Assembly Bill 32 Environmental Justice Advisory Committee (EJAC)
DRAFT Recommendations to the California Air Resources Board (CARB) on the Low Carbon Fuel Standard Regulation Updates

Draft Version 2: August 28, 2023

Amended Language Highlighted Based on 8/25/2023 EJAC Discussion

At the August 25, 2023, EJAC meeting, the fourth item on the agenda is "Discussion on the Low Carbon Fuel Standard Panel and Provide EJAC Recommendations to CARB".

The draft EJAC resolution below supports the August 25th discussion in preparation for the joint EJAC/CARB Board meeting planned for September 14, 2023. EJAC recommendations are advisory in nature.

WHEREAS, the Low Carbon Fuel Standard (LCFS) has exacerbated and entrenched air, water, and odor pollution in communities most impacted by environmental injustices;

WHEREAS, The LCFS has worsened environmental injustice issues across the state, nation, and world by increasing and entrenching pollution on the frontlines of industrial agribusiness;

WHEREAS, California Air Resources Board (CARB) has the authority to regulate methane emissions from livestock as soon as January 1, 2024, pursuant to Health and Safety Code section 39730.7(b).

WHEREAS, the LCFS has exacerbated and entrenched harmful pollution in frontline oil refinery communities;

WHEREAS, the LCFS has exacerbated and entrenched harmful pollution from tailpipes by incentivizing combustion fuels;

WHEREAS, the LCFS has exacerbated and entrenched harmful pollution to global communities from deforestation and using food for fuels;

WHEREAS, the LCFS has exacerbated and entrenched harmful pollution in communities near and regions containing large dairies and other confined animal feeding operations by incentivizing the production, storage, and land application of wet manure;

WHEREAS, insofar as the LCFS reduces carbon emissions from the transportation sector, the provision of LCFS credits for carbon removal such as direct air capture eliminates the possibility of reducing commensurate carbon emissions and co-pollutant emissions from the transportation sector through the LCFS;

WHEREAS, insofar as CARB's goal for carbon removal is to be carbon negative, issuing LCFS credits for carbon removal such as direct air capture (DAC) ensures that it will not be carbon negative but rather offset continued burning of fossil fuels;

WHEREAS, the provision of LCFS credits for direct air capture harms frontline communities both directly with harms and risks from capturing and storing the carbon, and indirectly from displaced renewable deployment that could reduce emissions from fossil fuel power plants, as well as from foregone reductions in transportation sector emissions;

Therefore, be it resolved that the EJAC recommends that the CARB board direct staff to address the above risks, threats, and harms to environmental justice communities by incorporating the following changes, referenced throughout as the "Comprehensive EJ Scenario" into the Low Carbon Fuel Standard through the current rulemaking:

001.1
1. Conduct and incorporate a full life cycle assessment of all air pollution and greenhouse gas (GHG) emissions for all pathways, and their implications for environmental justice communities.
2. Conduct a full accounting of GHG and air pollution emissions associated with pathways relying on the production of fuel from livestock and dairy manure. 001.2
3. 001.3 Eliminate avoided methane credits effective January 1, 2024.
4. Eliminate credit generation for pathways relying on the production of fuel from livestock and dairy manure for emissions reductions that otherwise would have occurred or were legally or contractually required to occur. 001.4
5. 001.5 Cap the use of lipid biofuels at 2020 levels pending an updated risk assessment to determine phase out timelines for high-risk, crop-based feedstocks.
6. Prohibit enhanced oil recovery as an eligible sequestration method. 001.6
7. 001.7 Do not issue LCFS credits for carbon removal projects such as Direct Air Capture.
8. Consider the inclusion of intrastate jet fuel and marine fuels as a deficit generator and provide analysis of this option as part of the LCFS. 001.8

001.9 Be it further resolved that the EJAC recommends that CARB formally consider the Comprehensive EJ Scenario as a regulatory alternative in the LCFS rulemaking process.

Be it further resolved that the EJAC recommends that CARB reform the LCFS to strengthen the Low Carbon Fuel Standard's support for zero emission vehicles including mass transit vehicles, drayage duty trucks, and heavy duty trucks. 001.10

001.11 Be it further resolved that the EJAC recommends that CARB immediately initiate formal rulemaking for the regulation of livestock methane pursuant to Health and Safety Code section 39730.7(b).

Subject	Bring the LCFS in Line with State Goals

Comment

Dear California Air Resources Board,

I am writing to point out what a lost opportunity it would be to adopt the proposed amendments to California's Low Carbon Fuel Standard, thereby continuing to subsidize the use of combustion fuels when the public is calling for zero-emission transportation systems and the earth is crying out for an end to carbon pollutior

Historically, every year, California has spent 80% of the Low Carbon Fuel Standard's three- to four-billion dollars on combustic technology. This money should be spent, instead, on non-combustior technologies, to speed the state's transition to a zero-emissions future.

002.1 California cannot meet its clean air and climate goals without bringing the Low Carbon Fuel Standard's several billion-dollar program in line with those goals.

I trust, therefore, that you will reject the proposed amendments and overhaul the program accordingly.

Thank you for your serious consideration of my comments.

Sincerely,
Mary Ames
30657 Sky Terrace Dr Temecula, CA 92592-3257

Subject	Low Carbon Fuel Standard is the goal and a necessity

Comment

Dear California Air Resources Board,

I am a high risk asthmatic. This means that I read the quality oi the air daily, several times a day, in some circumstances, to determine the quality of the air in order to plan whether I am abl to exercise outside that day .

I am not alone. There are many like me in this city, country, world.

You have a role and responsibilities to further proposals that could impact me and the millions of others who have compromised breathing because of air quality. Subsiding and supporting combustible fuels is not a compatible strategy that will meet these goals for clear air.

003.1

Stick with the plan. Make air quality standards the priority at any and all turns.

Make wise and ecological decisions and stop wavering and thinking that it is something that can be negotiated. Breathing is not a negotiable issue.

Sincerely,
paula levine
SUSSEX St San Francisco, CA 94131

Subject	Proposed changes to LCFS

Comment

Please stop making it harder and harder to operate a business in California. Every year there is a new fee or in the case here, additional costs and less credits for doing the right things (e.g operating electric equipment at my facility).

I am opposed to reduction in number of credits generated by e-forklifts for the reasons below:

004.1

- Unlike other EVs, most forklifts do not have energy measurement devices, making this an additional expense in hardware as well as resources to implement
- The reduction of credit generation will make it difficult to finance implementation the required metering.
- I Recommend leaving the current credit generation or evaluating ways to temper the reduction
- These changes make it more difficult for smalle operations to participate as the cost of metering cannot be split across as many forklifts as larger operations
- Implementation of metering:

004.2

- More time needed for implementation: The time needed to evaluate appropriate solutions relative to specific flee (e.g. charger frequencies) and operating conditions (i.e. cold storage) and cost-effectiveness relative to estimated revenue.
- If more time is not allowed, there may be month or up to a year that we are not able to participate in this program, which is a dramatic change rather than the more typical phased-in approach used by CARB to avoid volatile impacts on businesses.

004.3

- Recommend extending estimation method for several quarters to give industry opportunity to adapt.

Regards,
Yasser Jaber

Subject	LCFS Pricing
Comment	What is CARB doing to support their mandates and make it financially possible for companies by increasing the price and demand for LCFS credits? It is clear you want cleaner air, but at current LCFS pricing it does not support this initiative. Something needs to be done fast this year to improve the prices.

Comment

Dear Carb,
I encourage you to give a constant look to the California Low Carbon Fuel Standard Credit price in order to make them economic viable for long term investments in the sector.

Current price (mid January 2024) is around 65 USD/ton and it is nc feasible for planning long term investments that also contribute : a better environment in California and worldwide.

In my opinion, you should make sure to regulate the sector and tal actions to make sure that California Low Carbon Fuel Standard
006.1 Credit price can be constantly above the 200 USD/ton threshold anc possibly hit 300 USD/ton to boost investments in the sector and make California a better environment.

I really hope immediate actions to get those results and see a spike in the Credit starting from January 2024

Regards,
Massimo Fiorella

Subject	Transportation vs Food

Comment

One issue of concern has been the use of food crops for transportation fuel - specifically the use of soy beans for renewable diesel. While we love the increased use of R99 in boat trucks and generators I was thinking back to the problems attributed to the corn ethanol industry and its impact on food co prices.
https://www.farmaid.org/blog/askfarmaid/does-corn-and-ethanol-eff

To understand this issue I contacted Professor Aaron Smith, PhD, the Ag Econ Department at the University of California, Davis. From him I learned that the soy beans produce both oil and meal, where the meal is used for animal feed - primarily chickens in th US and hogs in China. Historically on the commodity market the prices of oil and meal moved together depending on the crop suppl each year; however a few years ago the prices unlinked because of the demand for the oil increased more than the demand for soy mea Today while oil makes ups 20% of the weight it provides 40% of t value for a crop of soy beans.

Going forward, in reaction to the higher demand and higher price oil we would expect to see more soy beans planted. This will also increase the supply of soy meal, without a corresponding increase in demand. The net result could be lower prices for soy meal that goes to feed chickens in the US.
Contrary to the problems caused by ethanol, the move to soy-base renewable diesel could also benefit farmers who buy soy meal for feed.

California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

As a renewable fuel producer and participant in CARB's LCFS program, my team and I value the partnership and mission shared with you and your state to reduce the carbon intensity of transportation fuels.

I am writing to share our company's perspective on two key program areas for your consideration. These requests address the topics of **firm rotation** and **less intensive verification**.

Firm Rotation

The existing regulations within the LCFS verification program stipulate a mandatory rotation of audit firms every six years to assess participants' carbon intensity (CI) and fuel quantities compliance.

Our request is that CARB amend the mandatory firm rotation regulation to include an exception for licensed CPA firms. Of the 30 approved LCFS verification bodies, there are only four licensed CPA firms.

> ***An approved verification body, that is also a licensed CPA firm, exceeds the standards in place for verification bodies and is already subject to***
> 008.1 ***additional oversight on the entity's quality control system in accounting and auditing practices through the required AICPA peer review process.***
>
> ***Due to the increased regulatory oversight, we suggest a CPA firm not be subject to the audit firm rotation but would instead adhere to a Lead Verifier rotation after six consecutive years.***

A licensed CPA firm differs from other consulting agencies by adhering to more rigorous standards and oversight at a state and national level. If a verification body were to violate a Lead Verifier rotation requirement, it would put the firm license at risk. The firm

license is required for all services provided by the firm, not just the LCFS verification services, thereby ensuring adherence to requirements.

Licensed CPA firm requirements

- A licensed CPA firm must be comprised of over 50% of the ownership being licensed CPAs.
    - To earn the accreditation to be a CPA, one must pass a rigorous four-part CPA exam, accumulate education hours, and in many states, one must fulfill 1-2 years of work experience.

- 3-year peer review audit
    - Each licensed CPA firm must enroll in an approved peer review program with reviews conducted every 3 years. The peer review requirement is a requirement of the American Institute of Certified Public Accountants (AICPA) and is an external review of a firm's quality control system in accounting and auditing practices. CPA firms' peer review results can be found on AICPA's website under the Peer Review Public File Search.

- State Boards of Accountancy (SBOA) are found in each state's statute to aid state governments in the licensing and regulation of the public accounting profession.
    - SBOAs provide further oversight on CPA firms by evaluating CPA licensees' examinations and regulatory oversight to ensure a firm is practicing within their statutory scope.

The audit quality and efficiency improve as the auditor becomes more familiar with our company's processes. In addition, with the limited number of firms available as verification bodies and a five-year lookback period in place, it is proving difficult to identify a quality verification body that is not also working with our facility in other consulting capacities. The number of people available with the proper expertise to assist us in design and development of projects and to reserve for verification purposes has proven even more limiting, which is also why we request a Lead Verifier rotation rather than a full firm rotation.

Less Intensive Verification

Regarding less intensive verification, we noted in Appendix E staff's proposal for less intensive verifications for when electricity is used as a transportation fuel, allowing verification bodies to skip site visits if they visited the site in the last two years and issued a positive verification statement.

The rationale for this proposed change states, "there is little change of operation from reporting period to reporting period thus reducing the benefit of annual site visits." Additionally, staff rationale states, "There is no or little risk to the integrity of the LCFS program to allow for less intensive verification services without a site visit in the annual verifications for the following two years. This should reduce the cost of verification services which is often passed on to program participants."

Currently, the proposed language limits this allowance for less intensive verifications to QFTR third-party verification bodies for fuel reporting entities only reporting electricity transactions.

008.2 We agree with the staff's stated rationale, but **we request for less intensive verification to be extended as an option for verification bodies on all validations and annual verifications for any reporting entities**.

In CARB's MRR program (section 95130), less intensive verification is applied without prejudice to verification services by accredited verification bodies.

We agree with staff that less intensive verification leads to little to no risk to the integrity of the LCFS program and that there is little change in operation from reporting period to reporting period, while also providing cost savings to verification providers and passed on to our company as program participants.

We acknowledge the importance of adhering to CARB's specified conditions that necessitate comprehensive verification services. These conditions include the issuance of an adverse verification statement or a qualified positive verification statement in the preceding year and the occurrence of a change in operational control of the reporting entity in the previous year.

Thank you for your time and consideration. Please reach out to us if you have any questions.

Sincerely,

Doug Sommer

January 30, 2024

California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

Christianson PLLP is a full-service public accounting firm located in Willmar, Minnesota and has worked with renewable fuels producers for over 30 years, providing technical assistance and professional services that promote industry compliance.

We are honored to be the chosen and trusted fuel pathway verification body for several biofuel producers across our nation that participate in CARB's LCFS program.

We are writing to share our perspective on two key program areas for your consideration. These requests address the topics of **firm rotation** and **less intensive verification**.

Firm Rotation

The existing regulations within the LCFS verification program stipulate a mandatory rotation of audit firms every six years to assess participants' carbon intensity (CI) and fuel quantities compliance.

Our request is that CARB amend the mandatory firm rotation regulation to include an exception for licensed CPA firms. Of the 30 approved LCFS verification bodies, there are only four licensed CPA firms.

009.1

> ***An approved verification body, that is also a licensed CPA firm, exceeds the standards in place for verification bodies and is already subject to additional oversight on the entity's quality control system in accounting and auditing practices through the required AICPA peer review process.***
>
> ***Due to the increased regulatory oversight, we suggest a CPA firm not be subject to the audit firm rotation but would instead adhere to a Lead Verifier rotation after six consecutive years.***

A licensed CPA firm differs from other consulting agencies by adhering to more rigorous standards and oversight at a state and national level. If a verification body were to violate a Lead Verifier rotation requirement, it would put the firm license at risk. The firm license is required for all services provided by the firm, not just the LCFS verification services, thereby ensuring adherence to requirements.

Licensed CPA firm requirements

- A licensed CPA firm must be comprised of over 50% of the ownership being licensed CPAs.
    - To earn the accreditation to be a CPA, one must pass a rigorous four-part CPA exam, accumulate education hours, and in many states, one must fulfill 1-2 years of work experience.

- 3-year peer review audit
    - Each licensed CPA firm must enroll in an approved peer review program with reviews conducted every 3 years. The peer review requirement is a requirement of the American Institute of Certified Public Accountants (AICPA) and is an external review of a firm's quality control system in accounting and auditing practices. CPA firms' peer review results can be found on AICPA's website under the Peer Review Public File Search.

- State Boards of Accountancy (SBOA) are found in each state's statute to aid state governments in the licensing and regulation of the public accounting profession.
    - SBOAs provide further oversight on CPA firms by evaluating CPA licensees' examinations and regulatory oversight to ensure a firm is practicing within their statutory scope.

In addition to the information noted above, we can also note that through the first three years of the LCFS program, familiarity and efficiency have been gained, allowing us to find and resolve additional issues in reporting.

In the first year, extensive time is spent understanding the company's processes, controls around the processes, software and methodologies around fuel pathway reporting. While comprehending these aspects and pinpointing significant overarching issues or addressing numerous items during a company's initiation into the program, there is a possibility that additional issues might go unnoticed in the initial year of reporting.

The audit quality and efficiency improve as the auditor becomes more familiar with the client and their processes. Upon resolution of the major items, the auditor can redirect their time and energy towards other areas, thereby uncovering additional issues that might have been overlooked in the initial year of review.

Less Intensive Verification

Regarding less intensive verification, we noted in Appendix E staff's proposal for less intensive verifications for when electricity is used as a transportation fuel, allowing verification bodies to skip site visits if they visited the site in the last two years and issued a positive verification statement.

The rationale for this proposed change states, "there is little change of operation from reporting period to reporting period thus reducing the benefit of annual site visits." Additionally, staff rationale states, "There is no or little risk to the integrity of the LCFS program to allow for less intensive verification services without a site visit in the annual verifications for the following two years. This should reduce the cost of verification services which is often passed on to program participants."

Currently, the proposed language limits this allowance for less intensive verifications to QFTR third-party verification bodies for fuel reporting entities only reporting electricity transactions.

009.2 We agree with the staff's stated rationale, but **we request for less intensive verification to be extended as an option for verification bodies on all validations and annual verifications for any reporting entities.**

In CARB's MRR program (section 95130), less intensive verification is applied without prejudice to verification services by accredited verification bodies.

We agree with staff that less intensive verification leads to little to no risk to the integrity of the LCFS program and that there is little change in operation from reporting period to reporting period, while also providing cost savings to verification providers and passed on to program participants.

We acknowledge the importance of adhering to CARB's specified conditions that necessitate comprehensive verification services. These conditions include the issuance of an adverse verification statement or a qualified positive verification statement in the preceding year and the occurrence of a change in operational control of the reporting entity in the previous year.

In addition to the cost-savings rationale mentioned in Appendix E, allowing for less intensive verification reduces the amount of greenhouse gas emissions from traveling to site visits for our many clients spread out throughout the country. In 2023, our team traveled 21,818 miles solely via passenger vehicles, with supplementary air travel to personally visit a portion of our client base. Through less intensive verification, this is an easy way to reduce carbon emissions while maintaining the program's integrity.

We at Christianson PLLP thank you for your time and consideration. Please reach out to us if you have any questions.

Sincerely,

Kari Buttenhoff, CPA

Comments on the Proposed Low Carbon Fuel Standard Amendments Related to the Reduction of EER Ratio for Forklift Trucks with <12,000 lbs Lift Capacity

010.1 In response to CARB's proposed Low Carbon Fuel Standard Amendments, we would like to submit our strongest opposition to the reduction of EER Ratio for Forklift Trucks with <12,000lbs Lift Capacity by 50%, down to 1.9 from the current value of 3.8.

CARB is also mandating the use of metering to meter the credits for forklift trucks. Note that reducing the EER ratio by 50% reduces the number of credits generated by two-thirds, or 67%. When the two are combined, i.e., reducing EER to 1.9 and metering the electricity dispensed for forklifts, the total number of credits per forklift truck will be reduced by >90%. In fact, this is evident from CARB's projected published CATs model output file for 2025, where the LCFS credits generated by forklifts in 2025 are projected at 174,459 credits, dropping from a peak of 1.882 million LCFS credits in 2023, a 92.7% reduction in the number of credits.

This proposed reduction in EER is an attempt to allow forklift trucks to earn credits. However, its impact will prevent most participants from being able to claim any credits under the program. The cost of the added metering requirements and the major reduction in the number of credits that can be generated will make it uneconomical for most users to remain or opt into the program. This is especially the case for smaller and medium-sized operators of forklifts. In essence, CARB is actually phasing out forklifts with lift capacity <12,000 lbs, one of the first proposals they proposed.

010.2 One of the justifications that CARB has given in the statement of reasons is that many of the forklifts have successfully transitioned to zero-emission technology, which is widely available. Yet, CARB doesn't seem to have a standard to apply across the board when a certain pathway or technology has successfully transitioned to low/zero-emission or becomes widely available. For example, biodiesel and renewable diesel are also becoming widely available, and the share of biodiesel and renewable diesel in the diesel mix has exceeded 57%. Yet, CARB has not placed any limits on these two fuel alternatives. In fact, biodiesel and renewable diesel have negatively impacted LCFS credit prices to the point where many technologies are no longer feasible and can no longer benefit from the LCFS program.

Given the above facts, we strongly oppose reducing the EER ratio for forklifts with lift capacities <12,000 lbs. Reducing the EER ratio is a death sentence to forklift truck LCFS crediting.

Respectfully.

January 30th, 2023

Comments on the Proposed Low Carbon Fuel Standard Amendments Related to CARB's CI Targets and the Proposed Ratcheting Mechanism

In response to CARB's proposed Low Carbon Fuel Standard Amendments, we would like to submit our opposition to the proposed ratcheting mechanism and the CI reduction schedules.

We have been investing heavily in deploying and financing EV fast chargers throughout California. To reduce the initial capital outlay by end users, we have developed a business model based on cost and revenue sharing, considering the projected charger use and the LCFS credit revenue that can be generated. However, the blow-up in the LCFS credit bank size and the significant drop in LCFS credit prices, down to the mid-50s, have greatly impacted our business model and eliminated our ability to finance future projects. How does CARB expect investors to invest in deploying new zero-emissions technologies if there is no way to ensure a minimum LCFS credit pricing and minimal returns?

The influx and unlimited supply of biodiesel and renewable diesel have destroyed the LCFS credit market. If no measures are placed, pricing and investors' confidence in the program will continue to erode. CARB will not, and cannot, meet any of its target CI reduction goals if no aggressive measures are adopted.

The proposed LCFS amendments are supposed to drive stronger target reductions and greater investments in new technologies. However, it has had the opposite effect as the market has reacted very negatively to these amendments, where the LCFS credit prices have fallen sharply, down to ~$55 /MT. At these price levels, many technologies can't be funded.

CARB proposed a soft approach to tightening targets if prices are too low, which is not working and may never work as the time lag to implement any ratcheting is too long. Instead, we strongly believe that CARB should reverse its strategy and start with tighter targets and tighter policies that can result in the immediate recovery of credit prices, which can be loosened if the prices become too high. This is the only way to save the LCFS program and allow new technologies to be funded.

To shore up the falling LCFS credit prices, we strongly recommend that CARB place a cap on biofuels 011.1
011.2 and correct the oversized negative CI scores awarded to biogases. In addition, instead of raising the CI target by 5% in 2025, CARB should start by raising the 2024 CI target by 5%. CARB should also allow the ratcheting mechanism to be triggered annually while giving CARB the option to decide if ratcheting is 011.3
needed or not.

We are committed to helping California reach its target CI reduction goals and hope the board will push CARB to address the above concerns to ensure the success of the LCFS program.

Respectfully.
/s/

Subject	LCFS Regulation Feedback

Comment

The New LCFS Regulation was supposed to inspire the achievement of stronger target reductions; it has done the opposite. Prices are currently 55 USD/MT; many technologies at these prices cannot be funded. The market has reacted poorly to the AAM and step-down.

The approach ARB seems to have taken is allowing the legislation t tighten if prices are too weak. However, the problem with this is the time it takes for the results of tightening to manifest and market dynamics in between (many models predict we are going to have very low prices for the next few years, and most models lose their accuracy the farther out they try to predict because of changing market dynamics; one example is the underestimation of renewable diesel adoption).

An alternative approach is to start with very tight policies and
012.1 give ARB the option of loosening the legislation. this would look
like "We are triggering AAM twice today, but reserve the right to
use an Auto-Decelaration mechanism starting in 2028" for example.

Lastly, another recommended mechanism that can be employed is an
"ARB LCFS containment fund", this fund will have the power to buy
012.2 credits in the market when prices are low, and sell them when
prices are high. There would be a few other hurdles to work
through, but a fund like that would surely allow market prices to
converge faster, and would also help California reach its goals.

MOTIVE INFRASTRUCTURE SOLUTIONS

February 1, 2024

California Air Resources Board 1001 I Street
Sacramento, CA 95814

RE: CARB Proposed 2024 LCFS Amendments

In response to CARB's proposed Low Carbon Fuel Standard Amendments, we want to voice our concerns regarding the worsening level of LCFS credit prices and CARB's proposed ratcheting mechanism.

Motive Energy is a leading provider of energy management solutions, including solar energy systems, energy storage, and EV charging solutions. We are a leading installer of EV chargers (level 2 and level 3) throughout California. We have also financed many EV charger installations by leveraging the LCFS credits generated by these chargers. The program has been a win-win for both the state in meeting its CI reduction targets and end users who can reduce their initial capital investments.

However, the significant drop in LCFS credit prices has prevented us from financing further charger installations and is increasingly discouraging many end users from committing capital to charger installations. We have seen the credit prices collapse from the $200 level to ~$56 as of the last week of January 2024. CARB has not acted to provide any price support and has left many investors in deep red.

The proposed increase of the CI target in 2025 and the proposed ratcheting mechanism will not impact LCFS credit prices nor give investors or end users any confidence in the program.
The unlimited biodiesel and renewable diesel supply has destroyed the LCFS credit market. If no measures are put in place to cap the supply of biofuels, it will continue to erode pricing and investors' confidence in the program. CARB will not be able to meet any of its target CI reduction goals if no stringent measures are adopted.

While the proposed LCFS amendments are intended to drive stronger target reductions and greater
investments in new technologies, they have the opposite effect as the market reaction has been very
013.1 negative, where LCFS credit prices have fallen sharply (~$56 /MT). CARB's proposed amendments
include no actions to support LCFS credit prices in 2024. This will further increase the size of the
credit bank throughout 2024, which will further exacerbate the LCFS credit price. The proposed
increase in CI target by 5% in 2025 will do very little against an oversized credit bank to recover
credit prices. In addition, the proposed ratcheting mechanism will not be able to support the credit 013.2
prices due to the long time lag before it kicks in and its bi-annual triggering nature.

CARB should start with tighter targets and policies that can result in the immediate recovery of credit
prices. CARB can then loosen these targets if the prices become too high. Without that, new
technologies cannot be funded, and CARB will not be able to meet its goals. To that end, we
013.1 propose that CARB moves its 5% step up in CI target to 2024 and allow the ratcheting mechanism to 013.2
be triggered annually.

We are committed to helping California reach its target CI reduction goals, and we hope the board will push CARB to address our concerns to ensure the success of the LCFS program.

Respectfully.

January 31, 2024

California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

As a renewable fuel producer and participant in CARB's LCFS program, my team and I value the partnership and mission shared with you and your state to reduce the carbon intensity of transportation fuels.

I am writing to share our company's perspective on two key program areas for your consideration. These requests address the topics of **firm rotation** and **less intensive verification**.

Firm Rotation

The existing regulations within the LCFS verification program stipulate a mandatory rotation of audit firms every six years to assess participants' carbon intensity (CI) and fuel quantities compliance.

Our request is that CARB amend the mandatory firm rotation regulation to include an exception for licensed CPA firms. Of the 30 approved LCFS verification bodies, there are only four licensed CPA firms.

014.1 > ***An approved verification body, that is also a licensed CPA firm, exceeds the standards in place for verification bodies and is already subject to additional oversight on the entity's quality control system in accounting and auditing practices through the required AICPA peer review process.***
>
> ***Due to the increased regulatory oversight, we suggest a CPA firm not be subject to the audit firm rotation but would instead adhere to a Lead Verifier rotation after six consecutive years.***

A licensed CPA firm differs from other consulting agencies by adhering to more rigorous standards and oversight at a state and national level. If a verification body were to violate a Lead Verifier rotation requirement, it would put the firm license at risk. The firm license is required for all services provided by the firm, not just the LCFS verification services, thereby ensuring adherence to requirements.

Licensed CPA firm requirements

- A licensed CPA firm must be comprised of over 50% of the ownership being licensed CPAs.
    - To earn the accreditation to be a CPA, one must pass a rigorous four-part CPA exam, accumulate education hours, and in many states, one must fulfill 1-2 years of work experience.

- 3-year peer review audit
    - Each licensed CPA firm must enroll in an approved peer review program with reviews conducted every 3 years. The peer review requirement is a requirement of the American Institute of Certified Public Accountants (AICPA) and is an external review of a firm's quality control system in accounting and auditing practices. CPA firms' peer review results can be found on AICPA's website under the Peer Review Public File Search.

- State Boards of Accountancy (SBOA) are found in each state's statute to aid state governments in the licensing and regulation of the public accounting profession.
    - SBOAs provide further oversight on CPA firms by evaluating CPA licensees' examinations and regulatory oversight to ensure a firm is practicing within their statutory scope.

The audit quality and efficiency improve as the auditor becomes more familiar with our company's processes. In addition, with the limited number of firms available as verification bodies and a five-year lookback period in place, it is proving difficult to identify a quality verification body that is not also working with our facility in other consulting capacities. The number of people available with the proper expertise to assist us in design and development of projects and to reserve for verification purposes has proven even more limiting, which is also why we request a Lead Verifier rotation rather than a full firm rotation.

Less Intensive Verification

Regarding less intensive verification, we noted in Appendix E staff's proposal for less intensive verifications for when electricity is used as a transportation fuel, allowing verification bodies to skip site visits if they visited the site in the last two years and issued a positive verification statement.

The rationale for this proposed change states, “there is little change of operation from reporting period to reporting period thus reducing the benefit of annual site visits.” Additionally, staff rationale states, “There is no or little risk to the integrity of the LCFS program to allow for less intensive verification services without a site visit in the annual verifications for the following two years. This should reduce the cost of verification services which is often passed on to program participants.”

Currently, the proposed language limits this allowance for less intensive verifications to QFTR third-party verification bodies for fuel reporting entities only reporting electricity transactions.

014.2 We agree with the staff’s stated rationale, but **we request for less intensive verification to be extended as an option for verification bodies on all validations and annual verifications for any reporting entities.**

In CARB’s MRR program (section 95130), less intensive verification is applied without prejudice to verification services by accredited verification bodies.

We agree with staff that less intensive verification leads to little to no risk to the integrity of the LCFS program and that there is little change in operation from reporting period to reporting period, while also providing cost savings to verification providers and passed on to our company as program participants.

We acknowledge the importance of adhering to CARB’s specified conditions that necessitate comprehensive verification services. These conditions include the issuance of an adverse verification statement or a qualified positive verification statement in the preceding year and the occurrence of a change in operational control of the reporting entity in the previous year.

Thank you for your time and consideration. Please reach out to us if you have any questions.

Sincerely,

Chris Stowe

Subject	Cap vegetable oil-based fuels eligible for the LCFS
Comment	I encourage the Board to include a strong cap on vegetable oil-based fuels eligible for the LCFS to help strengthen and stabilize California's LCFS. This should be done in conjunction with and in addition to proposed chain of custody tracking requirements for virgin vegetable-based oils. This will have the added benefit of combatting greenwashing claims due to the climat[e] and land use impacts from rapidly increasing use of vegetable-bas[ed] oil feedstocks.

Subject	Proposed reduction of credits for forklifts

Comment

Dear CARB,
We are very concerned about your proposed changes to the LCFS Program.

016.1 We oppose the proposed reduction in credits generated by e-forklifts. Unlike other EV's, our forklifts do not have energy measurement devices. We would be faced with the additional expense of purchase and installation of such devices.

LCFS Credit reduction will make it more difficult for our small family-owned business to purchase and install meters to continue t participate in this program. We are not as capable of installing measurement devices as other large companies nor do we have the number of forklifts over which to spread the costs of such device: Our rural location leads to additional risk in the implementatior of metering due to issues with internet connectivity.

016.2 If one or both of these proposed changes must be implemented, please allow us a minimum of 2 years before adoption. This time will allow us to evaluate and install the necessary equipment.

Please maintain the current level of credits and do not impose metering requirements so that operations like ours can continue to phase out the use of internal combustion forklifts and adopt the use of electric units.

Thank you,
Mike Noland

Subject	SUBJECT: California Air Resources Board (CARB): Low Carbon Fuel Standar Elimination of

Comment

February 5, 2024

California Air Resources Board
1001 Street
Sacramento, CA, 95814

SUBJECT: California Air Resources Board (CARB): Low Carbon Fuel Standards: Elimination of Intrastate Fossil Jet Fuel Exemption - OPPOSE

Dear Members of the California Air Resources Board,

The Valley Industry & Commerce Association (VICA) asserts its opposition to the proposed elimination of the Low Carbon Fuel Standard (LCFS) exemption for intrastate fossil jet fuel. We firml
017.1 believe that the current proposal, if implemented, would fall shor of achieving its intended goal to increase Sustainable Aviation Fuel (SAF) production and mitigating greenhouse gas emissions, while inevitably leading to significant economic burdens on the aviation industry, travelers, and consumers.

VICA recognizes the aviation industry's commitment to voluntarily using cleaner alternatives in aviation fuel, as exemplified by the production of over 11.6 million gallons of Alternative Jet Fuel in 2022, working in alignment with California's environmental objectives to reduce greenhouse gas emissions. However, VICA contends that the proposed CARB regulation faces critical challenges to its feasibility that would, ultimately, undermine it core objective of enhancing SAF and Alternative Jet Fuel (AJF) utilization.

A core issue is the limits on AJF or SAF production. While SAF is being developed and provided, the technological landscape currentl would not align with CARB's stringent requirements, as there is currently a shortage of producers capable of meeting the demand fo AJF and SAF. Technological limitations would also impede the industry's ability to scale up AJF and SAF production to meet proposed standards; therefore, imposing such regulations would be premature, undoubtedly harming the industry and leading to adverse consequences for the broader economy.

The anticipated escalation of costs for the aviation industry resulting from this CARB ruling would not only impact aviation providers, but also directly affect travelers in the form of substantial airfare and fee hikes. These economic burdens would impede the movement of travelers while increasing the cost for the shipment of goods and products, resulting in increased costs for individuals, families, and businesses.

Considering these substantial concerns, VICA strongly urges CARB to
reconsider the proposed LCFS exemption elimination and instead
focus on a collaborative approach with the aviation community that
017.1 allows for necessary technological advancements and infrastructure
development before stringent regulations are considered. This
approach would ensure a seamless transition to cleaner aviation
fuels without compromising our economic stability.

For these reasons, we staunchly oppose the proposed ruling.

Sincerely,

Stuart Waldman
VICA President

EARTHJUSTICE

<u>VIA</u>: ELECTRONIC MAIL ONLY

February 5, 2024

Chair Liane Randolph and
Members of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814
cotb@arb.ca.gov

Re: Low Carbon Fuel Standard – Suggested Process for Rule Adoption

Dear Chair Randolph and Members of the Board:

Earthjustice respectfully requests that the California Air Resources Board (CARB) hold the March 21, 2024 meeting on the Low Carbon Fuel Standard (LCFS) as a non-voting item and bring back a final proposal for the Board to vote in July of this year. We do not make this request lightly. In rulemaking after rulemaking, we have opposed stakeholder efforts to delay life-saving regulations, particularly the landmark zero-emissions regulations like the Advanced Clean Fleets Rule and the Locomotive Rule. Here, however, the Board should measure twice and cut once, instead of barreling forward with a proposal that, as we explain below, lacks sufficient Board input. Importantly, this amendment process, which proposes targets through 2045, comes at an inflection point as California leaves polluting fuels behind and moves toward a zero-emission transportation system. CARB must get the policies right in this update to ensure that the LCFS both supports California's Zero Emission Vehicle (ZEV) goals through the tens of billions of investment dollars that flow through the program, and avoids exacerbating the State's environmental injustices. Below, we explain why holding a non-voting meeting in March and directing staff to come back in July with a revised proposal are necessary steps to achieving an LCFS that aligns with our zero-emission future. 018.1

I. The Board has not had a chance to weigh in on staff's proposal.

Most regulations heard by the Board include a non-voting Board meeting after the staff proposal is available. In September 2023, CARB staff held an informational meeting that provided a high-level summary of potential proposals. The proposed text was not released until December 2023, more than three months after the meeting. At the September meeting the Board provided initial reactions based on the limited information provided by staff at that time, and there are now additional issues where the Board should insist on providing feedback – especially since there is an actual proposal for review.

Earthjustice acknowledges that not all CARB regulations require two Board meetings. However, the norm for several years has been two meetings for major regulations. A one-meeting approach should not be tested on the LCFS, which is uniquely complex and wide-

CALIFORNIA OFFICE 707 WILSHIRE BLVD., SUITE 4300 LOS ANGELES, CA 90017

T: 415.217.2000 F: 213.403.4822 AMARTINEZ@EARTHJUSTICE.ORG WWW.EARTHJUSTICE.ORG

ranging, and poses profound environmental justice implications. Accordingly, it should be given adequate time for the Board to consider.

II. We request a reasonable opportunity to allow important conversations and a public workshop by staff to discuss recent changes.

The request to defer the vote to July would allow Board members to direct staff on the current proposal at a non-voting March meeting and allow staff to hold a public workshop on the significant changes made since past workshops and in accordance with additional Board direction at the non-voting meeting. This public engagement is crucial given the major implications of this program. 018.2

III. Staff made significant changes to the proposal from what was presented at public workshops and at the Board meeting, and only one of those changes was at the direction of the Board.

Staff have been conducting workshops on potential LCFS change concepts for three years. Yet, the proposal issued in December 2023 has many elements that differ significantly from what had been discussed publicly over this time period. Some of the significant changes include:

1. Inclusion of (inadequate) safeguards in response to Board direction on crop-based feedstocks that have not been publicly explained or vetted;
2. Backsliding on avoided methane policy from what was presented at multiple workshops and which runs *counter* to the Board's expressed concerns in September of 2023;
3. Changes to the automatic acceleration mechanism from staff's initial proposal;
4. Easing of violation provisions not previously discussed publicly;
5. Allowing retroactive crediting for pathways that favors non-ZEV fuels not previously discussed publicly; and
6. Changes to the use of base credit funds not previously discussed publicly.

These are not minor matters related to the program design. Rather, they represent core issues that require more Board and public debate.

IV. Without a second Board meeting, Staff will need to make at least one 15-day change, which creates an extremely tight timeline for Board review.

The current proposal will necessarily need some changes because some issues are not fully clarified. Clarifications and other changes will require staff to issue a 15-day change. If CARB staff are requesting Board approval on March 22, 2024, Earthjustice estimates the timeline as follows:

- **February 20:** Public comment period closes.
- **March 5:** Last business day for staff to post a 15-day change, assuming these materials do not need additional changes before a Board vote.
- **March 19:** Public comment period on changes closes.

- **March 21:** Board hearing and public comments. Staff must respond to any new environmental issues raised in oral or written comments before the Board vote. Staff would not be required to respond to non-environmental assessment comments prior to the Board vote.
- **March 22:** Board vote.

Under this rubric, there would not be adequate time between the March 19 close of comment on the 15-day changes and the March 22 vote for staff or the Board to review public comments or for the Board to provide direction to Staff.

Thus, the Board would be asked to vote on text released less than three months prior that differs from what was discussed publicly for many years and will guide investment decisions and climate and air quality results for decades. The Board must be given more time to consider such a consequential set of changes to this important program.

V. Providing 3-4 months of additional time for debate and input will not impede the rulemaking process.

The Office of Administrative Law (OAL) published the Notice of Proposed Action in the California Regulatory Notice Register on January 5, 2024. Per OAL, a "state agency must complete its rulemaking and submit the rulemaking file to OAL within one year of the date of publication of a Notice of Proposed Action ("Notice") in the Notice Register." A delay of 3-4 months should not affect staff's ability to complete the rulemaking, while giving time to the public and the Board to carefully consider the proposed changes.

VI. An additional 3-4 months will keep CARB on track for a 2025 implementation date, consistent with the current proposal for updating the carbon intensity benchmarks.

The current proposal includes an update to the carbon intensity benchmarks starting in 2025. The request to delay a vote by 3-4 months would **<u>not affect this timeline</u>**. Earthjustice approximates a revised timeline as:

- **March 21:** Board direction to staff on critical issues.
- **May:** Staff hold a public workshop to discuss proposed changes.
- **June:** Staff issue a 15-day change.
- **July:** Board vote.

VII. More time is needed to address EJAC recommendations and concerns.

In 2022, Chair Randolph committed to establish a permanent Environmental Justice Advisory Committee (EJAC). CARB subsequently established a permanent EJAC in March 2023, with a mission of "advis[ing] the Board on environmental justice considerations, prioritizing racial equity, related to implementation of AB 32, via input to CARB on the Scoping Plan Updates and any other pertinent matter related to the implementation of AB 32."[1]

Since then, the EJAC has convened for numerous meetings, with many of these meetings including LCFS as an agenda item, indicating high interest in the regulation.[2] In August 2023, the EJAC presented a draft resolution to CARB, which recommended eight changes to the LCFS. Only one of these eight recommendations is partially included in the staff's proposal. The perceived lack of acknowledgment or consideration of their resolution could cast doubt on the sincerity of establishing the permanent EJAC. By providing more time for Board action, staff would have additional time to interact with the EJAC and consider their proposed changes.

