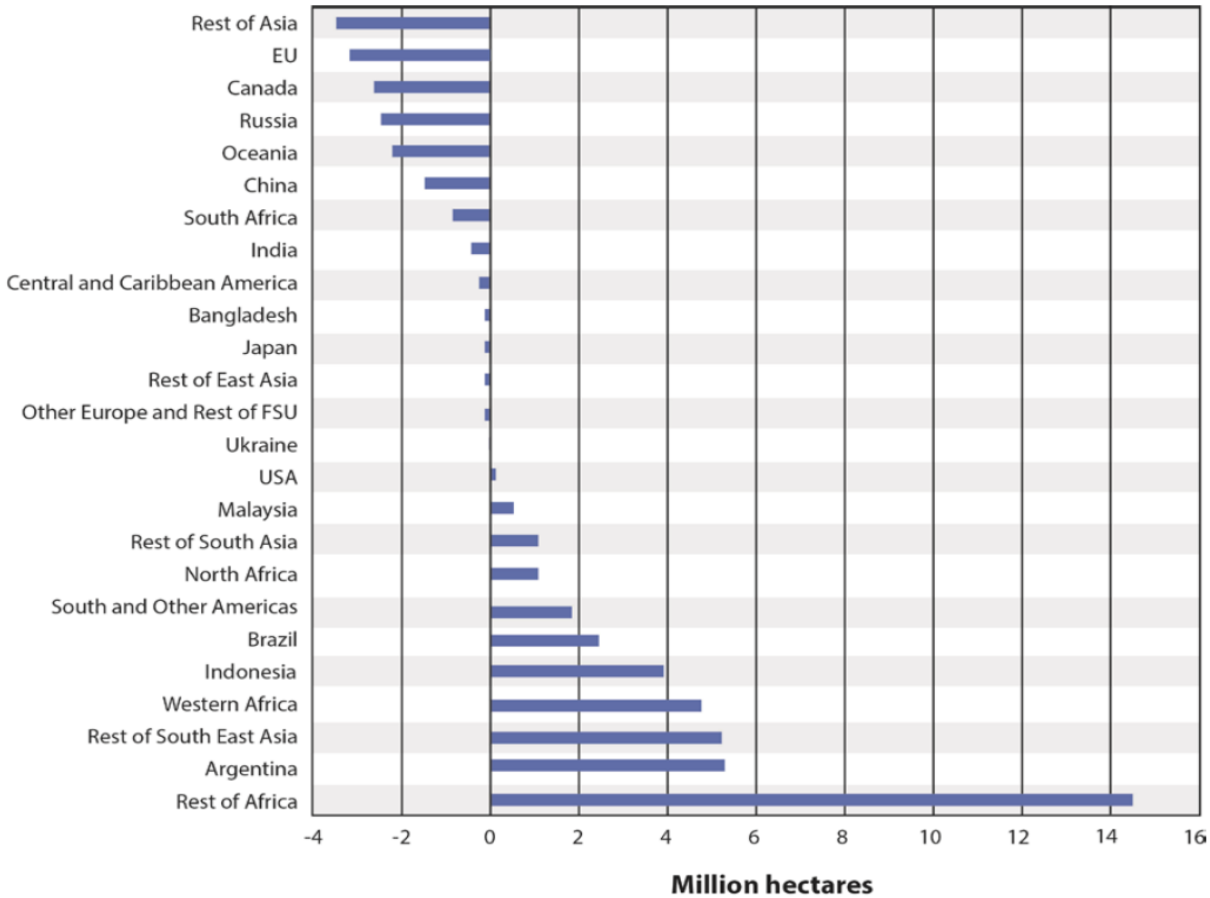

Figure 8. Change in Arable Land Plus Permanent Crops: 2004–2006 to 2010–2012

According to Babcock & Iqbal, the land use emissions implications in countries and regions where cropland decreased or stayed the same are that:

> …the type of land converted to accommodate biofuels was not forest or pastureland but rather **cropland that did not go out of production**. Calculation of foregone carbon sequestration depends on what would have happened to the cropland if it did not remain in crops which, in turn, depends on where the cropland is located and the potential alternative uses. **The magnitude of the change in estimated CO2 emissions from cropland that is prevented from going out of production relative to forest that is converted to cropland is potentially large.**[8]

Unfortunately, CARB's GTAP analysis suggests there was conversion of forest and grassland to crops in regions where real-world data show cropland actually contracted. The disagreement

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

[8] *Id.*

between GTAP predictions and real-world data highlights the implausibility of GTAP results for certain regions. CARB can—and should—correct its analysis to better align with real-world land use patterns. The following section provides a method for calibrating CARB's GTAP model to better reflect observed land use changes.

c. CARB should use data from Babcock & Iqbal (2014) to immediately calibrate its GTAP model to reflect real-world land use change patterns in key regions.

As stated in the Babcock & Iqbal paper, CARB should not presume that higher crop prices have caused conversion of forest and grassland to crops in countries and regions where cropland has actually decreased over the past 10 years. Thus, we believe CARB should calibrate its GTAP model to disallow forest and grassland conversion in AEZs and regions for which empirical data show forest or grassland expansion and/or cropland contraction. This can be easily accomplished by excluding GTAP predicted land conversions for the countries in Figure 8 of Babcock & Iqbal that show negative extensive change (i.e., loss of cropland). A more detailed method for accomplishing this calibration is available in comments submitted to CARB by Air Improvement Resource on Dec. 4, 2014.[9]

It could be argued that these countries should still be subject to emissions penalties for foregone sequestration, in that biofuels demand may have caused some cropland to remain in production that may otherwise have transitioned to some other use. But this should only be done if it can be demonstrated that the alternative use of the land would have resulted in carbon sequestration that is greater than the sequestration achieved if the land remained engaged in crop production.

For the countries in Figure 8 that *do* show extensive land use change over the past 10 years, CARB can continue to rely on GTAP predictions, but should also conduct more intensive research to better understand the precipitating causes of land conversions at the extensive margin in those countries. For example, while Sub-Saharan Africa (excluding South Africa) shows significant extensive change over the past decade, it is likely unrelated to biofuels expansion in the U.S. According to Babcock & Iqbal, "The extent to which extensive expansion in African countries was caused by high world prices is likely small for the simple reason that higher world prices were not transmitted to growers in many African countries."[10]

In the longer term, CARB should migrate to the soon-to-be-released dynamic version of GTAP that contains updated baseline economic data. Further, CARB should closely monitor efforts to validate and back-cast the new version of GTAP and be prepared to consider new results from these exercises.

d. CARB's GTAP Analysis Should Adopt CA-GREET2.0 Assumptions for Co-products Displacement Rates

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

[9] Air Improvement Resources comments available at: http://www.arb.ca.gov/fuels/lcfs/regamend14/air_12042014.pdf
[10] Babcock, B.A. and Z. Iqbal (2014) at 16.

The recently released CA-GREET2.0 model correctly assumes that distillers grains from ethanol production displace both corn and soybean meal in livestock and poultry rations.[11] The total mass of corn, soybean meal, and urea displaced by 1 pound of distiller grains is 1.111 pounds. While this assumption has modest impacts for the direct emissions associated with corn ethanol's lifecycle, the impacts on land use are significant. We have detailed these impacts in many previous comments to CARB, dating back to 2008.

Unfortunately, CARB's GTAP analysis continues to assume 1 pound of distillers grains displaces only 1 pound of corn. This is problematic for at least two reasons: 1) CARB's assumptions and boundary conditions for estimates of direct and indirect emissions should be consistent and uniform, 2) CARB's current GTAP assumptions on distillers grains displacement are simply inconsistent with the reality of how distillers grains are fed.

We are fully aware that there is no simple method for setting displacement ratios in GTAP, as interactions amongst the various sectors in the model are characterized in terms of economic values (e.g., expenditures, receipts, etc.). However, the economic values representing ethanol co-products in CARB's GTAP model are based on the 2004 database. Obviously, there have been significant changes in the distillers grains market since 2004; the ways in which these co-products are traded, priced, and fed have evolved dramatically. As we have discussed in previous comments to CARB, the agency can better reflect real-world feeding practices (i.e., some displacement of soybean meal) by adjusting the economic values associated with co-product trade in GTAP. RFA believes CARB must make this adjustment to ensure consistent boundaries and assumptions across its direct and indirect emissions analysis.

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

e. CARB <u>Still</u> Has Not Justified its Proposal to Use a Yield-Price Elasticity Value That is Lower than Recommended by Both Purdue and CARB's Own Expert Work Group. CARB Should Use 0.25 as the Central Value, Not the Proposed Value of 0.185.

Despite new data and published scientific papers supporting the use of a range for YPE of 0.14-0.53, CARB continues to propose using a range of 0.05-0.35. CARB staff has continued to ignore input from stakeholders, academia, and its own Expert Work Group on this parameter, instead relying on input from paid contractors at UC Davis and its own "expert judgment."

In Appendix I, CARB states that "[a]n expert from UC Davis, contracted to conduct a review and statistical analysis of data from a few published studies also concluded that YPE values were small to zero." Yet, it is quite clear from the brief (and somewhat unclear) report from the UC Davis contractor that the YPE response was examined only over the short term (i.e., 1-2 years).

This is inappropriate and scientifically indefensible, as demonstrated by previous stakeholder comments and remarks from Purdue University. For example, during the March 11 workshop on

[11] The latest version of CA-GREET2.0 is available at: http://www.arb.ca.gov/fuels/lcfs/ca-greet/ca-greet.htm

ILUC, Purdue University Prof. Wally Tyner explained why it is inappropriate to include short-run estimates in the range used for CARB's analysis, stating:

> The yield-price elasticity is a *medium-term elasticity*…and we normally think of that as about 8 years. I personally think, and our group thinks, that any of those papers in the literature that represent one year are *totally irrelevant* to this. They may be fine for a one-year estimate, but a one-year estimate is totally irrelevant. Most of the short-term estimates are very low and most of the medium-term [estimates] were much higher—in the range of the 0.25 that we currently use.[12]

Tyner underscored this point again in a note to CARB following the March 11 workshop: "The yield to price elasticity does not measure changes over one crop year. In fact, ***any estimate done over one year would be totally inappropriate for GTAP and should be excluded from consideration in determining appropriate values for the parameter***."[13]

Babcock and other members of the Expert Work Group's Elasticity Subgroup agreed that the use of a short-run elasticity is inappropriate for the purposes of CARB's GTAP scenario runs:

> …to the extent that existing studies provide reliable one-year estimates, they underestimate the long-run response of yields to price. There are sound theoretical reasons for believing that there are lags in the response to higher crop prices. Farmers have an incentive to adopt higher-yielding seed technologies and other management techniques with higher prices. Switching from one seed variety or technology such as seed-planting populations, may require more than a single season to accomplish. And there are likely five to 15 year lags involved in developing new seed varieties and new management techniques that may be only profitable under high prices.[14]

The Schlenker work, which has served as the basis of CARB's use of inappropriately low YPE values, was critiqued by the EWG's Elasticities Subgroup. The subgroup raised several concerns with the Schlenker data, none of which (to our knowledge) have been adequately addressed by CARB staff. In short, the Elasticities Subgroup found that, "[t]he Roberts and Schlenker (2010) results provide ***no evidence that there is not a price-yield relationship***,

they just find evidence that any short-run price yield relationship is overwhelmed by variations in yields caused by weather."[15]

f. The GTAP model's inability to explicitly consider double-cropping further justifies the use of a higher range of price-yield elasticity values.

As explained by CARB's EWG, "…higher prices give farmers a greater incentive to double crop."[16] Indeed, Babcock & Iqbal adds to the body of empirical evidence that double-cropping has significantly increased during the recent period of higher commodity prices (see also Babcock & Carriquiry[17]). Unfortunately, GTAP simulations do not explicitly allow increased demand for agricultural commodities to be satisfied through increased double-cropping. <u>While we believe the best way to account for the impact of double-cropping is to calibrate the GTAP model to the Babcock & Iqbal data (as described in previous sections), and alternative method would be to raise the yield-price elasticity in regions where double-cropping is known to occur</u>.

The EWG Elasticities Subgroup recommended that the price-yield elasticity parameter could be used to partially account for double-cropping responses. In its final report, the subgroup explained that "the reality of double cropping" *by itself* justified the use of a positive (i.e., non-zero) value for the price-yield elasticity.[18] The subgroup recommended that "…for countries that have the opportunity to double crop, such as the U.S., Brazil, Argentina, and some Asian rice producing countries such as Thailand…an additional increment should be given to the price-yield elasticity."[19] To date, CARB staff has failed to account for increased double-cropping in its GTAP modeling scenarios. At a minimum, 0.25 should be used as an average value, and an additional increment of 0.1 should be added (total = 0.35) for regions where double-cropping is known to occur.

II. The New CA-GREET2.0 Model Marks a Major Improvement Over CA-GREET1.8b. However, Certain Improvements to CA-GREE2.0 Are Still Needed to Better Reflect the Direct Carbon Intensity of Ethanol Pathways

In general, RFA supports CARB's decision to revise and update its CA-GREET model based on the Argonne National Laboratory GREET1_2013 model. We believe Argonne's GREET1_2013 model contains a number of important improvements and updated inputs that more accurately reflect the current CI performance of corn ethanol and many other fuel pathways. Much has changed since CARB released the original CA-GREET model more than six years ago; ethanol and feedstock producers have rapidly adopted new technologies and practices that have significantly reduced the fuel's lifecycle CI impacts. Thus, it is encouraging to see the CA-

[19] *Id.*

GREET model finally catching up to the actual state of the industry. However, we believe the CA-GREET2.0 model could be further improved by adopting the recommendations below.

a. CARB Should Reduce Denaturant Content in Fuel Ethanol to 2.49% to Reflect Real-World Conditions

In order to comply with Federal requirements, ethanol producers limit the denaturant content of commercial fuel ethanol to 2.49% or less. GREET1_2013, upon which CA-GREET2.0 is based, appropriately assumes denaturant content is 2%. However, Appendix C to the ISOR specifies that CA-GREET2.0 assumes the non-ethanol content of denatured fuel ethanol is 5.4%, with 2.5% being denaturant, 1% being water, 0.5% being methanol, and 1.4% being "other." While denatured fuel ethanol does contain trace amounts of water (1% or less), methanol and "other" components are generally absent from the fuel or present in amounts below those specified by CARB. Further, CARB assumes that all non-ethanol constituents of denatured fuel ethanol—including <u>*water*</u> and "other"—have the same carbon intensity as CARBOB. This is an unsubstantiated and unfair assumption. CARB should fix the denaturant content at 2.49% and treat any remaining non-ethanol constituents (which would be mostly water) as having the same CI as the ethanol.

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

b. CARB Should Include the GREET1_2013 Default Value for Enteric Fermentation Impacts in the Corn Ethanol Pathway

For the CA-GREET2.0 model, CARB is proposing to exclude the GREET1_2013 credit for methane emissions reduction resulting from feeding DDGS. We strongly disagree with this proposal and CARB's rationale for the exclusion. We recommend that CARB adopt the GREET1_2013 methane emissions reduction credit for use in CA-GREET2.0.

CARB states that an "expanded system boundary" would be required for inclusion of methane emission reductions resulting from feeding DDGS to livestock. This implies that CARB views methane emissions reductions as a potential indirect or consequential effect. It could be argued that reduced methane emissions from livestock are a direct effect of corn ethanol expansion (via increased DDGS feeding). Nonetheless, even if we accept the argument that methane emission reductions are an *indirect* effect, CARB has no defensible reason for excluding these emission reductions. That is because CARB <u>*already has expanded the boundary conditions for its corn ethanol pathways to include consequential/indirect effects such as purported land use changes*</u>. CARB has also proposed to include indirect emissions associated with irrigation constraints, and at one point CARB was considering inclusion of hypothetical emissions that would indirectly result from "holding food consumption constant." Thus, CARB is proposing to include a number of potential indirect/consequential emissions sources in the corn ethanol lifecycle, but plans to selectively exclude potential emissions reductions (i.e., credits). This reflects inconsistent and asymmetrical boundary conditions (and possible bias) in CARB's analysis of corn ethanol emissions.

III. CARB's Compliance Scenario Assumptions Regarding the Availability of Sugarcane Ethanol and Related Credit Generation Seem Highly Implausible

CARB's new compliance scenarios continue to grossly over-estimate the amount of imported sugar-derived ethanol that is likely to be available to the U.S. and California marketplace in the future. As a result, CARB adopts an overly optimistic view of potential LCFS credit generation in the 2015-2020 timeframe.

In Appendix B, CARB states that its sugarcane ethanol estimate is derived from the Food and Agricultural Policy Research Institute's (FAPRI) World Agricultural Outlook. It should be noted that due to budget constraints, FAPRI has not produced a comprehensive World Agricultural Outlook report since 2011. It is unfathomable that CARB would rely on the 2011 FAPRI publication for its projections of sugarcane ethanol availability when more current projections are available from multiple sources.

Indeed, FAPRI itself continues to publish annual "Projections for Agricultural and Biofuel Markets."[20] These projections are published in March of every year. Much has changed in the Brazilian and world sugar and ethanol sectors since 2011, and FAPRI has since significantly revised its outlook for U.S. imports of sugarcane ethanol.

FAPRI's 2014 projections include yearly estimates of U.S. ethanol imports through 2023. FAPRI projects that U.S. ethanol imports will average **182 mg per year** in the 2015-2023 timeframe, with exports never exceeding 197 mg in any single year. *Importantly, these projections include the effects of the California Low Carbon Fuel Standard*. According to FAPRI:

- "Sugarcane ethanol imports from Brazil continue to decline in 2014 before leveling out."
- "Lower RFS requirements for advanced biofuel could imply reduced ethanol imports."
- "However, *low-carbon fuel requirements in California provide some incentive for continued ethanol imports*."

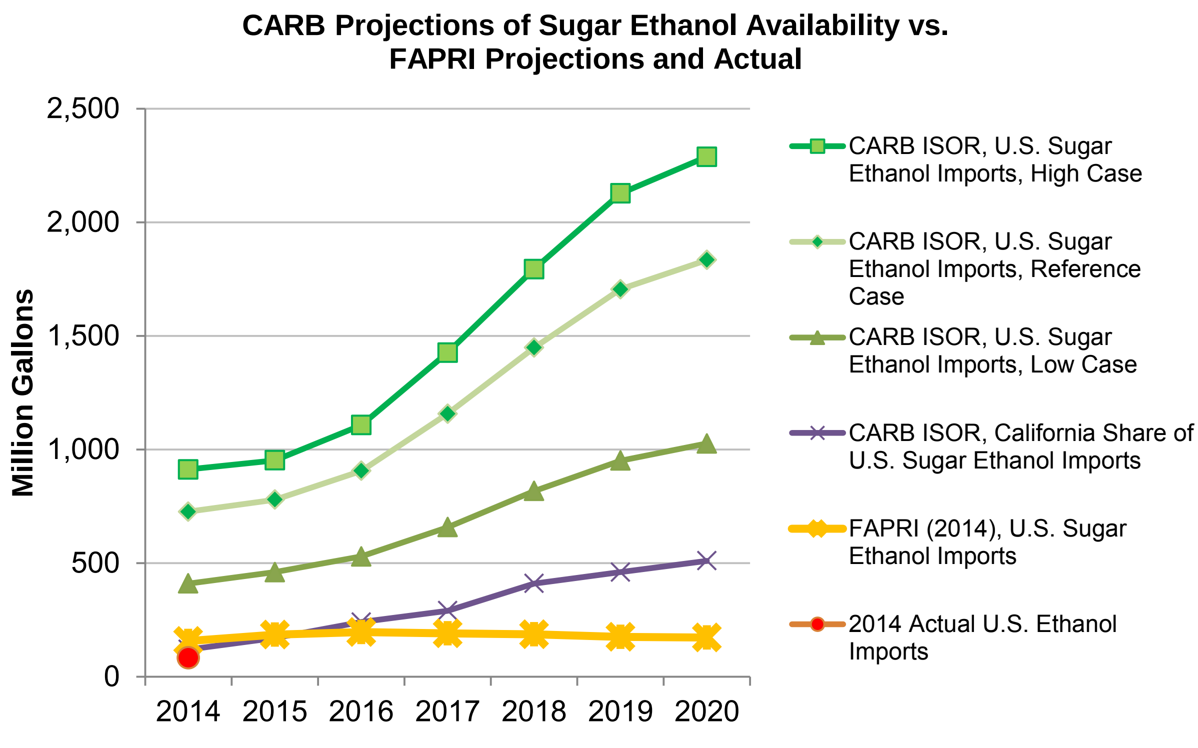
Thus, CARB's current 2020 projections (Appendix B reference, high and low cases) of sugarcane- and molasses-based ethanol are roughly 6-13 times higher than FAPRI's current outlook, which *do* take into the account the likely "pull" from the LCFS. Further, total ethanol imports to the entire United States (most of which were sugar-derived) were just 84 million gallons in 2014, compared to CARB's compliance scenario assumption of 410-912 million gallons. In fact, CARB's projection that California would receive 120 million gallons of sugar-related ethanol in 2014 is 42% larger than actual imports to the entire U.S. Of the 84 million gallons imported by the U.S., only 7.96 million gallons—or 9.5% of the U.S. total—entered through California ports. Thus, actual California imports in 2014 were equivalent to just 6.6% of the volume anticipated by CARB.

Reproduction of Comment Letter 8_OP_LCFS_RFA Comments LCFS 8-1 through LCFS 8-14

[20] 2014 FAPRI Baseline available here: http://www.fapri.missouri.edu/outreach/publications/2014/FAPRI_MU_Report_02_14.pdf

Similarly, CARB's projection that California will receive 510 million gallons of sugar-derived ethanol in 2020 compares to FAPRI's projection that the entire U.S. will receive only 172 million gallons of sugar ethanol that year.

CARB has suggested that higher LCFS credit values could lure larger volumes of sugar ethanol to California than projected by FAPRI. However, empirical data from the past four years show no discernible relationship between credit values and sugarcane ethanol imports to California.[21] It is also worth noting that Brazil is soon increasing its ethanol blend rate, which will further reduce the amount of sugarcane ethanol that is available to export.



We strongly recommend that CARB refine its estimates of sugar-related ethanol and use FAPRI's latest projections of sugarcane ethanol availability when conducting its analysis of potential fuel availability.

* * * * *

Thank you for considering RFA's comments on the ISOR for the re-adoption of the LCFS. We would be pleased to address any questions you may have regarding the contents of these comments or any other issues related to ethanol's role in the LCFS.

Executive Summary

Economics models used by California, the Environmental Protection Agency, and the EU Commission all predict significant emissions from conversion of land from forest and pasture to cropland in response to increased biofuel production. The models attribute all supply response not captured by increased crop yields to land use conversion on the extensive margin. The dramatic increase in agricultural commodity prices since the mid-2000s seems ideally suited to test the reliability of these models by comparing actual land use changes that have occurred since the price increase to model predictions. Country-level data from FAOSTAT were used to measure land use changes. To smooth annual variations, changes in land use were measured as the change in average use across 2004 to 2006 compared to average use across 2010 to 2012. Separate measurements were made of changes in land use at the extensive margin, which involves bringing new land into agriculture, and changes in land use at the intensive margin, which includes increased double cropping, a reduction in unharvested land, a reduction in fallow land, and a reduction in temporary or mowed pasture. Changes in yield per harvested hectare were not considered in this study. Significant findings include:

- In most countries harvested area is a poor indicator of extensive land use.
- Most of the change in extensive land use change occurred in African countries. Most of the extensive land use change in African countries cannot be attributed to higher world prices because transmission of world price changes to most rural African markets is quite low.
- Outside of African countries, 15 times more land use change occurred at the intensive margin than at the extensive margin. Economic models used to measure land use change do not capture intensive margin land use changes so they will tend to overstate land use change at the extensive margin and resulting emissions.
- Non-African countries with significant extensive land use changes include Argentina, Indonesia, Brazil, and other Southeast Asian countries.
- Given the lack of a definitive counterfactual, it is not possible to judge the consistency of model predictions of land use to what actually happened in each country. Some indirect findings are that model predictions of land use change in Brazil are too high relative to other South American countries; and model predictions of increasing extensive land use that are larger than what actually occurred are consistent with actual land use changes only if cropland was kept from going out of production rather than being converted from forest or pasture.

The contribution of this study is to confirm that the primary land use change response of the world's farmers from 2004 to 2012 has been to use available land resources more efficiently rather than to expand the amount of land brought into production. This finding is not necessarily new and it is consistent with the literature that shows the value of waiting before investing in land conversion projects; however, this finding has not been recognized by regulators who calculate indirect land use. Our conclusion that intensification of agricultural production has dominated supply response in most of the world does not rely on higher yields in terms of production per hectare harvested. Any increase in yields in response to higher prices would be an additional intensive response.

Using Recent Land Use Changes to Validate Land Use Change Models

In the mid-2000s prices for major agricultural commodities began a long, sustained increase. Prices increased dramatically due to growth in demand for food and biofuel producers, underinvestment in agricultural infrastructure and technology, and poor growing conditions in major producing regions. Figure 1 shows the percent change in inflation-adjusted prices received by US producers for corn, soybeans, wheat, and rice relative to the previous five-year average.[1] The predominance of negative changes shows that since 1960 average real prices for these commodities have dropped. These figures show that the commodity price boom in the early 1970s resulted in the largest increase in real prices, but the recent increase in prices since 2006 resulted in the longest sustained increase, especially for corn and soybeans. For wheat and rice, real prices increased sharply in the mid-2000s and have stayed high even though the year-over-year increases were not as long lasting as for corn and soybeans. The magnitude of these real price increases after such a prolonged and sustained period of flat or falling prices presents a unique opportunity to quantify how world agriculture responds to incentives to produce more.

The United States, California, and the EU have enacted regulations based in part on model predictions of agricultural supply response to price increases induced by increased biofuel production. The model predictions of land use changes are called indirect land use changes because the predicted changes are due to a modeled response to higher market prices rather than a direct response to the need to grow more feedstock for biofuel production. Thus, for example, the corn used to produce corn ethanol in the United States was met by US corn production; however, the diversion of corn from other uses increased corn prices and crop prices of other commodities that compete with corn for market share and land. Because corn and other commodities are traded on world markets, prices in other countries also increase. The response in the US and in other countries to these higher prices is what the models measure.

[1] Prices are average annual prices received by US farmers adjusted by the US CPI.

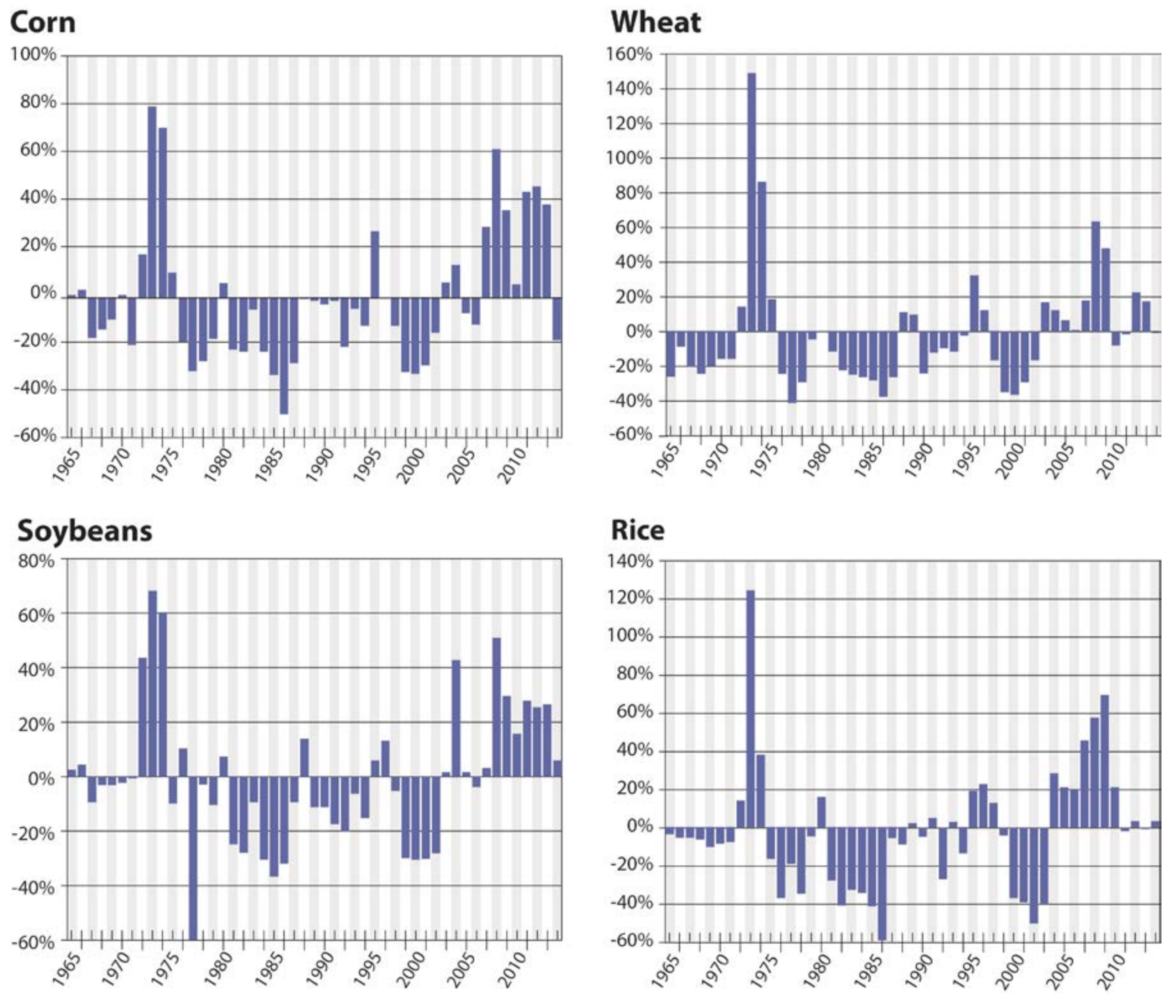

Figure 1. Deviations in Real US Commodity Price Levels from Lagged Five-Year Average Measuring World Land Use Changes

Some portion of the higher prices since the mid-2000s was caused by increased biofuel production. For example, Fabiosa and Babcock (2011) estimate that 36% of the corn price increase from 2006 to 2009 was due to expanded ethanol production. Carter, Rausser, and Smith (2010) estimate that 34% of the corn price increase between 2006 and 2012 was due to the US corn ethanol mandate. This implies that a portion of the actual response of land use since this price increase is due to US ethanol production. Other factors such as crop shortfalls and other sources of increased demand account for the rest of the price increase.

Because indirect land use is a response to higher market prices, model predictions of land use change should be similar whether the higher prices came from increased biofuel production, increased world demand for beef, or from a drought that decreased supply in one or more major producing areas. This implies that the pattern of actual land use changes that we have seen since the mid-2000s should be useful to determine the reliability and accuracy of the models that have been used to measure indirect land use. The purpose of this paper is to look at what has happened over approximately the last 10 years in terms of land use changes and to determine whether and how these historical changes can provide insight into the reliability of model-predicted changes in land use. We address the following questions in this paper:

- How has cropland changed around the world in approximately the last 10 years?
- What were the major drivers of observed land use changes?
- When can actual land use changes be compared with model predictions?
- What can be said about the types of land that were actually converted?

How Has Harvested Area Changed Since 2004?

The most complete source of data on annual cropland is from the Statistics Division of FAO (FAOSTAT), which measures annual harvested area by crop and country. These data have been widely used to measure the impact of biofuel production on expansion of land used in agriculture (Roberts and Schlenker 2013) and to calibrate the land cover change parameter in the GTAP model (Taheripour and Tyner 2013). Figure 2 shows the change in harvested land according to FAO. The data are smoothed by calculating the change in harvested area as the average in 2010, 2011, and 2012 minus the average in 2004, 2005, and 2006. The earlier period measures harvested area before the large increase in price. The later period represents harvested area after prices had increased substantially. India, China, Africa, Indonesia and Brazil had the largest increase in harvested land. These data seem to suggest that these countries had the largest increase in land conversion; however, harvested land is not equal to planted land. Harvested land will deviate from planted land when a portion of planted land is not harvested and when a portion of land is double or triple cropped.

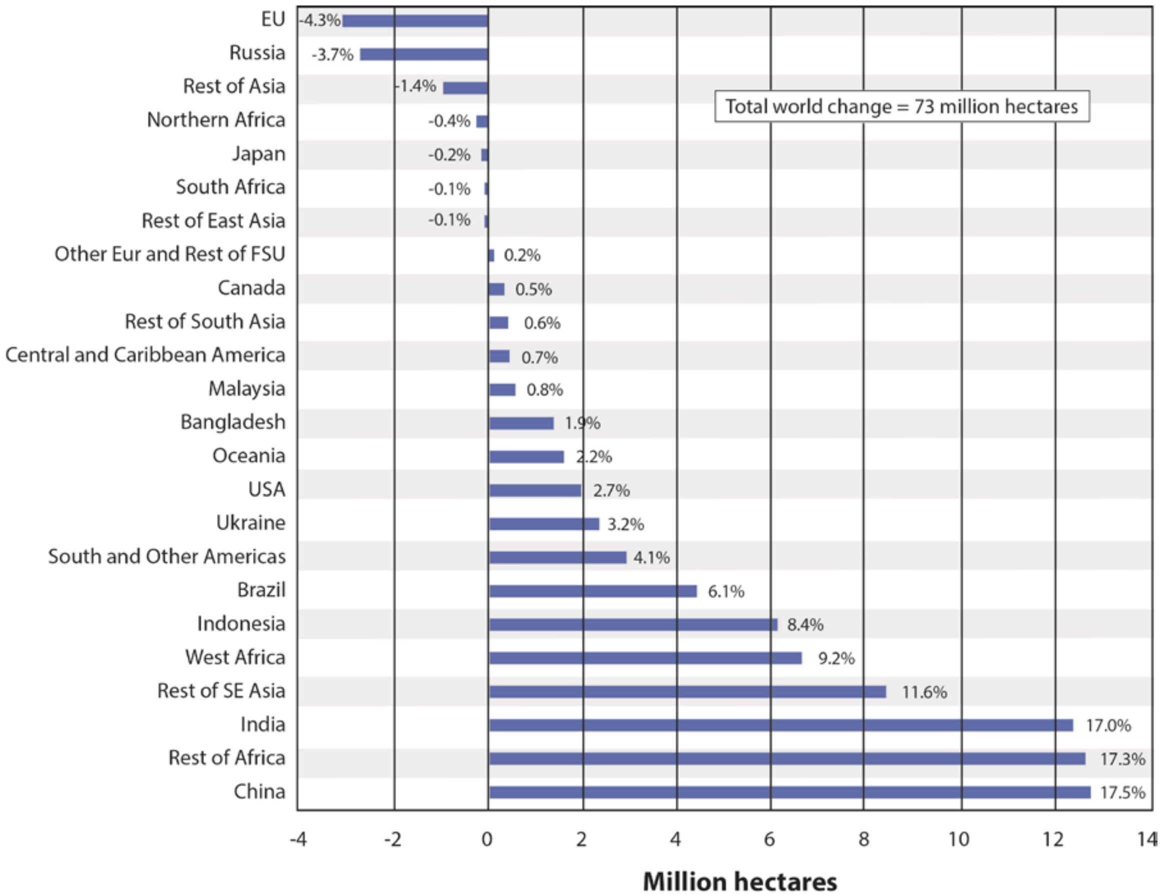

Figure 2. Change in Harvested Land 2010–2012 Average Minus 2004–2006 Average and Country's Share of Total World Change
Source: FAOSTAT

Suppose that a portion of land that is planted to a first crop is not harvested and that a portion of first crop land that is harvested in a country is double-cropped, which simply means that a second crop is planted on land that was already planted to a crop in the same year.[2] By definition, total harvested land, H, equals total harvested land from the first crop, H_1, plus total harvested land from the second crop, H_2. Total harvested land from the first crop equals total land planted to the first crop, P_1 minus land that was planted but not harvested, a_1. Thus we have in any year t

$$P_{1,t} = H_t - H_{2,t} + a_{1,t}$$

[2] Throughout this article land the phrase double crop should be interpreted as two or more crops being grown on a single parcel of land.

For the purpose of greenhouse gas emissions from land use changes, it is most relevant to calculate the change in planted area between two time periods $t = T$ and $t = 0$. Thus, we have

$$P_{1,\mathrm{T}} - P_{1,0} = (H_T - H_0) - (\mathrm{H}_{2,\mathrm{T}} - H_{2,0}) + (a_{1,\mathrm{T}} - a_{1,0})$$

If second crop acreage has increased over time, then use of FAO data on total harvested land overstates land use change by this amount. If the change in first crop land that is not harvested also increases over time, then at least some portion of this upward bias in measuring land use change is overcome. If, instead, the amount of unharvested land has decreased over time then the upward bias is increased. A more in-depth examination of data available for a few countries gives insight into the extent to which use of FAO harvested area data provides a good indication of land use changes.

United States

Figure 3 illustrates that reliance on harvested area as an indicator of land use change can lead to a large bias, and shows annual changes in harvested and planted land to corn in

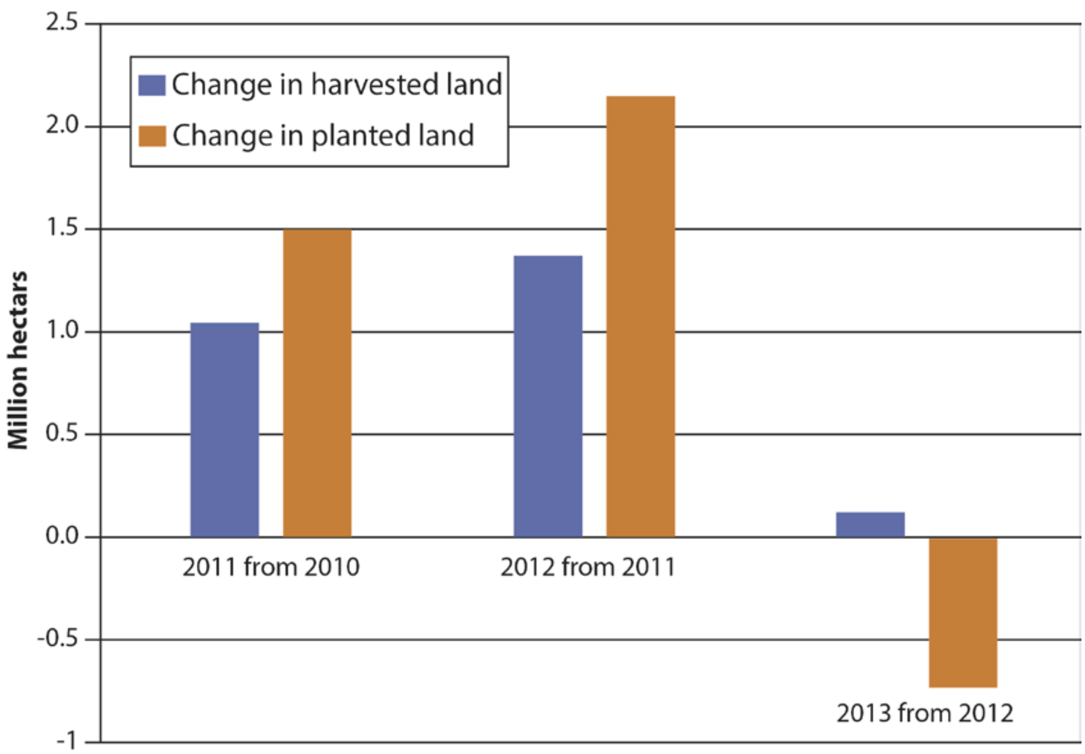

Figure 3. Annual Change in Harvested and Planted Corn Land in the United States

the United States from 2011 to 2013. A widespread drought in the United States resulted in an increase in the amount of planted land that was not harvested. Thus in 2012, use of harvested land to measure land use change understates land use change, whereas in 2013, it overstates land use change. Taking average changes over some time period will reduce the impact of an outlier like 2012, but it will not eliminate it. Thus, use of 2012 harvested data in the United States will tend to understate land use change relative to an earlier period and overstate it relative to a later period. Because data on US planted land is available from USDA's National Agricultural Statistics Service, it makes much more sense to use these data rather than FAO harvested land data.

Brazil

Brazil is another country that collects data on both harvested and planted land.[3] In addition, Brazil collects data on land that is double cropped. Figure 4 shows total harvested land and total harvested land from double cropped land. The axes have been set to the same scale to show that a large proportion of the increase in Brazilian harvested land is a result of increased double cropping. The change in total harvested land from 2004–2012 is 5.4

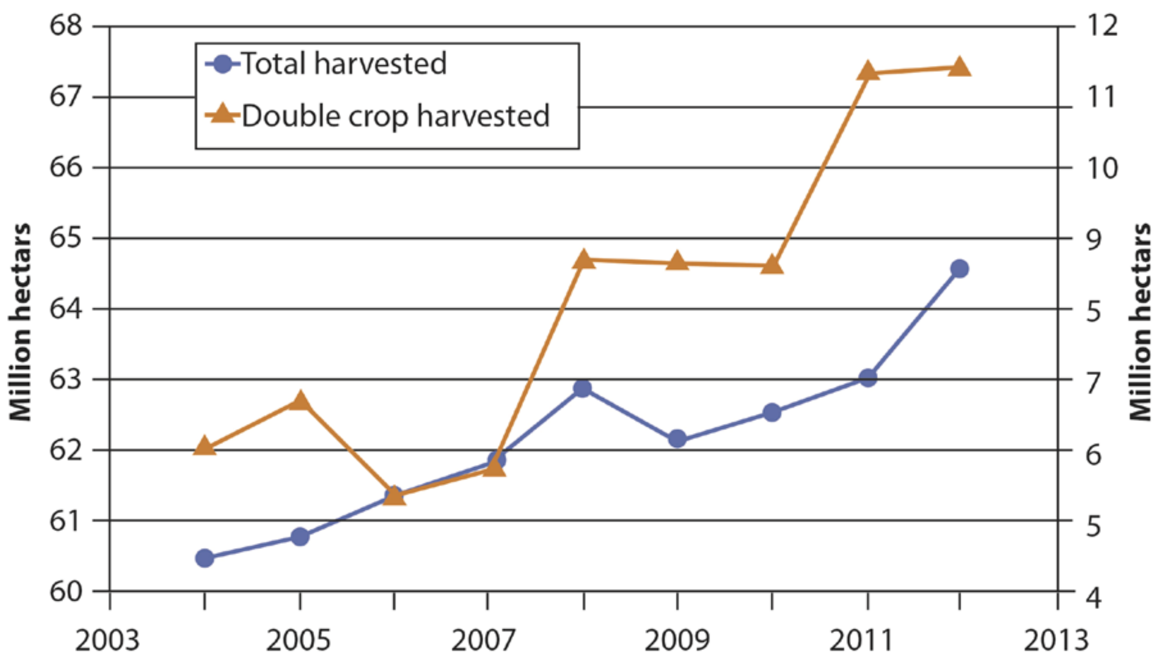

Figure 4. Brazil Harvested Land Data

[3]Brazilian IBGE data is available at http://www.sidra.ibge.gov.br/bda/pesquisas/pam/default.asp?o=27&i=P

million hectares. The change in double cropped land is 4.1 million hectares. Thus, more efficient use of land accounts for 76% of the change in harvested land in Figure 4.

India

Figure 2 shows that India increased harvested area by 6.8% from 2004–2006 to 2010–2012 which is 12.4 million hectares. Given India's long agricultural history it seems unlikely that so much land would be suitable for conversion to crops in such a relatively short time. India collects data on both planted and harvested land as well as double cropped land (India Ministry of Agriculture). Figure 5 shows that the variation in multiple crop area explains most of the variation in total planted area, which includes double cropped area. Subtracting double cropped area from total planted area shows that net planted area decreased by 147,000 hectares between 2004–2006 and 2010–2012. What then accounts for the increase in harvested area? Figure 6 shows that the proportion of planted area that is harvested has increased dramatically over this time period. An examination of previous years' data shows that the wide gap between planted and harvested

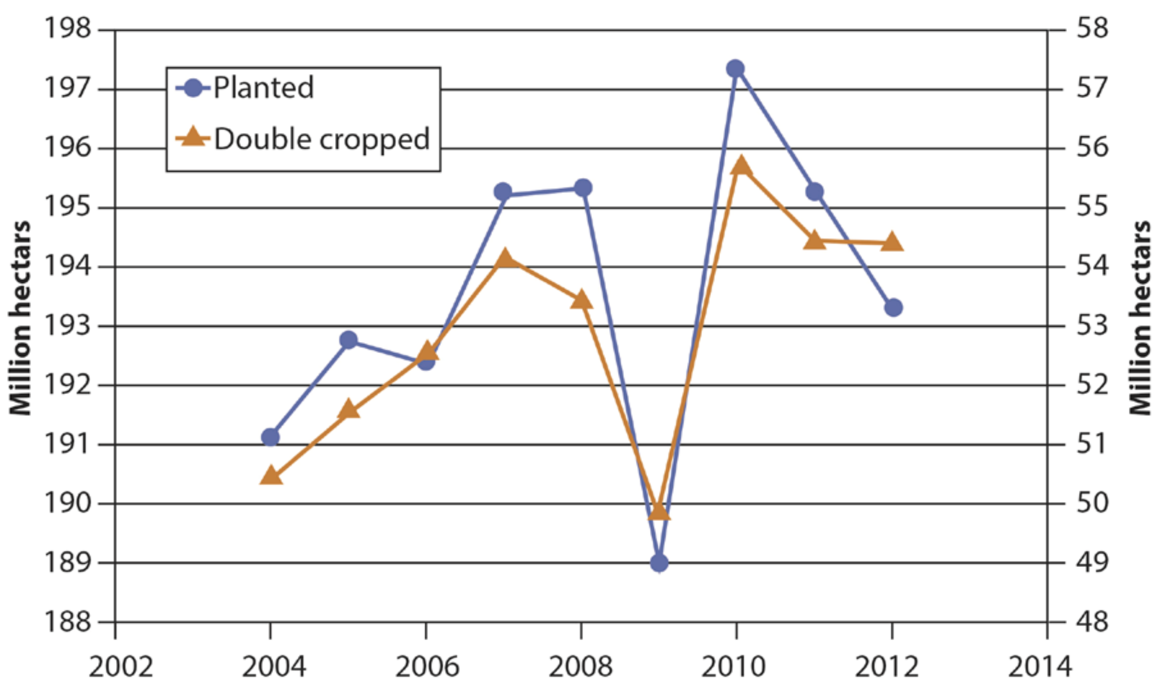

Figure 5. Total Planted and Multiple Crop Area in India

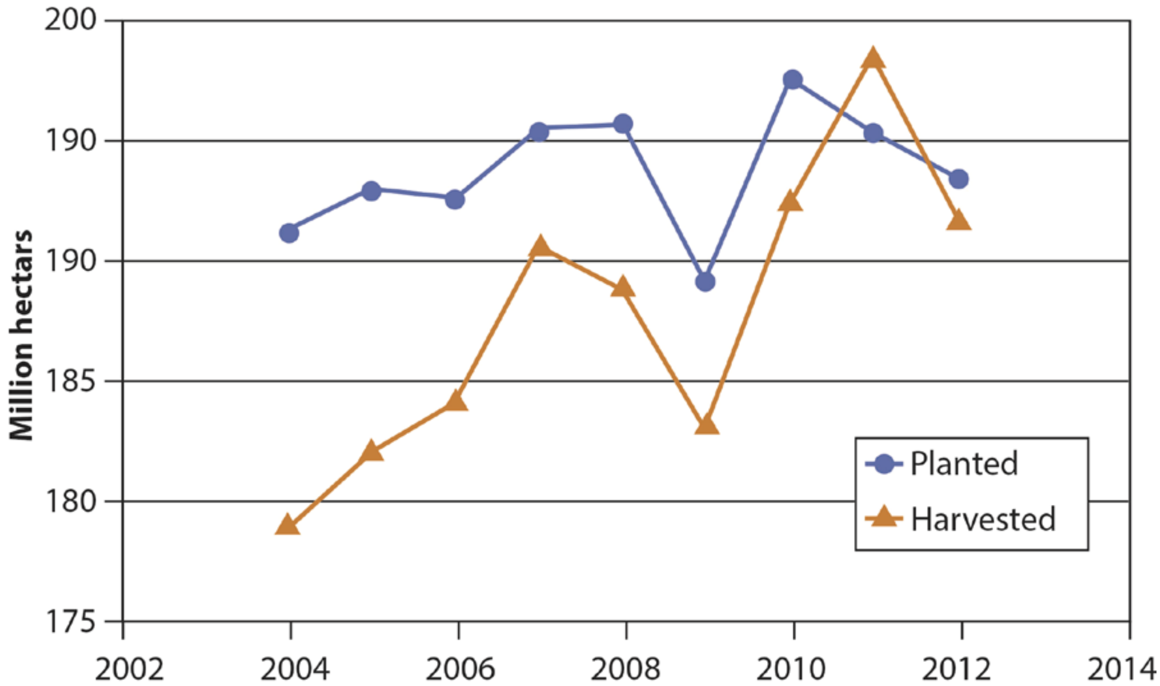

Figure 6. Total Planted and Harvested Area in India

area shown in Figure 6 from 2004 to 2006 was typical. For example, the 2004–2006 gap averages 10.6 million hectares, and the gap from 1992 to 2000 averages 10.4 million hectares. The average gap in 2010 and 2012 is 3.4 million hectares. Thus, an increase in double cropped area accounts for about 3.5 million hectares of the increase in harvested area, and a decrease in non-harvested area accounts for another 7 million hectares. Thus, all of the increase is harvested area is accounted for by intensification of land use. One reason why non-harvested area has increased so much is the 6 million hectare increase in irrigated area from 2004 to 2011. More irrigation allows a greater proportion of planted area to grow to maturity, thereby making it worth harvesting. In addition, India increased support prices and input subsidies in the mid-2000s to combat stagnant growth in the agricultural sector. These actions, combined with the expansion of irrigation, increased the opportunity cost of not harvesting land.