VIII. The LCFS is complex, and most of the Board members are new and may benefit from more time to understand and weigh in on staff's proposals.

The LCFS is one of the most complex climate regulations, if not the most complex regulation, that the State implements. The regulation spans multiple sectors and has gotten more complicated with time. Other states look to the California LCFS as the gold standard and generally align with its policies, so the impact of policy decisions is far-reaching.[3] Since 2018, the last major update of the regulation, a majority of the Board is new.[4] Specifically, the following Board Members did not participate in the last LCFS amendment process:

- Board Member Cliff Rechtschaffen (appointed September 2023);
- Board Member Susan Shaheen, Ph.D. (appointed January 2023);
- Supervisor V. Manuel Perez (appointed January 2023);
- Senator Henry Stern (appointed January 2023);[5]
- Supervisor Eric Guerra (appointed January 2023);
- Supervisor Nora Vargas (appointed February 2022);
- Board Chair Liane Randolph (appointed December 2020);
- Council Member Davina Hunt (appointed December 2020);
- Tania Pacheco-Werner, Ph.D. (appointed December 2020); and
- Board Member Gideon Kracov (appointed December 2020).

Given that this will be the first time that 10 of 16 Board members hear a major update to the LCFS, there is benefit from more time to understand the program and the menu of policy options available to them.

[5] Ex-Officio member.

Earthjustice reiterates its request to include the LCFS at the March Board meeting as a non-voting item, allowing Board members to hear from both stakeholders and Staff in a common forum before providing policy direction. Earthjustice further requests that staff conduct a public workshop on proposed changes. Moreover, a voting Board meeting necessarily needs more time to allow adequate public process. Implementing these requests would not affect the start date of staff's proposal to adjust the benchmarks beginning in 2025.

We appreciate your consideration of this request. Please do not hesitate to reach out if you would like to discuss the content of this letter.

Sincerely,

Adrian Martinez
Deputy Managing Attorney

CC: Governor Newsom
Yana Garcia, Secretary for Environmental Protection
Dr. Steve Cliff

RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

As a renewable fuel producer and participant in CARB's LCFS program, my team and I value the partnership and mission shared with you and your state to reduce the carbon intensity of transportation fuels.

I am writing to share our company's perspective on two key program areas for your consideration. These requests address the topics of **firm rotation** and **less intensive verification**.

Firm Rotation

The existing regulations within the LCFS verification program stipulate a mandatory rotation of audit firms every six years to assess participants' carbon intensity (CI) and fuel quantities compliance.

Our request is that CARB amend the mandatory firm rotation regulation to include an exception for licensed CPA firms. Of the 30 approved LCFS verification bodies, there are only four licensed CPA firms.

019.1

> ***An approved verification body, that is also a licensed CPA firm, exceeds the standards in place for verification bodies and is already subject to additional oversight on the entity's quality control system in accounting and auditing practices through the required AICPA peer review process.***
>
> ***Due to the increased regulatory oversight, we suggest a CPA firm not be subject to the audit firm rotation but would instead adhere to a Lead Verifier rotation after six consecutive years.***

24500 US Highway 14
PO Box 96
Lamberton, MN 56152
Ph.: 507-752-6160
Toll Free: 888-MOREE85
Fax.: 507-752-6162
Email: info@highwaterethanol.com
www.highwaterethanol.com

A licensed CPA firm differs from other consulting agencies by adhering to more rigorous standards and oversight at a state and national level. If a verification body were to violate a Lead Verifier rotation requirement, it would put the firm license at risk. The firm license is required for all services provided by the firm, not just the LCFS verification services, thereby ensuring adherence to requirements.

Licensed CPA firm requirements

- A licensed CPA firm must be comprised of over 50% of the ownership being licensed CPAs.
    - To earn the accreditation to be a CPA, one must pass a rigorous four-part CPA exam, accumulate education hours, and in many states, one must fulfill 1-2 years of work experience.

- 3-year peer review audit
    - Each licensed CPA firm must enroll in an approved peer review program with reviews conducted every 3 years. The peer review requirement is a requirement of the American Institute of Certified Public Accountants (AICPA) and is an external review of a firm's quality control system in accounting and auditing practices. CPA firms' peer review results can be found on AICPA's website under the Peer Review Public File Search.

- State Boards of Accountancy (SBOA) are found in each state's statute to aid state governments in the licensing and regulation of the public accounting profession.
    - SBOAs provide further oversight on CPA firms by evaluating CPA licensees' examinations and regulatory oversight to ensure a firm is practicing within their statutory scope.

The audit quality and efficiency improve as the auditor becomes more familiar with our company's processes. In addition, with the limited number of firms available as verification bodies and a five-year lookback period in place, it is proving difficult to identify a quality verification body that is not also working with our facility in other consulting capacities. The number of people available with the proper expertise to assist us in design and development of projects and to reserve for verification purposes has proven even more limiting, which is also why we request a Lead Verifier rotation rather than a full firm rotation.

Less Intensive Verification

Regarding less intensive verification, we noted in Appendix E staff's proposal for less intensive verifications for when electricity is used as a transportation fuel, allowing verification bodies to skip site visits if they visited the site in the last two years and issued a positive verification statement.

The rationale for this proposed change states, "there is little change of operation from reporting period to reporting period thus reducing the benefit of annual site visits." Additionally, staff rationale states, "There is no or little risk to the integrity of the LCFS program to allow for less intensive verification services without a site visit in the annual verifications for the following two years. This should reduce the cost of verification services which is often passed on to program participants."

Currently, the proposed language limits this allowance for less intensive verifications to QFTR third-party verification bodies for fuel reporting entities only reporting electricity transactions.

019.2 We agree with the staff's stated rationale, but **we request for less intensive verification to be extended as an option for verification bodies on all validations and annual verifications for any reporting entities.**

In CARB's MRR program (section 95130), less intensive verification is applied without prejudice to verification services by accredited verification bodies.

We agree with staff that less intensive verification leads to little to no risk to the integrity of the LCFS program and that there is little change in operation from reporting period to reporting period, while also providing cost savings to verification providers and passed on to our company as program participants.

We acknowledge the importance of adhering to CARB's specified conditions that necessitate comprehensive verification services. These conditions include the issuance of an adverse verification statement or a qualified positive verification statement in the preceding year and the occurrence of a change in operational control of the reporting entity in the previous year.

Thank you for your time and consideration. Please reach out to us if you have any questions.

Sincerely,

Brian Kletscher

Subject	Consider Innovative Production Method Lowers CI >60%

Comment

We kindly request consideration of adding to CCR Section 95489(c)(1)(A), Chemistry Replace Steam, as an innovative production method. This will incentive crude producers to stop using steam to extract heavy oil, reducing emissions in California's most disadvantaged communities while reducing overall fossil fuel demand. 020.1

Approving this incentive could reduce oil extraction emissions millions tons of CO2e, eliminating 1 billion mcf of natural gas burned by 2035. Reducing the dirtiest oil's carbon intensity over 60%. California producers will deliver the cleanest crude to California refineries, reducing emissions, imports, costly refinery
upgrades all while supporting a cleaner transition.

The chemistry proposed is plant based, pH neutral and biodegradable. This is safer, cleaner and more expensive than steam. Which is why approval of this innovation is necessary to accomplish the mission of CCR Section 95489. All approved innovations in 95489(c)(1)(A) are aimed at reducing, replacing or eliminating burning natural gas, either for steam or electricity. Approved innovations are reducing around 55,000 tons CO2e per year.
Approving this innovation reduce millions of tons within the first
two years.

This chemistry has so many other applications than just oil and gas. The biggest opportunities in O&G are the dirtiest production methods, which is steam in California and Canada. Next would be heavier oils from Alaska North Slope.

This chemistry outside O&G is an all-natural firefighting suppression innovation, lower emissions in agriculture, water treatment, enhanced oil recovery, eliminating solvents and harmful cleaning products, soil remediation, and the opportunities keep growing.

Attached is how chemistry replaces steam, and an application for approval. The chemistry proposed is plant based, pH neutral and biodegradable, that is 13x lower carbon intensity than steaming.

> Thank you for your consideration for creating California's clean transition.

APPLICATION TO THE EXECUTIVE OFFICER FOR LCFS CREDITS

FOR USING INNOVATIVE METHODS FOR CRUDE PRODUCTION

OR AMEND §95849(c)(1)(A)

CYCLIC STEAM REPLACEMENT

CLEAN SURFACTANT ENERGY (CSE) PROJECT

RENEWABLE AND BIODEGRADABLE SURFACTANT

Site:

Thermal Heavy Oil Fields, California

See what chemistry reducing viscosity looks like in the following video:

[VIDEO]

EXECUTIVE SUMMARY

Respectfully, to the Executive Officer:

We apply for approval of a groundbreaking innovation in crude oil production—chemistry that replaces steam emissions and lowers the carbon intensity in California's thermal enhanced oil recovery ("TEOR") operations. Awarding credits for the CRSE process aligns perfectly with the innovative crude oil production credit provisions of Cal. Code of Regulations, Section 95489(c)(1)(A).

TEOR relies on steam injection to reduce oil's viscosity, improve mobility, and increase production rates. However, as thermal heavy oil fields deplete, the Carbon Intensity (CI) rises in proportion to the Steam Oil Ratio (SOR). The CRSE process employs chemistry to reduce oil viscosity, improve mobility, and increase production rates of clean incremental oil. Cyclic steam is the business-as-usual method to produce incremental oil. This proposed chemistry innovation could eventually replace all steam injection while delivering similar volume of oil without the emissions of current TEOR methods.

We are asking CARB to approve chemistry that replaces steam, as an innovative crude oil production method that is immediately scalable, sustainable and passes a cost-benefit analysis. The CRSE process enables Net Zero that is affordable, reliable and competitive. Decarbonizing goals require decarbonizing tools. Without approval, cyclic steam will continue polluting California's most vulnerable communities.

CARB can reasonably anticipate a reduction of over 30% in emissions associated with steam injection in TEOR projects. According to the OPGEE model, the carbon intensity of incremental oil from chemistry is 60-80% lower than steam.

Approving this method allows for chemistry to economically replace more than 2,600,000 tons of CO2 emitted per year from California's TEOR operations.

Using current natural gas prices, $5.12 per mcf, steam costs across California's largest TEOR fields are $12.18 per barrel of oil. The cost of chemistry is $15.00 per barrel of oil. Approval results in a $5.61 per barrel of oil incentive to TEOR producers in the project area to replace steam with chemistry. This ultimately could push emission reductions even higher than 30%.

Approving this "Chemistry Replacing Steam" category under the Innovative Crude Oil Production Methods rewards producers for reducing and replacing steam injection, resulting in lower emissions while maintaining normal decline rates. The result is cleaner oil delivered to California refineries, contributing to a lower-carbon future for California—a meaningful win-win. Lowering California's crude oil carbon intensity by more than 60% from 106 to 40 kg CO2e / barrel of oil.

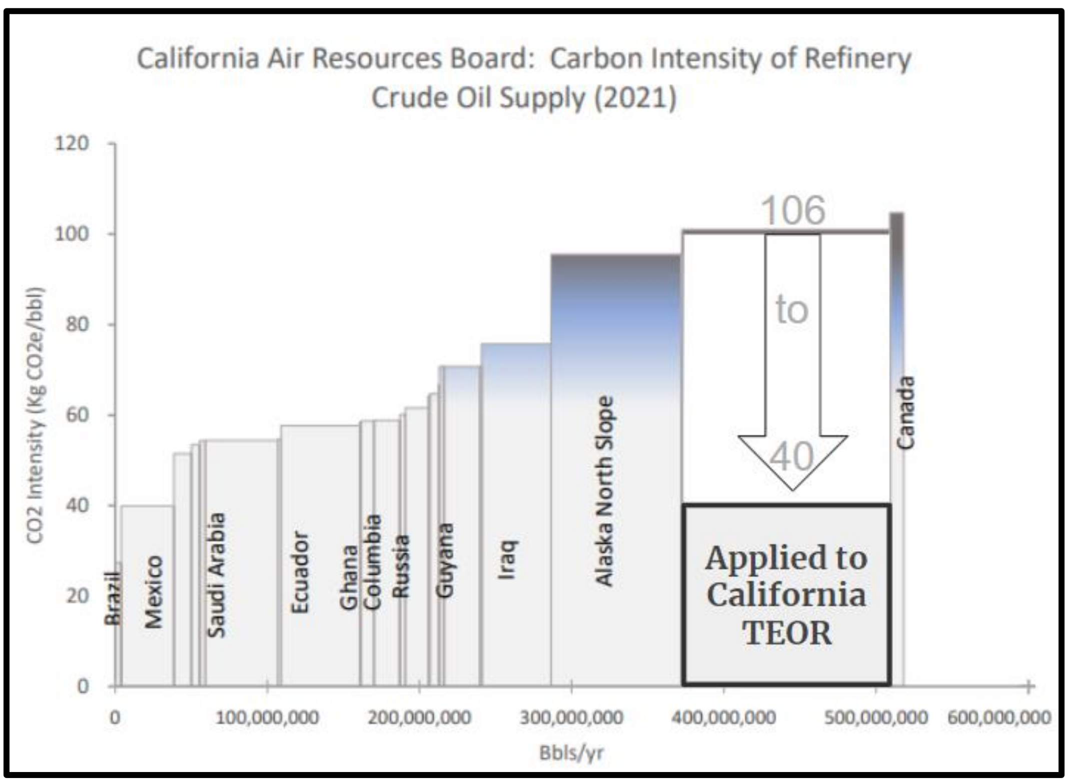

TABLE OF CONTENTS

LIST OF APPENDICES

APPLICATION TO THE EXECUTIVE OFFICER

I. Project Description: Chemistry Reduces Steam Emissions (CRSE).

The focus of this application is replacement of cyclic steam injection-- the method practiced in all California TEOR fields—with clean, safe chemistry to achieve the GHG reduction goals of this agency. The CRSE process enables CARB to play offense against climate change by rewarding oil companies for significant emission reductions.

The CRSE process is the stimulation of producing oil wells with a *nature-based,* pH neutral, renewable, and biodegradable proprietary formula surfactant that replaces steam. It is an advanced chemical and mechanical innovation that reduces emissions by 1) replacing steam, 2) lowering energy to lift oil, 3) reducing system friction, 4) improving downhole efficiency and 5) lowering heat required to separate heavy oil and water—resulting in a true low-carbon oil.

Unfortunately, since 2010, the CI of the largest heavy oil fields in California has increased 27%. Over the same period, only ten (10) Innovative Crude Method projects have been approved, collectively reducing no more than about 55,753 tons of CO2 per year (all solar electricity projects). In contrast, heavy oil-steam injection wells have injected 347.18 million barrels of steam through the first nine (9) months of 2023 to extract 52.18 million barrels of oil, giving a weighted SOR of 6.78 for the 9 largest TEOR fields in California, Table I.

Table I. 2023 Forecast of California's Largest Heavy Oil Field.

Field	Steam[1]	Oil[2]	SOR'23	County

2 - CALGEM All Well Types				
Waterflood oil and potential steam classified under another well type				

CalGEM 2023 first 9 months steam/water volume injected, and oil produced. There is not a good way to separate steam from water injected and the associated oil. Attempted to be as conservative with the average SOR.

Source: California Department of Conservation: Well Production and Well Injection 2021-2023

Steam injection requires burning natural gas to heat fresh water that is injected underground into the heavy oil reservoirs. A barrel of steam emits approximately 23.677 kg CO2e. The SOR is the efficiency measurement of a field's response to steam. Since steam is directly related to emissions of burning natural gas, the SOR is directly related to oil's CI.

There are two types of steam injection: 1) continuous; and 2) cyclic. Continuous steam injection, as the name suggests, is continuous steam volume sent to an injector which provides support to a pattern of producing wells. Cyclic steam injection is specifically applied to producing wells to 'stimulate' oil production from the producers, measured as incremental oil. Cyclic steam is the most common practice for stimulating incremental oil.

Incremental oil is the increase in oil production from the 'stimulation' above a baseline assuming the stimulation never took place. When the stimulated production declines to the baseline, there is no longer incremental oil. The amount of cyclic steam injected determines the amount of incremental oil produced, and corelates directly to a TEOR field's SOR.

Industry widely accepts the SOR as the efficiency measurement of steam injection and emissions per barrel of oil produced. An example: A thermal field with a 10.0 SOR means 1,000 barrels of steam are injected, and 100 barrels of incremental oil are returned. *Vice versa*: 100 barrels of incremental oil produced with CRSE, in the 10 SOR field example, replaces 1,000 barrels of steam.

The CI of heavy oil cannot be reduced without a scalable innovation like CRSE that can be applied to every well to eliminate emissions caused by generating steam. The CI of the incremental oil from CRSE is 60-80% lower. Utilization at about 30%, projects carbon emission avoided will exceed 2,000,000 metric tons annually. (Please refer to Appendix C.)

CRSE chemistry reduces oil's viscosity without steam, avoiding emissions, reducing pollution, reducing freshwater usage and increasing oil production. This method changes both the numerator and the denominator of the CI calculation. The emissions avoided are proportionate to the SOR and the total volume of incremental oil.[1]

As the CRSE project eliminates cyclic steam *and* produces incremental oil, the combination reduces SOR and GHG in the petroleum supply chain. The result perfectly answers the call of CCR Section 95489(c)(1)(A). Thinking globally, but

[1] OPGEE models Midway Sunset 10% incremental oil with and without steam, 29.33 to 3.54 gCO2/

acting locally, this agency can utilize CRSE to balance the need for emission reductions and energy security.

The CRSE project is the essence of energy efficiency, i.e., using less energy by eliminating cyclic steam to perform the same job (extraction of crude oil). In the process, CRSE cuts energy use; reduces air pollution; lessens freshwater usage; and poses no threat to water quality.

CRSE produces heavy oil with significantly less energy compared to steam, using chemistry, rather than heat, to reduce the Interfacial Tension (IFT) of oil in the formation.[2] This reduction eliminates the need for steam to lower oil viscosity. The product and process reduce CI from the baseline comparison by *far more* than the minimum of 0.10 gCO2e/MJ required by Cal. Code Regs. Title 17 § 95489.

CARB's 2030 CI target for the state's oil extraction industry will be achieved with a 45% adopted, this goal could be achieved in twenty-four (24) months.

The downhole placement of CRSE reduces friction in the artificial lifting and transportation process. Application of CRSE requires very limited energy inputs and results in near zero emissions. Using a limited equipment footprint, consisting of light duty trucks with a low- pressure pump, the CRSE is efficiently and safely placed. This equipment's footprint can be quickly scaled up across the region.

This project warrants rapid approval, first, because the innovative method can be easily scaled to impact every TEOR well that is, or will be, cyclic steamed. Second, this is the only reasonable solution to enable the oil industry to achieve

---

MJ.

[2] Incremental oil results from combination of the following: 1. removing organic deposits; 2. destabilizing emulsions; 3. modifying completion and wellbore region to water-wet state; and 4. mobilizing contacted oil.

20% CI reduction by 2030 and beyond. Third, approval will create a clean oil demand, prompting further innovation in production of cleaner crude by reducing reliance on steam, lowering harmful emissions, reducing freshwater demand, while providing economic security for impacted communities of the San Joaquin Valley. Ultimately, it must be acknowledged that achieving decarbonizing *goals* requires decarbonizing *tools* like the CRSE process.

The CRSE advantage is akin to the avoided emissions associated with solar steam generation. The avoided emissions from replacing steam are based on the average steam quality, multiplied by the SOR, multiplied by the amount of incremental oil produced by the innovative crude production method.

Assuming 60% steam quality for our example above: 100 barrels of oil incremental, and 10 SOR, avoids 1,000 barrels of steam, the emissions avoided is 23,677 gCO2e/barrels of steam. This is equivalent to 23,677,000 gCO2e or 23.67 tons CO2e for 100 barrels of incremental oil.

This agency has mandated that the Low Carbon Fuel Standard is designed *to decrease the carbon intensity of California's transportation fuel pool and provide an increasing range of low carbon and renewable alternatives.* Companies should be motivated to innovate ways to decrease steam *and* find new ways to make cleaner incremental oil. By accomplishing both objectives, the CRSE process achieves the essential purpose of the LCFS program.

A. CRSE Reduces Drilling and Workover Tasks.

The CRSE process enables a win-win by reducing steam injection volumes, greenhouse gas emissions *and* the SOR of TEOR production. While GHG reduction is guaranteed, incremental production is equally certain. Ultimately, the need to drill more wells is reduced by recovery of incremental oil. CRSE contributes to a resilient clean energy future.

The benefits of CRSE over cyclic steam injection also include lower injection pressures on the tubulars in each well. There is no heat to cause thermal expansion which jeopardizes wellbore integrity. The CRSE process uses the hydrostatic pressure of the well to push fluids into the formation. CRSE can employ recycled produced water in the process, rather than fresh water.

B. Process of Applying Renewable and Biodegradable Surfactant in the Producing Zone to Replace Steam Injection Is New.

The CRSE formulation was first achieved in the last year. The chemistry of the plant-based surfactant is a unique trade secret. Field and lab testing has been ongoing.

GHG reduction coupled with incremental oil from a nature-based process is revolutionary because conventional industry wisdom has formulated an "either or" decision. The operator can *either* cut emissions *or* maintain production. *Until now*, the industry has resisted the possibility of *achieving both critical goals*.[3]

Heavy oil operators have learned if they reduce steam injection, oil production declines almost immediately. Following conventional wisdom, the operator will never be able to reduce CI values *without* the CRSE innovation. Too, CRSE is the most efficient means available to achieve the desired outcome: lower CI, delivering cleaner crude oil to California refineries.

[3] Recent oil prices prompted increases in cyclic steam injection that would have been avoided with CRSE in use.

II. Process Diagrams

The CRSE process requires access to the same annulus or tubing string found in all existing wells. The product is pumped under low pressure down the backside of the well and the hydrostatic head of the fluid column pushes CRSE into the reservoir. The precise mechanical means of delivery will vary slightly from well-to-well and field-by-field.

The CRSE process takes sixty (60) minutes on-site. The well is put into circulation for twenty-four (24) hours, then returned to production. CRSE can be applied throughout the remaining economic life of the TEOR well. Please refer generally to diagrams at Appendix A.

III. Map and Location

The list of fields and opt-in operators which have cyclic steam or steamflood type well codes according to CalGEM, is listed in Appendix B (California Heavy Oil Production).

IV. Estimate of LCFS Credits

The renewable and biodegradable characteristics of the CRSE product is part of the value proposition in this application. Please refer to the LCA for Product and Process at Appendix C.

The credit calculation for crude oil produced or transported using any other innovative method listed in section 95489(c)(1)(A) can by used to calculate credits generated and *could* employ the following formula:

$$\text{Credits}_{innov}(MT) = \left(\text{Avoided}_{emissions} \times \text{SOR}_{cyclic} \times V_{innov} - \text{Emissions}_{innov} \times T_{innov}\right) \times C$$

Figure 1. Suggested Chemistry Reduces Steam Credit Calculation

Where, Credits_{Innov} (MT) is the amount of LCFS credits generated (a positive value), in metric tons, by the volume of a crude oil produced or transported using the innovative method and delivered to California refineries for processing.

$\text{Avoided}_{emissions}$ assuming displacement of steam produced using a natural gas fired once through steam generator are correlated with the steam quality as tabulated in section 95489(c)(1)(F).

SOR_{cyclic} is the fields previous year's SOR cyclic steam jobs.

V_{innov} is the volume, in barrels, of crude oil produced or transported using the innovative method and delivered to California refineries for processing. If the crude produced or transported using the innovative method and delivered to California refineries is part of a blend, then V_{innov} is the volume of blend delivered to California refineries times the volume fraction of crude within the blend that was produced or transported using the innovative method.

Emissions_{innov} are the life cycle emissions for the CRSE product and process, with the units of $gCO2e/bo_{innov}$.

T_{innov} is the number of treatments performed contributing to V_{innov}.

Where, C is $10x^{-6}$ MT/gCO_2e conversion.

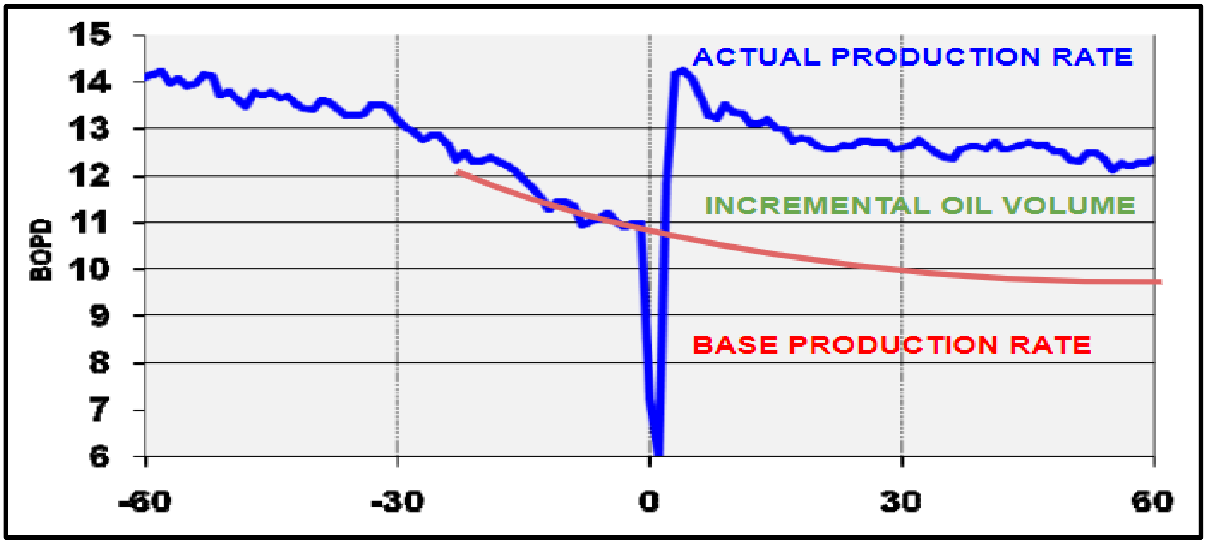

Figure 1. Volume Incremental Oil, V_{innov}

Incremental oil calculated from application of either cyclic steam or CRSE is actual production minus base production over a duration to determine volume. This is an example of a normalized plot over time, left is -60 days before job performed at time 0, to 60 days after job performed. This is an example of how incremental oil volume can be calculated for both cyclic steam jobs and CRSE.

V_{innov} is the volume of incremental crude oil produced using this method. This is calculated on a well-by-well basis as the difference between a forecasted base production and actual production. The difference between actual and base production equals positive incremental oil over a duration of time. The time that incremental oil becomes negative, or another intervention is initiated, actual production falls below the forecasted base production, or until another incremental oil intervention is initiated.

V. Opt-in Producers

The Opt-in Producers include TEOR operators presently using heat produced by cyclic steam to reduce viscosity of crude oil within the producing zone (Table III). The geographic location of the target fields is Table IV.

Table III. Opt-in Producers Steam Well Codes

Cymric	McKittrick	Wilmington
Edison	Midway-Sunset	
Edison, NE	Mount Poso	

CalGEM operators own well type of cyclic steam, CS or steamflood, SF.

The CRSE process is the only scalable potential for TEOR extraction companies to achieve a 20% CI reduction by 2030. It requires producers to adopt and scale CRSE, or similar advancements if they become available, to replace 45% of steam injection. Please refer to LCFS Credit Calculation at Appendix D.

The need for this process is made urgent in the context of a climate crisis by the deleterious trend of increasing steam injection *and* increasing SOR. Without approval of the CRSE application, oil companies will continue to inject more steam into the ground, causing more dangerous emissions, in pursuit of the remaining economic barrels of oil. CRSE is an immediate opportunity to reverse this trend.

Table V represents nine (9) months of data projected over twelve (12) months with a forecasted 7.80% increase of steam and emissions while oil decline rates accelerate. This relates to injecting more steam into the ground, more deadly emissions into the air and a higher decline rate. Most troublingly, it results in more emissions and less oil. This trend will continue until an economic alternative appears.

Table V: Three Year Steam Oil Change

YEAR	STEAM[1] bbls	OIL[2] bbls	% CHANGE	
2021	468,490,097	82,910,163	Steam%	Oil %
2022	453,476,668	76,921,783	-3.20%	-7.22%
Assume 22 to 23	438,944,366	71,365,927	-3.20%	-7.22%
Forecast 2023	474,332,861	69,578,400	4.60%	-9.55%
23 Fore-Assume	**35,388,496**	**(1,787,527)**	**7.80%**	**-2.32%**
1 - CALGEM Well Type SC, SF, OG, UNK - may not capture all steam				
2 - CALGEM All Well Types- includes waterflood oils.				

Table V is California's top 9 TEOR fields trend. Assume 22 to 23 is 'nothing changes from 22 to 23 scenario, could expect these numbers. Forecast 2023 is 9 months actual forecasted for 12 months.

23 Fore – Assume is the difference between Forecast 2023 minus Assume 22 to 23.

This trend will likely continue with depleted reservoirs.

Forecasting the nine (9) largest TEOR fields, producers are on track to inject 35 million more barrels of steam, nearly 828,000 tons of CO_2, and produce 1,700,000 barrels of oil less. More emissions that are uneconomical. This results in higher SORs and higher CIs. Expect more of this without CRSE. While employing CRSE would have improved those numbers significantly.

VI. CRSE and Confidential Business Information

The formulation of CRSE used downhole in any well will vary slightly to address specific geochemistry and downhole conditions. The principal product delivered by the project is a renewable and biodegradable surfactant formulated as a trade secret under proprietary terms and conditions.

VII. Reporting and Recordkeeping

Opt-in Producers will provide records of production and steam inputs from the normal course of operations to establish the historical SOR baseline. The same details are reported monthly to CalGEM. The incremental oil will be based on a well-by-well decline rate, as if the stimulation hadn't occurred. The incremental oil will be calculated above the baseline until production drops below the baseline.

Reporting will ensure compliance with robust standards of additionality, quantification, and permanence. Records will facilitate third-party audit of emissions claims and enable all interested parties to track and audit credits. Monitoring, reporting, and verification ensure that the CRSE project performs as predicted by project design.

VIII. CRSE Process Meets Standard Interpretation of CARB Regulations.

This application relates to a new innovative chemical method to reduce emissions and decarbonize oil production, incorporating Cal. Code of Regulations, Title 17, Section 95489(c)(1)(A), which provides, in pertinent part:

> For the purpose of this section, an innovative method means crude production or transport using one or more of the following technologies:

> 1. Solar steam generation (generated steam of 45 percent quality or greater). Steam must be used onsite at the crude oil production or transport facilities.
>
> 2. Carbon capture and sequestration (CCS). Carbon capture must take place onsite at the crude oil production or transport facilities.
>
> 3. Solar or wind electricity generation. To qualify for the credit, electricity must be produced and consumed onsite or be provided directly to the crude oil production or transport facilities from a third-party generator and not through a utility owned transmission or distribution network. Energy storage may be used to increase the quantity of electricity supplied to crude oil production or transport facilities from intermittent solar and wind electricity generation sources.
>
> 4. Solar heat generation including, but not limited to, boiler water preheating and solar steam generation with a steam quality of less than 45 percent. Heat must be used onsite at the crude oil production or transport facilities.
>
> 5. Renewable natural gas (RNG) or biogas energy. RNG or biogas must be physically supplied directly to the crude oil production or transport facilities.

Id.

The regulation is an open invitation to innovate the production of oil for one purpose: to reduce GHG emissions. Because the process proposed serves that purpose at scale, CRSE justifies *chemical reduction of viscosity* as a new category of innovative production method to eliminate steam *and* reduce emission of greenhouse gases.

Moreover, the innovative methods which have been previously approved, arguably encompass the functional advantages of CRSE and should justify approval of this application. Providing the same energy savings and emission reductions by innovative chemistry may prompt approval of this application without adding to the enumerated methods.

A. Reducing oil viscosity with a renewable product satisfies Method No. 1.

The CRSE process is a lower carbon alternative to solar steam generation whether viewed as a substitute or a perfect complement to steam by reducing oil viscosity. In direct competition, CRSE produces higher emission reductions than can be achieved by production from solar steam alone.

B. Sequestering carbon captured in CRSE satisfies Method No. 2.

The product is plant-based, absorbing carbon as it grows. By injecting the high carbon material into a geologic formation, the project sequesters carbon at every wellbore stimulation.

C. Renewable Product Facilitating Production Satisfies Method Nos. 3-5.

Downhole delivery of CRSE, a renewable and biodegradable product, to produce incremental oil is the functional equivalent of providing renewable energy for use in the production facility. It is simply an alternative tool for decarbonizing oil production.

D. Scalability Allows CRSE to Achieve High Volume Emission Reductions.

Oil and gas extraction have always confronted a declining denominator of the CI calculation. In heavy oil, reducing the emissions (numerator) as oil production (denominator) declines, still increases CI. Increasing oil production (denominator) while reducing emissions, is the only available means, given the constraints of technology and economics, to reduce CI of TEOR operations.

All current CARB innovative production methods focus on limited-scale emission reductions. None of these approved methods increase oil production.

None of them reduce operating costs. There is no economic incentive for the oil and gas industry to change, until they see a way to reduce emissions and extract more oil, in a truly scalable way. CRSE is that opportunity.

Replacing the business-as-usual method with the CRSE process delivering 60-80% lower emissions is the urgently needed answer. This innovation for the oil industry will spark new opportunities to replace high CI activities with lower carbon alternatives to achieve the desired outcome for all stakeholders.

CONCLUSION

Considering the urgent need to reduce emissions associated with production of oil in one of the most productive regions of the United States, the opportunity to cut emissions *and* maintain normal production decline rates justifies the expedited approval of this application. By reducing the amount of steam injected and complementing other methods to mitigate emissions, the applicant presents a rare win-win opportunity for this agency and the oil industry. We respectfully request your expedited approval of this innovative crude oil production method, recognizing its potential to revolutionize the industry and create a positive impact on both the environment and the economy.

Dated: December 15, 2023

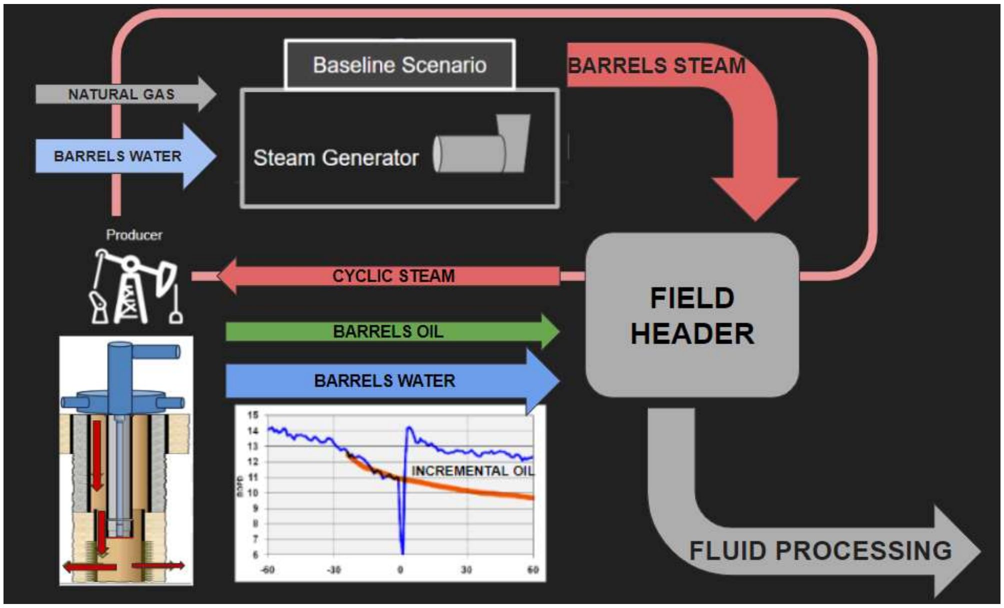
Respectfully Submitted,

Jesse Holman, CEO
Senergy, Inc.

LIST OF APPENDICES

APPENDIX A. Process Diagrams

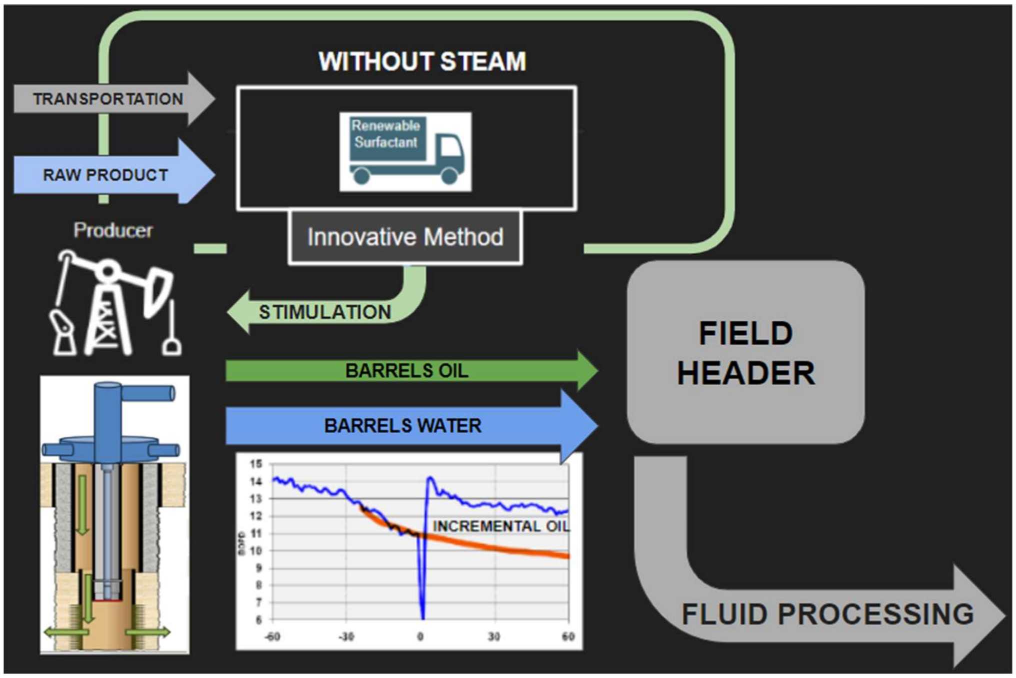
Baseline Scenario: Cyclic Steam



Cyclic steam used on producers for enhancing oil production.

A cyclic steam job is used to stimulate incremental oil in producer wells, the pumping unit is stopped, steam is diverted from the field header, down the flowline, into the backside annulus of the well delivering a predetermined volume of steam for a period of time. The steam is turned off and the well is put back on production. The steam volume injected must be recovered which contributes additional energy above the emissions injected. The well is back producing oil and water.

Innovative Method: CRSE replaces Cyclic Steam



Stimulation product assists with chemistry at fluid processing plant, there is no additional waste streams created.

Clean Surfactant Energy stimulation is a renewable and biodegradable stimulation fluid. The well is shut down and isolated. Stimulation fluid is injected using low pressure centrifuge pump and reused lease water, approximately 25 barrels of water to hydrostatically push stimulation fluid into the formation. The well is then put in a 24 hour circulation period before being returned to production. The treatment process requires less than 20 minutes of pump time before moving on to the next well. The stimulation fluid is of similar components of chemistries injected at the fluid processing facility and improves the existing separation streams without creating any additional waste streams.

What does this look like in the field?