China

FAO harvested area data shows an increase of 8% from 160 million hectares to 173 million hectares from 2004–2006 to 2010–2012. Figure 2 in Cui and Kattumuri (2012) shows that total cultivated land in China dropped from about 130 to about 122 million hectares from 1996 to 2008. The four reasons cited for the loss of agricultural land are urbanization, natural disasters, ecological restoration, and agricultural structural adjustment, with restoration and urbanization accounting for about 80% of losses. Cui and Kattumuri (2012) claim that the loss of agricultural land slowed down in 2004 and 2005 only because of "…stringent land protection policies" (p. 14). Based on this conclusion, it seems that economic forces in China were trying to reduce cultivated land, not increase it, in the mid-2000s. If correct, then it seems highly unlikely that a significant portion of the increase in harvested area was caused by an increase in the amount of land cultivated. If both FAO harvested area data and data used by Cui and Kattumuri (2012) are correct, then at least 38 million hectares of harvested area came from double cropped land in 2004–2006 and 51 million hectares of harvested area came from double cropped areas in 2010–2012.

Sub-Saharan African Countries

Figure 2 shows that sub-Saharan African countries have been large contributors to increases in harvested land. With some exceptions, much of African crop production is carried out by small-scale producers without use of modern technologies. While differences exist between countries, typically most production is consumed domestically and most commercial trade occurs between adjoining African countries (Minot 2010). Sub-Saharan African countries account for 34 of the top 50 countries in the UN data base in terms of population growth rates in 2010.[4] The average population growth rates for these 34 countries in 2010 was 2.93%. Leliveld et al. (2013) show that food production in Tanzania has just about matched population growth and that almost all of the food production increase has been due to an increase in the amount of land planted. Although it is possible to plant more than one crop in many African countries by developing shorter-season varieties and better management (Ajeigle et al. 2010), a lack of access to technology and capital is one defining characteristic of traditional agriculture in sub-Saharan Africa, so there is no evidence that double cropping is widely adopted. Thus, the change in harvested land shown in Figure 2 for African countries is likely a better measure of the change in planted land than in other countries.

[4] Population growth rates are available at http://data.worldbank.org/indicator/SP.POP.GROW/countries?display=default

Indonesia

Figure 7 shows the change in area harvested from 2004–2006 to 2010–2012 for the top eight crops and for all other crops in Indonesia according to FAOSTAT. As shown most of the expansion has occurred in rice and palm oil fruit. Because perennial crops do not generally produce more than one crop per year, the extent to which FAO harvested land data overstates the change in planted land is limited. Adding the change in harvested land of palm, rubber, coffee, coconuts, and cocoa together accounts for 54% of the change in harvested area. According to USDA-FAS (2012) the availability of suitable rice-growing land is severely restricted in Indonesia. Most of the increase in harvested rice area that has been achieved has come about from investment in irrigation facilities that allow two or three crops of rice to be planted on the same land rather than a single crop. The extent to which intensification explains the 1.4 million hectare increase in rice harvested area shown in Indonesia cannot be determined by harvested area data alone. However, given that Indonesia is one of the world's most densely populated countries, and 1.4 million hectares represents a 12% increase in harvested production, it is unlikely that a significant portion of this 1.4 million hectares is new land. According to USDA-FAS (2012) about

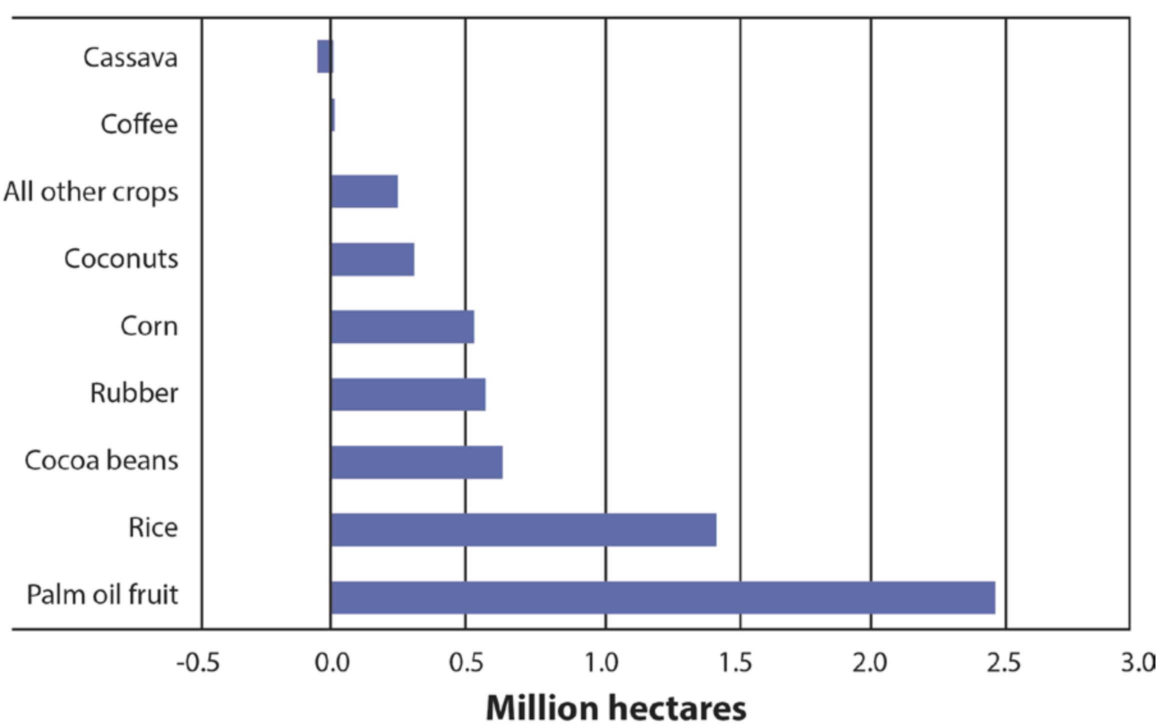

Figure 7. Change in Harvested Area by Crop for Indonesia as Reported by FAO

50% of Indonesian rice area grew rice in both the rainy and dry seasons in 2011, which implies that there is significant room for harvested area growth with greater irrigation. Thus it is likely that most of the increased rice area in Indonesia is accounted for by increased double and triple cropping.

Swastika et al. (2004) explain that most corn production in Indonesia is grown on land that produces two crops. Corn is typically grown with tobacco, cassava, another corn crop, or sometimes with rice. Given land constraints in Indonesia and the significant expansion of palm oil production, which has been accomplished by converting forestland and cropland (Susanti and Burgers 2013; Koh and Wilcove 2008), it is likely that a significant portion of the corn production increase came about by increasing double cropped area.

An Alternative Measure of Land Use Change

Use of harvested area to measure land use change can lead to a large bias in estimates of how much land has been converted to crops from other uses. While this may be an obvious point, it is too often missed in analysis of land use changes. Reliable country-specific data, such as in the United States, that can measure the change in net planted area should be used when available. Where it is not available, land cover data can be used. For global coverage FAOSTAT data on arable land and land planted to permanent crops are available. The FAO definition of arable land is "the land under temporary agricultural crops (multiple-cropped areas are counted only once), temporary meadows for mowing or pasture, land under market and kitchen gardens, and land temporarily fallow (less than five years). The abandoned land resulting from shifting cultivation is not included in this category."[5] This definition is different than the common meaning of arable land—land that is capable of producing a crop rather than land that is actually in crop production. Adding FAO's measure of arable land to land that is in permanent crop provides a measure of land use that is appropriate to use in determining the amount of new land that has been brought into production. Figure 8 reproduces Figure 2 using this measure with the exception of the United States, for which USDA's NASS planted area data is used. For the United States, total planted area of principal field crops minus double crop area is

[5] http://faostat.fao.org/site/375/default.aspx

used instead of FAOSTAT data because FAOSTAT reports a 9 million hectare loss in total cropland because of a sharp reduction in temporary pasture.

The implications of Figure 8 are strikingly different than Figure 2. Furthermore the Figure 8 data is much more consistent with the country-specific data in China, India, Brazil, Indonesia, and Africa. Figure 8 data suggest that the net change in global cropland over this period is 24 million hectares. African countries increased cropland by 20 million hectares. Other countries with more than a million-hectare increase include Argentina, Indonesia, Brazil, Rest of Southeast Asia, Rest of South Asia, and South and Other Americas. Countries with significant reductions in cropland include the EU, Canada, China, Russia, and South Africa.

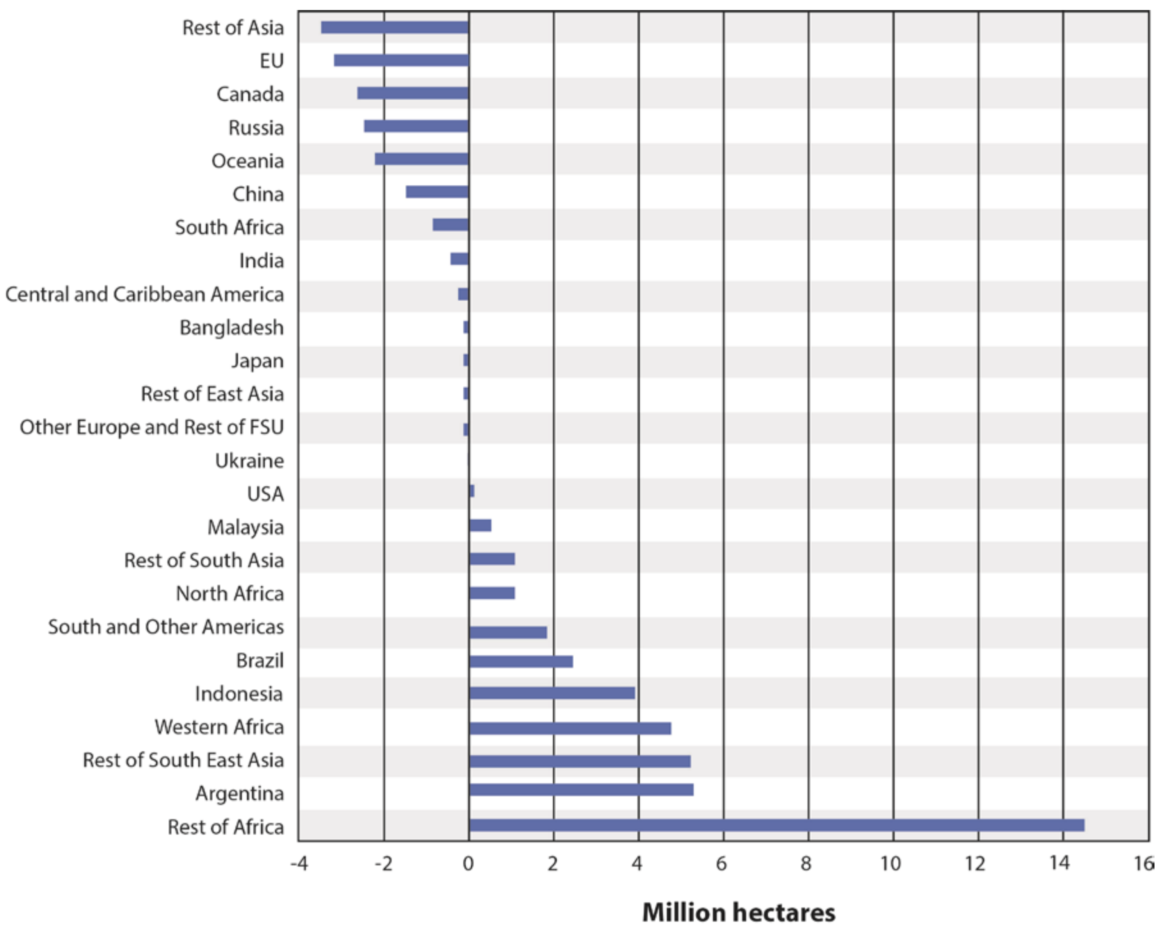

Figure 8. Change in Arable Land Plus Permanent Crops: 2004–2006 to 2010–2012

The data in Figures 2 and 8 can be used to determine the relative importance of land use changes at the intensive and extensive margin. Intensive margin changes are changes in double cropped area and a reduction in land that is available to plant but that is not harvested. The total change in harvested area in Figure 2 is the sum of extensive changes and intensive changes to land use. Thus, intensive changes equal the total change in harvested area from Figure 2 minus the changes in cropland given in Figure 8.[6] Both intensive and extensive changes are shown in Figure 9. Countries are sorted from the left according to their level of extensive acreage changes.

Most of the change in land use in African countries and Argentina is at the extensive margin. Most or all of the response in the developed world, India, China, South Africa, and the rest of Asia is at the intensive margin. The response in Indonesia and Brazil is mixed.

Major Drivers of Recent Land Use Changes

Broadly speaking, the land use changes shown in Figure 9 are consistent with a model of the world in which countries that have available land to convert to agriculture will have relatively more extensive land use change than countries that have long histories of agricultural development and limitations on available land. Thus, one major driver of recent land use changes is the availability of land to convert to agriculture. Most developed countries, along with China and India, have little land available, however, countries in Africa and South America have abundant land resources. There are striking differences, however, in land use indicated by Figure 9 that must be due to other drivers.

Growing demand for soybean imports was a major driver of land use decisions in Argentina, Brazil and the United States. The increased demand for soybeans resulted mainly from China's decision to meet its domestic needs for soybeans through imports rather than domestic production. This decision freed up resources in China to devote to production of other commodities and led to much higher soybean area in Argentina, Brazil, and the United States. Higher demand for high-protein foods in China and other developing countries increased the demand for soybean meal.

[6]One other use of this measure as an indicator of the amount of land that is used in agriculture is OECD-FAO (2014) when total agricultural land is discussed.

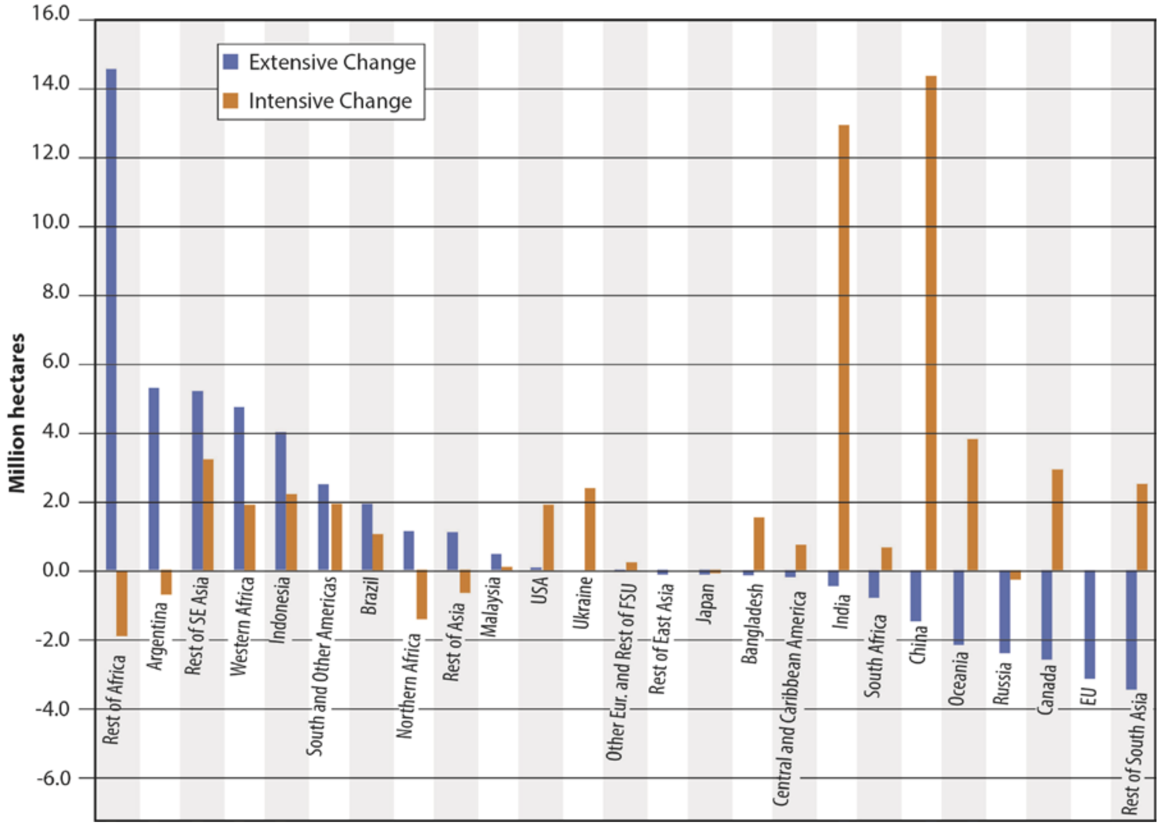

Figure 9. Extensive and Intensive Land Use Changes: 2004–2006 to 2010–2012

Increased demand for vegetable oils for food production, cooking, and biodiesel increased the demand for soybean oil.

Brazil responded to this increased soybean demand by expanding soybean area, however, a second crop of corn was planted on a good portion of expanded soybean acreage. This expansion in double cropping reduced the amount of corn area planted to the first crop of corn. Thus, Brazil expanded at both the extensive and intensive land use margins.

Argentina also expanded soybean area, but it did so at the extensive margin rather than by intensifying land use. The prime soybean production areas in Argentina are farther south than in Brazil, which shortens the time period available for double cropping. However, a second crop of soybeans can be planted in Argentina after winter wheat is harvested in December. One explanation for a lack of intensification is that Argentine area planted to wheat has declined from about 6 million hectares in 2005 to 3.6 million hectares in 2012. This decline simply means that there is less land available for double cropping soybeans after wheat. Therefore, if soybean area needs to increase, less wheat land means less land available for double cropping, thus, soybean first crop area by definition must increase. The decline in wheat area has been mainly driven by government policy interventions in the form of export taxes and export subsidies that were implemented in a way that favored soybeans over corn and wheat (Nogues 2011). This suggests that government policy is what caused a lack of an intensive land use response in Argentina, in contrast to the significant intensive response shown in Figure 9 in Brazil and other South American countries.

As discussed, Indonesian expansion of palm production was accomplished at least in part at the extensive margin. This expansion resulted from increased investment drawn to the industry due to higher profit margins caused by higher prices and higher yields. The higher prices resulted from an overall increase in demand for vegetable oil, driven by increased demand for food production, cooking oil, biodiesel, and other uses. The data show that Indonesian expansion of rice and corn harvested area was done at the intensive margin because the area devoted to perennial crops in Figure 7 is greater than the total extensive expansion shown in Figure 9.

Sugarcane and soybeans account for nearly all of the land expansion in Brazil. Increased sugarcane production was used to meet growing demand for sugar and to meet growing domestic demand for ethanol. The number of flex vehicles in Brazil grew by 20 million from 2005 to 2012. If all of these vehicles used ethanol, Brazilian consumption of ethanol in 2012 would have exceeded 24 billion liters just from these vehicles, and additional consumption would have come from the 15 million gasoline vehicles in Brazil. Actual consumption in Brazil was about 18 billion liters.[7] These figures demonstrate that the growth in sugarcane area was primarily driven by the Brazilian government policy that increased the sales of flex vehicles in Brazil. The expansion in Brazilian soybean area was driven by increased world demand for soybean imports, which was mainly driven by China, as previously discussed. The ability to plant a second crop of corn after soybean due to adoption of shorter-season soybeans and agronomic advances reduced the amount of new land that was needed to accommodate this expansion.

[7] All figures on Brazilian vehicle numbers and ethanol consumption were obtained from UNICA: http://www.unicadata.com.br/?idioma=2

In China, India, and most of the developed world, agricultural land resources are limited. Limited land resources means that expansion at the extensive margin is costly relative to expansion at the intensive margin. Thus, we see a large response in both China and India at the intensive margin rather than the extensive margin. Cui and Kattumuri (2012) argue that Chinese intensification would have been even greater but for the government policy objective of maintaining a minimum of 120 million hectares of land in agriculture. India's intensification was facilitated by government investment in irrigation facilities and price subsidies that increased agricultural profitability (OECO-FAO 2014).

The lack of a large extensive response in Ukraine, Russia, and other FSU countries is somewhat surprising given the availability of land. The lack of response at the extensive margin could be due to a lack of investment in the agricultural sectors of these countries.

How much of the changes in land use shown in Figure 9 can be attributed to high commodity prices cannot be known precisely without observing an alternative history in which the run-up in commodity prices did not occur. Economic theory suggests that some portion of the changes in Figure 9 came about because of high prices in those countries where high world prices were transmitted to farmers. However, some of the changes in land use would have occurred even if prices had remained constant at their 2004–2006 levels.

The extent to which extensive expansion in African countries was caused by high world prices is likely small for the simple reason that higher world prices were not transmitted to growers in many African countries. Minot (2010) concludes that domestic grain prices in Tanzania bear little relationship to world prices. In a more complete study, Minot (2011) studies price transmission in multiple markets in Ethiopia, Ghana, Uganda, Zambia, Mozambique, Tanzania, Kenya, South Africa, and Malawi. Of the 62 markets studied, he found that only 13 showed a statistically significant long-run relationship with world prices. He found some evidence of a linkage in large urban centers and in coastal markets, which is consistent with markets in cities and in coastal ports being more integrated with world markets. However, given his overall findings, these limited linkages to world prices did not find their way through to rural areas where most crops are grown. With such weak evidence supporting price transmission to rural areas one can conclude that the main driver of land expansion in many African countries was not higher world prices.

Empirical Measures of Land Use Changes

Aggregating land use changes across all countries, the aggregate world extensive change was a net increase of 24 million hectares from 2004–2006 to 2010–2012. The aggregate world intensive land use change was 49.1 million hectares. Thus, across all countries, more intensive use of existing land was double the change from more extensive use of land. Outside of African countries, the aggregate intensive change in land use was almost 15 times as large as extensive changes. This wide disparity between more intensive use of land and more extensive use means that the reliability of current models used to estimate indirect would be dramatically increased if they were modified to account for non-yield intensification of land use.

The recent historical changes in land use can provide some guidance about the effect of dramatically higher prices on land use change over an eight-year period. An estimate of the amount of extensive land use change that can be attributed to higher commodity prices can be made under fairly restrictive assumptions.

First is assuming that land use change at the extensive margin due to high prices is zero in those countries or regions in Figure 9 that had negative extensive changes. This assumption implies that the forces that caused countries to lose agricultural land during this time would have caused the same amount of loss even without the high prices. Clearly, it would seem that at least some land in these countries was kept in production from the high prices, so this assumption understates land use change at the extensive margin. From a greenhouse gas perspective, this assumption is equivalent to saying that the net amount of carbon sequestration that would have occurred on land that was kept in production by high prices in these countries is negligible.

Second is assuming that all the extensive margin changes in Figure 9 in countries and regions that have positive changes are due to high world prices. This too is an extreme assumption because some land would have been brought into production even if commodity prices had not increased. Thus this assumption overstates the response of land use at the extensive margin.

If we include extensive changes in Africa, then world extensive land use changes equals 41.2 million hectares, which represents a 2.68% increase over the average level of land in production in 2004–2006. If we assume that the extensive land use changes in

Africa were primarily caused by internal domestic food demand from growing populations and income, and they would have occurred even without high world commodity prices, then the extensive land use increase equals 20.7 million hectares or 1.35%.

It is instructive here to make a rough estimate of the response of the world extensive margin to aggregate higher commodity prices. The average real prices of corn, soybeans, wheat, and rice received by US farmers increased by 123%, 85%, 59%, and 47% respectively in 2010–2012 relative to 2004–2006. A simple average of these price increases is 78%. With this real price increase, the elasticity of the world extensive margin is 0.034 if African extensive response is included, and 0.017 if the African extensive response is not included.

Similarly, if the intensive response in countries and regions where the response is negative is set to zero, then the aggregate intensive response to high prices is 49.1 million hectares if we attribute all the intensive response to higher prices. Without the African country response, the aggregate response is 47.2 million hectares. The resulting elasticities of intensive response are 0.041 and 0.039. Thus, if we attribute all the African extensive land use changes to high prices, then the world intensive elasticity is 19% higher than the extensive elasticity. If none of the African response is attributed to higher prices than the non-African intensive elasticity is almost three times as great as the extensive response.

These rough estimates demonstrate that the primary land use change response of the world's farmers in the last 10 years has been to use available land resources more efficiently rather than to expand the amount of land brought into production. This finding is not new and is consistent with the literature that finds significant option value in waiting to convert land (Song et al. 2011). OECD-FAO (2009) recognized that intensive land use change has been the driving force behind higher production levels, however, this finding has not been recognized by regulators who calculate indirect land use. Note that our measure of more efficient land use does not include higher yields in terms of production per hectare harvested. Any increase in yields would be an additional intensive response. Rather the intensive response measured here is due to increased multiple cropped area, a reduction in unharvested planted area, a reduction in fallow land, and a reduction in temporary pasture. Because greenhouse gas emissions associated with an intensive response are much lower than emissions caused by land conversions (Burney, Davis, and Lobell 2010), ignoring this intensive response overstates estimates of emissions associated with land use change because most of the land use change that has occurred is at the intensive rather than extensive margin.

Comparison of Actual Land Use Changes with Model Predictions

Model predictions of land use change from increased biofuel production are conceptually appealing. This is because the effects of higher biofuel production on land use are measured in isolation—the effects of everything else that influences agriculture are held constant. Thus, the effects of biofuel production alone can, at least conceptually, be measured. The way that the models assume increased production impacts land use is through higher prices. Thus, if the actual changes in land use in Figure 9 were the result of a response to the large increase in commodity prices that actually occurred, then it seems reasonable to compare model predictions to the actual changes that occurred. However reasonable this seems, we simply do not know with certainty what land use changes would have occurred without the increase in commodity prices. What needs to be compared to model predictions is the difference in land use with the commodity price increase relative to what it would have been without the commodity price increase.

What information then can be gleaned from a comparison of model predictions with actual changes? At one extreme, if none of the observed changes in extensive land use were the result of high prices, then we know that indirect land use is not empirically important because land use changes are caused by other forces. At the other extreme, if extensive land use would have stayed constant at base period levels if prices had not increased then all of the observed changes resulted from high prices. In this case it would be valid to judge the accuracy of model predictions with observed changes, because both would be caused by price responses. Reality likely falls somewhere in between these two extremes in that land use in 2012 would have been different than in 2004 even without the price increase, and that at least some portion of the observed changes we see can be attributed to higher prices. Taheripour and Tyner (2013) use observed land use changes as a guide to selection of a key model parameter in GTAP in an attempt to reconcile model predictions with observed changes. Hence, they assume that observed changes in land use are a useful guide to determine how the GTAP model should predict how land use changes in response to a change in commodity prices.

The two most widely used international models used in the United States to predict land use changes associated with increased biofuel production are GTAP and FAPRI (Gohin 2014). Both models allowed crop yields to respond to higher prices, and neither model allowed land use intensity, as measured here, to increase. Given that the primary way that non-African countries have increased effective agricultural land was through intensification, both models have an upward bias in their predictions of land use change at the extensive margin in non-African countries.[8]

Figure 10 shows the predicted increases in cropland from the FAPRI model that was used by the Environmental Protection Agency to determine greenhouse gas emissions

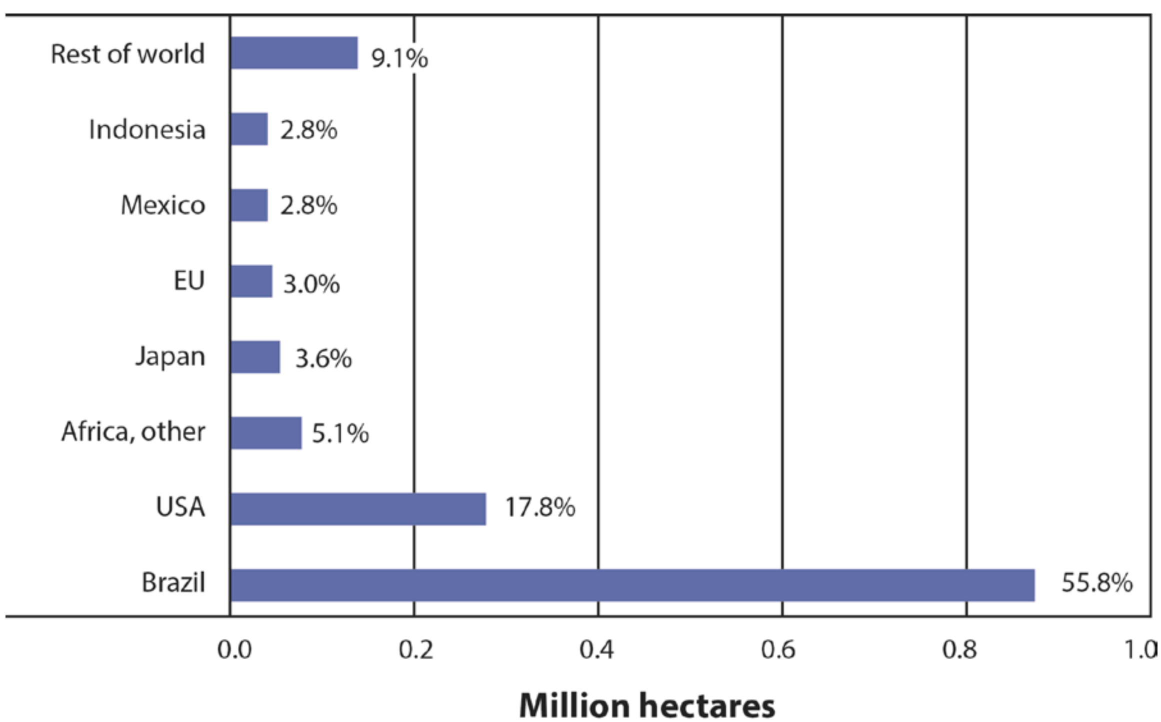

Figure 10. Predicted Land Use Change in EPA "All Biofuel" Scenario: Hectares and Share of World Total

[8] One way that production per unit of agricultural land can increase in the GTAP model is through its yield elasticity, therefore at least some of the upward bias in GTAP's prediction of extensive land use changes is offset by using a yield elasticity value that is higher than can be supported empirically.

associated with land use changes from increased biofuels. What is illustrated is the difference between EPA's "Control Case" that includes levels of biofuels in the RFS and EPA's "AEO Reference Case," which contains lower levels of biofuels (EPA 2010). This scenario simulated increases in many different biofuels including biodiesel made from vegetable oil and waste greases, corn ethanol, sugarcane ethanol, and cellulosic ethanol. How these land use changes were calculated is that the FAPRI predictions of land use in the AEO Reference Case were subtracted from the predictions in the Control Case. The total predicted world change in land use is 1.45 million hectares.

What is striking about Figure 10 is the concentration of predicted land use change in Brazil and the United States. These two countries account for almost 75% of the total predicted change in land use, with Brazil alone accounting for more than half of all change in the world at the extensive margin. In the AEO Reference Case total cropland in Brazil is increasing, thus the predicted increase in area must come from conversion of land that would have been devoted to other uses.

The first valid comparison that can be made between the CARD-FAPRI model prediction and what actually occurred is that the predicted land use change in Brazil due to higher prices is far too high relative to land use changes that actually occurred at the extensive margin in Argentina and other South American countries. As shown in Figure 9 Argentina and other South American countries together increased land use at the extensive margin by almost four times as much as did Brazil. The CARD-FAPRI model results used by EPA predicted almost no land use change in Argentina and other South American countries due to higher prices. It is notable that the CARD-FAPRI model predicted that growth in Brazil cropland from 2002 to 2009 would be about 9.1 million hectares, whereas Argentina's growth would be 3.7 million hectares in the Reference Case. Thus, the larger increase in agricultural area in Argentina that actually occurred cannot be attributed to the model being right about predicting a larger baseline increase in Argentina than in Brazil. The first conclusion one can draw from this comparison is that the CARD-FAPRI model dramatically over-predicted land use change in Brazil relative to Argentina and other South American countries.

The CARD-FAPRI prediction that the United States would account for about 18% of the world's increase in extensive land use seems inconsistent with the large changes that occurred in African countries and Argentina. The only way that the US land use prediction is consistent with the historical record is if cropland in the United States would have dropped by a large amount in the absence of the large price increase. The CARD-FAPRI model predicted that US crop area would decline in both the Reference and Control Cases.

The CARD-FAPRI model includes some South African production and a limited number of other crops in a limited number of African countries. The CARD-FAPRI model implicitly assumes that most of African agricultural production of major crops is isolated from world markets. As discussed above if this isolation is in fact a correct characterization of African agriculture, then the large land use changes in African countries shown in Figure 9 would have occurred even without the high commodity prices. The only other conclusion that can be drawn regarding African countries is that the CARD-FAPRI model underpredicts land use changes there to the extent that land use in African countries responded to world prices.

The commodity price increases that led to the Figure 10 predicted changes in land use were a 3.1% increase in corn prices and a 0.8% increase in soybean prices. These simulated price changes are dwarfed by the actual price changes that have occurred as shown in Figure 1. The FAPRI model prediction of a small increase in extensive land use in Japan and the EU due to small changes in price seems inconsistent with the fact that land use in Japan has been largely unchanged over the last 10 years and the EU has experienced a decline in land use. Again, it is not possible to know the extent to which a small increase in world commodity prices would have kept a small amount of land in production in the EU.

The small model-predicted change in Indonesia in extensive land use is generally consistent with observed changes if we assume that no changes would have occurred except for the higher market prices that actually occurred and not from government development priorities.

Figure 11 shows predicted land use changes by the GTAP model. [9] GTAP predicts that 38% of land use changes occur in the United States. As discussed, although

[9] GTAP model predictions of land use changes associated with biofuels vary across publications. Figure 11 land use change predictions were taken from Hertel et al. (2009) which were published about the same time that California's Air Resources Board was making their determination of greenhouse gas emissions from land use change that relied on GTAP model predictions. For the purposes of this paper, we assume that the

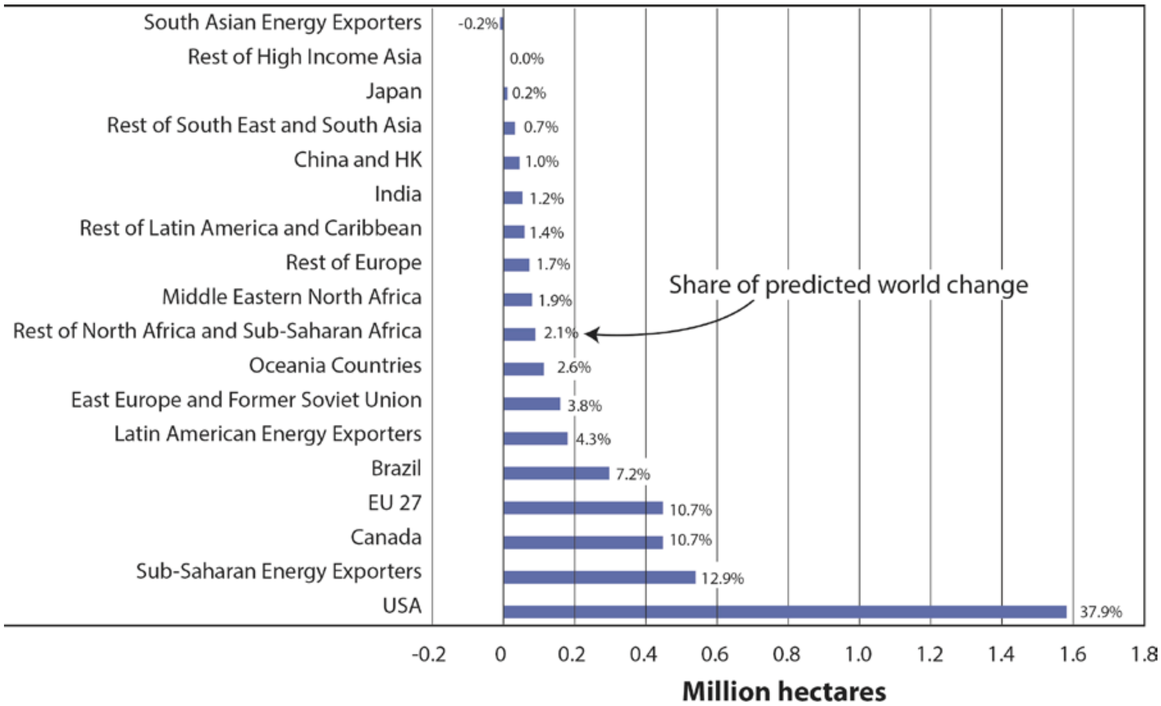

Figure 11. GTAP Predictions of Indirect Land Use Change from Corn Ethanol
Source: Hertel et al. (2009)

this seems like a large over-prediction of the US contribution, it is not possible to say this prediction is inconsistent with the recent historical data given that we cannot observe what land use would have been without the price increase. However, for this prediction to be true, the fairly small price increase simulated by GTAP would have kept a sizeable amount of land in production in the United States.

As with the CARD-FAPRI model, GTAP over-predicts the land use change for Brazil relative to other Latin American countries assuming that the baseline in Hertel et al. (2009) shows Brazil's area increasing more than agricultural area in the rest of Latin America. This baseline level of data was not available for inspection but GTAP's baseline was developed using 2001 data that incorporates land use changes that occurred in previous years. Brazil's agricultural land was expanding in this prior period, so it is reasonable to assume that Brazil's land use in the baseline was increasing more than in

Figure 11 land use changes are consistent with those used by California. There exist many GTAP-based estimates of land use change due to biofuels. An alternative estimate was provided by Tyner (2010). First and Second Generation Biofuels: Economic and Policy Issues, Presented at the Third Berkeley Bioeconomy Conference, June 24, 2010, http://www.berkeleybioeconomy.com/wpcontent/uploads//2010/07/TYner%20Berkeley%20June%202010.pdf.

other South American countries. This would imply that the predicted change in Brazil relative to the rest of Latin America is too large.

Despite the large discrepancies between model predictions and the actual land use changes that have occurred since 2004 it simply is not possible to conclude with certainty that the model predictions have been proven wrong and should be disregarded. For example, the Hertel et al. (2009) prediction that large land use changes from output price increases resulting from US corn ethanol production would occur in the United States, Europe, and Canada seems inconsistent with the fact that cultivated land decreased in the EU and Canada and stayed constant in the United States despite price changes that were many times larger than those predicted by the model. However, it could be that the amount of actual land reduction that would have occurred in the EU and Canada would have been much larger without the commodity price boom and that if actual land use changes were calculated relative to what would have happened without the price impact then the GTAP model predictions would be consistent with what we observe. Thus, without being able to observe the alternative history that did not contain the commodity price boom, it is not possible to conclude with certainty that the model predictions are wrong. As Babcock (2009) pointed out, economists who run models to predict future land use changes are in the enviable position that skeptics of the predictions will find it difficult to use the actual land use change data to prove that the model predictions were wrong. However the historical record of land use changes can be used to provide insight into the types of land that were converted assuming that the model predictions are correct.

Using the Historical Record to Guide Estimates of Land Conversion

Table 1 below presents some GTAP results that were used by California's Air Resources Board to calculate CO_2 emissions associated with land conversion due to corn ethanol production. By regressing emissions on the amount of land converted, it is possible to obtain a rough estimate of how each of the four land conversions affect estimated emissions separately. Table 2 provides the regression results.

An increase in land conversion increases GTAP's estimates of emissions. Conversion of a million hectares of forest increases emissions much more than conversion of pasture. How to interpret these coefficients is that a one million hectare increase in, for

Table 1. GTAP Model Predictions of Land Conversion and Associated GHG Emissions

	Forest Converted		Pasture Converted		
Scenario	U.S.	ROW[a]	U.S.	ROW	LUC Emissions
		million hectares			*gCO_2e/MJ*
A	0.70	0.34	1.04	1.96	33.6

Land Type Converted	Impact on Emissions
	gCO_2e/MJ
US Pasture	6.17
ROW Pasture	3.08
US Forest	22.69
ROW Forest	14.41

Source: Estimated from Table 1.

example, US pasture to crops, leads to a 6.17 increase in emissions measured by grams CO_2 per MJ of gasoline energy replaced by corn ethanol. Across all seven scenarios the average prediction of forest conversion in the United States is 0.58 million hectares.

Multiplying 0.58 by 22.69, which is the coefficient relating conversion of forest to emissions, results in an estimate of the average contribution of US forest conversion to the final CO_2 emission number. The result is that GTAP estimates that conversion of US forests contributes 13.06 gCO_2/MJ or 43% of total estimated emissions.

As shown in Figure 8, US cropland did not appreciably increase at the extensive margin in response to higher prices on average in 2010–2012 relative to 2004–2006.[10] As

[10] A more detailed examination of US data is provided in the next section, which shows there is some evidence of an increase in planned area to be planted from 2007 to 2013. The 2004–2006 and 2010–2012 time periods were used to make US data consistent with available data for other countries.

discussed in the previous section, it is not possible to conclude whether the GTAP model prediction that US cropland would be 1.6 million hectares higher due to higher prices is inconsistent with what actually happened, because it could be that US cropland would have declined from 2004 to 2012 if the higher prices had not occurred. For example, if US cropland would have declined by 5 million hectares if the high prices had not occurred, then the GTAP prediction that 1.6 million of these hectares would have been kept in production is consistent with the historical record. More formally, a necessary condition for consistency of the model prediction of an increase in US cropland due to higher prices is that US cropland would have declined by at least the amount of the model prediction were it not for the higher prices that actually occurred.

So suppose that there would have been a 5 million hectare decline in US cropland were it not for the higher prices and the GTAP prediction is correct that 1.6 million hectares of this land would have been kept in production because of higher prices caused by corn ethanol production. This means that the type of land converted to accommodate biofuels was not forest or pastureland but rather cropland that did not go out of production. Calculation of foregone carbon sequestration depends on what would have happened to the cropland if it did not remain in crops which, in turn, depends on where the cropland is located and the potential alternative uses. The magnitude of the change in estimated CO_2 emissions from cropland that is prevented from going out of production relative to forest that is converted to cropland is potentially large. For example, from Table 2, converting one million hectares of grassland instead of forest would reduce land-based CO_2 emissions by 11.3 gCO_2e/MJ in the rest of the world and by 16.5 gCO_2e/MJ in the United States. If foregone carbon sequestration is less than the amount of carbon lost from converting pasture to crops then the magnitude of the emission reduction would be larger.

The countries in Figure 8 that either had negligible or negative extensive land use changes should be presumed to not have converted pasture or forest to crops in response to biofuel-induced higher prices. Rather, the presumption should be that any predicted change in land used in agriculture came from cropland that did not go out of production. From Figure 11 this would include Canada, the EU, Russia, the Ukraine, and India.

The countries in Figure 8 that had significant extensive land increases cannot be presumed to have only kept cropland in production because of biofuels. Whether the expanded cropland due to the portion of the actual price increase attributable to biofuels expansion came from cropland that would have gone out of production or from pasture is an accounting decision. For these countries that expanded extensive land use, the historical pattern of where in the country the land use expansion occurred provides insight into the type of land that was converted to crops.

Brazil is one country that expanded extensive land use and has data on where this expansion occurred. Figure 12 shows each state's share of extensive land use change in Brazil measured by the change in the 2010–2012 average from the 2010–2012 average.[11] Not surprisingly extensive land use increased the most in Mato Grosso. Expansion of sugarcane area in Sao Paulo explains its increase. The states of Goias, Maranhao,

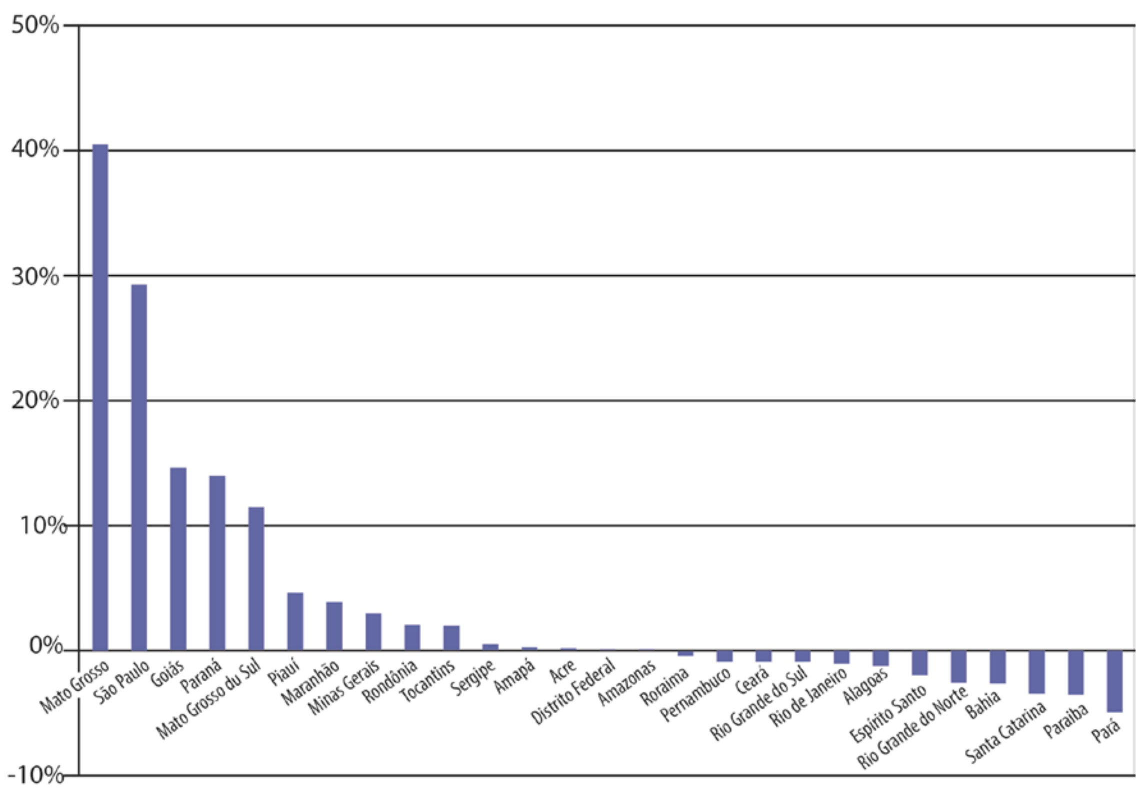

Figure 12. State Share of Brazil's Change in Extensive Land Use from 2004–2006 to 2010-2012.

[11]Only land that was planted to crop was considered in calculating each state's share of extensive land use change. The cropland planted data comes from the IBGE website: http://www.sidra.ibge.gov.br/bda/acervo/acervo9.asp?e=c&p=PA&z=t&o=11. Total planted cropland in Brazil is less than FAOSTAT data on arable land plus permanent crops that was used to determine extensive and internsive land use changes in Figure 10 and 11.

Tocantins, and Piaui all have large land areas in the vast Brazilian Cerrado biome which has also seen large-scale development (The Economist). Rondonia is the only state in the Amazon biome that shows an increase in cropland. Where cropland has expanded in Brazil (and in other countries where data allows) can be used as a guide to determine if model predictions of the type land converted are accurate.

A More Detailed Look at US Extensive Area Data

Figure 13 shows what has happened to one measure of US cropland from 1993 to 2013. This measure is area planted to US principle crops as measured by USDA-NASS, less double cropped harvested area, plus fallow cropland. This measure reached its peak in 1996. In 2007, this measure increased after a long downturn, suggesting some impact of higher prices. However, in 2010 it fell below 130 million hectares before increasing in 2011 and 2012. It is somewhat surprising that total land in agriculture has not increased more than indicated since 2006 because land enrolled in the Conservation Reserve

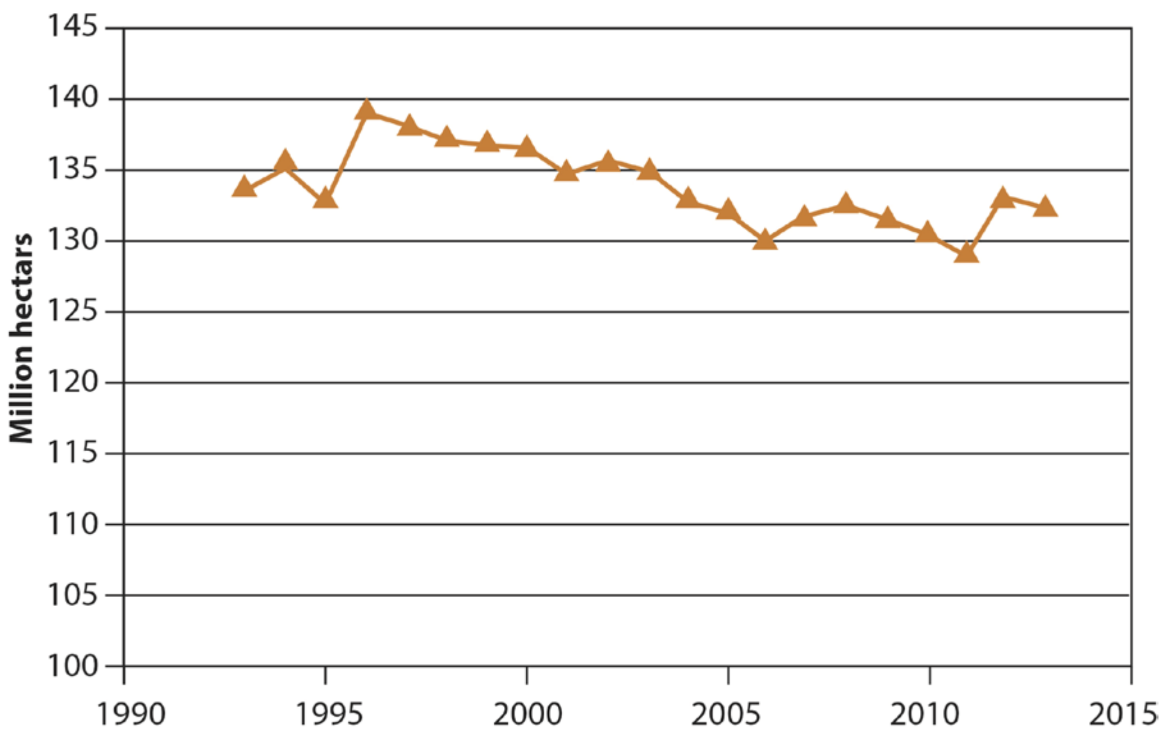

Figure 13. US Cropland Since 1993

Program (CRP) declined by 4 million hectares from 2007 to 2013. One explanation for a lack of response in this measure of land use could be an increase in area that is reported as prevented planting area.