A – Chemical Totes
B – Water Source
C – Manifolded Suction Transfer Hoses
D – C-Pump (130 psi/4 bpm)
E – Pressure Hose (note check valve at E2)

Connected to Wells Flow Line

APPENDIX C. LCFS Credit Calculation

The credit calculation for crude oil produced or transported using any other innovative method listed in section 95489(c)(1)(A) can by used to calculate credits generated and *could* employ the following formula:

$$\text{Credits}_{innov}(\text{MT}) = (\text{Avoided}_{emissions} \times \text{SOR}_{cyclic} \times V_{innov} - \text{Emissions}_{innov} \times T_{innov}) \times C$$

Figure 1. Suggested Chemistry Reduces Steam Credit Calculation

Where, Credits_{Innov}(MT) is the amount of LCFS credits generated (a positive value), in metric tons, by the volume of a crude oil produced or transported using the innovative method and delivered to California refineries for processing.

$\text{Avoided}_{emissions}$ assuming displacement of steam produced using a natural gas fired once through steam generator are correlated with the steam quality as tabulated in section 95489(c)(1)(F).

SOR_{cyclic} is the fields previous year's SOR cyclic steam jobs.

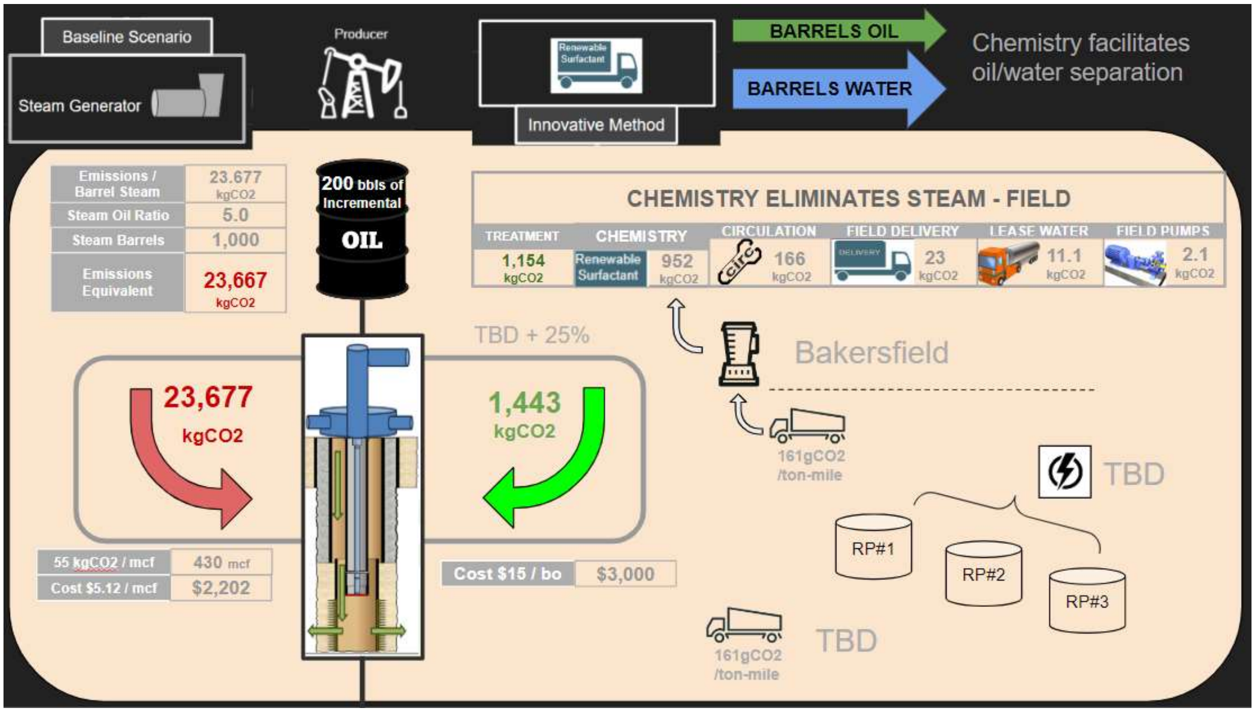
V_{innov} is the volume, in barrels, of crude oil produced or transported using the innovative method and delivered to California refineries for processing. If the crude produced or transported using the innovative method and delivered to California refineries is part of a blend, then V_{innov} is the volume of blend delivered to California refineries times the volume fraction of crude within the blend that was produced or transported using the innovative method.

Emissions_{innov} are the life cycle emissions for the CRSE product and process, with the units of $gCO2e/bo_{innov}$.

T_{innov} is the number of treatments performed contributing to V_{innov}.

Where, C is $10x^{-6}$ MT/gCO_2e conversion.

APPENDIX D. LCA for Product and Process



Lifecycle analysis of 200 barrels of oil, cyclic steam (baseline) SOR of 5 and Chemistry Reduce Steam (innovation).

The distance the raw products travel, and the blending electricity are currently unknown. We have added a 25% buffer for these emissions.

Source:

Vegetable Oil: https://www.epa.gov/sites/default/files/2015-07/documents/emission-factors_2014.pdf

Freight: Transportation value of 161 gCO2/ton-mile.

Steam Emissions from CARB.

Steam quality	*Avoided emissions (gCO_2e/bbl solar steam)*
95% and above	34,875
85% to <95%	30,443
75% to <85%	28,188
65% to <75%	25,932
55% to <65%	23,677
45% to <55%	21,421

APPENDIX E: Reporting and Record Keeping

Oil and steam volumes are reported and recorded to CalGEM agency. The additional record keeping required is the incremental oil volume using CSE. This requires a forecasted baseline production rate as if the stimulation didn't take place. Incremental oil is the difference between actual production post stimulation and the forecasted baseline until actual production falls below the baseline. This volume of incremental oil will be used to determine the credits available.

Therefore, records for incremental oil volume will vary well. The overall steam oil ratio and carbon intensity of the field will decline over time in accordance with the summation of all treatments that produce incremental oil.

APPENDIX F: Summary of Innovative Method Applications

SUMMARY OF INNOVATIVE METHOD APPLICATION

A. CRSE Delivers Emission Reductions *Beyond* Elimination of Steam in California.

1. Reduce lifting energy required in current levels of oil production.
2. Reduce maintenance demands for tubulars in existing oil wells.
3. Reduce drilling of new wells to bolster oil production.
4. Lower carbon emissions in production of heavy oil imported to California.
5. Reduce fuel consumed to transport imported crude to California refineries.
6. Reduces emissions in water flood production fields worldwide.
7. Increases efficiency of oil sand production in Alberta.
8. Reduces waste and downtime in aging refineries.
9. Encourages lower-carbon fuel production.
10. Sequesters carbon in geologic storage.

B. CRSE Delivers Advantages *Beyond* Decarbonization.

1. Reduce freshwater usage in oil and gas operations.
2. Increase recycling of produced water.
3. Efficient water polishing on-site.
4. Eliminate synthetic surfactants.
5. Cleanup facilities and sites.

C. CRSE Chemical Innovation Reduces Emissions *Beyond* the Oil Industry.

1. Firefighting:
   a) Reducing surface tension of water decreases evaporation before water reaches fuel.
   b) Reducing surface tension of water increases uptake on contact with fuel.
   c) Both effects increase firefighting efficiency at any scale.
   d) Efficiency reduces wildfire emissions.
   e) Efficiency saves water.
   f) Eliminates PFOAs.
2. Agriculture:
   a) Reducing surface tension of water increases plant uptake of moisture, reducing demand for water *and* improving yield.
   b) Reducing surface tension of water increases plant uptake of nutrients, reducing use of NPK fertilizer that contaminates water.
3. Environmental Remediation:
   a) Reducing surface tension of water improves removal of volatile organic compounds in soil.
   b) Reducing surface tension of water improves removal of oil spill contamination.
4. Cement Production:
   a) Reducing surface tension of water allows additives to reduce weight while increasing strength.

    b) Decreasing volume of cement production reduces carbon emissions.
5. Desalinization:
    a) Reducing surface tension of water improves efficiency of reverse osmosis.
    b) Cleaning RO filters prolongs the service life of the filter material.

D. Approving CRSE Application Puts a Carrot Before the Oil Industry Horse.

1. Increasing stakeholder expectations raise incentives for enterprise-level decarbonization.
2. Emerging laws and evolving regulations make decarbonization a C-suite priority.
3. Leaders will recognize competitive efficiency to seize growth opportunities.
4. Every measurable carbon reduction is progress to be encouraged.

E. Application Justifies Expeditious Approval of New Innovative Method.

1. Better to decarbonize than await a perfect solution.
2. Uncertainty should not create inertia.
3. CARB should lead the field.

F. CRSE Reduces More GHG Emissions than Currently Approved Methods Combined.

1. Section 95489(c)(1)(A) lists five (5) technologies approved as innovative methods.
2. The five (5) approved methods reduce emissions from generating steam.
3. CRSE eliminates steam generation altogether.

Subject	End the current LCFS policies that reward factory farm polluters

Comment

Governor Newsom and administration, please understand my concern.

Factory farm gas is not clean energy. It's composed primarily of
methane, a potent greenhouse gas that traps 80 times more heat tha
carbon dioxide.

The extraction of methane from factory farm waste does nothing to
alleviate the massive harm inflicted by factory farms on local
communities. The production of methane from factory farms causes
public health and climate impacts, compounding the existing impact
from factory farms.

The LCFS is a California policy, but it is driving the expansion
factory farms and factory farm gas in numerous states, including
state. Last Friday I attended an all day Ag Bioscience Conference
that was sponsored by Duke Energy. The only type of Climate
solution discussed was Agrivoltaics, of which I approve and
encourage farmers to include in the long-term plans for their lan
Solar farms on Ag land make a lot of sense, not burning and
producing more Methane that our atmosphere already cannot take.
What kind of technology is? This is a set back to our survival,
is a FALSE CLIMATE SOLUTION and it should be stopped. Please do
nothing to incentivize polluting factory farms. We have enough of
024.1 them in Indiana and I don't want any more. Turn to cleaner energy
technology now. Thank you, Julie Lowe, Columbus, Indiana

Comment

Dear Governor Newsom and Members of the California Air Resources Board (CARB),
I have concerns regarding California's Low Carbon Fuel Standard (LCFS) and to implore you to take immediate action to address the environmental injustices embedded in the program.

LCFS has become the nation's largest and most lucrative pollutior trading scheme for factory farm biogas, perpetuating harmful practices rather than serving its environmental objectives.
027.1 It is driving the construction of more factory farms and factory farm biogas projects in states far from California, causing severe harm to air, water, public health, rural economies, and overall quality of life. Incentives for more factory farms is not a solution for combatting climate pollution by factory farms.

I urge you to consider and prioritize the following reforms to the LCFS:

027.2 Eliminate "avoided methane crediting" in 2024.
027.3 Address inaccuracies in the Life Cycle Assessment that ignore associated up and downstream greenhouse gas emissions from factory farm gas production.
027.4 Remove the 10-year "grace period" for factory farm gas producers.
027.5 Stop double counting by allowing factory farm gas projects paid fo and claimed by other programs to sell LCFS credits as well.

Subject	New rules for CARB

Comment

California is exporting its dirty energy policy to rural communities throughout the U.S. without regard for the local impacts. The existing LCFS rules perpetuate environmental injustic by disproportionately harming low-income communities and communities of color.

Factory farms, predominantly located in these marginalized areas, cause severe harm to our air, water, public health, rural economies, and overall quality of life.

This year, the California Air Resources Board (CARB) has the chanc to adopt new rules that would realign the LCFS with California's environmental justice commitments and stop rewarding factory farms for their pollution.

029.1 CARB's Environmental Justice Advisory Committee presented a clear alternative to the dirty status quo, and submitted a resolution calling for an end to the current LCFS policies that reward factor farm polluters.

Please do the right and sustainable thing. Thank you.

February 9, 2024

California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

As a renewable fuel producer and participant in CARB's LCFS program, my team and I value the partnership and mission shared with you and your state to reduce the carbon intensity of transportation fuels.

I am writing to share our company's perspective on two key program areas for your consideration. These requests address the topics of **firm rotation** and **less intensive verification**.

Firm Rotation

The existing regulations within the LCFS verification program stipulate a mandatory rotation of audit firms every six years to assess participants' carbon intensity (CI) and fuel quantities compliance.

Our request is that CARB amend the mandatory firm rotation regulation to include an exception for licensed CPA firms. Of the 30 approved LCFS verification bodies, there are only four licensed CPA firms.

031.1

> ***An approved verification body, that is also a licensed CPA firm, exceeds the standards in place for verification bodies and is already subject to additional oversight on the entity's quality control system in accounting and auditing practices through the required AICPA peer review process.***
>
> ***Due to the increased regulatory oversight, we suggest a CPA firm not be subject to the audit firm rotation but would instead adhere to a Lead Verifier rotation after six consecutive years.***

A licensed CPA firm differs from other consulting agencies by adhering to more rigorous standards and oversight at a state and national level. If a verification body were to violate a Lead Verifier rotation requirement, it would put the firm license at risk. The firm

license is required for all services provided by the firm, not just the LCFS verification services, thereby ensuring adherence to requirements.

Licensed CPA firm requirements

- A licensed CPA firm must be comprised of over 50% of the ownership being licensed CPAs.
  - To earn the accreditation to be a CPA, one must pass a rigorous four-part CPA exam, accumulate education hours, and in many states, one must fulfill 1-2 years of work experience.

- 3-year peer review audit
  - Each licensed CPA firm must enroll in an approved peer review program with reviews conducted every 3 years. The peer review requirement is a requirement of the American Institute of Certified Public Accountants (AICPA) and is an external review of a firm's quality control system in accounting and auditing practices. CPA firms' peer review results can be found on AICPA's website under the Peer Review Public File Search.

- State Boards of Accountancy (SBOA) are found in each state's statute to aid state governments in the licensing and regulation of the public accounting profession.
  - SBOAs provide further oversight on CPA firms by evaluating CPA licensees' examinations and regulatory oversight to ensure a firm is practicing within their statutory scope.

The audit quality and efficiency improve as the auditor becomes more familiar with our company's processes. In addition, with the limited number of firms available as verification bodies and a five-year lookback period in place, it is proving difficult to identify a quality verification body that is not also working with our facility in other consulting capacities. The number of people available with the proper expertise to assist us in design and development of projects and to reserve for verification purposes has proven even more limiting, which is also why we request a Lead Verifier rotation rather than a full firm rotation.

Less Intensive Verification

Regarding less intensive verification, we noted in Appendix E staff's proposal for less intensive verifications for when electricity is used as a transportation fuel, allowing verification bodies to skip site visits if they visited the site in the last two years and issued a positive verification statement.

PureField INGREDIENTS

The rationale for this proposed change states, “there is little change of operation from reporting period to reporting period thus reducing the benefit of annual site visits.” Additionally, staff rationale states, “There is no or little risk to the integrity of the LCFS program to allow for less intensive verification services without a site visit in the annual verifications for the following two years. This should reduce the cost of verification services which is often passed on to program participants.”

Currently, the proposed language limits this allowance for less intensive verifications to QFTR third-party verification bodies for fuel reporting entities only reporting electricity transactions.

031.2 We agree with the staff’s stated rationale, but **we request for less intensive verification to be extended as an option for verification bodies on all validations and annual verifications for any reporting entities.**

In CARB’s MRR program (section 95130), less intensive verification is applied without prejudice to verification services by accredited verification bodies.

We agree with staff that less intensive verification leads to little to no risk to the integrity of the LCFS program and that there is little change in operation from reporting period to reporting period, while also providing cost savings to verification providers and passed on to our company as program participants.

We acknowledge the importance of adhering to CARB’s specified conditions that necessitate comprehensive verification services. These conditions include the issuance of an adverse verification statement or a qualified positive verification statement in the preceding year and the occurrence of a change in operational control of the reporting entity in the previous year.

Thank you for your time and consideration. Please reach out to us if you have any questions.

Sincerely,

Teri Klitzke

Subject Stop incentivizing factory farm gas.

Comment

```
* Stop awarding the biggest polluters!
* Stop increased GHG emissions as a result of factory farming.
* Dairy manure contributes to about a third of the nitrate
polluting groundwater in the Central Valley and has polluted in
many areas 30-40% of private wells.
* It takes about 2 agricultural acres per head of cattle to susta:
just feeding them, which is then not available for feeding people
Incentivizing factory farms makes this worse. Biogas digester
promotion aggravates the problem and dairy herds become just the
first stage of an industrial money-making scheme that is already
severely impacting our public health and our environment.
* CARB disregards violations of out-of-state rules and regulation:
```

Re: Opposition to California Air Resources Board Proposal to Regulate Jet Fuel

Dear CARB Board of Directors,

The Orange County Hispanic Chamber of Commerce is writing to share our serious concern and opposition to the recent California Air Resources Board (CARB) proposal to regulate jet fuel under its Low Carb Fuel Standard (LCFS) program.

The Orange County Hispanic Chamber of Commerce represents the interests of and provides access to Orange County's 30,000 Hispanic-owned businesses. We support the development of these businesses by providing opportunities for networking, legislative advocacy, access to capital, education and training programs.

The U.S. airline industry plays a vital role in California's economy. Furthermore, the industry is committed to reducing its climate impact and achieving "net zero" carbon emissions by 2050. Transitioning to Sustainable Aviation Fuels (SAF) is core to this commitment, and the industry has pledged to work with governments and other stakeholders to make three billion gallons of SAF available in the United States by 2030. Achieving these goals requires new and additional policy incentives, streamlined permitting processes, and close collaboration among airlines, fuels industry, manufacturers, environmental organizations and governments, among others.

With respect to SAF, California has established itself as an early leader in attracting investment, production, and use of SAF through the existing Low Carbon Fuels Standard (LCFS) Program, which provides an opt-in credit for SAF that helps reduce the price difference between SAF and conventional jet fuel. This voluntary regulatory structure has been successful in enabling the growth of the SAF market in California and across the country. CA has the most viable market for SAF today in the United States and as airlines increase their demand for SAF the market continues to grow.

Aviation accounts for 2.6% of the US GHG emissions but 5% of US GDP and 4.1% of CA's GDP. There are 380 thousand employees of US Commercial aviation firms based in California, with an overall economic impact of $194 billion[1]. Aviation is critical to driving California's economy and it's rank as the 5th largest economy in the world, enabling $114 Billion in annual trade flows and underpinning the of many of the rest of California's biggest economic drivers such as agriculture, tourism, manufacturing, banking, technology and small business. Ensuring a healthy and vibrant aviation industry is essential to California's future, and leveraging CARB's early leadership on SAF can enable California leadership in the emerging SAF production industry, creating new jobs and economic development opportunities.

033.1

With this context, we express our serious concern with a new proposal by the California Air Resources Board (CARB) to regulate jet fuel as an obligated fuel under the LCFS Program. CARB's proposed changes to the LCFS program include a proposal to eliminate the existing exemption for conventional jet fuel use for flights within the state of California. This proposed change is unlikely to result in increased SAF production, availability, or use in California, but would lead to higher jet fuel prices. The primary impediment to increased SAF production and availability in California remains the higher cost of SAF for producers and buyers relative to conventional jet fuel and renewable diesel. The CARB proposal would not meaningfully address this fundamental challenge and therefore unlikely to meaningfully increase SAF supply or use.

The proposal seeks to regulate jet fuel and reduce emissions from aviation, both of which are pre-empted under federal law a fact that CARB recognized when it exempted jet fuel in 2018.[2]. Aviation has unique circumstances, that go beyond considerations of interstate commerce, for the safe operation and maintenance of aircraft that the federal government has recognized in the EPA's Clean Air Act and the jurisdiction of the FAA.

1 *The Economic Impact of Civil Aviation on the U.S. Economy, State Supplement, US Department of Transportation, November 2020*

2 CARB stated that "*[s]ubjecting aircraft fuels to annual carbon intensity standards would raise federal preemption issues*" available at https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2018/lcfs18/isor.pdf?_ga=2.259407882.1202437490.1641 231788-253234234.1573227006

These statutory authorities establish clear and broad federal authority for regulating jet fuel and aircraft engine emissions that pre-empts California from regulating jet fuel under the LCFS program.

Moving forward with eliminating the fossil jet fuel exemption and implementation of a new obligation will likely result in litigation that will be lengthy, costly and do nothing to advance the mission of more SAF production and uplift. Engaging in litigation will divert resources from the state and the aviation industry that would be better spent enabling greater SAF production. Our mutual interest is to increase SAF production, availability, and use and the most effective way to accomplish this is to continue the positive, collaborative approach represented by the existing "opt-in" mechanism
033.1 developed by CARB and the aviation community.

Based on these considerations, we urge CARB to reconsider and withdraw the proposal to remove the exemption for jet fuel for intrastate flights and instead preserve the existing opt-in approach for SAF and partner with the aviation sector and stakeholders across the emerging SAF ecosystem on new policies and approaches to rapidly increase the availability of SAF in California. We urge CARB to focus on the ultimate goal – how to get more SAF into planes in California by reducing barriers to production, availability and use.

Sincerely,

Reuben Franco
President & CEO
The Orange County Hispanic Chamber of Commerce

VIA ELECTRONIC DELIVERY

RE: Potential issue with CA-GREET 4.0 Electricity Emission Factor

Dear Mr. Botill,

In review of the default electricity emission factors proposed in the 2024 Low Carbon Fuel Standard (LCFS) Amendments, U.S. Venture has identified a potential modeling issue we submit for your consideration. As you know, U.S. Venture has actively participated in the LCFS since 2017. U.S. Venture is a leading vertically integrated solutions provider proficient in refined products, alternative fuels, and environmental credits. We will submit an additional set of comments on the LCFS Amendments, but submit this feedback on the CA-GREET 4.0 (CA-GREET) model to facilitate improvements to the model and emission factors.

034.1 In review of the default electricity emission factors in the CA-GREET model, an issue was identified in the regional refactoring by CARB staff that may need attention. U.S. Venture was evaluating the various calculation approaches utilized across the different methodologies (CA-GREET, National GREET, GHGenius, OpenLCA, etc.), when we ran into an issue which we could not reconcile. We found that the default electricity emission factors within CARB's Tier 1 calculators, which are derived from the CA-GREET model, (relative to the EPA eGRID 2021 numbers used in GREET) may be off by a significant amount.

CARB provided document "Appendix B: CA-GREET 4.0 Supplemental Document", which explains how they recalculated the electricity emission factors using the fuel mix from eGRID 2021. Unfortunately, as we reviewed the draft CA-GREET calculator to figure out how these fuel mix factors were utilized, we identified an issue. CARB adjusts the National GREET calculator, which uses an NERC region map (11 regions) to determine electricity emission profiles, to one that uses the eGRID subregions (27 regions). This appears to be okay on the surface, but there is a core INDEX formula inaccuracy in the CA-GREET calculator which is being caused by the adjustment of 11 regions to 27, and can't be fixed with the data which is available in the calculator. The formula inaccuracy is not easily noticeable, because there is an IFERROR correction in the formula which defaults ("value in error") to an incorrect conclusion, so the formula doesn't simply fail with reference errors. If this INDEX function was corrected, the default electricity emission factors could change significantly.

Below are some screenshots from the CA-GREET 4.0 draft calculator which layout my findings.

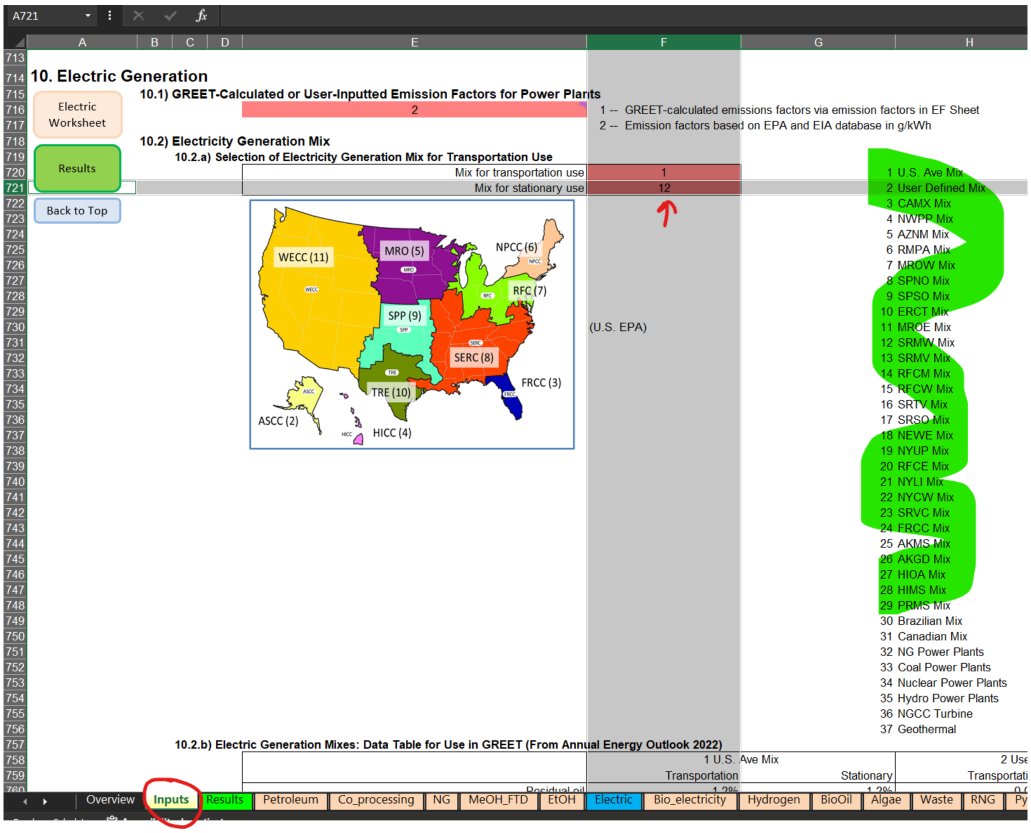
Ready Calculate Accessibility: Investigate

4. Subregion Selection-Inputs tab: Screenshot 2 is looking for something 11 and under, but since there are 27 subregion selections, the vast majority (subregion selections 12 - 27) will drive the formula above to IFERROR correct to the U.S. average. This does not seem correct. Even if this were to be the case, for any subregion selection 11 and under, the INDEX formula operates "correctly," but then pulls a reference for an NERC region which has no association with the eGRID subregion selection the user made, which in turn drives an inaccurate calculation.



Thank you for the opportunity to provide feeback on the proposed LCFS regulations. We support CARB in its efforts to accelerate the carbon intensity reduction of transporation fuels through the LCFS Program, and appreciate the inclusiveness of stakeholders and thoroughness of its actions throughout the 2023/2024 LCFS rulemaking process. If CARB would like any further clarification on the comments above, please let us know.

Sincerely,

/Josh Thome/

California Air Resources Board
1001 I Street
Sacramento, CA 95814
RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

As a renewable fuel producer and participant in CARB's LCFS program, my team and I value the partnership and mission shared with you and your state to reduce the carbon intensity of transportation fuels.

I am writing to share our company's perspective on two key program areas for your consideration. These requests address the topics of **firm rotation** and **less intensive verification**.

Firm Rotation

The existing regulations within the LCFS verification program stipulate a mandatory rotation of audit firms every six years to assess participants' carbon intensity (CI) and fuel quantities compliance.

Our request is that CARB amend the mandatory firm rotation regulation to include an exception for licensed CPA firms. Of the 30 approved LCFS verification bodies, there are only four licensed CPA firms.

035.1 ***An approved verification body, that is also a licensed CPA firm, exceeds the standards in place for verification bodies and is already subject to additional oversight on the entity's quality control system in accounting and auditing practices through the required AICPA peer review process.***

Due to the increased regulatory oversight, we suggest a CPA firm not be subject to the audit firm rotation but would instead adhere to a Lead Verifier rotation after six consecutive years.

A licensed CPA firm differs from other consulting agencies by adhering to more rigorous standards and oversight at a state and national level. If a verification body were to violate a Lead Verifier rotation requirement, it would put the firm license at risk. The firm license is required for all services provided by the firm, not just the LCFS verification services, thereby ensuring adherence to requirements.

Licensed CPA firm requirements

- A licensed CPA firm must be comprised of over 50% of the ownership being licensed CPAs.
    - To earn the accreditation to be a CPA, one must pass a rigorous four-part CPA exam, accumulate education hours, and in many states, one must fulfill 1-2 years of work experience.

- 3-year peer review audit
    - Each licensed CPA firm must enroll in an approved peer review program with reviews conducted every 3 years. The peer review requirement is a requirement of the American Institute of Certified Public Accountants (AICPA) and is an external review of a firm's quality control system in accounting and auditing practices. CPA firms' peer review results can be found on AICPA's website under the Peer Review Public File Search.

- State Boards of Accountancy (SBOA) are found in each state's statute to aid state governments in the licensing and regulation of the public accounting profession.
    - SBOAs provide further oversight on CPA firms by evaluating CPA licensees' examinations and regulatory oversight to ensure a firm is practicing within their statutory scope.

The audit quality and efficiency improve as the auditor becomes more familiar with our company's processes. In addition, with the limited number of firms available as verification bodies and a five-year lookback period in place, it is proving difficult to identify a quality verification body that is not also working with our facility in other consulting capacities. The number of people available with the proper expertise to assist us in design and development of projects and to reserve for verification purposes has proven even more limiting, which is also why we request a Lead Verifier rotation rather than a full firm rotation.

Less Intensive Verification

Regarding less intensive verification, we noted in Appendix E staff's proposal for less intensive verifications for when electricity is used as a transportation fuel, allowing verification bodies to skip site visits if they visited the site in the last two years and issued a positive verification statement.

The rationale for this proposed change states, "there is little change of operation from reporting period to reporting period thus reducing the benefit of annual site visits." Additionally, staff rationale states, "There is no or little risk to the integrity of the LCFS program to allow for less intensive verification services without a site visit in the annual verifications for the following two years. This should reduce the cost of verification services which is often passed on to program participants."

Currently, the proposed language limits this allowance for less intensive verifications to QFTR third-party verification bodies for fuel reporting entities only reporting electricity transactions.

035.2 We agree with the staff's stated rationale, but **we request for less intensive verification to be extended as an option for verification bodies on all validations and annual verifications for any reporting entities.**

In CARB's MRR program (section 95130), less intensive verification is applied without prejudice to verification services by accredited verification bodies.

We agree with staff that less intensive verification leads too little to no risk to the integrity of the LCFS program and that there is little change in operation from reporting period to reporting period, while also providing cost savings to verification providers and passed on to our company as program participants.

We acknowledge the importance of adhering to CARB's specified conditions that necessitate comprehensive verification services. These conditions include the issuance of an adverse verification statement or a qualified positive verification statement in the preceding year and the occurrence of a change in operational control of the reporting entity in the previous year.

Thank you for your time and consideration. Please reach out to us if you have any questions.

Sincerely,

Amy Hofmeister

Subject Factory Farm Gas in California's Fuel Standards

Comment

Dear Board Members,
I'm against including factory farm gas in California's Low Carbon
Fuel Standard. This will not be a positive solution for our climat
crisis. One of the main reasons to nix factory farm gas from the
standard is that it will encourage more large factory farms, makir
it harder for small family farms to prosper while these corporate
036.1 farms push down market prices with overproduction. More issues wit
this bill include the fact that multinational large meatpackers
will be paid for their pollution, and the bill will create
incentives via government subsidies to support anaerobic digester
for factory farm gas.
This would add more factory farms which will lead to more methane
more water and air pollution, more corporate consolidation. I'm ir
the Midwest and know this will not lead to less carbon release in
our atmosphere. Please strike this portion of the amendments.
Thank you for allowing comments.

Subject	California Bio Gas Bad Idea
Comment 038.1	Please do not allow the CA Air Resources Board to allow corporate factory farms across the country to sell methane to this misguided system- which is not a solution to our country's air pollution problem. We must stop allowing big corporate farms to create this hazardous gas in the first place.

```
Please do not include factory farm gas in the new California Low
Carbon Fuel standard.  Doing so is harmful to the environment by
encouraging more factory farms.  These are polluting to our land,
water and air quality resources.
Corporate out of state and in many cases out of country businesse
will profit from this change.
Thank you for not including factory farms in your efforts to lowe
carbon emissions
```

Comment	CARB lies about the efficiency of EVs!! In their ARB/MSD/7-6-94 they claim that battery efficiency is 80% and motor is 90%. These are LIES!!!! Charging a battery in one hour has an efficiency of 5.88%, in 15 minutes ONLY 0.3675%!! The motor efficiency depends on how many stops are made. Each time the motor starts the motor and system efficiency are almost ZERO!!!! Every time the motor starts the battery efficiency is also degraded because of the high motor starting current!!!! 040.1

February 15, 2024

To: California Air Resources Board

Re: Low Carbon Fuel Standard - https://ww2.arb.ca.gov/rulemaking/2024/lcfs2024

The Institute for Agriculture and Trade Policy (IATP) welcomes the opportunity to comment on the California Air Resources Board (CARB) proposed amendments to its Low Carbon Fuel Standard (LCFS). IATP is a 38-year-old, non-profit organization with headquarters in Minnesota that works nationally and internationally for fair and sustainable food and trade systems.

Throughout IATP's history, we have seen firsthand the economic and environmental harm the transition to large-scale confined animal feeding operations (CAFOs) has caused to rural communities in Midwest states. California's LCFS, unfortunately, has contributed to the further expansion of the CAFO system in Midwest states, such as Minnesota and Wisconsin, through its skewed emissions intensity scoring and associated credits for CAFO-derived biogas. An analysis by CoBank concluded that incentives and credits generated through California's LCFS "are the main source of revenue for dairy digester projects."[1] We do not believe biogas projects that subsidize Midwest CAFOs are consistent with California's LCFS intention and purpose: to reduce California's GHGs through its transportation sector by requiring cleaner fuels.

IATP offers the following comments on the LCFS's proposed amendments:

<u>CARB's LCA for biogas excludes significant emissions</u>

Biogas derived through methane digesters on large-scale CAFOs requires enormous quantities of animal manure. The largest source of direct methane emissions from dairy and beef CAFOs is the animals themselves (at least two-thirds), the remaining emissions (methane and nitrous oxide) come from giant, often liquified, waste lagoons. Hog CAFO emissions come entirely from liquified manure storage. Other greenhouse gas emissions associated with the CAFO system include feed production and the spreading of manure on neighboring fields. Despite the significant emissions coming from the CAFO system, CARB's current emissions intensity analysis gives biogas a negative carbon intensity score, lower than any other transportation fuel, including electricity produced by solar and wind energy which produce no discernable waste, emissions or water pollution.[2]

MINNEAPOLIS | WASHINGTON, D.C. | BERLIN

1700 SECOND STREET NE, SUITE 200 MINNEAPOLIS, MINNESOTA 55413 | +1 612-870-0453 | IATP.ORG

We urge CARB to reconsider how it calculates its biogas emissions intensity score in the following five areas:

1) The "avoided methane" crediting policy assumes that open air flaring is the only option for dairy, beef or hog producers and that captured methane is an "avoided emission." This ignores alternative approaches to raising animals (such as on appropriately scaled, pasture-based systems that avoid giant liquid manure lagoons all together) and better manure management (such as lower-emitting dried manure
042.1 systems). In other words, the CAFO system itself and its management of manure is demonstrably avoidable.
2) CARB's low score for biogas and ensuing credits incentivizes more manure production from large CAFOs. As farmers struggle through volatile and often below-cost markets, payments for waste production create a new income stream that can subsidize larger herd sizes to produce more manure and access more LCFS credits.[3] The growth of CAFOs mean additional direct cow-related emissions. Currently, CARB does not have an effective system to track operations seeking biogas credits that are expanding their herd size (with associated additional methane emissions), or whether the LCFS is helping to finance new CAFOs with additional emissions.
3) The state does not account for several major sources of CAFO emissions within its biogas scoring system. CAFO systems are entirely dependent on low cost (sometimes below cost) feed often from off the farm, just as ethanol or biodiesel are entirely dependent on corn and soy production. The LCA for biogas from beef, dairy and hog CAFOs does not include the significant emissions associated with feed, including nitrous oxide emissions associated with fertilizer use (particularly for corn) and emissions associated with the harvest, processing and transport of feed to the CAFO. The LCA also doesn't include emissions from cows themselves in the case of dairy and beef. Finally, the LCFS does not count the emissions associated with the application of biogas digestate on the land, which can emit more methane and nitrous oxide than undigested manure.[4]
4) There is growing evidence that CAFOs with biogas digesters are still significant sources of methane emissions. Recent Food & Water Watch research found that 15 California dairies, with biogas digesters receiving credits through the LCFS, emitted enough methane to be tracked by satellite and imaging aircraft.[5] Other researchers have found that digester systems often leak, leading to an underestimation of their emissions.[6] Methane leaks from digesters could contribute to as much as a 15% loss rate — cutting into its emissions intensity score and making it impossible to be a net loss emitter.[7]
5) CARB doesn't adequately consider new models of methane digesters, where manure or gas are trucked from several surrounding CAFOs to a centralized digester. For

[3] https://hoards.com/article-30925-energy-revenue-could-be-a-game-changer-for-dairy-farms.html

[6] https://www.sciencedirect.com/science/article/pii/S2590332222002676
[7] https://iopscience.iop.org/article/10.1088/1748-9326/ab9335

example, a Wisconsin digester project is accessing LCFS credits sources from three local dairies.[8] A proposed Minnesota digester would collect manure from four dairies in three counties.[9] Each project includes an enormous amount of additional truck traffic and fuel use to be workable, not to mention the emissions associated with each individual CAFO.

<u>CARB ignores impacts on rural communities outside of California</u>

042.2 One of the stated objectives of the LCFS and associated amendments is "to strengthen equity provisions and promote investment in low income, rural communities…." While the LCFS extends well beyond the boundaries of California, with projects all over the country, CARB's Standard Regulatory Assessment Analysis notably does not consider rural communities outside of California. We strongly urge CARB to conduct analysis and monitoring of whether low-income, rural communities outside of California are benefiting from biogas investment through the LCFS, including a process for direct public input from community-members.

California's LCFS has already sent credits to multiple dairy farms in western Minnesota, throughout Wisconsin and in states around the country.[10,11] Last month, Minnesota's Public Utility Commission held a hearing in western Minnesota for a $13.9 million plan for a 28-mile pipeline of methane gas from four local dairies into a nearby natural gas pipeline.[12] The project developers have stated they plan to have California's LCFS credits help pay for the project. Another digester in western Minnesota is capturing nearly 700,000 gallons of daily manure from three big dairies to power a digester that has partially financed by carbon credits.[13] Minnesota lost nearly 150 dairy permits in 2023, much of them due to the shift toward larger dairy CAFOs. Biogas digesters are too costly for small and mid-sized dairies, and the economics don't work for those not located near natural gas pipelines. In essence, CARB's LCFS system is picking winners and losers in states outside of California.

<u>The phase out timing for biogas credits is too long</u>

042.3 CARB's current "deliverability" requirements that out-of-state biogas be simply added to a North American pipeline — without assurance that it will be used in California — run counter to the intention of the LCFS and greatly weaken the effectiveness of the policy. The proposed amendments to strengthen the "deliverability" requirement for projects started after 2029,

[11] https://foodandwater.maps.arcgis.com/apps/mapviewer/index.html?webmap=a40e6dc32bfa4165af469b3a648d4a76

[12] https://www.agweek.com/livestock/dairy/minnesota-puc-to-host-meeting-on-13-9m-pipeline-transporting-renewable-natural-gas-from-dairy-farms

[13] https://www.dmt-cgs.com/minnesota-first-rng-plant-amp-americas-dmt/

with a 10-year grace period, unnecessarily delaying a much-needed fix that could and should happen next year.

CARB's own Initial Statement of Reasons (ISOR) admits that biogas takes up only a fraction of vehicle fuel use and that biogas use will decline as zero emission vehicles penetrate the market.[14] There is an acknowledgement that biogas as a transportation fuel will need to transition out of the fuel mix to avoid stranded assets. We agree and would argue that waiting until after 2029 (with an additional 10-year grace period) to phase out biogas crediting is an excessively long period and should be eliminated, particularly for a transportation fuel that depends on waste production and could add GHG emissions in its production.

<u>Guardrails for crop-based biofuels are threatened by Sustainable Aviation Fuels</u>

A recent National Academy of Sciences paper on life cycle assessments highlighted the critical importance of evaluating scale when assessing different transportation fuels.[15] The proposed amendments open the door for the inclusion of Sustainable Aviation Fuels (SAF) for flights within the state of California. The future of the SAF market is highly speculative. The World Resources Institute estimates that to meet the Energy Department's stated goal on SAF it would require an additional 114 million acres of corn, 20% more than current corn acreage.[16] This type of major expansion in corn production would have a profound effect on land use change. We urge CARB to consider the impact of the additional inclusion of SAFs within the
042.4 LCFS credit system for California and land use emissions in other states and countries.

<u>The LCFS Amendments Ignore California's own Environmental Justice Advisory Committee</u>

The state's Environmental Justice Advisory Committee (EJAC) was sharp in its criticism of the current LCFS, including the way CARB has evaluated CAFO biogas. In its comment, the Advisory Committee stated, "The LCFS has exacerbated and entrenched harmful pollution in communities near and regions containing large dairies and other confined animal feeding
042.5 operations by incentivizing the production, storage, and land application of wet manure."[17] EJAC specifically called on CARB to " Conduct a full accounting of GHG and air pollution emissions associated with pathways relying on the production of fuel from livestock and dairy manure"; "Eliminate avoided methane credits effective January 1, 2024;" and "Eliminate credit generation for pathways relying on the production of fuel from livestock and dairy manure for emissions reductions that otherwise would have occurred or were legally or contractually required to occur." EJAC further recommends that CARB take steps to "immediately initiate formal rulemaking for the regulation of livestock methane."

Carlsbad, CA 92011 USA

February 20, 2024

The Honorable Steven S. Cliff

Executive Officer

California Air Resources Board

Sacramento, CA 95814

Re: Proposed Amendments to the Low Carbon Fuel Standard Regulation

Dear Executive Officer Cliff,

Anaergia Services LLC (Anaergia) is a global leader in diverting organics from landfill-bound waste and converting them into renewable fuel and soil amendments. Based in Carlsbad, CA, Anaergia is actively deploying anaerobic digesters in California and converting landfill-diverted organic waste into carbon-negative fuels. Our Rialto Bioenergy Facility (RBF) – the largest landfill-diverted-organics-to-renewable-fuel facility in America – can process over 175,000 tons per year of diverted organics and produce 1,000,000 MMBtu/yr of renewable natural gas (RNG). After 4 years of planning and construction with over $180M invested, RBF is operational and has created at least 50 permanent jobs, hundreds of construction and service jobs, and over 500,000 hours of construction work.

These facilities are part of the 160 new projects that CalRecycle estimates are needed to meet California's statutory organic waste landfill diversion goals established under SB 1383 (Lara, Chapter 395, Statutes of 2016). A strong LCFS program is critical for the long-term success of RBF and is foundational to continued investment in development and expansion of similar critical infrastructure, which are foundational for achieving carbon neutrality by no later than 2045.

Biomethane, including biomethane from landfill-diverted organic waste, is a critical tool in meeting the State's targets, and it is essential that biomethane production within the State is not only supported but increased to achieve the necessary methane and carbon dioxide reductions most rapidly and most cost-effectively. Anaergia is heartened at the success to date of the LCFS in advancing biomethane production in the State and nationwide, in part through the adoption of similar programs which build on California's. However, we urge CARB to consider the below strategies preserve and accelerate progress made to date towards the State's and LCFS program's ambitious carbon intensity reduction goals.

Increase Near-Term Carbon Intensity (CI) Reduction Targets

043.1 We are supportive of CARB's proposed carbon intensity (CI) reduction targets. However, we encourage even more ambitious near-term targets to match statewide greenhouse gas reduction target codified in SB 32 (Pavley, Chapter 249, Statutes of 2016). While we are supportive of the increased 2045 carbon intensity target, emissions reduction in the near-term is most critical to avoid runaway climate change and its most harmful effects. We have seen the success of the LCFS in driving rapid transition towards renewables and decarbonization in the transportation industry. As California's largest source of emissions, the transportation sector must play a leading role in achieving the State's climate change and air quality objectives. Therefore, carbon intensity targets under the LCFS should be no less than statewide greenhouse gas reduction targets. Adopting higher near-term LCFS carbon intensity reduction targets of at least 40% will not only drive progress towards long-term Statewide climate goals; this change will also incentivize

Anaergia Services, LLC
705 Palomar Airport Rd, Ste 200
Carlsbad, CA 92011 USA

near-term achievement of emissions reductions, especially in the transportation sector and communities where they are needed most, providing additional runway to mitigate and reverse climate change. Anaergia encourages CARB to **adopt a more aggressive 2030 CI reduction target (40-55%) to be consistent with SB 32.** It is not the time to set manageable goals and to delay more significant reductions; rather, we must make leaps in carbon emissions reductions to secure additional runway to mitigate and reverse climate change.

Maintain Avoided Methane Crediting Beyond 2040

043.2 Anaergia urges the LCFS to maintain consistency with other California climate programs and with the LCFS itself. Of critical importance maintaining the GREET-based lifecycle approach to emissions accounting for biomethane, which is currently accurately employed for all other eligible LCFS fuels. Eliminating avoided methane crediting for only biomethane would represent a singular and premature change in accounting. Further, this change would contradict the program's design and objectives, the established GREET model, accepted science, and California's progress towards SLCP emissions reductions goals.

There are numerous avenues to achieve SB 1383 compliance, not all of which are equal from an emissions perspective. A particularly important tool is anaerobic digestion (AD) of landfill-diverted organics to generate biomethane, which results in greater methane emissions reductions than composting organic waste, while also generating RNG to reduce fossil fuel use. On balance, with the increased climate benefit of AD, these complex facilities are more expensive to construct and operate, especially in California. Investment and sustainable operation of organic waste digesters relies on adequate revenue generation through the project lifecycle, primarily through biomethane sales. With facility lifespans in excess of 20 years, eliminating avoided methane crediting – even as soon as 2040 – negatively impacts revenue available to finance these capital-intensive facilities. The resulting major reductions in expected revenue will halt investment and therefore the SLCP reduction potential of projects in operation and development today. These complex facilities are not financeable without long-term (20+ year) avoided methane crediting, especially as no other equivalent program has yet been established to appropriately incentivize biomethane uptake.

The full lifecycle benefits of AD must be accounted for via appropriate methane crediting and biomethane valuation to promote organic waste digesters and achieve SLCP reductions goals. Currently, it is clear that California-generated biomethane from organic waste does **not** have a market value reflective of its real-life climate benefits, nor sufficient to garner the needed investment: CalRecycle estimates over 100 such facilities are needed in California to accommodate the 20 million tons per year of organics that must be diverted from landfill per SB1383; however, RBF is the only such food waste digester currently operating in the State. (This is compounded by the near-term lack of deliverability requirements.) The premature and arbitrary elimination of biomethane crediting will further disincentivize development of this effective methane reduction strategy in two ways: first, by devaluing biomethane and negatively impacting project economics; and second, by creating uncertainty in the market and thereby reducing investor confidence and financeability. In short, changing the approach to avoided methane crediting in the LCFS will jeopardize
043.2 cont the State's ability to meet its SLCP reduction goals and to develop additional biomethane supplies necessary to achieve carbon neutrality.

Maintaining credits for avoided methane emissions beyond 2040 is absolutely essential to the continued operations of existing facilities generating biomethane from landfill-diverted organics, the

Anaergia Services, LLC
705 Palomar Airport Rd, Ste 200
Carlsbad, CA 92011 USA

development of and investment in additional similar facilities, and ultimately the achievement of SB 1383, SB 32, and AB 1279 (Muratsuchi, Chapter 337, Statutes of 2022). Eliminating avoided methane credits will irreparably damage the industries sorely needed to achieve the State's highest priority climate goals.

Update Tier 1 Calculator for Food Waste Biomethane to Reflect Latest Science on GCE

043.3

Part and parcel with maintaining avoided methane crediting is ensuring the Tier 1 simplified calculator for Biomethane from Anaerobic Digestion (AD) of Organic Waste (OW) accurately quantifies the carbon intensity of biomethane from landfill-diverted organics. The LCFS Program has consistently presented on the importance to update aspects of the LCFS program to "reflect evolutions in technological performance and data availability.[1]" Anaergia commends CARB for updating the calculator in recognition of fugitive methane emissions from landfills' open face and the negligible gas collection efficiency (GCE) within the first few years of disposal of organics in landfill. However, more changes to the calculator's default assumptions are necessary to match the latest science, including recent US EPA findings published in October 2023.

Currently, the calculator assumes that t 75% of methane emissions from organics in landfill is captured starting at Year 4, based on a stipulated assumption from a 1997 US EPA study. This value, which the EPA study itself identifies as a placeholder value in the absence of more data, has been repeatedly shown to be a severe underestimate by more recent work leveraging advanced data collection methodology in California, the US, and worldwide. A 2019 study by NASA JPL estimates that landfills' contribution to the state's methane emissions is double current estimates – approximately 41% of all methane point source emissions in California.[2] This conclusion is supported by a report published by the Maryland Department of Energy finding that emissions from landfills were "four times greater" than previous estimates and were the leading source of methane emissions (37%) in the state.[3] The updated estimates were facilitated by the use of direct measurements instead of models. The NASA JPL study, in particular, deployed specialized airborne imaging spectrometers attached to drones, which could rapidly map methane plumes.[4] Deploying this remote sensing technology significantly improved the determination of methane emissions associated with landfills. In exceptional alignment with these studies, in October 2023, EPA published its findings that 61% of methane generated by food waste in landfill is emitted to atmosphere (i.e., a GCE of only 39%).

With CARB's endorsement of EPA as standard-bearer for capture rate, this EPA-quantified value should immediately replace a previous, outdated estimate. It is critical that CARB utilize the findings of improved monitoring and analysis techniques from the last quarter-century to inform and update the default landfill GCE. **We strongly urge CARB to update its 75% methane landfill capture assumption in the LCFS Tier 1 Calculator to reflect this latest EPA-published value**, which clearly affirms that landfill GCE in use at the State and national levels are well below the current default assumption.

Updating the fugitive methane emission factor will more accurately reflect the avoided carbon emissions associated from biomethane produced from anaerobic digestion of landfill-diverted organic waste. A more

Anaergia Services, LLC
705 Palomar Airport Rd, Ste 200
Carlsbad, CA 92011 USA

accurate CI score for biomethane from organic waste digestion will accelerate the deployment of anaerobic digestion throughout the State for landfill-diverted organics. This in turn can help the state achieve its goals to reduce SLCP emissions, per SB1383. Ultimately, this simple calculator update to reflect the latest landfill monitoring techniques and data can have an outsized impact on minimizing fugitive emissions of SLCP at landfills. Neglecting to correct the Tier 1 default GCE will result in the continued undervaluation of biomethane from organic waste and severely dampened investment in critical climate mitigating infrastructure.

Conclusion

Climate change is a grave threat to our environment and our economy. California has set an ambitious climate strategy and laws to reduce greenhouse gas emissions. Maintaining and improving LCFS is essential to support the development of a robust supply of in-state, carbon-negative biomethane, helping to achieve the State’s targeted reductions in SLCP emissions and encouraging in-state economic development.

In particular, avoided methane crediting is a powerful tool as a market signal to encourage investment and advance California climate goals – and it’s efficacy hinges on its correct CI determination through GREET. Updates to LCFS that enable the most accurate avoided methane crediting on a lifecycle basis will incentivize investment in food waste diversion infrastructure in California – where its benefit is most keenly felt – and establish a strong pipeline of cost-effective, carbon-negative biomethane generation to support both the transportation sector under LCFS and ultimately non-transportation sectors as well.

We deeply appreciate your leadership in mitigating climate change and hope that our comments will help to make these excellent programs work even better in the future.

Subject	large corporate farms

Comment

I am truly concerned about having more huge corporate farms moving into our state. (Missouri). And, paying them for the methane they produce would invite MORE to come to our state. 044.1
They are often owned by out of country people from China and other places that do not have our best interests at heart.
They raise animals in crowded, unhealthy, unnatural, conditions that are not humane..............
They are harmful to our water supply and harmful to the environment..........
Seems we can do a better job of raising animals on a smaller, more natural basis.............and more humane.

Respectfully,
Sherry Kerr

Sacramento, CA 95814

Re: Proposed Amendments to the Low Carbon Fuel Standard

Dear Chair Randolph,

We appreciate the opportunity to provide feedback on the proposed Draft Amendments to the Low Carbon Fuel Standard.

Fidelis New Energy, LLC ("Fidelis") is an energy transition company driving decarbonization through investments in renewable fuels, low-carbon intensity products, and carbon capture and storage. Using proprietary technology and processes, Fidelis aims to develop, invest, and deliver climate positive and carbon negative infrastructure to reach carbon reduction and climate positive targets. Fidelis develops carbon negative sustainable aviation fuel, renewable diesel, renewable naphtha, clean hydrogen, and clean ammonia infrastructure; in addition to developing and operating CO2 capture units, pipelines, sequestration wells, and related transportation and sequestration infrastructure.

We applaud the California Air Resources Board's efforts to pursue means of ensuring the continued success of the low carbon fuels standard. Our comments on proposed changes to the Standard are as follows:

Fidelis Supports Expanding Definitions for Acceptable Biomass Waste Feedstocks

045.1 It is critical for CARB to adopt a broader biomass definition in not only the most recent LCFS legislative proposal, but all future policy rulings by the Agency. The proposed utilization of arbitrary terms such as "unmerchantable" and certain "diameter sizes" for secondary material unnecessarily limits the potential feedstock pool, in potentially counterfactual ways, ultimately limiting the adoption of carbon neutral and negative technologies.

045.2 Furthermore, it is unreasonable to qualify material based upon diameter. This is out of alignment with existing federal programs and would be a departure from industry norms. Tracking and classifying material eligibility based on material diameter is not practical for companies to pursue from an effort, in-field feasibility, and cost perspective. Anything that is deemed as incidental material should be permissible as biomass feedstock, regardless of size. This would be inclusive of larger diameter residues, sawmill residues, and other to-be-defined materials.

One telling example would be the application of woody biomass generated as debris resulting from a natural disaster, such as a hurricane. In Louisiana, roughly 2 million tons of debris are generated per parish due to hurricane damage. Material generated in this quantity, and this quality, are generally destined to be landfilled as a means of disposal/use. From this perspective, the material

(832) 551-3300

is truly "unmerchantable". However, this hurricane debris - largely felled trees, large limbs and branches, fibrous industrial debris such as wooden planks and sidings from buildings, etc.- would then fall outside the identified diameter limitations currently proposed, limiting a positive utilization option and further impairing the local environment. Based on the current proposed biomass limitations, this hurricane debris would not be viewed as a usable feedstock, despite its utilization in fuel/power production being a greener alternative than the material going to landfill to decompose.

045.3 In Fidelis' experience, a common point of concern amongst stakeholders is the availably and longevity of biomass supply. Focusing narrowly on specific forestry residuals, such as fire mitigation clearings, will restrict the longevity and sustainability of biomass management industries, and pits various regions of the US against one another, rather than focusing on the scientific benefits of biomass management in general. For the bioeconomy to flourish, all available biomass opportunities must be accessible to producers for credit generation including management actions necessary to maintain a healthy ecosystem, such as thinning. It is vital that the legislation considers the economic and environmental benefits of utilizing biomass uniquely to all regions and not through a narrow consideration of biomass impacts specific to certain regions, such as fire management areas. This is important because fire management and mitigation only applies as a main driver for biomass in a few western states while it is not directly applicable for most of the available biomass in the United States.

Louisiana is one of the most prolific managed forestry regions in the world, with roughly 290 million tons per year of pulpwood and forest residuals harvested every year across the entire region. Pulpwood, sometimes referred to as "pre-commercial thinnings" or "secondary residuals", is a byproduct of prudent forestry management generated in to ensure healthy forest stands and state, local, and private habitat management.

Though there are some market outlets for this material today, the utilization of forestry management byproducts would not result in market distortion for these products. In fact, a market for this material is necessary to continue supporting proper timberland forestry management whereby the historical offtake demand for this material at pulp and papermills is significantly receding. With the closure of the papermills, there currently exists few viable markets for low-grade or waste timber in the Southeast, resulting in an increase of forest biomass thinnings left to decay on the forest floor where it is converted into CO2 that is released into the atmosphere. Without a healthy market for pulpwood and low-grade fiber in the area, forestry management on hardwood stands would no longer be economically feasible, reducing the ability to properly manage forests. This would result in unhealthy and low-quality timber stands that would take decades to recover, in addition to unmanaged ecosystems that will impair local wildlife. Projects participating in the LCFS program would provide a viable and sustainable market for low-grade hardwood and softwood fiber. This in turn would allow foresters to effectively manage the region's forest resources. Effective forestry management practice results in positive environmental impacts such as: increased carbon stocks stored in living large older trees and improved habitats for endangered species.

HOUSTON, TEXAS 77024
(832) 551-3300

Forestry suppliers would comply with operational integrity requirements, as many of these documentation and planning practices are industry standard today. For example, in Louisiana, a forestry management plan precedes harvests with the express purpose of supporting suspected and known endangered species on the sites. In forestry managed areas, plans are reviewed by biologists, academics, agency staff, and the public (in the case of state-owned land). All forestry management operations are currently documented. This documentation covers all harvest and thinning operations and includes property descriptions, dates of treatment(s), employed contractors, current stand conditions, volumes, and future planned activities. Supporting the low-grade wood market in the region allows forest managers to appropriately maintain forest stand health as well as habitats of endangered species found on the managed properties.

Guided by a life-cycle emissions analysis approach, Fidelis recognizes the climate-positive opportunity to utilize a wide variety of potential biomass sources, including pulpwood, as a renewable fuel feedstock, providing an alternative use for byproduct materials.

Fidelis Supports Scoping Feasible Traceability and Certifiability Procedures

045.4 Letters of attestation are an appropriate means of providing feedstock certification that aligns with the 7 priorities identified by CARB in its recent LCFS proposal, as well as appropriately fitting the maturity of the upstream biomass industry.

In terms of establishing a chain of custody for traceability purposes, bills of lading ("BOLs") are a tool used by multiple sectors today to trace material movements along their supply chains. Whether it be forestry management materials, landfill diversion, ag residues, or other material groups, BOLs provide a means of tracing the supply chain of custody for biomass to be used by BECCS facilities from the point of origin to final user. As a legally binding document, BOLs provide a complete description of shipments and parties involved, including:

- The quantity, value, and weight of the cargo.
- A complete description of items within the cargo, and its freight classification.
- The shipping and receiving parties as well as their signatures and the shipping date.
- Location of origin and destination

By tracking and documenting these components, BOL's ensure that there is oversight from point of origin to transport vehicle, to staging destination (if applicable) to end-user. In doing so, this document creates a receipt for the products, and generates a traceable supply chain for BECCS facilities.

Depending on the type of biomass material being utilized and the scale of the BECCS facility, the length and structure of the supply chain will vary. BOL's will allow these variances to be captured. Two examples that help demonstrate this difference are:

FIDELIS NEW ENERGY, LLC
109 NORTH POST OAK, SUITE 140
HOUSTON, TEXAS 77024
(832) 551-3300

- Residues sourced from a local mill and trucked to the BECCS facility.
    - In the case of mill residues and chips, the point of origin would be the mill where the materials were generated as a secondary waste in the milling process and loaded for transit. It is at this point that the residues would become a secondary product eligible as a feedstock for usage under CARB's LCFS, as well as other programs, given they are a waste stream and were not purposefully generated as a fuel or feedstock.
    - A single BOL would be generated in this instance: at the loading of materials onto a truck at the local mill, to be delivered to the BECCS facility and signed by the receiving personnel on site with specific details around the batch (volume, product, quality, etc.).
    - Because these feedstocks are a processing residue resulting from the production of primary materials such as finished lumber, furniture, pallets, barrels, etc., it is an undue burden upon the mill owner to trace residues upstream of the facility. Furthermore upstream actions were not intended for the utilization or consumption of these residual fibers. Should these fibers not be utilized, mills would landfill the product, leading to CO2 emissions in the decomposition process.
- Pulpwood, and other byproducts and residues, sourced from managed forestry stands.
    - In the case of this example, this could include but would not be limited to: wood fiber of low grade quality and various diameters, material falling within a pulp classification, limbs/tops/slash/bark, or other low-grade material that would be harvested, potentially in-woods chipped, and/or left on the forest floor.
    - In the case of forestry management material, the point of origin would be where this pulpwood and low-grade fiber would be collected, and potentially chipped, and loaded into trucks at the timber stand where the material was harvested as part of established forestry management practices and loaded for transit.

045.4 cont Tracking BOLs from point of origin to the end-user will enable the certifiability of the material utilized for the benefit of BECCS facilities, increasing oversight and transparency across the supply chain.

Fidelis Supports More Aggressive CI Benchmark Carbon Intensities and GHG Targets

We applaud the California Air Resources Board's efforts to implement more stringent carbon intensity benchmarks to support the continued success of the low carbon fuels standard.

The Low Carbon Fuel Standard has doubled the volume of low carbon fuels over the past ten years, diversified the fuel supply mix in California, and has overperformed compliance targets. This

FIDELIS NEW ENERGY
CLIMATE POSITIVE CARBON NEGATIVE

HOUSTON, TEXAS 77024
(832) 551-3300

overwhelming success of the program supports long term aggressive carbon intensity benchmark as well as near term strengthening measures. Fidelis encourages CARB to adopt the compliance
045.5 targets as modeled in the February workshop of 30% by 2030, 45% 2035, 65% by 2040, and 90% by 2045, along with a one-time step down in 2025 of an incremental 5%. Through these compliance targets, CARB will enable continued investment and development of low carbon fuels and deliver material reductions in transportation emissions.

As noted on the LCFS program dashboard, 35% (4.7 million) of the 13.4 million credits cumulatively banked from the program's inception were generated in the four-quarter period ending in Q3 2022.[1] Based on the rapid accumulation of credits, Fidelis applauds CARB for considering an acceleration mechanism to adjust compliance targets based on the performance of the LCFS market. This acceleration mechanism will ensure market certainty for industry to develop and deploy the required low carbon fuel infrastructure and ensure that emissions are rapidly, but feasibly, reduced to deliver both climate and air quality improvements to Californians. Furthermore, implementing an automatic acceleration mechanism allows the LCFS program to be more dynamic, send a positive market signal to renewable sector investors, and reach its decarbonization targets faster.

045.6 Furthermore, Fidelis supports the proposed auto-acceleration structure applied when the trigger criteria have been met (with limitations noted below). As such, all future years of the program schedule should be impacted accordingly. Rather than sending a one-time signal and holding the program at the new target for an additional period (i.e., a "freeze"), we believe that impacting all future years in the program sends a strong and consistent market signal. This will further encourage projects and investments in the decarbonization sector and allow the LCFS program to accelerate its progress towards California's GHG reduction goals.

To maintain an active level of oversight on the program's acceleration, Fidelis supports a limit on the number of consecutive auto-accelerations that can be implemented. Fidelis recommends that CARB be required to provide their approval on a third program auto-acceleration, if both trigger criteria are satisfied and there have been two consecutive prior auto-acceleration periods implemented.

In addition to these future compliance targets, Fidelis supports CARB's consideration of a one-time stepdown in the benchmark carbon intensity near term to address the rapid accumulation of excess credits. Of the 13.4 million credits in the cumulative bank, 4.7 million excess credits were added to the cumulative bank in the four-quarter period ending in Q3 2022. With the average
045.7 quarterly deficit generation over this period being 5.1 million credits, the credit generation was outpacing deficits by almost an entire quarter of expected deficit generation. Fidelis recommends that CARB implements the proposed 5% stepdown in 2025 to address this growth. This step down will provide market confidence in credit pricing, enabling near term investments required to support the strengthened carbon intensity requirement.

Fidelis Supports Adopting Intrastate Jet Fuel as Deficit Generator

Through the LCFS program, California has been the global leader in the deployment of low carbon fuels. The incentivization of SAF in the Inflation Reduction Act has encouraged significant deployment of SAF facilities and alternative Jet fuel generating credits in the LCFS market since 2019. Fidelis encourages California to continue leading the deployment of alternative jet fuel (SAF) at scale by making conventional Jet Fuel a deficit generating fuel when used on intrastate
045.8 flights. This amendment will directly incentive the utilization of alternative jet fuel at scale, resulting in decreased greenhouse gas emissions and improved air quality.

Respectfully submitted,

Fidelis New Energy, LLC

California Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Ms. Sahota:

Re: Intrastate Fossil Jet Proposal

Chevron appreciates the opportunity to review and comment on the subject Low Carbon Fuel Standard rulemaking proposal.

Chevron is a major refiner and marketer of petroleum products and renewable fuels in the state of California and a regulated party under the Low Carbon Fuel Standard (LCFS). Chevron is also an international producer of lower carbon intensity fuels with a global integrated procurement, distribution, and logistics network and 11 biorefineries in the U.S. and Europe.

Chevron is submitting multiple letters on key topics under the 2024 LCFS rulemaking. Following are our comments on the proposal to introduce LCFS deficits for intrastate fossil jet fuel consumption.

<u>Key Messages</u>

- Adding deficits for intrastate fossil jet consumption will not encourage faster adoption of alternative jet fuel.
- Designating refiners and importers as the first reporting entities creates an impractical framework for compliance.
- Measuring intrastate jet fuel consumption is more complex than one might expect.
- CARB has not proposed critical definitions or verification protocols to enable compliance.

<u>CARB's Proposal</u>

CARB proposes to remove the exemption for fossil jet fuel under the LCFS, unless that fuel is demonstrated to have been used for interstate or international flights. The intent is to assign deficits to fossil jet fuel used on intrastate flights, defined as taking off from a California airport and landing at another California airport. The rationale for this proposal is that "California must reduce GHG emissions from aviation." However, CARB has proposed refiners and importers of jet fuel as the first reporting parties for fossil jet fuel, treating jet fuel in the same way that gasoline and diesel fuel are treated. There are several problems with this proposal.

Our Family of Brands

Chevron Products Company
A Division of Chevron U.S.A., Inc.

dgilstrap@chevron.com

Fossil Jet Deficits Would Have No Effect on AJF Growth

The proposed deficits will add a new cost to air transportation within the state of California. However, the credits needed to satisfy this new obligation are far more likely to come from established fuels under the LCFS: ethanol, biodiesel, renewable diesel, RNG, and electric vehicles. While Alternative Jet Fuel (AJF), commonly referred to as Sustainable Aviation Fuel, qualifies as an opt-in fuel under the LCFS, the proposed deficits do nothing to improve the economics of its use.

047.1 The market-based structure of the LCFS is a critical element of the program's success to date. Credits generated by one fuel can be used to satisfy the deficits from another, even if it is not a direct substitute. This has enabled the rapid growth of fuels like renewable diesel and renewable natural gas, which play a large role in compliance with the deficits from both gasoline and diesel. Adding deficits for fossil jet fuel will not drive growth in AJF because the fundamental hurdle is that AJF is more expensive to produce than renewable diesel. A fossil jet obligation will not change the compliance value of AJF. Credits from fuels that are more economic would satisfy the new obligation.

Further, demand for AJF is growing without the proposed changes. The apparent logic is that adding deficits for intrastate jet will boost demand for AJF, but demand is not the problem. In the Initial Statement of Reason for this rulemaking, CARB describes emission reduction targets set by several airlines, who are pursuing increased AJF use to meet those targets. CARB also discusses the conversion of multiple California refineries to produce bio-based fuels, including AJF. This is all happening without the proposed fossil jet deficits, which will do nothing to improve the economics of those efforts.

The LCFS is already doing its part to encourage AJF adoption through the ability to opt in and generate credits. If CARB is looking to increase the incentive for AJF, it is worth considering an approach proposed by alternative jet fuel producers in their comments during the 2018 rulemaking[1].

047.2
> *Another benchmarking approach that would be more consistent with ARB's regulatory authority would be to establish a fixed benchmark standard for conventional jet fuel. This would be consistent with conventional jet fuel's LCFS exemption and would appropriately recognize the difference between CARB's regulatory authority over diesel and gasoline and its authority to provide a voluntary incentive in the aviation sector. Rather than a curve, such an approach would establish a fixed benchmark. It would logically be fixed at the CA-GREET 3.0 carbon intensity score that ARB determines for conventional jet fuel for 2010.*

This approach recognizes the global nature of jet fuel as compared to gasoline and diesel, while adding a competitive incentive for AJF. There is logic in this proposal and it would be far more effective than adding deficits for approximately 10% of the jet fuel consumed in the state.

The Proposed Approach Is Not Practical

CARB has proposed to include fossil jet fuel in the LCFS in the same manner as gasoline and diesel with certain uses exempted. The intent is to obligate only intrastate jet but executing this will be extremely problematic. Designating refiners and importers as the first reporting entities

[1] https://www.arb.ca.gov/lists/com-attach/119-lcfs18-WjsHawdgV1sEclUn.pdf

will bring all fossil jet fuel produced in the state into the program, meaning that CARB will be regulating interstate and international commerce. This is because:

047.3

- Refiners and importers will not have the information needed to separate intrastate jet fuel use from interstate and international use.
- This will require reporting all produced and imported jet fuel.
- The LCFS obligation for this fuel will then have to be passed through the supply chain until it reaches the aircraft operators.
- Aircraft operators (airlines, shipping companies, small aircraft owners) are the only parties who will have the information necessary to determine intrastate use versus exempt uses.

There are numerous points in the supply chain where title transfer can take place. This includes, but is not limited to, refinery gates, pipeline transactions, truck deliveries from terminals, in-tank transfers, and sales from airport storage (see Figure 1). At none of these points will the division between intrastate and interstate/international use be known. The LCFS obligation must ultimately be transferred to the aircraft operators who are the only parties that could segregate and report the intrastate and exempt volumes. For multiple reasons, the segregation will be challenging to do accurately, with the likely outcome that some of the LCFS burden will be placed on jet fuel used for interstate and international flights.

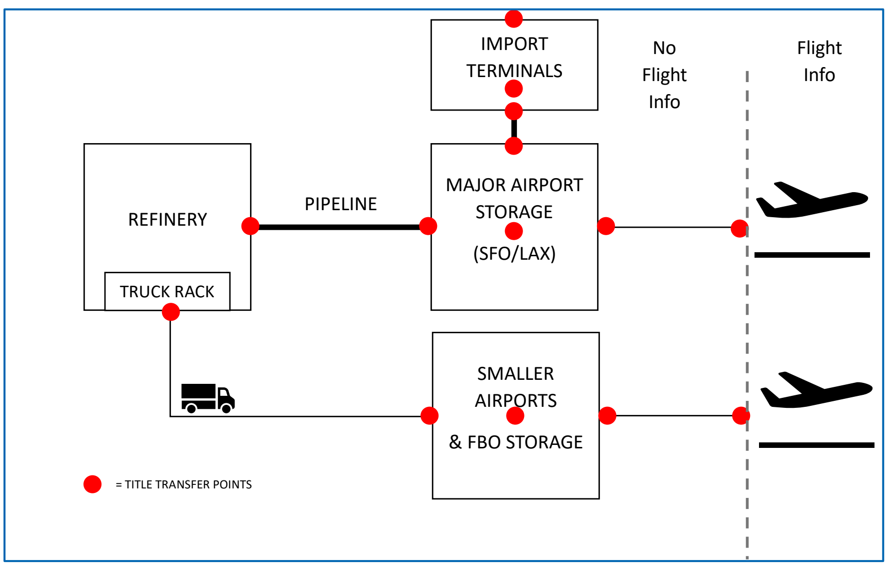

Figure 1. Jet fuel supply chain title transfer points

This adds a significant volume of additional reporting under the LCFS to track jet fuel production and import, purchase and sale, and ultimate consumption, only to have 90% (per CARB's estimate) of the fuel in question ultimately reported as exempt. This would also require changes to hundreds of contracts between parties involved in the jet fuel supply chain in California. Chevron alone has dozens of contracts related to jet fuel supplied on pipelines, via truck deliveries, terminal storage locations, and airport storage within California.

To further complicate the proposed approach, not all intrastate flights will have been fueled within California. It is common practice for aircraft to fuel at one airport (which could be outside California) and not refuel until multiple legs of a flight have been completed. This means an aircraft could fuel outside California, make multiple stops within the state, and refuel again out-of-state. So, CARB's proposal will not only end up regulating interstate/international use but will also exclude a portion of intrastate use.

047.3 cont While regulating intrastate jet fuel will not address CARB's goal of growing AJF use, if CARB chooses to proceed with this concept, it would be much more practical to designate the aircraft operators as the first reporting entity and avoid the excessive additional reporting activity and unavoidable inaccuracies described above.

Tracking and Reporting Intrastate Use Will Be Challenging

Designating aircraft operators as the first reporting entities will reduce the administrative burdens of the program but challenges with accuracy will remain. It is likely that aircraft operators will have to create new accounting and reporting systems to accurately measure and record fuel consumption for any California intrastate leg of a flight. Requiring that intrastate consumption be reported will add a significant, labor-intensive burden for aircraft operators.

047.4 A simple multiplier based on miles traveled between California airports and assumed fuel consumption could reduce the effort needed. However, aircraft size and type would have to be considered. This would lead to establishing multiple factors and clear guidelines from CARB on how to apply them, adding significant additional work for both aircraft operators and CARB staff.

This all assumes that this new obligation applies to a few large airlines and shipping companies. CARB must consider the added burden for small aircraft operators that fuel at fixed base operators (FBOs). It would be impractical to expect individual aircraft owners to understand and comply with this obligation under the LCFS. Even if the obligation belongs to a fuel supplier or the FBO itself, small aircraft owners would have a role to play in tracking and reporting intrastate jet fuel consumption.

More Specific Guidelines Are Needed

The minimal regulatory amendments made in this proposed rulemaking do not provide sufficient guidelines for compliance.

047.5

- An exemption is proposed for fossil jet fuel used for interstate or international flights but no definition is provided for these types of flights.
- No method is provided for measuring jet fuel use.
- § 95500(c)(1)(A) requires verifiers to include the transaction type "Fossil Jet Fuel Used for Intrastate Flights" in the scope of their review but it is not clear when this transaction type would be used and no parameters are given for verifying its use.
- As written, the proposed regulation requires parties to report production, import, purchase, sale, and all other transaction types that could apply to fossil jet fuel.
- No method is given for then reporting the portion of that fuel that is exempt based on interstate or international use.

Conclusion

CARB should remove the proposed introduction of deficits for intrastate jet fuel use. It does not address the intended goal of growing AJF. Instead, it introduces a confusing accounting burden into the California jet fuel supply chain and increases the cost of air travel without a corresponding benefit. Further, the burden will almost certainly increase the costs of interstate and international jet fuel use for flights that depart from California. To improve crediting for AJF under the LCFS, CARB could consider the 2018 proposal to use a fixed benchmark for AJF crediting. Absent that, it would be more effective to pursue an incentive program outside the LCFS to provide more direct encouragement for AJF growth.

Thank you for the opportunity to comment on these matters. If you have any questions regarding our comments, please contact me at (925) 842-8903 or DGilstrap@chevron.com.

Don Gilstrap
Manager, Fuels Regulations

February 14, 2024

Rajinder Sahota
Deputy Executive Officer – Climate Change and Research
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Ms. Sahota:

Re: Biogas & H2 Proposals

Chevron appreciates the opportunity to review and comment on the subject Low Carbon Fuel Standard rulemaking proposal.

Chevron is a major refiner and marketer of petroleum products and renewable fuels in the state of California and a regulated party under the Low Carbon Fuel Standard (LCFS). Chevron is also an international producer of lower carbon intensity fuels with a global integrated procurement, distribution and logistics network and 11 biorefineries in the U.S. and Europe.

Chevron is submitting multiple letters on key topics under the 2024 LCFS rulemaking. Following are our comments on the proposed amendments related to biogas and hydrogen.

Key Messages

- The 50% capacity limit on Hydrogen Refueling Infrastructure (HRI) credits will stall investment.
- Chevron supports book-and-claim accounting for hydrogen.
- The deliverability requirement and carbon intensity (CI) threshold for pipeline hydrogen are counterproductive.
- Reversing crediting for avoided methane runs counter to the goals of the LCFS and could cause backsliding.
- New deliverability requirements for biogas are unnecessary and will inhibit biogas investment.

HRI Crediting

048.1 The rationale that limiting HRI crediting to 50% of capacity will encourage wider scale growth is flawed. The current LDV HRI program does not have a capacity constraint, yet it has still fallen short of hitting the 2.5% obligation maximum each quarter due to the economic, technological, and permitting challenges of building hydrogen infrastructure. Shell's recent announcement that

Chevron Products Company
A Division of Chevron U.S.A., Inc.
6001 Bollinger Canyon Rd, San Ramon, CA 94583
925 842 8903
dgilstrap@chevron.com

048.1 cont they will close several stations is illustrative of the challenges faced in this space[1]. For heavy- and medium-duty (MHD) fueling stations, these challenges are only amplified due to the high capital requirements, lack of available fueling technology, and large land use requirements. Chevron urges CARB to remove the capacity limit and continue with a 15-year crediting window to encourage growth. If there is a capacity constraint and a shorter pathway length, then the prospect of lower returns would likely limit program participation.

048.2 Chevron requests that CARB work with industry to develop a realistic solution to differentiate reporting between light-duty and MHD vehicles for HRI crediting purposes. Since these are public access locations, there are little to no means for tracking hydrogen vehicle size to identify if the vehicular weight is less than 8,500 lbs, or within 8,501 lbs to 14,000 lbs GVWR. Also, unlike CNG, separate nozzles are not used for light duty vs. MHD vehicles today. The newly developed NREL heavy duty fueling protocol may allow for separate nozzles for fueling, however it will take many years for the industry to transition.

<u>Hydrogen Book-and-Claim</u>

048.3 The proposal to allow book-and-claim accounting for dedicated hydrogen pipelines is a constructive addition to the LCFS. However, imposing carbon intensity (CI) and deliverability constraints are unnecessary. There is no rationale for treating the CI of hydrogen shipped via pipeline differently than hydrogen shipped by truck. This only serves to encourage inefficiency in the supply chain. The market will reward lower-CI hydrogen without the need for these constraints.

CARB's expressed intent is to align with practices being established under the Inflation Reduction Act (IRA). This is unnecessary and counterproductive. The IRA includes arbitrary carbon intensity thresholds set by Congress, and the Treasury department is just beginning to establish organizational capability in this space. By contrast, the LCFS program is far more advanced and mature than these new measures and operates well as a technology-neutral and market-based approach. This is evidenced by CARB's focus on CI as the vehicle for GHG reduction, as opposed to providing credit for only certain technologies.

<u>Tier 1 Hydrogen Calculator</u>

048.4 Chevron applauds CARB's work to establish a simplified Tier 1 calculator for hydrogen pathways. This will greatly increase speed to market implementation. CARB's incorporation of feedback from industry is appreciated as well. This enables a more accurate and realistic approach from the beginning.

<u>Avoided Methane Crediting</u>

048.5 Chevron disagrees with the sunsetting of avoided methane crediting for biogas pathways under the LCFS. This is a demonstrated, significant reduction in greenhouse gas emissions that would otherwise be released to the atmosphere. Additionally, limiting incentives for biogas and renewable natural gas producers to reduce methane emissions is inconsistent with the Subnational Methane Action Coalition's statement of purpose and the 2021 Global Methane Pledge.

048.6 It is encouraging, however, that CARB has set a timeline that will avoid near-term stranded investments and allow for the establishment of new policies to encourage biogas use in other

[1] California's Hydrogen Economy Dealt A Hammer Blow By Shell's Exit (forbes.com)

sectors. If new programs do not arise to direct biogas and renewable natural gas to stationary sectors, we urge CARB to revisit this proposal in a future rulemaking to avoid backsliding.

Biogas Deliverability Requirements
While we appreciate the reasonable implementation timeline for the newly proposed
048.7 deliverability requirements, this also has the potential to deter growth and cause potential backsliding. The current approach to book-and-claim accounting is practical, aligns with other U.S. policies, and provides the most effective means of reducing GHG emissions, which are global in nature.

Thank you for the opportunity to comment on these matters. If you have any questions regarding our comments, please contact me at (925) 842-8903 or DGilstrap@chevron.com.

Sincerely,

If you have any questions or comments please contact Clerk of the Board at (916) 322-5594.

February 15th, 2024

The Honorable Liane Randolph
Chair California Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Chair Randolph:

As a developer of dairy digester RNG and biogas to electricity projects for EV charging in West Coast states, Promus Energy appreciates the opportunity to comment on the proposed changes to the CA Low Carbon Fuel Standard (LCFS). Promus values CARB's serious consideration and incorporation of feedback provided by us and other stakeholders as revisions to the LCFS program have been carefully crafted over the last several years.