The US crop insurance program creates an incentive for farmers to report area that they had planned to plant but were not able to due to adverse weather. This land is called prevented planted acres. Farmers who buy crop insurance receive a crop insurance payment on these acres. Aggregate data on the amount of prevented planted acres can be added to the Figure 13 data to measure how much land US farmers intend to plant each year. Data on the area designated as prevented planting area are available since 2007.[12] Figure 14 shows the change in CRP land since 2007 (grey line), the change in US cropland since 2007 (blue line calculated from Figure 13), and the change in intended planted land since 2007 (orange line). It is striking how close the change in intended

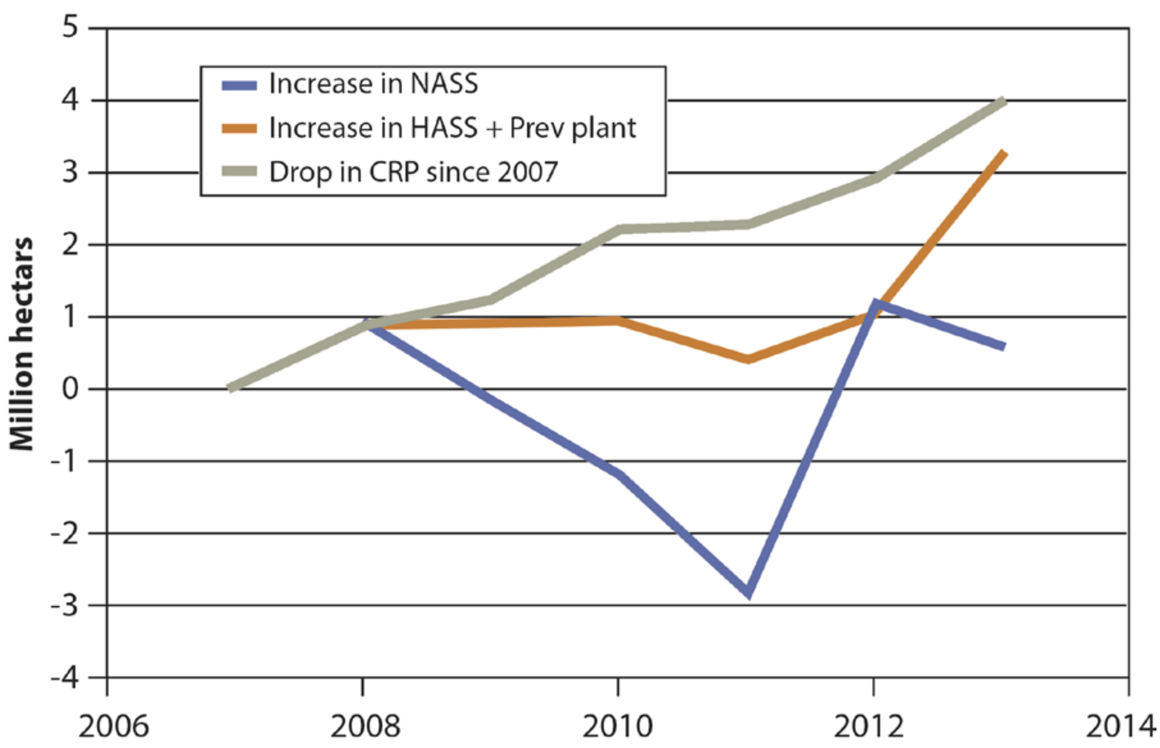

Figure 14. CRP Land Showing up as Increased Prevented Planting Acres

[12] Prevented planting has been part of the US crop insurance program before 2007 but data on total area designated as prevented planting are not readily available.

planted land is to the reduction in CRP, and it is also striking how little of the land that is no longer enrolled in CRP shows up as land in production.

What can be concluded from this more detailed examination of extensive land use in the United States is that the data seem to indicate a reversal of a long-term trend of declining total US cropland since 1996 beginning in 2007—the first crop planted in response to significantly higher prices for US corn and soybeans. The large reduction in land enrolled in CRP is much greater than the amount of land that is reported as being in productive use in crop production. This suggests that there is an abundance of ex-CRP land that is available for planting or that a large proportion of ex-CRP land has not yet been available for crop production and is being reported as having been prevented from being planted. The data are consistent with any increase in extensive land use since prices increased in 2006 as coming from a stock of available land that had been planted to crops previously or from land that was enrolled in CRP. This finding is consistent with USDA (2013), which found that the only net contributor to US cropland from 2007 to 2010 was a reduction in CRP land. There was no net increase in cropland from conversion of forests, from conversion of urban land, or from conversion of pasture.

Conclusions

That countries primarily responded to higher world prices by intensifying land use rather than by converting land from forests and pastures should not be surprising. Many countries, such as China and India, simply do not have available land to bring into agriculture. In countries with land suitable for crops, the investment and other transaction costs of developing new land make the process quite costly relative to the cost of increasing the intensity of land use. In addition, the value of waiting to invest in land conversion projects is large, which leads to a significant delay in land conversions.

The pattern of recent land use changes suggests that existing estimates of greenhouse gas emissions caused by land conversions due to biofuel production are too high because they are based on models that do not allow for increases in non-yield intensification of land use. Intensification of land use does not involve clearing forests or plowing up native grasslands that lead to large losses of carbon stocks.

The recent data on land use changes reveals the importance of policy in determining land use decisions. In Argentina, higher export taxes and quotas on corn and wheat relative to soybeans caused soybean area to increase and wheat area to decrease. The drop in wheat area limits the availability of land on which soybeans can be double cropped which means that expansion of soybeans can only take place by replacing existing crops or by expanding onto new lands. In Brazil, increased enforcement of laws restricting clearing of forests and the resulting drop in the rate of deforestation is consistent with Brazil expanding land use at both the intensive and extensive margin.

It might be argued that recent data are a poor indicator of what we should expect to happen if more time passes because supply response is always larger in the long-run than in the short-run. Land conversion takes time but the time gap used here to measure land use change is long enough to allow a significant amount of change to happen. In addition, the incentive to expand agricultural supply between 2006 and 2012 was as strong as any period since at least 1960. Furthermore, if the recent sharp declines in commodity prices continue then the incentive to expand supplies in the future will be muted.

We plan on extending our analysis of land use changes by attempting to develop a statistical model to explain more systematically why some countries expanded land use more at the extensive margin and others expanded more at the intensive margin. Such a model could provide better insights into the role that policy, price transmission, and resource availability plan in determining agricultural supply response. Improved understanding could be useful to future attempts at estimating greenhouse gas emissions caused by extensification of agricultural production.

Abstract: Estimates on impacts of biofuel production often use models with limited ability to incorporate changes in land use, notably cropping intensity. This review studies biofuel expansion between 2000 and 2010 in Brazil, the USA, Indonesia, Malaysia, China, Mozambique, South Africa plus 27 EU member states. In 2010, these countries produced 86 billion litres of ethanol and 15 billion litres of biodiesel. Land use increased by 25 Mha, of which 11 Mha is associated with co-products, i.e. by-products of biofuel production processes used as animal feed. In the decade up to 2010, agricultural land decreased by 9 Mha overall. It expanded by 22 Mha in Brazil, Indonesia, Malaysia, and Mozambique, some 31 Mha was lost in the USA, the EU, and South Africa due to urbanization, expansion of infrastructure, conversion into nature, and land abandonment. Increases in cropping intensity accounted for 42 Mha of additional harvested area. Together with increased co-product availability for animal feed, this was sufficient to increase the net harvested area (NHA, crop area harvested for food, feed, and fiber markets) in the study countries by 19 Mha. Thus, despite substantial expansion of biofuel production, more land has become available for non-fuel applications. Biofuel crop areas and NHA increased in most countries including the USA and Brazil. It is concluded that biofuel expansion in 2000–2010 is not associated with a decline in the NHA available for food crop production. The increases in multiple cropping have often been overlooked and should be considered more fully in calculations of (indirect) land-use change (iLUC). © 2013 Society of Chemical Industry and John Wiley & Sons, Ltd

Introduction

Increased biofuel production has led to criticism and concerns about food availability while it is feared that rising demand for cropland will lead to deforestation, grassland conversion and increased Greenhouse Gas (GHG) emissions from these land use changes. The main criticism is based on expected impacts of biofuel production following the introduction of dedicated biofuel targets and policies.[1–3]

Commonly used economic models in biofuel policy evaluation include multimarket partial equilibrium models such as the FAPRI-CARD, ESIM, and IMPACT model, and computable general equilibrium (CGE) models such as the Global Trade Analysis Project (GTAP), LEITAP and the Modeling International Relationships in Applied General Equilibrium (MIRAGE) model. Most models were originally developed to evaluate agriculture or climate policies and were later adapted to incorporate biofuel production.[4–6] This has consequences for the way the models have been implemented. Early applications, for example, did not consider generation of co-products (by-products of the biofuel production process which are mostly used as animal feed)[1,7] while second-generation biofuel production technology, at least in early applications, was not included.[4]

Other restrictions include limited ability to adjust to accelerations in yield improvement[7] or to changes in crop rotation.[9] Most models do not consider double-cropping (cultivation of two or more crops on the same plot within a given year), while changes in fallow or other unmanaged land can only be accommodated to a limited extent,[8] which is considered a significant drawback of model results.[7] Changes in programs offering farmers compensation for not cultivating arable land (Conservation Reserve Program (CRP) in the USA and Set-Aside in the EU), for example, were often not adequately represented. Further, models do not fully incorporate impacts of trade policies (e.g. preferential biofuel imports[8]), crop tillage,[10] or agro-ecological conditions in crop production areas.

While the exact consequences of these limitations remain unclear, there is a risk that relevant changes in crop production patterns, partly triggered by biofuel policies, may not be sufficiently covered in the analysis. Scenarios for future crop production published by the Food and Agriculture Organization (FAO) suggest that increasing cropping intensity will be an important source of additional crop biomass. According to Nachtergaele *et al.*,[11] cropping intensity is projected to increase by a total of 4% in developing countries between 2006 and 2050. For developed countries, however, the forecast increase is 7%. Global average is projected to increase by 6%.

Central to the debate on the impact of biofuel production is the question to what extent current policies are causing alienation of land from food and feed production. At the core is the way increased biomass requirements are to be met by area expansion, yield improvement or by increased cropping intensity. Bruinsma[12] estimated that 80% of the projected growth in crop production in developing countries up to 2050 would come from intensification in the form of yield increases (71%) and higher cropping intensities (8%). Higher shares are projected in land-scarce regions such as South Asia and the Near East/North Africa where increases in yield would need to compensate for the expected decline in the arable land area. Arable land expansion will remain an important factor in crop production growth in many countries of sub-Saharan Africa and Latin America; although less so than in the past.

Given the large (albeit possibly temporary) increases in crop prices, the general expectation that biofuels will permanently push up demand for food crop biomass plus the fact that farmers in the past have shown to be able to respond effectively to changes in crop demand might have to be moderated. Especially the projected increases in cropping intensity may be on the low side. Using data for 1962–2007, OECD-FAO[13] for example calculated that half of the realized increases in the harvested area were attributable to increased cropping intensity (the other half have been related to area expansion).

More recently, reduction of (fodder and) CRP area and increased double-cropping have been reported for the USA.[14] For example, about 16% of 2008 corn and soybean farms had brought new acreage into production since 2006. This new, formerly uncultivated, land accounted for approximately 30% of the reported farm's expansion in total harvested acreage. Most acreage conversion came from uncultivated hay. Some 15% of corn and soybean farms reported a harvested acreage (summing up all crops) exceeding their arable area in 2008, implying an increase in double-cropping. These farms reported greater expansion in harvested biofuel crop acreage than other farms, suggesting double-cropping is a quick and effective strategy to generate additional biofuel crop biomass.

Given the above limitations, economic model impact assessments of biofuel policies should be considered with care. Consequences of the limitations on the modeling outcome are difficult to assess but they may be considerable. The introduction of co-products in a GTAP evaluation of US and EU biofuel policies, for example, was

© 2013 Society of Chemical Industry and John Wiley & Sons, Ltd

assessed to reduce the need for land conversion with 27%.[6] According to Croezen and Brouwer,[15] scenarios including second-generation biofuel technologies resulted in land-use requirements that were 50% lower as compared to scenarios which did not include lignocellulosic biofuel conversion technologies.

In summary, the use of estimates of biofuel scenarios based on incomplete information could generate misleading estimates. Another risk is the inadequate input use, which could give an incorrect impression with respect to day-to-day crop management practices such as input use efficiency. Consequently, perspectives for (sustainable) biomass production for biofuel and food/feed applications may be estimated incorrectly.

With a view to improving the accuracy of data for evaluations of biofuel policy impacts, this paper assesses data from different sources of biomass production of eight major biofuel producers. We analyze biofuels and feedstock increases of major biofuel feedstocks between 2000 and 2010, and their impacts on land use in Brazil, the USA, the EU, China, Indonesia, Malaysia, South Africa, and Mozambique. Together, these countries represent a large majority of global biofuel production. Local conditions for crop and biofuel production will be described in a generalized way. In order to determine the impact of biofuel policies, production volumes will be compared to those of 2000, clearly before most countries introduced biofuel-related policy measures. An important distinction will be made between the amount of biomass (crop feedstocks) that is used to generate biofuels, the amount of land that is needed to produce the biomass, and the average number of harvests that can be generated from arable land (resulting from the prevalence of fallow and double-cropping in a given region). The paper will make use of the following concepts:

- Harvested area: the crop area that is harvested in a country or region in a given year. This differs from the amount of arable land, as land may be harvested several times, while fallow land is not harvested at all.
- Agricultural area in a given country or region. This includes arable land (cultivated with arable crops, i.e. food and feed crops), permanent grassland and agricultural tree crops (fruits, beverages, stimulant crops)
- Cropping intensity: the ratio of harvested crop area to the amount of arable land.*

The relation between these concepts is the following equation:

- Harvested area = arable area * cropping intensity (1)

In our analysis, we estimate land and biomass balances. Based on the volume of biofuels produced, the equivalent amount of biomass and the required area of land is calculated. These estimates are based on detailed material collected and analyzed for a book on biofuel crop production systems currently in preparation. The review is organized as follows. First, it describes available land resources in the study countries. Next, it presents biofuel production in 2010 which is compared to that in 2000. Implications of biofuel expansion for land use are given, as are other changes in land use that have been observed. This is followed by a discussion and some conclusions.

Land resources

An overview of land cover and land use in the study countries is presented in Table 1. China, Brazil, and the USA are the largest countries, Brazil having the largest forest area (nearly 40% of the study countries total). Agricultural area is high in China, the USA and (on a relative scale) the EU, Mozambique, and South Africa. Most arable land is found in the USA, China, and the EU, permanent grasslands being important in China (hosting more than one-third of the study area grassland), the USA, and Brazil. We calculated cropping intensity, expressed as the sum of all harvested crop area during a given year divided by the total arable land (the Multiple Cropping Index or MCI). MCI was originally introduced as a measure for cropping intensity of tropical farming systems,[16] but can be calculated for temperate regions as well.[12] MCI in the study countries varies between 0.53 in South Africa, 1.45 in China. It is around 0.8 in Brazil, the USA, and the EU.

Biofuel production

Sugarcane is the predominant feedstock for ethanol production in tropical regions (Table 2). In temperate areas, ethanol is mostly made from cereals (corn in the USA and China, wheat in the EU and China). Main biodiesel feedstocks are soybean (Brazil, USA), rapeseed (EU), and oil palm (Indonesia and Malaysia). There are other feedstocks of minor importance, such as castor beans in Brazil, sunflower in the EU and Jatropha in Mozambique, but these are not included in the analysis.

Large differences exist in the way fields are prepared for biofuel production. There are a number of practices which

*Note: this is not similar to the intensity of crop production (amount of inputs used per ha or amount of yield realized per ha).

EU	Sugarbeet	Ethanol	Plowing	Moderately high
Indonesia and Malaysia	Palm oil	Biodiesel	Pre-harvest burning	Moderately low
China	Corn	Ethanol	Plowing	Very high
China	Wheat	Ethanol	Plowing	Very high
Mozambique	Sugarcane	Ethanol	Pre-harvest burning	Moderately high
South Africa	Sugarcane	Ethanol	Pre-harvest burning	High

determine the performance of the biofuel production chain including pre-harvest burning of sugarcane leaves and plowing for arable crops. Burning leaves of sugarcane is common practice before manual harvesting in order to avoid injuries to laborers. This causes a considerable loss of leaf material and soil organic matter, while emissions of particulate matter cause a threat to the laborers' lungs. This practice is gradually being phased out in Brazil where mechanical green harvesting is becoming more common. Plowing arable fields, causing loss of soil carbon, is common in the EU and in China, but less so in the Midwest of the USA and soybean cultivation in Brazil, who have adopted conservation agriculture. Use of fertilizers and agro-chemicals is highly variable. Input use in feedstock production is low to moderately low in Brazil and in the USA (corn), Indonesia, Malaysia and Southern Africa. It is high in the production of cereals (USA, EU, and China) and rapeseed. Sugarbeet holds an intermediate position.

The main output data are presented in Table 3. Crop yield is high for sugarcane (Brazil, South Africa), sugarbeet, and oil palm. Cereal yields are high for corn in the USA, but less so for corn and wheat in the EU and China. Rapeseed and soybean yields are modest. Ethanol yields are highest for sugarbeet, and sugarcane (Brazil). Highest biodiesel yields were observed for oil palm (Indonesia, Malaysia). Generation of co-products is also quantified, as these can be applied in the livestock industry. Major biofuel crops are well established feed crops, which holds especially for corn and soybean. Co-products considered in this study include dried distillers' grains with solubles (DDGS), soy meal, rapeseed meal, beet pulp, and palm meal. It was decided to use a simple mass balance approach to distinguish between crop biomass used for biofuel production and for feed applications. Biofuel land claims were calculated by allocating a share of total land use according to the ratio of total crop feedstocks used for biofuels. Co-product yields were calculated using conversion data and converted into tons per ha equivalent

which allows better comparison. Co-product yields are high for corn (USA), oil palm, and sugarbeet. Yields are low for rapeseed and soybean, while no co-products for the food or feed market are generated by sugarcane-ethanol.

Ethanol production in the study countries, amounting to 17 billion litres in 2000, rose to 86 billion litres in 2010 (Table 4). Most of the increase was realized in the USA, which was responsible for a production of 50 billion litres in 2010. Brazil is the second-largest producer with 28 billion litres, followed by the EU and China. Increases have been relatively high in China, the USA, and the EU. Biodiesel production rose from 0.8 to 15 billion litres. The EU is the highest producer, followed by Brazil and the USA. Indonesia, Malaysia, Mozambique, or South Africa are not producing significant amounts of biofuels, although they may be important producers in their respective regions. Biofuel production in the study countries (86 and 15 billion litres of ethanol and biodiesel, respectively) represents 97% and 77% of the global total production level. Thus, conclusions of global significance can be drawn from the analysis of the study countries.

Table 4. Biofuel production in the study countries (billion l).

Notes: N.i. = not included; Neg. = negligible.

Land use

Land used for biofuel expansion was calculated by dividing increased biofuel production presented in Table 4 by biomass to biofuel conversion rates taken from literature. Since 2000, biofuel expansion in the study countries has claimed an additional 25 million ha of cropland (Table 5). As 11 million ha is allocated to co-products, net biofuel expansion amounts to 14 million ha. Over 85% of area expansion occurred in the USA, where increased biofuel production has occupied over 5 million ha, and in the the EU and Brazil. Co-product generation is relatively high in the USA and the EU. The main crops used to produce biofuels (corn, wheat, soybean, and rape), are dominant feed crops whose nutritive characteristics have long been known. Low co-product ratio in Brazil is explained by the high share of sugarcane, whose residues are mostly used in the production of biofuels or electricity (co-generation). Vinasse is recycled and used as fertilizer.

Since 2000, countries of the study area have seen a net decline in agricultural area by 9 million ha. Loss of agricultural area in the USA, the EU, China, and South Africa amounted to 31 million ha, which is mostly compensated

South Africa	0.12	0.04	0.1	–2.7	–1.2	–4.0
All	24.9	11.4	13.5	–9.0	41.5	19.0
Global total				–47.8	91.5	

by expansion of agricultural land in Brazil (plus 12 million ha), Indonesia/Malaysia (plus nine million ha), and Mozambique. Net global loss of agricultural area amounted to 48 million ha. In many cases, loss of agricultural area has been much larger than net expansion of biofuel area. This was the case in the EU, China, and South Africa. It is only in the USA that biofuel expansion is the dominant cause of agricultural land use loss.

Increasing the cropping frequency on arable land – reflected by an increase of the MCI – allows farmers to increase the harvested area on shrinking agricultural areas. This has facilitated *additional* crop harvests equivalent to 42 million ha. More than half of this expansion was realized in China, where government policy has been oriented toward improving (maintaining) food production capacity. MCI also added considerable harvested areas in the USA, Brazil, the EU, Indonesia, and Malaysia. The role of MCI in improving agricultural output since 2000 can hardly be overemphasized. Global increases, equivalent to 92 million ha of harvested crops, have been more than sufficient to compensate for losses of agricultural area.

Improvement of MCI in all but one case is more than sufficient to compensate for expansion of biofuel area: this is the case in Brazil (where MCI generated 5 million ha while biofuels required 3 million ha – a positive balance of nearly 2 million ha), the USA (11 *vs.* 5 million ha), EU (0.2 million ha balance), Indonesia/Malaysia (plus 2 million ha), China (19 million ha) and Mozambique (0.8 million ha). South Africa, which noted a decline of MCI, is the exception to the rule of increased cropping intensity.

The combined effect of biofuel expansion, changes in agricultural area, and improvement of MCI generally is positive. Together, countries included in the study increased harvested area for non-biofuel purposes of 19 million ha. This increase allowed improved availability of crop production for traditional food, feed, and fiber (FFF) markets. Net FFF area increased in most of the cases, except for the EU and South Africa.

Discussion

Following changes in biofuel policies in the course of the first decade of the twenty-first century, a strong expansion in biofuel production was observed in the USA, the EU, China, and many other countries. The 34 study countries realized an increase in ethanol production of 68 billion litres and 14 billion litres of biodiesel in 2010 as compared to 2000. These increases, however, were not sufficient to fully satisfy biofuel policy objectives in the USA and the EU. China, Indonesia, and Malaysia have adjusted policies in response to substantial consumption of food cereals and high palm oil prices, respectively. For the near future, further expansion of biofuel production is expected especially in the USA, Brazil, Argentina, and the EU. Smaller, but significant, development may be expected elsewhere.

Land devoted to biofuel production was calculated at 32 million ha in 2010, an increase of 25 million ha as compared to 2000. Of this increase, 11 million ha can be allocated, using standard conversion rates, to co-products. This means that nearly half of the increase in biofuel area in fact is used to generate crop biomass for the livestock feed market. Clearly, ignoring co-product generation in early biofuel impact assessments has led to an overestimation of land requirements, in most cases by 40% or more. The contribution of feed co-products is relatively high in the USA, China, and the EU due to the large share of cereals with high feed yields. It is low in Brazil where ethanol production is dominated by sugarcane which generates no

© 2013 Society of Chemical Industry and John Wiley & Sons, Ltd | *Biofuels, Bioprod. Bioref.* (2013); DOI: 10.1002/bbb

feed co-products. However, it should be noted that the co-generation of electricity from sugar cane residues has not been included in the calculations.

Biomass used for biofuel production, calculated from biofuel literature and FAO statistics, amounted to 527 million ton in 2010. This is an increase of 334 million ton, of which 80 million tons is for co-product generation. Biofuel expansion therefore required 254 million tons of crops. Area expansion, amounting to 25 million ha (including co-products), has been relatively stronger due to a shift from high yielding (ton per ha) sugarcane to cereals like corn and wheat and to oil crops like soybean and rapeseed all which have much lower yields than sugarcane. Implications for land use will, however, also depend on the role of yield improvement. In literature, different assumptions on yield improvement can be found. For US corn, for example, Searchinger *et al.*[19] assumed a maximum of 20% yield improvement in 30 years. Others have suggested that a considerable share of corn used in biofuels in the USA could be generated by yield improvements.[20] One should be extremely careful comparing crop yields as these tend to show large year-to-year variations. However, US corn yields calculated from FAOSTAT data suggest that a significant part of these yield improvements already has taken place between 2000 and 2010. Indicative yield improvements (3-year averages) during this period of sugarcane in Brazil and wheat in the EU have been 17% and 11%, respectively.

The changes in land use that were reported are most revealing. The loss of agricultural area due to urbanization, etc., in industrial countries (USA, EU, South Africa) is two times larger than biofuel expansion (31 *vs.* 14 million ha). Expansion of agricultural area in other countries (Brazil, Indonesia, Malaysia, and Mozambique) amounted to 22 million ha. Changes in intensification of arable cropping are even larger. On a global scale, the MCI increased by 7% in a period of ten years. This may not seem high, but as it applies to an area of 1.4 billion ha, the implications are enormous. In the study area, improvement of cropping intensity has been variable. It rose by 14% in China, 10% in Brazil and Mozambique, and 4% in the EU. Other countries take an intermediate position.

For the entire study area, 42 million ha of crop harvested area has been generated. Consequently, the reduction of unutilized arable land (CRP in the USA, set-aside in the EU plus fallow) and an increase in double-cropping has been sufficient to generate nearly three times the amount of biofuel land expansion. Both fallow reduction and double-cropping seem to have been largely ignored in the debate so far which is a serious omission. Improved MCI was identified as a major source of increased harvested area by OECD-FAO,[12] but the consequences for land availability vis-à-vis future biofuel expansion tend to have been overlooked. Bruinsma[11] focused mainly on yield improvement. Economic models used in evaluation of biofuel policies appear to have neglected the potential contribution of MCI.

In the future, MCI may be expected to show further increases. The magnitudes will, however, depend on crops and farming systems. Tropical regions have a larger potential for double-cropping (provided sufficient water is available). Cereals and pulses, having relatively short growing cycles, provide good perspectives. Sugarcane, occupying land year round, has limited potential for increased MCI. Climate change may, however, also offer new opportunities for temperate regions, for example, when temperatures in spring allow early harvesting of winter cereals.[17]

The approach that was followed has a number of advantages. Calculating full biomass balances allowed the assessment of biofuel feedstocks available for animal feed and – consequently – gives a realistic assessment of the amount of feedstocks required for biofuel production. Requirements of biofuel production for biomass and land resources were calculated with local data, thus incorporating a realistic assumption of cultivation practices, crop rotations, yields, and conversion efficiencies. The use of full land balances has put land demand for biofuels in perspective, integrating many processes which affect land requirement and changes in land use. Limitations of the approach are related to the large number of data that are needed. Data on crop rotations and cultivation practices often have a local nature which makes it difficult to obtain a more generic picture at the national level. Data on double-cropping and biomass to biofuel conversion are extremely difficult to obtain while the exact relation between biofuel production and increased MCI needs to be investigated. Calculations, finally, have been restricted to major biofuel feedstocks.

Notwithstanding these limitations, the implications of the findings are substantial. The impact of the increases in cropping intensity can hardly be overemphasized. On the one hand, observed MCI improvement since 2000 demonstrates that projected biofuel crop areas (estimated up to 50 million ha in 2050) can easily be compensated. In one decade, enhanced cropping intensity generated as much as 92 million ha of extra harvested crops worldwide. This is surprisingly high, and the consequences are clear. While biofuel production may occupy a significant amount of crop land in the future, there are strong drivers of crop area expansion which may be able to generate similar – or larger – additional harvested areas

© 2013 Society of Chemical Industry and John Wiley & Sons, Ltd | *Biofuels, Bioprod. Bioref.* (2013); DOI: 10.1002/bbb

in biofuel countries. Thus, there is little reason to expect that biofuel expansion will lead to substantial reductions of area of food/feed production. For the first decade of the twenty-first century, net harvested area for traditional (non-biofuels) biomass markets in the study area increased by 19 million ha.

The outcomes of this study are relevant to the debates related to biofuel production. Our review clearly shows that biofuel expansion has not been the major factor causing land-use change. Loss of arable land due to urbanization, etc., has claimed over twice as much land. This loss is almost certainly permanent, which is not the case for biofuel production. Further, increased intensity of arable land use has generated more than sufficient harvested area to fully compensate biofuel expansion. This makes claims of land-use changes caused by biofuel expansion (as caused by biofuel policies) less convincing.

Consider, for example, projected land use change caused by EU biofuel policies. In 2020, an additional area of 0.5 million ha has been projected to be devoted to biofuels in Brazil.[2] Only 15% of this is associated with deforestation. These are small figures, which suggest that the role of biofuel expansion as a major driving force for deforestation in Brazil needs to be reconsidered (26 million ha of forest was lost since 2000). Projected land-use change due to EU policies should also be compared to the increase of MCI observed in Brazil, generating almost (five million ha or) *ten* times the amount lost to EU biofuel exports in just one decade. In the light of these figures it is hard to imagine that biofuel policies alone are the dominant source of land-use change or deforestation.

The food *versus* fuel debate, further, needs to be enriched. While biofuel expansion in the study area has claimed 14 million ha of arable land, this area is more than compensated for by increased cropping intensity. FAOSTAT data clearly show that harvested area for food/feed markets has increased. They also show that biomass availability for food and feed applications has gone up. Further, it is not biofuel expansion but loss of agricultural land due to urbanization, etc., that is the major threat to land (biomass) availability. All this needs to be considered in the debate. The outcomes of this study show that it is essential for policy impact analyses to use statistical data to check model projections. Further, the analysis should be based on full – and not partial – biomass and land balances. Initial restrictions in model applications, ignoring co-product generation, seem to have given strongly misleading conclusions. Excluding double-cropping or cropping intensity in biofuel policy analysis has been another limitation which has had a major impact on the results. It is suggested, therefore, to incorporate local and national data on crop cultivation (e.g. crop rotations) in assessment studies of biofuel policies.

Keeney and Hertel[8] indicated that forecasting environmental impacts of biofuel policies requires both careful model formulation as well as sufficient empirical knowledge of supply and demand. Currently, only a few key parameters (e.g. yield elasticity, acreage response elasticity) determine the outcome of land-use change modeling studies. It should be checked to what extent popular analytical models correctly predicted adjustments in crop production and land-use practices. Essential elements that may have been lacking include changes in fallow and double-cropping, accelerations in yield improvement, and loss of agricultural land due to urbanization, infrasructure and industry.

Special attention is merited for cropping intensity, as well as non-biofuel crop yield improvement.[7] In this process, predicted changes in crop production and land use should be critically evaluated. Keeney and Hertel,[8] for example, predicted an increase of crop production to coincide with a reduction of forest and pasture areas in the USA, the EU, and Latin America. FAO statistics have shown that, during the last decade, forest area in the USA and EU has *increased* while grassland area remained constant in the USA and in Brazil.

The implication of this analysis for estimations of GHG emissions from biofuel production is potentially substantial. Very high assessments of carbon releases due to indirect land-use changes[2,18] have been used to underpin adjustments in biofuel policies in the EU. This review shows that a careful reconsideration of the generally assumed view that biofuels are important causes of indirect land use change is in place. Whereever feasible, this should be done using observed – rather than modeled – data.

Conclusion

This review addressed the impact of increased biofuels production on land use in major biofuel producing countries using full land balances based on land and crop statistics. Biofuel expansion is often considered a major threat for biomass availability for food and feed production and an important source of land use change. However, this analysis based on FAO statistics on crop production and land use in the period 2000 to 2010 shows that the impact of biofuel expansion on land use has been limited. An increase of 14 million ha was noted in 34 major biofuel producing nations over a period of a decade.

© 2013 Society of Chemical Industry and John Wiley & Sons, Ltd

During the same period, increased cropping intensity generated over 42 million ha of extra crop land – three times the biofuel expansion. Further, an area of 31 million ha of agricultural area was lost (amongst other due to urbanization) in the USA, the EU, China, and South Africa. Consequently, there are strong drivers for expansion of land availability for traditional food and feed markets which has led to increased food and feed crop area. With the exception of the USA, biofuel expansion has not made up more than a quarter of the total loss of agricultural land.

This information should be considered in discussions on food vs. fuel debate and land-use change caused by biofuel policies. Existing frameworks need to be reconsidered. For example, biofuels *cannot* be identified as the most important or single global cause of land-use change. Other drivers have caused more (and more permanent) loss of agricultural area including process of urbanization, infrastructure development, tourism and even conversion into nature (an additional 8 million ha of forest have been established in the USA and the EU since 2000). Observed changes in land use caused by biofuel policies are very small in comparison to other changes.

Models used to evaluate biofuel policies should be enriched by incorporating more and better information on (changes in) land use and local cropping patterns, as well as differences in current and potential productivities in different agro-ecologies and farming systems. Finally, the relation between increased multiple cropping and biofuel production should be further investigated.

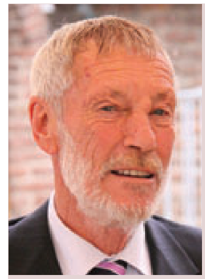
Hans Langeveld

Hans Langeveld, agronomist, develops and evaluates bioenergy and biobased production chains. His main focus is on feedstock availability, land use change, soil carbon dynamics and GHG emissions. He studied sustainable land use in five continents and co-authored many scientific papers as well as books on farming systems and the biobased economy.



Herman van Keulen

Herman van Keulen was trained as a soil scientist and production ecologist at Wageningen University. During his carreer, he wrote many crop growth models. Herman developed innovative concepts in soil water modelling and sustainability research and has been an expert on crop growth, animal production systems and sustainable land use for over four decades.

John Dixon

John Dixon is Principal Regional Adviser, Asia and Africa, Australian Centre for International Agricultural Research. He has over 30 years of developing country experience with agricultural research and development, including cropping systems, economics and natural resource management with the CGIAR system and the FAO UN.

Foluke Quist-Wessel

Foluke Quist-Wessel is senior agronomist and director of AgriQuest. She holds an MSc. in Tropical Crop Science (Wageningen University) and focuses on agricultural production systems, rural development, food security and chain development. Previously, she worked at Plant Research International (Wageningen UR), and Biomass Research.

The commenter is supportive of ARB's proposed modifications to section 95488 which streamline the re-certification process. The commenter however points out that it is somewhat unclear how ARB staff would handle the producer-specific inputs demanded by the CA-GREETv2.0 life cycle analysis model.

Agency Response: ARB staff appreciates the support provided by the commenter. In response to the Commenter's concern with regards to producer-specific inputs, staff is presently developing an administrative approach to processing re-certification of legacy pathways. Guidance will be provided on re-certification issues at a public workshop to be conducted after the proposed Board Hearing.

1235. Comment: **LCFS SF12-2**

The commenter supports the proposed prioritization of fuel pathway re-certifications for "batch processing."

Agency Response: ARB staff appreciates the support for the pathway re-certifications.

1236. Comment: **LCFS SF12-3**

This Comment is related to the definition and interpretation of a "Tier 1" fuel.

Agency Response: Please see response to **LCFS FF44-13**.

1237. Comment: **LCFS SF12-4**

Tier 1 fuels should be excluded from the Provisional Pathway requirements described in section 95488(d)(2).

Agency Response: Please see response to **LCFS SF4-1.**

1238. Comment: **LCFS SF12-5**

The commenter believes the requirement of one quarter of operational data for a provisional pathway will discourage investment and recommends allowing approval based on pilot plant data.

Agency Response: See response **LCFS FF56-2**.

1239. Comment: **LCFS SF12-6**

The commenter urges ARB to revise its indirect land use change (ILUC) analysis to reflect the best available science and data.

Agency Response: The comment is not relevant to any of the 15 day changes presented. However, ARB's response to this comment is:

The iLUC analysis as currently proposed by ARB is based on the latest and best available scientific and economic information. These values were developed by accounting for updates in land use change science and methodologies in economic modeling of such effects. See responses to **LCFS 8-1** through **LCFS 8-14**.

1240. Comment: **RFA Comment Letter**

Agency Response: Page 4 – 65 is a reproduction of comment letter **8_OP_LCFS_RFA** comments **LCFS 8-1** through **LCFS 8-14**.

Re: The Proposed Re-Adoption of the Low Carbon Fuel Standard

COMMENTS OF SOLAZYME, INC. ("So1azymc")

Solazyme appreciates the opportunity to comment on the California Air Resources Board's (ARB's) proposal for the 2015 Re-Adoption of the Low Carbon Fuel Standard (LCFS), and we are supportive of the LCFS. Solazyme was founded in California over 12 years ago and is based in South San Francisco. We are in commercial production and already selling biofuel to private fleets in the US, and we are eager to supply advanced biofuels for the California market.

Introduction to Solazyme

Solazyme has pioneered an industrial biotechnology platform that harnesses the prolific oil-producing ability of microalgae. Our platform is feedstock flexible and can utilize a wide variety of plant-based sugars such as sugarcane-based sucrose, corn-based dextrose, and sugar from other biomass sources including cellulosics. By growing our proprietary microalgae in the absence oflight using fermentation tanks to convert photosynthetic plant sugars into oil, we are in effect utilizing "indirect photosynthesis." Solazyme develops and manufactures products for the food, skin-care, industrial chemical and lubricants, and industrial/military fuels sectors.

Solazyme is Currently Producing Advanced Biofucls

At Solazyme, we are creating clean, low carbon, renewable algae-derived advanced biofl.tels. The company's tailored oils are refined into cost-effective, high-quality, on-spec "drop-in" replacements for diesel and jet fuels. Solazyme's algae-derived fuels are compatible with existing infrastructure, meet industry specifications, and can be used with fact01y-standard engines, without modifications. The company has worked with Chevron, UOP Honeywell, and other industry leading refining partners, to produce SoladieselRn®renewable diesel, Soladiesel® renewable diesel, and Solajet® renewable jet fuel for both military and commercial application testing.

After extensive work with the US Department of Defense, the US Navy, United Airlines, Volkswagen, and others, Solazyme is now producing blends of its fuels for private users in the United States. In fact, we have supplied more than four million gallons for fuel blends to private fleet operators to date. This work has shown that we can supply at scale in an efficient, cost-effective way and we are looking to expand our supply base. A well-designed LCFS would help significantly in allowing us to introduce this innovative fuel to California.

Advanced Biofuel Products

- SoladieselnD® is a I00% algae-derived biodiesel that can be used with facto1y-standard diesel engines without modification. The fuel is fully compliant with the ASTM D 6751 specifications for Fatty Acid Methyl-Esther based (FAME) fuel that meets ASTM D 975, and significantly outperforms ultra-low sulfur diesel in total THC, carbon monoxide and particulate matter tailpipe emissions. SoladieselBD®also demonstrates better cold temperature properties than any commercially available biodiesel.
- SoladieselRD® is a I00% algae-derived renewable diesel fuel. It is a drop-in altemative to standard diesel fuels that meets ASTM D 975. Chemically indistinguishable from petroleum-based diesel, the fuel's tailpipe emissions also release fewer particulates and meet the new American Society for Testing and Materials (ASTM) standards for ultra-low sulfur diesel.
- Solajet® is a renewable aviation fuel refined from Solazyme's algal oil. It is the world's first microbially-derived jet fiJel to meet key industry specifications for commercial aviation, ASTM D 1655. Solajet is compatible with existing infrastructure while offering key benefits, including a faster, farther and greater payload; reduced wing heat stress; lower flammability; lower smoke emissions; longer storage life; and ultimately, lower maintenance cost.
- Since 2008, Solazyme has partnered with the US Navy and the Department of Defense to develop, test and ce11ify advanced drop-in renewable fuels that meet their strictest standards. Specifically, Solazyme has developed jet fuel, marine diesel and on-road diesel that have been rigorously tested by the U.S. Navy and shown to meet its HRD-76 and HRJ-5 military specifications. We are proud that Solazyme fuels were used as the reference fuels during the Navy's successful multi-year certification process for renewable marine diesel fuel.

General Comments

Provisional Pathways (pg. 91-92)

The language in Section 95488, and specifically 95488(d)(2), is greatly conceming to Solazyme because of the upfront requirements for a new pathway. The latest language has made necessary improvements, such as the removal of the 2 year monetization hold, but there are still real issues for innovative producers looking to enter the market. For instance, the proposal still requires applicants to have been in full commercial production for at least one fi.Jll calendar quarter before applying for a new pathway. This timeline is not feasible for two reasons. First, biofuel refiners use or blend a broad array of feedstocks when making biodiesel or renewable diesel (e.g., cooking oil, tallow, soy oil, etc.). The dynamic nature of feedstocks processed at a facility over the course of one quarter would make it near impossible to generate consistent data for one new feedstock, even though most new feedstocks are very similar chemically and would provide very similar data. LCFS SF13-1

In addition, this timeline does not match the natural course of the commercialization process for a new biofuel. It is standard practice for biofuel refiners to take time to scale up a new feedstock while it is introduced, typically by running small batches over time. That means that the refiners will not generate a qumier's worth of consistent data on the new feedstock during its early adoption. This requirement will therefore significantly delay the opportunity for a new pathway and delay advanced biofuels from being introduced into California. It creates an undue administrative burden on the refiners to test and qualifY new feedstocks. This will greatly reduce their enthusiasm to incorporate new feedstocks and unfairly drives down the value of these new feedstocks. Instead, this requirement rewards incumbents.

Furthermore, as new feedstock producers enter the California market, this will create a proliferation of pathways for ARB staff to handle. Most feedstock providers will partner with numerous refiners to produce the end product: biodiesel or renewable diesel. This means there will be a two year process for each refiner, as well as a new pathway application for each refiner, for the ARB to review.

California and the ARB have typically lead adoption for new technologies, and we hope this legacy continues, particularly at a time when so many technologies are poised to enter the market.

Batch Processing in2016 (pg. 58)

Solazyme would also like clarification on the process outlined in Section 95488(a)(3). We understand that there are a large number of existing pathways to recertify and we support efforts to expedite this process. That said, the current language seems to indicate that each fuel type would get recetiified at different times. This does not provide a level playing field for the various fuel types and all those who have worked hard to participate in the LCFS. By applying new numbers to fuel types at different times, the ARB would inherently give an advantage to the groups that are recertified first. Instead, the new numbers should be applied at the same time.

Conclusion

Solazyme understands that lack of verification for CI data for already approved pathways is an important concern. We appreciate the revisions made in the June 4 draft rule to remove the 2 year monetization hold and reinforce the authority of the ARB Executive Officer to, instead, enforce CI verification compliance. This is a much fairer approach than upfront requirements that would punish new producers. There is still work to be done, however, in ensuring that the additional upfront requirements to establish a pathway do not significantly delay (or halt) the entry of advanced biofuels to the California market.

We appreciate having this opportunity to provide comments. Please contact me if you have any questions or require additional information.

Sincerely,

Graham Ellis

13_SF_LCFS_SI

1241. Comment: **LCFS SF13-1**

This comment is related to the 'full quarter of operations' requirement specifically as it applies to multiple feedstocks used to make transportation fuel, commercialization and scale-up of processes, and prioritization of processing of pathway applications.

Agency Response: See response to **LCFS FF56-2, LCFS SF12-5, and LCFS SF8-22**.

Because different feedstocks may have different upstream direct and indirect GHG emissions impacts, ARB would prefer the fuel pathway to be based on a specific feedstock used (or feedstock most commonly expected to be used) to produce the transportation fuel. Alternatively, the applicant can demonstrate worst-case scenario modeling and selectively base the application on one feedstock.

With regards to the commenter's comments on priority processing of applications for re-certification in batches based on fuel type (pursuant to section 95488(a)(3) of the modified regulation order), staff responds that the prioritization was based on the largest volumes of low carbon fuels (by fuel type) reported in the LCFS Registration System or LRT. Staff believes that for most applicants seeking re-certification, the transition to a newer CI would be seamless.

Branch Chief, Transportation Fuels Branch
1001 I Street
Sacramento, CA 95814

Re: Third Notice of Proposed 15-day Regulation Order containing Modified Text and Availability of Additional Documents and Information for the Proposed Re-Adoption of the Low Carbon Fuel Standard

Dear Samuel Wade:

On behalf of DuPont, thank you for the opportunity to comment on the Third Notice of Proposed Modified Text for the LCFS. DuPont has significant investments in advanced biofuels that meet the specified greenhouse gas reduction threshold. These fuels will make transformative contributions to our nation's energy security, reduce greenhouse gas emissions and strengthen rural economies. These fuels represent a tremendous shift in how we energize our planet and are being commercialized due in large part to visionary state fuels programs like the CA Low Carbon Fuel Standard.

We look forward to doing business in California; however as raised in prior comments, DuPont has one significant remaining concern with the Third Notice of proposed modification to Obtaining and Using Fuel Pathways in Section 95488(d). In Section 95488 (d)(1)(D), the proposed text would allow assigning a temporary fuel production code carbon intensity (CI) that could apply for two quarters. The issue with this approach is that the temporary CI could expire prior to a fuel pathway being approved. This limitation is unnecessary and overly restricts the Air Resources Board's ability to be flexible when needed. A new fuel producer must have 3 months of operational data before submitting a new pathway request pursuant to Section 95488 (d)(2). Completing and submitting an application form after the first 3 months of operation will take several weeks. We are concerned that the fuel pathway approval process could extend beyond the period of time covered by the temporary fuel production code. It is incredibly important for new advanced biofuel producers to be able to sell into the CA market from the first day of operation and continue without a lapse in valid carbon credits.

Therefore, DuPont recommends that the regulations be modified to allow the Air Resources Board flexibility to extend the period of time for temporary fuel production codes, when circumstances warrant an extension or when a new fuel producer is actively seeking a fuel pathway approval.

LCFS TF1-1

Introduction

DuPont is an industry leader in providing products for agricultural energy crops, feedstock processing, animal nutrition, and biofuels. Our three-part approach to biofuels includes: (1) improving existing ethanol production through differentiated agriculture seed products, crop protection chemicals, as well as enzymes and other processing aids; (2) developing and supplying new technologies to allow conversion of cellulose to ethanol; and (3) developing and supplying next generation biofuels with cellulosic ethanol and biobutanol.

We bring the perspective of a company deeply involved in the agricultural and biofuels industries. Our seed business DuPont Pioneer sells corn seed to farmers growing for a variety of end-use markets, including grain ethanol production. Our intimate relationship with our farmer customers and our extensive research provides us significant insight into the agronomics of the harvest and management of corn stover as a cellulosic feedstock. We provide a variety of products for the grain ethanol business as well, including saccharification enzymes and fermentation processing aids, and so have an intimate knowledge of the operation of these relevant sugar fermentation operations.

DuPont began its research into cellulosic technology a decade ago. What started as a lab scouting project grew into a full scale commercialization effort. In 2009, DuPont opened a demonstration facility in eastern Tennessee producing cellulosic ethanol from both corn stover and switchgrass. For the past four years, we have brought together growers, academia, public institutions like the USDA and custom equipment makers to conduct harvest trials on corn stover. All this work culminated in the groundbreaking of a 30 million gallon per year facility in December of 2012 in Nevada, Iowa, located approximately 40 miles north of Des Moines. I am happy to report that we are in the very final stages of construction, commissioning has been initiated and we will be open for business later this year. We anticipate that a number of other companies in addition to DuPont will bring cellulosic volumes to the market. Multiple companies are constructing, starting up or operating facilities producing renewable fuels from a wide variety of cellulosic feedstocks including corn stover, switchgrass, wheat straw, municipal solid waste and wood fiber. Many of these are large, well-capitalized, sophisticated companies with long track records in designing, constructing and operating manufacturing facilities. This diversity of operations provides a high level of confidence for multiple technologies succeeding at commercial scale.

In addition to cellulosic ethanol, DuPont is pursuing another advanced renewable fuel with our partner BP in a 50/50 joint venture called Butamax™. The joint venture has developed and extensively tested bio-butanol, a higher alcohol fuel produced by fermenting biomass. Biobutanol has excellent fuel properties, with higher energy density than ethanol and the ability to be distributed via the existing gasoline infrastructure, including pipelines. It also reduces volatility, allowing butanol gasoline blends to be used in the summer in regions that currently require waivers from air quality regulation for the use of ethanol-gasoline blends. Because butanol has less affinity for water and is a weaker solvent than ethanol, it will be more compatible with existing equipment, including small engines.

The proposed modification to Provisional Pathways

In the Proposed 15-day Regulation Order containing the Third Notice of Modified Text and Availability of Additional Documents and Information for the Proposed Re-Adoption of the Low Carbon Fuel Standard, the Air Resources Board proposes the following in Section 95488 (d)(1)(D):

> (D) A temporary FPC approved for use by the Executive Officer will be permitted for LRT-CBTS reporting purposes for up to two quarters. Reporting will be granted only for the quarter during which a temporary FPC is approved for use and the subsequent full quarter.

Analysis and Recommendations

The proposed text is overly restrictive on the Air Resources Board preventing any flexibility to extend a temporary FPC beyond two quarters. In detail, our concerns with the proposed approach are as follows:

1. The current proposed text would by default assign a temporary, conservative CI value to these fuels that can only be applied for two quarters. This means that the temporary CI credits could lapse before the fuel pathway is approved. Any waiting period that prevents these fuels from receiving CI credit is fundamentally unfair and is not based on principles of sound science. LCFS TF1-2

2. Any waiting period that prevents a biofuels producer from receiving CI credits will prevent and delay fuel from being sold in California. DuPont's cellulosic ethanol is being manufactured in Iowa. Without the benefit of the CI credit, it would be unreasonable for us to make special arrangements to ship our fuel to California. In addition, obligated parties in California would have no reason to purchase fuel without CI credits. Given their obligations under the LCFS, they would need to purchase fuel with CI credits. LCFS TF1-3

3. Any waiting period that prevents a biofuels producer from receiving CI credits would create an unfair competitive advantage for existing fuel producers. These producers would not be required to wait to receive CI credits thereby rewarding current producers. LCFS TF1-4

4. New facilities need to be able to sell fuel for full market value from initial production and on a continuous basis in order to survive. Biofuels facilities do not have storage capacity beyond one or two days of fuel production. In addition, encouraging growth in the cellulosic and advance biofuels sector can only be achieved with supportive federal and state biofuels policies. A waiting period for CI credits would discourage rather than encourage growth. LCFS TF1-5

5. The temporary fuel production code CI for cellulosic ethanol is 41.05 as set forth in Table 7 in Section 95488. There is a very high probability that after one quarter of production and subsequent quarters of energy data submitted, that the CI value for this fuel will be reduced significantly. Therefore, there should be very little risk in allowing the Air Resources Board the flexibility to extend the temporary FPC if circumstances warrant it. LCFS TF1-6

Given the concerns above, DuPont recommends that the regulations be modified to provide the Air Resources Board the requisite flexibility to extend the assigned temporary fuel production code CI value as long as necessary while the new producer is actively pursuing a new pathway approval.

Thank you for the opportunity to comment on the Third Notice of the Proposed 15-day Regulation Order for the Proposed Re-Adoption of the Low Carbon Fuel Standard as this is an important issue for DuPont's biofuels business. Please contact me at Jan.Koninckx@dupont.com if you have any questions about the comments provided.

Sincerely,

Jan Koninckx

1_TF_LCFS_DuPont Responses

1242. Comment: **LCFS TF1-1 through LCFS TF1-6**

These comments relate to the two-quarter limit on using Temporary Pathway CIs specifically as it applies to commercialization and scale-up of new processes. The commenter sees potential for economic hardship if Temporary Pathways expire before a full pathway application is approved.

Agency Response: ARB staff has recognized the commenter's concerns. The Table 7 is available to any regulated party who has purchased a fuel, but unable to determine its CI associated with that fuel. As stated in the staff Initial Statement of Reasons (ISOR) (Summary of Section 95488(d), p VIII-11):

A fuel provider is seeking to sell a volume of fuel which has no CI associated with it. Section (d) provides a table of temporary default CIs that can be used to report transactions involving such fuel.

Therefore, Table 7 provides the flexibility which allows applicants to sell their fuels in California market while their fuel pathway applications are in the process for its certification. However, staff urges applicants to submit their applications at the same timeframe when a temporary fuel CI code is activated in the LRT-CBTS system for their use and reporting. ARB staff has assessed carefully and determined that two quarters (180 days) should be sufficient enough for staff to complete the certification process without any impact on regulated party to generate some credits for the interim period.

Growth Energy's Comments on July 31, 2015, 15-Day Notice for the Proposed Revisions to the LCFS Regulation

Growth Energy submits the following comments on the California Air Resources Board's ("CARB") July 31, 2015, Notice of Public Availability of Modified Text and Availability of Additional Documents (the "Third 15-Day Notice") for CARB's proposed revisions to the Low Carbon Fuel Standard (the "LCFS regulation").

The Third 15-Day Notice represents the third time CARB staff has performed substantive modifications to the proposed LCFS regulation since it initially circulated an Initial Statement of Reasons (the "ISOR") and an Environmental Analysis ("EA") for public review on December 30, 2014. CARB circulated the first 15-day notice for public review on June 4, 2015 (the "First 15-Day Notice"). CARB circulated the second 15-day notice for public review on June 23, 2015 (the "Second 15-Day Notice").

LCFS TF2-1

In light of all the remaining and important open issues, uncertainties, inconsistencies, and procedural errors that have marked this regulatory process, Growth Energy believes that the Board cannot take final action on the now thrice-amended regulatory proposal without publication of a new rulemaking notice that allows 45 days for public comment, leading to a new public hearing. In addition, Growth Energy submits the following comments on the Third 15-Day Notice. Submitted with these comments are the declarations of James M. Lyons and Thomas L. Darlington, which are enclosed as Attachments "A" and "B," respectively.

A. CARB's Assumptions Regarding the Usage of Renewable Natural Gas <u>in Heavy-Duty Vehicles Are Not Supported by Substantial Evidence</u>

1. CARB's Analysis of Renewable Natural Gas is Internally Inconsistent with CARB's Method of Analysis for Electric <u>Vehicles</u>

LCFS TF2-2

As part of its recent 15-day notice, CARB added a spreadsheet entitled "Estimate of Electricity Use by ZEVs" to the rulemaking file. The spreadsheet reveals the assumptions made by CARB staff in estimating the amount of electricity that would be used by light-duty battery electric vehicles (EVs) and plug-in hybrid electric vehicles (PHEVs). This analysis was used to develop "illustrative compliance scenarios and evaluat[e] potential compliance curves" included in Appendix B of the ISOR (and updates). The assumptions include the values for the number of EVs and PHEVs in operation, vehicle miles traveled, and fuel efficiency, which are generally consistent with the conclusions published by CARB staff in connection with the Zero Emission Vehicle (ZEV) regulation, which requires automobile manufacturers to produce EVs and PEHVs and offer them for sale in California. (Decl. Lyons ¶ 6.) This information is necessary to understand how CARB staff "arrived at its conclusions regarding the use of electricity as a transportation fuel in the light-duty vehicle fleet, which . . . is critical to assessing the veracity of the illustrative compliance scenarios, the environmental analysis of the proposed LCFS regulation and the estimated cost of the regulation." (*Id.* ¶ 8.) CARB has not explained why this information was not included in the original 45-day notice, nor why it waited until now to make the information available for public comment. The 15 days allowed for public review and comment are insufficient, although Growth Energy has attempted to prepare limited, time-constrained comments in Attachment "A." Among other problems, the record does not include any comparable information for the use of renewable natural gas in heavy-duty vehicles. In fact, CARB staff has advised that it "never performed an analysis similar to that disclosed for ZEVs for natural gas usage by heavy-duty vehicles under the LCFS." (Decl. Lyons ¶ 9.) This is surprising and raises serious concerns regarding the validity of the LCFS illustrative compliance scenario and, consequently, the environmental and economic analysis that were based upon that scenario. (See *id.*) "Further, it is impossible for any stakeholder or reviewing body such as the Office of Administrative Law to understand how the staff arrived at its conclusions regarding the use of electricity as a transportation fuel in the light-duty vehicle fleet, which again is critical to assessing the veracity of the illustrative compliance scenarios, the environmental analysis of the proposed LCFS regulation, and the estimated cost of the regulation." (*Id.*)

LCFS TF2-2 cont.

LCFS TF2-3

Because CARB's methods of analysis for EVs/PHEVs and natural gas are internally inconsistent, CARB's conclusions regarding natural gas usage are not supported by substantial evidence. (See, e.g., *Friends of Oroville v. City of Oroville* (2013) 219 Cal.App.4th 832, 844 [concluding that "speculative and contradictory conclusions do not close the evidentiary sufficiency gap involving the City's finding that the Project's GHG emissions will have a less than significant environmental impact after mitigation."]; see also *Vineyard Area Citizens for Responsible Growth, Inc, v. City of Rancho Cordova* (2007) 40 Cal.4th 412, 439 ["Factual inconsistencies and lack of clarity in the FEIR leave the reader – and the decision makers – without substantial evidence for concluding that sufficient water is, in fact, likely to be available for the Sunrise Douglas project at full build-out."].)

Accordingly, before CARB considers the revised LCFS regulation for approval, it should first disclose the assumptions and analysis used to estimate the use of natural gas in heavy-duty vehicles. Under its certified program, the Board must then permit full public comment and conduct a public hearing. (17 Cal. Code Regs., §§ 60000-60007.)

LCFS TF2-4

2. CARB Has Failed to Meet its Information Disclosure Requirements With Respect to the Use of Natural Gas in <u>Heavy Duty Trucks</u>

"CARB's projected increase in natural gas use in heavy-duty vehicles relative to 2014 levels is 2.6 times in 2020 and 4.4 times in 2025." (Decl. Lyons, Exhibit B-1.) To meet these increases, there would need to be "a massive increase in natural gas as a fuel for heavy-

LCFS TF2-5

duty vehicles, which directly implies a similar massive increase in the number of heavy-duty natural gas vehicles in operation in California." (*Id.*, Exhibit B-3.) Notably, however, CARB's analysis includes no estimate of "number of vehicles required" to meet the projected increase in natural gas as a fuel for heavy-duty vehicles, nor is there any evidence in the record "to support that it is reasonably foreseeable that the required number of vehicles will be in operation in California" to correspond to this demand. (*Id.*, Exhibit B-3.)

CARB's failure in this regard has resulted in a flawed and unreliable analysis. First, by (i) failing to estimate the number of vehicles required to meet CARB's projected increase in natural gas, and (ii) failing to include any evidence that it is "reasonably foreseeable" such increase would occur, CARB has failed to meet its information disclosure obligations under CEQA. Specifically, CEQA requires that an environmental analysis "provide sufficient information to enable the "'public [to] discern . . . the 'analytic route . . . from evidence to action . . . .'" (*City of Maywood v. Los Angeles Unif. Sch. Dist.* (2012) 208 Cal.App.4th 362, 393 [quoting *Calif. Oak Found. v. Regents of Univ. of Calif.* (2010) 188 Cal.App.4th 227, 262].) Because CARB staff did not prepare any detailed estimate of natural gas use by heavy-duty vehicles, and CARB's conclusions regarding natural gas usage are "unsupported by empirical or experimental data, scientific authorities, or explanatory information of any kind," the public and the decision makers have been left without any "basis for a comparison of the problems involved with the proposed project and the difficulties involved in the alternatives." (*Citizens to Preserve the Ojai v. County of Ventura* (1985) 176 Cal.App.3d 421, 429.) LCFS TF2-5 cont.

CARB's failure to provide evidence supporting any increase in heavy-duty gas vehicles in California is particularly puzzling here, as any such increase is contrary to the evidence. Analysis by Sierra Research shows "there will be no significant increase in either the heavy-duty natural gas vehicle population or natural gas use by such vehicles unless CARB requires the purchase and use of such vehicles." (Decl. Lyons, Exhibit B-3.) LCFS TF2-6

Specifically, there "are no existing CARB regulations like the ZEV mandate that require dramatic increases in the sale of heavy-duty natural gas vehicles." (*Id.*) "[I]ncreases in the California heavy-duty natural vehicle population will" therefore "be driven by market forces," and "[i]f CARB believes that the market will drive those increases, staff needs to explain why and allow the public to comment on that explanation." (*Id.*, Exhibit B-4.)

Moreover, any projected increase in the entry of a significant number of heavy-duty natural gas vehicles into the market is contradicted by CARB's own data, which show "substantial barriers to increases in heavy-duty natural gas populations." (*Id.*, Exhibit B-4.) These barriers include: (1) Shorter range between refueling; (2) Increased weight; (3) 10 to 15% lower fuel economy; (4) Higher purchase costs which range from $30,000 to $80,000 per vehicle; (5) Higher maintenance costs of 1-2 cents per mile; and (6) a limited number of LCFS TF2-7 publically accessible refueling stations. (*Id.*) There is simply no evidence CARB took these factors into account when it estimated future natural gas use by heavy-duty vehicles. LCFS TF2-7 cont.

If the entry of heavy-duty natural gas vehicles into the market does not materialize, there will also be potentially significant environmental effects, as regulated parties would have to look to other fuels to comply with the LCFS regulation. If heavy-duty users turn to biodiesel, for example, the LCFS regulation has the potential to increase NOx emissions statewide, including "significant increases in NOx emissions in the South Coast and San Joaquin Valley air basins which are already in extreme non-attainment of the federal ozone NAAQS and moderate non-attainment of the federal fine particulate NAAQS." (Decl. Lyons ¶ 13.) LCFS TF2-8

In any event, CARB's analysis relies upon "unsupported speculation that contradicts economic logic and CARB staff assessments of heavy-duty natural gas vehicles outside of the LCFS rulemaking process." (Decl. Lyons ¶ 13.) Because there is no evidence to suggest a significant increase in heavy-duty gas vehicles is "reasonably foreseeable," and in fact the evidence points to the exact opposite conclusion, CARB's analysis does not "provide sufficient information to enable "'public [to] discern . . . the 'analytic route . . . from evidence to action . . . .'" (See *City of Maywood, supra*, 208 Cal.App.4th at 393.) As a result, CARB's environmental analysis should be revised to address whether a significant increase in heavy-duty gas vehicles is truly reasonably foreseeable. LCFS TF2-9

3. CARB Must Revise its Economic Impact Analysis to Account for the Need for California's Heavy-Duty Gas Vehicle Population to More than Quadruple By 2025

Because there is no analysis in the ISOR (or elsewhere) regarding the number of vehicles required to meet CARB's projected increase in natural gas, Sierra Research performed this analysis. According to Sierra Research, to meet CARB's projected increase, the number of California Heavy-Duty Natural Gas Vehicles would need to more than ***quadruple*** in just ten years. California heavy-duty vehicle users would need to spend approximately $2.4 billion to meet CARB's fuel forecast in order to use natural gas instead of diesel vehicles, in addition to increased maintenance costs of between $22 and $44 million per year. (Decl. Lyons, Exhibit B-4.) LCFS TF2-10

These costs were not included by CARB in its economic analysis for the LCFS regulation, as required under the Government Code, including Sections 11346.3 and 11346.5. (Decl. Lyons, Exhibit B-4.) Because CARB's economic analysis does not take into consideration over $2.4 billion in additional costs associated with the need for California businesses to purchase heavy-duty natural gas vehicles to meet CARB's projections of natural gas usage, CARB's economic impact assessments are not adequately supported by "facts, evidence, documents, testimony or other evidence." (Govt. Code, § 11346.5(a)(8).) If CARB does not agree with our cost estimate, it should explain why, and provide a different estimate along with the basis for its different estimate. If CARB does not believe that these costs must be considered in the current rulemaking, it must explain why. LCFS TF2-10 cont.

4. CARB Failed to Address the Potential Environmental Impacts Associated with the Potential Inability to Meet CARB's 2025 Natural Gas Targets

As explained above, CARB's estimates for natural gas usage by heavy-duty vehicles is exceptionally optimistic, and unlikely to be realized. Nevertheless, there is no indication in CARB's environmental document that CARB analyzed the potential impacts associated with the inability to meet those optimistic targets. LCFS TF2-11

Specifically, if there is no demand in California for the $2.4 billion in heavy-duty natural gas vehicles contemplated under the revised LCFS regulation, this will have a substantial impact on CARB's estimation of credits and deficits generated by the proposed LCFS regulation. For example, if demand for natural gas remains at 2014 levels – *i.e.*, 110 million diesel gallon equivalents – during the years 2015 through 2025, natural gas credits will be reduced significantly, while diesel deficits will increase. (Decl. Lyons, Exhibit C-1.) This would result in deficits of -3.85 MMTs in 2025 for the May 22 natural gas compliance scenario alone, along with net total deficits for the LCFS program generally. (*Id.*, Exhibit C-1, C-2.) LCFS TF2-12

Accordingly, CARB must significantly reevaluate the number of credits and deficits that will likely result from the implementation of the LCFS regulation, (Decl. Lyons, Exhibit C-1), and evaluate the potential environmental effects associated with the potential credit imbalance caused by the proposed LCFS regulation. Thereafter, CARB should recirculate both the environmental analysis and the revised LCFS regulation for public review.

B. CARB's Indirect Land Use Change Factor for Corn Ethanol Is Based on Incomplete Data and Faulty Analysis, and Lacks Evidentiary Support

CARB's proposed revisions to the LCFS regulation contemplate a land use change ("LUC") value for corn ethanol of 19.8 gCO_2e/MJ. This value is based, in large part, on the Global Trade Analysis Project Model (the "GTAP Model"). The price-yield elasticity[1] of a particular biofuel "is an important parameter used in the GTAP [M]odel to estimate the LCFS TF2-13

[1] "[P]rice-yield elasticity is a measure of the change in yield with a change in price of a commodity." (Decl. Darlington ¶ 4.) For example, "[a] price-yield elasticity of 0.25 . . . means that if corn prices increase by 1%, corn yield would be expected to increase by 0.25%." (*Id.*) "The increase in yield is brought about by producers using seed types that are resistant to drought and disease, more intensive planting, possibly more fertilizer, irrigation, and other methods." (*Id.*)

magnitude of land use changes" that CARB contends is associated with that biofuel. (Decl. Darlington ¶ 4.)

To calculate the corn ethanol LUC value, CARB staff used the average of five price-yield values [0.05, 0.10, 0.175, 0.25, and 0.35], which is 0.185. (*Id.* ¶ 6.) To select these five values, CARB used (1) input from the expert working group (EWG) on elasticities, (2) its own review of various price-yield studies, and (3) a report by David Rocke reviewing some price-yield studies. The data Rocke relied upon to critique one of the studies, the Perez study, was not provided by ARB for review until August 1, 2015. (Decl. Darlington ¶ 7.) As with the late addition of the ZEV spreadsheet to rulemaking file, CARB's failure to comply with the Government Code's requirements is unexplained, prejudicial, and impossible to correct merely by allowing a brief period for review with no opportunity for the public to address at a hearing by the Board. LCFS TF2-13 cont.

As is now plainly apparent, in light of the late addition of the Rocke data to the rulemaking file, the 0.185 price-yield value is not supported by the evidence. CARB's own Elasticity Values Expert Working Group (EWG) recommended a mid-point value of 0.25.[2] The only report relied upon by CARB to support a lower price-yield value was prepared by David Rocke of UC Davis. The Rocke analysis is based on only one set of data – a 2012 dissertation by Juan Francisco Rosas Perez, who concluded that price-yield response was approximately 0.29. Despite claiming to use that data set, the Rocke study ignored the Perez data, and somehow concluded the price yield should be lower. (*Id.* ¶¶ 16-18.) Until approximately August 1, 2015, the rulemaking file did not contain an explanation as to how the Rocke study reached this conclusion or performed his statistical analysis. (*Id.* ¶ 7.) Once the information was finally made available to the public, it became readily apparent the lower price-yield values were deeply flawed and unsupported by the evidence. Specifically, although the Perez study found a price-yield value of 0.29, Rocke used the same data as Perez to reach an entirely different result, *i.e.*, that "price elasticities of yield" are "small to zero." (Decl. Darlington ¶ 18.) This conclusion is contrary to the evidence, misinterpret the Perez study, and is based on modeling practices that are inconsistent with the methods CARB has used for other rulemakings. LCFS TF2-14

First, in performing his "simple" analysis, Rocke only used "a small part of the Perez data." (Decl. Darlington ¶ 23.) Because Rocke's analysis only uses a small portion of the Perez data, and CARB relied upon the Rocke analysis to depart from the 0.25 price yield value recommended by its own EWG, CARB's use of a price-yield value of 0.185 is unsupported by the evidence. Without public access to the data on which he relied, the public was completely mislead about the nature of Dr. Rocke's analysis and its unreliability. LCFS TF2-15

[2] *Final Recommendations from the Elasticity Values Subgroup*, ARB LCFs Expert Workgroup, *available at* http://www.arb.ca.gov/fuels/lcfs/workgroups/ewg/010511-final-rpt-elasticity.pdf

Rocke's conclusions also misinterpret the Perez study, and are thus wholly unreliable. The entire point of the Perez study was to show how "a wide range of related parameters" affect the price yield values. (Decl. Darlington ¶ 20.) Rocke, however, simply took a small subset of the parameters, and determined based on the incomplete data there was no price yield elasticity. (*Id.* ¶ 16-19.) Nothing in the open record from Dr. Rocke or any other source explains why he took that approach. LCFS TF2-16

Rocke's method of modeling is also inconsistent with the methods CARB has used for other rulemakings. (Decl. Darlington ¶ 19.) Rocke's simple modeling focuses only on one parameter, which has a higher likelihood of resulting in conclusions suggesting a certain parameter is statistically insignificant. (*Id.*) Reliable and scientifically defensive modeling practices include a full range of inputs that could influence vehicle emissions; for example, CARB's Predictive Model for gasoline estimates emissions from cars and trucks in response to a number of gasoline inputs, including sulfur, benzene, T50, T90, aromatics, olefins, volatility, and total oxygen. (*Id.* ¶ 19 n.14.) Rather than relying upon Rocke's conclusions based on incomplete data, CARB should instead rely upon the conclusions of its own EWG, and studies LCFS TF2-17 that are internally consistent with the methodologies it uses in other contexts. Among other steps that CARB must take now, Dr. Rocke's analysis, including the data on which he relied, must receive the external scientific review mandated by Section 57004 of the Health and Safety Code. One, though by no means the only, indication of the need for external review is the fact CARB's own EWG examined the same issue, yet reached a vastly different result. If CARB does not agree, it should explain its reasons for disagreement in full, and address the following issues: LCFS TF2-18

- Whether CARB believes Rocke's very limited analysis of price and supply data alone constitutes an adequate analysis of the Perez data, when CARB's own typical methods of analyzing data are much more robust than those employed by Rocke.

- Why CARB deviated from the EWG recommendation of 0.25 for a central value or average value for YPE.

- What exactly was wrong with how Perez handled autocorrelation in his analysis.

(See *id.* ¶ 25.)

CARB's improper reliance on the Rocke data has significant real-world consequences. Using a factually-supported price-yield value, such as the 0.25 recommended by CARB's EWG, the LUC for corn ethanol would be 17.3 gCO_2/MJ, compared to the 19.8 gCO_2/MJ using the proposed inputs. (Decl. Darlington ¶ 32.) Although Growth Energy considers the use of indirect LUC factors in the LCFS regulation to be generally unsound, CARB has included LUC factors as a component of the Carbon Intensity ("CI") Value placed on a fuel LCFS TF2-19 by CARB. If CARB inaccurately calculates the LUC (and thus the CI Value) of a fuel – such as corn ethanol – as being too high, it will prevent achievement of reductions in greenhouse gas emissions in the most cost-effective manner possible, which is the purpose of the LCFS regulation and a mandatory duty under the 2006 Global Warming Solutions Act. By reducing the CI value assigned to corn ethanol above a level that is scientifically supportable relative to other renewable fuels, CARB is incentivizing the use of fuels that do not provide the maximum GHG reductions in a cost-effective manner. The LCFS regulation will create incorrect "market signals" contrary to the intended effect of the overall LCFS program.[3] (*Cf. id.* ¶ 33.)

LCFS TF2-19 continued

To avoid these potential adverse consequences, and to develop LUC Values (and thereby CI Values) that are based on scientific data and the facts, the GTAP should use a price-yield value that is no less than 0.25, the amount recommended by CARB's EWG. If CARB does not take this action, it should explain why in a new rulemaking notice and permit testimony at a public hearing.

C. Because the 15-Day Review Period Provides Insufficient Time for Commenting Parties to Evaluate the New Evidence and Modifications to the Revised LCFS Regulation, CARB Should Recirculate the EA

Finally, it bears further emphasis that fifteen calendar days provides insufficient time for the public to review CARB's modifications to the proposed LCFS regulation.

LCFS TF2-20

The 15-Day Notice not only includes substantial modifications to the proposed LCFS regulation, but extensive new information regarding CARB's analyses. This information includes, for example, detailed information underlying CARB's analysis of EVs/PHEVs and information regarding the Rocke analysis. This information appears to have been available since the original 45-day comment period, and Growth Energy's representatives have requested that information on many occasions since that time. The statement in the 15-day notice that CARB is seeking public comment on the additional materials in "the interests of fairness and transparency" is ironic, and misleading. It has taken the pressure of litigation against CARB under the Public Records Act – in which CARB has raised its duties under the rulemaking-file provisions of the Government Code as a type of defense – to force CARB to put the new materials in the rulemaking file. CARB initially resisted that Public Records Act request with dilatory motions practice, until the Court with jurisdiction in that case became fully engaged in the issues. No private party should have to bear the expense of attempting to require a public agency to comply with its information disclosure obligations under the Government Code during the rulemaking process, yet this is exactly what CARB forced Growth Energy to do here.

LCFS TF2-21

3 See CARB, "Staff Report: Initial Statement of Reasons, Proposed Regulation to Implement the Low Carbon Fuel Standard," Vol. I at VI-20 (March 5, 2006), available at http://www.arb.ca.gov/fuels/lcfs/030409lcfs_isor_vol1.pdf.

Rather than providing all interested parties, including Growth Energy, with an adequate opportunity to review these highly relevant documents – which, as explained above, show fundamental flaws in CARB's analysis – CARB instead placed the documents into the rulemaking file concurrently with its third 15-day notice. Fifteen days is simply insufficient for technical experts with relevant knowledge of the subject matter of the proposed LCFS regulation; certainly, a member of the public with no technical or legal background could not meaningfully be asked to provide comments on CARB's modifications and new evidence within this short timeframe. LCFS TF2-22

In light of the foregoing, and the significant new information provided by CARB with respect to its analysis of the revised LCFS regulation, CARB should recirculate both the proposed LCFS regulation and a revised EA for 45-day review. LCFS TF2-23

STATE OF CALIFORNIA

BEFORE THE AIR RESOURCES BOARD

Declaration of James M. Lyons

I, James Michael Lyons, declare as follows:

1. I make this Declaration based upon my own personal knowledge and my familiarity with the matters recited herein. It is based on my experience of nearly 30 years as a regulator, consultant, and professional in the field of emissions and air pollution control. A copy of my résumé can be found in Exhibit A.

2. I am a Senior Partner of Sierra Research, Inc., an environmental consulting firm located at 1801 J Street, Sacramento, California owned by Trinity Consultants, Inc. Sierra specializes in research and regulatory matters pertaining to air pollution control, and does work for both governmental and private industry clients. I have been employed at Sierra Research since 1991. I received a B.S. degree in Chemistry from the University of California, Irvine, and a M.S. Degree in Chemical Engineering from the University of California, Los Angeles. Before joining Sierra in 1991, I was employed by the State of California at the Mobile Source Division of the California Air Resources Board (CARB).

3. During my career, I have worked on many projects related to the following areas: 1) the assessment of emissions from on- and non-road mobile sources, 2) assessment of the impacts of changes in fuel composition and alternative fuels on engine emissions, including emissions of green-house gases, 3) analyses of the unintended consequences of regulatory actions, and 4) the feasibility of compliance with air quality regulations.

4. I have testified as an expert under state and federal court rules in cases involving CARB regulations for gasoline, Stage II vapor recovery systems and their design, factors affecting emissions from diesel vehicles, evaporative emission control system design and function, as well as combustion chamber system design. While at Sierra I have acted as a consultant on automobile air pollution control matters for CARB and for the United States Environmental Protection Agency. I am a member of the American Chemical Society and the Society of Automotive Engineers and have co-authored nine peer-reviewed monographs concerned with automotive emissions, including greenhouse gases and their control. In addition, over the course of my career, I have conducted peer-reviews of numerous papers related to a wide variety of issues associated with pollutant emissions and air quality.

5. This Declaration summarizes the results of my review of the CARB Notice of Public Availability of Modified Text and Availability of Additional Documents for the Proposed Re-Adoption of the Low Carbon Fuel Standard Regulation (the LCFS Regulation) dated July 31, 2015. I have performed this review as an independent expert

for Growth Energy. If called upon to do so, I would testify in accord with the facts and opinions presented here.

6. According to CARB staff, the illustrative compliance scenario published in the ISOR and last updated as part of the May 15-day notice has been used for a number of purposes. These include preparation of the environmental analysis[1] and assessment of economic impacts.[2] In response to a lawsuit under the Public Records Act and discussions between counsel for CARB and Growth Energy, CARB has recently added a spreadsheet entitled "Estimate of Electricity Use by ZEVs" to the rulemaking file. This spreadsheet reveals the assumptions made by CARB staff in estimating the amount of electricity that would be used by light-duty battery electric vehicles (EVs) and plug-in hybrid electric vehicles (PHEVs) for the purposes of developing illustrative compliance scenarios and evaluating potential compliance curves as documented in Appendix B of the Initial Statement of Reasons (ISOR) and subsequent updates. These assumptions include the number of EVs and PHEVs in operation, as well as the annual number of miles traveled and the fuel efficiency of the vehicles. In general, the assumptions reflect the regulatory requirements of the Zero Emission Vehicle (ZEV) regulation,[3] which requires automobile manufacturers to produce EVs and PEHVs and offer them for sale in California. LCFS TF2-24

7. Once it became clear that CARB was using ZEV vehicle population estimates to estimate the amount of electricity expected to be used as a fuel for light-duty vehicles in developing the LCFS illustrative compliance scenario, Growth Energy renewed earlier requests for similar data used by CARB to estimate of the amount of natural gas that will be used in heavy-duty vehicles under the LCFS. I understand that, since the publication of the July 31 public notice, counsel for CARB has advised counsel for Growth Energy that no heavy-duty natural gas vehicle population estimates were used to prepare the LCFS illustrative compliance scenario. I further understand that CARB staff never performed as analysis similar to that disclosed for ZEVs to estimate natural gas use in heavy-duty vehicles under the LCFS. This is surprising, and raises serious concerns regarding the validity of the LCFS illustrative compliance scenario, and therefore the environmental and economic analyses that were performed based on it.

8. If, unlike the situation with ZEVs, CARB has failed to perform any technical analysis to estimate the amount of natural gas that would be used in heavy-duty vehicles which have been assumed in the illustrative compliance scenario and evaluation of potential compliance curves, the compliance scenario and all conclusions drawn from it cannot be relied upon. Further, it is impossible for any stakeholder or reviewing body LCFS TF2-25

---

[1] See page V-1 of the LCFS ISOR.

[2] See page VII-15 of the LCFS ISOR.

[3] See for example the ZEV population forecasts in Table 3.6 of www.arb.ca.gov/regact/2012/zev2012/zevisor.pdf.

such as the Office of Administrative Law to understand how the staff arrived at its conclusions regarding the use of electricity as a transportation fuel in the light-duty vehicle fleet, which again is critical to assessing the veracity of the illustrative compliance scenarios, the environmental analysis of the proposed LCFS regulation, and the estimated cost of the regulation. LCFS TF2-25 continued

9. Although it is not possible to understand how CARB staff arrived at its estimates of natural gas use in heavy-duty vehicles based on the available information, it is possible to estimate what CARB's assumptions would have been if staff performed the analysis required to provide a technical basis that would justify the forecast use of natural gas in heavy-duty vehicles. Once these estimates are established, it is then possible to assess their implications with respect to the veracity of the illustrative compliance scenarios, the environmental analysis of the proposed LCFS regulation, and the estimated cost of the regulation. LCFS TF2-26

10. I have estimated the increase in the number of heavy-duty natural gas vehicles that would be required to come into operation in California in order to consume the volume of natural gas forecast by CARB staff. I have also performed an analysis to determine if that required increase in vehicle population is reasonably foreseeable. Both analyses are documented in Exhibit B to this declaration. As demonstrated by these analyses, the required increase in the number of heavy-duty natural gas vehicles is large, and the available data and information contradict CARB's unsupported assumptions regarding large increases in the use of natural gas in heavy-duty vehicles.

11. Exhibit B also identifies substantial costs that would be incurred as a result of CARB's natural gas usage assumptions that were not considered in the assessment of the economic impacts of the LCFS regulation. To the extent that CARB staff continues to rely on its current illustrative compliance scenario, which incorporates flawed assumptions regarding natural gas use in heavy-duty vehicles, these costs must be included in the economic impact assessment. LCFS TF2-27

12. The correction of CARB's use of flawed assumptions regarding increased natural gas use in heavy-duty vehicles would significantly impact the results of the illustrative compliance scenario. As shown in Exhibit C, using corrected assumptions that limit natural gas use in heavy-duty vehicles to 2014 volumes and increase the use of diesel fuel, total LCFS credit balances under the compliance scenario become negative for the years 2021 to 2025, indicating that compliance with the LCFS regulation will not be feasible based on the remaining assumptions. LCFS TF2-28

13. CARB staff might try to develop illustrative compliance scenarios based on other assumptions. These other assumptions would likely include greater use of biodiesel in heavy-duty vehicles. As I have shown previously,[4] increased use of biodiesel in LCFS TF2-29

[4] See Appendix I of Growth Energy's February 17, 2015 comments on the Alternative Diesel Fuel and LCFS regulations.

heavy-duty diesel vehicles under the proposed LCFS and Alternative Diesel Fuel regulations will lead to increased NOx emissions, including significant increases in NOx emissions in the South Coast and San Joaquin Valley air basins which are already in extreme non-attainment of the federal ozone NAAQS, and moderate non-attainment of the federal fine particulate NAAQS. However, given CARB's reliance on the original illustrative compliance scenario in performing the environmental analysis and assessment of economic impacts, revisions to those analyses would also have to be performed if CARB revises the illustrative compliance scenario. In any case, at present CARB is relying on unsupported speculation that contradicts economic logic and CARB staff assessments of heavy-duty natural gas vehicles outside of the LCFS rulemaking process.

LCFS TF2-29 continued

I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct.

Executed this 17th day of August, 2015 at Sacramento, California.

Résumé

James Michael Lyons

Education

1985, M.S., Chemical Engineering, University of California, Los Angeles

1983, B.S., Cum Laude, Chemistry, University of California, Irvine

Professional Experience

4/91 to present — Senior Engineer/Partner/Senior Partner
Sierra Research

Primary responsibilities include oversight and execution of complex analyses of the emission benefits, costs, and cost-effectiveness of mobile source air pollution control measures. Mr. Lyons has developed particular expertise with respect to the assessment of control measures involving fuel reformulation, fuel additives, and alternative fuels, as well as accelerated vehicle/engine retirement programs, the deployment of advanced emission control systems for on- and non-road gasoline- and Diesel-powered engines, on-vehicle evaporative and refueling emission control systems, and Stage I and Stage II service station vapor recovery systems. Additional duties include assessments of the activities of federal, state, and local regulatory agencies with respect to motor vehicle emissions and reports to clients regarding those activities. Mr. Lyons has extensive litigation experience related to air quality regulations, product liability, and intellectual property issues.

7/89 to 4/91 — Senior Air Pollution Specialist
California Air Resources Board

Supervised a staff of four professionals responsible for identifying and controlling emissions of toxic air contaminants from mobile sources and determining the effects of compositional changes to gasoline and diesel fuel on emissions of regulated and unregulated pollutants. Other responsibilities included development of new test procedures and emission standards for evaporative and running loss emissions of hydrocarbons from vehicles; overseeing the development of the state plan to control toxic emissions from motor vehicles; and reducing emissions of CFCs from motor vehicles.

4/89 to 7/89 Air Pollution Research Specialist
California Air Resources Board

Responsibilities included identification of motor vehicle research needs; writing requests for proposals; preparation of technical papers and reports; as well as monitoring and overseeing research programs.

9/85 to 4/89 Associate Engineer/Engineer
California Air Resources Board

Duties included analysis of vehicle emissions data for trends and determining the effectiveness of various types of emissions control systems for both regulated and toxic emissions; determining the impact of gasoline and diesel powered vehicles on ambient levels of toxic air contaminants; participation in the development of regulations for "gray market" vehicles; and preparation of technical papers and reports.

Exhibit B

Estimation of the Heavy-Duty Natural Gas Vehicle Requirements Implied by CARB's LCFS Illustrative Compliance Scenario

LCFS TF2-30

As described in detail in the ISOR and Appendix B to the ISOR, in developing proposed revisions to the Low Carbon Fuel Standard (LCFS) regulation, CARB staff has prepared an "illustrative compliance scenario" which, for purposes of its Environmental Assessment, must be "reasonably foreseeable."[1] However, CARB staff has failed to publish many of the assumptions and data that underlie that scenario, making it impossible to understand the technical basis, if any, which supports CARB's claim that the scenario is in fact reasonably foreseeable. In particular, CARB staff has failed to provide any technical basis that supports the large increase in natural gas use by heavy-duty vehicles assumed in the compliance scenario. As documented below, an analysis that estimates the implications of CARB's assumptions regarding natural gas use in heavy-duty vehicles indicates that the CARB assumptions are not in fact reasonably foreseeable. Given this, CARB's environmental analysis and its assessment of the economic impacts of the proposed LCFS regulation are flawed and cannot be used to comply with the California Environmental Quality Act (CEQA) or the rulemaking requirements of the Administrative Procedures Act (APA).

CARB Staff Assumptions Regarding Natural Gas Use in Heavy-Duty Vehicles

CARB staff has published several versions of the compliance scenario during the course of the LCFS rulemaking process. The most recent version is dated May 22, 2015 and is titled "Analysis of Compliance Curve Reflecting the Impact of May 2015 Proposed 15-Day Changes." The CARB assumptions regarding conventional and renewable natural gas to be used in heavy-duty vehicles as a function of time are presented in Table 1 in diesel equivalent gallons. As shown, CARB assumes a dramatic increase in total natural gas use over time, with that gas being derived from "renewable" sources that include landfills and waste digesters. More specifically, CARB's projected increase in natural gas use in heavy-duty vehicles, relative to 2014 levels, is 2.6 times greater in 2020 and 4.4 times greater in 2025.

Required Heavy-Duty Natural Gas Vehicle Populations

Using CARB staff's assumptions regarding natural gas use in heavy-duty vehicles, it is possible to estimate the required number of heavy-duty vehicles as a function of time. This process begins with determining the current population of heavy-duty natural gas vehicles in California. Data regarding that population (exclusive of conversions) in 2013 have been published by the

[1] See pages ES-18 and 19 of the LCFS ISOR.

National Renewable Energy Laboratory.[2] These data can then be used with EMFAC2014 annual mileage accumulation rates and an average natural gas fuel economy value of 5.6 miles per diesel equivalent value for the 2013 fleet[3] to estimate natural gas use. These data and the resulting estimate of natural gas consumption by heavy-duty vehicles in 2013 are presented in Table 2. As shown, the estimated volume of 102 million diesel equivalent gallons for the 2013 fleet is in reasonable agreement with the 2014 CARB assumed value of 110 million.

Assuming that both the relative distribution of heavy-duty natural gas vehicles in the fleet and their fuel economy remain constant, the growth in vehicle population required to satisfy CARB's forecast demand is directly proportional to the growth in that demand. The resulting populations for 2015 to 2025 are shown in Table 3. It should be noted that while the assumption of constant fuel economy is likely to be incorrect, the expected increase in fleet fuel economy would only serve to increase the number of natural gas vehicles required to consume the fuel volumes assumed by CARB for future years.

Assessment of Required Heavy-Duty Natural Gas Vehicle Populations

As documented above, the CARB illustrative scenario assumes a massive increase in natural gas as a fuel for heavy-duty vehicles, which directly implies a similar massive increase in the number of heavy-duty natural gas vehicles in operation in California. Although, CARB staff might be able to show that it is possible to divert the forecast volume of natural gas intended for other purposes to use as a transportation fuel, staff has apparently not estimated the number of vehicles required nor published any data or analysis to support that it is reasonably foreseeable that the required number of vehicles will be in operation in California. Rather, as is demonstrated below, what is reasonably foreseeable is that there will be no significant increase in either the heavy-duty natural gas vehicle population or natural gas use by such vehicles unless CARB requires the purchase and use of such vehicles.

LCFS TF2-31

It should be noted that while there are several existing CARB regulations that have resulted in the deployment of natural gas vehicles, such as Solid Waste Collection Vehicle rule and the Fleet Rule for Transit Agencies, those regulatory programs are mature and will not lead to further increases in heavy-duty natural gas vehicle use. There are simply no existing CARB regulations like the ZEV mandate that require dramatic increases in the sale of heavy-duty natural gas vehicles. Given this, increases in the California heavy-duty natural vehicle population would have to be driven by market. If CARB believes that the market will drive those increases, staff needs to explain why and allow the public to comment on that explanation. Indeed, CARB's own recent assessment of heavy-duty natural gas vehicle technology[4] compares heavy-duty natural gas vehicles with diesel vehicles and notes that natural gas vehicles suffer from a number of disadvantages including the following: LCFS TF2-32

1. Shorter range between refueling;
2. Increased weight;
3. 10 to 15% lower fuel economy;
4. Higher purchase costs which range from $30,000 to $80,000 per vehicle;
5. Higher maintenance costs of 1-2 cents per mile; and
6. A limited number of publically accessible refueling stations.

All of these factors serve as substantial barriers to increases in heavy-duty natural gas populations. For example, multiplying the $55,000 mid-point of the range in increased vehicle costs by the estimated 44,924 additional natural gas vehicles that would be required in 2025 to meet CARB's fuel forecast, indicates that an additional $2.4 billion dollars would have to be spent by California heavy-duty vehicle users in order to use natural gas instead of diesel vehicles. Similarly, the increased maintenance costs associated with the additional natural gas vehicles would amount to between $22 and $44 million in 2025 alone. There are also substantial costs associated with installation of natural gas refueling facilities.[5] It should be noted that these costs were not included by CARB staff in its economic analysis of the LCFS regulation.

The two primary advantages associated with natural gas vehicles that have been identified by CARB staff are (1) lower tailpipe emissions of particulate matter and oxides of nitrogen, and (2) lower fuel price. Given that less expensive diesel vehicles will be available, the lower emission levels associated with natural gas vehicles are unlikely to influence the purchasing decisions of vehicle operators. In addition, given the recent changes in the oil prices, the price difference between natural gas and diesel fuel has dropped dramatically as shown in Figure 1, which was obtained from a U.S. Department of Energy website.[6] It should be noted that the price differential shown in Figure 1 does not reflect the 10 to 15% lower fuel economy cited by CARB as a disadvantage of natural gas vehicles, which would further reduce the price differential. Further, current EIA forecasts for diesel fuel prices indicate that lower prices will persist for a considerable period of time.[7] Given this, the advantage associated with lower prices for natural gas does not appear to be a substantial factor. LCFS TF2-33

[4] See www.arb.ca.gov/msprog/tech/presentation/lowernoxfuel.pdf.
[5] See www.afdc.energy.gov/uploads/publication/cng_infrastructure_costs.pdf.
[6] See www.afdc.energy.gov/fuels/prices.html.
[7] See Table 12 at www.eia.gov/forecasts/aeo/tables_ref.cfm.

Overall, as documented above, there are substantial disadvantages associated with heavy-duty natural gas vehicles relative to diesel vehicles, and there is no technical basis that supports CARB's implied assumption that there will be a dramatic increase in the population of such vehicles. This conclusion is supported for the nation as a whole by EIA which forecasts little growth in the number of heavy-duty natural gas vehicles, and a decrease in the total amount of natural gas used by those vehicles over time.[8] CARB's LCFS illustrative compliance scenarios are therefore based on arbitrary and unsupported speculation which is inconsistent with CARB's own analysis outside the LCFS rulemaking process and with EIA's analysis. LCFS TF2-34

Figure 1

Exhibit C to Declaration of James M. Lyons

Exhibit C

Impact of CARB's Flawed Assumption Regarding Natural Gas Use in Heavy-Duty Vehicles on CARB Illustrative Compliance Scenario

As described in Attachment B, it has only now become apparent that CARB's LCFS Illustrative Compliance Scenario envisioning dramatic growth in natural gas use by heavy-duty vehicles has no empirical or specific analytic basis. The available information shows now and has long shown that the only reasonable assumption is that there will be little or no growth in natural gas use in heavy-duty vehicles. Given this, it is important to understand the impact associated with correcting CARB's flawed assumptions for the Illustrative Compliance Scenario. LCFS TF2-35

In order to perform this assessment, the May 22 Illustrative Compliance Scenario was used as the starting point, and CARB staff's assumptions regarding the use of conventional natural gas and renewable natural gas were corrected such that the total demand for natural gas remained at 110 million diesel gallon equivalents during the years 2015 through 2025. It was assumed that renewable gas would be used to the maximum degree feasible based on CARB's original forecast up to a maximum of 110 million diesel gallon equivalents. Diesel fuel was assumed to replace the reduced volume of natural gas relative to CARB's original assumptions. LCFS TF2-36

In Table 1, the original May 22 diesel deficit and conventional and renewable natural gas credit volumes are compared to those resulting from the corrected assumptions described above. As shown, the corrected assumptions lead to reduced natural gas credits and increased diesel deficits, relative to the May 22 version.

Table 1
Calendar Year 2014-2025 Diesel Deficit and Natural Gas Credit Volumes
(Flawed vs. Corrected NG Use Assumptions)

	MMTs of Credits or Deficits											
	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
	May 22 Scenario											
Diesel Deficits	-0.46	-0.45	-0.91	-1.57	-2.23	-3.33	-4.41	-4.30	-4.27	-4.23	-4.26	-4.29
Conv. Natural Gas Credits	0.19	0.15	0.10	0.09	0.07	0.05	0.01	0.01	0.01	0.01	0.01	0.01
Renewable NG Credits	0.18	0.50	0.66	0.85	1.22	1.54	2.01	2.53	2.88	3.23	3.58	3.93
Sum	-0.09	0.20	-0.15	-0.63	-0.94	-1.74	-2.39	-1.76	-1.38	-0.99	-0.67	-0.36
	May 22 Scenario - With Corrected Heavy Duty Natural Gas Assumptions											
Diesel Deficits	-0.46	-0.45	-0.92	-1.60	-2.30	-3.47	-4.65	-4.60	-4.62	-4.64	-4.72	-4.81
Conv. Natural Gas Credits	0.19	0.12	0.05	0.02	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Renewable NG Credits	0.18	0.50	0.66	0.85	1.03	0.99	0.96	0.96	0.96	0.96	0.96	0.96
Sum	-0.09	0.17	-0.20	-0.72	-1.27	-2.47	-3.69	-3.64	-3.66	-3.68	-3.76	-3.85

A similar comparison of total LCFS program credits and deficits as well as the total credit balance is provided in Table 2. As highlighted in Table 2, with the corrected assumptions, the credit surpluses forecast by CARB for the years 2021 to 2025 become deficits indicating that compliance with the LCFS regulation would not occur. Therefore, CARB's conclusion that compliance with the LCFS regulation is demonstrated by the May 22 version of the Illustrative Compliance Scenario is incorrect and has no empirical or analytical support in the rulemaking file.

CARB staff could try to formulate other Illustrative Compliance Scenarios that demonstrate compliance based on other assumptions, which would likely include greater use of biodiesel in heavy-duty vehicles. However, use of these different assumptions would require revisions to CARB staff's environmental and economic analyses, which should be made available for public review and comment.

Exhibit A to Declaration of Thomas L. Darlington

CALIFORNIA ENVIRONMENTAL PROTECTION AGENCY

CALIFORNIA AIR RESOURCES BOARD

DECLARATION OF THOMAS L. DARLINGTON

I, Thomas L. Darlington, declare as follows:

1. I am an engineer with training and expertise in lifecycle emissions analysis, the use of models to estimate lifecycle emissions and to attribute emissions to the production, distribution and use of various fuels, and use of regulations to control mobile-source emissions. My areas of expertise also include land-use change ("LUC") modeling and the application of econometric models to attributional and consequential lifecycle emissions analysis. Following my graduation from the University of Michigan in 1979, I served for eight years as an Engineer and Project Manager at the United States Environmental Protection Agency's Motor Vehicle Emissions and Fuels Laboratory in Ann Arbor, Michigan. Thereafter I worked at Detroit Diesel Corporation and General Motors Corporation, and as the Director of Mobile Source Programs at Systems Application International. I am the President of Air Improvement Resource ("AIR"), a company formed in 1994 to provide mobile source emission modeling to government and industry. A copy of my CV is attached to this Declaration as Exhibit "A."

2. I have participated on behalf of renewable fuels producers in the public consultation and rulemaking processes at the California Air Resources Board ("ARB" or "the Board") to consider, adopt and revise the low-carbon fuel standard ("LCFS") regulation since 2008. I testified at the Board's February 2015 hearing concerning proposed amendments to the LCFS regulation. I am fully familiar with the models released by CARB to establish and implement the LCFS regulation, including the versions of the Global Trade Analysis Project ("GTAP") modeling systems used by CARB or proposed for use by the CARB staff as part of the current and proposed LCFS regulation.

3. I make this Declaration based upon my personal knowledge, my training and expertise, and my familiarity with the subjects that I address here.

A. Overview of LCFS Regulation's Treatment of Price-Yield Elasticity

4. The price-yield elasticity is an important parameter used in the GTAP model[1] to estimate the magnitude of land use changes in response to biofuel expansion. The price-yield elasticity is a measure of the change in yield with a change in price of a commodity. A price-yield elasticity of 0.25, therefore means that if corn prices increase by 1%, corn yield would be expected to increase by 0.25%. The increase in yield is brought

[1] GTAP stands for Global Trade Analysis Project, which is the model ARB uses to develop the land use impacts of biofuels.

about by producers using seed types that are resistant to drought and disease, more intensive planting, possibly more fertilizer, irrigation, and other methods.

5. The increase in investment by producers to achieve a higher yield is justified by the increase in the prices the producer will obtain for the crop. In GTAP, the predicted increase in prices is a result of "shocking" the model with increased demand for feedstocks for biofuels. When the model is shocked with this increase in demand, the model responds by simulating an increase in price of various commodities. This in turn leads to some crop switching (to biofuel feedstocks), higher yields on existing land (due to the YPE elasticity) and conversion of pasture and, to a much lesser extent, forest to cropland.[2]

6. In GTAP, the price-yield parameter (or elasticity) is referred to as YDEL; ARB refers to it as YPE. ARB used five different price-yield elasticities in its analysis of land-use emissions (0.05, 0.1, 0.175, 0.25, and 0.35) for all biofuels.[3] The average of these five values is 0.185.

7. To select these five levels, ARB relied on (1) input from the expert working group (EWG) on elasticities, (2) its own review of various price-yield studies, and (3) a report by David Rocke reviewing some price-yield studies.[4] While the Rocke report was provided by ARB with the ISOR, the data Rocke relied upon to critique one of the studies, the Perez study, was not provided by ARB for review until August 1, 2015.

8. ARB's comments on the Rocke study appear at the end of Attachment 1 to Appendix I of the ISOR. Appendix I discusses the land use emissions estimated by ARB, and Attachment 1 discusses ARB's method for determining YPE values to use in estimating land-use emissions. ARB's summary of the Rocke report is below:

> Staff contacted with David Rocke from the University of California, Davis to perform a statistical analysis of the data used by some of the researchers in Table 1-2. David reviewed analysis (and data where available) for Goodwin et al, Perez, and Berry and Schlenker and additional studies and concluded based on methodologically sound analyses, yield price elasticities are small to zero.

9. Since ARB relied on Rocke's review of recent studies in selecting YPE values, we reviewed Rocke's analysis of the Perez data, and his review of the other studies. In this report, we will show that:

(i) ARB's Elasticity Values Expert Working Group (EWG) recommended a mid-point value of 0.25, not 0.185.

LCFS TF2-37 (cont. on pg 3, bottom)

[2] In the real world, fallow or idled lands are also converted to crops resulting in little real land use change. However, GTAP currently does not currently model the conversion of idle or fallow land.

[3] Table I-4, Appendix I, Detailed Analysis for Indirect Land Use Change, Initial Statement of Reasons, ARB.

[4] *Statistical Issues Related to the Low-Carbon Fuel Standard,* David M. Rocke, PhD, October 31, 2014, under contract 13-405 (2014).