Promus is pleased with CARB's proposed changes that will support the LCFS credit market and send the long-term market signals investors need to fund low carbon intensity (CI) fuel development projects.

Carbon Intensity Target Adjustments and Impact on Credit Prices:

We support incorporation of a one-time 5% "step down" in the CI target in 2025. 049.1

- This step down, and the subsequent anticipated increase in LCFS credit pricing, would jumpstart investment in low-CI projects and bolster the confidence lenders need to fund these projects.

However, Promus is concerned that CARB's analysis shows credit prices will dip to levels around $76 by 2030.

- Prices dipping this low by 2030 after their projected increase in 2025 makes it difficult for lenders to have sufficient confidence that low CI fuels projects will produce strong enough financial returns in the near term. While anticipated credit prices in 2025-2027 are at levels that support low CI fuels projects, these prices do not stay high long enough to generate attractive returns on project investments and inspire lender confidence.
- 049.2 Promus urges CARB to consider ways to minimize or eliminate the dip in credit prices by 2030, such as by setting a greater than 30% CI reduction target by 2030 sufficient to restore and stabilize healthy credit pricing. BTR's analysis presented during the May 2023 LCFS workshop indicated that a 2030 CI reduction target of greater than 30% will be required to prevent the credit bank from growing again within just a few years after the one-time step down. Preventing renewed growth of the credit bank is essential to supporting healthy LCFS credit market dynamics. Promus supports a CI reduction of 35% by 2030 to ensure strong short- to medium-term credit prices needed to spur investment in low CI fuels projects.[1]

Clarification Needed for Biomethane Avoided Emissions Crediting:

049.3 Promus appreciates that CARB is extending up to three ten-year crediting periods for biomethane avoided emissions crediting for projects that break ground before 2030. However, we ask that CARB clarify a few points:

- Will the three ten-year crediting periods for avoided emissions crediting also extend to biomethane to electricity for EV charging pathways, or will they only apply to biomethane to
049.4 CNG, LNG, and Hydrogen pathways? Certainty for these crediting periods is essential for the financeability of biomethane to electricity projects and the reduction of electricity CI for EV charging.
- The following statement in the Proposed Regulation Order that describes the three ten-year crediting period suggests that a project needs to be certified by 2030 for it to be eligible: "The Executive Officer may renew crediting periods for fuel pathways certified before January 1,
049.5 2030, for up to three consecutive 10-year crediting periods."[2] However, this conflicts with statements later in that section and in other documents that suggest that the project must only have broken ground by 2030 to be eligible for the three ten-year crediting period. Could you please clarify the eligibility requirements?

We appreciate the opportunity to provide feedback on the proposed changes to the LCFS program.

Thank you for your consideration.

Sincerely,

Dan Evans, President

Sacramento, CA 95814

Re: Brimstone's Comments on the Proposed Low Carbon Fuel Standard Amendments

Dear Mr. Botill:

050.1 Brimstone appreciates the opportunity to comment on the proposed amendments to the Low Carbon Fuel Standard (LCFS). Brimstone supports California's climate change goals, including achieving carbon neutrality and net-negative greenhouse gas emissions no later than 2045. Currently, the LCFS provides one of the only regulatory markets in the world for carbon removal. This is a critical element of the program, and we strongly support the inclusion of carbon removal via direct air capture (DAC) as a credit-generating pathway under the LCFS.

050.2 Because carbon removal is so critical to achieving California's goals, we further encourage CARB to develop additional carbon removal protocols as it implements SB 905, including mineralization of carbon dioxide from the atmosphere and ocean. LCFS amendments should accommodate new carbon removal pathways, if and when they are adopted in the future. We accordingly urge CARB to consider 15-day changes to the LCFS proposal that would allow new carbon removal pathways to be included in the program, provided they meet the additionality, permanence, and other requirements of existing CCS Protocol.

About Brimstone

Brimstone is a California-based company, headquartered in Oakland, with a carbon-negative process for making ordinary portland cement. Cement has nearly the same greenhouse gas impact as all the world's cars on the road today, and it has traditionally been one of the most difficult materials to decarbonize – until now.

Our process produces ordinary portland cement from calcium silicate rocks, which do not contain CO_2, rather than limestone. It avoids any process emissions associated with producing portland cement and produces a magnesium byproduct that passively mineralizes CO_2 from the ocean or air and permanently stores it as magnesite rock.

Brimstone is upending the conventional wisdom that CO_2 process emissions are a necessary outcome of cement production and that carbon capture and sequestration (CCS) and associated high costs and/or subsidies are required to decarbonize the traditional process. We are also proving that carbon removal and direct greenhouse gas emission reductions at their source can, and should, go together, and need not be considered tradeoffs.

LCFS amendments should allow mineralization or other potential new carbon removal or DAC protocols to be used if they are adopted separately

050.2 cont We encourage CARB to allow the utilization of diverse carbon removal solutions that extend beyond existing CCS Protocols to be included in the LCFS. Specifically, we ask that CARB consider broadening definitions and references to CCS, DAC and the CCS Protocol to make clear that new carbon removal protocols may be developed and added to the CCS Protocol, and that if/when they are, projects utilizing those protocols would be eligible to generate credits under the LCFS, just like DAC projects currently can do.

As described above, approaches like Brimstone's that utilize natural carbon mineralization pathways offer highly efficient, enduring, and scalable methods of carbon removal. Strategies to remove carbon from the ocean may require less energy than removing carbon from the air, or in the case of mineralization, offer greater efficiencies for carbon removal and sequestration. Broadening the definition of eligible DAC projects and related CCS references to encompass additional promising carbon removal strategies by reference that may be adopted by the Board in the future will help to unleash solutions with significant potential for a widespread impact, which will be needed to achieve California's carbon neutrality objectives.

Conclusion

Thank you again for the opportunity to comment on the proposed LCFS amendments. We look forward to working with you and other stakeholders through the LCFS amendment process, SB 905 implementation, and other forums to keep the state on track to meet and exceed its climate goals. Please do not hesitate to reach out if you have any questions about Brimstone or these comments.

Thank you,

Simon Brandler
VP of Policy & Public Affairs
Brimstone

Subject	Factory Farm Gas in California's Fuel Standards
Comment	

Dear Board Members,
I'm against including factory farm gas in California's Low Carbon
Fuel Standard. This will not be a positive solution for our
climate
crisis. One of the main reasons to nix factory farm gas from the
standard is that it will encourage more large factory farms,
making
051.1 it harder for small family farms to prosper while these corporate
farms push down market prices with overproduction. More issues
with
this bill include the fact that multinational large meatpackers
will be paid for their pollution, and the bill will create
incentives via government subsidies to support anaerobic digesters
for factory farm gas.
This would add more factory farms which will lead to more methane,
more water and air pollution, more corporate consolidation. I'm in
the Midwest and know this will not lead to less carbon release in
our atmosphere. Please strike this portion of the amendments.
Thank you for allowing comments.

Subject DISASTER POTENTIAL FROM BIOGAS

Comment

There are already enough uncontrolled releases of methane from
multiple major sources in multiple major countries, from unmanage
landfill gas to fracking and pipeline release. Methane is much
more damaging to atmospheric protection of the planet than CO2.
Concentrated manure is a preventable source, and this process is
poorly captured. Pipeline losses will also apply to "biogas". In
052.1 addition to environmental impacts, community planning for emergenc
situations is usually under-assessed and under-developed. These
become gigantic explosion risks, whether or not the methane is
intended to be collected.

Subject	Factory Farming and the allegiance to disregard

Comment

I often wonder what kind of human has the gall, emotional paralysis, and substantial lack of compassion that they are able t bear witness to the horrendous living conditions and ultimately, barbaric death these sentient beings are subjected to.

One might argue, "they don't know any different." To that I ask, i you grew up with debilitating physical abuse in your house, would you think that was normal and you would be fine because you don't know any better?

If we are being honest with ourselves, the answer would be no.

What if our babies, as soon as they are born, are taken from us. Chained to a dog house until they are sold to be killed and we are then raped of the nutrients our body made specifically for our offspring so someone else could get money.

Money. For what? To drive a stupid fancy car? To buy a big house you eventually take for granted? To tell people you have x amount of dollars so you can make yourself feel a little better about being you?

It's trafficking at the most basic level.you have advocated for this. You have sold yourself and your basic human beliefs for paper.

Take a step back and think about what factory farming really is ar then look at yourself in the mirror in a quiet room and sit with the fact that YOU have killed, abused, and neglected your fellow beings so YOU could have money. How sad of an existence is that really?

How cheap your soul is to be bought so easily and at the disregarded suffering of others. Think of your most beloved relative who as a child, you thought hung the moon. What would the think if they walked beside you everyday and watched what you did to animals.

It's a shame, really. We all used to have compassion, empathy, ar respect for all those around us. I dream of a time when we get bac to that. Sure, there are populations who consume meat and that is choice we all have the right to bare. What's wrong with doing it the right way and having pride in what you contribute to the worl Where has the pride gone?

064.1 End factory farming. It's what's good for all of us and something we collectively can be so proud to be a part of.

Subject Get Rid of Factory Farms and all the extras that come with it

Comment

Factory farming is the one of the biggest atrocities of modern day living.

065.1 We vegans. vegetarians have proven meat is not a necessity at all in the human diet. STOP playing around with regulations that pretend to show you care about the environment. Humans are as much as animals a connecting power to the environment. We are not seperate but a part or partner to it. I have a sort of PTSD from watching a few slaughterhouse videos to help keep me on my track o meatless diet and compassion for our fellow sweet animals like the cows, sheep, goats, pigs, ducks, turkeys, and chickens etc. Man is in a state of CONFUSION in the walls of confinement of buildings, roads, etc. Only an old time native American Indian can tell you what it feels like to know the spiritual tie to the land they were so proudly apart of. Simple living was a direct connection to trut at all times and to all places in time. They could feel the energy from the earth entering their being as some of us awakened can now too. Their intuition was outstanding and their ability to communicate with ancestors.

California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

As a renewable fuel producer and participant in CARB's LCFS program, my team and I value the partnership and mission shared with you and your state to reduce the carbon intensity of transportation fuels.

I am writing to share our company's perspective on two key program areas for your consideration. These requests address the topics of **firm rotation** and **less intensive verification**.

Firm Rotation

The existing regulations within the LCFS verification program stipulate a mandatory rotation of audit firms every six years to assess participants' carbon intensity (CI) and fuel quantities compliance.

Our request is that CARB amend the mandatory firm rotation regulation to include an exception for licensed CPA firms. Of the 30 approved LCFS verification bodies, there are only four licensed CPA firms.

067.1 ***An approved verification body, that is also a licensed CPA firm, exceeds the standards in place for verification bodies and is already subject to additional oversight on the entity's quality control system in accounting and auditing practices through the required AICPA peer review process.***

Due to the increased regulatory oversight, we suggest a CPA firm not be subject to the audit firm rotation but would instead adhere to a Lead Verifier rotation after six consecutive years.

A licensed CPA firm differs from other consulting agencies by adhering to more rigorous standards and oversight at a state and national level. If a verification body were to violate a Lead Verifier rotation requirement, it would put the firm license at risk. The firm

license is required for all services provided by the firm, not just the LCFS verification services, thereby ensuring adherence to requirements.

Licensed CPA firm requirements

- A licensed CPA firm must be comprised of over 50% of the ownership being licensed CPAs.
    - To earn the accreditation to be a CPA, one must pass a rigorous four-part CPA exam, accumulate education hours, and in many states, one must fulfill 1-2 years of work experience.

- 3-year peer review audit
    - Each licensed CPA firm must enroll in an approved peer review program with reviews conducted every 3 years. The peer review requirement is a requirement of the American Institute of Certified Public Accountants (AICPA) and is an external review of a firm's quality control system in accounting and auditing practices. CPA firms' peer review results can be found on AICPA's website under the Peer Review Public File Search.

- State Boards of Accountancy (SBOA) are found in each state's statute to aid state governments in the licensing and regulation of the public accounting profession.
    - SBOAs provide further oversight on CPA firms by evaluating CPA licensees' examinations and regulatory oversight to ensure a firm is practicing within their statutory scope.

The audit quality and efficiency improve as the auditor becomes more familiar with our company's processes. In addition, with the limited number of firms available as verification bodies and a five-year lookback period in place, it is proving difficult to identify a quality verification body that is not also working with our facility in other consulting capacities. The number of people available with the proper expertise to assist us in design and development of projects and to reserve for verification purposes has proven even more limiting, which is also why we request a Lead Verifier rotation rather than a full firm rotation.

Less Intensive Verification

Regarding less intensive verification, we noted in Appendix E staff's proposal for less intensive verifications for when electricity is used as a transportation fuel, allowing verification bodies to skip site visits if they visited the site in the last two years and issued a positive verification statement.

The rationale for this proposed change states, "there is little change of operation from reporting period to reporting period thus reducing the benefit of annual site visits." Additionally, staff rationale states, "There is no or little risk to the integrity of the LCFS program to allow for less intensive verification services without a site visit in the annual verifications for the following two years. This should reduce the cost of verification services which is often passed on to program participants.”

Currently, the proposed language limits this allowance for less intensive verifications to QFTR third-party verification bodies for fuel reporting entities only reporting electricity transactions.

We agree with the staff’s stated rationale, but **we request for less intensive**
067.2 **verification to be extended as an option for verification bodies on all validations**
and annual verifications for any reporting entities.

In CARB’s MRR program (section 95130), less intensive verification is applied without prejudice to verification services by accredited verification bodies.

We agree with staff that less intensive verification leads to little to no risk to the integrity of the LCFS program and that there is little change in operation from reporting period to reporting period, while also providing cost savings to verification providers and passed on to our company as program participants.

We acknowledge the importance of adhering to CARB’s specified conditions that necessitate comprehensive verification services. These conditions include the issuance of an adverse verification statement or a qualified positive verification statement in the preceding year and the occurrence of a change in operational control of the reporting entity in the previous year.

Thank you for your time and consideration. Please reach out to us if you have any questions.

Sincerely,

Subject	Biogas
Comment 070.1	Biogas from CAFOs is neither clean nor naturally renewable. It's not a replacement for clean solar, water, wind, and geothermal energy. It does not solve the environmental degradation or the human and other animal suffering caused by factory farming. This Earth Day, we must reject biogas in favor of energy and agricultural changes that can actually build a sustainable, just future.

Subject	ZEVs

Comment

Please refrain from using the term "ZEV" or, at the very least, refrain from blanketly including electric vehicles in your definition. The California Low Carbon Fuel Standard is a complete well to wheel GHG emission program. The California power grid is far from zero emissions (even if you exclude all the uncontrolled burn emissions from forest fires caused by downed power lines). Electricity from the California power grid is the baseline source of fuel for most electric vehicles and thus, they are not "zero emission vehicles" per the very foundations of your policy.

071.1 If CARB wishes to include some electric vehicles in this definition, it should limit the vehicles to only those using hard-wired renewable power to refuel their vehicles as per CARB guidance on the use of renewable electricity.

I have doubts that even the vehicles mentioned above should qualif as a ZEV as GHG emissions from battery production and the production of solar panels are also not "zero emission" but I wil concede that one could interpret those as outside the scope for "fuel" within LCFS policy but CARB should further give guidance that the materials used to generate, store, or utilize fuel are outside the scope of the AB 32 policy.

CARB could choose to change this definition to zero tailpipe emission vehicles but it should refrain from using the "ZEV" acronym which is marketing tool for electric vehicle manufacturer and irrelevant to a well to wheel GHG emission policy. It is confusing to LCFS stakeholders and general population.

Subject	Do Not Invest In Biogas

Comment

California has more industrial dairies than any other state so it is polluting rivers, depleting groundwater, and emitting disastrou greenhouse gasses!!

I experienced a NATIONWIDE food recall of California vegetables du to urine and feces run off from cows, into nearby vegetable farms

077.1

Now, factory farm polluters claim they are environmentally friendl because they produce "biogas."

Even worse, they are using tax dollars to fund this harmful greenwashing because the fact is Biogas is unsustainable and unnecessary--it does not reduce the dairy industry's environmental footprint!!

Investing in biogas means investing in even more factory farm pollution.

Subject Comment on proposed low carbon fuel standard amendments

Comment

To whom it may concern,
I am a lifelong Missouri resident with a long family history of small farmers. I have seen the harm inflicted by factory farms in my state, and I am fully aware of the negative impacts of factory farms on the environment, public health, animal welfare, and local economies. Nobody in Missouri wants these harmful farms - we want to support local small farms with regenerative practices.
When I learned that the CARB wants to include factory farm gas in
082.1 its Low Carbon Fuel Standard, I became so confused. The science is very clear that methane is not a climate-friendly gas. Everyone is aware that factory farms are nothing but harmful. Allowing factory farms to sell the methane created by housing massive numbers of cows and hogs as a supposedly "carbon negative fuel" is a completely harmful and misguided idea. Please consider the negativ consequences of this proposal and scrap it. We can do better.
Thank you for your time,
Briana

Shell USA
West Corporate Relations
1121 L Street, Suite 700

Sacramento, CA 95814

February 15, 2024

Ms. Rajinder Sahota
Deputy Executive Director – Climate Change and Research
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: Shell USA, Inc. Comments on Proposed 2024 Low Carbon Fuel Standard Amendments

Dear Ms. Sahota,

Shell USA, Inc. (Shell) appreciates the opportunity to provide comments on the subject proposed amendments to the Low Carbon Fuel Standard (LCFS). Shell shares a legacy of energy innovation with California that spans over a century, and we appreciate CARB's commitment to incentivizing investments in clean energy. In addition to marketing traditional fuels and electric vehicle charging we deliver low-carbon fuels such as biofuels, renewable natural gas (RNG) and hydrogen. Shell and its affiliates provide secure energy today and look ahead to the evolving energy needs of California and the nation. We are proud to work with our customers and the state to provide a viable energy system that relies, in part, on the regulatory constructs including the LCFS.

Shell respectfully submits these comments for the purpose of helping develop a robust regulatory structure. As always, we welcome the opportunity to answer any questions you may have.

GENERAL COMMENTS

Intrastate Fossil Jet Fuel – More Needs to Be Done Before It Can Become a Deficit Generator

The proposed regulations require fuel importers and producers to determine (a) what is intrastate aviation and (b) how and where the purchasers (i.e. the airlines) consume jet fuel.

088.1 Fuel importers and producers cannot comply because in large part they aren't able to track where their jet fuel is consumed. Accordingly, fuel importers and producers cannot provide any information regarding what portion of their jet fuel is interstate vs. intrastate. Fuel importers and producers only know the amount of jet fuel delivered to storage facilities.

In our view, the language related to intrastate fossil jet fuel should be removed until these issues can be properly vetted.

Eliminate Limitations on Book-and-Claim Accounting for Hydrogen

088.2 As you know, Shell has been very active in developing hydrogen projects in the state, and we are concerned that limiting book-and-claim accounting for hydrogen will constrain growth. This undermines California's immediate need to significantly increase hydrogen as detailed in the 2022 Scoping Plan Update. The LCFS program includes CI benchmarks, and these should be used as the singular determining factor to drive CI reductions and the credit values.

Facilities with an EPA Pathway Should be Exempt from Additional Sustainability Criteria

088.3 Shell appreciates that the proposed amendments do not place arbitrary caps on crop-based feedstocks given that there is no evidence currently suggesting that these feedstocks are resulting in deforestation or adverse land use change. CARB's goal is to prohibit bringing new land into agricultural production for biofuel feedstocks. However, this is currently addressed in the EPA Renewable Fuel Standard. The EPA requires that crop-based feedstocks come from existing agricultural land cleared or cultivated prior to December 19, 2007. If the feedstock was grown outside the United States or Canada then the EPA will require entities to map and track to ensure that this requirement is met (See, 40 CFR 80.1454(c)). However, for feedstock coming from a crop grown in the United States or Canada, the EPA checks when it issues its Renewable Volume Obligation that the 2007 baseline amount of agricultural land in the United States or Canada has not been exceeded (See, 40 CFR 80.1454(g)).

Program Streamlining

The LCFS program has expanded over the years, and it is understandable that some inefficiencies have come about. For CARB and the State to reach its ambitions in a timely manner Shell recommends working with regulated entities to streamline the program. Like many other organizations Shell has a list of suggestions for improving the efficiency of the program that we would appreciate discussing at the appropriate time.

SPECIFIC COMMENTS

Below is a list of items related to the updated regulation language for consideration.

Section 95486.1 Generating and Calculating Credits and Deficits Using Fuel Pathways

088.4 Subparagraph (g): This section essentially punishes operations by way of a four- or five-to-one deficit for inaccurately predicting CI over a 24-month period. Shell urges CARB to reconsider the severe deficit requirement for pathway holders that exceed their CI in a 24-month period. This new obligation would cause a punitive deficit four times the amount of the annual excess CI generated plus an invalidation of excess credits, effectively resulting in a penalty of five times the amount of the annual excess CI generated. This scheme punishes operations and will deter investment in clean fuels development.

Section 95486.3 Generating and Calculating Credits for ZEV Fueling Infrastructure Pathways

Subparagraph (a) Medium- and Heavy-Duty Hydrogen Refueling Infrastructure (MHD-HRI) Pathways: Here, Shell merely seeks clarification.

088.5 With regard to subparagraph (D)(1) Shell asks that CARB confirm that this only applies when subparagraph (D) is met. In other words, "Any station built as a required mitigation measure pursuant to the California Environmental Quality Act…is not eligible for MHD-HRI crediting" if it "is permitted to operate prior to January 1, 2022, or..."

088.6 Subparagraph (4)(F): This language needs some flexibility because it does not account for the reality that operators, despite good faith efforts, may not be able to comply with the 24-month operability requirement[1]. Shell requests a mechanism to seek a variance or waiver from the Executive Officer from the 24-month operability requirement for good cause shown.

Section 95488.6 Fuel Pathway Application Requirements and Certification Process

088.7 The Tier 1 Calculator for Hydrogen is a valuable addition to the program for both applicants and CARB staff as it reduces complexity and time. Shell asks that the calculator include "process energy," displacing natural gas, for book-and-claim. If it isn't included, this will force applicants to submit a Tier 2 pathway to get credits for the process energy utilized, which is counter to the goal of promoting low CI fuels.

Section 95488.10 Maintaining Fuel Pathways

088.8 Subparagraph (b): Shell is concerned with the language, "the Executive Office *may* perform credit true up" and requests this is changed to "*shall* perform." Further, the language should be clear that credit true ups go back to a facility's startup date and include the approval of both temporary and provisional pathways from startup. Clarity and certainty regarding the rules are important to encourage investments needed to achieve implementation of the important low carbon fuels infrastructures.

Appendix B: CA-GREET4.0 Supplemental Document - Modifications Incorporated in CA-GREET 4.0

088.9 A backhaul energy intensity was added to ocean tanker transport for Brazilian sugarcane. The language indicates this is based on data provided by fuel suppliers; however, this does not apply to all fuel suppliers. Shell requests that pathways should determine whether a backhaul is included and this can be confirmed through the verification process.

In conclusion, Shell appreciates the opportunity to engage in the LCFS rulemaking. It is more important than ever that the state maintains its leadership in the clean energy space as other states actively seek to adopt similar programs. Stabilizing the market and careful consideration to changes are critical to continued success of the LCFS program. Thank you for your consideration of our input and thank you for your hard work and leadership of this important program.

Sincerely,

Steve Lesher/dem

Steve Lesher
Manager of Corporate Relations, U.S. West Coast
Shell USA, Inc.

---

[1] It has been Shell's experience in building and operating both light-duty and heavy-duty stations there are certain conditions that are beyond the control of the operator. For example, local permitting delays, unavailability of renewable hydrogen, etc.

Board Comments Home

February 16, 2024

Liane Randolph, Chair
California Air Resources Board
And Members of the Board
1001 I Street
Sacramento, CA 95814

RE: Public Comment on LCFS Rulemaking – Don't accelerate the LCFS Program

Madame Chair and Board Members,

089.1a Consumer Watchdog urges the California Air Resources Board to reject the proposed acceleration of carbon intensity standards under the Low Carbon Fuel Standard (LCFS) Program.

089.1b Gasoline prices in California are too high and the expansion of the LCFS will add more than 50 cents per gallon to the cost of California gasoline by 2026, according to CARB's own estimates (CARB SRIA page 57 here: https://ww2.arb.ca.gov/sites/default/files/2023-09/lcfs_sria_2023_0.pdf

California gasoline prices have consistently been $1.20 more than American gas prices, despite the fact that state environmental fees and extra taxes add only 70 cents more per gallon. The burden on working families in California is too much. Currently, the LCFS adds only 10 cents per gallon to a gallon of gas as part of the added fees. Quintupling that amount is unfair to drivers and will have dubious environmental benefits as the proposed acceleration of carbon intensity requirements is structured.

Ratcheting down Carbon Intensity reduction targets for transportation fuels is a noble goal. If the board adopts the staff recommendation, however, it will cause irreparable pain to consumers at the pump while facilitating continued, unacceptable damage to the environment.

The Low Carbon Fuel Standard (LCFS) program is meant to cut greenhouse gas emissions. It does this by mandating reductions in the average carbon intensity of transportation fuels sold in California. The program requires companies that sell gasoline and diesel fuels to purchase LCFS credits that CARB awards to cleaner fuel alternatives, including credits generated from biofuels and from non-combustion alternatives like electric vehicles.

089.2 By prioritizing biofuels over electrification, CARB has created a monster that is sucking up unreasonable subsidies at the expense of drivers, creating incentives for refiners to decrease

6330 San Vicente Blvd. Suite 250 Los Angeles, CA 90048
Tel: 310-392-0522 • Fax: 310-392-8874
www.ConsumerWatchdog.org

needed refining capacity, and aiding deforestation in the Amazon by propping up soybean farming.

CARB policies have brought a flood of renewable diesel into California's market by assigning overly generous Carbon Intensity scores on the premise that renewable diesel is far less carbon polluting than it is in reality.

One of the main beneficiaries has been big oil refiners who have converted two of their refineries to cash in on the renewable diesel gold rush CARB has created. The refiners have found a way to decrease gasoline inventories, so they can jack up gas prices from a tighter market. A history of the California oil refining market, where five oil refiners make 98% of the gasoline, shows that oil refiners have looked for ways to create a tighter market so they can charge more for gasoline.[1] CARB has given Marathon and Phillips 66 the incentive to take 13% of the state's gasoline refining capacity offline to produce renewable diesel.

The manufacture of renewable diesel, which earns more LCFS credits than any other project type, is particularly dangerous as it involves the use of highly [flammable methanol] to break up vegetable oils and animal fats. Worker overexposure can cause neurological damage. Two refineries, Marathon and Phillips 66, are on the verge of completing their conversions to make

[1] Memos from West Coast oil refiners from the 1990s, released by United States Senator Ron Wyden (D-Ore.), show that reducing refining capacity to maximize profits is a deliberate business strategy. An internal Chevron memo, for example, stated: "A senior energy analyst at the recent API [American Petroleum Institute] convention warned that if the U.S. petroleum industry doesn't reduce its refining capacity, it will never see any substantial increase in refinery margins." It then discussed how major refiners were closing down refineries. Not surprisingly, subsequent oil company profit reports show each dramatic gasoline price spike over the last decade has been mirrored by a corresponding corporate profit spike. An internal memo from Mobil discussed how the oil giant worked to "keep down" a smaller refiner, Powerine, from opening up its refinery as way to increase its profits by calling for increased environmental protections on the refiner. Then the memo talks about a Plan B of buying up the refiner's production should it open. Buying up other competitors' output and preventing new production are hardly the hallmarks of a competitive market. Similarly, a Texaco memo warned that "supply significantly exceeds demand year-round. This results in very poor refinery margins and very poor refinery financial results. Significant events need to occur to assist in reducing supplies and/or increasing the demand for gasoline." In the subsequent years, California's refineries consolidated and contracted. In 2005, our consumer group teamed up with Sen. Barbara Boxer (D-Calif.) and Attorney General Bill Lockyer in getting Shell Oil to reverse its decision to bulldoze its Bakersfield refinery, and to instead sell it. Internal documents showed that the refinery was making among the highest profits of all Shell refineries. That indicated the company wanted to make supplies even tighter, driving prices artificially higher. Nonetheless, Shell continued to lean on Flying J, the new owner, who eventually shuttered the refinery. For example, leaders of the United Steel Workers local at the refinery charged Shell with "trying to shut down our plant" by shutting off pipelines and demanding payment 30 days in advance. The union memo to members said Shell had refused an offer of eight days' advance payment. The erasure of the Big West refinery took 2% of the state's gasoline and 6% of diesel offline. Oil refiners in California have systematically shut down refiners and refineries as a way of maximizing their profits. See the following memos from Chevron, Texaco, and Mobil:
https://consumerwatchdog.org/wp-content/uploads/2023/12/Chevron-5103.pdf
https://consumerwatchdog.org/wp-content/uploads/2023/12/Texaco-5104.pdf
https://consumerwatchdog.org/wp-content/uploads/2023/12/Mobil-5105.pdf

renewable diesel full tilt in the Bay Area at Marathon's Martinez refinery and Phillips' Rodeo refinery. Marathon's Martinez refinery has already experienced two large fires. The manufacturing process is energy-intensive and renewable diesel combustion still produces both planet-cooking carbon dioxide and nitrogen oxide, a critical component of photochemical smog that is damaging to public health.

Biodiesel has a limited use for certain trucks but cannot be used for most vehicles that consumers drive. Based on credit generation data from the CARB LCFS Dashboard and average annual LCFS credit prices from UC Davis, about $17 billion worth of LCFS credits were issued from 2013 through 2022, with about 80% going to biofuels, and only about 20% going to EVs and electrification that produce zero emissions. The program's funding for electrification has played an important role in helping local governments and other public actors relying on the sale of credits afford projects that move them away from fossil fuels. But these benefits are being overshadowed by the harms being done by the program's primary beneficiaries, the biofuels industry.

The preponderance of projects the LCFS supports still produce planet-damaging and toxic emissions rather than moving far more quickly to a zero-emissions transportation structure via electrification. Both Marathon and Phillips 66 are investing in U.S. soybean processing plants as their renewable diesel requires large amounts of soybean oil that is rapidly becoming a preferred feedstock. Almost all the renewable diesel produced in America is consumed in California because of the LCFS program. Most of it is from out of state or imported from South American countries that are home to tropical rainforest that extends across several of them.

Phillips 66 plans to produce renewable diesel using soy bean oil from Argentina, the world's largest exporter of soybean oil, according to the Union of Concerned Scientists. "This one huge facility could potentially consume about half Argentina's soybean exports and 20 percent of global exports," according to UCS senior scientist Jeffrey Martin. Demand for soy and palm oil is displacing communities and leading to the slashing and burning of South American rainforests, according to Rainforest Rescue. "This deforestation is accelerating climate change by releasing billions of tons of CO_2 into the atmosphere — by some estimates, deforestation has a greater impact on the climate than the world's entire fleet of motor vehicles," the organization reports. "Moreover, arable land is scarce, and its use for fuel crops is contributing to rising food prices and world hunger."

The LCFS has been the nation's primary driver of factory farm biogas development, according to Food & Water Watch. Big Oil and Big Ag behemoths such as Chevron, BP, Shell, Smithfield, Perdue, and Tyson have invested heavily in a national methane production network from livestock waste that generates revenue from so-called "clean energy" renewable biogas under credit trading schemes such as the LCFS.

Such systems are in fact giant sources of pollution featuring vast manure lagoons that increase methane emissions, shoot pollutants such as ammonia and hydrogen sulfide into the air, and sicken communities.

CARB staff appears to have discounted such criticism in preparing its recommendation. When a
089.3 scientist and former CARB fuel chief criticized CARB's relationships to gas lobbyists, staff was barred from speaking with him by CARB's lead climate executive, Rajinder Sahota, according to an article in Capital & Main.

As UCS senior scientist Jeremy Martin, writes, "In my feedback over the last 2 years, I argued CARB should cap support for bio-based diesel made from vegetable oil and phase out credits for avoided methane pollution to wind down what has become, in effect, a poorly run offset program. Bio-based diesel and manure biomethane generate a lot more credits than an accurate assessment of their climate benefits would support and are causing additional problems to boot. Unfortunately, the official proposal ignores the oversupply of low value credits and focuses almost exclusively on increasing demand by accelerating the pace of the program. This won't work—and will make the LCFS needlessly costly for California drivers, while postponing the needed reforms that would restore the stability of the LCFS."

The technical complexity of biofuels policy makes it hard for consumers to understand what they are being asked to pay for, and industry benefits from the opacity. Financially disinterested experts have articulated substantial problems with the program's performance, which staff has ignored.

A vote for the staff proposal is a vote to ask California drivers to pay an additional 50 cents per gallon of gasoline to support biofuels that contribute to air pollution, increase food prices, and increase deforestation in the Amazon. CARB must ensure that the transition away from fossil fuels results in a zero-carbon emissions economy not an economic bonanza for biofuels polluters.

Sincerely,

Jamie Court

Subject	Urgent Call for Ethical and Environmental Reforms in California’s Agriculture

Comment

Dear Governor Newsom and Members of the California Air Resources Board,

I am reaching out to express my profound concern not only about th environmental impact of factory farming in California but also about the inherent cruelty to animals that these industrial practices perpetuate. The support for biogas production from industrial dairies under the Low Carbon Fuel Standard (LCFS) policies, while intended to promote renewable energy, inadvertentl endorses and sustains these harmful and inhumane practices.

The state of California has long stood as a beacon of progress in environmental protection and ethical standards. However, the
090.1 continued financial incentives for biogas as a byproduct of factor farming practices are in stark contradiction to these values. Beyond the significant issues of water pollution, groundwater depletion, and greenhouse gas emissions, the system of factory farming inflicts tremendous suffering on countless animals. These sentient beings are confined in overcrowded, unnatural conditions, deprived of their basic instincts and welfare, all in the name of efficiency and profit.

Supporting biogas production under the current LCFS policies not only overlooks but also financially rewards the environmental degradation and animal cruelty inherent in the factory farming model. This approach detracts from the urgent need to shift towar more sustainable and humane agricultural practices. It sends a misleading message that we can mitigate climate change without addressing the root causes of these crises, including the ethical treatment of animals.

I implore you and the CARB to reconsider the implications of supporting biogas production within the LCFS. This is a pivotal moment to align our environmental policies with a broader vision o sustainability that includes animal welfare. We must end the cycle of cruelty and environmental harm by investing in alternatives tha respect animal rights and contribute to a healthier planet.

I urge you to take a stand against the greenwashing of factory farming and to lead the way in adopting policies that promote genuine sustainability, respect for animal life, and the wellbein of our communities. The upcoming review of LCFS policies presents an invaluable opportunity to correct our course and commit to a future that values all forms of life and the integrity of our environment.

Thank you for considering this critical issue. I trust in your leadership to make decisions that reflect our shared values of compassion, sustainability, and justice.

Sincerely,
Adam Aranyos

February 14, 2024

Liane Randolph, Chair
CARB Board Members
California Air Resource Board

Re: 45-day Amendment Package of Proposed Changes to the Low Carbon Fuel Standard

Chair Randolph and Board Members,

RPMG Inc. (RPMG) is a biofuel marketing company representing our owner and marketing partner ethanol facilities located throughout the Midwest. Our member facilities provide both ethanol and distillers corn oil (DCO) as essential inputs to California's low carbon fuels market in material quantities. Since the Program's inception over a decade ago, RPMG has supported California's clean transportation fuel policy, and worked diligently with CARB staff to improve the administration of the Program. RPMG looks forward to the approval and use of E15 in California. This logical next regulatory step for lowering the carbon intensity of California's gasoline supply will also provide further reduction in criteria air pollutants, thus achieving the dual goals being sought by CARB. The amount of ethanol used in California is not a function of LCFS incentives, but rather is a function of the State and Federal air quality rules requiring the use of Reformulated Gasoline and an Oxygenate. Ethanol's role in California's gasoline market is firmly established and has been since the mandated phaseout of MTBE. Under these air quality requirements, there is already a mandate for ethanol that is independent of the LCFS. The LCFS incents lower carbon ethanol *per gallon*, but the existing fuel regulations dictate the *total volume* consumed.

Our member facilities are continually investing in lower carbon technologies, innovating production methodologies and ways to reduce carbon emissions to the atmosphere. These technologies include corn kernel fiber ethanol, wholistic facility efficiency upgrades, waste heat recovery, and Carbon Capture and Storage (CCS).

RPMG appreciates the opportunity to comment on this important rulemaking effort. Our comments below reflect the issues directly impacting RPMG and our member plants. They are presented in order of importance. We respectfully request the Board direct staff to continue working on the following identified issues. Given the importance, and frequency at which LCFS amendments occur, it is critical to take the time now to correct these deficiencies.

Sustainability Requirements for Crop-Based Feedstocks [§ 95488.9(g)]

092.1 RPMG is fundamentally opposed to the proposal in § 95488.9(g) *Sustainability Requirements for Crop-Based Feedstocks* based on several significant practical, policy, and technical issues highlighted for your consideration.

092.1 cont Despite the title of this newly drafted section, there is nothing proposed that clearly defines or expresses what CARB's expectations regarding sustainability are, in theory or practice. Instead, CARB has outsourced this concept. This regulatory sustainability model was not workshopped, nor presented in any draft fashion to stakeholders over the previous two years of informal rulemaking efforts.

It is clear through reviewing transcript of the September 2023 CARB Board hearing and stakeholder feedback at the informal workshops, that questions and concerns have been raised and debated regarding a potential increase in crop-based feedstocks for Renewable Diesel from virgin materials. That dialogue does not reconcile with what is written as proposed regulatory text. Staff's proposal is too broad and far-reaching to be adopted on its first pass.

Set to begin in 2028, the proposed sustainability requirements unilaterally require *all* crop-based feedstocks used for *all* fuel pathways (liquid, gaseous, electric) indiscriminate of vehicle class or engine technology be certified. The requirement imposed on the marketplace is to 'maintain continuous' certification by a yet-to-be determined, yet-to-be vetted and yet-to-be CARB-approved certification system. The requirement's goal of demonstrating *all* agricultural-based feedstocks is farmed, harvested, and developed in a "sustainable" manner without elaboration stands in contrast to practical regulations. As proposed, without obtaining this TBD certification, all biofuel pathways will be assigned an uneconomic carbon intensity value equivalent to fossil diesel. Low carbon fuel producers have responded to the signals of the LCFS program to reduce carbon emissions quantified in the fuel products they supply to California. The introduction of this section in this manner, as written and without even a definition of 'sustainability', is disingenuous toward the investments made and common goals we seek to achieve in mitigating impacts to the environment we all share and will not achieve its implied purpose.

From a technical perspective, and as has been pointed out by numerous LCFS stakeholders, this regulation already includes overly conservative Indirect Land Use Change (iLUC) values on all crop-based feedstock. iLUC is a sufficient mechanism for deterring high biodiverse land conversion within the supply chains of fuels delivered to California complying with the LCFS. It is important to note that an increased volume of ethanol used in California will not result in an increase of acreage used for feedstock production. To institute further, undefined, Sustainability certification requirements to these same crop-based feedstock supply chains ignores this pre-existing function of the regulation. It also infringes upon, and compounds, the conservative fundamental mechanics of performing a well to wheel lifecycle analysis.

The LCFS lives within a Federal Clean Air Act framework of fuel regulations. Underpinning this California program is the USEPA's Renewable Fuel Standard (RFS). Crop-based feedstocks are an integral part of U.S. domestic and global agricultural commodity markets. The RFS rightfully administers a feedstock aggregate compliance approach for domestic agriculture feedstocks under § 80.1454 (c)(1)(i). The domestic agricultural community has testified and commented on the complexities of commercial grain commodity markets in numerous federal, international, and regional fuel regulation proposals. RPMG points CARB staff to the public record comments submitted to USEPA for the RFS program on this issue for in-depth

092.1 cont resource review [1]. Given the crop-based feedstock sustainability requirements are not aligned with other policy frameworks, and as such are not needed, RPMG recommends § 95488.9(g), as proposed, be removed in its entirety.