(ii) ARB arbitrarily relied on the Rocke study to select a range of YPE values and a mid-point that were significantly lower than what the EWG recommended. LCFS TF2-38 (cont. on pp 4 -6)

(iii) The Rocke study critically evaluated another study, the Perez study that derived a price yield value of 0.29, which supports the EWG recommendation to ARB. LCFS TF2-39 (cont. on pp 6-7)

(iv) The Rocke study used only part of the Perez data to attempt to duplicate Perez's results. Since the Perez results were not duplicated by Rocke's analysis of the Perez data, Rocke assumed that Perez's results were inappropriately determined. Rocke's analysis constitutes bad modeling practice, is inconsistent with ARB's modeling methodologies used in connection with other regulations, and is unsupported by the evidence in the Perez study. LCFS TF2-40 (cont. on pp 7-8)

(v) Emissions associated with indirect land use change for biofuels are significantly greater (i.e., 15% higher for corn ethanol) with a central YPE value that ARB chose of 0.185 than with the 0.25 that EWG recommended. LCFS TF2-41 (cont. on pp 9-11)

Each of these aspects is discussed further below. As an initial matter, however, it is important to be clear that the time allowed for comment on the new material placed in the docket is not sufficient to prepare all the analysis that could and should be possible in a regular 30- or 45-day comment period. For example, now that the limitations of the Rocke study are known, including the fact that Rocke relied on only a very limited set of the Perez data, stakeholders should be permitted time to conduct studies that use the best available scientific data to assess the relationship between price and yield, and to submit a full price-yield analysis to CARB for consideration in the current rulemaking. AIR has done what is possible in the limited time allowed, but does not understand why it has taken until August 2015 to provide materials that were requested in the fall of 2014. AIR's ability to comment has been limited and prejudiced by this delay. LCFS TF2-42

B. ARB's Elasticity Values Expert Working Group (EWG) <u>Recommended a Mid-Point Value of 0.25, not 0.185</u>

10. The EWG's summary recommendation on price-yield is as follows: LCFS TF2-37 continued

It is not clear if GTAP can assign different elasticities to different crops in different countries. If not then if the long-run price-yield elasticity not accounting for double-cropping is set at 0.175, and if South America and the United States are the countries that contribute the most incremental commodity production in response to higher prices, *then a mid-point value of 0.25 for the price-yield*

> *elasticity seems reasonable* (emphasis added). If differentiation can occur by country, then setting the price-yield elasticity to 0.175 for countries with no double cropping, 0.25 for the U.S. and 0.30 for Brazil and Argentina will provide a more reasonable approximation to reality."[5]

LCFS TF2-37 continued

When ARB varied price-yield, they did this variation for all countries simultaneously, (i.e., they did not utilize separate values for the US and Brazil/Argentina). Thus, the EWG recommendation is clear – the central, or average value used in land use modeling, if regional-specific values are not used, should be 0.25.[6]

C. ARB Arbitrarily Relied on the Rocke Study to Select a Range of YPE Values and a Mid-Point that Were Significantly Lower <u>Than What the EWG Recommended</u>

LCFS TF2-38 continued

11. ARB's Attachment 1 to Appendix I contains a discussion of the EWG recommendations, the Rocke report, and other recent YPE research. ARB summarizes the recent research in the table below, which is taken directly from Attachment 1 of Appendix I of the ISOR.

[5] *Final Recommendations from the Elasticity Values Subgroup*, ARB LCFs Expert Workgroup, http://www.arb.ca.gov/fuels/lcfs/workgroups/ewg/010511-final-rpt-elasticity.pdf

[6] In Attachment 1 to Appendix I of the ISOR, ARB quotes the EWG report statement "perhaps a reasonable increment to the short-run elasticity to account for long-run response is 0.05, which brings the average value between 0.10 to 0.25." This seems to support the ARB-selected central value of 0.185. However, the quote is followed by a paragraph where the EWG discusses the impacts of double-cropping on its YPE recommendation. Thus, the range of "between 0.10 to 0.25" was not the EWG's final recommendation on YPE, as the final recommendation is given two paragraphs later. Additionally, the GTAP model ARB used to model land use emissions is capable of having separate price-yield elasticities by region, so ARB could have adopted the EWG recommendation to utilize 0.25 for the US, 0.30 for Brazil/Argentina, and 0.175 for all other countries.

Table 1-2. Updated Literature Estimates of YPEs				
Authors	Period	Elasticity	Crop	Data, Method
Huang and Khanna	1977-2007	0.15	U.S. corn, soybean, wheat	County level data, instrumental variable (IV)
Smith and Sumner	1961-2005	Negative and Significant	U.S. corn	County level data, ordinary least squares (OLS)
Berry and Schlenker	1961-2009	0.1, Net	U.S. corn	Country level data, instrumental variable
Goodwin, et al	1996-2010	0.01 short run, 0.19-0.27 long run	Iowa, Illinois, Indiana Corn	Ordinary least squares
Perez	1960-2004	0.29	Iowa corn and soybeans	Duality-Bayesian

12. The first three studies appear to support low YPEs. The last two studies support the EWG recommendation of a central value of 0.25. With regard to the Smith and Sumner study, ARB notes that it is "a work in progress."[7] It is also worth noting that none of these studies evaluate double-cropping. Double- or multiple-cropping, is the common practice of planting more than one crop on the same land in the same year. Researchers use higher values of YPE to simulate double- or multiple-cropping.

LCFS TF2-38 continued

13. ARB contracted with Rocke to evaluate the last three studies (Berry and Schlenker, Goodwin, and Perez). ARB summarized Rocke's conclusions:

> David (Rocke) reviewed analysis (and data where available) for Goodwin et al, Perez, and Berry and Schlenker and additional studies, and concluded that based on methodologically sound analyses, yield price elasticities are generally small to zero.[8]

14. ARB's conclusion in Attachment 1 to Appendix I is as follows:

> Taking all these (issues) into consideration, and with a wide range of likely values for YPE from published literature, staff used a range of values between 0.05 and 0.35 to conduct scenario runs for all biofuels studied for the LCFS. These input values are used for all

[7] See footnote 55 of Attachment 1 to Appendix I of the ISOR.

[8] Appendix I to ISOR, Attachment 1-5.

crops and regions for the 30 scenario runs conducted for each of the 6 biofuels.[9]

LCFS TF2-38 continued

15. ARB failed to inform the public that its central or average value was 0.185, or 26% less than the EWG recommendation. ARB clearly relied on the Rocke analysis to select a central value that was less than the EWG recommendation.

D. The Rocke Study Critically Evaluated Another Study, the Perez Study, that Derived a Price Yield Value of 0.29, that Supports the EWG Recommendation to ARB

LCFS TF2-39 continued

16. While Rocke reviewed all three studies, he only obtained and analyzed data from one study – the Perez study.[10]

> The data were used in a 2012 dissertation of Juan Francisco Rosas Perez. In these works, the price elasticity of yield was estimated from data on corn (maize) in Iowa for 1960-2004, and was said to be in the range of 0.29. The data set was publicly available so it was used for a re-analysis. The analysis used by Perez was complex, and can be criticized for insufficiently handling autocorrelation in the series. Therefore, a simpler analysis was conducted that should have similar results to the more complex analysis if the latter is not flawed.[11]

17. Rocke performed time-series regressions of corn supply in a given year by corn price in that year, by corn supply in the previous year, and by corn price in the previous year. Rocke used the log of these variables in his regressions, apparently on the premise that the coefficient for price (either the current year or the previous year) would provide a measure of YPE. Rocke failed to find a relationship between yield and price in either the current or previous year. As noted above, Rocke attributes Perez' finding of a YPE of 0.29 to Perez insufficiently handling autocorrelation. Autocorrelation is the concept of supply in the current year being somewhat dependent on supply in the previous year rather than on other factors such as price.

18. In his final statement in the report for ARB, Rocke states:

> As documented in Berry (2011), Berry and Schlenker (2011) and Roberts and Schlenkler (2013), much of the literature providing purported estimates of the price elasticity of yield is deeply methodologically flawed. In addition to the problems of endogenity and autocorrelation that are badly handled, there are other important issues. In Goodwin et al, for example, 15 years of data are multiplied into 405 datapoints by considering 27 different districts. But there

[9] Attachment 1 to Appendix I, 1-6.

[10] *Essays on the environmental effects of agricultural production*, Juan Francisco Rosas Perez, Iowa State University (2012). Graduate These and Dissertations. Paper 12737. http://lib/dr.iastate.edu.etd.

[11] Rocke, page 5.

are still only 15 price values and it is hard to believe that the strong relationships of weather, price, and technology within a given year can be handled by econometric tricks. The analyses, such as those by Roberts and Schlenker (2013) that are methodologically sound all show small to zero price elasticities of yield.[12]

LCFS TF2-39 continued

In other words, Rocke dismisses both Goodwin and Perez as methodologically unsound.

19. We repeated Rocke's simplified analysis of the Perez data. We were able to replicate Rocke's results, using two different statistical packages, in order to establish our ability to work with Rocke's methods. We did not have adequate time to replicate Perez's analysis. Fundamentally, price-yield elasticity cannot be properly estimated with ordinary least squares (OLS) regressions of current price, last year's price, the current supply, and last year's supply only (i.e., the Rocke simplified analysis). Such a narrowly focused analysis is unreliable and is an indefensible modeling practice, and it is not a practice that ARB relies on in other analyses it performs.[13] There are too many other factors influencing yield (supply) that should be accounted for in a reliable prediction model.

E. The Rocke Study Only Used Part of the Perez Data to Attempt to Duplicate Perez's Results

LCFS TF2-40 continued

20. In his 2012 dissertation entitled "Essays on the Environmental Effects of Agricultural Production," Juan Francisco Rosas Perez describes his complex, multi-faceted agricultural prediction system. The mechanics, mathematical, and statistical components of this system cannot be fully addressed in this report, given the limited time since its relevance to the Rocke work and the relevant content of the dissertation have become available and known. Nevertheless, in brief: Perez's model is designed to estimate the impact on supply (and under his assumptions the underlying yield) in relation to a wide range of related parameters. The estimated yields can be determined for corn, soybeans, other crops, and livestock products.

21. The related parameters used by the Perez model are divided into two categories, "inputs," which are usually more time dependent and variable, and so-called "netputs," which are usually more stable. The inputs category includes the quantities and prices for fertilizer, hired labor, and intermediates. The broad intermediate parameters cover seeds, pesticides, energy (petroleum fuels, natural gas, and electricity), and other

[12] Rocke, page 6.

[13] ARB's Predictive Model for gasoline is a good example of the modeling practices that ARB relies on (see www.arb.ca.gov/fuels/gasoline/premodel/premodel.htm.) The Predictive Model estimates emissions from cars and trucks in response to a number of gasoline inputs, including sulfur, benzene, T50, T90, aromatics, olefins, volatility, and total oxygen. All of these inputs are recognized to influence vehicle emissions to varying degrees. If ARB were to analyze the emissions data focusing on only one of these fuel parameters at a time, it would likely find certain fuel parameters to be statistically insignificant. ARB did not do that; it analyzed all of the input parameters that affect emissions simultaneously in creating the Predictive Model. Similarly, ARB should, in determining the impact of price on yield, not rely on analyses that examine only price impacts on yield, but rely on studies that attempt to model as many factors as possible on crop yields.

purchased intermediate inputs (contract labor services, custom machine services, machine and building maintenance and repairs, and irrigation). The "netputs" category includes agricultural capital, Conservation Reserve Program (CRP) land, family labor, farmland, and farm related output. In his analysis, Perez obtained data from 1960-2004 and transformed it to fulfill the requirements of his model.

LCFS TF2-40 continued

22. The results of Perez's model are summarized in the table below, which was taken directly from his report. As can be seen, the elasticity of corn yield to corn price ranges from 0.14 to 0.53, with a median of 0.29.

Table 9. Corn yield elasticities with respect to selected prices and quantities.

	Lower bound	Median	Upper bound
Elasticity of corn yields with respect to:			
Corn price	0.14	0.29	0.53
Hired Labor price	-0.29	-0.12	0.01
Intermediate Inputs price	-0.43	-0.15	-0.01
Fertilizer price	-1.09	-0.17	0.04
Hired Labor quantity	0.000	0.190	0.461
Intermediate Inputs quantity	0.412	0.420	0.429
Fertilizer quantity	0.413	0.422	0.431

Note: Lower and upper bounds represent extremes of the 95% highest probability interval of the marginal posterior density function of each elasticity.

23. Clearly the Perez analysis takes into account many more factors affecting yield than Rocke's simple analysis of only a small part of the Perez data. The fact that Rocke's simple analysis using incomplete data failed to confirm the Perez results does not negate the Perez results. The Perez results also fall in line with the Goodwin et al results. Goodwin et al performed a detailed analysis similar to Perez, where many factors affecting yield were included in the prediction model.

24. Regarding Rocke's criticism of Perez insufficiently handling autocorrelation, Perez does address this issue in the dissertation:

> We assume there is no autocorrelation within equations, but that there is a contemporary correlation among the equation errors. The assumption of autocorrelation absence arises from the fact that, prior to the estimation, we take pseudo-differences of the time-series to remove serial autocorrelation found in the time series.[14]

[14] Perez, page 100.

Either Rocke failed to read this part of the dissertation, or he did read it and disagreed with how Perez handled autocorrelation. In either case, Rocke does not explain in his report for ARB what is wrong with how Perez handled autocorrelation.

LCFS TF2-40 continued

25. Rocke's simple analysis, using only some of the Perez data, is not supported by the evidence, and does not negate the Perez results. ARB's reliance on Rocke's evaluation of the Perez data in selecting price yield values is misplaced. If CARB does not agree with our position on Rocke's analysis, it should explain why, in full detail, and provide us and other stakeholders an adequate opportunity to respond before taking final action on the LCFS regulatory proposal. In particular, CARB should address the following issues:

- Whether ARB believes Rocke's very limited analysis of price and supply data alone constitutes an adequate analysis of the Perez data, when ARB's own methods of analyzing data are much more robust that Rocke's;
- Why ARB deviated from the EWG recommendation of 0.25 for a central value or average value for YPE; and
- What exactly was wrong with how Perez handled autocorrelation in his analysis.

F. LUC Emissions For Biofuels Are Significantly Greater With a Central YPE Value of 0.185, as Opposed to the 0.25 Recommended By the EWG

LCFS TF2-41 continued

26. Emissions attributed to LUC for biofuels are significantly higher, and will be overestimated, with a YPE value of 0.185 than with 0.25.

27. AIR has run the GTAP model that ARB uses to estimate land use change emissions for various biofuels. We were able to replicate many of ARB's land use emission outputs, in order to establish our ability to work with ARB's model.

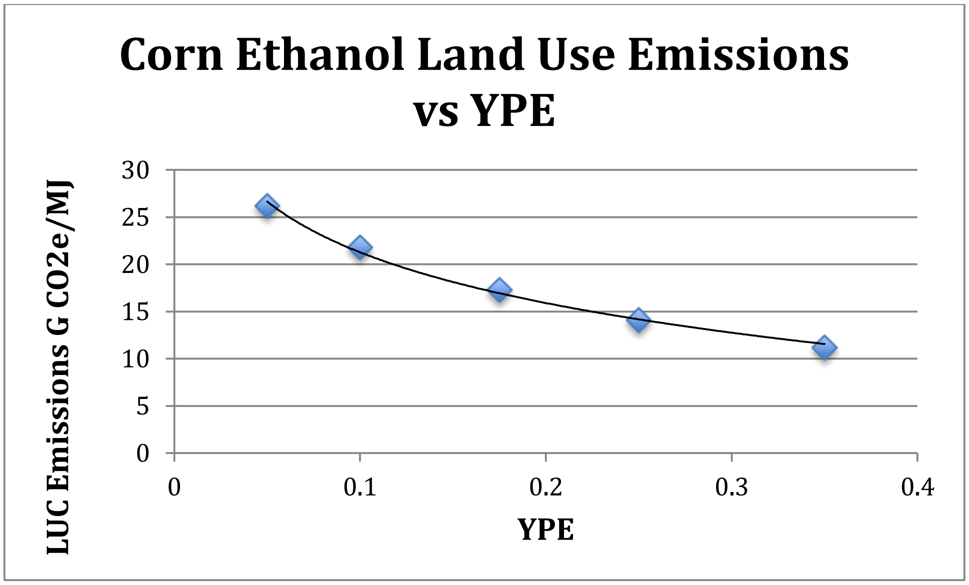
28. ARB ran 30 different GTAP scenarios for each biofuel to estimate LUC emissions. The LUC emissions were estimated as the average of the 30 unique scenarios. For corn ethanol, ARB's average of the 30 scenarios is 19.8 gCO_2/MJ of ethanol. In each of these scenarios, ARB varied several input elasticities, including the price-yield elasticity and two other elasticities. As indicated earlier, there are five input price-yield elasticities, and the average of these is 0.185, which is lower than the central value of 0.25 recommenced by the EWG. To do this correctly, one would have to select five price-yield elasticities whose average is 0.25. One possibility—and one that CARB should either use, or justify not using—would be to select the following elasticities: 0.15, 0.20, 0.25, 0.30, and 0.35.[15] These would be used in place of the current price-yield elasticities, and the input elasticities of the other two inputs would remain the same. The 30 scenarios should

[15] There are many other price-yield elasticities that would average 0.25; this is only one example.

then be re-run and new average emissions would be estimated from the new GTAP runs. This average value would then be compared to the 19.8 gCO_2/MJ.

LCFS TF2-41 continued

29. To illustrate the impact of the price-yield parameter on corn ethanol land use emissions, we provide a chart below which uses ARB's estimate of corn ethanol land use emissions at the five different YPE values. This chart uses scenarios 2, 4, 6, 8, and 10 in ARB's Table I-4. The other elasticities were held constant in these scenarios; only YPE was altered.



30. The chart shows the high degree of sensitivity of land use emissions for corn ethanol to this input parameter. Small changes in the range and average of YPE values chosen for this analysis are important in estimating land use emissions from biofuels.

31. The time allowed for comments on the Rocke report did not allow running 30 new scenarios. Instead, we ran just two scenarios; one using the ARB average inputs, and a second one using 0.25 for price-yield and the average inputs for the other two elasticities. These two scenarios are shown in Table 1. Given the time constraints, we assume that the difference in these two scenarios will approximate the difference between the two averages of 30 scenarios. The actual differences could be either greater or lesser than estimated here.

Table 1. Scenarios Used to Estimate Impact of Difference Between EWG Recommendation and ARB Price-Yield				
Scenario	Price-Yield	PAEL	ETA	Irrigation Constraint
1 – EWG price yield, ARB average for all other	0.25	0.3/0.15	Baseline	On
2 – ARB average	0.185	0.3/0.15	Baseline	On

PAEL = yield elasticity target for cropland/pasture
ETA = elasticity of effective area with respect to harvested area

LCFS TF2-41 continued

32. The land use emissions we obtained for these two scenarios are shown in Table 2. We have used ARB's latest AEZ-EF model with GTAP to estimate emissions for these two scenarios. The corn ethanol LUC emissions difference is 2.5 g CO_2/MJ. Therefore, we would expect that if the 30 scenarios were actually run for both cases, the difference in the averages of the 30 scenarios would be close to 2.5 g/MJ; however, it could be higher because Scenario 2, which represents average ARB inputs, is 17.14 gCO_2e/MJ, and the average of the 30 scenarios for corn ethanol is higher at 19.8 gCO_2e/MJ.

Table 2. Corn Ethanol LUC Emissions (gCO2e/MJ)	
Scenario	LUC Emissions
1 – EWG	14.64
2-ARB	17.14
Difference (2-1)	2.50 (15%)

ARB's corn ethanol land use value is 19.8 gCO_2e/MJ. If the emissions of the 30 scenarios run with new YPE values with an average of 0.25 are 2.5 gCO_2/MJ lower, then the new corn ethanol land use value would be 17.3 gCO_2e/MJ.

33. There would be corresponding changes in all biofuels if ARB adopted the EWG central value of 0.25 for price-yield. In addition, the baseline carbon intensities for 2016-2020 would also change, as well as the annual targets, because 10% corn ethanol is included in the baseline 2016-2020 values.

I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct.

Executed this 17th day of August, 2015 in Holland, Michigan.

Thomas L. Darlington

Exhibit A to Declaration of Thomas L. Darlington

Thomas L. Darlington

President, Air Improvement Resource Inc.

Profile

Thomas L. Darlington is President of Air Improvement Resource, a company formed in 1994 specializing in mobile source emission modeling. He is an internationally recognized expert in mobile source emissions modeling, lifecycle analysis, and land use modeling.

Professional Experience

1994-Present	President, Air Improvement Resource
1993-1994	Director, Mobile Source Programs, Systems Application International
1989-1994	Senior Engineer, General Motors Corporation, Environmental Activities
1988-1989	Senior Project Engineer, Detroit Diesel Corporation
1979-1988	Project Manager, U.S. EPA, Ann Arbor, Michigan

Recent Major Projects

- Developed Life Cycle reports and complete applications for 8 plants for the California Low Carbon Fuel Standard; six are currently registered, two plants are pending. Five plants were corn ethanol plants, one is sorghum and two are cellulose.
- Participated in and provided written comments on ARB's three 2014 iLUC workshops
- With Purdue and Don O'Connor, conducted study of iLUC emissions of rapeseed and other oilseeds in 2013 utilizing an updated version of GTAP
- Reviewed EPA's palm oil iLUC emissions in 2013
- Submitted comments on ARB's new GREET2.0 model
- Reviewed CARB's land use emissions for soybean biodiesel
- Reviewed the land use impacts of the RFS2 from EPA, including the notice of Proposed Rule, Regulatory Impact Analysis, and approximately one hundred documents in the rulemaking docket.
- Completed a land use study for Renewable Fuels Association and reviewed California Air Resource Board's Initial Statement of Reasons for the Low Carbon Fuel Standard
- Represented three stakeholders in the recent development of the ARB Predictive Model for reformulated gasoline in California (Alliance of Automobile Manufacturers, Renewable Fuels Association and Western States Petroleum Association)
- Represented two stakeholders in EPA's development of the MOVES on-highway emissions model (Alliance of Automobile Manufacturers and Engine Manufacturers Association)

Exhibit "B"

- Developed the effects of ethanol permeation on on-highway and off-highway mobile sources in California and other states for the American Petroleum Institute
- Studied gasoline and diesel fuel options for Southeast Michigan (for SEMCOG, API and Alliance of Automobile Manufacturers)

"Study of Transportation Fuel Life Cycle Analysis: Review of Economic Models Use to Assess Land Use Effects", CRC-E-88-3, July 2014.

"Land Use Change Greenhouse Gas Emissions of European Biofuel Policies Utilizing the Global Trade Analysis Project Model", Darlington, Kahlbaum, O'Connor, and Mueller, August 30, 2013.

"A Comparison of Corn Ethanol Lifecycle Analyses: California Low Carbon Fuels Standard (LCFS) Versus Renewable Fuels Standard (RFS2)", June 14, 2010. Renewable Fuels Association and Nebraska Corn Board. This study compared and contrasted the corn ethanol lifecycle analyses performed by both CARB (as a part of the LCFS) and the EPA (as a part of RFS2).

"Review of EPA's RFS2 Lifecycle Emissions Analysis for Corn Ethanol", September 25, 2009. Conducted for Renewable Fuels Association. This study reviewed EPA's land use GHG emissions assessment for corn ethanol, including the FASOM and FAPRI models and Winrock land-use types converted and emission factors by ecosystem type. The study made many recommendations for improving the land-use and emissions modeling.

"Review of CARB's Low Carbon Fuel Standard Proposal", April 15, 2009. Conducted for Renewable Fuels Association. This study reviewed CARB's analysis of land use emissions using GTAP6 and CARB's overall lifecycle emissions for corn ethanol. This study made many recommendations for improving the land use and lifecycle emissions of corn ethanol.

"Emission Benefits of a National Clean Gasoline", August 2008. Conducted for the Alliance of Automobile Manufacturers. This study evaluated the nationwide criteria pollutant emission reductions of a national clean gasoline standard.

"Land Use Effects of Corn-Based Ethanol", February 25, 2009. Conducted for Renewable Fuels Association. This study evaluates possible land use changes and GHG emissions associated with these land use changes as a result of the renewable fuel standard mandated 15 billion gallons of corn ethanol required by calendar year 2015. The study utilized projections of land use in the US and rest of world performed by Informa Economics, LLC, as well as newer estimates of the land use credits of co-products produced by ethanol plants to evaluate possible land use changes.

"On-Road NOx Emission Rates From 1994-2003 Heavy-Duty Trucks", SAE2008-01-1299, conducted for the Engine Manufacturers Association. This study examined

manufacturers consent decree emissions data to determine on-road NOx emission rates, and deterioration in emissions from heavy-duty vehicles. (Peer reviewed publication)

"Evaluation of California Greenhouse Gas Standards and Federal Energy Independence and Security Act - Part 2: CO2 and GHG Impacts", SAE2008-01-1853, conducted for the Alliance of Automobile Manufacturers. This paper evaluated the comparison of greenhouse gases from cars and light trucks in the US under both the Federal and California GHG policies. (Peer reviewed publication)

"Effectiveness of the California Light Duty Vehicle Regulations as Compared to Federal Regulations", June 15, 2007. Conducted with NERA Economic Consulting and Sierra Research for The Alliance of Automobile Manufacturers. This study compares the emission benefits of the California and Federal light duty vehicle regulations for HC, CO, NOx, PM, SOx, and Toxics taking into account the difference in emission standards, new vehicle costs and its effect on fleet turnover, new vehicle fuel economy and its effect on vehicle miles traveled, and other factors. Both the EPA MOBILE6 and ARB EMFAC on-road emissions models were used to estimate changes in emissions inventories.

"The Case for a Dual Tech 4 Model Within the California Predictive Model", May 20, 2007. Conducted with ICF International and Transportation Fuels Consulting for the Renewable Fuels Association (RFA). This study developed separate emissions vs fuel property models for lower and higher Tech 4 (1986-1995) vehicles, and showed that utilizing this alternative Predictive Model would result in a higher compliance margin for fuels containing higher volumes of ethanol. It was thought that this could lead to higher ethanol concentrations in the state, but even if the dual model is not used, it is a better representation of the 2015 inventory than the ARB single model.

"Updated Final Report, Effects of Gasoline Ethanol Blends on Permeation Emissions Contribution to VOC Inventory From On-Road and Off-Road Sources, Inclusion of E-65 Phase 3 Data and Other Updates", June 20, 2007. Conducted for the American Petroleum Institute. This report updates the earlier March 3, 2005 report for API utilizing data collected by CRC and others since of the time of the earlier report.

Final Report, Development of Technical Information for a Regional Fuels Strategy, February 28, 2006. Conducted for the Lake Air Directors Consortium (LADCO). This report provided guidance to the LADCO states (Midwestern states) concerning how to model different types of fuel control programs (in particular) using EPA mobile source models, and how to set up the baseline input files so that results are consistent between the different states.

"Emission Reductions from Changes to Gasoline and Diesel Specifications and Diesel Engine Retrofits in the Southeast Michigan Area", February 23, 2005. Conducted for the Southeast Michigan Council of Governments (SEMCOG), the Alliance of Automobile Manufacturers, and the American Petroleum Institute. This study examined the on-road and off-road emission benefits of many different possible gasoline and diesel fuel

specifications that the state could adopt to help meet the 8-hour ozone standards. This study formed the basis for the state's move to lower RVP summer gasoline.

"Examination of Temperature and RVP Effects on CO Emissions in EPA's Certification Database, Final Report", CRC Project No. E-74a, April 11, 2005. Conducted for the Coordinating Research Council. This study compared CO vs temperature results from the MOBILE6 model to the certification data, and recommended further testing, which is being conducted by the CRC at this time.

"Effects of Gasoline Ethanol Blends on Permeation Emissions Contribution to VOC Inventory From On-Road and Off-Road Sources" March 3, 2005. Conducted for the American Petroleum Institute (API). Using data from the CRC-E-65 program, and data collected by the California EPA and Federal EPA, this study estimated the impacts of ethanol use on increasing permeation VOC emissions from on-road vehicles, off-road equipment and vehicles, and from portable containers. Emission inventory estimates were made for a number of geographical areas including the state of California, and results showed that the permeation effect increases anthropogenic VOC inventories by 2-4%.

Review of EPA Report "A Comprehensive Analysis of Biodiesel Impacts on Exhaust Emissions", February 11, 2003. Conducted for the American Petroleum Institute. This study critically examined the methods that EPA used to develop the impacts of biodiesel fuels on HC, CO, NOx, and PM emissions.

"Well-To Wheels Analysis of Advanced Fuel/Vehicle Systems – A North American Study of Energy Use, Greenhouse Gas Emissions, and Criteria Pollutant Emissions", May 2005. Conducted for General Motors Corporation, with Argonne National Labs. This study examined many different well to wheels pathways for various fuels, and their impacts on GHG and criteria pollutant emissions.

"Potential Delaware Air Emission Impacts of Switching From MTBE to Ethanol in the Reformulated Gasoline Program", May 26, 2005. Conducted for Lyondell Chemical Company. This study examined the HC, CO, and NOx impacts of switching from MTBE to ethanol.

"Potential Massachusetts Air Emission Impacts of Switching From MTBE to Ethanol in the Reformulated Gasoline Program" June 17, 2005. Conducted for Lyondell Chemical Company. This study is similar to the Delaware study above.

"Potential Maryland Air Emission Impacts of a Ban on MTBE in the Reformulated Gasoline Program", October 18, 2005. Conducted for Lyondell Chemical Company. This study is similar to the Delaware study above.

"MOBILE6.2C with Ethanol Permeation and Ethanol NOx Effects", February 8, 2005. Conducted for Health Canada. This study modified the MOBILE6.2C model for ethanol permeation VOC and ethanol NOx effects.

2_TF_LCFS_GE

1243. Comment: **LCFS TF2-5, LCFS TF2-8, TF2-9, TF2-11, TF2-12, TF2-19, TF2-23, TF2-29, TF2-30, and TF2-36**

Agency Response: The responses to these comments are in "Responses to Comments on the Draft Environmental Analysis for the Low Carbon Fuel Standard and Alternative Diesel Fuel Regulations."

1244. Comment: **LCFS TF2-1**

The comment suggests that it is improper to amend a regulatory proposal for a third time, and recommends that ARB start the process over with a new 45-day notice.

Agency Response: ARB staff disagrees, because the APA clearly contemplates that an agency may amend a pending proposal to address an omission or in response to comments from the public.

1245. Comment: **LCFS TF2-2**

The comment relates to a spreadsheet included in the 3rd 15 day notice addressing electricity use estimates included in the illustrative compliance scenario published in the ISOR. The comment states that "CARB has not explained why this information was not included in the original 45-day notice, nor why it waited until now to make the information available for public comment", and argues that the 15 day comment period is insufficient.

Agency Response: ARB staff disagrees that the 15-day period was insufficient in light of the fact that ARB's proposal neither requires nor is predicated on a set amount of electricity usage in transportation. This detail had been sought by and provided to a single stakeholder. ARB determined it should also be made available to the public. ARB placed this material in the record to provide another layer of detail on the inputs to the calculations of electricity consumption used by electric vehicles expected as a result of California's Advanced Clean Cars (ACC) regulation. The relevant part of the information in the spreadsheet was already included in Table B-17 of Appendix B that was released with the ISOR. Table B-17 includes the estimates of the number of electric vehicles anticipated due to the ACC regulation and their corresponding electricity consumption for each year from 2015 through 2020. These estimates were used to quantify light duty vehicle (LDV) electricity use and LCFS credit generation in the

Illustrative Compliance Scenario -- Tables B-22, B-23, and B-24. The more detailed material included in the 3rd 15 Day Notice provides detail on the average e-VMT per ZEV and the average efficiency of ZEVs, shown in the Table B-17. The details provided are consistent with current, publicly-available information on the efficiency and use of ZEVs. The spreadsheet also shows estimates for the full analysis period 2014 through 2025.

ARB staff has not modified its estimates of the number of ZEVs or electricity usage in the updated illustrative compliance scenarios released to demonstrate the impact of the proposed 15 day changes.

1246. Comment: **LCFS TF2-3**

The comment questions why material similar to the electricity use estimates related to natural gas (NG) vehicles was not included in the 3rd 15-day notice.

Agency Response: The comment-is not directed to any material provided for comment in the 3rd 15-day notice, and as such needs no response. ARB staff disagrees with the implication that the rulemaking record is not complete; in light of the fact that ARB's proposal neither requires nor is predicated on a set amount of natural gas usage in transportation. However, for clarity purposes ARB staff is addressing some of the concerns related to NG projections raised in other comments by Growth Energy. Please see responses to **LCFS TF2-5, TF2-6,** and **TF2-7.**

1247. Comment: **LCFS TF2-4**

The comment argues that ARB's treatment of electricity and NG fuel use forecasts are inconsistent and not supported by substantial evidence.

Agency Response: The comment is not directed to any change in the 3rd 15-day notice, and as such needs no response. However, for clarity purposes ARB staff note that the there is no legal or technical rationale for using parallel methodologies when estimating future fuel consumption of different fuels by different vehicle types. The method used for electric vehicles was included only because of one stakeholder's interest in how the anticipated penetration of electric vehicles pursuant to the ACC regulation (which provided an estimate of vehicle numbers but not fuel consumption) translates into fuel use. Forecasts of fuel use and availability were made independent of vehicle numbers for the other fuels included in the illustrative scenarios. See responses to **LCFS TF2-2, TF2-3, TF2-5, TF2-6,** and **TF2-7.**

1248. Comment: **LCFS TF2-6**

These comments argue that ARB has failed to meet disclosure requirements with respect to NG fuel forecasts, has failed to project the number of NG vehicles and has failed to identify the basis for the fuel estimate it used.

Agency Response: See response to **LCFS TF2-5**.

1249. Comment: **LCFS TF2-7**

These comments argue that ARB has failed to meet disclosure requirements with respect to NG fuel forecasts, has failed to project the number of NG vehicles and has failed to identify the basis for the fuel estimate it used.

Agency Response: See response to **LCFS TF2-5**.

1250. Comment: **LCFS TF2-10**

The comment argues that ARB did not include NG vehicle costs in the economic impact analysis.

Agency Response: The comment is not directed to any change in the 3rd 15-day notice, and as such needs no response. However, for clarity purposes ARB staff note that the ISOR is explicit that the LCFS is unlikely to impact, in any significant way, the amount of NG that is consumed by vehicles (ISOR Appendix B pages B-27 and B-28). Therefore there is no reason to perform an economic impact assessment of the LCFS relative to the number of NG vehicles.

1251. Comment: **LCFS TF2-13**

This comment (and those following, through **LCFS TF2-19**) is under the caption: "CARB's Indirect Land Use Change Factor for Corn Ethanol Is Based on Incomplete Data and Faulty Analysis, and Lacks Evidentiary Support." The comment states that in calculating the LUC value for corn ethanol ARB used a variety of inputs. In particular, the commenter refers to two conflicting opinions – both in the ISOR and appendices – one a report by David Rocke and one a student dissertation by Juan Francisco Rosas Perez. The comment then concludes that ARB failed to comply with the Government Code because data was added to the record as part of a 15-day change.

Agency Response: The third 15-day change did not change ARB's iLUC for corn ethanol. That value and the supporting analysis and information were all set forth in the initial notice package for the LCFS re-adoption, and extensively commented on by this commenter and dozens of other parties. No further response is needed regarding the corn ethanol iLUC value, analysis, or supporting information.

The data added to the record was not the basis for the corn ethanol iLUC value. The basis for that value, as the comment itself acknowledges, was in the ISOR. Because the commenter expressed interest in seeing a data set used by both Rosas Perez and Rocke, largely compiled from publicly-available information, ARB added the data set to the record so that all interested parties would have ready access. Now, ironically, the commenter complains that it was improper to share that data set as part of a 15-day notice.

The commenter appears to mistakenly assume that ARB relied on the data set or somehow based the corn ethanol iLUC value on the Rosas Perez data set. In reality, ARB determined the corn ethanol iLUC value as described in the 295-page Staff Report, and the 113-page appendix regarding iLUC.

1252. Comment: **LCFS TF2-14**

The commenter believes that Dr. Rocke misinterpreted the Rosas-Perez study by only analyzing a small subset of parameters (or even one parameter as stated) in contrast with Rosas-Perez who showed that a wide range of parameters affect YPE values. According to the commenter, there is no justification why Dr. Rocke used this approach and Dr. Rocke's simple analysis, which concluded that YPE is small to zero, is deeply flawed, unsupported by evidence, and inconsistent with modeling practices used by ARB for other rulemakings. Also, according to the commenter, , the public was completely misled about Dr. Rocke's approach to estimating YPE using Perez's data because ARB did not make the Rosas-Perez data available and ARB erred in using Dr. Rocke's report to support using a lower yield-price value.

Agency Response: The comment appears aimed at Dr. Rocke's analysis rather than ARB's analysis, and needs no response beyond the extensive responses to the timely comments on the initial notice package. See e.g. **LCFS 8-9**, **LCFS 46-79**, **LCFS 46-86**, and **LCFS 46-102**. Although ARB did not adopt the conclusion reached by either J.F. Rosas Perez or by David Rocke, their respective analyses were included in that initial notice package and comments on those analyses were timely during that initially noticed comment period.

ARB does not agree with the commenter's assertion that ARB's analysis and the information on which it was based was "finally made available to the public" only on "approximately August 1, 2015." In fact, the public, including the commenter, commented extensively on ARB's analysis long before August 1, 2015. See e.g. **LCFS 8-9**, **LCFS 46-79**, **LCFS 46-86**, and **LCFS 46-102**. Further, as the record reflects, the debate about YPE was robust and public. YPE has been the subject of public workshops over several years, and the initial notice package for this rulemaking, released in December 2014, included a 32-page public notice, the 295-page Staff Report, and a 113-page appendix devoted entirely to iLUC

Notably, and as described in the ISOR and its appendices, ARB did not adopt Dr. Rocke's conclusion. In Appendix I, Attachment 1-5, ARB stated "researchers use different econometric methods to derive relationship between yield and price. They sometimes report contrasting values even when using the same data." This is evident from the various studies cited in Appendix I, Attachment 1. Given that there is no consensus in the academic and scientific community about definite values for YPE even when using the same data, ARB used an approach to account for all likely values for YPE. Accordingly, staff used a range between 0.05 and 0.35. This has been document in Attachment 1 of Appendix I of the ISOR. The public was provided ample opportunity to comment on *ARB's* analysis and conclusions.

For the analysis conducted by Dr. Rocke, all years that were included in the Perez data were considered. The variables used were price and supply, and sound modeling principles were used based on Granger Causality. This analysis was used to test whether the complex analysis in Perez was improving elasticity estimates, or whether the Perez results were the artifactual results of using many variables and choosing from among hundreds of possible models with widely varying elasticity estimates in order perhaps to produce an intended result. The commenter's statement is completely contradictory to sound principles of data analysis, where including many variables generally produces false positives, as one could argue Perez's elasticity result would be classified. According to Dr. Rocke, if a reasonable simple analysis produces a null result, but a complex, opaque analysis shows significance, the complex analysis is likely suspect.

See also response to **LCFS TF2-40**, **LCFS FF45-1**, **LCFS 46-12**, **LCFS 46-79**, **LCFS 46-103**, **LCFS 46-102**, **LCFS 46-107**, and **LCFS 8-9.**

1253. Comment: **LCFS TF2-15**

The commenter believes that Dr. Rocke misinterpreted the Perez study by only analyzing a small subset of parameters (or even one parameter as stated) in contrast with Perez who showed that a wide range of parameters affect YPE values. There is no justification why Dr. Rocke used this approach. Dr. Rocke's simple analysis which concluded that YPE is small to zero is deeply flawed, unsupported by evidence, inconsistent with modeling practices used by ARB for other rulemakings. Also, by not making the data available, the public was completely misled about Dr. Rocke's approach to estimating YPE using Perez's data. Finally, ARB used David's report to support using a lower yield-price value.

Agency Response: See responses to **LCFS TF2-13** and **LCFS TF2-14**.

1254. Comment: **LCFS TF2-16**

The commenter believes that Dr. Rocke misinterpreted the Perez study by only analyzing a small subset of parameters (or even one parameter as stated) in contrast with Perez who showed that a wide range of parameters affect YPE values. There is no justification why Dr. Rocke used this approach. Dr. Rocke's simple analysis which concluded that YPE is small to zero is deeply flawed, unsupported by evidence, inconsistent with modeling practices used by ARB for other rulemakings. Also, by not making the data available, the public was completely misled about Dr. Rocke's approach to estimating YPE using Perez's data. Finally, ARB used David's report to support using a lower yield-price value.

Agency Response: See responses to **LCFS TF2-13** and **LCFS TF2-14**.

1255. Comment: **LCFS TF2-17**

The commenter believes that Dr. Rocke misinterpreted the Perez study by only analyzing a small subset of parameters (or even one parameter as stated) in contrast with Perez who showed that a wide range of parameters affect YPE values. There is no justification why Dr. Rocke used this approach. Dr. Rocke's simple analysis which concluded that YPE is small to zero is deeply flawed, unsupported by evidence, inconsistent with modeling practices used by ARB for other rulemakings. Also, by not making the data available, the public was completely misled about Dr. Rocke's approach to estimating YPE using Perez's data. Finally, ARB used David's report to support using a lower yield-price value.

Agency Response: See responses to **LCFS TF2-13** and **LCFS TF2-14**.

1256. Comment: **LCFS TF2-18**

The commenter instructs ARB that it must seek external scientific review of Dr. Rocke's analysis, and must answer a series of interrogatories.

Agency Response: Regarding external review, as required by statute, ARB sent for external review ***ARB's*** findings, conclusions and the assumptions on which the scientific portions of the proposal were based. The pertinent statute does not require ARB to seek separate, expensive, time-consuming scientific review of every ***other party's*** document, submission, conflicting opinion and dataset contained in the vast rulemaking record.

The interrogatories make no recommendation or objection to the third 15-day changes, and need no response.

1257. Comment: **LCFS TF2-20**

The commenter believes that the 15-day public comment period provided was inadequate and that ARB should re-start the entire rulemaking process based on the addition of a handful of technical documents that the commenter itself requested.

Agency Response: ARB disagrees. ARB complied with all requirements of the APA, and ARB's decision to provide materials not covered by the APA's rulemaking file provisions do not indicate otherwise. ARB staff also disagrees with the commenter's characterization of the relevant documents as "extensive new information regarding CARB's analyses." As the commenter indicates, some of the data pertained to "the Rocke analysis," not ARB's analysis, and, as discussed in Response **TF2-2**, the other document contained some background information (the relevant portions of which were provided in the ISOR's Appendix B and none of which represents a new analyses or alters the proposed regulation in any way).

ARB staff also disagree with the commenter's characterization of ARB's actions related to the commenter's Public Records Act as "dilatory" and notes that the court also expressly rejected this characterization in the only ruling (a tentative one) that has been issued in the relevant litigation. In addition, the commenter's opinions concerning ongoing litigation are not directed to any change in the 3rd 15-day notice, and as such need no response.

1258. Comment: **LCFS TF2-21**

The commenter believes that the public comment period established by the California Legislature in Government Code sections 11346.8, subds. (c)(d) and 11347.1 is inadequate, thus ARB should re-start the entire rulemaking process based on the addition of a handful of technical documents that the commenter itself requested. The remainder of the comment consists of complaining about the burdens of litigation that the commenter itself initiated against ARB.

Agency Response: In regard to the public comment period, see response to **LCFS TF2-20**. In regard to ongoing litigation, the comment is not directed to any change in the 3rd 15-day notice, and as such needs no response.

1259. Comment: **LCFS TF2-22**

The commenter believes that the 15-day public comment period was inadequate, thus ARB should re-start the entire rulemaking process based on the addition of a handful of technical documents that the commenter itself requested.

Agency Response: See response to **LCFS TF2-20**.

1260. Comment: **LCFS TF2-24**

The commenter attaches another declaration from Jim Lyons, this one expressing Mr. Lyons' surprise that an estimate of natural gas usage in transportation was not determined based on the number of NGVs in future. For Mr. Lyons that "raises serious concerns" about the validity of ARB's compliance scenario. The declaration includes a conclusory statement that it is "not possible" for anyone to understand how ARB reached conclusions about "the use of electricity as a transportation fuel in the light-duty fleet" in connection with the illustrative scenario.

Agency Response: This comment is not directed to any change in the 3rd 15-day notice, and as such needs no response. However, for clarity purposes ARB staff note that the alleged flaws in the analysis of future natural gas demand (the criticism that ARB staff made no detailed estimate of the number of NGVs), are without merit.

First of all, the proposal does not require the use of NGVs or natural gas. The illustrative scenario was used for various purposes as a reasonably possible forecast, although neither required nor concretely predicted. The illustrative scenario does not bind natural gas producers, natural gas vehicle manufacturers, ARB or anyone else in any way. Indeed, the LCFS—the *regulation* at issue here—is designed to let market participants determine which fuels are used to comply with the LCFS. Any future forecast regarding such a regulation will contain some uncertainty and is not therefor invalid, whatever the commenter means by having serious concerns.

Second, ARB disagrees with the implication that ARB needed to know the NGV population in order to forecast natural gas use. Appendix B of the ISOR contains explicit discussion of how ARB considered estimates of the potential for growth in the use of NG as a fuel independent of any requirement of the LCFS (See pages B-24 to B-26 and B-35). A number of NG growth estimates were available to the ARB as the ISOR was being developed. These included estimates by the California Energy Commission, ICF consulting, the Boston Consulting Group, and the EIA. Each is referenced in the ISOR and was publically available at the time the ISOR was released. These references projected substantial growth in NG use, thus providing ARB staff with the information needed to include NG as a fuel that might be used to comply with the LCFS.

Lyons' declaration includes a conclusory statement that it is "not possible" for anyone to understand how ARB reached conclusions about "the use of electricity as a transportation fuel in the light-duty fleet" in connection with the illustrative scenario. ARB disagrees; the ISOR includes an entire Appendix B, consisting of 41 pages and 31 referenced sources explaining how the illustrative scenario, including for electricity, was developed. The portion of the comment that refers to electric vehicles has also been addressed in the response to **LCFS TF2-3.**

In addition**,** for clarity purposes we have addressed many of the NG related concerns in previous responses. Comments related to the adequacy of ARB's estimates of NG use were addressed in responses **LCFS TF2-5, TF2-6**, and **TF2-7**. Comments related to concerns about economic assessments were addressed in response **LCFS TF2-10**. Comments related to environmental analyses were addressed in response **LCFS TF2-11**.

1261. Comment: **LCFS TF2-25**

The commenter attaches another declaration from Jim Lyons, this one expressing Mr. Lyons' surprise that an estimate of natural gas usage in transportation was not determined based on the number of NGVs in future. For Mr. Lyons, that "raises serious concerns" about the validity of ARB's compliance scenario.

Agency Response: See response to **LCFS TF2-24**.

1262. Comment: **LCFS TF2-26**

The declaration from Jim Lyons challenges assumptions in the illustrative scenario, Appendix B to the ISOR.

Agency Response: See response to **LCFS TF2-24**.

1263. Comment: **LCFS TF2-27**

The declaration from Jim Lyons challenges assumptions in the illustrative scenario, Appendix B to the ISOR.

Agency Response: See response to **LCFS TF2-24**.

1264. Comment: **LCFS TF2-28**

The declaration from Jim Lyons challenges assumptions in the illustrative scenario, Appendix B to the ISOR.

Agency Response: See response to **LCFS TF2-24**.

1265. Comment: **LCFS TF2-31**

The comment, in the form of an "Exhibit B", is used to present calculations of the number of NG vehicles needed to use the fuel projected in the ISOR, and are presented to support the concerns previously expressed in comments **LCFS TF2-4** through **TF2-12.**

Agency Response: These comments are related to the ISOR Appendix B -- issues not included in the 3rd 15 Day notice, and are not directed to any material provided for comment in the 15-day proposal, and as such needs no response.

1266. Comment: **LCFS TF2-32**

The comment, in the form of an "Exhibit B", is used to present calculations of the number of NG vehicles needed to use the fuel projected in the ISOR, and are presented to support the concerns previously expressed in comments **LCFS TF2-4** through **TF2-12.**

Agency Response: These comments are related to the ISOR Appendix B -- issues not included in the 3rd 15 Day notice, and are not directed to any material provided for comment in the 15-day proposal, and as such needs no response.

1267. Comment: **LCFS TF2-33**

The comment, in the form of an "Exhibit B", is used to present calculations of the number of NG vehicles needed to use the fuel projected in the ISOR, and are presented to support the concerns previously expressed in comments **LCFS TF2-4** through **TF2-12.**

Agency Response: These comments are related to the ISOR Appendix B -- issues not included in the 3rd 15 Day notice, and are not directed to any material provided for comment in the 15-day proposal, and as such needs no response.

1268. Comment: **LCFS TF2-34**

The comment, in the form of an "Exhibit B", is used to present calculations of the number of NG vehicles needed to use the fuel projected in the ISOR, and are presented to support the concerns previously expressed in comments **LCFS TF2-4** through **TF2-12.**

Agency Response: These comments are related to the ISOR Appendix B -- issues not included in the 3rd 15 Day notice, and are not directed to any material provided for comment in the 15-day proposal, and as such needs no response.

1269. Comment: **LCFS TF2-35**

The comment, in the form of an "Exhibit C", seeks to support and present the concerns related to credit generation from NG fuel forecasts used in the illustrative compliance scenario previously expressed in comment **LCFS TF2-12.**

Agency Response: This comment is not directed to any change in the 3rd 15-day notice, and as such needs no response.

1270. Comment: **LCFS TF2-37**

The comment states that ARB should explain why 0.25 was not used (EWG recommended value) in a new rulemaking notice and permit testimony at a public hearing.

Agency Response: ARB has explained the approach used in the iLUC analysis in Appendix I of the ISOR; nothing changed in the third 15-day notice. No response to the commenter's renewed critique of iLUC is required

See also responses to **LCFS 8-1**, **LCFS 8-4**, **LCFS 8-9**, **LCFS 46-102**, **LCFS B12-6**, **LCFS B12-32**, **LCFS FF45-1**, **LCFS FF45-1**, and **LCFS TF2-40**.

1271. Comment: **LCFS TF2-38**

The comment states that ARB arbitrarily relied on the Rocke Study to select a range of YPE values and a Mid-Point that were significantly lower than what the EWG recommended.

Agency Response: See response to **LCFS TF2-14**.

1272. Comment: **LCFS TF2-39**

States that Rocke dismissed Goodwin and Perez analyses as methodologically flawed. Repeated and replicated Rocke's results but could not replicate Perez's results. States that Rocke's simplified analysis is not a good measure to estimate YPE and the analysis is unreliable and constitutes indefensible modeling practice (unlike practice used by ARB in other analyses).

Agency Response: Virtually all of this comment critiques Rocke's analysis which was (1) not ARB's conclusion on YPE, and (2) released with the ISOR. Insofar as the comment critiques Rocke's analysis, it is untimely and unrelated to the third 15-day notice.

Insofar as the commenter's expert states that he could not reproduce Perez' results, ARB notes the comment, and further notes that David Rocke attempted to reproduce Perez's results but after spending a large amount of time deciphering the data and information, concluded that the Perez analysis is complex, opaque, and poorly documented that the result is likely not reproducible. See also responses to **LCFS TF2-14** through **LCFS TF2-17**.

1273. Comment: **LCFS TF2-40**

The commenter states that since Dr. Rocke used a simple analysis using incomplete data to invalidate Perez's results, it does not imply that Perez's results are not relevant. The Goodwin results fall in line with Perez's results. If ARB does not agree with commenter's position on the Rocke analysis, staff must address the following:

- Why staff believes Rocke's simple analysis with limited data from the Perez study constitutes an adequate analysis
- Why ARB deviated from the EWG recommendation of 0.25 value for YPE
- What was the issue with Perez's handling of autocorrelation

Agency Response: ARB does not agree with commenter regarding the quality of Dr. Rocke's analysis, except for the prior statement that it could be reproduced. More importantly, ARB does not agree it relied on Dr. Rocke's analysis to determine the YPE values in the iLUC analysis. As explained in ISOR Appendix I, given the disagreement between researchers on specific values (or range) for YPE, ARB used a range of values for YPE between 0.05 and 0.35 to account for all likely values for this elasticity parameter. See also response to **LCFS TF2-14**, **LCFS TF 2-15**, **LCFS TF 2-16**, **LCFS 8-9**, **LCFS 46-12**, **LCFS 46-102**, **LCFS B12-32**, and **LCFS FF45-1**.

ARB is not required to answer the interrogatories constituting the balance of this comment; they are neither recommendations nor objections. See also responses to **LCFS TF2-14** through **LCFS TF2-17**.

1274. Comment: **LCFS TF2-41**

The comment states that the YPE of 0.185 will over estimate iLUC. The use of YPE of 0.25 will result in changes to iLUC values for other biofuels also.

Agency Response: ARB's iLUC and YPE determinations as set forth in the ISOR were extensively commented on by the public, including this commenter during the 45-day comment period, as well as for years preceding this rulemaking. The third 15-day notice did not set forth any analysis, conclusion, support or change regarding ARB's determinations. Commenter's untimely repetition of its views following the third 15-day notice needs no response in this context. Nevertheless, ARB repeats that it does not currently plan to change the iLUC determinations presented in the ISOR. See also responses to **LCFS 8-9**, **LCFS 46-102**, **LCFS B12-32**, and **LCFS FF45-1**.

1275. Comment: **LCFS TF2-42**

In an attached declaration, Mr. Darlington complains that the release of additional data on July 31, 2015 (the dataset used by David Rocke and Juan Francisco Rosas Perez to draw conflicting conclusions) did not give him or the public sufficient time to conduct studies to assess the relationship between price and yield, and to submit an analysis to ARB.

Agency Response: ARB disagrees; the LCFS adoption first began in 2008, and continued in 2009, and has been effective since January 2010. The re-adoption process began in 2014, including a working group on iLUC and a public workshop on iLUC, culminating in a 45-day notice, ISOR, and two Board hearings in 2015. During all of that time, the relationship between price and yield has been hotly, publicly, and thoroughly debated. The suggestion that Mr. Darlington's chance to conduct research or participate in the debate was limited to 15 days in August 2015 is simply wrong.

SUBJECT: REQUEST FOR EXTERNAL PEER REVIEW OF STAFF'S METHODOLOGY IN CALCULATING FUEL CARBON INTENSITIES AND USE OF THREE LIFE CYCLE GREENHOUSE GAS EMISSIONS MODELS

Dear Mr. Aguila:

This letter responds to the attached January 21, 2015 request by the California Air Resources Board (ARB) for a external peer review of the staff reports entitled, Staff Report: Calculating Life Cycle Carbon Intensity of Transportation Fuels in California; Calculating Carbon Intensity Values of Crude Oil Supplied to California Refineries; and Calculating Carbon Intensity Values from Indirect Land Use Change of Crop-Based Biofuels.

To begin the process for selecting reviewers, I contacted the University of California, Berkeley (University) and requested recommendations for candidates considered qualified to perform the assignment. The University was provided with the January 21, 2015 request letter to me, and attachments, and no additional material was asked for or forwarded to augment the request. This service by the University includes interviews of each promising candidate and is supported through an Interagency Agreement co-signed by Cal/EPA and the University.

Each candidate who was both interested and available for the review period was asked to send me a completed Conflict of Interest (COI) Disclosure form and Curriculum Vitae to begin the review process. The cover letter for the COI form describes the context for COI concerns that must be taken into consideration when completing the form. "As noted, staff will use this information to evaluate whether a reasonable member of the public would have a serious concern about [the candidate's] ability to provide a neutral and objective review of the work product."

In subsequent letters to candidates approving them as reviewers, I provided the attached January 7, 2009 Supplement to the Cal/EPA Peer Review Guidelines, which, in part serves two purposes: a) it provides guidance to ensure confidentiality through the course of the external review, and, b) it notes reviewers are under no obligation to discuss their comments with third-parties after reviews have been submitted. <u>We recommend they do not</u>. All outside parties are provided opportunities to address a proposed regulatory action, or potential basis for such, through a well-defined rulemaking process.

Later, I sent each reviewer the material to be reviewed and a detailed cover letter to initiate the review (example attached). The letter included as an attachment a summary overview for the many documents and a Disclaimer. The Disclaimer noted supporting documents were either entirely or partially not peer – reviewed, and that reviewers were ultimately responsible for assessing the relevance and accuracy for the content of all information upon which the staff report is based.

Also attached to the cover letter was the January 21, 2015 request for reviewers to me. Its Attachment 2 was highlighted as the focus for the review. Each reviewer was asked to address each conclusion, as expertise allows, in the order given. Thirty days were provided for the review. I also asked reviewers to direct enquiring third-parties to me after they have submitted their reviews.

Reviewers' names, affiliations, curriculum vitae, and reviews are being sent to you now with this letter. All attachments can be electronically accessed through the Bookmark icon at the left of the screen.

Approved reviewers are as follows:

SUBJECT: REQUEST FOR EXTERNAL PEER REVIEW OF STAFF'S METHODOLOGY IN CALCULATING FUEL CARBON INTENSITIES AND USE OF THREE LIFE CYCLE GREENHOUSE GAS EMISSIONS MODELS

By way of this memorandum, California Air Resources Board (ARB/Board) staff requests external peer review of the following:

1. *Staff Report: Calculating Life Cycle Carbon Intensity of Transportation Fuels in California*
2. *Staff Report: Calculating Carbon Intensity Values of Crude Oil Supplied to California Refineries*
3. *Staff Report: Calculating Carbon Intensity Values from Indirect Land Use Change of Crop-Based Biofuels*

The reports describe staff's methodology for calculating carbon intensity (CI) values with the use of three life cycle greenhouse gas (GHG) emissions models. Fuel CI is measured on a life cycle basis and represents the equivalent amount of carbon dioxide (CO_2e) emitted over all stages of the fuel's life, from production, to transport, and to use in a motor vehicle. Depending on the fuel, GHG emissions from each step may include carbon dioxide (CO_2), methane, nitrous oxide, and other GHG contributors. The overall GHG contribution from each step may be expressed as a function of the energy that the fuel contains. Thus, CI is expressed in terms of grams CO_2 equivalent per megajoule (CO_2e/MJ). In preparing each report referenced above, staff used the following life cycle GHG emissions model(s) to calculate fuel CI values, respectively:

1. California Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (CA-GREET) Model
2. Oil Production Greenhouse Gas Emissions Estimator (OPGEE) Model

The energy challenge facing California is real. Every Californian needs to take immediate action to reduce energy consumption. For a list of simple ways you can reduce demand and cut your energy costs, see our website: http://www.arb.ca.gov.

California Environmental Protection Agency

Printed on Recycled Paper

3. Global Trade Analysis Project (GTAP-BIO) Model combined with the Agro-Ecological Zone Emissions Factor (AEZ-EF) Model

For each review topic identified below, staff suggests the following number of reviewers and areas of expertise:

1. Life Cycle Carbon Intensity: Life cycle analysis of transportation fuels.

   A minimum of two reviewers who are familiar with well-to-wheel life cycle analysis related to transportation fuels. Experience with the CA-GREET model is optional.

2. Crude Oil Carbon Intensity: Life cycle analysis of crude oil production methods.

   A minimum of two reviewers who are familiar with crude oil production, developing models for GHG life cycle assessments of crude production, and the application of life cycle analysis models for the assessment of crude production emissions.

3. Indirect Land Use Change: Economic modeling of agricultural impacts, including general expertise with global economic models used to estimate indirect land use effects, carbon emissions inventory, and release of carbon emissions from land conversion.

   A minimum of three reviewers are requested for this complex review. Collectively, reviewers must have expertise in the following areas: econometric modeling, dynamics of land cover change, carbon emissions, and uncertainty analysis. For the uncertainty analysis, the reviewer must be familiar with Monte Carlo simulations. All reviewers must also be familiar with the GTAP model (or similar computable general equilibrium model), its database, application of economic models to estimate land conversions, protocols established by the Intergovernmental Panel on Climate Change or other global agencies for GHG accounting and carbon dynamics in various ecosystems, and changes in carbon stocks resulting from land conversion.

The specific charge or statement of work for each set of reviews is provided in Attachment 2. Peer review comments will be addressed by ARB staff in the final staff reports and submitted to the Board as part of the rulemaking to re-adopt the Low Carbon Fuel Standard (LCFS) regulation by July 2015. The proposed LCFS regulation is scheduled to be presented to the Board on February 19, 2015. The final Board hearing to take action for approval is currently scheduled on July 23, 2015.

The following attachments are enclosed:

1. Attachment 1 - Plain English Summary of Staff's Methodology In Calculating Fuel Carbon Intensities
2. Attachment 2 - Description of Scientific Bases to be Addressed by Peer Reviewers
3. Attachment 3 - List of Participants Associated with the Development of Fuel Carbon Intensities
4. Attachment 4 - References

The staff reports and other supporting documentation will be ready for review by **February 5, 2015**. Staff requests that the peer review be completed and comments from the reviewers be received by **March 10, 2015.**

If you have questions regarding this request, please contact Ms. Aubrey Gonzalez, Air Resources Engineer, Substance Evaluation Section at (916) 324-3334 or by email at aubrey.gonzale@arb.ca.gov.

Thank you for your time and consideration of this request.

ATTACHMENT 1

Plain English Summary of Staff's Methodology in Calculating Fuel Carbon Intensities

Air Resources Board (ARB) staff prepared three reports entitled:

1. Staff Report: Calculating Life Cycle Carbon Intensity of Transportation Fuels in California
2. Staff Report: Calculating Carbon Intensity Values of Crude Oil Supplied to California Refineries
3. Staff Report: Calculating Carbon Intensity Values from Indirect Land Use Change of Crop-Based Biofuels

The reports describe staff's methodology for calculating fuel carbon intensity (CI) with the use of life cycle greenhouse gas (GHG) emissions models. CI is a measure of the GHG emissions per unit of energy of fuel and is measured in units of grams of carbon dioxide equivalent emissions per mega joule of fuel energy (gCO_2e/MJ).

The determination of fuel CI is fundamental to the reporting and compliance determination provisions of the Low Carbon Fuel Standard (LCFS) regulation.

1. Life Cycle Fuel Carbon Intensities

This section describes the basic methodology for calculating direct life cycle CIs for LCFS fuels. The basic analytical tool for identifying and combining the necessary fuel life cycle data and calculating the direct effects is the Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model. Dr. Michael Wang, of the U.S. Department of Energy's Argonne National Laboratory, began developing the GREET model in 1996. Dr. Wang and his colleagues have updated the model several times since the publication of "*GREET 1.0 – Transportation Fuel Cycles Model: Methodology and Use*[1]," which documented the development of the first GREET version of the model. GREET 2014 is the latest version of the model and was released on October 3, 2014.[2]

For purposes of Assembly Bill 1007 and the LCFS, the model was modified to better represent California conditions. The revised version of the Argonne model is referred to as the California-modified GREET (CA-GREET). Staff used the latest version (2.0) of the CA-GREET model to calculate life cycle CIs from direct emissions from transportation fuels in California.

---

[1] Wang, M. Q. *GREET 1.0-: Transportation Fuel Cycles Model: Methodology and Use*. Argonne, IL: Argonne National Laboratory, 1996.

[2] Argonne National Laboratory, U.S. Department of Energy. "GREET Model." Accessed December 12, 2014. https://greet.es.anl.gov/.

The CA-GREET model, like the original GREET model, was developed in Microsoft Excel. The CA-GREET Excel spreadsheet is publicly available at no cost. The model is a sophisticated computational spreadsheet, with thousands of inputs and built-in values that feed into the calculation of energy inputs, emissions, CIs, and other values.

In general, each fuel pathway is modeled in GREET as the sum of the GHG emissions resulting from the following sequence of processes:

- Feedstock production
- Feedstock transport, storage, and distribution (TSD)
- Fuel production
- Production of co-products
- Finished fuel TSD
- Fuel use in a vehicle

The CA-GREET modifications are mostly related to incorporating California-specific conditions, parameters, and data into the original GREET model. The major changes incorporated into the CA-GREET model are listed below:

- Marine and rail emissions reflect in-port and rail switcher activity with an adjustment factor for urban emissions;
- Natural gas transmission and distribution losses reflect data from California gas utilities;
- The fuel properties data for California Reformulated Gasoline Blendstocks for Oxygenate Blending (CARBOB), ultra-low sulfur diesel (ULSD), California reformulated gasoline, natural gas, and hydrogen were revised to reflect California-specific parameters;
- The electricity transmission and distribution loss factor was corrected to reflect California conditions; the electricity mix was also changed to reflect in-State conditions, both for average and marginal electricity mix;
- The California crude oil recovery efficiency was modified to reflect the values specific to the average crude used in California including crude that is both produced in, and imported into, the State;
- Crude refining for both CARBOB and ULSD was adjusted to reflect more stringent standards for these fuels in California;
- Tailpipe CH_4 and N_2O emission factors were adapted for California vehicles where available;
- The process efficiencies and emission factors for equipment were changed to reflect California-specific data; and
- Landfill gas to compressed natural gas (CNG) pathway was coded into the CA-GREET pathway.[3]

[3] California Air Resources Board. *Proposed Regulation to Implement the Low Carbon Fuel Standard Staff Report: Initial Statement of Reasons, Volume I*. March 5, 2009. Pages IV-8–IV-10.

The basis of all fuel pathway CIs under the LCFS is the life cycle inventory (LCI) data contained in the CA-GREET 2.0 spreadsheet. LCI data quantifies the relevant energy, material, and waste flows into and out of the fuel production system. Emission factors and process efficiencies are also used to calculate CIs.

Staff used standard industry assumptions and best practices in applying the model. Examples of the LCI, emissions, and efficiency data found in CA-GREET 2.0 follow:

- *Agricultural Feedstock Production*

    - Argonne National Laboratory (ANL) describes the material and energy flows used in the six cellulosic pathways included in the GREET1 2013[4] version of the model in a document entitled "*Material and Energy Flows in the Production of Cellulosic Feedstocks for Biofuels for the GREET^{TM} Model*.[5]" This document draws on multiple peer-reviewed journal articles and data from the U.S. Department of Agriculture (USDA), U.S. Department of Energy (DOE), National Renewable Energy Laboratory (NREL), U.S. Environmental Protection Agency (U.S. EPA), and other sources.

    - ANL provided background details on its updated life cycle analysis of sorghum ethanol in a 2013 paper entitled "*Life-cycle energy use and greenhouse gas emissions of production of bioethanol from sorghum in the United States*.[6]" This paper draws on information from a wide variety of sources, including the USDA, the United Nations Food and Agricultural Organization, U.S. EPA, and other peer-reviewed literature.

    - The USDA's Economic Research Service reported the results of a 1996 survey of sorghum producers.[7] This report contained information on fertilizer, farm chemical, and on-farm fuel use.

- *Fuel Production*

    - NREL reported on its simulation of the process of converting corn stover to ethanol through dilute-acid pretreatment, enzymatic saccharification, and co-fermentation.[8] NREL's simulation was conducted using the Aspen Plus process modeling software.

[4] Systems Assessment Section, Center for Transportation Researcher, Argonne National Laboratory, 2013.
[5] Wang, Z. *et al*. *Material and Energy Flows in the Production of Cellulosic Feedstocks for Biofuels for the GREET^{TM} Model.* Energy Systems Division, Argonne National Laboratory. October 2013.
[6] Cai, H. *et al.* Biotechnology for Biofuels. *Life-cycle energy use and greenhouse gas emissions of production of bioethanol from sorghum in the United States.* 2013, 6:141.
[7] U.S. Department of Agriculture. Economic Research Service. February 1997.
[8] National Renewable Energy Laboratory and Harris Group. May 2011.

- U.S. EPA published the results of simulations of the energy needed to produce ethanol from sorghum as part of a formal rulemaking under 40 CFR Part 80.[9] These simulations were carried out by USDA and drew on prior simulations of the corn ethanol production process. All simulations were carried out using Aspen process modeling software.

- The energy requirements of producing ethanol from sugar cane were drawn in part from an article entitled "*Life cycle assessment of Brazilian sugarcane products: GHG emissions and energy use.*[10]"

- *Feedstock and Fuel Transport*

  ANL describes the updates it has made to the transportation LCI data in the GREET model in a 2013 paper (Dunn et al. October 7, 2013). Revisions to the energy intensity and emissions associated with locomotives, pipelines, heavy-duty trucks, ocean-going vessels, and barges are presented. The updates are based on information from the U.S. Department of Transportation, U.S. Energy Information Administration, U.S. EPA, Journal articles, and other sources.

- *Emission Factors*

  - U.S. EPA's Clearinghouse for Inventories and Emission Factors (Air CHIEF) CD ROM.[11] The Air CHIEF CD contains emission factors and software tools designed to assist with the estimation of emissions from a wide variety of stationary and point sources. It contains Volume I of the Agency's Compilation of Air Pollutant Emission Factors (AP-4), and the latest National Emission Inventory documentation for criteria and hazardous air pollutants.

  - ANL's "Updated Emission Factors of Air Pollutants from Vehicle Operations in GREET™ using Motor Vehicle Emission Simulator (MOVES).[12] This report documents ANL's approach to updating gasoline and diesel vehicle emissions factors to account for changes in engine technology and fuel specifications; deterioration of emission control devices with vehicle age; implementation of emission control inspection and maintenance programs; and the adoption of advanced emission control technologies, such as second-generation onboard diagnostics (OBD II), selective catalytic reduction, diesel particulate filters, and diesel oxidation catalysts. To best capture the effects of these factors, ANL used the U.S. EPA's latest mobile-source emission factor model, the MOVES.

[9] U.S. Environmental Protection Agency. December 17, 2012

[10] Seabra *et al. Life cycle assessment of Brazilian sugarcane products: GHG emissions and energy use*. 2011.

[11] U.S. Environmental Protection Agency, Emissions Factor and Inventory Group. 2005.

[12] Cai, et al. September 2013.

Previously, vehicular emission factors were estimated using the U.S. EPA's MOBILE6.2 and the California ARB's EMFAC models.

- The 2010 baseline tailpipe emission factors for CARBOB, California Reformulated Gasoline, and ULSD in the model are from the following sources: CO2 emissions for these fuels were calculated based on the carbon content, assuming complete combustion to CO2, and corrected for carbon emitted as CH4.

- Tailpipe emission factors for CNG-powered light- and heavy-duty trucks are from the U.S. EPA's Emission Inventory.[13]

- Tailpipe emission factors for LNG-powered heavy duty LNG trucks are from U.S. EPA's Emission Inventory.[14]

- The guidelines issued by the Intergovernmental Panel on Climate Change (IPCC) on performing national greenhouse gas inventories.[15] These guidelines provide detailed instructions on the preparation of national GHG inventories, as well as GHG emission factors that can be used in the preparation of those inventories. The GREET model utilizes many of these factors (e.g., N_20 emissions from agriculture).

- Emissions from the generation of grid electricity are calculated using regional electrical generation energy mixes (e.g., natural gas, coal, wind, etc.) from the U.S. EPA's Emissions and Generation Resource Integrated Database (eGRID).[16] The CA-GREET uses energy mixes from the 26 eGRID subregions.

CA-GREET 2.0 is a modified version of the previously peer-reviewed GREET1 2013.[17] Michael Wang and his team at ANL developed GREET1 2013. The software platform for both models is Microsoft Excel. The process for converting ANL's model to a California-specific version consisted primarily of adding the necessary California-specific LCI data and emission factors. A comprehensive list of revisions is maintained on the CA-GREET web site.[18] Among those revisions are the following:

- Crude oil recovery efficiency was modified to reflect the values specific to the average crude used in California, including crude that is both produced in, and imported into, the State;

- Tailpipe CH4 and N20 emission factors were adapted for California vehicle where available, in light of the fact that California has stricter vehicle emissions standards than were assumed in developing GREET1 2013;

[13] U.S. Environmental Protection Agency. 2014b.
[14] U.S. Environmental Protection Agency. 2014b.
[15] Eggleston *et al*. 2006.
[16] U.S. Environmental Protection Agency. 2014a.
[17] Systems Assessment Section, Center for Transportation Research, Argonne National Laboratory, 2013.
[18] http://www.arb.ca.gov/fuels/lcfs/ca-greet/ca-greet.htm

- The U.S. EPA's eGRID[19] was the source of the grid electricity generation energy mixes used in CA-GREET 2.0. An electrical energy generation mix is the mix of energy sources (e.g., natural gas, coal, hydroelectric dams, etc.) used to generate the electricity provided to a regional electrical grid.

Based on staff's assessment of available life cycle inventory sources, emissions, and efficiency data, ARB staff concludes that the assumptions and inputs used in CA-GREET 2.0 to calculate direct life cycle fuel CIs are reasonable and the model was applied appropriately under the LCFS.

2. Crude Oil Carbon Intensity Values

A portion of the CI of gasoline and diesel baseline fuels are the emissions associated with producing and transporting crude oil to a refinery. Staff used the previously peer-reviewed Oil Production Greenhouse Gas Emissions Estimator (OPGEE) model to calculate CIs of all crudes supplied to California refineries. These "well-to-refinery-entrance-gate" emissions estimated by OPGEE can vary significantly depending on the method of production and field-specific production parameters. The CIs calculated using the OPGEE model is combined with the appropriate CIs from the CA-GREET model to calculate a total life cycle CI for gasoline and diesel.

Staff used standard industry assumptions and best practices in applying the model. Figure 1 shows the main input parameter sheet used in OPGEE to estimate CI values for crude production and transport. Figure 1 also indicates whether the parameter is generally known or assumed, based on a smart default, or based on simple default. For each crude source, staff has searched available government, research literature, and internet sources to determine each of these inputs.

1.8.2.1	Ocean tanker	Mile	Known
1.8.2.2	Barge	Mile	0
1.8.2.3	Pipeline	Mile	Known
1.8.2.4	Rail	Mile	0
1.8.3	Ocean tanker size, if applicable	Ton	250000
1.9	Small sources emissions	gCO_2eq/MJ	0.5

Based on staff's assessment of available government, research literature, and internet sources for each crude source, ARB staff concludes that the assumptions and input parameters used in OPGEE to calculate CI values for crude oil production and transport are reasonable and the model was applied appropriately under the LCFS.

3. Indirect Biofuel Carbon Intensity Values

Current generation of biofuels are mostly derived from crop-based feedstocks (e.g., corn), which traditionally have been used for human consumption or as feed for livestock. The diversion of crops from food or feed markets to biofuel production creates an additional demand to produce the biofuel feedstock. Crop producers in the region which mandates the biofuel, either resort to crop switching (e.g., soybeans to corn) or convert new land to meet the new demand. Any demand that is not met locally[20] is transmitted to the global marketplace and met by production of the agricultural commodity or commodities in other countries. A direct consequence of this 'domino' effect is that new land areas are converted to grow crops. This unintended consequence is termed indirect Land Use Change (iLUC). Converting non-cropland to cropland leads to GHG emissions which are termed "iLUC emissions."

To estimate iLUC emissions, staff selected a global economic model developed by Purdue University called GTAP (Global Trade Analysis Project). In the iLUC analysis, the GTAP model was modified to account for biofuels and their co-products. This model, termed GTAP-BIO represents all sectors of the global economy in an aggregated form, and interactions among various sectors and resources are represented using various internal and external parameters. The model uses a baseline global equilibrium of all sectors in which supply equals demand in all sectors. The model is then "shocked" by increasing biofuel production by an appropriate volume. To meet this new requirement, the model allocates existing resources and also accounts for additional production of crops, ultimately ensuring a new global equilibrium is achieved. The changes in land uses (classified as forestry, pasture, cropland, and cropland-pasture in the model) computed by the model are then used in combination with a carbon emissions model called Agro-Ecological Zone Emission Factor (AEZ-EF) model to estimate the CO_2-equivalent emissions from land-use change.

The AEZ-EF model utilizes soil and biomass carbon stock data for different land types and regions of the world and calculates emission factors for land conversions. The model estimates the CO_2-equivalent GHG flows when land is converted from one type to the other (e.g., forest to cropland). The GHG flows are summed globally and divided by the total quantity of fuel produced to produce a value in grams CO_2e per megajoule of fuel (g CO_2e/MJ). Given the likely range of values for parameters that have the largest influence on model outputs, staff used a scenario approach that used different combinations of input values (within the range derived from literature review and expert

[20] Crop switching leads to local regions producing additional crop required for biofuel production at the expense of another crop not being grown. In the global marketplace, demand for crop that is not grown leads to a different region (or country) that converts new land to agricultural production to satisfy the demand for the crop that has been displaced.

opinion) to estimate output iLUC values for each set of input values. The output iLUC values (CIs) from all the scenario runs was then averaged and proposed to be used as indirect CI for that specific biofuel in the LCFS regulation. For the current analysis, staff has analyzed iLUC emissions for corn ethanol, sugarcane ethanol, soy biodiesel, canola biodiesel (also called rapeseed biodiesel), palm biodiesel, and sorghum ethanol.
The original modeling results were published in 2009 and when the LCFS regulation was adopted, stakeholders raised the issue of uncertainty in the output values for iLUC. Staff, working with the University of California, developed a Monte Carlo approach for estimating total uncertainty of iLUC resulting from variability in individual parameters.

Since 2009, there have been numerous peer-reviewed publications, dissertations, and other scientific literature, that have focused on various aspects of indirect land use changes related to biofuels. Staff has reviewed published articles, contracted with academics, and consulted with experts, all of which have led to significant improvements to the GHG modeling methodologies and analysis completed in 2009.

Specific model and iLUC analysis updates in the current revised modeling include:

- Use of the GTAP 7 database and baseline data for 2004 (the 2009 analysis used a 2001 baseline),
- Addition of cropland pasture in the U.S. and Brazil,
- Re-estimated energy sector demand and supply elasticity values,
- Improved treatment of a corn ethanol co-product (distillers dried grains with solubles - DDGS),
- Improved treatment of soy meal, soy oil, and soy biodiesel,
- Modified structure of the livestock sector,
- Improved method of estimating the productivity of new cropland,
- More comprehensive and spatially explicit set of emission factors that are outside of the GTAP-BIO model,
- Revised yield response to price,
- Revised demand response to price,
- Increased flexibility of crop switching in response to price signals,
- Incorporation of an endogenous yield adjustment for cropland pasture,
- Disaggregated sorghum from the coarse grains sector to allow for modeling iLUC impacts for sorghum ethanol,
- Disaggregated canola (rapeseed) from the oilseeds sector to facilitate modeling of iLUC for canola-based biodiesel,
- Included data for palm in the oilseeds sector to estimate iLUC for palm-derived biodiesel,

- Developed regionalized land transformation elasticities for the model using recent evidence for land transformation[21],
- Split crop production into irrigated versus rain-fed and developed datasets and metrics to assess impacts related to water-constraints in agriculture across the world. Details of the modeling efforts to include irrigation in the GTAP-BIO model is included in a report by Taheriour et al.[22] Determining regions of the world where water constraints could limit expansion of irrigation was developed by researchers at the World Resources Institute (WRI) and is detailed in reports published by WRI[23,24], and
- Disaggregated Yield Price Elasticity (YPE) parameter into regionalized and crop-specific values. For the current analysis, however, the same YPE value is used for all regions and crops.[25]

The primary input to computable general equilibrium models such as GTAP is the specification of the changes that will, by moving the economy away from equilibrium, result in the establishment of a new equilibrium. Parameters, such as elasticities, are used to estimate the extent which introduced changes alter the prior equilibrium. Listed below are the inputs and parameters that the GTAP uses to model the land use change impacts of increased biofuel production levels. Also listed are some of the important approaches used by staff for the current analysis.

- Baseline year: GTAP employs the 2004[26] world economic database as the analytical baseline. This is the most recent year for which a complete global land use database exists.

- Fuel production increase: The primary input to computable general equilibrium models such as GTAP is the specification of the changes that will result in a new equilibrium. “Shock’ corresponds to an increase in the volume of biofuel production used as an input to the model to estimate land use changes.

- Yield Price Elasticity (YPE): This parameter determines how much the crop yield will increase in response to a price increase for the crop. Agricultural crop land is more intensively managed for higher priced crops. If the crop yield elasticity is 0.25, a P percent increase in the price of the crop relative to input cost will result in a percentage increase in crop yields equal to P times 0.25. The higher the

[25] Staff conducted scenario runs using different values of YPE. For each run, YPE was the same across all regions and crops.
[26] For the 2009 regulation, the baseline year was 2001.

elasticity, the greater the yield increases in response to a price increase. For the 2009 modeling, ARB used a yield-price elasticity value range of 0.2 to 0.6. Purdue researchers have used a single YPE value of 0.25 based on an econometric estimate made by Keeney and Hertel.[27] The Keeney-Hertel estimate of 0.25 is obtained by averaging two values (0.28 and 0.24) from Houck and Gallagher,[28] a value from Lyons and Thompson[29] (0.22) and a value from Choi and Helmberger[30] (0.27). An expert from UC Davis, contracted to conduct a review and statistical analysis of data from a few published studies, also concluded that YPE values were small to zero. Staff conducted a comprehensive review of all available data and reports on YPE and concluded that YPE values were likely small. However, to account for the different values of YPE from recent studies and recommendations from the Expert Working Group (EWG), staff has used values of YPE between 0.05 and 0.35, for the current analysis. Details of the review conducted by staff on YPE are provided in Attachment 1.

- Elasticity of crop yields with respect to area expansion (ETA): This parameter expresses the yields that will be realized from newly converted lands relative to yields on acreage previously devoted to that crop. Because almost all of the land that is well-suited to crop production has already been converted to agricultural uses, yields on newly converted lands are almost always lower than corresponding yields on existing crop lands. For the 2009 regulation, the scenario runs utilized a value of 0.25 and 0.75 for this parameter, based on empirical evidence from U.S. land use and expert judgment on the productivity of the new cropland. For the current analysis, Purdue University used results from the Terrestrial Ecosystem Model (TEM) to derive estimates of net primary productivity (NPP), a measure of maximum biomass productivity. The ratio of NPP of new cropland to existing cropland was used to estimate ETA for a given region/AEZ and is detailed in Taheripour et al.[31] ETA values used in the current analysis are provided in Table 2 on the following page

GTAP modeling provides an estimate for the amounts and types of land across the world that is converted to agricultural production as a result of the increased demand for biofuels. The land conversion estimates made by GTAP are disaggregated by world region and agro-ecological zones (AEZ). In total, there are 19 regions and 18 AEZs. The next step in calculating an estimate for GHG emissions resulting from land conversion is to apply a set of emission factors. Emission factors provide average values of emissions per unit land area for carbon stored above and below ground as well as the annual amount of carbon sequestered by native vegetation. The amount of "lost sequestration capacity" per unit land area results from the conversion of native vegetation to crops. For the 2009 regulation, staff used emission factor data from Searchinger et al. (2008)[32].

In the 2009 modeling, each of the 19 regions had separate emission factors for forest and pasture conversion to cropland but these emission factors did not vary by AEZ within each region. Because land conversion estimates within each region differ significantly by AEZ and both biomass and soil carbon stocks also vary significantly by AEZ, emission factors specific to each region/AEZ combination provide a more appropriate assessment.

ARB contracted with researchers at UC Berkeley, University of Wisconsin-Madison, and UC Davis to develop the agro-ecological zone emission factor (AEZ-EF) model. The model combines matrices of carbon fluxes ($MgCO_2\ ha^{-1}\ y^{-1}$) with matrices of changes in land use (hectares or ha) according to land-use category as projected by the GTAP-BIO model. As published, AEZ-EF aggregates the carbon flows to the same 19 regions and 18 AEZs used by GTAP-BIO. The AEZ-EF model contains separate carbon stock estimates ($MgC\ ha^{-1}$) for biomass and soil carbon, indexed by GTAP AEZ and region, or "Region-AEZ".[33,34] The model combines these carbon stock data with assumptions about carbon loss from soils and biomass, mode of conversion (i.e., whether by fire), quantity and species of carbonaceous and other greenhouse gas (GHG) emissions resulting from conversion, carbon remaining in harvested wood products and char, and foregone sequestration. The model relies heavily on IPCC greenhouse gas inventory methods and default values (IPCC 2006[35]), augmented with more detailed and recent

[32] This data set is referred to as the "Woods Hole" data because it was compiled by Searchinger's co-author, R. A. Houghton, who is affiliated with the Woods Hole Oceanographic Institute.

data where available. Details of this model, originally published in 2011 is available in reports submitted to ARB by Holly Gibbs and Richard Plevin.[36,37] In response to stakeholder feedback from workshops, this version was modified and the updates include:

- Contributions to carbon emissions from Harvested Wood Products (HWP) was updated in the model using data compiled by Earles et al.[38]
- Additional modifications to HWP were performed using above-ground live biomass (AGLB) after 30 years in each region
- Updated the peat emission factor to 95 Mg CO_2/ha/yr, using the ICCT report[39]
- Added OilPalmCarbonStock based on Winrock update to RFS2 analysis.[40,41]
- Updated forest biomass carbon, forest area, and forest soil carbon data using latest data from Gibbs et al.[33]
- Updated IPCC_GRASSLAND_BIOMASS_TABLE with data from Gibbs et al.[33]

Based on the iLUC analysis, ARB staff concludes that the assumptions and input parameters used in the GTAP-BIO and AEZ-EF models to estimate indirect land use change for biofuels are reasonable and the models were applied appropriately under the LCFS.

ATTACHMENT 2

Description of Scientific Bases of the CI Methodology to be Addressed by Peer Reviewers

The statutory mandate for external scientific peer review (H&SC section 57004) states that the reviewer's responsibility is to determine whether the scientific basis or portion of the proposed rule is based upon sound scientific knowledge, methods, and practices.

We request your review to allow you to make this determination for each of the following conclusions that constitute the scientific basis of the staff reports. An explanatory statement is provided for each conclusion to focus the review.

For those work products that are not proposed rules, reviewers must measure the quality of the product with respect to the same exacting standard as if it were subject to H&SC section 57004.

The following conclusions are based on staff's assessment of the results from the life cycle greenhouse gas (GHG) emissions models and information provided in:

1. *Staff Report: Calculating Life Cycle Carbon Intensity of Transportation Fuels in California*
2. *Staff Report: Calculating Carbon Intensity Values of Crude Oil Supplied to California Refineries*
3. *Staff Report: Calculating Carbon Intensity Values from Indirect Land Use Change of Crop-Based Biofuels*

A brief description of each of the models used by staff is provided in Attachment 1.

1. <u>Life Cycle Fuel Carbon Intensities</u>

Based on staff's assessment of available life cycle inventory sources, emissions, and efficiency data, ARB staff concludes that the assumptions and inputs used in CA-GREET 2.0 to calculate direct life cycle fuel CIs are reasonable and the model was applied appropriately under the LCFS.

2. <u>Crude Oil Carbon Intensity Values</u>

Based on staff's assessment of available government, research literature, and internet sources for each crude source, ARB staff concludes that the assumptions and input parameters used in OPGEE to calculate CI values for crude oil production and transport are reasonable and the model was applied appropriately under the LCFS.

3. Indirect Biofuel Carbon Intensity Values

Based on the iLUC analysis, ARB staff concludes that the assumptions and input parameters used in the GTAP-BIO and AEZ-EF models to estimate indirect land use change for biofuels are reasonable and the models were applied appropriately under the LCFS.

4. Big Picture

Reviewers are not limited to addressing only the specific assumptions, conclusions, and findings presented above, and are also asked to contemplate the following questions:

(a) In reading the staff reports and supporting documentation, are there any additional substantive scientific issues that were part of the scientific basis or conclusion of the assessments but not described above? If so, please comment on them.

(b) Taken as a whole, are the conclusions and scientific portions of the assessments based upon sound scientific knowledge, methods, and practices?

Reviewers should note that in some decisions and conclusions necessarily relied on the professional judgment of staff when the scientific data were incomplete (or less than ideal). In these situations, every effort was made to ensure that the data are scientifically defensible.

The proceeding guidance will ensure that reviewers have an opportunity to comment on all aspects of the scientific basis of staff's assessments. At the same time, reviewers also should recognize that the Board has a legal obligation to consider and respond to all feedback on the scientific portions of the assessments. Because of this obligation, reviewers are encouraged to focus their feedback on scientific issues that are relevant to the central regulatory elements being proposed.

EXTERNAL PEER REVIEW OF STAFF'S METHODOLOGY IN CALCULATING CARBON INTENSITY VALUES AND USE OF GREENHOUSE GAS EMISSIONS MODELS

Dear Professor Matthews,

The purpose of this letter is to initiate the peer review process. Staff will not communicate with the approved reviewers, such as yourself, nor know their identities, until I formally transmit the reviews to them.

Included in this letter as attachments are the following:

a. **Attachment 1:** Summary Overview of Reports to Review

b. **Attachment 2:** January 21, 2015 Request for External Peer Review of Staff's Methodology in Calculating Fuel Carbon Intensities and Use of Three Life Cycle Greenhouse Gas Emissions Models, including four attachments, signed by Jim Aguila, Branch Chief, Program Planning and Management Branch. ***Please use the enclosed January 21, 2015 letter, and its attachments, as the basis for your review.***

c. **Attachment 3:** January 2009 Supplement to the Cal/EPA Peer Review Guidelines

d. **Attachment 4:** Peer Review Package – Review Materials. Three staff reports are submitted for peer review:

   1. *Staff Report: Calculating Life Cycle Carbon Intensity Values of Transportation Fuels in California* (Staff Report 1)
   2. *Staff Report: Calculating Carbon Intensity Values of Crude Oil Supplied to California Refineries* (Staff Report 2)
   3. *Staff Report: Calculating Carbon Intensity Values from Indirect Land Use Change of Crop-Based Biofuels* (Staff Report 3)

   Hard copies of these reports are provided in the enclosed binder and separated by individual tabs, numbered 1, 2, and 3, and labeled accordingly. For each review topic, reviewers may turn directly to the specific sections in the binder and the corresponding electronic files provided on the enclosed CD, also numbered and labeled accordingly.

All review materials, including the three staff reports (provided as hard copies in the enclosed binder), as well as electronic files (provided as electronic files saved on enclosed CD), including software and program packages, bibliographical references, and supporting documents, are labeled accordingly. ***The complete list of all review materials and corresponding labels are provided below:***

REVIEW MATERIAL	LABEL
1. **Staff Report: Calculating Life Cycle Carbon Intensity Values of Transportation Fuels in California** (Staff Report 1)	**Binder, Tab 1** – *Staff Report 1: Direct Life Cycle Carbon Intensity*
2. **CD** – Electronic Files: References	**CD, Folder 1** – *1. CA-GREET* **Subfolder**: *References*
3. **Staff Report: Calculating Carbon Intensity Values of Crude Oil Supplied to California Refineries** (Staff Report 2)	**Binder, Tab 2** – *Staff Report 2: Crude Oil Carbon Intensity*
4. **CD** – Electronic Files: References	**CD, Folder 2** – *2. OPGEE* **Subfolder:** *References*
5. **Staff Report: Calculating Carbon Intensity Values from Indirect Land Use Change of Crop-Based Biofuels** (Staff Report 3)	**Binder, Tab 3** – *Staff Report 3: Indirect Land Use Change*
6. **CD** – Electronic Files: References, Software and Program Files, Instructions, and Other Background Documents	**CD, Folder 3** – *3. GTAP-BIO_AEZ-EF* **Subfolders:** *I. Software and Program Packages* *II. References* *III. Other Background Documents*

All bibliographical references, supporting files, and other supporting documents are provided on the enclosed CD or as electronic links. If you wish to review references that are not provided as hard copy or live links, please contact me immediately and I will see that you receive them.

<u>Comments on the foregoing</u>:

a. <u>Attachment 1 to the January 21, 2015 request letter provides context for the review</u>. Attachment 1 provides a description for each staff report and is numbered and labeled accordingly.

b. <u>Attachment 2 to the January 21, 2015 request letter provides focus for the review</u>. Attachment 2 provides the conclusion for each staff report and is numbered and labeled accordingly.

c. The January 7, 2009 Supplement. In part, this provides guidance to ensure the review is kept confidential through its course. The Supplement notes reviewers are under no obligation to discuss their comments with third-parties after reviews have been submitted. We recommend they do not. All outside parties are provided opportunities to address a proposed regulatory action through a well-defined regulatory process. Direct third-parties to me.

Disclaimer:

Attachment 1 to this letter places the technical reports and supporting documents in context with respect to the subjects they are addressing. Reviewers may need to scrutinize references and supporting documents in detail. The materials identified as that which must be reviewed (required) and that which should be evaluated (optional) is intended to be helpful guidance by the Air Resources Board (ARB) staff. However, reviewers are ultimately responsible for assessing the relevance and accuracy of the content of all information upon which the staff report to be reviewed is based.

Please return your review directly to me. Questions about the review, or review material, should be for clarification, in writing – email is fine, and addressed to me. My responses will be in writing also. The ARB should not be contacted. I will subsequently forward all reviews together with reviewers' CVs.

I would appreciate your review being completed by Monday, April 27, 2015.

Your acceptance of this review assignment is most appreciated.

Regards,

Gerald W. Bowes

3) Attachment 3 – January 2009 Supplement to the Cal/EPA Peer Review Guidelines
4) Attachment 4 – Peer Review Package – Review Materials

January 7, 2009

Supplement to Cal/EPA External Scientific Peer Review Guidelines – "Exhibit F" in Cal/EPA Interagency Agreement with University of California
Gerald W. Bowes, Ph.D.

Guidance to Staff:

1. Revisions. If you have revised any part of the initial request, please stamp "Revised" on each page where a change has been made, and the date of the change. Clearly describe the revision in the cover letter to reviewers, which transmits the material to be reviewed. The approved reviewers have seen your original request letter and attachments during the solicitation process, and must be made aware of changes.

2. Documents requiring review. All important scientific underpinnings of a proposed science-based rule must be submitted for external peer review. The underpinnings would include all publications (including conference proceedings), reports, and raw data upon which the proposal is based. If there is a question about the value of a particular document, or parts of a document, I should be contacted.

3. Documents not requiring review. The Cal/EPA External Peer Review Guidelines note that there are circumstances where external peer review of supporting scientific documents is not required. An example would be "A particular work product that has been peer reviewed with a known record by a recognized expert or expert body." I would treat this allowance with caution. If you have any doubt about the quality of such external review, or of the reviewers' independence and objectivity, that work product – which could be a component of the proposal - should be provided to the reviewers.

4. Implementation review. Publications which have a solid peer review record, such as a US EPA Criteria document, do not always include an implementation strategy. The Cal/EPA Guidelines require that the implementation of the scientific components of a proposal, or other initiative, must be submitted for external review.

5. Identity of external reviewers. External reviewers should not be informed about the identity of other external reviewers. Our goal has always been to solicit truly independent comments from each reviewer. Allowing the reviewers to know the identity of others sets up the potential for discussions between them that could devalue the independence of the reviews.

6. Panel Formation. Formation of reviewer panels is not appropriate. Panels can take on the appearance of scientific advisory committees and the external reviewers identified through the Cal/EPA process are not to be used as scientific advisors.

7. Conference calls with reviewers. Conference calls with one or more reviewers can be interpreted as seeking collaborative scientific input instead of critical review. Conference calls with reviewers are not allowed.

Guidance to Reviewers from Staff:

1. Discussion of review.

Reviewers are not allowed to discuss the proposal with individuals who participated in development of the proposal. These individuals are listed in Attachment 3 of the review request.

Discussions between staff and reviewers are not permitted. Reviewers may request clarification of certain aspects of the review process or the documents sent to them.

Clarification questions and responses must be in writing. Clarification questions about reviewers' comments by staff and others affiliated with the organization requesting the review, and the responses to them, also must be in writing. These communications will become part of the administrative record.

The organization requesting independent review should be careful that organization-reviewer communications do not become collaboration, or are perceived by others to have become so. The reviewers are not technical advisors. As such, they would be considered participants in the development of the proposal, and would not be considered by the University of California as external reviewers for future revisions of this or related proposals. The statute requiring external review of science-based rules proposed by Cal/EPA organizations prohibits participants serving as peer reviewers..

2. Disclosure of reviewer Identity and release of review comments.

Confidentiality begins at the point a potential candidate is contacted by the University of California. Candidates who agree to complete the conflict of interest disclosure form should keep this matter confidential, and should not inform others about their possible role as reviewer.

Reviewer identity may be kept confidential until review comments are received by the organization that requested the review. After the comments are received, reviewer identity and comments must be made available to anyone requesting them.

Reviewers are under no obligation to disclose their identity to anyone enquiring. It is recommended reviewers keep their role confidential until after their reviews have been submitted.

3. Requests to reviewers by third parties to discuss comments.

After they have submitted their reviews, reviewers may be approached by third parties representing special interests, the press, or by colleagues. Reviewers are under no obligation to discuss their comments with them, and we recommend that they do not.

All outside parties are provided an opportunity to address a proposed regulatory action during the public comment period and at the Cal/EPA organization meeting where the proposal is considered for adoption. Discussions outside these provided avenues for comment could seriously impede the orderly process for vetting the proposal under consideration.

4. Reviewer contact information.

The reviewer's name and professional affiliation should accompany each review. Home address and other personal contact information are considered confidential and should not be part of the comment submittal.

Amit Kumar, PhD, P.Eng.

Position: Associate Professor; NSERC/Cenovus/Alberta Innovates Associate Industrial Research Chair in Energy and Environmental Systems Engineering; Cenovus Energy Endowed Chair in Environmental Engineering

Contact Information: Department of Mechanical Engineering, University of Alberta, Edmonton, Alberta, Canada, T6G 2G8; E-mail: Amit.Kumar@ualberta.ca; Tel: +1-780-492-7797; Admin Office: +1-780-492-3712; Website: http://www.energysystems.ualberta.ca/

Education
PhD - Mechanical Engineering, University of Alberta, Edmonton, Canada - 2004
MEng, 2000, Energy Technology, Asian Institute of Technology, Bangkok, Thailand - 2000
BTech (Hons), 1997, Energy Engineering, Indian Institute of Technology, Kharagpur, India - 1997

Appointments
- Sept. 2012 – Present, NSERC/Cenovus/Alberta Innovates Associate Industrial Research Chair in Energy and Environmental Systems Engineering, University of Alberta, Edmonton, Alberta, Canada
- Sept. 2012 – Present, Cenovus Energy Endowed Chair in Environmental Engineering, University of Alberta, Edmonton, Alberta, Canada
- July 2011 – Present, Associate Professor (tenured), Department of Mechanical Engineering, University of Alberta, Edmonton, Alberta, Canada
- August 2005 – June 2011, Assistant Professor, Department of Mechanical Engineering, University of Alberta, Edmonton, Alberta, Canada

Research Interests: Energy and environmental modeling; life cycle assessment; techno-economic assessment; renewable and non-renewable energy sources

Summary of Supervision Experience Current/Past: Total - 100**;** Direct supervision: 11 PhD, 42 Master's, 12 RAs, 11 PDFs, and 20 undergraduate students (UG). Co-supervision: 3 Master's and 1 UG.

Summary of Student's Examination Committees: 82 examination committees (38 MSc; 44 PhD examination committees).

Publication and Presentations: 56 peer reviewed journal publications; 2 book chapters; 190 conference presentations and publications (33 invited); 53 technical reports.

Research funding: More than C$6 million; more than 30 different funding agencies including industries and government.

Awards and Media Mentions: 7 awards; 20 media mentions

Research Networks – International and National (as member/theme lead): 4

Key Expert Review Panels International/National: European Commission (HORIZON 2020, FP7); National Science Foundation, USA; Natural Sciences and Engineering Research Council of Canada (NSERC).

Chair/Moderator/Organizer Conference and Workshops: More than 30

Publications *(underline indicates graduate students, undergraduate student, research assistants or postdoctoral fellows)*

Book Chapters

- Wang, S. and A.F. Clarens (2012) "The effects of CO_2-brine rheology on leakage processes in geologic carbon sequestration" Water Resources Research. *48, W08516.*

(ii) Five other significant publications

- Clarens, A.F., E.P. Resurreccion, M.A. White, L.M. Colosi. (2010) "Environmental Life Cycle Comparison of Algae to Other Bioenergy Feedstocks" Environmental Science and Technology. 2010, 44, (5), 1813-1819
- Clarens, A.F., H. Nassau, E.P. Resurreccion, M.A. White, L.M. Colosi (2011) "Environmental Impacts of Algae-Derived Biodiesel and Bioelectricity for Transportation" Environmental Science and Technology. 45 (17), 7554–7560
- Liu, X., A.F. Clarens, L.M. Colosi. (2012) "Algae biodiesel has potential despite inconclusive results to date" Bioresource Technology. 104, 803-806

- Clarens, A. F., K. F. Hayes, S. J. Skerlos "Feasibility of Metalworking Fluids Delivered in Supercritical Carbon Dioxide." Journal of Manufacturing Processes. 2006, 8(1) 47-53.
- Clarens, A., A. Younan, P.E. Allaire "Feasibility of Gas-Expanded Lubricants for Increased Energy Efficiency in Tilting-Pad Journal Bearings." ASME - Journal of Tribology. July 2010

d. Synergistic Activities

- Carbon dioxide leakage from deep sequestration sites - Developing fundamental knowledge in the means by which carbon dioxide rises through deep and shallow aquifers as a means by which to estimate and predict significant leakage pathways for storage of CO_2 in the deep subsurface.
- Algae-based CO_2 Sequestration and Bio-based feedstock research - Evaluating the use of algae-based bioenergy processes to remediate existing environmental challenges. Life cycle assessment tools are being used to identify leverage points in the algae production process and study specific ways in which to improve the overall environmental profile of the system. A recent focus has been on wastewater streams to remove estrogenic contaminants and take up nutrients.
- GELs: Gas Expanded Lubricants for energy efficiency - Working to create entirely new concept for delivering tunable mixtures of lubricants and gas a moderate pressures to rotating machinery as a method to improve energy efficiency and reduce lubricant consumption.
- Faculty Advisor, Engineering Students Without Borders (2009-present) Advised student-led group managing multiple national and international service projects using an annual operating budget of $25,000. Continuation of work performed during graduate school as founder of local Engineers With-out Borders chapter.
- University Teaching Fellow (2010-11) - Selected as one of six junior faculty members University wide to engage in intensive year-long pedagogical training program that included redesign of a course and the creation of novel teaching content and tools.