From an authority perspective, CARB's proposal outsources the standard to an external certification body. The most prevalently used Sustainability certification standards in use at this time were mandated by directives and legal frameworks in foreign countries, and then developed by non-governmental organizations. RPMG understands the importance of sustainability, but developing a California legally binding requirement overseen by foreign non-governmental organizations and private entities is an abdication of authority, nor does it ensure domestic feedstocks meet the unknown definition of "sustainable." As written, there is no defined means of mitigating those risks should this proposed language be adopted. Should a satisfactory certification standard not be available, or the accepted standard changes, all crop-based fuels pathways in the LCFS program would default to a CI for fossil diesel.

The reasoning for this third-party auditing per the ISOR is based on the fact auditing has been done in other biomass-based energy programs. The introduction of more certification requirements is tantamount to more Audit Burden. There has not been any indication or case made that this proposal will result in emission GHG reductions, while forcing additional audit requirements, upstream to a U.S. domestic and global farmer stakeholder community that was not represented in the rulemaking process. This additional Audit Burden will only serve to increase costs, time demands, and superfluous recordkeeping without providing any benefit to the environment or to the LCFS carbon credit marketplace. There would be no economic incentive to put these additional requirements in place – for any fuel supply chain. It also further exacerbates a distinct increased demand for capable subject matter experts in field, available, and accredited auditors. The LCFS is already complicated, this proposal compounds that complexity several fold. Audit Burden, and stakeholder burn-out, are real issues, especially as clean fuel programs expand in a patchwork fashion across the continent, each with unique requirements. Cost benefit considerations are necessary yet haven't been discussed. RPMG recommends CARB take the time to have that conversation before instituting these requirements.

092.2 The debate for what constitutes "sustainable" activity or behavior is an important conversation. RPMG recommends we take the time to have that conversation before instituting requirements of this magnitude without even expounding upon what the time and cost requirements will be, nor the impact on national and international fuel markets. It is fundamentally necessary in RPMG's opinion to remove this proposed section in its entirety at this time. For these reasons RPMG is opposed to this new mandate as currently proposed.

[1] https://www.regulations.gov/comment/EPA-HQ-OAR-2005-0161-3210

<u>Verification Body Rotation Requirements</u> [§ 95503]

092.3 RPMG remains opposed to the existing mandated verifier firm rotation which requires verifiers to be on a six-year rotation and must suspend all services for three years following the rotation before providing any further verification services. RPMG has warned of the impact of this requirement in previous amendment packages[2,3]. We are revisiting this issue as the verification component of the Program has matured and pathway holders are getting close to the mandated rotation timeline. RPMG requests that CARB reverse this early policy decision.

Partner or lead verifier rotation is a sufficient alternative. RPMG strongly believes mandated firm rotation is in conflict to CARB's and stakeholders' mutually beneficial desire to leverage efficiencies amongst existing stakeholder verification programs. CARB has historically stated their interest in incorporating a firm rotation requirement is to ensure "fresh eyes" and impartiality among firms. The stated benefits of mandated rotation by CARB can be achieved at the partner or lead verifier level. RPMG believes the program's detailed accreditation and CARB approval of verification plans and sampling strategies are sufficient to ensure impartiality.

CARB further elaborates this requirement has been successfully demonstrated through administering the Mandatory Reporting Rule (MRR) under Cap-and-Trade. RPMG maintains there are crucial differences between Cap-and-Trade and LCFS. Required firm rotation does not adequately allow for a regulated entity to consider a verification body's basic knowledge of an industry or individual business practices. This will result, without question, in a loss of engagement efficiency and overall dissatisfaction of the verification experience. Regulated entities have commercial operations to manage. Excessive time spent on repeated and recurring introductions of a new auditor to those operations is not an effective use of enterprise resources, and it will amount to a loss in productivity and increased costs—costs not considered by CARB.

A firm rotation requirement is not only problematic for regulated parties but also for verifiers. Verifiers are already required to become accredited and incur the associated cost of undergoing the necessary training and travel. Once accredited, the verifier experiences a forced reduction in revenue in off years due to loss of clients which results in a necessitation of higher base fees. This inflated cost structure ultimately makes its way to California fuel consumers, undermining program cost containment efforts. For all of these reasons, RPMG urges CARB to incorporate a partner rotation requirement in lieu of a firm rotation requirement for LCFS verifiers.

<u>Indirect Accounting Mechanisms</u> [§ 95488.8 (i) & (h)]

092.4 RPMG recommends that the proposed amendments for indirect accounting for low-CI electricity, biomethane and low-CI hydrogen be expanded to allow the use of indirect accounting mechanisms to all pathway types for process energy, e.g. liquid biofuel production. All other pathway holders must have

---

[2] Microsoft Word - RPMG LCFS Proposal Comment Letter 4.23.18 - Update 2.docx (ca.gov)

[3] Microsoft Word - RPMG LCFS 15-day Comment Letter 7-5-18 v5.docx (ca.gov)

direct connections from renewable or low-CI process energy in order to reduce the CI score. The following is suggested language to § 95488.8 (h) as well as removing the language regarding direct connection § 95488.8 (h)(1)(B).

> § 95488.8. Fuel Pathway Application Requirements Applying to All Classifications.
>
> (1) Low-CI electricity must be supplied from generation equipment under the control of the pathway applicant *or subject to a firm power purchase agreement (PPA) from generating equipment within the same balancing authority as the facility.*

The ISOR describes this preferential treatment as assistance and states this is necessary because there has been very little interest in indirect accounting renewable electricity ZEV pathways under the current rule. It may be true this accounting method has not been widely used in ZEV pathways, but it is a very narrow view of the fuel landscape. The 2022 Scoping Plan update clearly outlines a significant role for liquid biofuels through 2045. By tipping the scale, the proposed regulation is not "allowing the market to determine how the carbon intensity of California's transportation fuels will be reduced."[4] Not only is this a violation of technology neutrality, an original fundamental tenet of the LCFS, it leaves significant carbon reduction out of the program. Liquid biofuel producers have the capacity, both technical and capital, to greatly reduce their carbon intensity scores with the correct regulatory signals.

Credit True Up After Annual Verification [§ 95488.10 (b)]

RPMG strongly supports this aspect of the regulatory package.

Per the current regulation, fuel pathways that achieved additional carbon reductions demonstrated with a lower verified CI score had their additional generated credits assigned to the Program's buffer account. Under the proposed regulations, the fuel pathway holder that has a lower verified operational CI may perform a credit true up and the additional credits are assigned to the pathway holder.

092.5 Entities reporting lower verified CI scores have not been able to claim the additional credits due to the prohibition of retroactive credit claims in the regulation (95486(a)(2)). The addition of the proposed credit true up is an added benefit for the pathway holder, the program, and the environment as it provides the incentive to continue to lower greenhouse gas emissions.

RPMG also believes the credit true up proposal supports improved regulatory compliance and administrative efficiency. Today's system of subjecting pathway holders to both administrative adjustments and potential enforcement action for any CI exceedance, without the counterbalance of receiving additional credits for all incremental CI reductions is a scheme that is punitive in both directions. This newly proposed language is an incentive and will thus encourage pathway holders to improve CI

[4] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2018/lcfs18/fsorlcfs.pdf?_ga=2.118890249.1658159364.1707157899-1753130937.1706029505

scores without having to reapply for incremental production efficiency changes in their CI Scores. This administrative efficiency will also benefit CARB's pathway staff.

092.6 One additional note on this issue is that the proposed regulations need more clarification for entities utilizing Temporary CI scores. RPMG requests CARB provide further guidance document(s) to provide instructions on completing a credit true up for pathway holders who may have Temporary CI scores and certified or provisionally certified CI scores within the same compliance year.

<u>New Automatic Deficit Obligation Penalty</u> [§ 95486.1 (g)]

Beginning in 2025, it is proposed that a fuel pathway holder for a non-provisional fuel pathway generates a non-linear deficit obligation following a verified CI exceedance. If a verified CI exceedance does occur, pathway holders will face an automatic deficit obligation of a 4:1 ratio. RPMG understands this new section is intended to work in conjunction with the True Up provisions noted above. While we are supportive of the True Up change because it fairly addresses overcompliance, we oppose the current proposal for Deficit Obligation as it is unnecessarily punitive. If a pathway holder overperforms they receive a 1:1 credit, but if there is an underperformance, then the penalty is 4:1. An objective of the LCFS has always been to ensure that the environmental integrity of the market remains whole. Therefore, requiring a 1:1 adjustment of any deficit obligation before an enforcement action is initiated remains an appropriate remedy.

092.7

This two-step process would be a more balanced approach to pathway holders seeking to recertify under the new CA-GREET 4.0 model update required by the regulation. Each, and every, pathway will be updated in short order, and therefore each LCFS stakeholder will be tasked with the same decision of how much Margin of Safety to apply. With the current 4:1 vs 1:1 risk/reward structure, it can be imagined that more conservative CI scores will be requested. This will lead to a market lag in actual credit generation, a deferred return on investment, and potential unintended market consequences such as the impacts to the new Auto Acceleration Mechanism based on credit-deficit numbers that may not accurately reflect market conditions in real-time.

<u>Tier I/II Applications</u> [§ 95488.6 (a) & 95488.7 (a)]

All Tier 1 and Tier 2 applications must contain data consisting of the most recent 24-month period of operation, or at least three months of operation for provisional fuel pathway applications. Additionally, it is proposed that an application does not have more than three months between the end of the reported data period and date of its submission. RPMG understands that Tier 1 and Tier 2 applications with the most up-to-date operational data are essential. The proposed also states that if a pathway application cannot be validated, it must be resubmitted with the "most recent operational data".

092.8 RPMG recommends CARB clarify this "most recent operational data" requirement as it is unclear what time period is actually being sought or allowed. For example, if an application is resubmitted in January, does the provision require October through December data, or just a data period that is within three months of the resubmitted application (July-September). If the applicant must resubmit operational data, the time and expense to gather the data is costly and time-consuming. CARB providing application approvals within an adequate time would ensure the application has up-to-date information and the responsibility is put on CARB rather than the applicant.

<u>Tier 1 Calculator and Instruction Manual</u>

In reviewing the proposed CA-GREET 4.0 Starch and Fiber Ethanol T1 Calculator and Instruction Manual, RPMG encourages CARB to refine the following sections of the calculator and instruction manual:

1. A summary line should be added to the Site-Specific Input tab to aid in user reconciliation of aggregated monthly entries and Verifier reference in summarization detail.
2. The default value option for feedstock transport should be expanded to include more regions of biofuel production in addition to the present 9 state region identified. Identifying and producing records for harvest sites and collection sites is labor intensive. Without the option of a default value, certain applicants may choose simply not to participate due to this impediment. At the very least, the demonstration of feedstock transport mileage where a default value is not an option should be limited to a one-time Validation and not an on-going data collection exercise.
3. This iteration of the CA-GREET 4.0 T1 calculator should consider secondary and alternative energy directed to and allocated for co-product processing energy. For example, if an alternative energy source is consumed to operate only the drum dryer to bake Dried Distiller's Grain with Soluble, 092.9 the entry field for co-products should be broadened to capture this alternative energy source emission factor for the relevant allocated proportion and not simply default to the assumed primary process energy emission factor as the only option for calculation.
4. RPMG proposes all CA-GREET 3.0 Standard Methods and CARB designated Protocols, used by pathway holders since the last amended regulation effective for 2019, be provided to the public in an accessible online library or website. This will help all applicants to be able to access the same information and provide awareness of existing Standard Methods and Protocols developed after the adoption and issuance of T1 Calculator materials.
5. We noted the Emission Factor for Fiber Enzymes has been modified transitioning from 1,207 grams CO_2e per pound in CA-GREET 3.0 to 525 grams CO_2e per pound in CA-GREET 4.0. Staff has been explained this change is attributable to assuming a 50% moisture content of Enzymes received and used, and that the EF now compensates for this rate of moisture inclusion. RPMG recommends documenting the rational and basis for this change. Further RPMG recommends that CARB affirm in program guidance or Instruction Materials that if the moisture content of a received Fiber Enzyme formulation is greater than 50%, a pathway applicant can approach CARB for an Operating Condition to allow the use of an alternatively modified moisture compensated Emission Factor and they do not need to pursue a T2 pathway application.
6. RPMG and our affiliated producer pathway holders support the incorporation of the Pathway Summary into the CA-GREET 4.0 T1 Calculator. The presence of Operating Conditions within the Pathway Summary should be relied upon for both formal pathway and Operating Condition

acceptance and thereafter for Annual Fuel Pathway Reporting (AFPR) re-affirmation. Having all Operating Conditions singularly incorporated here will simplify the report submission and Verification process for all stakeholders. This should be clearly expressed in AFPR guidance and instruction for reporting expectations.

7. The CA-GREET 4.0 SFE T1 Calculator applies an emission factor for "Evaporative Emissions." It is not clearly identified in LCFS CA-GREET 4.0 material what this emission factor represents. When consulted directly, Staff explained it is meant to consider emissions of Volatile Organic Compound (VOCs) assumed in the production profile of ethanol plants. However, all U.S. domestic ethanol production facilities are obliged to implement and comply with Leak Detection and Repair (LDAR) mandates overseen by USEPA. Adherence to LDAR makes the presence of this additional assumed emission factor unnecessary and results in an arbitrary inflation of the CI score result. This emission factor should be removed from the CA-GREET 4.0 SFE T1 Calculator.

In addition to the comments outlined above, RPMG supports the comments submitted by our industry partners including Renewable Fuels Association (RFA), Growth Energy, ACE Ethanol LLC, and Christianson PLLP.

In Closing

RPMG would like to again highlight the benefits that our industry has made to California's GHG programs and thank CARB for the opportunity to contribute toward the improvement of this regulatory proposal. We would also reiterate that with a regulatory structure which promotes innovation the biofuels industry can continue to lead the way in terms of reducing the Carbon Intensity of the biogenic liquid fuel market that will remain in the state for years to come. RPMG looks forward to continuing these conversations and is available to clarify any suggestion provided in this letter. Please contact me with any questions or comments at (952) 465-3255 or jnowicki@rpmgllc.com.

Thank you,

Jesse Nowicki
Regulatory and Compliance Specialist

Comments on Proposed Low Carbon Fuel Standard Amendments

Dear California Air Resources Board (CARB) Low Carbon Fuel Standard Program Staff:

Thank you for the opportunity to provide comments in response to the draft amendments to the Low Carbon Fuel Standard.

As background, Oberon is an innovative California company founded in San Diego 13 years ago with a focus on decarbonizing the global LPG/propane industry while laying the foundation for renewable hydrogen. We are accomplishing this today by producing renewable dimethyl ether (DME) at our Brawley, California production facility. Oberon's rDME® brand fuel can be made from various in-state waste streams (*e.g.*, dairy manure biogas, waste water treatment biogas), which can enable smaller, often stranded, biogas suppliers to participate in the LCFS program and produce low carbon DME.[1] Oberon's rDME fuel can reduce the carbon footprint of transportation when used as a: 1) blending agent with Liquid Petroleum Gas (LPG)/propane; 2) hydrogen carrier to power the growing fuel-cell electric vehicle and stationary source market; and 3) diesel substitute. This range of creative applications that clean fuels, such as DME, can support is underscored in the recently adopted 2022 Scoping Plan Update—DME along with other clean alternatives to petroleum are a key part of the solution if the state is to reach its legislatively-mandated greenhouse gas reduction targets.

Responses to Draft Amendments

094.1 Oberon strongly supports the proposed amendment package and urges adoption. In the 'Other Comments' section below we offer suggestions for further clarity where the draft amendment may benefit from a more fulsome consideration of rapidly developing technology and commercial practices.

We also express our gratitude for your engagement and support for DME and we note with pleasure the inclusion of DME on *Table 4. Energy Densities and Conversion Factors for LCFS Fuels and Blendstocks*.

[1] The California Air Resources Board has estimated dairy biogas-based DME made by the Oberon process has a carbon intensity of -278. rDME® is a trademark of Oberon Fuels, Inc.

Other Comments

- **Program Stringency**

094.2 While we believe that the proposed 5% step-down in stringency will help to course-correct the market, it simply does not go far enough considering the size of the cumulative credit bank, which is anticipated to increase its rate of growth as new clean fuel projects that have been or are being constructed bring more clean fuels to market. The step-down should be increased by at least 7%, which, for perspective, translates into a 2030 target of at least 32% reduction in the CI relative to the 2010 baseline. While a 7% step-down will still leave many credits in the cumulative credit bank, this single adjustment will translate into millions of additional tons of GHG emission reductions that would've otherwise gone unaddressed.

- **Avoided Methane Crediting**

094.3 CARB's draft regulatory language is silent on avoided emissions credits from feedstocks other than dairy, swine, and organics diverted from landfill. While we believe the current Tier 2 process is sufficient for a user to develop and CARB to approve avoided emissions credits for feedstocks such as poultry manure, project developers and users may benefit from further regulatory clarity.

- **Livestock Offset Protocol**

094.4 The Livestock Offset Protocol (LOP) uses methane conversion factors taken from Chapter 10 of the 2006 Intergovernmental Panel on Climate Change ("IPCC") entitled *Emissions from Livestock and Manure Management* ("Chapter 10"). Section 10.4 of Chapter 10 (pp. 35 – 52) provides these factors for many types of livestock in addition to dairy and swine, including poultry (both layers and broilers) and beef cattle. CARB may amend the LOP or create a separate LOP for the LCFS to add user clarity for other feedstocks.

- **Biomethane Crediting – Book-and-Claim**

094.5 CARB should expand the exemption to the deliverability requirements beyond hydrogen to include use in fuel production where biomethane is an intermediate feedstock if the finished fuel is physically delivered into California.

With appropriate limits and the verification and validation procedures CARB already has in place, we believe there is an opportunity to incentivize investments that deliver substantial reductions in greenhouse gas emissions while retaining the critical oversight and compliance that has been foundational to the success of the program.

845 15th ST, SUITE 103 #49216, SAN DIEGO, CA 92101
619.255.9361 WWW.OBERONFUELS.COM

- **Book-and-Claim of Low-CI Hydrogen**

094.6 We recognize that meeting California's ambitious goals for deploying large scale hydrogen projects will need to incorporate low carbon intensity hydrogen carriers such as DME. We ask that CARB consider adding explicit language or clarity around the opportunity to apply Book-and-Claim for renewable hydrogen pathways that involve an intermediate step or use of hydrogen carrier-molecules. This approach is fundamental to rapidly ramping up the use of renewable hydrogen as envisioned by the Scoping Plan and the ARCHES effort.

- **Credit True-up**

094.7 The proposal includes true-up provisions where verified operational CI's are drawn on to potentially adjust the credits based on certified CI's. The proposal indicates that a shortfall (i.e., a verified operational CI that is higher than the certified CI upon which project credits were generated) will result in a penalty the applies a multiplier to the shortfall. Further, the language indicates that in the event the operationally verified CI is lower than the certified CI (i.e., it failed to generate as many credits as it could have) the Executive Offer (EO) "may" make the appropriate adjustment (true-up) by awarding additional credits to the applicable fuel reporting entity. The word "may" should be deleted. If the operationally verified CI, including an affirmative verification statement, is lower than the certified CI that was the basis for credit generation, the EO "must" award the supplemental credits supported by the underlying documentation.

094.8 The concept of adjustment to credits based on operationally verified CI's is sound. However, limiting the proposal to certified CI's is a significant oversight. The proposal should be carried over and applied to temporary and provisional CI's as fuel providers may rely on these CI's for months, or even years, as a more refined pathway is evaluated and subsequently approved.

Recommendations for Future Action

Oberon encourages CARB to ensure there continues to be a market for low-CI liquid and gaseous fuels as they are an important decarbonization tool, especially in sectors that are hard to decarbonize. Oberon recommends that CARB send a clear policy signal that biofuels (e.g., biomethane, renewable propane, renewable DME) are necessary and effective decarbonization strategies in these other sectors (e.g., residential, commercial, industrial) and are fundamental to the state meeting its ambitious GHG reduction targets.

As the state transitions out of combustion in the transportation space gaseous and liquid fuels will continue to support the industrial, commercial, and residential sectors with escalating pressure to drive down GHG emissions. One approach for doing so is stronger signals and incentives for the production and use of low-CI fuels in those sectors.

Expanding the LCFS or creating a LCFS-like structure to help facilitate decarbonization of other gasoline-, diesel-, fossil natural gas-, and propane-fueled applications in residential, commercial, and industrial markets is an opportunity that merits attention. Doing so would reward investments and use of cleaner fuels by these legacy sectors that are not anticipated to be electrified for many decades. In the last year new domestic and international policies have been established to apply the LCFS approach beyond transportation fuels such as Vermont's Clean Heat Standard, the Canadian Clean Fuel Regulation, and the EU ETS II which cover both transportation and non-transportation fuel. Policy expansion, as signaled in the Initial Statement of Reasons for the proposed LCFS amendments, will support additional reductions in greenhouse gas emissions by further accelerating the market development of low carbon fuels such as renewable DME.

Thank you for your time and consideration. Please do not hesitate to contact me at cristin.reno@oberonfuels.com with any questions.

Sincerely,

Cristin Reno

AMERICAN BIOGAS COUNCIL

RE: American Biogas Council Comments on the Proposed Amendments to the Low Carbon Fuel Standard

Dear Chair Randolph and Members of the Board,

The American Biogas Council (ABC) appreciates the opportunity to comment on the proposed amendments to the Low Carbon Fuel Standard (LCFS). The ABC is the voice of the U.S. biogas industry dedicated to maximizing carbon reduction and economic growth using biogas systems. We represent more than 400 companies in all parts of the biogas supply chain that are leading the way to a better future by maximizing all the positive environmental and economic impacts biogas systems offer when they are used to recycle organic material into renewable energy and soil products.

Biogas systems protect our air, water, and soil by recycling organic material, like food waste and manure, into renewable energy and soil products. Biogas systems are, at their heart, a biological means to capture methane that would otherwise be emitted into the atmosphere for use as a renewable fuel. This process specifically decreases baseline methane emissions by converting methane back into carbon dioxide. All of this is an effort to protect our air, water, and soil – crucial parts of the solution to the challenges the California Air Resources Board (CARB) seeks to address. The scientifically-based design of the LCFS recognizes the benefits of projects that collect biomethane that would otherwise be emitted to the atmosphere making it available for use in transportation. As a result, millions of gallons of petroleum-based diesel fuel have been replaced with clean biomethane over the past several years delivering substantial reductions in greenhouse gas (GHG) emissions as well as other co-benefits (e.g., reductions in emissions of particulate matter). Furthermore, in August 2023, CARB announced that in Q1 2023 clean fuels replaced more than 50% of the diesel used in the state for transportation purposes, equating to nearly two billion gallons of avoided fossil diesel use in 2022.[1] This further underscores the success of the program and continued need for the LCFS to deliver GHG reductions from the transportation sector.

Over the past year and a half, CARB staff have held numerous public workshops to gather feedback on potential changes to the program, where ABC participated, and we are pleased to see that the rulemaking is nearing completion. The ABC would like to underscore the importance of concluding this rulemaking as soon as possible. Any further delay to the rulemaking diminishes the necessary signal the market needs to facilitate and encourage continued investments in clean fuels. Without a strong policy signal, the state risks missing opportunities to further reduce GHG emissions from transportation fuels. Thus, the ABC urges CARB staff and the Board to finalize this rulemaking no later than the end of Q2 2024.

Strengthening Carbon Intensity (CI) Targets

The ABC applauds CARB and is encouraged to see that the proposed amendments aim to set more ambitious carbon intensity (CI) targets. A strong CI reduction target is a critical component for driving down GHG emissions in the transportation sector, reducing reliance on petroleum fuels, and transitioning to electric vehicles where feasible. However, we believe that there is both room and need to go further. Using the numbers from CARB's Quarterly Summary Report and averaging the rate of credit growth over the past five available quarters, it shows that the current scale-up in the production of clean fuels will continue to generate credits with the cumulative bank likely eclipsing 25 million by the end of 2024.[2] The proposed increase in stringency falls short of what the market can deliver, and as a result, is missing an opportunity to deliver

[1] California Air Resources Board, *For the first time 50% of California Diesel Fuel is replaced by clean fuels*. August 23, 2023. https://ww2.arb.ca.gov/news/first-time-50-california-diesel-fuel-replaced-clean-fuels
[2] California Air Resources Board, *LCFS Data Dashboard Figure 3 – Quarterly Summary Report*. https://ww2.arb.ca.gov/resources/documents/lcfs-data-dashboard

1126 I Street SE, Washington DC 20003 | 202-640-6595
team@americanbiogascouncil.org | www.americanbiogascouncil.org

millions of additional tons of reductions in GHG emissions called for in statute and further underscored in the update to the state's Scoping Plan as approved by the Board in December 2022.

The ABC believes that there are two key adjustments that CARB can make to the stringency as part of the 15-day change process that do not require new economic or environmental analysis as they fall within the scope of the work CARB has already included in the Initial Statement of Reasons (ISOR). Specifically, by increasing the step-down as well as pulling forward the effective date for triggering the Auto Acceleration Mechanism (AAM) CARB can "recapture" reductions in GHG emissions that will otherwise be lost with the current proposal. Doing so will also send a clear, supportive market signal to continue investments in clean fuels that would otherwise be constrained by the current proposal. The description below provides additional detail on these two recommendations.

096.1 While we believe that the proposed 5% step-down in stringency is good start at course-correcting the market, it simply does not go far enough considering the size of the cumulative credit bank, which is anticipated to increase its rate of growth as new clean fuel projects that have been or are being constructed bring more clean fuels to market. Within the boundaries of staff's existing environmental and economic analysis, the step-down must be increased by <u>at least</u> 7%, which, for perspective, translates into a 2030 target of at least 32% reduction in the CI relative to the 2010 baseline. While a 7% step-down (20.75% CI target) will still leave many credits in the cumulative credit bank, this single adjustment will translate into millions of additional tons of GHG emission reductions that would've otherwise gone unaddressed. ABC would like to emphasize that a 7% step down should be the minimum considered, and that it is possible, based on recent modeling by ICF, for CARB to be more aggressive with the step-down, noting that a step-down of 11.25% (25% CI target) is feasible, and would sufficiently address the excess credits in the cumulative credit bank.[3]

096.2 As designed, the first year that the AAM could impact program stringency is 2028---four years from now! The concept and need for the AAM is to respond to clear overperformance of the program and to send an unambiguous market signal to investors that the program is nimble and will respond to opportunities to deliver additional GHG reductions rather than "add to" an excessively large credit bank that is at odds with the objectives of the program. Waiting four years is too long, and the ABC recommends pulling the date for triggering the AAM forward. The AAM should be based on 2025 data with the trigger assessment occurring in May 2026, and the AAM being applied in 2027 providing the applicable conditions are met, thus increasing the program stringency for 2027. Relying on 2025 as the first eligible year for triggering the AAM is appropriate as one of the main objectives of the step-down is to bring the program into balance. Therefore, assessing the impact of the step-down on the market based on 2025 data, including the cumulative bank and the rate of credit to deficit generation, is aligned with the principles of the program. With this approach, the AAM could theoretically increase the stringency of the program in 2027 and 2029 (i.e., triggered twice prior to 2030 providing the conditions for the triggering the AAM are satisfied), better ensuring that potential emission reductions are not left on the table in the event the program continues to overperform following the Board's adoption of the amendments. 096.3 Furthermore, it is important to note that the proposed 3:1 ratio (i.e., cumulative bank/average quarterly deficits) that would trigger the AAM is likely inadequate. For example, in 2022, a year where there is general stakeholder consensus that the LCFS was overperforming, the AAM would not have triggered using CARB's current proposal. Updated ICF modeling shows that changing the cumulative credit bank to average quarterly deficit ratio threshold from 3 to 2.5 or lower would position the AAM to be more responsive to overperformance of the program, thus delivering additional reductions in GHG emissions.[4]

Avoided Emission Crediting

The proposed amendments seek to phase out avoided emission pathways for projects that break ground after December 31, 2029, for biomethane used as a transportation fuel through 2040 and for biomethane used to produce hydrogen through 2045. 096.4 While we understand that CARB's intention here is to begin to transition biomethane away from the transportation sector, the underlying rational is being construed by some as science-driven rather than a policy decision concerning the phase out of combustion in transportation. ABC does not support the phaseout of avoided emission credits.

[4] ICF, *Analyzing Future Low Carbon Fuel Targets in California*. February 2024. https://static1.squarespace.com/static/5b57ab49f407b4a7ffa44ffa/t/65cd3c74d1a72f445cdc7a7e/1707949173143/ICFReport2024.pdf

Avoided methane emissions are a critical part of science-based, life cycle assessments, and their inclusion in carbon intensity scores is consistent with internationally recognized standards of carbon accounting. The science is robust and recognizes that the baseline includes methane emissions that would otherwise be released into the atmosphere. As stated in our previous comment letters to CARB, recognizing avoided methane emissions and its role as a short-lived climate pollutant, while incentivizing its removal from the atmosphere, has proven highly successful in supporting the reduction of millions of metric tons of carbon dioxide equivalents. We strongly encourage CARB to continue its longstanding commitment to a science-driven framework that utilizes proven science including Argonne National Laboratory's GREET model. In the event CARB maintains its plans to phase out eligibility for avoided methane in vehicle fuels, we encourage CARB to be clear that it is a policy decision associated with CARB's efforts to transition biomethane into non-vehicle sectors (e.g., residential, commercial, and industrial uses). CARB should be explicit that the policy decision to discontinue recognition and eligibility of avoided methane emissions in vehicle pathways should not be interpreted as a departure from the established rigorous science of accounting for the benefits of avoiding methane emissions which continues to be appropriate for non-vehicle sectors. ABC does, however, recognize that avoided emission credits for biogas to electricity projects remain, and applaud CARB for recognizing the value of these projects by proposing to retain this aspect of the program.

Book-and-Claim and Deliverability Requirements

Book-and-Claim has allowed the LCFS to evolve by supporting investments in clean fuels that have helped the program remain one of the most influential and successful transportation decarbonization policies in the country. To date, CARB's approach to indirect accounting in the program has been pivotal in its success, including its principles of driving GHG emissions down, facilitating investments and production of clean fuels, and in supporting increased clean fuel options for consumers.

While CARB's proposal clearly outlines recommendations related to book-and-claim for biomethane as directed to end use
fuel consumption and hydrogen production, it does not adequately address biogas and biomethane as directed to electricity
production. There are three key areas that CARB should address to ensure that biogas and biomethane can support
electricity production in support of transportation decarbonization. The first is to allow biogas to electricity projects to utilize
book-and-claim anywhere in the Western Electricity Coordinating Council (WECC), as is already the case in Oregon under
096.5 their Clean Fuels Program. Currently, the LCFS requires electricity to be physically delivered to California. This would
eventually result in regulatory consistency for projects with the same feedstock (i.e., biomethane) once the deliverability
requirements for that fuel are realized. Second, biogas-to-electricity projects where electricity generation and biogas
production are not co-located should be eligible to participate in the LCFS. This is in-line with the California Renewable
Portfolio Standard's (RPS) treatment of "directed biogas" and allows greater project penetration by supporting optimal siting
096.6 of both the biomethane source and the electricity generator rather than forcing co-location. Third, notwithstanding the
preceding constraints, there are clear guidelines and requirements for how electricity, as a LCFS fuel, can utilize book-and-
claim to move electricity from point of generation to end use. There is not, however, clear information on how biogas or
096.7 biomethane can utilize book-and-claim to move RNG to electricity generation. ABC recommends that CARB provide
clarification that biomethane may utilize book-and-claim in this context. Further, we recommend that book-and-claim for
096.8 biomethane to electricity remain unconstrained by timeline restrictions proposed for biomethane to end use and biomethane
to hydrogen production. We believe this is appropriate to support zero-emission vehicle aspirations beyond 2030.

The ABC is also requesting CARB provide further guidance on the proposed deliverability requirements. The proposed
amendments aim to adopt the California RPS requirement of ensuring biomethane injected into a common carrier pipeline
physically flows towards California 50% of the time. This referenced RPS framework does not, however, provide clarity on
096.9 how those biomethane molecules can be traced to California, how a 50% average flow toward California may be modeled,
nor expected geographical indications of regions anticipated to remain eligible for book-and-claim accounting. Moreover,
limiting book-and-claim to physical deliverability requirements risks the LCFS becoming a less effective decarbonization
program and undermines California's interest in rapidly ramping up the production and use of renewable hydrogen—a
foundational principle in establishing ARCHES, which is at odds with CARB's proposal, to implement deliverability
requirements for hydrogen projects utilizing biomethane.

It remains to be seen if and how the proposed deliverability requirements can be harmonized with the California Public Utilities Commission's (CPUC) SB 1440 program, as suggested. It has been clear over the past year that CARB was exploring potential deliverability requirements. However, throughout that process an actionable plan outlining the strategy and evidence necessary for imposing delivery requirements never emerged. Rather, stakeholders continued to raise concerns about the lack of a feasible plan which continues with the ambiguity of the proposed amendments. Therefore, the

ABC recommends that the deliverability requirement language be removed from the proposal to allow for further stakeholder engagement in support of a clear and actionable plan for consideration in a subsequent rulemaking.

True-up Provisions

The proposal includes true-up provisions where verified operational CI's are drawn on to potentially adjust the credits based
on certified CI's. The proposal indicates that a shortfall (i.e., a verified operational CI that is higher than the certified CI upon
which project credits were generated) is subject to a "penalty" that is 4 times the spread for the applicable volume of fuel. The
096.10 rationale for a 4X spread is unclear as a smaller spread (e.g., 2X) serves as a significant disincentive to producers for being
overconfident in their analysis. Further, the language indicates that in the event the operationally verified CI is lower than the
certified CI (i.e., it failed to generate as many credits as it could have) the Executive Offer (EO) "may" make the appropriate
adjustment (true-up) by awarding additional credits to the applicable fuel reporting entity. The word "may" should be deleted.
096.11 If the operationally verified CI, including an affirmative verification statement, is lower than the certified CI that was the basis
for credit generation, the EO "must" award the supplemental credits supported by the underlying documentation.

The concept of adjustment to credits based on operationally verified CI's is sound. However, limiting the proposal to certified
CI's is a significant oversight. The proposal must be carried over and applied to temporary and provisional CI's as fuel
096.12 providers may rely on these CI's for months, or even years, as a more refined pathway is evaluated and subsequently
approved by CARB.

Temporary CI's have been an important option under the program, but applicants can be reluctant to use them given the heavy credit discounting relative to facility-specific provisional CI's. Correcting for any under (or over) crediting while a temporary CI is used will help streamline and simplify the program as well as send a stronger signal to the market that investments in clean low-CI fuels will be rewarded. Further, including temporary CI's as part of the true-up process will reduce the pressure on CARB from developers to process LCFS applications quickly which has been an ongoing and growing challenge under the program. The concept of adjusting the awarding of credits based on operationally verified CI's is a key principle that supports innovation and must be reflected from project initiation, where a temporary CI is used, throughout the project's lifetime to properly account for and reward the associated reductions in greenhouse gas emissions. Credits should be awarded based on real-world operational experience and therefore adjusted accordingly when the temporary CI which is applied understates the benefits.

New Markets

As the technology in the transportation sector continues to evolve and advance towards lower carbon alternatives, ABC members are following suit and are ready to serve these new markets, such as alternative jet fuel (AJF), low-CI hydrogen, as well as exploring opportunities where biomethane can be utilized outside of transportation. As these markets continue to grow, the ABC asks CARB to remain mindful of the success of the historical framework of the program and to continue to apply it to newer pathways and technologies, including the use of avoided emissions and book-and-claim.

If CARB's goal is to transition biomethane out of the vehicle sector, the ABC strongly encourages CARB to ensure there
continues to be a market for low-CI biomethane as it is an important decarbonization tool, especially in sectors that are hard
to decarbonize. For example, the CPUC's SB 1440 program creates a biomethane procurement mandate for the state's
largest utilities, however, the program excludes dairy biomethane due to the credit it currently receives in the LCFS.[5] With
CARB's intention of phasing out all biomethane crediting for transportation fuel by the end of 2040, it makes sense for the
CPUC to integrate dairy biomethane into the SB 1440 program which will allow for more market choice and volumes of
renewable fuel for utilities to procure. The industrial sector is also another area where biomethane can help significantly
reduce emissions, particularly at facilities that are large natural gas users and where electrification is not currently feasible.
However, there isn't one, all-encompassing policy that drives biomethane, and other low-CI clean fuels, towards that use
case. Thus, the ABC recommends that CARB, starting with the 2024 amendments to the LCFS, send a clear policy signal
096.13 that biomethane is a necessary and effective decarbonization strategy in these other sectors (e.g., residential, commercial,
industrial) that are fundamental to the state meeting its ambitious GHG reduction targets.

[5] California Public Utilities Commission, *Decision Implementing Senate Bill 1440 Biomethane Procurement Program: R.13-02-008*, page 4. https://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M453/K954/453954308.PDF

The ABC would also like to extend its support for CARB's proposal of eliminating the exemption for intrastate fossil jet fuel from the program starting in 2028. This will allow for continued and increased momentum for AJF production and use and will
096.14 help drive down GHG emissions in the aviation sector. Furthermore, the 2022 update to the Scoping Plan calls for 80% of aviation fuel demand in 2045 to be met by AJF.[6] The growth of AJF use is a new market opportunity for biomethane as it can be an important input for the fuel, helping it achieve lower CI's. The magnitude of ambition the state has called for will require the industry to significantly scale-up production and use of AJF, and for that reason, the ABC requests that CARB begin to
096.14 think about the framework and guardrails needed to achieve the 80% goal set forth in the Scoping Plan and leverage all of the tools available to the vehicle market, such as book-and-claim and avoided emissions accounting, to make this goal a reality.

Conclusion

The LCFS continues to be a flagship policy that drives investments in low carbon fuels and is delivering millions of tons of reductions in greenhouse gases to meet California's statutory commitments. The program is also protecting communities throughout the state by transitioning from petroleum to much cleaner fuels, including biomethane. The LCFS is the hallmark of effective environmental policy in that it: 1) sets clear, science-based targets; 2) establishes clear regulations for program implementation; and 3) provides the market with the flexibility to innovate. There is a clear reason that other states and nations model their efforts on California's LCFS. The ABC and its hundreds of members are proud to help build on this success story and are committed to CARB's efforts to continue to drive down emissions from transportation fuels.

Thank you for the opportunity to comment on the proposed amendments, and we look forward to engaging with CARB staff on these topics.

Sincerely,

Patrick Serfass
Executive Director

COALITION FOR CLEAN AIR

February 16, 2024

California Air Resources Board
1001 I Street,
Sacramento, California 95814
Via Electronic submittal

Re: Amendments to the Low Carbon Fuel Standard

To the Air Resources Board:

The Coalition for Clean Air has long supported the Low Carbon Fuel Standard as an essential tool for reducing harmful emissions from the transportation sector, California's largest source of both air and climate pollution. The LCFS supports both the end goal of achieving zero-emission transportation and the interim goal of substituting low carbon renewable fuels for gasoline and diesel during the current period when we still have combustion vehicles on the road. Because of the magnitude of our air pollution and climate crises, we now need the LCFS to both work harder, through greater stringency, and work smarter, by incenting the cleanest fuels and avoiding harms to communities.

Having participated in the September 28 Board hearing and reviewed the December 19 Initial Statement of Reasons, we support both major and minor revisions to the staff proposal. **Most importantly, we are concerned that the absence of a cap on crop-based biofuels jeopardizes the success of the entire LCFS.**

We support the following amendments to the LCFS:

1. **Limit crediting of crop-based biofuels.**
CARB should establish guardrails to prevent incentivizing conversion of crop lands to fuel production, which exacerbates already-existing food shortages in much of the world. While biofuels made from wastes can provide a net climate benefit, using productive land to produce fuel is detrimental to the climate, because carbon-absorbing natural land
101.1 elsewhere will be converted into crop production.

At a minimum, CARB should immediately cap lipid biofuels at 2020 levels, to avoid being swamped with soy-based diesel fuels that are shuffled in from other states, depress LCFS credit values and provide no additional benefit to our climate, because they are

660 South Figueroa Street, Suite 1140
Los Angeles, California 90017

1107 Ninth Street, Suite 630
Sacramento, California 95814

www.ccair.org

already required for compliance with the Federal Renewable Fuel Standard. Ultimately, these fuels should be phased out of the LCFS.

2. **Increase the stringency of the program, and add an acceleration mechanism.** Meeting California's greenhouse gas emission caps under SB 32 and AB 1279 will require more rapid progress in phasing out petroleum fuels in the transportation sector, our largest source of climate-changing emissions. Alongside CARB's regulations and incentives for deploying cleaner engines, and the state's as-yet unrealized targets for reducing vehicle miles travelled, the LCFS provides a vital tool for curbing transportation emissions, as reiterated by the 2022 Scoping Plan Update, which calls for a 94% reduction in petroleum use and identifies the LCFS as a key route to that goal. Therefore, we support the proposed standard of a 30% reduction in fuel CI by 2030, and
101.2 90% by 2045, with inclusion of an automatic acceleration mechanism as a backstop to
101.3 assure that the market in cleaner fuels stays at a robust level.

3. **Remove the exemption for aviation fuel by 2026 for both intrastate and interstate flights.** Conventional jet fuel should be held to the same standard as other petroleum-based transportation fuels. California currently lacks a comprehensive plan for decarbonizing aviation fuels, and including conventional aviation fuel as a deficit generator under the
101.4 LCFS would help to spur innovation in cleaner fuels and equipment. Cleaning up aviation fuels and equipment will also help protect the health of workers and communities who are most exposed to the emissions from this sector.

4. **Use utilities' base residential LCFS credits to promote equity in zero-emission personal mobility and deployment of clean medium and heavy-duty vehicles.** LCFS base residential credit proceeds generated by EDUs from electricity used as a
101.5 transportation fuel should be used to effectively and equitably hasten the adoption of zero-emission electrified transportation, with a focus on disadvantaged and low-income communities. We and our allies are submitting a separate letter on this topic.

5. **Maximize the benefits of the proposed medium- and heavy-duty fast charging infrastructure program by increasing flexibility to better support the deployment of necessary infrastructure.** CARB regulations, which we support, require a transition to zero-emission engines in buses, trucks and other medium and heavy-duty vehicles. That transition is essential to solving our air pollution and climate crises, and infrastructure challenges are probably the biggest single obstacle to success. Therefore, we support the proposed creation of an infrastructure crediting mechanism for medium and heavy-duty refueling for zero-emission vehicles, both battery-electric and fuel-cell electric.

101.6

But the success of the MHD-FCI provision will be constrained by the geographic limitation to projects *"Located within one mile of a reading or pending electric vehicle Federal Highway Administration Alternative Fuel Corridor or on or adjacent to a* *property used for medium or heavy-duty vehicle overnight parking, or has received capital funding from a State or Federal competitive grant program that includes location evaluation as criteria."* We recommend removing these geographic restrictions, as they will undercut program effectiveness, delay deployment, and increase costs for charging and grid upgrades.

6. **Allow crediting in the marine sector.**
101.7 We urge CARB to allow credits for zero-emission transportation fuels used for ocean-going vessels, and to simplify the process for credits for shore power installations serving electrified harbor craft and for dispensing green hydrogen. The marine sector is a substantial source of emissions in much of the state, and the LCFS can spur conversion to cleaner fuels and support CARB's regulations of ocean-going vessels and commercial harbor craft.

7. **Phase out crediting of oil projects.**
101.8 California should be planning a transition away from fossil fuels, so allowing credits for oil projects provides a perverse incentive to perpetuate the very problem that the LCFS seeks to solve. These credits should be phased out sooner than the 2040 date proposed by the ISOR.

CARB should regulate methane emissions from large dairies.
101.9 This issue is not included within the four corners of the LCFS rulemaking but is related. Dairies are the largest California source of methane, a potent short-lived climate pollutant. CARB should require the large dairies to reduce their emissions of both manure and enteric methane. The regulations should also strive to protect local communities from the adverse impacts of large-scale dairy production.

We look forward to continued discussions as the Board considers the LCFS amendments.

Respectfully,

Bill Magavern

Comment	As a nation we spend an inordinate amount of money on corn and bea agriculture and helping confinement feeding operations. Our agricultural policies are having far reaching effects on invasive species. Cattle, goat and sheep producers are having a tough time competing with subsidized CAFO production and invasive are taking over as grassland farmers go out of business.

Comment	As a person that lives near a giant swine confinement, I protest the building of any more of these factory facilities. This one has devastated my neighborhood and forced many people to move away. Because of the ventilation systems that must be engaged at all times, the collection of methane from this system is incomplete so that much methane escapes. Other pollution includes water pollutio after the effluent is spread on fields. Our stream team finds excess nitrogen in the streams every spring. Building more of thes giant facilities will only mean more pollution. Don't be fooled by promises that they will produce power that can be used. They don't

Comment

119.1 I understand wanting to make air quality better; however, capturing methane gas from farms would exacerbate another problem which is factory farming of animals. This practice abuses farm animals and increases corporate takeover of family farms of US citizens by Chinese and Brazilian corporations and/or governments

It's a horrible idea that only increases corporate profits at the expense of humane farming practices in the US by family farmers.

Comment

Hello.
My name is Beth Jones. I'm with a Midwest grassroots organization
called PROTECT POMME DE TERRE. Pomme de Terre is our local lake ar
river that is at risk of being polluted with waste water from a B
BEEF processing facility that thinks they can do whatever they war
to our land and water ways with no consequences. In the past year
they have found out that we at Protect Pomme de Terre will not
stand for it. This California law is ruining our Midwestern
aquaphers. They have already destroyed Iowa. We in Missouri sit or
one of the biggest and most pristine aquaphers in The country. We
will NOT STAND BY AND WATCH FACTORY FARMS DESTROY IT! If Californ
120.1 wants to make methane then they should move all the factory farms
out there and let them continue to destroy Californians
environment. See how the people out there that like that methane
also like the mess that creates it. Thank you very much for your
time.

Comment

Dear Mr. Botill:

Thank you for the opportunity to comment on the Proposed Low Carbo
Fuel Standard (LCFS) Amendments and updated Life Cycle Analysis (LCA) and Documentation. The LCFS is one of the most powerful climate change policies in the world, uniquely supporting a wide array of innovative, low-carbon fuel production pathways. Its success has proven a model for similar programs that are emerging in other states and countries. We strongly encourage the Californi
Air Resources Board (CARB) to amend the program in a manner that protects and builds on its successful, technology-neutral and science-based approach to ensure the program continues to drive innovation and greenhouse gas reductions for decades into the future.

DUCTOR®

February 16, 2024

Matthew Botill
California Air Resources Board
1011 I Street
Sacramento, CA 95814

Subject: Comments on the Proposed Low Carbon Fuel Standard Amendments

Dear Mr. Botill:

Thank you for the opportunity to comment on the Proposed Low Carbon Fuel Standard (LCFS) Amendments and updated Life Cycle Analysis (LCA) and Documentation. The LCFS is one of the most powerful climate change policies in the world, uniquely supporting a wide array of innovative, low-carbon fuel production pathways. Its success has proven a model for similar programs that are emerging in other states and countries. We strongly encourage the California Air Resources Board (CARB) to amend the program in a manner that protects and builds on its successful, technology-neutral and science-based approach to ensure the program continues to drive innovation and greenhouse gas reductions for decades into the future.

Ductor offers the following high level comments, which are elaborated on further below. Additionally, we appreciate the opportunity to comment on the updated lifecycle analysis models and documentation, including revised Tier 1 calculators, which we will comment on separately.

- The LCFS has proven one of the most powerful programs in the world for reducing potent short-lived climate pollutants. It can similarly be applied to reduce even more potent nitrous oxide (N_2O) emissions, which have yet to be addressed in California's otherwise comprehensive climate change framework. ***We encourage CARB to leverage the LCFS to account for avoided N_2O emissions and enable reductions from this potent source of greenhouse gas emissions.***
- Protecting technology neutrality and enabling innovation is central to the success of the LCFS. ***We recommend minor changes to clarify provisions related to biogas pathways from poultry litter.*** This includes:
  - ***Creating a definition of "waste" that includes poultry litter***, including from layer, broiler, and turkey operations.
  - ***Clarifying language related to crediting for avoided methane emissions*** from manure and organic waste pathways.
  - ***Adding language to clarify applicability of crediting for avoided N_2O emissions for organic waste pathways.***

121.3
- Avoided methane crediting and book-and-claim access for biogas projects are central to enabling biogas projects and associated emissions reductions. ***We urge CARB to avoid restricting avoided methane crediting or biogas book-and-claim accounting in the program.***
- The proposed targets and structure of the auto acceleration mechanism (AAM) are insufficient to reverse the accumulation of credits in the market. We urge 15-day changes that would:
  - ***Increase the stringency of the step down*** to levels needed to restore healthy market conditions,
  - ***Apply the step down as soon as the regulation takes effect*** (e.g., Q3 2024),
  - ***Increase the 2030 target to levels needed to achieve the state's climate change goals, and no less than 40%,*** and
  - ***Move the AAM forward a year and remove the restriction against applying it in consecutive years.***

About Ductor

Ductor was founded in 2009 with the ambitious aim of creating a solution that would help solve today's environmental challenges in the energy and agriculture sectors. Today, we build, own, and operate turnkey microbiological facilities, turning organic resources from the agricultural sector into sustainable fertilizers and biogas. With two plants in Mexico and Germany and numerous projects in the pipeline, we are living up to our purpose and unlocking bio-resources to make food sustainable and energy clean.

Ductor's technology transforms nitrogen-rich organic resources from agriculture, aquaculture, and other organic sources into energy and fertilizers. We specialize in feedstock that cannot be used directly in conventional anaerobic digestion and biogas facilities. This feedstock is fed into the Ductor pre-process, where an IP-protected consortium of microorganisms and the IP-protected Ductor process converts them via fermentation and subsequent ammonia recovery into organic and sustainable liquid nitrogen fertilizer. The feedstock is further processed via anaerobic digestion to generate biogas, which is upgraded to pipeline quality. The digestate is further processed into additional fertilizing and soil-improving products.

Ductor's technology targets the poultry sector, which is growing globally to meet the increasing demand for meat and egg products. Driven by population growth, urbanization, and rising incomes, global per-capita consumption of poultry meat increased from 3.1 kg to 15 kg between 1964 and 2013, while global per-capita consumption of eggs grew from 4.7 kg to 9.2 kg. The poultry sector generates a large quantity of litter consisting of manure, egg wash water, waste bedding, waste food, and feathers. The amount of litter depends on the frequency of the removal of litter, which varies from country to country. According to the USDA, as much as 1.4 billion tons of manure is produced annually by the 9.8 billion head of livestock and poultry in the United States. Sustainable and alternative treatment options for this growing waste stream are needed to address environmental and emissions impacts associated with poultry litter management, storage, and land application.

Reducing N_2O emissions a missing piece of California's climate framework, should be supported through LCFS

California has correctly emphasized targeted efforts to reduce emissions of methane and other potent short-lived climate pollutants,[1] and has recognized the LCFS as a critical element to achieving these reductions in the agricultural sector.[2] Yet very little has been done to address even more potent N_2O emissions. While methane is about 30 times more potent than CO_2 over 100 years,[3] for example, N_2O is about 10 times worse still – about 300 times more potent than CO_2 over 100 years. Methane, as a short-lived climate pollutant, dissipates from the atmosphere in about a decade, but N_2O is a long-lived gas whose potent warming impacts will persist for over a century once it reaches the atmosphere.

The majority of N_2O emissions in California comes from the agricultural sector (specifically, fertilizer use/soils and manure management),[4] and according to the 2022 Climate Change Scoping Plan, CARB envisions few if any N_2O emissions reductions through mid-Century.[5] In fact, the Scoping Plan modeling shows agricultural N_2O becoming one of the largest sources of greenhouse gas emissions in the state in the future.[6] Fortunately, agricultural N_2O emissions can be readily addressed through improved manure management practices (especially at egg laying and poultry farms) and greater use of sustainable agricultural practices, including the use of renewable fertilizers, organic farming, and other strategies.

The state can enable significant reductions in agricultural N_2O emissions by accounting for avoided N_2O emissions in LCFS pathways and taking additional steps to support markets for renewable fertilizers and organic agriculture.

121.1 There is already a precedent for considering N_2O emissions within LCFS pathways. CARB currently accounts for avoided N_2O emissions associated with composting food scraps in their Tier 1 Organic Waste (OW) calculator. Excluding similar considerations for agricultural feedstocks appears arbitrary, especially given the critical role N_2O emissions play in the agricultural sector.

Clearly support poultry-based pathways in the LCFS

California has more than 10 times as many head of poultry (egg laying hens, broiler chickens and turkeys) than dairy cows and more than 200 times more poultry head than swine.[7,8] Yet, while the LCFS acknowledges dairy and swine pathways, it does not currently reference poultry-based pathways. Biogas pathways from poultry litter provide significant opportunity to support additional biogas supplies, while serving to improve nitrogen management associated with

[3] And more than 80 times worse than CO_2 over 20 years.
[4] https://ww2.arb.ca.gov/sites/default/files/2023-12/ghg_inventory_scopingplan_2000-21n2o.pdf
[5] CARB (2022) 2022 Scoping Plan for Achieving Carbon Neutrality, California Air Resources Board, December.
[6] For example, compare Figures 2-5 and 4-19 in the 2022 Scoping Plan.
[7] https://www.statista.com/statistics/196085/top-us-states-by-number-of-chickens/
[8] https://www.nass.usda.gov/Quick_Stats/Ag_Overview/stateOverview.php?state=CALIFORNIA

poultry operations. These pathways support efforts to address water quality issues and reduce potent N_2O emissions, while also reducing methane and creating new supplies of renewable fertilizers to support organic farming, broader sustainable agricultural practices, and additional N_2O reductions from crop management and soils.

While poultry-based pathways (Figure 1) and avoided N_2O emissions are included in the GREET 4.0 model,[9] they are not referenced in the regulation or regulatory documents. Directly incorporating poultry litter-based pathways, avoided N_2O emissions, and renewable fertilizer co-products into the regulation will clarify the opportunity for poultry-based pathways and allow these projects to come on-line more quickly in support of the state's climate change and environmental goals. Specifically highlighting N_2O emissions will provide an important signal that the state is committed to reducing these emissions, alongside other greenhouse gas emissions.

1.3) Assumptions for Anaerobic Digestion of Animal Waste

Source of Assumptions: U.S.

U.S.

	Beef	Dairy Cow	Dairy Heifer	Swine	Layer	Broiler and Turkey
121.2 Share of Livestocks	0.0%	0.0%	0.0%	0.0%	75.0%	25.0%

Figure 1. Snapshot of CA GREET4.0 RNG Tab. The yellow cells indicate inputs. A red box is drawn around "Layer" (poultry), and "Broiler and Turkey" livestock categories.

Accordingly, we urge CARB to consider minor changes to clarify and elevate opportunities for these pathways, including the following:

- Create a definition of "waste" to clarify the new definition of "organic waste."[10] The definition of waste should be broad enough to include animal wastes and manures. Waste could refer to materials with limited immediate use, requiring disposal, originating from forestry, agriculture, livestock, municipalities, or industries.

- Ensure equal treatment for all organic waste pathways as it relates to avoided methane crediting and align the regulation with the organic waste Tier 1 calculator, which includes credit for avoided N_2O, with the following changes to § 95488.9:

  (f) Carbon Intensities that Reflect Avoided Methane and Nitrous Oxide Emissions from ~~Dairy and Swine~~ Animal Manure or Organic Waste ~~Diverted from Landfill Disposal~~.

    (1) A fuel pathway that utilizes biomethane from ~~dairy cattle or swine~~ animal manure digestion may be certified with a CI that reflects the reduction of greenhouse gas emissions achieved by the voluntary capture of methane, provided that:

[9] CARB (2023). Biomethane from Anaerobic Digestion of Organic Waste (Calculator). Avoided N_2O emissions are included for Food Scrap pathways.
[10] "Organic Waste" is defined as material that meets both the LCFS definitions of "biomass" and "waste." However, there is no definition in the regulation for "waste."

121.2 cont (A) A biogas control system, or digester, is used to capture biomethane from manure management on ~~dairy cattle and swine~~ farms that would otherwise be vented to the atmosphere as a result of livestock operations from those farms.

(B) The baseline quantity of avoided methane reflected in the CI calculation is additional to any legal requirement for the capture and destruction of biomethane.

(2) A fuel pathway that utilizes an organic waste ~~material~~ may be certified with a CI that reflects the reduction of greenhouse gas emissions achieved by the voluntary diversion from decomposition in a landfill or other reference case and the associated fugitive methane and nitrous oxide emissions, provided that:

(A) The organic waste ~~material~~ that is used as a feedstock would otherwise have been disposed of by landfilling or in a manner in which decomposition emissions in the reference case can be quantified and verified, and the diversion is additional to any legal requirements for management of the organic waste, including ~~for~~ the diversion of organics from landfill disposal.

(B) Any degradable carbon that is not converted to fuel is subsequently treated in an aerobic system or otherwise is prevented from release as fugitive methane. Upon request, the applicant must demonstrate that emissions are not significant beyond the system boundary of the fuel pathway.

(C) The baseline quantity of avoided methane reflected in the CI calculation is additional to any legal requirement for the avoidance or capture and destruction of biomethane.

(D) Credit for avoided nitrous oxide reflected in the CI calculation shall reflect the quantity of avoided nitrous oxide emissions, including decomposition emissions in the reference case, and is subject to approval by the Executive Officer and verification requirements in §95500.

- Update the reference in § 95488.1(d)(2) as follows:
  - Biomethane from sources other than those listed under the Tier 1 classification in (c)~~(5)~~(4), above;

Avoid restricting avoided emissions crediting or biogas book-and-claim accounting

121.3 We strongly oppose any restrictions to avoided emissions crediting, including avoided methane or N_2O, or book-and-claim accounting of biomethane pathways. These elements are critical to supporting biomethane projects from manure and organic waste resources and emissions

reductions from the most potent climate forcers, including methane and N_2O. Additionally, book-
121.4 and-claim accounting of biomethane is necessary to bring additional volumes of biomethane to
California and displace fossil-based natural gas, almost all of which comes from outside the
State, and is itself acquired and delivered via similar book-and-claim procedures.

121.5 We urge CARB to maintain existing provisions for book-and-claim accounting of biomethane
and avoided emissions, with the minor amendments proposed above, to support a growing
organic waste biomethane market with the associated carbon, SLCP and N_2O emissions benefits.
Additionally, we urge CARB to allow book-and-claim accounting of biomethane to power plants
to generate LCFS credits for electric vehicle charging, in order to advance the State's zero
121.6 emission vehicle (ZEV) goals, provide equitable treatment between electricity and hydrogen-
based fuel pathways, and support a shift of biomethane from CNG vehicles to ZEVs and
stationary sources.

Strengthen targets to restore the health of the program and ensure its ongoing success

In previous comments, we have consistently supported the following elements of a strengthened program:

- An immediate step-down in carbon intensity sufficient to reverse the trend of an accumulating bank of excess credits that is serving to dampen credit prices and restrict investment in new clean fuel pathways,
- A strengthened 2030 target, in-line with Scoping Plan targets and the ICF analysis, of at least 40%, and
- A responsive AAM that would automatically strengthen the program should the market continue to out-perform regulatory requirements, and therefore support additional low carbon fuel volumes and emissions reductions.

We appreciate that the regulatory proposal includes elements of these objectives. However, we
note that based on external analysis from ICF and others, and as indicated by the market
response following release of the regulatory proposal (credits are now trading at their lowest
level since the regulation was last amended), the targets appear insufficient to achieve these
outcomes. We encourage changes that would align with the objectives listed above, including (1)
121.7 strengthening the step-down and applying it as soon as the regulation takes effect, (2)
121.8 strengthening the 2030 target, to at least 40% in-line with the Scoping Plan and ICF analysis, and
121.9 (3) allowing the AAM to be more responsive to the market, including allowing it to be triggered
based on 2025 market data and to be triggered in consecutive years if needed.

Conclusion

We very much appreciate your work, and the work of other CARB staff, to engage stakeholders throughout this process. We understand the wide array of issues related to the LCFS program that are under consideration for amendments, and we appreciate your efforts to strengthen the program and advance California's climate change and related objectives.

Thank you for your consideration of these comments, and please do not hesitate to reach out with any questions.

Sincerely,

Bernard C. Fenner

Subject Proposed Low Carbon Fuel Standard Amendments

Comment

Please stop encouraging CAFOs, which is what this proposal will do 122.1
Missouri and the nation need small farmers who care about the land, our communities and our country. Giving preference to large corporations who are often foreign owned and do not care for anything but making money is wrong. Please wake up to what pride of ownership and pride of caring for our land and communities is all about. You are supposed to represent those who elected you, and not those paid to lobby for corporate interests. Please have the courage to stand up and actually represent the people of Missouri rather than multinational corporations.

Subject	No Factory Farm funding
Comment	Please do NOT use taxpayer dollars to pay for ANYTHING for farms that harm the environment, especially oil or gas that pollutes our air. Gas should be a thing of the past and certainly not something that taxpayers purchase without our approval. Most Californians do not want to spend our taxes funding factory farms in any way. Than you for considering those who pay here in the Golden State.

Subject	Protect our environment and food supply by ending factory farming

Comment

Instead of investing in factory farming biogas, invest in sustainable humane certified farms and dairies. As a progressive and forward-thinking state, Californians are aware of the significant body of research that shows large scale factory farms, dairies and feedlots lead to environmental damage, lower quality food and milk, and unnecessary cruelty to the sentient beings who
125.1 nourish us. California should be following the example of the various farms within our state and country who truly care about th environment by utilizing regenerative practices while providing a high-quality food supply and treating the animals who feed us with the care they deserve. See Niman Ranch, Clover, Force of Nature, Rancho Llano Seco, Stemple Creek Farm, Hart Dairy, Organic Pasture Dairy, etc. Let's truly be a forward-thinking state by ending factory farming once and for all. Thank you.

Matthew Botill
California Air Resources Board (CARB)
1001 I Street
Sacramento, CA 95814

Re: Blue Planet Comments on the Proposed Low Carbon Fuel Standard Amendments

Dear Mr. Botill:

Blue Planet Systems Corporation (Blue Planet) appreciates the opportunity to comment on the proposed amendments to the Low Carbon Fuel Standard (LCFS). Blue Planet supports CARB's initiatives to advance California's climate change goals, including supporting development of key carbon capture, utilization and storage (CCUS) and direct air capture (DAC) technologies through the LCFS. We encourage CARB to expand their CCUS definition to allow for other permanent, non-geologic approaches to carbon sequestration to support state goals around deep decarbonization, carbon neutrality and achieving the Scoping Plan objectives.

About Blue Planet

Blue Planet is a California company developing technology and products related to economically sustainable carbon management. Our goal is to solve the carbon capture problem by converting CO_2 into high-value building materials. Our technology can be deployed at a wide array of difficult-to-decarbonize industries, including cement and facilities involved in any number of transportation pathways participating in the LCFS – including ethanol, renewable gasoline/diesel, hydrogen, biogas, electricity, or direct air capture. Importantly, our technology captures not only CO_2, but also particulate matter, NO_x, SO_x and other pollutants hazardous to surrounding communities. We are currently constructing and beginning operations of a plant in Pittsburg, California on the Sacramento Delta, and our carbon-sequestered aggregate has been utilized at San Francisco International Airport, where carbon-sequestered concrete is specified.

Blue Planet's technology produces coarse and fine limestone aggregates made from sequestered CO_2 utilizing the carbon mineralization process. It fosters lower-cost carbon capture, including from direct air capture or other carbon removal pathways, by avoiding the need to purify and enrich captured CO_2 before use, reducing the cost and energy needs associated with carbon capture. It is also fully scalable and can be applied to any facility in any part of the state where concrete is utilized, regardless of its proximity or access to a geological sequestration site.

Carbonate mineralization offers a significant and permanent carbon storage and utilization solution

Almost all of earth's carbon – about 99 percent – is stored naturally through the process of mineralization in limestone rock. Trillions of tons of CO_2 have been safely and naturally stored as carbonate mineral for over 100 million years. As described previously in comments to CARB related to the Scoping Plan,[1] and validated in peer-reviewed research,[2] the mineralization process permanently stores carbon in rock, which can then be used in concrete and stored in our built environment. Just as very high heat (~1500^{o}C) is necessary break limestone into its constituent elements (CaO and CO_2) to make cement, similar conditions would be required to release captured CO_2 once it has been mineralized back to limestone.

Additionally, since concrete is the most widely used building material on earth, every year California (and the world) use enough rocks in concrete that we could store all emissions from major industrial sources in our buildings and roads. Compared to geological sequestration, which only entails cost,[3] carbon capture and conversion – in particular carbon storage in concrete – provides a value-added market that can make carbon capture cost effective without additional public subsidy.

While several technical, legal, and economic questions remain related to geologic sequestration, many of which CARB and other agencies will address through implementation of SB 905 (Caballero, Chapter 359, Statutes of 2022), carbonate mineralization offers a fully scalable, permanent carbon storage solution, ready for deployment today. Through the SB 905 process, we also hope CARB will consider developing new CCS Protocols, including for carbonate mineralization. We appreciate the state repeatedly already recognizing this opportunity, including:

- In the Final 2022 Scoping Plan Update, CARB discusses the role of carbon capture and carbonate mineralization in the context of decarbonizing cement and other sector transitions, stating "Direct air capture and carbon mineralization have high potential capacity for removing carbon..."[4]

- The CEC identifies carbonate mineralization, including carbon storage in aggregates, as one of the most promising strategies for decarbonizing the cement sector:[5]

> Capturing carbon from industrial processes and then utilizing it in a product is considered one of the essential components for mitigating CO_2 emissions since it can achieve net negative emissions, especially for sectors that are unable to achieve zero emissions. For example, carbon capture and utilization appear to be a pathway to achieve significant decarbonization of the cement industry where 60 percent of the carbon dioxide is from process emissions… For instance, carbon capture and utilization in the cement industry has recently emerged with

[1] https://www.arb.ca.gov/lists/com-attach/73-sp22-kickoff-ws-UTMGbFElVGJQCQd3.pdf

[2] For example, see: Xi, F., Davis, S., Ciais, P. et al. Substantial global carbon uptake by cement carbonation. Nature Geosci 9, 880–883 (2016). https://doi.org/10.1038/ngeo2840

[3] Unless it is used for enhanced oil recovery, which is unlikely in California given prohibitions included in SB 905 (Caballero, Chapter 359, Statutes of 2022) and SB 1341 (Limón, Chapter 336, Statutes of 2022).

[4] CARB (2022) 2022 Scoping Plan for Achieving Carbon Neutrality, California Air Resources Board, November 16, pg. 221. https://ww2.arb.ca.gov/sites/default/files/2022-11/2022-sp.pdf

[5] See pg. 10 at: https://esd.dof.ca.gov/Documents/bcp/2223/FY2223_ORG3360_BCP5441.pdf

sustainable techniques to use carbon emissions in concrete production. Some emerging utilization techniques, such as mineral carbonation, includes adding carbon into cement to enhance the concrete's compressive strength. With almost 4 billion tons of construction aggregate produced in North America, mineral carbonation could be the most efficient route to CO_2 utilization.

LCFS amendments should allow use of additional CCUS strategies as new CCS Protocols are developed

The LCFS is a critical program for advancing California's climate objectives, and likely the most important program to advance CCUS and carbon dioxide removal, both of which will be necessary to achieve California's goals of carbon neutrality and achieve and maintain net-negative greenhouse gas emissions. Indeed, the Final Scoping Plan identifies a significant role for CCUS to play in decarbonizing transportation fuel pathways and supporting carbon dioxide removal, both in 2030 and through 2045. We hope CARB will recognize the promising role that CCUS in aggregates and concrete – as well as other emerging CCUS and carbon dioxide removal strategies – can play in helping to achieve carbon neutrality and net-negative emissions in California and make further amendments to the LCFS to allow new protocols to be deployed as they are developed and adopted.

Unfortunately, while the regulatory language already references the CCS Protocol, in several instances the language also references geologic sequestration, CO_2 transport by pipeline, or other items that seem unnecessary to utilizing the current CCS Protocol in the program and serve to limit eligibility of potential new protocols as they are developed. **We hope you will consider 15-day changes to remove references in the regulation related to CCUS that serve to limit potential new CCUS and Carbon Dioxide Removal Protocols from being utilized in the future, and clarify that future protocols would be eligible under the LCFS, should they be developed and adopted.** In particular, we urge the following changes:

- Update the definition of "Carbon capture and sequestration (CCS) project" in § 95481(a) to remove language limiting the potential use of non-geologic sequestration projects:

  "Carbon capture and sequestration (CCS) project" means a project that captures or removes CO_2 by an eligible entity specified in section 95490(a) of this subarticle~~,~~ ~~transports the captured CO_2 to an injection site, and injects~~ and permanently sequesters the captured CO_2 pursuant to the Carbon Capture and Sequestration Protocol and as specified by section 95490 of this subarticle.

127.1

- Clarify that new protocols added to the CCS Protocol will be eligible to generate credits under the LCFS and similarly remove limiting language related to potential CCUS Protocols in § 95490:

  (a) Eligibility. The following entities are eligible to submit applications and, if approved, receive credits associated with net GHG reductions from CCS projects, in accordance with following protocol or any subsequent version, which ~~is~~ are incorporated herein by reference and ~~is~~ referred to as the "CCS Protocol" hereafter.

  Industrial Strategies Division, California Air Resources Board. August 13, 2018. Carbon Capture and Sequestration Protocol under the Low Carbon Fuel Standard.

127.1 cont

(1) Alternative fuel producers, petroleum refineries, and oil producers that capture CO_2 on-site, including at the location of the production of hydrogen used as an intermediate input, and ~~geologically~~ permanently sequester CO_2 either on-site or off-site.

(2) An entity that employs direct air capture to remove CO_2 from the atmosphere using chemical and/or physical separation and ~~geologically~~ permanently sequester the CO_2.

(A) Direct air capture and sequestration projects must be physically located in the United States.

(B) If CO2 derived from direct air capture is converted to fuels, it is not eligible for project-based CCS credits. However, applicants may apply for fuel pathway certification using the Tier 2 pathway application process as described in section 95488.7.

(3) An entity that employs a technology to capture or remove and permanently sequester CO_2 from the atmosphere in accord with the provisions of the "CCS Protocol" or any subsequent version or protocol.

(b) General Requirements.

(1) Projects and fuel pathways claiming CCS credits must comply with the CCS Protocol. To be considered in compliance with the CCS protocol, a project must be issued executive orders and meet all the requirements throughout the project life in accordance with the permanence requirements of the CCS protocol.

(2) Credit determination for any project that utilizes CCS must be performed in accordance with the accounting requirements of the CCS protocol.

(3) Except for direct air capture and sequestration projects or other projects as deemed appropriate, credits must be prorated based on the volumes delivered to California.

(c)(2)(B) An engineering drawing(s) or process flow diagram(s) that illustrates the project and clearly identifies the system boundaries, relevant process equipment, mass flows, including the quantity of CO_2 injected into pipeline or delivered by other modes of transport for CO_2 ~~injection~~ sequestration, and energy flows necessary to calculate the CCS credit;

(c)(2)(G) Executive orders issued pursuant to the permanence requirements of the CCS protocol, certifying the sequestration site or method as capable of permanently storing CO_2 and authorizing ~~operation and~~ credit generation.

(g)(2) Energy use and chemical use data for the carbon capture facility and CO_2 ~~injection~~ sequestration facility;

- Also remove limiting language in § 95489(e)(1)(D)(1):

CO_2 capture from existing anthropogenic sources at refineries, or at hydrogen production facilities that supply hydrogen to refineries, and subsequent ~~geologic~~ sequestration;

Support maintaining project-based crediting for CCS projects

Blue Planet strongly supports exempting CCS projects from the proposed phase out of project-
127.2 based crediting for petroleum projects. We agree with the rationale for this proposal presented
in the ISOR.

Quickly enabling a wide array of CCUS projects and protocols will accelerate California's climate change goals

Now is the time to fully enable CCUS as a solution to ensure the California stays on track to achieve its Scoping Plan objectives. By incorporating the changes referenced above to avoid presuming geologic sequestration remains the only CCS Protocol available in California and preserving project-based crediting opportunities for CCS projects, the LCFS can continue provide a strong signal for investment in CCUS and DAC projects. The next step is to develop new CCS Protocols, as referenced in SB 905 and through implementation of that legislation, and incorporate CCUS into the Cap-and-Trade program. We look forward to continuing to engage in all of these forums.

Thank you for your consideration of these comments, and please do not hesitate to reach out if you have any questions about Blue Planet, our technology, or the recommendations and comments offered in this letter.

Thank you,

Laura Berland-Shane
Vice President, Government Affairs
Blue Planet Systems Corporation

134.1 Eliminate avoided methane crediting for fuel derived from livestoc
manure.

134.2 - Oppose Proposed LCFS Amendment Loophole to Allow Petroleum
Projects with Carbon Capture & Storage Past the 2040 Phase-out.

I recommend a number of measures, to wit:
134.3 Conduct and incorporate a full life cycle assessment of all air
pollution and greenhouse gas (GHG) emissions for all pathways, anc
their implications for environmental justice communities.

134.4 - Create ZEV multipliers to boost electric school bus and electric
public transit bus and rail system deployments.

134.5 - Eliminate credit generation from factory farm gas projects that
would have happened anyway due to other programs or investments.

134.6 - Include intrastate jet fuel as a deficit generator and include
California's share of the fuel used in interstate and internationa
flights.

134.7 - Allow credits for zero-emission transportation fuels used for
ocean-going vessels, and simplifying the process for credits for
shore power installations serving electrified harbor crafts and fo
dispensing green hydrogen.

Subject	Environmental Efficiency

Comment

I'd like to introduce a new term / measure when considering energy
"Environmental Efficiency". For example, the average, grid-scale
solar / storage operation has an Environmental Efficiency of 1.1
MWh / acre. A large nuclear plant, with a large "safety barrier",
has an Environmental Efficiency of ~40 MWh / acre. And a next-gen
136.1 natural gas fired generating station has an Environmental
Efficiency of ~80 MWh / acre.

In other words, while a 24,000 MWh / day natural gas generating
station might sit on a half-square mile of land, a similar solar /
storage operation would require ~40 square miles of land; obscenel
abusive and low Environmental Efficiency.

And that does not include any of the raw materiel / rare earths
mining, production in highly polluting countries such as China, no
the poor performance and accelerated life-time performance
degradation.

Then there is the human rights issue, but that might be better
captured in a separate category.

The point being there is "no free lunch"; miles and miles of virg
lands and waters are being abused, animals of land, sea and air ar
being murdered and all for the whimsy of politicians in DC and
Davos.

Remember, fossil fuels, such as natural gas, are simply Mother
Nature's stored solar energy; she's a very clever Lady.

Comment

137.1 - Eliminate avoided methane crediting for fuel derived from livestock manure.

137.2 - Oppose Proposed LCFS Amendment Loophole to Allow Petroleum Projects with Carbon Capture & Storage Past the 2040 Phase-out.

137.3 - Eliminate credit generation from factory farm gas projects that would have happened anyway due to other programs or investments.

Plus:

137.4 - Conduct and incorporate a full life cycle assessment of all air pollution and greenhouse gas (GHG) emissions for all pathways, anc their implications for environmental justice communities.

137.5 - Create ZEV multipliers to boost electric school bus and electri public transit bus and rail system deployments.

137.6 - Include intrastate jet fuel as a deficit generator and include California's share of the fuel used in interstate and internationa flights.

137.7 - Allow credits for zero-emission transportation fuels used for ocean-going vessels, and simplifying the process for credits for shore power installations serving electrified harbor crafts and fo dispensing green hydrogen.

California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

As a renewable fuel producer and participant in CARB's LCFS program, my team and I value the partnership and mission shared with you and your state to reduce the carbon intensity of transportation fuels.

I am writing to share our company's perspective on two key program areas for your consideration. These requests address the topics of **firm rotation** and **less intensive verification**.

<u>Firm Rotation</u>
The existing regulations within the LCFS verification program stipulate a mandatory rotation of audit firms every six years to assess participants' carbon intensity (CI) and fuel quantities compliance.

Our request is that CARB amend the mandatory firm rotation regulation to include an exception for licensed CPA firms. Of the 30 approved LCFS verification bodies, there are only four licensed CPA firms.

> ***An approved verification body, that is also a licensed CPA firm, exceeds the standards in place for verification bodies and is already subject to additional***
> 138.1 ***oversight on the entity's quality control system in accounting and auditing practices through the required AICPA peer review process.***
>
> ***Due to the increased regulatory oversight, we suggest a CPA firm not be subject to the audit firm rotation but would instead adhere to a Lead Verifier rotation after six consecutive years.***

A licensed CPA firm differs from other consulting agencies by adhering to more rigorous standards and oversight at a state and national level. If a verification body were to violate a

Lead Verifier rotation requirement, it would put the firm license at risk. The firm license is required for all services provided by the firm, not just the LCFS verification services, thereby ensuring adherence to requirements.

Licensed CPA firm requirements

- A licensed CPA firm must be comprised of over 50% of the ownership being licensed CPAs.
    - To earn the accreditation to be a CPA, one must pass a rigorous four-part CPA exam, accumulate education hours, and in many states, one must fulfill 1-2 years of work experience.

- 3-year peer review audit
    - Each licensed CPA firm must enroll in an approved peer review program with reviews conducted every 3 years. The peer review requirement is a requirement of the American Institute of Certified Public Accountants (AICPA) and is an external review of a firm's quality control system in accounting and auditing practices. CPA firms' peer review results can be found on AICPA's website under the Peer Review Public File Search.

- State Boards of Accountancy (SBOA) are found in each state's statute to aid state governments in the licensing and regulation of the public accounting profession.
    - SBOAs provide further oversight on CPA firms by evaluating CPA licensees' examinations and regulatory oversight to ensure a firm is practicing within their statutory scope.

The audit quality and efficiency improve as the auditor becomes more familiar with our company's processes. In addition, with the limited number of firms available as verification bodies and a five-year lookback period in place, it is proving difficult to identify a quality verification body that is not also working with our facility in other consulting capacities. The number of people available with the proper expertise to assist us in design and development of projects and to reserve for verification purposes has proven even more limiting, which is also why we request a Lead Verifier rotation rather than a full firm rotation.

Less Intensive Verification

Regarding less intensive verification, we noted in Appendix E staff's proposal for less intensive verifications for when electricity is used as a transportation fuel, allowing verification bodies to skip site visits if they visited the site in the last two years and issued a positive verification statement.

The rationale for this proposed change states, "there is little change of operation from reporting period to reporting period thus reducing the benefit of annual site visits." Additionally, staff rationale states, "There is no or little risk to the integrity of the LCFS program to allow for less intensive verification services without a site visit in the annual verifications for the following two years. This should reduce the cost of verification services which is often passed on to program participants."

Currently, the proposed language limits this allowance for less intensive verifications to QFTR third-party verification bodies for fuel reporting entities only reporting electricity transactions.

138.2 We agree with the staff's stated rationale, but **we request for less intensive verification to be extended as an option for verification bodies on all validations and annual verifications for any reporting entities.**

In CARB's MRR program (section 95130), less intensive verification is applied without prejudice to verification services by accredited verification bodies.

We agree with staff that less intensive verification leads to little to no risk to the integrity of the LCFS program and that there is little change in operation from reporting period to reporting period, while also providing cost savings to verification providers and passed on to our company as program participants.

We acknowledge the importance of adhering to CARB's specified conditions that necessitate comprehensive verification services. These conditions include the issuance of an adverse verification statement or a qualified positive verification statement in the preceding year and the occurrence of a change in operational control of the reporting entity in the previous year.

Thank you for your time and consideration. Please reach out to us if you have any questions.

Sincerely,

Robbi Buchholtz

GENERATE

February 20th, 2024

Matt Botill
Chief, Industrial Strategies Division
California Air Resources Board
1001 I Street, Sacramento, CA 95814

Mr. Botill and CARB Staff,

I am pleased to write to you on behalf of Generate Capital, PBC ("Generate") regarding the current rulemaking process to update and strengthen the Low Carbon Fuel Standard ("LCFS"). Generate is a leading sustainable infrastructure company based in San Francisco. Generate builds, owns, operates, and finances infrastructure solutions for clean energy, transportation, water, waste, agriculture, and smart cities. Founded in 2014, Generate partners with technology and project developers to deliver affordable, reliable, and sustainable resources to over 2,000 customers, companies, communities, school districts and universities.