Review of the Methodology Used in Calculating Fuel Carbon Intensities and of the Use of Three Life Cycle Greenhouse Gas Emissions Models

Amit Kumar, Ph.D., P.Eng.
Associate Professor
Department of Mechanical Engineering
University of Alberta
Edmonton, Alberta, Canada T6X 0A3

May 5, 2015

Background

This response is based on a request for review of staff reports prepared by the Air Resources Board (ARB) of the California Environmental Protection Agency (Cal/EPA). The staff reports focus on the methodology of estimating life cycle greenhouse gas (GHG) emissions from different crude oils processed in California refineries. In light of my expertise, this review is focussed predominantly on the conclusions in Staff Report 2 titled “Calculating Carbon Intensity Values of Crude Oil Supplied to California Refineries” (Memorandum dated January 21, 2015 from Mr. Jim M. Aguila (ARB) to Dr. Gerald W. Bowes (Cal/EPA), Attachment 2). In addition to the specific comments on Staff Report 2, the review comments also include a general assessment of the material provided for review.

Conclusion 2: Crude Oil Intensity Values

Based on staff’s assessment of available government, research literature, and internet sources for each crude source, the ARB staff concludes that the assumptions and input parameters used in OPGEE to calculate CI values for crude oil production and transport are reasonable and the model was applied appropriately under the LCFS.

Comments

In my opinion, the OPGEE model used to estimate the life cycle carbon intensity (CI) of various crude oils refined in California refineries is detailed in terms of the different unit operations involved in the production, transportation, and refining processes of crude oils. The model includes a comprehensive framework for the consideration of the characteristics of production wells, crude oils, refining processes, and crude oil transportation. The estimated CI values are reasonable; however, there are important points that should be taken into account when using these estimates. My comments are given below on various aspects of the methodology, input data, and assumptions, and include suggestions for a path forward.

Methodology: As there are many unit operations considered in an estimation of life cycle GHG emissions from the various crude oils refined in California's refineries, the data for these assessments have been either developed or collected from various sources by the ARB staff. Any variation in these assumptions and input data will have an impact on the overall life cycle GHG footprint. Hence it is very challenging to arrive at a single estimated life cycle GHG emissions value for a particular crude oil. The values in the report (e.g., Table 1, Appendix H) are specific estimates for various crudes. It might be useful if the numbers are associated with some uncertainty or range. This would help address the variations in estimated values found in different studies for a particular crude oil.

PR-1

Effect of GHG emission allocation strategies: The method of allocating refinery and upstream emissions to transportation fuels has a major impact on the life cycle GHG emission results. The process level allocations could be in the form of an energy and/or mass basis. Some of these allocation strategies have been made in an earlier study to understand differences in allocation on refinery levels and sub process levels [1]. In the ARB staff report, there needs to be a justification for the allocation method used. Some consideration should also be given to other allocation strategies, such as the allocation of emissions based on fuel hydrogen content, to study their impact on life cycle GHG emissions. Different existing studies use different allocation techniques and report varying results. A consensus on the allocation strategy is needed to help inform policy formulation and decision making.

PR-2

Use of GHGenius data and assumptions for heavy crude oil from the Canadian oil sands: An LCA is a highly informative but labor-, time-, and research-intensive method. There are several LCA models available [2-5] that would help reduce the workload to perform an LCA for any pathway by providing the basic framework and database. These models provide varying results based on different assumptions, database inventories, and data sources. There are limitations in using these models for the oil sands-based heavier crudes from Canada that are processed in California's refineries. The limitations are specifically related to the assumptions and methodologies built into the model. The ARB report based on the OPGEE model has considered assumptions and inputs from GREET and GHGenius, and the ARB staff report has specifically used the GHGenius model assumptions and input data for a life cycle assessment of transportation fuels from the oil sands.

GHGenius is based on an estimate of GHG emissions with direct input of process fuel consumed per unit of fuel delivered. The direct relationship between mass and volume is used to proceed from one unit operation to the other. For example, one mass unit of synthetic crude oil (SCO) is assumed to be same as one mass unit of bitumen. This may not always be appropriate as the mass of SCO is always less than bitumen and depends on the upgrading operation. GHGenius considers the API (American Petroleum Institute) gravity relations between feeds to be mass additive, which is not fully justified (the density of crude is additive in volume).

Diesel fuel is one of the main sources of energy for bitumen extraction through surface mining. The estimate of diesel required in the OPGEE model, which is based on the GHGenius model, is almost 100 times higher than the values used in the GREET model and up to 7 times higher than the results of another recent study [6]. This assumption needs to be justified in the report as it has an impact in the overall GHG emissions. PR-3

The assumptions in the OPGEE model based on GHGenius regarding electricity production and export from the oil sands are only partially justified. This model uses Alberta's grid electricity ratio for electricity production and electricity export from the oil sands. This assumption is not clear as most of the electricity production in the oil sands is on site and from natural gas. And the extra electricity exported displaces Alberta's grid electricity, of which 53.1% is from coal, 37.4% from natural gas, and the rest from other resources such as hydro, wind, and biomass [7]. This assumption on Alberta's grid electricity ratio for electricity production and export has a significant impact on the overall life cycle GHG emissions of oil sands-based crudes and hence needs further justification. PR-4

Steam Assisted Gravity Drainage (SAGD) is another method of bitumen extraction in the oil sands. One of the key limitations to SAGD in the ARB report (as this is based on GHGenius model) is in the area of electricity and steam generation. The consideration of the cogeneration of electricity and steam is very limited. The limited consideration does not represent the actual scenario in oil sands SAGD operations. The use of cogeneration in SAGD operations is expected to increase in future, and this increase will have a significant impact on the overall life cycle GHG emissions. PR-5

The upgrading of bitumen produced from the oil sands is an energy-intensive process. The requirement of energy is dependent on the techniques used for upgrading. Most of the energy requirement comes from conventional sources of energy (e.g., natural gas and electricity). Coke, which is one of the by-products of the upgrading process, could be used for energy, but its use depends on the different industrial operations. The majority of the coke is stockpiled and not combusted. This stockpiling should be considered in a life cycle GHG emissions assessment as it has a significant impact on the overall estimated values. PR-6

Upgrading operations consume significant quantities of hydrogen to convert bitumen to SCO. There are very limited details on the amount of hydrogen consumed for upgrading bitumen from in situ recovery, and for upgrading bitumen from surface mining there is very limited information found in GHGenius. PR-6 cont

Fugitive emissions: The emissions over the life cycle of the production, processing, and use of the various crude oils are an important factor and have an impact on overall GHG emissions. There has been very limited effort to estimate these emissions. The OPGEE estimates these emissions based on the development of bottom-up parameter-based models; however, a real life measurement of these emissions is needed for a credible estimate. The fugitive emissions for different crudes could vary significantly as there are differences in the extraction, production, transportation, and processing of these oils. The emissions could differ significantly for the conventional and non-conventional sources of crude oils. PR-7

Biomass use for energy and fuels: Different jurisdictions use different sources of biomass to produce energy and fuels. These could be agricultural or forestry sources. The life cycle GHG footprint for various biomass feedstocks (e.g., wheat straw, corn stover, bagasse) depends on the jurisdiction where they are grown and also on the feedstock itself. These life cycle GHG footprints depend on the inputs (e.g., fertilizer, fuels) for biomass production, harvesting, collection, transportation, and conversion. It is very challenging to estimate these parameters for different jurisdictions. The use of different biomass for electricity generation could have an impact on the electricity generation grid mix for various jurisdictions. Hence this should be added as a cautionary note, and a range of life cycle estimates, as stated earlier, may be more appropriate. PR-8

Changing the electricity generation mix with time: The electricity grid GHG emissions for a particular jurisdiction depend on the type of fuels used to produce electricity. The type of fuels could vary significantly from one jurisdiction to another. The electricity grid mix changes continuously with changes in the amount and type of fuel used to produce electricity. For example, in Alberta, recently there has been a significant increase in natural gas-based power generation compared to coal-based power generation. There has also been a significant increase in wind power generation. These sources of power are continuously changing the grid intensity as natural gas- and wind-based electricity have lower GHG footprints than does coal power generation. This lowering of the grid intensity would have an impact on the life cycle GHG emissions of bitumen-based crude oil. There needs to be a system under the LCFS to account for this. PR-9

Future LCA footprints: In the current ARB report, the focus is on life cycle GHG emissions from the different crude oils that are processed in California's refineries. In future, and keeping in mind the current water availability issue in California, it would be important to also look at the life cycle water footprints of the different crude oils processed in California refineries. This could involve the development of methodologies to estimate the life cycle water consumption coefficients for various crude oils. PR-10

External Peer Review of "**Methodology in Calculating Fuel Carbon Intensities and Use of Three Greenhouse Gas Emissions Models"**

Overall summary statement: After reviewing the three staff reports describing the CI calculation methodology being proposed by CARB, I am confident that the methods are based on sound science and represents the state of the art in CI estimation.

With respect to the three staff reports that I reviewed, I have the following more specific questions and recommendation:

Life Cycle Fuel Carbon Intensities

Page 2. It would be useful to add a sentence or two in this overview report describing efforts by CARB to ensure that there is no double counting of emissions burdens between CA-GREET and the OPGEE modeling estimates. PR-11

Page 5. The CA-GREET model has been updated recently to include cellulosic feedstocks and sorghum. A cellulosic (corn stover) to ethanol pathway is also defined using data obtained using ASPEN plus. Is there any pilot or field data that can be used here to support the findings in the model? Also, is this the only Tier 2 pathway that has emerged in recent years? The report makes it seem like this may be the case. PR-12

Page 7. How do the emissions results from the MOVES model compare to those from the MOBILE6.2 model and the CARB EMFAC model? What prompted the switch other than the fact that the MOVES data is more current? PR-13

Page 8. How is uncertainty propagated through the series of models? I understand how uncertainty is handled in CA-GREET and in GTAP. In the context of the WTW calculations on page 8, does the aggregate carbon intensity value have a reliable uncertainty range associated with it? PR-14

Page 10. The language around the indirect accounting mechanisms as they relate to Tier 1 and Tier 2 fuels is a bit unclear. As written, the report states that the source must be directly consumed in the production process. But this is ambiguous in certain contexts such as those fuels that produce co-products. For example, if a corn feedstock were used to make ethanol and the stover were also used to make fuel (but was not consumed in the same production process) would that not trigger a switch from Tier 1 to Tier 2? It seems like it should but as written it might not. Clarifying this language is key for groups seeking to obtain co-product credit through the CA-LCFS. PR-15

Page 15. The difference between pathway CNG020 and CNG021 is not clear. PR-16

The OPGEE model goes into great detail cataloging the carbon intensity of different crude oils and the results are fascinating. But in light of the significant debate regarding iLUC, there is a big difference between the resolution of data for crude and for agricultural products. The report describes efforts to calculate this using AEZ and this is a strength of the approach. But I wonder whether CA-GREET is able to provide estimates at the same resolution for crop-based biofuel feedstocks coming from different regions of the US and the world? Does the model account for the same crop in difference between rain PR-17 fed and irrigated crops? How does the natural land use cover impact the emissions? What about amount of time the land has been in production? `The staff should consider the resolution of the data across these modeling platforms to ensure that they are comparable. PR-18

To what extent do the CI values from the different crude sources vary year to year? PR-19

The modeling efforts include "elasticity of crop yields with respect to area of expansion". Does it include changes to yield associated with improved technology and year-to-year variability that can come from things like the massive drought in the Midwest? PR-20

Crude Oil Carbon Intensity

How is enhanced oil recovery handled in the OPGEE model and would efforts to develop innovative EOR technologies that sequestered carbon qualify the resulting crude as an innovative pathway? PR-21

I don't know where CARB stands now wrt CO_2 EOR but if there is interest in developing a mechanism for oil producers to gain credit for producing lower CI crude through the LCFS (presumably from outside CA since very little EOR takes place in the state right now I believe), then I strongly encourage CARB to develop a mechanism to track the original source of the CO_2. Most of the CO_2 used in EOR in Texas comes from geologic formations were the carbon capture and sequestration benefits are non-existent. PR-22

The EPA Greenhouse Gas Reporting Program has been collecting data on emissions factors at the facility scale for several years. How do these self-reported emissions from EPA compare to the emissions factors from OPGEE? PR-23

How do significant price swings in crude oil prices (like the drop in prices observed over the past 6 months or a hypothetical spike in prices like the one that occurred in 2008) impact the composition of crude flowing to CA refineries? Are these fluctuations reflected in the CI calculations over such a short timestep? I recognize that this is partially an economic question and that it is therefor somewhat outside the scope of this analysis, but it seems reasonable to ask how the signals might impact the blend, which would impact the CI of the fossil transportation fuels being sold in the state. The report explains the 2010 baseline and how that will be used to lower the compliance target, but I am curious about extraneous market factors that could make meeting those targets unrelated to actual emissions reductions. PR-24

Indirect Land Use Change

This report describes the process by which the staff completed 30 scenarios and averaged the results. Were the scenarios all set up so that they would be equally likely? Additional text here would be useful. PR-25

The GTAP baseline is 2004 but that occurred before the major growth in corn ethanol production in the United States. I understand this has to do with the availability of economic databases. Are there efforts to update the model using more recent economic data? Is there an expectation that new data will provide different estimates based on changes in the biofuels landscape? PR-26

The report does not provide the actual value of the iLUC contribution that CARB is using but I found it online (30 g/MJ) and also learned that there is some disagreement in the community about which value is the most appropriate (and even whether iLUC as a mechanism is the most appropriate to capture the effect of biofuels expansion). I will not weigh in here other than to say that if the intent of CA-LCFS is to be technology-neutral then selecting a value that is at the high end of the distribution will create *de facto* caps that will suppress the development of certain fuels/pathways in the CA market. PR-27

Gerald W. Bowes, Ph.D.
Manager, Cal/EPA Scientific Peer Review Program
Office of Research, Planning and Performance
State Water Resources Control Board
1001 I Street
Sacramento, CA 95814

Dear Dr. Bowes:

Attached please find my scientific peer review of the materials requested in support of the CA LCFS re-adoption activities.

External to my scientific review, I wanted to note a few small things that might be useful for the staff in terms of making these documents ready for public dissemination.

* Make it clear that LCFS defines the CI units of gCO2e/MJ (p. 2 of CA-GREET Report) PR-28
* Figure 1 is not 'generalized' – one of the arrows refers to biofuel use PR-29
* In the middle of page 8, the VOC and CO factor determination description is hard to follow. I figured out the ratio for CO, and still it could be written more clearly (e.g., describe where the 0.85 and 0.43 values come from – and what specific reference VOC was used to generate the assumed value for 0.85?) PR-30
* There was no text description of Tier 2 Method 1 in the Summary Report PR-31

Thank you again for asking me to participate in this very worthwhile effort.

Sincerely,

H. Scott Matthews
Professor

Peer Reviewer Report

Methodology in Calculating Fuel Carbon Intensities and Use of Greenhouse Gas Emissions Models

April 25, 2015

I was asked by the State of California to review the staff reports and additional materials associated with the work produced in support of the California Low Carbon Fuel Standard (LCFS). It was an honor to be asked to look at this work, as the work done by this evolving team over time has been one of the most impressive scholarly efforts I have seen in my career. This team continues to do excellent work. Likewise, the goal and implementation of the LCFS has been one that has been successful in 'raising the bar' in terms of the expectations of performance in the transportation energy industry, and also in terms of nudging the federal government to adopt similar programs.

The specific statement of task I was given involved various aspects:

My scientific peer review responsibility was "to determine whether the scientific basis or portion of the proposed rule is based upon sound scientific knowledge, methods, and practices." Likewise, the focus is on the methods used to develop the carbon intensity (CI) values, as opposed to the LCFS program in general.

In addition, I was asked to assess the "Big picture" to ensure whether there are scientific issues not described or dealt with in the work.

Finally, I was asked to assess whether, overall, all of the work was based on sound science?

Note that via interactions with the organizers of the peer review, I was asked to focus on the GREET and OPGEE aspects of the work. I thus focused my review into those two components including review of the staff reports as well as the underlying electronic spreadsheets and references. [Note that while I am familiar with the kinds of models used in the GTAP and AEZ component, my review of that part was more cursory, consisting only of a review of the staff reports and a skim of the additional materials provided electronically. However I did not present scientific assessments of that component.]

Finally, I was asked to review the conclusions given by the staff, namely that the CA-GREET and OPGEE models used to calculate carbon intensity values (and GTAP for ILUC) are reasonable and that the models were applied appropriately under the LCFS.

Below I provide detailed review comments separated by the materials associated with the various subcomponents provided.

Three printed staff reports related to CA-GREET, OPGEE, and GTAP models, which are used to estimate the various carbon intensities.

Aside from small issues in terms of the details presented in these summaries, I found no issues of concern related to the high-level goals or methods used in these three domains.

Staff Reports and Plain English Summaries

I note that one thing not provided explicitly in any of the Staff Reports but which would have been useful was a succinct summary (box model diagram) of the three carbon intensity model components, as well as a short summary of the more specific quantitative aspects of the LCFS (10% goal by 2020). For the latter issue, this detail was available in the various links and support provided (e.g., the ISOR). PR-32

The plain English summaries did not seem to be very different than the text in the detailed staff reports. I saw no issues in those summaries for that audience but assume that those documents have been written in conjunction with technical writing experts.

Component 1 - CA-GREET

I found the CA-GREET related Staff Report report to be well organized and written. I note the following issues:

A small issue of concern, where the impact is hard to assess from the material provided, is the use of EPA AP-42 emissions factors. The reference date for the CD-ROM is 2005, but the underlying emissions factors for many processes in that document are much older than that. However there was not enough detail or method listed to give a sense of where those emissions factors were used, for what processes, etc. I trust that staff can develop more robust text that would help to clarify where they were used and any potential scientific impact from them. As a specific example recently noted by EPA (and a change forced by legal action), many of these values are quite old. I was unable to find the specific reference value in GREET/CA-GREET for these parameters but hopefully such changes could be made quickly – or at least added to a holding pile without holding up the re-adoption of LCFS. My first impression is that the net effect on a CO2e basis would be neutral between increasing VOC and decreasing CO emissions factors. (See http://www.epa.gov/ttn/chief/consentdecree/index_consent_decree.html) PR-33

Likewise, a similar concern is related to the version of the EPA MOVES model used. The ANL GREET reference (#13 in staff report) says that MOVES2010b was used (an update to previously using MOBILE6), however, MOVES2014 is available. Are there relevant differences? What is the anticipated update cycle? PR-34

The method uses the IPCC 100-year GWP factors, which I agree are the most relevant values to use. However the report and method should explicitly note that it uses these (rather than the 20 or 500 year values), and why. Too often in the past few years there have been attempts to abuse the GWP method to present results favorable to a particular fuel by cherry-picking higher GWP values that are associated with shorter time horizons. PR-35

The CA-GREET results shown on pages 14-15 (Tables 1 and 2) are presented as 'CI lookup tables'. As presented, it was not clear what these were. However from reading the ISOR my understanding is that these are default values determined ex ante by staff for a generic production of a Tier 2 fuel used for Method 1 (as a default value that would apply for a particular supplier unless they wanted to show a lower value from other use of the methods like 2A or 2B). My lack of understanding has no effect on the scientific merit of the work. PR-36

Although we were only directly provided the underlying GREET 2013 and 2014 Excel models, I was able to find information online related to the CA-GREET project, including downloadable versions of the Tier 1 and Tier 2 CA-GREET Excel spreadsheets. I see no scientific issues with respect to how the CA-specific functionality was added to the base GREET model (which was also presented in the documentation and reports provided).

The results (e.g., CI Lookup Tables) were presented as single values, as opposed to ranges or distributions. I understand that regulatory design is complex, and that providing planning certainty for companies is important, but in the end given the (un-shown) uncertainties it is possible that the actual reduction in greenhouse gas emissions is lower or higher than anticipated. The reports and tools do little to capture this. My scientific concern and how it relates to my focus on the CIs is that, as stated in the ISOR, the new LCFS will require Method 2A pathways to have 5.5 % (or 1 gCO2e/MJ – also about 5%) lower CIs. The uncertainties of the reference flows and the potentially modeled 2A pathways may have uncertainty greater than 5%, which has not been well established in the report. It is also not clear where this "5% threshold" came from. However, I do not view this as an issue with respect to the scientific credibility of the method, just in portraying the magnitude of overall potential benefits of the program and maintaining stakeholder confidence. PR-37

Notes on my review of additional resources listed in documents from Attachment 1 of Bowes' March 25 letter:

- I reviewed the staff's ISOR for the LCFS re-adoption (the Staff Reports provided to us are essentially excerpts of this document). This helped to fill in some of the gaps (identified above) with respect to how the pieces fit together.
- I am familiar with the GREET model since my own research group has used it for various projects in the past. As a result, I did not re-review individual sheets or cells of the spreadsheet model, as I know that this model has been developed with significant research and effort over the past decade.

- The study is based on the ISO LCA Standards. While I was unable to do a full review of every aspect in the comprehensive work, the work done in this study seems to conform to the LCA Standard.

Summary review of CA-GREET component of peer review:

The issues listed above are fairly cosmetic in nature. Thus, with respect to the three aspects I was asked to review:

(1) I agree with the staff's conclusion that "the assumptions and inputs used in CA-GREET 2.0 to calculate direct life cycle CIs are reasonable and the model was applied appropriately under the LCFS." The methods they have followed, including the use of literature sources and references, are consistent with what I would expect to use.

(2) With respect to the big picture issue, I do not believe there are any significant scientific issues that have been neglected in the method descriptions.

(3) Taken as a whole, I believe that all of the work done (including conclusions and scientific assessments) is based on sound science.

Component 2 – OPGEE Model

I again found the Staff Report report to be well organized and written. I was aware of but not familiar with the details of the OPGEE model before undertaking this review – I had only read a few of Professor Brandt's published papers. Unlike the GREET-based analysis, which significantly leverages an existing DOE/ANL model (GREET), most of OPGEE has been developed in the last few years and much has been done with the goal of supporting LCFS specifically. It thus represents a tighter fit to the work needed here. It is truly an impressive and expansive effort, especially given the relatively small research team involved in it as compared to other publicly available life cycle models.

The core results (updated for OPGEE v1.1) are the Lookup Table values as well as those that create the Baseline Crude Average CIs.

I noted the following issues in the OPGEE-related staff report:

Similar to my comments above associated with CA-GREET, I am admittedly uncomfortable in seeing the lookup table CI values represented with 4 significant digits (implying accuracy to the level of 10mg CO_2e/MJ. While the underlying model is comprehensive and rigorous, my concern would be that it is easy for the lookup table / model results to be construed as more exact than they may be (since the uncertainty is not able to be presented as such in these lookup tables). Similar to the fuel pathways above, the "extra digits" may in fact be a target for producers to seek their own pathway approvals because they can show them to be lower when in fact they are mostly just rounded off values (example – 10 instead of 10.35 would be 5% lower yet still within a reasonable uncertainty bound of 10.35). This is not explicitly an issue related to the scientific method used to generate the results (as

PR-38

requested in my peer review charge) but in application in the LCFS becomes an issue. Even removing one of these digits (one after the decimal point) would be an improvement. It is also potentially relevant because the Board has proposed a three-year model version update cycle, which to me suggests that nothing would officially change for 3 years). PR-38 cont

Notes on my review of additional resources listed in documents from Attachment 1 of Bowes' March 25 letter:

- I reviewed Chapter II and Appendix H of the ISOR. This helped to fill in some of the gaps (identified above) with respect to how the pieces fit together. There were too many references in Appendix H to read all of them in this review (some of them already referenced in the published journal papers). I studied a sample of them (Oil and Gas Journal articles, California monthly oil and gas reports, etc.) and agree that they are the relevant types of studies to create parameters or methods in estimating the needed CI values for this project. I note again that the attention to detail in this model, including the identification of production parameters for many foreign countries and fields, is extraordinary.
- The study is based on the ISO LCA Standards. While I was unable to do a full review of every aspect in the comprehensive work, the overall work done in this study seems to conform to the LCA Standard. Several of the main pieces behind OPGEE have already been published in peer-reviewed journal articles.

Summary review of OPGEE component of peer review:

The issues listed above are fairly cosmetic in nature (even my concern about presenting uncertain values). Thus, with respect to the aspects I was asked to review:

(1) I agree with the staff's conclusion that "the assumptions and inputs used in OPGEE to calculate CI values for crude oil production and transport are reasonable and the model was applied appropriately under the LCFS." The methods they have followed, including the use of literature sources and references, are consistent with what I would expect to use.

(2) With respect to the big picture issue, I do not believe there are any significant scientific issues that have been neglected in the method descriptions.

(3) Taken as a whole, I believe that all of the work done (including conclusions and scientific assessments) is based on sound science.

Component 3 – GTAP/Indirect Land Use Model

While my area of expertise is connected with the first two models, I did my best to read through the third modeling area. While I was unable to comprehend the model, data, or inputs at the same level of critical insight, I found nothing associated with that work that caused me to doubt its credibility. I thus agree with the staff's conclusion, have no big picture issues, and have no doubt that the work done was based on sound science.

A peer review as an input to the

EXTERNAL PEER REVIEW OF STAFF'S METHODOLOGY IN CALCULATING CARBON INTENSITY VALUES AND USE OF GREENHOUSE GAS EMISSIONS MODELS

Reviewer: Bruce A. McCarl, Principal, McCarl and Associates and, University Distinguished Professor of Agricultural Economics, Texas A&M University

Review date : April 29, 2015

Preface

As I understand it the peer review is intended to develop external review opinions on whether the CI methodology used by the ARB staff and supporting parties in calculating carbon intensity values and use of greenhouse gas emission models yields a valid scientific basis for the conclusions in the air resources Board staff reports.

I also believe that while I was sent three reports and a plain English version that I am only supposed to review those within my field of expertise which limits me to comment on

Calculating Lifecycle Carbon Intensity Values of Transportation Fuels in California, March 2015 (Staff Report 1)

Calculating Carbon Intensity Values from Indirect Land Change of Crop-Based Biofuels (Staff Report 3)

Additionally I will comment on the attachment entitled *Plain English summary of staff's methodology in calculating fuel carbon intensities*.

Basic findings

In attachment 2 of the request for external peer review originating from Mr. Jim Aguilia I note that I am supposed to express opinions on the conclusions from the staff reports. I will do this for each report separately.

Staff report 1 - lifecycle fuel carbon intensities

The conclusion stated is "based on staff's assessment of available lifecycle inventory sources, emissions, and efficiency data, ARB staff concludes that the assumptions and inputs used in CA-GREET 2.0 to calculate direct lifecycle fuel Cis are reasonable and the model was applied appropriately under the LCFS."

In my reading of the document I developed a number of notes commenting on presentation, assumptions and scientific basis. These appear below. My final opinion after that reading is that I agree with the staff and believe that the sources used, models used, emissions estimates and procedures within CA-GREET 2.0 provide a sound basis for subsequent use of the estimates that arise from its use and that in general the procedure is based on sound scientific knowledge, methods and practices.

Staff report 3 - calculating carbon intensity values from indirect land use change of crop-based biofuels

The conclusion stated is “based on the iLUC analysis, ARB staff concludes that the assumptions and input parameters used in the GTAP-BIO and AEZ– EF models to estimate indirect land use change for biofuels are reasonable and the models were applied appropriately under the LCFS.”

In my reading of the document I developed a number of notes commenting on presentation, assumptions and scientific basis. These appear below. My final opinion after that reading is that I agree with the staff and believe that the assumptions and input parameters used in GTAP-BIO and AEZ– EF plus the way those models were used provides a sound basis for development of results for subsequent use under the LCFS and that in general the whole procedure from assumptions through use is based on sound scientific knowledge, methods and practices.

Specific Comments

The comments below arise from a page by page reading of the staff reports. In places suggestions are made for document improvement. Also given this is a rapidly developing and advancing field some suggestions are made for future analyses with the model as the California rule and staff analysis moves into the future.

Comments arising during a reading of the document staff report 1: calculating lifecycle carbon intensity values of transportation fuels in California, March 2015

On page 3 of the staff report under section C in figure 1 it shows a picture of the life cycle analysis but in this it does not show emissions associated with the inputs to the feedstock production such as fertilizer and pesticides. GREET includes this and inclusion of such items in the Figure might lead to a more accurate portrayal of what's going on in GREET. PR-39

On page 5 a 1996 survey of sorghum producers is referred to as a source of some of the data although I am unclear to what extent this is relied on as substantially newer EPA study is also referenced. I believe in either case newer data could be obtained from the ongoing USDA ERS ARMS survey and the Sorghum Growers Association. There may be some reason to improve assumptions from survey results that are almost 20 years old. In particular the last 20 years in corn production has seen a big increase in yields with little increase in fertilizer. This may also be true for sorghum. Also sorghum yields have increased and with a long the increase in yields probably comes an increase in costs in terms of seed and harvesting effort. . PR-40

On page 6 A particular treatment process for cellulosic biofuels is covered. Today a few companies are just finalizing construction of or are initially operating commercial scale cellulosic biofuel facilities. It would probably be more accurate going into the future to use what can be obtained about those processes as opposed to a lab process using this particular method. I personally am not aware of exactly what methods are being used in those emerging commercial cellulosic plants but the companies may well have created lifecycle estimates for consideration of their fuels under the advanced biofuel category. PR-41

In general use of the GREET assumptions and methodology is scientifically sound as the ANL GREET group is the world leader in life cycle assessment and widely accepted in the government and profession.

On page 9 where tier 1 fuels are listed that perhaps the list should be expanded. In particular given that earlier in the briefing paper text that there is discussion about sugarcane ethanol I would probably have said starch and sugar-based ethanol including that from corn and sugar as those are the two largest sources currently. Under the biodiesel sources I might have listed soybean oil corn oil, canola, and other plant oils. PR-42

On page 10 when the paper mentions carbon capture and sequestration the terminology might be improved. Normally this is called carbon capture and storage. Also I might put in some wording regarding incorporation of carbon capture and storage into processing facilities. PR-43

In figure 2 under tier two generation I might call it ethanol from cellulosic sources. Restricting it to Stover is a pretty narrow set with dedicated bioenergy crops like switchgrass or miscanthus plus use of wood and other things are possible. At some point soon we may also need to list some sources of jet fuel. PR-44

Eventually I might worry some about the assumptions of spatial homogeneity. In particular, I know that for corn in the US there are regions where yields are close to hundred bushels an acre but that in other regions there are yields in excess of 200 bushels per acre. I also know that the fertilizer, seed, pesticides, and tillage requirements plus likely planting density and hauling requirements to get to a processing facility vary widely across regions. This would then lead me to wonder whether the GREET assumptions are appropriately differentiated on a spatial basis to reflect varying greenhouse gas intensity of various operations in various places. I do not think this is the currently the case. I would worry about this and might require people using the default values to justify that those default values would apply to their region in terms of the major ones in production quantities, fossil fuel, fertilizer use and hauling distances. PR-45

I agree with the conclusion the staff states on page 16 that the GREET uses appropriate methods. I believe it is a representation of the state-of-the-art of scientific knowledge and available data. However I must recognize that this is modeling and there almost always are ways models can be manipulated and slightly improved. In the future I might worry some about the sorghum and potential spatial homogeneity assumptions used. Also given the fact that the cellulosic industry is making its first commercial steps this means that the GREET assumptions will likely need to be updated going into the future. PR-46

Comments on staff report three calculating carbon intensity values from indirect land use change of crop-based biofuels

On page 2 I am not totally happy with the chosen wording. In particular the comment is made that the ARB staff has "identified an indirect effect that has a measurable impact on greenhouse gas emissions: land-use change". It's certainly fair to say that scientists and policymakers identified this well before the ARB so I would include some wording to indicate this is not an item uniquely identified by the ARB but rather is identified based on the scientific and policy dialogue. PR-47

In terms of documents scoping I see in the title the word land-use change. I think this is a rather narrow perspective and believe one should not strictly limit consideration of that indirect stimulated greenhouse gas emissions to only land-use change. In particular I believe consideration should involve both land-use change and other sources of emissions leakage. I feel when demand for biofuels increases that it either directly reduces the amount of crops in a region that enter the marketplace or causes a diversion of land away from conventional crop production to bioenergy feedstocks production. Both of these forces reduce the amount of conventional crops in the market place and raises market prices. In turn this would stimulate producers elsewhere to either bring nonagricultural lands into production (ILUC) or to adopt more intensive forms of agricultural production. Both of these actions increase greenhouse gas emissions outside of the target area. PR-48

Thus I would also not limit the discussion and the model GHG accounting to ILUC carbon emissions but would attempt to cover the fact that the excess or leaking GHG emissions include both those from indirect land use change and those from more intense production practices (heavier fertilizer use, more tillage etc). I believe within the GTAP framework that both of these are considered although I am unsure whether the other effects were included in the GHG accounting that ARB used.

On page 2 I agree with the ARB staff conclusion that the land-use impacts are significant and should be included in the fuel carbon intensities.

On page 2 I agree that the staff selected an appropriate global economic model in the form of GTAP.

On page 2 I again have some wording issues. In particular the report states supply equals demand in GTAP. I do not believe this is uniformly true. In general I believe supply is greater than or equal to demand and that in most sectors supply equals demand but cases like corn stalks have more supply than demand. PR-49

I agree with the staff that it's appropriate to shock the model by increasing biofuel production to a higher level of requirement.

On page 2 I do believe it's appropriate to combine GTAP with a more regionally specific emissions model (AEZ) and emissions assumption as was done in the analysts. I do believe in the future that the staff might consider broadening from just ILUC consideration to one that more broadly considers greenhouse gas emissions from any stimulated intensity expansion as discussed above plus, perhaps diminished livestock production (as has been found in my US studies due to increased feed prices). Just to clarify if we reduce corn in the market and Argentina responds by increasing heavily fertilized corn on lands that previously grew a less emitting crop then emissions go up from that source (an intensification response) along with the possibility of expanding cropped land use onto lands that were not previously used for crops. Simultaneously the increased cost of corn may stimulate less livestock production. PR-50

On page 2 I agree with the staff that it's appropriate to use a scenario approach with different combinations of input values to estimate the net greenhouse gas implications.

I believe it is appropriate across these assumptions that the staff average the results and not consider the results from one single scenario. I would note I might use a weighted average if I I had prior beliefs that some situations are closer to reality than others. In this case I would agree that a simple average is appropriate if there are no priors. PR-51

In the current analysis it appears that the staff has appropriately examined the current major liquid fuel sources including ethanol from conventional crops and biodiesel from conventional sources which are our only agricultural sources as of now. I do believe it will be worthwhile in the future to add ethanol from cellulosic sources, jet fuel may also come into the picture. PR-52

On page 5 I again have raised a wording issue. I do not totally agree with the statement that any demand that is not met locally is transmitted to the global marketplace and met by production of the agricultural commodity in other countries. In particular this could be met elsewhere in California, the rest of the US or globally. Also it is possible that this demand is not ever met when the cost in the other countries is more expensive than the result in market price. I might use wording more like where it could be met by production in other countries.

Elaborating I think some of the published findings with GTAP find the demand is not being completely replaced. I also recall a study by Murray and Wear that is references in the Murray, McCarl and Lee leakage piece where 86% of the reduced public timber harvest in the Pacific Northwest is replaced from sources in Canada, the US south and private lands in the Pacific Northwest. This means 14% of the market place reduction was never replaced. PR-53

On page 5 I believe one could elaborate a little bit upon the domino effect that is referred to here to illustrate a little more of the complex cities of the issue. What seems to happen in Brazil is that corn expanded in the far south displacing soybeans, then soybeans moved further north displacing grass and the livestock that were eating that grass. Then the livestock moved into the rain forest areas and land-use change occurred. The point is there may be more than one domino falling in the total process. PR-54

I also again would not solely limit my attention to indirect land use but talk about indirect land use and emissions changes in other emission categories as this ignores a possible intensification and livestock production reduction response. PR-54 cont

On page 4 I again believe it was appropriate for ARB staff to select the GTAP model. I agree it is mature. I believe the model scope description is appropriate. I believe you could strengthen your wording a little and say GTAP is widely used around the world and profession in various forms. PR-55

One page 4 I believe the statements about the AEZ model are appropriate and that this was an appropriate model to use and that it has a strong scientific basis.

I believe the modifications made to the GTAP and AEZ models were appropriate and needed. I believe this is a quite satisfactory modeling platform for the ARB analysis with a strong science and databases and that it has been appropriately modified to meet the needs of the ARB LCFS program requirements.

I believe doing the scenario runs that an average for each biofuel is appropriate.

I do believe that in the future it would be desirable to analyze a slightly wider variety of liquid fuels then appears within the list from corn ethanol to sorghum ethanol that is appears on page 6. In particular I think the staff might begin to address cellulosic ethanol since were just beginning to see commercial production and from what I hear jet fuel is emerging. PR-56

I do believe that the wording could be improved here in this discussion of scenario runs it would be nice to add another sentence or two on what the nature of those scenarios were i.e. alternative yield responses or the like. PR-57

Finally on page 6 I do agree that ARB staff has reached the right conclusions relative to the assumptions and input parameters in the GTAP and the AEZ models. I also believe those models were sound scientifically and data wise and thus were appropriately used to estimate indirect land use. I am unsure whether the analysis is actually broader than a ILUC analysis incorporating use of other inputs and possible livestock reductions. I believe G tab by its very nature would do that analysis but I'm not sure whether or not the ARB GHG accounting picked that up. PR-58

All things considered I agree that the models were applied appropriately to develop estimates relative to indirect land use change that can be used under the LCFS.

Comments based on attachment one plain English summary of staff's methodologies in calculating fuel carbon intensities

On page number one I'm a little confused by the referencing to the GREET model as in the technical memorandum it is referred to as GREET 2013 but here we see GREET 2014. Which one is being used? Or are these two names for the same thing? PR-59

On page number 2 under the bullet for feedstock production I might talk about feedstock production and production of major fossil fuel bearing inputs to include fertilizer, pesticides fossil fuels consumed etc. PR-60

Between page 2 and page 5 there is redundancy in the discussion of the California version of the GREET model. In particular there are two different discussions of what revisions were done and I would think including a single list of them all in one place would be valuable. Also I noticed that in staff report 1 that the shorter list is used. PR-61

On page 9 of the document there's a statement that I think should be more nuanced. In particular you say the diversion of crops from the food or feed markets to biofuel production creates an additional demand to produce the biofuel feedstock. I don't think that diversion create new demand. Rather it competes with existing demand. I would say it creates or it leaves unfilled demands in the food and fuel markets and therefore creates a demand to replace that food and feed from somewhere else. PR-62

Also in the next sentence rather than limiting discussion to the global marketplace I would say to the marketplace outside the region whether it be other areas in the United States, or the globe. Indirect land use does not only occur internationally it can also occur if California reduces production of some goods in favor of bioenergy and production is increased somewhere else in the US potentially on previously unused lands. While this section refers to indirect land use there is also use the possibility of more intense land-use in other regions for example with increased use of double cropping or less abandoned acres, both of which may well increase emissions from additional inputs. All of these would be present in the GTAP model in some form or fashion although it does not potentially do a very good double cropping. PR-63

In the total LCFS analysis in the future I would not dwell solely upon iLUC emissions as the only indirectly stimulated emissions. Rather I would also attempt to account for indirect stimulated emissions coming from other increases and decreases in emissions elsewhere in the world that may come from intensification and livestock use responses. PR-64

I do not believe that GTAP uses a baseline where supply equals demand in all sectors. I believe it is possible in the GTAP structure to have more supply than demand. For example demand for agricultural land in Brazil may not have total supply = total demand rather there may be other lands it can be drawn into agricultural land if the price is high enough and at current prices there may be more land available than is used. This is also true in terms of say corn Stover where the PR-65 current market price is basically just the cost of collecting it in at the farm level the price is zero as there's a greater available supply than there is a demand. PR-65 cont

In GTAP I believe that there also are increases in emissions from intensification (more irrigation or fertilization) so that the characterization of it only in terms of indirect land use change is not accurate. PR-66

In improving the indirect land use analysis when you're looking at corn ethanol byproducts there are also newer developments in terms of extracting corn oil from the DDGs. PR-67

In recent work Bruce Babcock has been looking at how intensity measures such as double cropping and less acreage abandonment have been stimulated by bioenergy prices and this may be something that analysts may want to look into in the future. PR-68

On page 11 I don't like the wording about the economy moving away from equilibrium. Rather I would say save moving the economy away from the current equilibrium to a new equilibrium. PR-69

On page 11 you indicate that irrigation was added to the model and I think this is a good move. I do think it's very important to have the water constraints on maximum use as for example that is a big factor here in the United States in many regions. I also think it may be important to have a maximum irrigable land constraint so that irrigation cannot move on to marginal lands. Generally such lands are distant from water sources and highly unlikely to ever be irrigated. PR-70

On page 11 you specify your fuel production increase and call this a shock. I think it is possible given the energy and corn prices that we may see fuel production move beyond say the limits imposed by the renewable fuel standard. As a consequence I think you might also need a market structure regarding the demand for bioenergy with it substituting in terms of heat content for petroleum-based gasoline. PR-71

On Page 12 there's a discussion of how yields respond to prices which is a good addition. However there might also be a discussion about how input usage and related emissions respond to yield increases. In particular in work I have done the elasticity of input usage response to yield increases is about 0.5 meaning that if you increase yields by 10% that you have a 5% increase in inputs including pesticides, harvest and probably fossil fuel inputs. Note You wouldn't, given recent US history, have much of an increase in US fertilizer use say for corn, but you might well for other crops. There also is likely to be an increase in double cropping and a reduction in idle acres particularly in international settings as shown in the recent work by Babcock. PR-72

In terms of the expansion on to marginal lands I believe that it would be good to have in the future a more rapid diminishing yield productivity as the marginal lands expand. The lands that I see around where I live that are marginal would clearly have diminishing productivity as you used more and more of them. Also I believe that it may well be necessary to restrict marginal PR-73 land production to only certain crops like energy crops like switchgrass rather than prime agricultural crops like rice, wheat and corn. PR-73 cont

On page 14 I think it’s highly appropriate to have the localized AEZ emission factor data that was developed.

On page 15 I find myself in concurrence that the ARB staff concluded that the assumptions are reasonable and that the models were applied appropriately. Naturally in a modeling exercise it’s also was possible to spend more money and improve some of the assumptions and I’ve entered a few suggestions above. I do believe at this point of the model is appropriate, scientifically sound and well grounded in the data and that this means it is scientifically valid for use.

II. Peer Review

Health and Safety Code Section 57004 sets forth requirements for peer review of identified portions of rulemakings proposed by entities within the California Environmental Protection Agency, including ARB. Specifically, the scientific basis or scientific portion of a proposed rule may be subject to this peer review process. In January 2015, ARB requested an external peer review of staff's methodology in calculating fuel carbon intensities and use of three life cycle greenhouse gas emissions models, including the California Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (CA-GREET) Model, Oil Production Greenhouse Gas Emissions Estimator (OPGEE) Model, and Global Trade Analysis Project (GTAP-BIO) Model combined with the Agro Ecological Zone Emissions Factor (AEZ-EF) Model. The peer review was completed in April 2015. The ARB staff would like to thank the reviewers for their time and input. The written reviews submitted by the peer reviewers are posted at the following web page: http://www.arb.ca.gov/fuels/lcfs/peerreview/peerreview.htm

To complete ARB's peer review request, the University of California chose four reviewers from a pool of qualified and interested candidates. The reviewers commented on GREET, iLUC and OPGEE models, and submitted their comments to ARB staff who, in turn, responded to the reviewers' comments in the pages below.

A. Agency Response to Peer Review Comments

1. Comment: **PR-1**

The reviewer recommends that the carbon intensity value for each crude oil include an uncertainty range.

Agency Response: The structure of the LCFS requires that each fuel pathway and each crude oil be assigned a single estimate for CI. Because of this, we use the best available data to estimate CI values and do not present uncertainty ranges associated with these values. However, Adam Brandt at Stanford University has published a few papers on the topics of model uncertainty and comparison of OPGEE model results to other LCA models as described in response to **LCFS 37-5**.

2. Comment: **PR-2**

The reviewer suggests giving consideration to alternative co-product allocation strategies to help in arriving at a consensus on allocation strategies.

Agency Response: For co-products of crude oil recovery, OPGEE provides the user with two alternative emissions accounting systems, co-product displacement, and allocation by energy content. The default method, and method used for the LCFS, is co-product displacement. All emissions are assigned to crude oil, and any co-products that are sold separately from the produced oil (e.g., natural gas, electricity, NGL) are assigned a coproduction credit for emissions avoided from the system that they displace. The approach here can therefore be described as a co-product emissions assessment via system boundary expansion rather than via allocation between products. In all cases, the energy consumption and GHG emissions of the displaced production system are calculated using GREET. For co-products produced as part of crude oil recovery, staff believes that co-product displacement is more appropriate than allocation by energy, mass, economic value, hydrogen content, or any other metric for allocating emissions. ISO guidelines also support the use of co-product displacement over allocation where possible.

3. Comment: **PR-3**

The reviewer states that the OPGEE value for diesel consumption during oil sands mining is an overestimate and requests a justification for the value.

Agency Response: As noted by the reviewer, energy consumption (or export) and fugitive emissions values in OPGEE for oil sands mining are based on data extracted from the GHGenius model. These are default values to be used in the absence of field-specific energy consumption data. If an oil sands producer does not believe that these defaults accurately represent their operations, they can provide field-specific energy consumption data to ARB for use in modeling the crude. As to the specific comment about diesel usage for mining operations, the OPGEE default intensity for integrated mines and upgraders is 0.074 MMBTU/bbl. At a heating value of ~5.5 MMBTU/bbl, this amounts to 0.013 MMBTU/MMBTU or 0.013 GJ/GJ. We can compare to a recent report updating the GREET model treatment of oil sands for Argonne National Laboratory (Englander and Brandt 2014)[60]. In this report which uses monthly data for all oil sands operations reported to the Alberta Energy Regulator, diesel use (mean) was 0.02 GJ per GJ of SCO delivered,

[60] Englander and Brandt (2014). Oil Sands Energy Intensity Analysis for GREET Model Update. Argonne National Laboratory, May 4th, 2014.

with a p10-p90 range of 0.01 to 0.03 GJ/GJ (Englander and Brandt, 2014, Table 9, p. 29). If anything, OPGEE diesel use may be low.

In mid-2014, ARB issued a contact to Adam Brandt of Stanford University together with Joule Bergerson at the University of Calgary and Heather MacLean at the University of Toronto. The project scope includes revisions to the treatment of oil sands mining and bitumen upgrading. Treatment of oil sands mining in the new model will be based on the GHOST model developed at the University of Calgary. Newly available data, such as for diesel fuel consumption suggested by the reviewer, will be considered in developing the revised model treatment of oil sands mining.

4. Comment: **PR-4**

The reviewer requests further justification for the assumptions in the OPGEE model regarding electricity production and export from the oil sands.

Agency Response: As noted by the reviewer, electricity import (or export) values in OPGEE for oil sands mining are based on data extracted from the GHGenius model. However, we do not assume the oil sands operators only generate power at grid average GHG intensities. The reported values in GHGenius are net imports or exports, after any on-site generation is consumed. Emissions from onsite electricity generation are accounted for through the import and combustion of natural gas. Moreover, the net electricity import or export values in OPGEE are default values to be used in the absence of field-specific energy consumption (or export) data. If an oil sands producer does not believe that these defaults accurately represent their operations, they can provide field-specific energy consumption data to ARB for use in modeling the crude.

For electricity import, OPGEE assumes a default grid electricity mix. If an oil sands producer can demonstrate that all electricity is produced onsite, then the modeling can be customized using the field-specific information.

For electricity export, the default allocation method is substitution for natural gas based electricity. While OPGEE allows for displacement of grid electricity, staff has decided to use displacement of natural gas based electricity in all cases, irrespective of production location. This method prevents achieving unreasonably large credits for operations with significant power export.

5. Comment: **PR-5**

The reviewer claims that the OPGEE treatment of cogeneration of steam and electricity is limited for the in situ extraction method of steam assisted gravity drainage (SAGD).

Agency Response: In OPGEE the modeling of fields that use steam injection can be done using either the steam injection worksheet of the standard model or using the bitumen extraction and upgrading worksheet. As noted by the reviewer, the bitumen extraction and upgrading worksheet is based on GHGenius and has limited functionality with regard to cogeneration of steam and electricity. However, for the LCFS crude oil CI calculations, ARB staff has chosen to model all thermally enhanced oil recovery (i.e. steam flooding, cyclic steam stimulation, and steam assisted gravity drainage) using the steam injection worksheet of the standard model. Using this approach, cogeneration can be varied from zero to 100 percent of the steam supply for crude production, with the remaining fraction produced using once-through-steam-generators. While the default is set to zero percent cogeneration, we welcome data from operators on the fraction of steam produced using cogeneration and will customize the modeling if appropriate data are provided.

6. Comment: **PR-6**

The reviewer recommends considering the stockpiling of coke in the assessment of emissions from upgrading of bitumen. The reviewer also comments on the limited details presented on the consumption of hydrogen for upgrading bitumen.

Agency Response: As per GHGenius model inputs, we assume only part of the coke is combusted. In OPGEE "Bitumen Extraction" sheet cell D227, the default value for consumption of coke for integrated mining operations is 0.205 MMBTU per bbl. At a heating value of ~5.5 MMBTU/bbl, this represents a fractional energy consumption of 0.037 MMBTU coke per MMBTU SCO produced or 0.037 GJ/GJ. The Argonne Laboratory Report cited above (Englander and Brandt 2014, Table 9, p. 29) gives the mean coke consumption for integrated operations of 0.03 GJ/GJ, with a P10-P90 range of 0.02 to 0.05 GJ/GJ. OPGEE coke consumption is therefore directly in line with reported AER coke consumption rates.

As to the production and consumption of hydrogen, future expansion of the model will treat hydrogen in more detail. As of now, hydrogen generation is treated as in the GHGenius model, which includes NG consumed as reported to regulators.

7. Comment: **PR-7**

The reviewer comments that fugitive emissions are important, that there has been very limited effort to estimate fugitive emissions, that fugitive emissions for different crudes could vary significantly, and that real life measurement of fugitive emissions would prove very helpful

Agency Response: Because on-site fugitive emissions data are generally not available for crudes produced worldwide we have based OPGEE default estimates for fugitive emission sources on published emission factors for crude production operations in the United States and California. Staff is very interested in obtaining additional data on fugitive emissions estimates for evaluation and incorporation into the model. Again, oil producers are encouraged to provide data supporting field-specific values for these emission factors.

8. Comment: **PR-8**

The reviewer comments that GHG emissions for biomass-based electricity can vary greatly depending on source of biomass.

Agency Response: We agree with the reviewer that the lifecycle emissions of biomass used for electricity can vary substantially depending on source of biomass and inputs for biomass growth, harvesting, collection, transport, and conversion. However, the default grid electricity mix used in OPGEE, and assumed for all crude modeling under the LCFS, assumes only 0.3 percent electricity from biomass, and therefore these differences in lifecycle emissions will have little effect on the carbon intensity of crude production.

9. Comment: **PR-9**

The reviewer states that the GHG emissions for electricity are highly dependent on the source of electricity and can change substantially over time, thereby affecting the carbon intensity of crude oil production in a given jurisdiction.

Agency Response: While we agree with much of the reviewer’s comment, OPGEE does not provide an automatic lookup table with differentiated grid electricity mixes for all oil producing regions worldwide. Therefore, ARB staff has chosen to use the OPGEE default grid electricity mix for all crudes, irrespective of production location.

10. Comment: **PR-10**

The reviewer comments that in addition to GHG emissions from crude production, ARB should estimate lifecycle water impacts of various crude oils.

Agency Response: While we agree that lifecycle water footprint may be an important issue for some oil producing regions, the LCFS is based on comparison of GHG emissions and therefore differences in water footprint are not germane to the regulation.

11. Comment: **PR-11**

The reviewer recommends that ARB document efforts to ensure that there is no double counting of emissions burdens between CA-GREET and OPGEE.

Agency Response: Staff acknowledges the need to be clear when discussing how the three models interact. Appendix C of the ISOR is explicit in the way that OPGEE interacts with CA-GREET 2.0. On page C-3, under, "Summary of Major Changes to GREET1 2013 to Produce CA-GREET 2.0", staff states:

"Staff modified GREET1 2013 to use the Oil Production Greenhouse Gas Emissions Estimator Version 1.1 Draft D (OPGEE) as the data source for estimating the carbon intensity (CI) of the crude oil used in California refineries. OPGEE estimates crude production and transport carbon intensities (CIs) based on oil field location and crude extraction technology. The use of OPGEE resulted in revisions to the refining efficiencies used for CARBOB and ultra-low sulfur diesel produced in California. For these two California fuels, we are currently modeling the process fuels mix and refining efficiencies using PADD 5 specific values (CARBOB: Table 31, pg. 60, CA ULSD: Table 35 pg. 65). It is necessary for staff to determine the CI of CARBOB and ultra-low sulfur diesel as accurately as possible, rather than using the US average, because these fuels are LCFS baseline fuels. We are not modifying gasoline or diesel processing for the rest of the US. Staff added crude oil recovery processing and emissions in CA-GREET 2.0 to closely approximate the carbon intensity determined by OPGEE (Table 27 page 56). The CA crude CI modeled in CA-GREET 2.0 matches the carbon intensity determined by OPGEE and approximates the fuel mix and efficiency determined for CA crude recovery by OPGEE."

Staff further refers to Table 27 on page 56 to detail how OPGEE is used for the upstream (non-refining stage) to determine the CI of the crude oil entering California refineries. In Table 27, staff states that the crude refining process has an input (crude oil CI from OPGEE) into the modeling of refining (done in CA-GREET 2.0). Staff further states, "Staff also added a CA Crude Recovery column that closely approximates the inputs to OPGEE and produces a petroleum crude CI equal to OPGEE. This allows the upstream emissions that are calculated during the refining process modeled in CA-GREET 2.0 for CARBOB and ULSD to be more accurate. See Petroleum Tab column beginning at cell D61." Staff further references the CARBOB and California ULSD refinery modeling as receiving the crude CI input from OPGEE rather than the crude CI that would be calculated by GREET1 2013 (the primary model basis for CA-GREET 2.0). Reviewing the model shows that the crude recovery and transportation is not double counted between OPGEE and CA-GREET 2.0. Appendix C is the basis for the, "CA-GREET 2.0 Supplemental Document[61]", which is incorporated by reference in the 15-day change package for the LCFS re-adoption and contains this information.

12. Comment: **PR-12**

The comment questions pilot data that could be used for modeling pathways and asks about corn stover being the only Tier 2 pathway modeled in recent years.

Agency Response: The commenter mentions that CA-GREET has been recently updated to include cellulosic feedstocks and sorghum. If more detailed information is needed regarding grain sorghum to ethanol LCA in CA_GREET 2.0, please refer to Appendix C of the ISOR or the latest update to the CA-GREET 2.0 Supplemental Document.[61]

There is data available for the corn stover to ethanol pathway provided in Appendix C of the ISOR. To more precisely address the commenter's question, the corn stover to ethanol pathway is a Tier 2 pathway. The regulation calls for Tier 2 pathways to be scrutinized from well (field) to wheels because staff is not as familiar with these

[61] The latest updates to the CA-GREET 2.0 Supplemental Document is available at the following site: http://www.arb.ca.gov/fuels/lcfs/ca-greet/ca-greet.htm

pathways. Applicants will supply all of the relevant information to use in conjunction with CA-GREET 2.0, Tier 2. Tier 2 pathways reduce the necessity of relying on general information from the scientific literature or other sources in advance of staff receiving a corn stover to ethanol pathway application or other Tier 2 pathway application. The Tier 2 application process and calculation of carbon intensity is as specific as scientifically possible to the applicant applying.

13. Comment: **PR-13**

The comment inquires about the differences between emissions results from MOVES, MOBILE6.2, and the CARB EMFAC model, and what factors prompted the switch to MOVES emission factors.

Agency Response: ARB staff adopted the heavy and medium duty transportation vehicle emission factors (EF) from GREET1_2014 to account for transport of feedstocks and fuel in pathway modeling. Those EFs were generated by Argonne National Laboratory (ANL) using the Motor Vehicle Emission Simulator (MOVES) (EPA, 2013) model. ANL provides rationale for its choice to update EFs in its paper, *Updated Emission Factors of Air Pollutants from Vehicle Operations in GREET™ Using MOVES* (Cai, Hao et al., 2013), stating:

> "*MOVES2010b replaces MOBILE6.2, the previous model for estimating on-road mobile-source emissions, as EPA's best available tool for quantifying criteria pollutant and precursor emissions from light- and heavy-duty vehicles*"

According to EPA (2013), the advances featured in the MOVES model, relative to its predecessor, MOBILE, include:

- Improved vehicle classification system: by mode of operation rather than by weight rating;
- Updated and improved particulate matter emission data; and
- Incorporation of additional emission measurement data from heavy-duty diesel crankcase ventilation and from extended idling.

Cai, Hao et al., 2013. Updated Emission Factors of Air Pollutants from Vehicle Operations in GREET™ Using MOVES. Energy Assessment Section, Energy Systems Division, Argonne National Laboratory. September 2013. https://greet.es.anl.gov/publication-vehicles-13

EPA, 2013. Motor Vehicle Emission Simulator (MOVES). http://www.epa.gov/otaq/models/moves.

14. Comment: **PR-14**

The commenter asks how uncertainty is propagated through the series of models, states they understand how uncertainty is handled in CA-GREET and GTAP, and questions if there is a reliable uncertainty range in the final carbon intensity.

Agency Response: The aggregate carbon intensity uncertainty based upon the three models - OPGEE, CA-GREET 2.0, and GTAP is not characterized in the scientific literature to-date. Each of these models incorporates various data types, each with their own levels of uncertainty. The uncertainty of every datum in each model is currently unknown. It is theoretically possible to determine an aggregate uncertainty or at least take the initial necessary steps if the scientific community selected specific pathways, identified the most uncertain and certain data, and determined whether there is a reliable or appropriate estimate of uncertainty in a datum or data set. At this time ARB is not aware of any researcher or group that has done this work. In any event, ARB is confident that the relative CI values between fuels are sufficiently accurate to provide an appropriate market signal to accomplish the goals of the LCFS.

15. Comment: **PR-15**

The commenter states that language around the [in the material provided for peer-review] indirect accounting as they relate to Tier 1 and Tier 2 fuels is a bit unclear. The commenter correctly points out or rather questions the difference between a Tier 1 or 2 facility and a Tier 1 or 2 pathway. The commenter goes on to provide an example of a Tier 1 facility producing a Tier 2 fuel, corn ethanol, corn stover ethanol, and co-products.

Agency Response: Please see the staff response to **LCFS FF44-13**. The facility/pathway terminology is also used in the regulation, in addition to the review material provided for peer review.

16. Comment: **PR-16**

The comment states that page 15 (referring to Table 2. Carbon Intensity Lookup Table for Diesel and Fuels that Substitute for Diesel) does not make clear the difference between pathways CNG020 and CNG021.

Agency Response: The two pathways for wastewater treatment sludge to CNG via anaerobic digestion are distinguished in the Staff Report by whether or not excess electricity is produced and exported to the grid. From Table 2, page 15 of the Staff Report (emphasis added):

- "**CNG020** Biomethane produced from the mesophilic anaerobic digestion of wastewater sludge at a California publicly owned treatment works; on-site, high speed vehicle fueling or injection of fuel into a pipeline for off-site fueling; **export to the grid of surplus cogenerated electricity**. (CI = 7.80 gCO2e/MJ)

- **CNG021** Biomethane produced from the mesophilic anaerobic digestion of wastewater sludge at a California publicly owned treatment works; on-site, high speed vehicle fueling or injection of fuel into a pipeline for off-site fueling. (CI = 30.98 gCO2e/MJ)."

In addition to this distinction, the Pathway Report specific to these pathways defines the size or capacity of the wastewater treatment facility for each fuel pathway code. CNG020 refers to a "Medium-to-Large" publicly owned treatment works (POTW), which is applicable to a range of wastewater inflow capacities of 21 to 100 million gallons per day (MGD), while CNG021 is relevant for a "Small-to-Medium" POTW with wastewater inflows of 5 to 20 MGD. Other differences in operating conditions and assumptions about energy sources and demand corresponding to the two capacity ranges are also described in this document.

17. Comment: **PR-17**

The commenter questions if GREET is able to provide estimates at the same resolution as the Agro-ecological Zone EmissionFactor (AEZ-EF) Model from different regions of US and the world. The commenter questions if the model accounts for the differences between rain-fed and irrigated crops. The commenter further asks how natural land use impacts the emissions. The commenter suggests to staff that they should consider the resolution of the data across these modeling platforms to ensure that they are comparable.

Agency Response: CA-GREET 2.0 uses inputs for specific parameters, which may in some cases, be able to provide resolution in a specific region. For example, corn grain fertilizer application is modeled as being a national average value based upon data from the USDA through Argonne National Laboratory's technical papers and specifically from the GREET1 2014 model release in this case. It may be possible to model corn grain fertilizer application in a different region or another part of the world within GREET if emission factors and parameters are adjusted appropriately. Sugarcane for ethanol production is modeled in GREET as if sugarcane is produced in Brazil, which would have to be modified to model a different type of cane grown in a more Mediterranean-type climate.

In the case of nitrous oxide emissions from above and below ground biomass, staff applied the IPCC Tier 1 default emissions, which are not specific to soil type, precipitation, topography, temperature, and other factors in a region where a particular biofuel feedstock is grown, but instead is a widely-accepted default "average" emission factor.

18. Comment: **PR-18**

The comment requests that staff consider the resolution of the data across modeling platforms to ensure they are comparable.

Agency Response: Please see response to **PR-17**.

19. Comment: **PR-19**

The reviewer asks about the extent to which crude carbon intensity values vary from year to year.

Agency Response: Carbon intensity values for various crude sources do vary from year to year as production parameters such as steam-oil-ratio, water-oil-ratio, and flaring rate change over time. These changes can be observed by comparing CI values for crudes used to calculate the 2010 baseline (i.e. Table 10 of the proposed regulation) to CI values for the same crudes in the crude lookup table (i.e. Table 8 of the proposed regulation). The CI values for 2010 baseline crudes are based on 2010 crude production data, while CI values for the proposed crude lookup table are based on 2012 crude production data. Future changes in crude CI will be captured by updating the crude lookup table on a three-year cycle.

20. Comment: **PR-20**

This comment inquires if the GTAP model accounts for year-to-year variability in yields and yield improvements resulting from technology improvements.

Agency Response: ARB thanks the peer reviewer for this comment. Since GTAP is a static model, the values used in the analysis cannot capture year-to-year variability from occurrences such as droughts in the Midwest U. S. Technology related yield improvements are implicitly included within the framework of the GTAP model.

21. Comment: **PR-21**

The reviewer asks how carbon dioxide enhanced oil recovery is handled in OPGEE and if CO_2 enhanced oil recovery would qualify as an innovative crude production method.

Agency Response: OPGEEv1.1 does not have the capability to explicitly model CO_2 enhanced oil recovery. During initial model development, this was not considered a priority as very little crude produced using this recovery method is supplied to California. In mid-2014, ARB issued a contact to Adam Brandt of Stanford University. The project scope includes new pathways for carbon capture with CO_2 enhanced oil recovery. These pathways will include both anthropogenic and natural sources of CO_2. The project is expected to be completed in 2016, at which time the draft model will be posted for public review and one or more workshops will be held to discuss the model changes. We intend to propose the new model, OPGEEv2.0, and new crude carbon intensity values for adoption in 2018.

Crude oil produced using carbon capture and sequestration may qualify under the innovative crude provision, provided that the capture of carbon occurs onsite at the crude oil production facility. Moreover, CCS projects must use a Board-approved quantification methodology including monitoring, reporting, verification, and permanence requirements associated with the carbon storage method being proposed for the innovative method. This quantification method is being developed and is expected to be available by 2017. See also the response to **LCFS 37-12.**

22. Comment: **PR-22**

The reviewer recommends that if ARB is considering credit for CO_2 enhanced oil recovery, then the source of carbon dioxide must be determined.

Agency Response: We agree with this comment. Under the LCFS innovative crude provision, credit will only be allowed if the carbon is captured onsite at the oil production facility. See also the response to **PR-21**.

23. Comment: **PR-23**

The reviewer asks how self-reported emissions under the EPA Greenhouse Gas Reporting Program compare to the emission factors used in OPGEE.

Agency Response: OPGEE uses EPA emission factors for several venting and fugitive emissions calculations. However, staff has not performed a detailed comparison of emissions data reported to EPA with emission factors used in OPGEE. Staff encourages individual crude producers to provide field-specific data if they believe that the emission factors or calculations performed in OPGEE do not accurately represent their operations.

24. Comment: **PR-24**

The reviewer asks how significant crude price swings affect the composition of crudes supplied to California refineries and how this may be reflected in the carbon intensity of the crude slate.

Agency Response: While it is true that the CI values for CARBOB and diesel and the LCFS compliance targets are set to a 2010 baseline, the LCFS does include a provision to track and account for changes in crude slate and any increases in average crude carbon intensity over time. Each year California refineries must report crude names and volumes for all crude supplied to each of their refineries. ARB staff then uses this reported data to calculate the Three-year Crude Average Carbon Intensity value (i.e. a rolling average crude CI using the most recent three years of crude supply). If the Three-year Crude Average CI is greater than the 2010 Baseline Crude Average CI, then the refineries are assessed an incremental deficit proportional to the increase in average crude CI.

25. Comment: **PR-25**

The peer reviewer wants clarification on details related to calculating the average iLUC value from the scenario runs (i.e., equal weighting).

Agency Response: Since there is no available information to support greater likelihood of some of the scenarios, ARB staff did not use a weighted approach instead used a simple averaging approach for the results of the 30 scenario runs. See also responses **LCFS 8-9**, **LCFS 46-79**, **LCFS 46-86**, and **LCFS 46-98**.

26. Comment: **PR-26**

Peer reviewer inquires if ARB is committed to updating the database from the 2004 baseline year and if making the change would impact the iLUC values.

Agency Response: The current analysis uses a 2004 GTAP baseline because this is the latest year for which detailed data was available for all sectors and industries used in ARB's version of the model. Purdue is currently in the process of updating the baseline to a 2010 timeframe. When the update is completed, ARB will consider updating the iLUC analysis. Refining the baseline of the model may change the iLUC estimate.

27. Comment**: PR-27**

The peer reviewer conveys his observation that groups within the community question the appropriate value for iLUC and some even question the validity of iLUC applied to biofuels. The reviewer also opines that since the LCFS is technology-neutral, selecting a value that is potentially at the upper end of likely values could create de facto caps which could suppress development of new fuels.

Agency Response: The iLUC value of 30.0 g/MJ for corn ethanol is not relevant to the current analysis. The LCFS program uses the totality of GHG emissions for every transportation fuel used to comply with the program. All fuels are scored on their lifecycle GHG emissions (direct and indirect emissions) and the program is designed to be technology and fuel neutral. The necessity to account for indirect Land Use Change (iLUC) effect has been and has been detailed in response to **LCFS 8-1**. ARB would therefore be remiss if it did not account for indirect land use change effects in the carbon intensities of crop-based biofuels.

The current iLUC value proposed by ARB for corn ethanol is 19.8 g/MJ. This value does not include only the high-end of likely values for iLUC emissions but reflects the average of 30 scenario runs. The 30 scenario runs were completed by utilizing a range of discrete values for each of the most important parameters identified from the Monte Carlo screening analysis. Furthermore, the Monte Carlo analysis uses outputs from hundreds of simulations and is able to isolate parameters in the GTAP model that have the largest impact on model outputs. The mean value estimated from the hundreds of

Monte Carlo simulations was used to corroborate the average value calculated from the scenario runs. The mean estimated from the uncertainty analysis is similar to the average calculated from the scenario runs for all of the 6 biofuels.

28. Comment**: PR-28**

The commenter states some suggestions to staff external to their scientific review. **PR-28** specifically states, "Make it clear that LCFS defines CI units of gCO_2e/MJ (p. 2 of CA-GREET Report)".

Agency Response: A more complete definition of CI is in the ISOR, page III-2, Section B. Definitions and Acronyms. This definition more clearly expresses that the energy units are in gCO_2e/MJ by stating, "Carbon intensity" means the amount of life cycle greenhouse gas emissions, *per unit of energy of fuel delivered*, expressed in grams of carbon dioxide equivalent per megajoule [mega Joule] (gCO_2e/MJ)." In this last definition presented, both the numerator (underlined above) and denominator (*italicized* and underlined above) are better defined than earlier definitions. The mega Joules of energy is the amount of energy (fuel energy) associated with the lifecycle gCO_2e from well (field, etc.) to wheels (WTW). WTW includes all GHG emissions (gCO_2e) involved with, but not necessarily limited to, the production of feedstock, transport of feedstock, production of fuel, delivery of fuel, combustion of the fuel, any indirect emissions (e.g., ILUC), and any co-product credits.

The main point of clarity in response to the comment is that the energy in MJ is the total amount of fuel, as energy, associated with the total lifecycle emissions in gCO_2e. Using an illustrative example, if an entity produced 8 MJ of fuel with the WTW emissions of 2 gCO_2e, the CI of the fuel would have a CI of 0.25 gCO_2e/MJ. In reference to the earlier definitions (in question) of the units of CI (gCO_2e/MJ), the 0.25 gCO_2e/MJ CI shown here as an example can now be used to determine the total emissions under the same conditions that would result if 50 MJ of fuel were produced, rather than 8 MJ. The resulting emissions would be (50 MJ)*(0.25 gCO_2e/MJ) = 12.5 gCO_2e, but the CI of the fuel remains 0.25 gCO_2e/MJ.

29. Comment**: PR-29**

The commenter states some suggestions to staff external to their scientific review. PR-29 states, "Figure 1 is not 'generalized' – one of the arrows refers to biofuel use".

Agency Response: Staff appreciates the recommendation to make the figure more general regarding the type of fuel used in a vehicle. Staff will consider providing more generally labeled components, of general LCA diagrams, in the future.

30. Comment**: PR-30**

The comment questions the reference used for VOCs, how to calculate this value, and states that staff could explain and write this more clearly.

Agency Response: The modeling of VOCs and CO emissions in CA-GREET 2.0 are based upon the assumption that these molecules are relatively short-lived as VOCs and CO and that these species are relatively-rapidly fully oxidized to CO_2.

The ISOR states that, "CA GREET 2.0 assumes that VOC and CO are converted to CO_2 in the atmosphere. It therefore, includes these pollutants in the total CO_2e value using ratios of the appropriate molecular weights. The ratio of the molecular weight of carbon to the molecular weight of CO_2 is 12/44 = 0.273. The CO_2e values of VOCs and CO are, therefore, 0.85/0.273 = 3.12, and 0.43/0.273 = 1.57, respectively." These values were imported from the GREET model from Argonne National Laboratory (ANL) that was used as the basis for CA-GREET 1.8b. The ANL GREET models (GREET1 2013 and GREET1 2014) contain these ratios and the resulting multiplier for global warming potentials (GWP) for CO and VOCs. Staff has used these ratios for CO and VOCs since the LCFS was adopted in 2009 and ANL GREET has as well.

31. Comment**: PR-31**

The commenter states some suggestions to staff external to their scientific review. PR-31 states, "There was no text description of Tier 2 Method 1 in the Summary Report".

Agency Response: The Tier 2 lookup tables (Table 1 and Table 2 in the staff report) are mentioned, which are also Method 1 pathways as discussed in the ISOR and regulation (Appendix A of the ISOR), which were provided for the peer reviewers.

32. Comment: **PR-32**

The commenter would have preferred staff including a summary of how the three models (a box model diagram) integrate into the CI determination of fuels in the LCFS program.

Agency Response: The iLUC analysis includes a graphical representation of the integration of the GTAP and AEZ-EF models in Appendix I of the ISOR. For OPGEE, a graphical representation of the model is provided in Appendix H of the ISOR. There is no graphical representation of the CA-GREET model. ARB acknowledges a graphical representation of the interaction of the three sets of models in estimating the total carbon intensity of a transportation fuel could be helpful.

Regarding GREET, ARB staff agrees with the commenter that a succinct summary (box model diagram) of the three carbon intensity model components, as well as a short summary of the more specific quantitative aspects of the LCFS (10 percent goal by 2020), could be useful. Staff appreciates the time the reviewer took to locate the goals of the LCFS in the ISOR. Staff hopes that Attachment 4 (listed below), which was provided to the peer reviewer, supplied the necessary information even though it was not succinct.

Air Resources Board (ARB) staff prepared three reports entitled:

Attachment 4

- Staff Report: Calculating Life Cycle Carbon Intensity of Transportation Fuels in California
- Staff Report: Calculating Carbon Intensity Values of Crude Oil Supplied to California Refineries
- Staff Report: Calculating Carbon Intensity Values from Indirect Land Use Change of Crop-Based Biofuels

Peer review material is available here for reference and public access: http://www.arb.ca.gov/fuels/lcfs/peerreview/peerreview.htm

33. Comment: **PR-33**

The comment expresses concern about the use of potentially-outdated EPA AP-32 emission factors and the lack of sufficient information provided to determine which values in the model originate from this source.

Agency Response: The purpose of the chapter (II. ASSUMPTIONS AND INPUTS) was not to provide a thorough documentation of values in the model, but rather to impart that the many necessary emission factors in GREET are adopted from widely-accepted, authoritative, standard sources for GHG emission-related factors such as U.S. EPA models (MOVEs, eGRID), International Panel on Climate Change, United Nations Food and Agriculture Organization, etc. The references to U.S. EPA AP-42 emissions factors were found by ARB staff within comments in the GREET model spreadsheet, specifically for small industrial biomass (willow and poplar) boilers.

Users and stakeholders may refer to the 2015 Initial Statement of Reasons (ISOR) Appendix C which thoroughly documents changes made to GREET1_2013 to create the CA-GREET2.0 model and provides many additional references for particular values and calculations used in CA-GREET. For references of values which were “inherited” by CA-GREET, or are not addressed in Appendix C, users must refer to Argonne’s series of publications regarding GREET model updates.

34. Comment: **PR-34**

The comment expresses concern about the use of MOVES2010 although a more recent update, MOVES2014 is available.

Agency Response: Unfortunately, the availability of MOVES2014, the LCFS re-adoption regulatory schedule and limitations on ARB staff resources did not allow a thorough comparison of MOVES2010b and MOVES2014 for all forms of transit. Staff did, however, compare diesel heavy-duty truck emission factors from the two models and found that, while there are significant reductions in all criteria pollutant emissions in MOVES2014, the CO_2 from combustion dominates the emission factor (EF), and the resulting impact in CO_2-equivalent is insignificant. For Class 8 (heavy-heavy duty) trucks, the MOVES2014 EF is 0.5 percent lower (on a gram CO2e per mile basis) than MOVES2010. The EF for Class 6 (medium-heavy duty) trucks was 0.05 percent lower in the newer MOVES version. For a typical transport distance of 100 miles (expected distances vary from 40 to 140 miles) by heavy-duty truck, the impact of using MOVES2010 data is less than 0.002 gCO_2/MJ.

Staff intends to institute a regular review and update cycle for all models used in support of the LCFS; at that time, emission factors from the latest version of MOVES may be utilized.

35. Comment: **PR-35**

The comment advises staff to explicitly note in the Staff Report which GWP factors were used and to supply the rationale for that choice.

Agency Response: ARB staff concurs with and regrets the oversight. The use of Global Warming Potentials from IPCC's AR4, on a 100-year time horizon in CA-GREET2.0 is noted in the Staff Report (page 8) and ISOR (page 106). These values were chosen for consistency with other ARB programs such as the state GHG Inventory.

36. Comment: **PR-36**

The commenter has questions about the CI lookup tables presented in the staff report.

Agency Response: The commenter is correct in their analysis of the purpose of Table 1 and Table 2 in the staff report and in the ISOR. These pathways are available to Tier 2 applicants if they have a fuel (gasoline or diesel) or a fuel substitute that they desire to sell in California that meets the conditions of these fuels in the referenced lookup tables. If a Tier 2 fuel can improve on the CI (reduction in CI) of a fuel in this table by a certain amount (specified in the regulation), then an applicant can apply for a Tier 2 Method 2A pathway using one of the lookup table pathways as a reference/basis pathway. If a lookup table pathway CI does not sufficiently apply to a Tier 2 applicant's fuel, as specified in the regulation; the Tier 2 Applicant must apply under Method 2B for which there is no reference pathway indicated by the lookup table CIs.

37. Comment: **PR-37**

The commenter has questions about the substantiality requirement under Tier 2 for Method 2A applications.

Agency Response: The substantiality requirement between the Tier 2 lookup table (also known as Method 1 reference pathways) and the Tier 2, Method 2A pathway is based upon a percent difference reduction in carbon intensity from the Method 1 lookup table. The ISOR states, "Proposed Method 2A pathways with CIs greater than 20 gCO_2e/MJ must have CIs that are 5.5 percent lower than the CIs of their reference pathways. Proposed pathways with CIs of 20 gCO_2e/MJ or less must have CIs that are at least one gCO_2e/MJ

lower than the CIs of their reference pathways." The purpose of these substantiality requirements is to incentivize reductions in CIs from the lookup table that are substantial and therefore warrant staff time to process Tier 2 applications. In the future, staff may develop Method 1 pathways that would be added to the lookup table (reference pathways) to allow applicants in Tier 2 to use the expedited Tier 2, Method 1 lookup table pathway process.

38. Comment: **PR-38**

The reviewer recommends reporting lookup table CI values to fewer than the currently reported four significant digits.

Agency Response: We realize that, because of the uncertainty in calculations, carbon intensities with fewer significant digits would have advantages. However, in the compliance schedule the incremental carbon intensity reductions of gasoline and diesel fuels are so small, especially in the initial years of the LCFS, that two digits past the decimal point were determined to be necessary to quantify the reductions. As the required CI reduction in the compliance schedule increases over time, we will evaluate the reviewer's suggestion to use fewer significant digits in reporting CI values for both crude oil and finished fuels.

39. Comment: **PR-39**

The commenter suggested that depicting the inputs to feedstock production such as agricultural fertilizers and pesticides lead to a more accurate assessment of how GREET works.

Agency Response: The commenter is correct; agricultural GHG emissions impacts from production of fertilizers and chemicals must be determined to evaluate the overall carbon intensity (CI) of the transportation fuel. While not explicitly depicted in the Figure 1 schematic of the Staff Report, those lifecycle GHG emissions impacts are normally calculated for each well-to-tank CI determination if such agricultural inputs are known to be utilized in the pathway.

40. Comment: **PR-40**

The commenter questions the agricultural data used for sorghum and corn in CA-GREET 2.0.

Agency Response: CA-GREET 2.0 uses corn farming data derived from GREET1 2014 that relies on a variety of data from the USDA and other sources, which were reviewed through Argonne National Lab (ANL) publications and technical reports and used in GREET1 2014.

The grain sorghum agricultural data was updated as referenced in Appendix C of the ISOR based upon collaboration between ARB, ANL and the National Sorghum Producers. Appendix C of the ISOR references the ANL technical memorandum, which is the basis of changes from GREET1 2013 to CA-GREET 2.0 for the grain sorghum to ethanol pathway. Staff notes that the structure of CA-GREET 2.0 is based upon GREET1 2013 even though some data for many pathways were updated from GREET1 2014 (e.g. agricultural inputs for corn production). For further clarification, please see Appendix C of the ISOR or the CA-GREET 2.0 Supplemental Document[62] that is incorporated by reference for the 15-day change package submitted for public comment on June 4, 2015[63].

41. Comment: **PR-41**

The commenter pointed out that the production of cellulosic biofuels is a nascent industry and it would be more accurate to model the lifecycle analysis of fuels using actual process data instead of laboratory scale or pilot plant data.

Agency Response: ARB staff worked closely with two cellulosic ethanol producers and their consultants to develop the LCFS fuel pathways[64] for ethanol derived from cellulosic residues which include sugarcane straw, wheat straw, and corn stover.
The pathways were developed from actual construction details, engineering drawings, process flow diagrams, and material and energy balances of as-built conditions, not laboratory-scale data. Both facilities have long since commenced commercial operation. It is customary for any new process, start-up, or commercial operation at a facility to ramp up production, and eventually reach

[62] CA-GREET 2.0 Model and Documentation: http://www.arb.ca.gov/fuels/lcfs/ca-greet/ca-greet.htm
[63] LCFS, HEARING ACTION AND SUPPLEMENTAL 15-DAY NOTICES http://www.arb.ca.gov/regact/2015/lcfs2015/lcfs2015.htm,
[64] See Abengoa Bioenergy Biomass of Kansas (Hugoton Cellulosic Ethanol Plant) LCFS pathways at http://www.arb.ca.gov/fuels/lcfs/2a2b/apps/abbk-etoh-012915.pdf, and GranBio BioFlex Plant LCFS pathway at http://www.arb.ca.gov/fuels/lcfs/2a2b/apps/gb-102414.pdf.

steady-state. Staff expects that if actual operations are significantly different from design conditions, or deviate on fuel process yields, for example, then the pathway CI would be amended by the applicant.

Staff further believes that enzyme and energy use at cellulosic biofuel production facilities might be verified as ARB develops its monitoring and verification program for the LCFS. Secondly, the proposed LCFS regulation accomplishes what the commenter recommends; what are called "Prospective" pathways is very limited under the new provisions. The plant has to be operating for at least a calendar quarter before a pathway application can be submitted. This means that ARB will be relying much more on operational data going forward.

42. Comment: **PR-42**

The commenter has suggestions for the list of Tier 1 fuels in the staff report.

Agency Response: ARB staff appreciates the commenter's suggestion that the list of Tier 1 fuels in the staff report include, "…starch and sugar-based ethanol including that from corn and sugar as those are the two largest sources currently. Under the biodiesel sources I might have listed soybean oil, corn oil, canola, and other plant oils." Staff reviewed page 9 of the staff report that the commenter references for making these suggestions. Staff found that starch and sugar-based ethanol is included on that page in the staff report, but it does not explicitly say corn and sugarcane ethanol. Staff also found under this same list of, "Tier 1 fuels include, but are not limited to:" for biodiesel and renewable diesel, "(…including but not limited to plant oils, tallow and related animal wastes, and used cooking oil)…" Staff believes that the information provided in the staff report is sufficient.

43. Comment: **PR-43:**

The commenter suggested that the ARB consider re-phrasing the "carbon capture and sequestration" terminology for Tier 2 pathways to "carbon capture and storage."

Agency Response: The Climate Change program of the Air Resources Board (ARB) has utilized both terms sequestration and storage interchangeably,[65] claiming it to be similar. The Carbon Capture and Sequestration stated in the Staff Report refers to the process by which large amounts of carbon dioxide (CO_2) are captured, transported, injected, and stored underground in geological formations such as depleted oil and gas reservoirs, un-mineable coal beds, and saline formations. ARB staff further asserts that there could be instances when carbon dioxide is sequestered but not stored, such as when carbon dioxide emissions from fermentation in ethanol production processes are captured, refined, and re-used in the carbonated beverage industry. In this case, the carbon dioxide is sequestered from one process, and temporarily stored in another.

44. Comment: **PR-44**

The commenter suggests that staff state ethanol from cellulosic sources, rather than corn stover ethanol. The commenter also suggests the need to list sources of jet fuel.

Agency Response: ARB staff appreciates the commenter's suggestion that Figure 2 in the staff report under Tier 2, should be called, "…ethanol from cellulosic sources…" The commenter goes on to say, "Restricting it to Stover [*sic*] is a pretty narrow set with dedicated bioenergy crops like switchgrass or miscanthus plus use of wood and other things are possible. At some point soon we may also need to list some sources of jet fuel." Staff notes that in Figure 2, under Tier 2, Next Generation Fuels that, "cellulosic alcohols" are stated and not only stover as the commenter suggests. Staff notes that under Tier 2 in Figure 2, under cellulosic alcohols, a number of other Tier 2 fuels are listed, one of the listed items is essentially redundant when comparing to cellulosic alcohols, it is, "Ethanol from straw/stover". Aviation fuel is not currently part of the LCFS, thus not analyzed in detail.

45. Comment: **PR-45**

The comment expresses concern about assumptions of spatial homogeneity implicit in the GREET model, citing the examples of wide variation in crop yields, agrochemical application rates, management practices and transportation distances.

Agency Response: Current practice is to use national average parameters in modeling agricultural phase emissions. verification of

[65] See http://www.arb.ca.gov/cc/ccs/ccs.htm

producer- or region-specific agricultural parameters might add costs and regulatory burden on pathway applicants. Applying standard assumptions about energy and material input quantities and crop yield incentivizes the use of crops with high productivity or low-input intensity over incremental improvements in management. This approach also may obscure the advantage some regions have over others, but is advantageous in that it relieves the need for verification of each input.

46. Comment: **PR-46:**

The commenter concurs with the conclusions presented in the Staff Report on the use of the CA-GREET 2.0 model to estimate direct GHG impacts of the fuel pathway. The commenter suggests that, in the future, the model should be open to improvement, and adapt to new feedstocks such as sorghum and cellulosic residues.

Agency Response: Staff believes that for most fuel pathways, the fundamental way to estimate GHG emissions impacts of processes and energy use using the CA-GREET model is likely to remain the same. User defined input parameters are provided for each pathway to the extent possible. For those pathways with new technologies, processes, or unique feedstocks that require a more complex analysis, the Tier 2/Method 2B application process offers more flexibility to the applicant for defining new assumptions, pathway system boundaries, custom calculations, and incorporating new life cycle inventory data.

47. Comment: **PR-47**

The peer reviewer wants staff to acknowledge that iLUC emissions were identified by researchers and policymakers prior to ARB considering including such emissions in its regulatory framework.

Agency Response: ARB staff concurs with the peer reviewer that academics and scientists were the first to publish peer-reviewed articles highlighting GHG emissions attributable to indirect land use effects from biofuel expansion. The language in the ISOR on indirect effects was ARB's effort to highlight that, in consultation with academics at UC Berkeley and UC Davis; the agency recognized the need to consider such effects in the life cycle analysis of transportation fuels and applied this approach in a regulatory context.

48. Comment: **PR-48**

The peer reviewer suggests that GHG accounting should have considered land use change in addition to other sources of emissions leakage. In particular, new land converted and intensification (e.g., fertilizer use, more tillage, etc.) of existing land should be accounted.

Agency Response: The indirect land use change analysis conducted by ARB tries to capture the totality of effects related to increased biofuel production, including land conversion and intensification as referenced by the peer reviewer. However, there are model and data limitations that limit staff's ability to capture all indirect effects. ARB used a modified version of the GTAP model to estimate the effects related to increased demand for biofuels; land conversion in regions near and remote to meet the new demand for the feedstock. One of the effects of intensification -- increased GHG emissions from increased fertilizer use -- has not been included in the current analysis due to lack of detailed data for all crops and regions. Tillage is currently not included as a parameter of influence in the current analysis. These will be considered in future updates to the iLUC estimates. See also **LCFS 46-82**.

49. Comment: **PR-49**

The peer reviewer states that supply does not equal demand in all cases and cites the example of corn stover where potential supply could exceed demand.

Agency Response: The GTAP model is a general equilibrium model and is built on a framework that supply equals demand for all components in the model. The peer reviewer however, highlights the potential for supply of corn stalks to exceed the demand for this product. In the current version of the ARB GTAP model, corn stalks are not considered as a 'commodity' which could be traded or used in the global market. The model therefore does not explicitly apply the supply equals demand constraint for this commodity. The same may apply to other commodities that are outside the model's framework. One or more versions of GTAP (from Purdue University) utilize corn stover and other corn derived products for the production of cellulosic biofuels. In these versions, the supply equals demand constraints are applied.

50. Comment: **PR-50**

The peer reviewer states that ARB should account for intensification of crops due to increased demand to produce a feedstock (for biofuel production) and in addition consider other responses such as decreased livestock production (due to higher feed costs).

Agency Response: The indirect land use change analysis accounts for the production of feedstock in regions remote from where the original feedstock was diverted to produce the biofuel. The GTAP model does account for likely reductions in livestock directly resulting from increased prices for livestock feed. Changes in GHG emissions from changes in livestock have not been included in the current analysis due to lack of detailed data for many regions of the world. Increase in emissions from intensification has also not been included in the present analysis due to lack of detailed data by crop, AEZ, and region.

51. Comment: **PR-51**

The peer reviewer supports ARB's approach with using a simple averaging approach if appropriate information was not available to support weighted averages of iLUC values.

Agency Response: See response to **PR-25**.

52. Comment: **PR-52**

The peer reviewer would like ARB to model emissions related to cellulosic and jet fuels in the future.

Agency Response: ARB staff acknowledges comments by the peer reviewer related to the inclusion of iLUC analysis for cellulosic biofuels and also to consider including jet fuel under the LCFS regulation. ARB plans to modify the GTAP model with additional data to include the capability for modeling iLUC estimates for cellulosic biofuels. Currently, LCFS includes all transportation fuels except jet fuel. ARB has no concrete plan to add jet fuel into the regulatory framework.

53. Comment: **PR-53**

The peer reviewer does not fully agree with the statement that supply equals demand. A study is cited where reduction in timber harvest in one region is not completely met by production in other regions of the world.

Agency Response: The GTAP modeling framework is built on econometrics of supply and demand. When there is a local demand, in the absence of trade, local demand equals local supply. But with national and international trade, local demand is transmitted to other regions which can provide supply to meet the local demand. A primary reason for ARB to use the GTAP model to estimate iLUC effects is that changes in demand at the regional level for food crops to produce biofuels has the effect of transmitting the demand to other regions if economics favor the production in regions remote from the original region. There is also the possibility that prices may change the production or demand of a given commodity or feedstock under a new equilibrium. An example is forest products from the managed forests land cover in the model. In instances where prices of producing forest products far exceed the price for this commodity, the model limits the production of such products.

54. Comment**: PR-54**

The peer reviewer highlights the domino effect of increased feedstock production in the global marketplace and the need to account for intensification and changes in livestock production.

Agency Response: ARB used the GTAP model to account for all potential impacts from the additional production of biofuels. The 'domino' effect as suggested by the peer reviewer is what ARB intended to capture by using an economic model with global coverage for all sectors, industries, and regions. As indicated in responses to **PR-48**, **PR-50**, and **LCFS 46-82**, emissions attributable to intensification was not included due to lack of detailed data by crop and region. As indicated in response to **PR-50**, decreases in livestock due to increase in feed prices is one of the impacts considered in the current analysis. In the future, when detailed data become available, ARB will consider including these elements in the iLUC analysis.

55. Comment**: PR-55**

The peer reviewer requests that ARB highlight the fact that the GTAP model is widely used around the world in various forms.

Agency Response: ARB indicated in the 2009 ISOR that GTAP was selected as a model for use in the iLUC analysis primarily because it was widely used by over 6,000 experts. Though primarily used for evaluating and predicting impacts of econometric policies (e.g., subsidies, tariffs, etc.) in the early years after the model was developed, it is now being used to estimate impacts of various scenarios including impacts of climate change on the global economy.

56. Comment**: PR-56**

The peer reviewer would like ARB to model emissions related to cellulosic and jet fuels in the future.

Agency Response: See response to comment **PR-52**.

57. Comment**: PR-57**

The commenter would have preferred to have additional details related to the scenario runs (e.g., alternative yield responses).

Agency Response: ARB used a Monte Carlo framework to identify important parameters with the greatest impacts on outputs from the GTAP model. The scenario runs used different values for these critical parameters to generate the set of 30 scenario runs used for each biofuel.

58. Comment**: PR-58**

The reviewer states that ARB has reached the right conclusions relative to assumptions and input parameters in the two models. The two models are scientifically sound and include robust data. Here again, the commenter highlights the need to account for other effects such as changes in livestock production.

Agency Response: The GTAP model used by ARB included all relevant inputs and modeling elements to estimate indirect land use change emissions related to the production of food-derived biofuels. The modeling also included likely changes in livestock from changes in feed prices. GHG emissions from changes in livestock were however not considered for the current analysis due to lack of detailed data by type of livestock and region.

59. Comment: **PR-59:**

The commenter expressed confusion at the different references to the GREET model, and was not sure which one was being used, and whether all references implied the same life cycle analysis model.

Agency Response: The CA-GREET 2.0 model being proposed for adoption is the life cycle analysis (LCA) model to be used by ARB staff to determine the GHG emissions impacts and fuel CI under the

LCFS. This model is an upgrade to the CA-GREETv1.8b (December 2009) model presently authorized by the ARB to be utilized for LCA determinations of fuel pathways under the existing LCFS regulation. The CA-GREETv2.0 model was developed using the GREET1_2013 LCA model developed by Argonne National Laboratory (ANL) as a basis. ANL updates their GREET LCA model almost annually, and a newer version of the GREET model (GREET1_2014) has been released to the public. No reference was made in the Staff Report to this version of the GREET model developed by ANL (other than its release date), nor has any part of this model been an influence for the upgraded CA-GREETv2.0 model being proposed for adoption.

60. Comment: **PR-60:**

The commenter suggested staff may wish to elaborate on "Feedstock Production," to include fertilizer in the discussion of how direct GHG impacts are determined.

Agency Response: The mining of crude feedstock for the production of gasoline and diesel was cited as an example for feedstock production-related GHG emissions impacts.
This example was cited for petroleum transportation fuel production. The commenter is correct that some other pathways (for example, crop-based biofuels) may employ the use of agricultural inputs for Feedstock Production; these include fertilizers and pesticides for crops, as well as fossil fuel inputs for farming, harvesting, collection, and transportation equipment, or employ electricity inputs to power irrigation pumps, for example. All of these uses impact Feedstock Production, including the upstream energy expended to manufacture fertilizers, for example.

61. Comment: **PR-61**

The commenter states that there is redundancy in the discussion of the California version of the GREET model between pages 2 and 5.

Agency Response: ARB staff appreciates the commenter's suggestion that there is some redundancy in discussing CA-GREET, on pages 2-5 in the material provided to peer reviewers (and publicly available) titled, "Attachment 1 - Plain English Summary of Staff's Methodology In Calculating Fuel Carbon Intensities". Any redundancy is due to the inclusion of an introduction and overview prior to the specific explanation.

62. Comment: **PR-62**

The peer reviewer would prefer to state that diversion of food crops to produce biofuel creates unfulfilled demands in the food and fuel markets which creates a demand to replace the diverted food or feed.

Agency Response: We agree with the peer reviewer that diversion of food crop to producing biofuel leads to competition between food and fuel industries for the same feedstock. This leads to shortages in the market triggering a demand to produce additional feedstock either regionally or internationally. Land conversions (and corresponding GHG emissions) to produce the additional food crop are estimated by the iLUC analysis conducted by ARB staff.

63. Comment: **PR-63**

The peer reviewer states that land conversion can occur even in local regions. Pressure to produce additional feedstock could incent double-cropping or growing crop on abandoned lands. Increased emissions from fertilizer and other inputs however, have to be captured.

Agency Response: We recognize that indirect effects could occur in regions either regionally or remote from where the demand for additional feedstock is triggered. The iLUC analysis transmits effects either regionally or internationally driven by the economics of producing the feedstock.

ARB staff also acknowledges the peer reviewer's concerns related to increased emissions from changes in agricultural practices. Intensification is captured in the current analysis (double cropping is implicitly considered) but the effects of increased used of fertilizer has not been considered. For response to fallow land see responses to **LCFS 46-83** and for fertilizer emissions, see **LCFS 46-82**. These will be considered in future updates to the iLUC estimates.

See also responses to **PR-48**, **PR-50** and **PR-54**.

64. Comment: **PR-64**

The peer reviewer suggests ARB consider not only iLUC, but other indirect sources of emissions. The reviewer highlights the need to account for changes in emissions from intensification and changes in livestock production.

Agency Response: See response to **PR-48** and **PR-54**.

65. Comment: **PR-65**

The peer reviewer states that supply does not equal demand in all cases.

Agency Response: The GTAP model is a general equilibrium model and is built on a framework that supply equals demand for all components in the model. The modeling framework starts with a baseline equilibrium which when used to estimate land use changes related to increased biofuel production ensures that new demand for agricultural land is met with an equivalent supply of land (from forest or pasture land in the model).

In the current version of ARB's GTAP model, corn stover is not considered a 'commodity' which could be traded or used in the global market. The model therefore does not explicitly apply the supply equals demand constraint for this commodity. The same may apply to other commodities that are outside the model's framework. One or more versions of GTAP (from Purdue University) utilize corn stover and other corn derived products for the production of cellulosic biofuels. In these versions, the supply equals demand constraints are applied.

See also response to comment **PR-49**.

66. Comment: **PR-66**

The peer reviewer requests that the GTAP model include elements to account for emissions from intensification and irrigation.

Agency Response: ARB staff understands that accounting for increases in emissions from intensification is important. Although ARB accounted for yield increases from intensification, it did not account for increases in GHG emissions from the increased use of fertilizers. This was because of lack of detailed data on the use of fertilizers and other agricultural inputs by crop/AEZ/region. The current version of the model does account for changes in GHG emissions from changes in irrigated land across the world.

67. Comment: **PR-67**

The peer reviewer requests that ARB account for corn oil byproduct from corn ethanol production in the iLUC analysis.

Agency Response: The iLUC emissions were estimated for the period 2004-2010 when extracting corn oil from DDGS was not a significant part of the corn ethanol production process. Therefore, the effect of corn oil extraction was not important for the time period under consideration. However, ARB recognizes that since this is a practice adopted by several facilities (beyond 2013), the direct emissions calculated using the CA-GREET model include provisions to account for changes to existing processes by ethanol and other biofuel producers.

68. Comment: **PR-68**

The peer reviewer suggests that, in future updates, ARB may want to consider inclusion of double cropping effects and changes in land abandonment as reported in the Babcock study.

Agency Response: The Babcock study presents the land cover changes across the world resulting from the totality of all effects (i.e., population and economic growth, weather conditions, drought, flooding, reforestation, GHG reduction incentives for agriculture, etc.). In contrast, ARB's analysis estimates land cover changes attributable only to biofuel expansion. It would be challenging to match the two sets of results that use different modeling metrics. In the future, if appropriate modifications can be made to the GTAP model to estimate the effects of all global activities, it may allow for comparison of model outputs to the totality of observed changes in land cover. See also response to **LCFS 8-5**.

69. Comment: **PR-69**

The peer reviewer requests clarity on the modeling protocol description.

Agency Response: ARB staff agrees with the peer reviewer's commenter about clearly specifying the protocol used in the analysis. The modeling estimated impacts in the global economy in moving from an initial equilibrium to a final equilibrium.

70. Comment: **PR-70**

The peer reviewer commends ARB for including irrigated lands and water constraints in the model. Additionally, the peer reviewer wants ARB to set a cap to limit the expansion of irrigable land into marginal land.

Agency Response: ARB staff accounted for limitations in water availability to be a constraint in the expansion of irrigated land in the current analysis. The model in its current form does not include a feature to address maximum irrigable land as suggested by the commenter. In the future, such a feature could be considered in the modeling structure if there is available data to support the inclusion.

71. Comment: **PR-71**

The peer reviewer suggests that fuel production could exceed the federal RFS2 mandates.

Agency Response: ARB staff acknowledges comments by the peer reviewer related to the potential for production of biofuels above the production targets mandated by the Renewable Fuel Standard. ARB has adopted a market structure that is flexible enough to account for production beyond the imposed 'shock' to the transportation energy market. .

72. Comment: **PR-72**

The peer reviewer highlights the need to account for emissions related to increased inputs to boost crop yields. Additionally, the peer reviewer requests that ARB consider double-cropping effects and land abandonment as highlighted in the recent Babcock paper.

Agency Response: ARB staff understands that accounting for increases in emissions from intensification is important. Although ARB accounted for yield increases from intensification, it did not account for increases in GHG emissions from the increased use of fertilizers. See response to **LCFS 46-82** to address the fertilizer use.

For the comment related to the Babcock, see response to **LCFS 8-5**.

See also responses to comments **PR-66** and **PR-68**.

73. Comment: **PR-73**

The peer reviewer suggests that, in future work, ARB account for the decreased productivity of marginal land.

Agency Response: ARB staff acknowledges the peer reviewer's concern related to lower productivity of marginal land. For the current analysis, the Terrestrial Ecosystem Model (TEM) was used to estimate relative productivity of new land (including marginal land) that comes into crop production. In view of peer reviewer's comment, ARB will review literature and published reports and will consider refining the analysis in the future. At that time, ARB will consider limiting marginal land to production of only specific crops such as switchgrass.