The LCFS has been a model climate policy. It has enabled the private sector to deploy billions of dollars into climate solutions to decarbonize California's transportation sector. The current amendments to the policy continue that leadership. In particular, by providing carbon intensity ("CI") reduction targets through 2045, the agency is allowing investors like us to have the policy certainty needed to deploy patient, long-term capital into climate solutions and the companies that build them.

As participants in this market, we agree with many of the updates CARB is proposing in this process. At the same time, there remain a handful of key topics where we would like to see amendments to the proposed regulation. In particular, the key areas on which we will provide commentary include:

- The changes to the diesel baseline and its impact on credit supply and demand;
- The CI step-down and the 2030 CI reduction target;
- The design of the Auto-Acceleration Mechanism ("AAM"), and;
- The treatment of Renewable Natural Gas ("RNG").

We look forward to discussing these and other aspects of the LCFS program with CARB staff as may be helpful to finalize the rulemaking process. Thank you for all of your hard work to ensure California continues to be a leader in the fight against climate change.

Sincerely,

Asher Goldman

Asher Goldman
Vice President
Generate Capital

140.1 Changing the diesel baseline reduces the ambition of the LCFS program and lessens the impact of the changes CARB is proposing; the CI reduction targets should be increased to counteract the change in the baseline

For the past several years, the conversation around potential LCFS amendments has focused on changing the CI targets in terms of percent reductions relative to the 2010 baseline. While the Initial Statement of Reasons ("ISOR") did adjust those CI reduction targets, it also meaningfully changed the 2010 CI baseline for diesel. While we are aware that this value does periodically change due to updated modeling, this instance was larger than any previous change.[1] As shown in Figure 1, by moving the 2010 baseline for diesel from 100.45 g/MJ to 105.76 g/MJ, the resulting CI targets shift up.

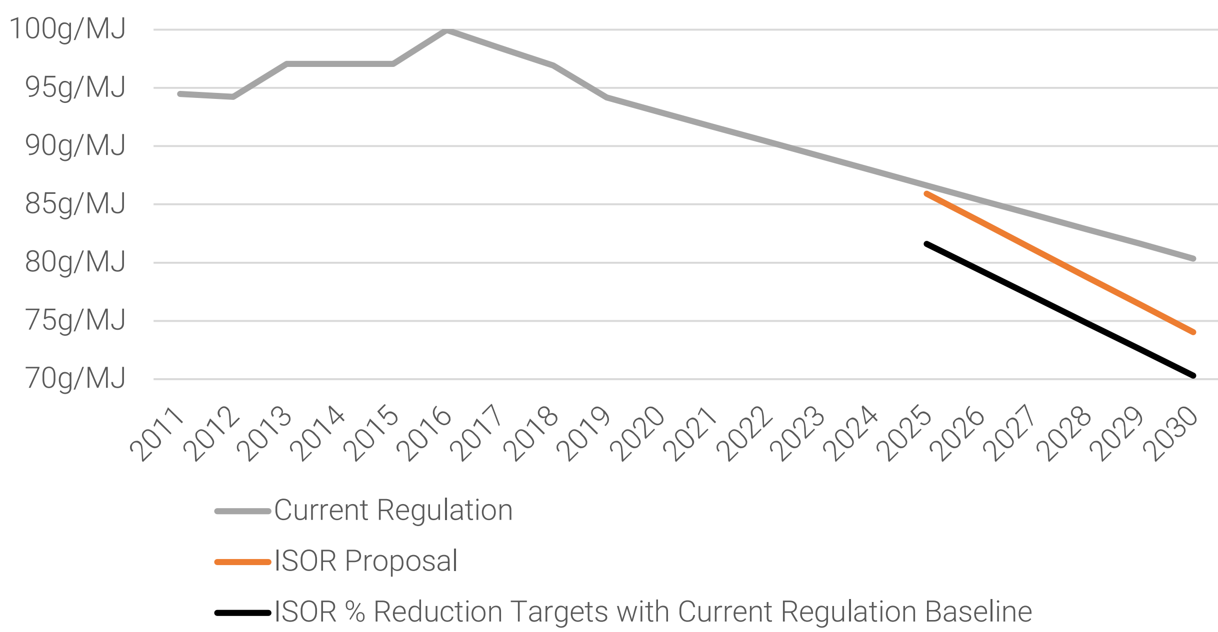

Figure 1: LCFS carbon intensity benchmarks for diesel fuel under different baseline values

The impact of this is significant. As CARB is aware, the volume of fossil diesel fuel used in California has fallen dramatically over the past several years; Q2 2023 had just 40% as much fossil diesel as Q2 2018.[2] With this change in baseline, fossil diesel will generate more deficits on a per-unit basis and diesel-replacements will generate more credits per unit. However, due to the declining fossil diesel volume, these per-unit increases do not cancel out in aggregate. Our modeling suggests that the credit bank will be 12.5M MT larger in 2030 than it would be with the baselines currently in effect (i.e., 100.45 g/MJ for diesel). **The outcome of this would be a reduced credit price, lower investment in climate solutions, and higher emissions levels.**

140.1 cont **To account for this change, we suggest that CARB adjust the CI reduction targets to make them ~3% more stringent.** This is particularly important for the CI step-down planned for Q1 2025; as can be seen in Figure 1, the baseline change practically undoes the impact of the step-down for the diesel pool.

[1] California Air Resources Board. *Proposed Amendments to the Low Carbon Fuel Standard*. December 2023. "Table 2. LCFS Carbon Intensity Benchmarks for 2011 to 2045 for Diesel Fuel and Fuels Used as a Substitute for Diesel Fuel". Page 65.
[2] California Air Resources Board. *LCFS Quarterly Data Spreadsheet*. January 2024.

In order to promote investment into climate solutions for California's transportation sector at the speed and scale needed, CARB must move the step-down to Q3 2024 and increase its magnitude, and increase the 2030 CI reduction target to between 32% and 35%

Generate is highly supportive of CARB providing the market with a long-term signal to reach deep levels of decarbonization via the 90% CI reduction target in 2045. This is precisely the type of policy certainty needed for investors such as Generate to make long-term investments into infrastructure projects needed to achieve the goals of the LCFS and the Scoping Plan. At the same time, we would like to see greater action in the near-term. In order to stimulate investment and infrastructure development in the next several years – a critical period to avoid exhausting our carbon budget – CARB should further the LCFS program's aims through 2030.

In the days following the publication of the ISOR, the market price of credits fell 22%, reaching the lowest levels since July 2016.[3] This reaction is the market unequivocally stating that the targets included in the ISOR are insufficient. At the current credit price – and those seen over the last two years – the market cannot support meaningful levels of investment into the decarbonization solutions needed to achieve the goals of the LCFS program or the Scoping Plan. We have experienced this first-hand: the low credit price environment has forced us to pause making new investments into LCFS-linked projects and companies. At a time when there are economic, social, and public health imperatives to accelerate our pace of decarbonization, the outcome of the most recent proposal would be lower investment, fewer projects, and greater emissions; in other words, this would be a missed opportunity.

140.1 cont Throughout the rulemaking process, Generate has consistently proposed 30% as the minimum viable 2030 target, a view reinforced with each successive LCFS data release. However, the change to the diesel pool's 2010 baseline value means that the significance of each "percent reduction" value using the updated baseline is actually ~3% less than it would have been under the prior rules; we should think of the proposed 2030 target as only 27%. Therefore, the proposed reduction target should be increased to between 32% and 35% for 2030.

140.2 Given the credit surpluses seen over the last two years, the step-down in the CI reduction schedule is critical. As CARB is likely aware, most market participants believe that 2024 will have a large number of excess credits produced, causing the bank to build rapidly – our modeling shows 11M more credits produced than deficits in 2024. In order to promote a stable market – one which avoids whiplash as we go from large quarterly surpluses to quarterly deficits – moving the step-down into 2024 and avoiding that bank build is crucial. In public workshops, CARB staff discussed the possibility of a 7/1/2024 step-down to the CI targets.[4] **We strongly support moving the step-down to 7/1/2024.** If CARB determines that Q1 2025 is the earliest that the step-down can be implemented, then we believe a much more aggressive step-down is warranted, as is shown in Table 1.

There are multiple ways of incorporating a mid-year CI change. CARB could implement a 7/1/2024 step-down and then have regular tightening on 1/1/2025. If CARB staff feels this is too aggressive, they could include a 7/1/2024 step-down and keep that CI reduction target through the 2025 calendar year. This moderated route may be attractive in that it avoids the projected 2024 credit bank growth without adjusting the CI target twice in six months. A third version of this would be to implement a smaller step-down on 7/1/2024 and then a larger step-

[3] Argus Media. *CA LCFS Spot Price.* Accessed February 2024.

[4] California Air Resources Board. *Public Workshop: Auto-Acceleration Mechanisms and Step Down Benchmark Considerations*. May 2023.

down on 1/1/2025; for example, CARB could opt for a 18.75% target for the second half of 2024 to mitigate (but not eliminate) the bank build in that year, and then have a second manual change to 22% in for 2025.

Step Down Timing	Step Down Magnitude	2030 Target
Q3 2024, CI targets held through 12/31/2025	21.50%	32%
Q3 2024, CI targets held through 12/31/2025	22.50%	30%
Q1 2025	21.50%	35%
Q1 2025	23.00%	32%
Q1 2025	24.00%	30%

Table 1: Generate recommendations for CI reduction schedule

Considering each of the aspects in concert with one another, Generate's **primary recommendation is for CARB to implement the step-down on 7/1/2024 to 21.50% below the 2010 baseline and maintain that target through 12/31/2025, alongside a 32% 2030 CI reduction target.** We have also prepared alternative designs if CARB wants to keep the 30% 2030 target and/or the Q1 2025 timing of the step-down, though the appropriate step-down magnitude increases if those elements of the ISOR proposal are retained.

The core rationale behind the recommendations above is that each of those designs would enable Generate and our competitors to build the climate solutions necessary to achieve CARB's policy goals, while ensuring that the LCFS program maintains a sensible credit bank to buffer price volatility. Building a market with reasonable, stable pricing allows investors like Generate to confidently deploy capital into projects that are needed for the scale of decarbonization which California is targeting; a market with significant volatility – as we have seen over the past several years – is not helpful to our goal of building infrastructure and deploying zero emission vehicles, meaning that investment happens more slowly, if at all. The four recommended designs would each motivate private capital to rapidly and efficiently decarbonize California's fuel system.

<u>The Auto-Acceleration Mechanism will promote a healthy, stable investment environment by continuously calibrating the LCFS's ambition</u>

We applaud CARB for including the AAM in the rulemaking proposal. The AAM will allow the market to expediently self-correct such that investors like us can have confidence to continue to deploy capital into the technologies needed for this program to continue its success in driving decarbonization of California's transportation sector. While we are excited about the inclusion of the AAM, there are several key points where CARB can improve the design to ensure that the mechanism functions as intended.

140.3 *Implementation of the AAM should be moved up by a year to reflect the mechanism's ongoing structure as proposed in the ISOR.*

CARB's proposed timeline for implementing the AAM currently has 2028 as the first year in which the AAM can amend CI reduction targets. If we treat the step-down planned for Q1 2025 as a manual iteration of the AAM (caused by 2023 overperformance) and apply CARB's logic on suspending the AAM the year after it activates, 2024 should be ineligible for AAM activation but 2025's performance should be able to trigger the mechanism. A 2025 triggering would impact CI targets in 2027, one year prior to when the ISOR currently proposes. We recommend adjusting the implementation timeline accordingly.

140.4 *The 75% bank-to-deficit trigger is too high and would allow for the types of market dislocations such as we have seen over the past two years.*

The proposed design for the AAM includes a trigger when the ratio of a given year's ending credit bank divided by the total deficit production in that year exceeds 75%. The issue with this is that a 75% bank-to-deficit ratio would be quite high in other commodity markets (where that metric is often referred to as the stock-to-use ratio).[5] Over the past 30 years, typical stock-to-use ratios in commodity markets have been below 40% and often under 10%.[6] To this point, in 2022 – a year in which the credit bank expanded by 55% and credit pricing fell by 54% – the AAM would not have been triggered under the proposed design with the bank-to-deficit ratio at "only" 71%.[7]

To support stable pricing in the LCFS market – and thereby allow investors to properly underwrite long-term investments into infrastructure projects – CARB would be well served to adjust the threshold for triggering the AAM to a bank-to-deficit ratio of 50%. This would allow the AAM to capture periods such as 2022 and adjust the targets of the program accordingly.

<u>While CARB has made progress in its proposed changes to RNG's treatment under the LCFS, there are additional amendments needed regarding avoided methane crediting and true ups to ensure private capital will target and prevent methane emissions</u>

CARB has shown leadership in arriving at a productive policy determination on RNG's treatment under the LCFS program. LCFS is fundamentally a technology-neutral policy which asks the market to determine the best and fastest way to decarbonize transportation. Avoiding prescriptive policy choices is key to allowing the market to do this efficiently and efficaciously. By protecting this ethos through this rulemaking, CARB is giving confidence to investors and project developers that their technology will not suddenly be eliminated from LCFS eligibility.

140.5 We endorse the comments from Amp Americas, the RNG Coalition, and the American Biogas Council on CARB's proposals regarding RNG.

CARB should condition phasing out avoided methane crediting on regulation of methane emissions.

Generate views preventing the emissions from agricultural methane to be no more or less valuable than preventing any other type of greenhouse gas emission, adjusted for global warming potential. The methane emitted is real, and solutions are needed to mitigate those emissions. While it is tempting to exclude certain emissions from our inventory, the climate

[5] Zulauf, et al. University of Illinois. *Stock-to-Use Ratios of US Corn, Soybeans, and Wheat Since 1960.* June 2021.
[6] Ibid
[7] California Air Resources Board. *LCFS Quarterly Data Spreadsheet*. January 2024.

does not care what laws we pass or what emissions we choose to ignore, only what gases we put into it. As such, we suggest that CARB amend the proposal phasing out avoided methane
140.6 crediting by 2040 for projects breaking ground in 2030 or later to be conditioned on direct regulation of these methane emissions. This would ensure that emissions do not suddenly increase in 2040 as the existing operating model for projects falls away.

140.7 *True ups to credit production are welcome and should be extended to Temporary Pathways, but the 4x penalty for overproduction will be an impediment to investment and to decarbonization.*

The clarity CARB has provided on "true ups" for RNG is valuable. This will better reflect the actual GHG impact made by each project, ensuring projects are not over- or under-compensated for the climate impact they make. With that said, we would like to see two changes to the draft language. First, as the RNG Coalition notes in their letter, it is unclear why CARB has changed its approach from what was discussed at public workshops regarding true ups for projects utilizing Temporary Pathways. As with latter pathways, the idea is only to correctly allocate value based on real-world climate impact. Second, it is unclear why CARB has proposed a 4x penalty for overproduction of LCFS credits. As staff is likely aware, conditions outside of the control of an investor or an operator can materially impact an RNG project's output and thereby its LCFS
140.8 credit production. For example, warmer conditions than normal can increase an anaerobic digester's output, resulting in over-production of credits. CARB's proposed 4x penalty is overly harsh and aims to prevent something outside of any operator's control. Instead, we suggest a bidirectional true up, with penalties only for intentional misrepresentations, fraud, or consistent and egregious overproduction.

<u>Closing Comments</u>

In summary, we are pleased with the process CARB has undergone over the past two years and with many of the policies CARB has included in the proposed regulation. With that said, we would like to see CARB continue to push the market to decarbonize California's transportation system faster. In particular, we would like CARB to consider the following proposals:

- Amending the timing of the step-down to 7/1/2024 and updating the step-down's magnitude to a minimum of 21.50%;
- Increasing the 2030 CI reduction target to at least 32%;
- Using an AAM design that will trigger at a 50% bank-to-deficit ratio and beginning the AAM one year earlier than proposed, and;
- Conditioning the phase out of avoided methane crediting for RNG on regulation of methane emissions and adjusting the design of credit production true ups.

Generate appreciates the opportunity to provide commentary and suggestions and looks forward to collaborating with CARB. Should you have any questions about the information contained herein, please do not hesitate to contact us.

Subject	Re: Proposed Amendments to the Low Carbon Fuel Standard

Comment

February 18, 2024
The Honorable Liane Randolph
Chair, California Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: Proposed Amendments to the Low Carbon Fuel Standard

Dear Chair Randolph:

As you may recall from your visit to our facilities several years ago, Calgren has been producing low carbon intensity renewable fuels in Pixley, California since 2008, shortly before the LCFS start date of January 1, 2010. While others in the renewable fuels industry have occasionally questioned the wisdom of California's LCFS, both in the courts and otherwise, we have been among your strongest and most consistent supporters from the very start. In addition, we remain especially proud of the fact that we have been able to bring well-paid jobs and economic activity to an impoverished area of our great state.

With that background, we offer the following constructive comments to the 45-day language to amend the LCFS:

1. We are disappointed that the proposed changes fail to leve playing field for in-state producers of biomethane.

In 2022 and 2023, CARB staff recommended that Book and Claim accounting for biomethane that is undeliverable to California be phased out. The changes now proposed have abandoned that approach and treat all out-of-state projects, even those that cannot possibly deliver into California, the same as we California producers.

To give but one example of the uneven playing field, California biomethane producers face ever increasing standards for injection into California's pipeline system; California's biomethane injection standards are far more stringent than biomethane producers face in any other state. Yet biomethane producers in those more lenient states may use the same Book and Claim accounting without having to meet the same injection standards. In earlier comments to CARB, we suggested that out-of-state producer: be required to meet California's injection standards to use Book and Claim, a concept we continue to support. California gets the vast majority of its pipeline natural gas from out-of-state, yet there is no mandatory testing of that gas as it enters our state. Hence a biomethane producer is actually (and no doubt inadvertently) encouraged to locate outside California's borders. That is at odds with the Independent Statement of Reasons (ISOR) provided in support of the proposed regulatory changes.

As noted above, CARB staff took a slightly different tack in recommending a sensible restriction - that Book and Claim for out-of-state biomethane producers injecting into pipelines that d not serve California be phased out. The proposed changes to the LCFS have abandoned this sensible approach in favor of applying t same restrictions to in-state producers as are applied to out-of-state producers. Frankly, we think both requirements shoul apply, i.e. that out-of-state biomethane producers that wish to u Book and Claim accounting both meet California's biomethane quali standards and demonstrate deliverability into California.

In addition to cleaning up California's environment and encouragi in-state commercial activity, another of CARB's laudable goals is to encourage enactment of LCFS-type regulations in other states (ex., page 15 of the ISOR). Those goals are actually (and, again, no doubt inadvertently) thwarted by CARB's willingness to award California carbon credits for renewable fuel that is already in u in those other target states.

In fact, we now take this argument one step farther. Ultimately, LCFS costs get passed on to California residents via higher vehic fuel costs. We applaud that willingness to pay what it takes to help clean up the air we breathe. But awarding LCFS credits for biomethane that cannot be delivered into California forces Californians to pick up the tab to help clean the air in other geographic regions. That's inappropriate.

It is a fact that new biomethane projects can achieve pipeline injection much quicker if they are out-of-state. While we don't agree with the logic, we have heard that one reason to initially award LCFS credits for out-of-state biomethane projects that cann deliver into California was to encourage the growth of in-state biomethane production. If so, that goal has been achieved; California biomethane producers are now capable of meeting California's current, commercially attractive biomethane demand.

Continuing to offer LCFS credits for undeliverable biomethane is both unwarranted and detrimental to California biomethane producers.

2. The proposed carbon intensity benchmarks should be stricte sooner, perhaps even this year.

LCFS credits have recently been trading below $60 per MT. As CARB has heard from all quarters, that is too low. In fact, the recent announcement that CARB would delay adoption of the LCFS changes to "re-evaluat[e] the carbon intensity benchmarks" caused the spot price of carbon credits to jump almost 10%. That is a clear sign that the proposed step-downs need to be more aggressive.

We have consistently endorsed both a stronger step-down and the adoption of an Automatic Acceleration Mechanism (AAM). We hereby urge that the AAM triggers be moved up. As proposed, the mechanism cannot be triggered earlier than 5/15/2027. That is too late.

3. Section 95482(g) prohibits dairy projects breaking ground 12/31/2029 from generating credits by supplying CNG vehicles after 12/31/2040.

It is difficult to see how this proposed change squares with the goal stated on page 4 of the ISOR of promoting investment in disadvantaged, low-income and rural communities. In California, those are the areas that have benefited from dairy digesters. Terminating credit generation for CNG vehicles before attractive alternatives are available is likely to halt all dairy digester projects that would otherwise break ground after 12/31/2029. For that reason, it is also likely to thwart the separate goal of supporting methane emissions reductions, also appearing on page 4 of the ISOR. In addition, using the LCFS in this manner to pick winners and losers is likely to make it more difficult for other jurisdictions to adopt LCFS-type programs, a goal that is stated on page 15 of the ISOR. We fervently believe that the capture of methane from dairies should be supported, for the overwhelmingly valid reasons stated beginning on page 29 of the ISOR and in

SB1382, not thwarted as in this proposed change.

4. Section 95486.1(g) assesses a penalty of four times the a(credit shortfall should a valid pathway holder receive a verified pathway higher than its certified pathway.

The change proposed in Section 95486.1(g) is at odds with the accurate statement in Section 95488.4 that CIs will inherently var and should not be penalized for such natural variance. It also potentially treats pathway holders worse than petroleum refiners, who have from January 1st through April 30th of each year to acquire Carryback Credits to satisfy prior year credit deficiencie under Section 95486(a)(5). As written, the corrective procedure of Section 95486(a)(5) is available to obligated parties, but it is not clear that it is available to pathway holders. On page 29 of Appendix E, Purpose and Rationale for Low Carbon Fuel Standard Amendments, the rational for the change to Section 95486.1(g) includes the statement that mechanisms exist to retroactively provide credits to fuel pathway holders when the verified operational CI is lower than the certified CI, but Section 95486(a)(5) is not mentioned. Pathway holders should either not be subject to the proposed penalty or should have a similar opportunity to acquire Carryback Credits.

The success of the LCFS is due in no small part to the enthusiast: support of California producers such as Calgren. We believe in CARB's goals and intend to continue to be among your most ardent supporters. If the comments above are adopted, we sincerely believ those shared goals will be greatly advanced.

Thanks again for all your far-sightedness.

Very truly yours,

Travis Lane, CEO

Board Comments Home

February 18, 2024

The Honorable Liane Randolph
Chair, California Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: Proposed Amendments to the Low Carbon Fuel Standard

Dear Chair Randolph:

As you may recall from your visit to our facilities several years ago, Calgren has been producing low carbon intensity renewable fuels in Pixley, California since 2008, shortly before the LCFS start date of January 1, 2010. While others in the renewable fuels industry have occasionally questioned the wisdom of California's LCFS, both in the courts and otherwise, we have been among your strongest and most consistent supporters from the very start. In addition, we remain especially proud of the fact that we have been able to bring well-paid jobs and economic activity to an impoverished area of our great state.

With that background, we offer the following constructive comments to the 45-day language to amend the LCFS:

1. *We are disappointed that the proposed changes fail to level the playing field for in-state producers of biomethane*.

In 2022 and 2023, CARB staff recommended that Book and Claim accounting for biomethane that is undeliverable to California be phased out. The changes now proposed have abandoned that approach and treat all out-of-state projects, even those that cannot possibly deliver into California, the same as we California producers.

141.1 To give but one example of the uneven playing field, California biomethane producers face ever increasing standards for injection into California's pipeline system; California's biomethane injection standards are far more stringent than biomethane producers face in any other state. Yet biomethane producers in those more lenient states may use the same Book and Claim accounting without having to meet the same injection standards. In earlier comments to CARB, we suggested that out-of-state producers be required to meet California's injection standards to use Book and Claim, a concept we continue to support. California gets the vast majority of its pipeline natural gas from out-of-state, yet there is no mandatory testing of that gas as it enters our state. Hence a biomethane producer is actually (and no doubt inadvertently) encouraged to locate outside California's borders. That is at odds with the Independent Statement of Reasons (ISOR) provided in support of the proposed regulatory changes.

As noted above, CARB staff took a slightly different tack in recommending a sensible restriction – that Book and Claim for out-of-state biomethane producers injecting into pipelines that do not serve California be phased out. The proposed changes to the LCFS have abandoned this sensible approach in favor of applying

11704 Road 120 • P.O. Box E • Pixley, CA 93256
Office Phone 559-757-3850 • Fax 559-757-3852

the same restrictions to in-state producers as are applied to out-of-state producers. Frankly, we think both requirements should apply, i.e. that out-of-state biomethane producers that wish to use Book and Claim accounting both meet California's biomethane quality standards and demonstrate deliverability into California.

141.2 In addition to cleaning up California's environment and encouraging in-state commercial activity, another of CARB's laudable goals is to encourage enactment of LCFS-type regulations in other states (ex., page 15 of the ISOR). Those goals are actually (and, again, no doubt inadvertently) thwarted by CARB's willingness to award California carbon credits for renewable fuel that is already in use in those other target states.

141.3 In fact, we now take this argument one step farther. Ultimately, LCFS costs get passed on to California residents via higher vehicle fuel costs. We applaud that willingness to pay what it takes to help clean up the air we breathe. But awarding LCFS credits for biomethane that cannot be delivered into California forces Californians to pick up the tab to help clean the air in other geographic regions. That's inappropriate.

It is a fact that new biomethane projects can achieve pipeline injection much quicker if they are out-of-state. While we don't agree with the logic, we have heard that one reason to initially award LCFS credits for out-of-state biomethane projects that cannot deliver into California was to encourage the growth of in-state biomethane production. If so, that goal has been achieved; California biomethane producers are now capable of meeting California's current, commercially attractive biomethane demand.

Continuing to offer LCFS credits for undeliverable biomethane is both unwarranted and detrimental to California biomethane producers.

2. *The proposed carbon intensity benchmarks should be stricter sooner, perhaps even this year.*

LCFS credits have recently been trading below $60 per MT. As CARB has heard from all quarters, that is too low. In fact, the recent announcement that CARB would delay adoption of the LCFS changes to "re-evaluat[e] the carbon intensity benchmarks" caused the spot price of carbon credits to jump almost 10%. That is a clear sign that the proposed step-downs need to be more aggressive.

141.4 We have consistently endorsed both a stronger step-down and the adoption of an Automatic Acceleration Mechanism (AAM). We hereby urge that the AAM triggers be moved up. As proposed, the mechanism cannot be triggered earlier than 5/15/2027. That is too late.

3. *Section 95482(g) prohibits dairy projects breaking ground after 12/31/2029 from generating credits by supplying CNG vehicles after 12/31/2040.*

It is difficult to see how this proposed change squares with the goal stated on page 4 of the ISOR of promoting investment in disadvantaged, low-income and rural communities. In California, those are the areas that have benefited from dairy digesters. Terminating credit generation for CNG vehicles before
141.5 attractive alternatives are available is likely to halt all dairy digester projects that would otherwise break

CALGREN
Renewable Fuels

ground after 12/31/2029. For that reason, it is also likely to thwart the separate goal of supporting methane emissions reductions, also appearing on page 4 of the ISOR. In addition, using the LCFS in this manner to pick winners and losers is likely to make it more difficult for other jurisdictions to adopt LCFS-type programs, a goal that is stated on page 15 of the ISOR. We fervently believe that the capture of methane from dairies should be **supported**, for the overwhelmingly valid reasons stated beginning on page 29 of the ISOR and in SB1382, not **thwarted** as in this proposed change.

4. *<u>Section 95486.1(g) assesses a penalty of four times the actual credit shortfall should a valid pathway holder receive a verified pathway higher than its certified pathway.</u>*

141.6

The change proposed in Section 95486.1(g) is at odds with the accurate statement in Section 95488.4 that CIs will inherently vary and should not be penalized for such natural variance. It also potentially treats pathway holders worse than petroleum refiners, who have from January 1st through April 30th of each year to acquire Carryback Credits to satisfy prior year credit deficiencies under Section 95486(a)(5). As written, the corrective procedure of Section 95486(a)(5) is available to obligated parties, but it is not clear that it is available to pathway holders. On page 29 of Appendix E, Purpose and Rationale for Low Carbon Fuel Standard Amendments, the rational for the change to Section 95486.1(g) includes the statement that mechanisms exist to retroactively provide credits to fuel pathway holders when the verified operational CI is lower than the certified CI, but Section 95486(a)(5) is not mentioned. Pathway holders should either not be subject to the proposed penalty or should have a similar opportunity to acquire Carryback Credits.

The success of the LCFS is due in no small part to the enthusiastic support of California producers such as Calgren. We believe in CARB's goals and intend to continue to be among your most ardent supporters. If the comments above are adopted, we sincerely believe those shared goals will be greatly advanced.

Thanks again for all your far-sightedness.

Liane Randolph, Chair
Members of the Board
California Air Resources Board
via electronic submittal

Re: Comments on the Proposed Amendments to the Low Carbon Fuel Standard and Initial Statement of Reasons, released December 19, 2023

Dear Chair Randolph and Board Members,

We are pleased to comment on the continued refinement of the Low Carbon Fuel Standard Program (LCFS), on behalf of Climate Action California, with more than 12,000 supporters around the nation.

We support the further lowering of the carbon intensity standard (CI)—provided that the new standard can be paired with the gradual reduction of crop-based fuels, as discussed below. This approach will continue to reward innovative fuels as it supports California's ultimate goal to eliminate greenhouse gas emissions (GHG) emissions from the transportation sector.

We suggest four improvements to the program that were not included or adequately addressed in the proposal.

1. <u>Crop-based fuels</u>

   The Initial Statement of Reasons (ISOR), like the existing LCFS regulation, recognizes that widespread land use change is a potential adverse effect of making fuel from crops. Yet the proposed solution largely ignores the central point: that *somewhere* in the world, financial incentives for biofuels will stimulate conversion of forest/grassland carbon sinks into new crop land.

In section 95488.9 subd. (g), the proposal requires that a fuel producer using crop- and forest-based feedstocks certify that the feedstock was not grown on *specific* land forested at any time after 2008. That requirement completely ignores the central concept of land use change, which is that growing enough food to feed the human population is a zero-sum game. This means that growing corn for fuel in Iowa results in the destruction of forest in Brazil to grow more food. Indeed, this is exactly what is happening. The ten-fold expansion of ethanol use in the US in recent years is reflected in expanded corn production on tens of millions of acres just in this country. And that expanded demand for corn, along with other fuel crops, is mirrored by extensive deforestation and planting of crops in the tropics.[1] Under the proposal that would still be allowed. Only one type of land conversion – cutting down a forest to grow fuel crops on the exact same acres – would not be rewarded with LCFS credits.

The Global Trade Analysis Project (GTAP) model that the LCFS currently employs discounts that effect with the explicit assumption that when food crops are diverted to fuel, instead of planting additional acres, people will simply eat less.[2] This is an unproven assumption—that people will watch their family go hungry rather than planting crops or buying food. Given that large uncertainty, the safer assumption is that the world's growing population will continue to demand food. That is exactly why LCFS recognizes the principles of land use change. The proposed certification process ignores the fact that crops are commodities, grown and sold in a global marketplace.

Most important for the LCFS update, research since the LCFS and GTAP model were adopted, increasingly indicates that emissions from land use change are significantly underestimated. As summarized in a recent brief from *Nature Climate Change*:

> Under current land-use regulation, carbon dioxide emissions from biofuel production exceed those from fossil diesel combustion. Therefore, international agreements need to ensure the effective and globally comprehensive protection of natural land before modern bioenergy can effectively contribute to achieving carbon neutrality.[3]

[1] E.g., J. Albert, Human Impacts Outpace Natural Processes in the Amazon, Science (1/27/2023) Vol. 379, Issue 6630.

[2] A second explicit, but dubious, assumption is that yields per acre will increase, but somehow emissions per acre will not change.

[3] L. Merfort et al., Nature Climate Change, Volume 13 | July 2023 | 610–612, 610 https://www.nature.com/articles/s41558-023-01711-7

Furthermore, land use change models used in Europe show that many crop-based renewable fuels have a *higher carbon intensity than petroleum fuels.* Based on modeling conducted by the LCFS team as part of the 2015 rulemaking[4] as well as in more recent academic research[5], emissions associated with producing crop-based biofuels are highly uncertain and are likely, in fact, be greater than fossil fuels on a full life cycle basis.

Given the uncertainties with land use change calculations, CARB should wind down crediting for all crop-based fuels by 2030, or sooner. The precautionary principle should apply.

143.1

Unwinding of problematic aspects of the LCFS program especially important for fuels that all agree will never aid in the realization of California's long-term vision of carbon neutral transportation. Crop-based liquid fuels support internal combustion (IC), and as such can fairly be viewed as prolonging the use of carbonaceous fuels and IC technology. Regardless of the precise CI, they will never support the deep reductions called for by both statute and the 2022 Scoping Plan Update.

2. Waste palm oil

The proposed amendments appropriately forbid fuel derived from palm oil feedstocks, recognizing that palm oil production is associated with significant adverse land use changes. CARB should be wary, however, of producers' claims that certain palm oil is waste. This is an expansive, lucrative end run around the prohibition. CARB does not have the enforcement reach to effectively check claims relating to commodity trades in distant countries; claims that certain oil is a waste product are extremely difficult to verify. Given the great risk of adverse land use change, the regulation should clarify that "derived from palm oil or palm derivatives" includes waste palm oil. That allows for a

143.2 simple chemical test – in California – for the presence of palm oil.

95482 subd. (f) should be amended to read:

> **Transportation fuel derived from palm oil or palm derivatives including waste palm oil is ineligible for LCFS credit generation. Any volumes of transportation fuel derived from palm oil or palm derivatives reported through the LCFS**

[4] https://ww3.arb.ca.gov/regact/2015/lcfs2015/lcfslSappi.pdf

[5] Lark et al., Environmental outcomes of the US Renewable Fuel Standard, PNAS 2022 Vol. 119 No. 9, available online at https://www.pnas.org/doi/10.1073/pnas.2101084119 . See also, https://www.wri.org/insights/us-renewable-fuel-standards-emissions-impact

program must be assigned the ULSD carbon intensity found in Table 7-1 of the LCFS regulation.

3. “Innovative” petroleum production

We were alarmed to read that the proposal enables specified petroleum development projects to earn credits for pumping oil from the ground until 2040.

The Initial Statement of Reasons (ISOR) says that the amendments’ goals, in concert with the 2022 Scoping Plan Update, include the following:

> The objective is to send clear, long-term market signals to support investment in low-carbon fuel production and technologies that are needed to achieve deep emissions reductions in the transportation sector while supporting the broader portfolio of zero-emission vehicle regulations and climate statutes. Another goal is to align the crediting opportunities in the LCFS with the fuel and technology pathways identified in the 2022 Scoping Plan Update. (ISOR, p.9)

Petroleum production, even using novel methods, will never lead to “deep emission reductions,” nor will it support “the broader portfolio of zero-emission vehicle regulations and climate statutess.” This ill-considered sop to the petroleum industry should be ended immediately.[6] It is impossible to see how continuing to incrementally reward petroleum production investments through 2039 aligns with California’s overarching goals.

143.3

Section 95489, subd. (c) should therefore be amended to read:

> ***Credits for Producing and Transporting Crudes using Innovative Methods*. Until December 31, 2025, credits may be generated for crude oil that has been produced or transported using innovative methods and delivered to California refineries for processing. Beginning January 1, 2026, no further credits may be generated under this paragraph (c).**

4. Avoided Emissions Crediting

Whenever an enterprise’s unregulated emissions are accepted as part of the environmental baseline, the LCFS counts capturing those emissions to produce fuel as “avoided emissions.” For example, fuels made with captured methane emissions yield extremely low CI scores, creating an especially lucrative stream of LCFS credits. As a result, a constituency is formed or strengthened against ever regulating the emissions in the first place.

[6] If the intent was to somewhat appease the petroleum industry, after legal challenges to the LCFS by the industry’s trade association and a raft of lawsuits by its ethanol-producing allies, we now know conclusively that appeasement failed.

Consistent with that thinking, landfills outside of California that are too small to be covered by EPA methane capture requirements, but big enough to be included in California's landfill methane regulation, are treated as if they were in California. Out-of-state landfill gas is scored like any other fuel, based on lifecycle emissions. To reward its capture in the first place as "avoided emissions" would make it harder for that other state to ever follow California's lead in controlling landfill methane beyond the federal requirements.

The same logic applies to biogas from dairies. Livestock emissions—both enteric and manure related—could be regulated. By treating all captured methane as "avoided emissions" California is creating an ever-stronger constituency against regulating livestock, which are by far the largest anthropogenic methane source in the state. While captured biogas can be used as a fuel, and earn a CI score better than fossil fuels, it should not be credited with avoided emissions. Such calculations should be phased out by 2025.

Section 95488.9, subd. (f)(3)(A) should be amended to read as follows:

143.4 **Crediting Periods. Avoided methane crediting for dairy and swine manure pathways as described in (f)(1) above, and for landfill diversion pathways as described in (f)(2) above, is limited to three consecutive 10 years crediting periods, counting from the quarter following Executive Officer approval of the application. The pathway holder must formally request each subsequent crediting period for the project through the LRT-CBTS. <u>Beginning January 1, 2025, the Executive Officer shall not approve or renew any avoided methane crediting for dairy and swine pathways.</u>**

Conclusion

We appreciate this chance to comment on the Low Carbon Fuel Standard amendments. Thank you for all of the work you and the staff do to protect Californians from air pollution and the worst impacts of climate change.

Sincerely,

Will Brieger

February 19, 2024

LCFS staff
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear CARB staff:

Subject: Feedback on newly proposed LCFS calculators

Dear CARB staff:

First of all, I would like to thank you for your work in the new LCFS calculators. The new versions of the calculators will help the industry streamline the pathway applications process for low carbon energy projects. In particular, we appreciate the new hydrogen calculator, building separate calculators for biodiesel and HEFA, and increasing the number of feedstocks that can be specified in the biodiesel calculator. I would also like to thank you for incorporating some of our previous comments into the new versions of the calculators.

Second, I would like to point out a few opportunities for improvement in the calculators that we reviewed:

- Consistency of by-product credit calculation in the HEFA calculator:
  - Light hydrocarbon used as H2 feedstock gets full displacement credit for natural gas displaced.
  - Light hydrocarbon used for alternate use gets energy allocation credit. Chevron continues to believe that the displacement method is the most appropriate approach to account for renewable propane and renewable fuel gas from hydrotreating lipids. That is because the
144.1 renewable propane/fuel gas is routed to the refinery's fuel gas system where it ***displaces fossil hydrocarbons and purchased natural gas*** that is used as make-up to the refinery's fuel gas system. Further, the allocation includes ILUC which appears to be different than what CARB has done in the past (ILUC wasn't included when applying energy allocation).
  - Light hydrocarbon to renewable propane sales gets energy allocation credit, but not on the ILUC piece. Again, renewable propane to non-transportation sales would most likely be displacing fossil propane or fossil natural gas (e.g., for home heating) and therefore would be appropriate to credit with a displacement method.
- LHV versus HHV calculations in the HEFA calculator:

When calculating by-product credits in the "pathway summary" tab applying the first two methods
144.2 above, it appears that the light hydrocarbons are expressed in a HHV-basis, and they are not converted to a LHV basis prior to applying the emission factors, which are expressed in an LHV-basis. We advise you to ensure that the heating values are consistently calculated on the same basis.

Our Family of Brands
Chevron Products Company
A Division of Chevron U.S.A., Inc.
6001 Bollinger Canyon Rd, San Ramon, CA 94583
925 842 8903
dgilstrap@chevron.com

- It would be helpful to put together a document explaining the logic behind major changes in emissions factors such as the following:
144.3
    - The emissions factor for UCO increased from 95 to 123 gCO_2e/MJ.
    - The natural gas emissions factor changed from 72,230 to 75,496 $gCO_2e/MMBTU$.

- "Manure-to-Biogas (LOP Inputs)" Tab –
    - L1.(1-6).14 Retention Time and Drainage – Required Annual Lagoon/Digester Cleanout
144.4
        - After production, many facilities remove excess water but do not fully cleanout the lagoon/digester to keep the microbes active. The requirement to cleanout the system annually in September per the calculator is inconsistent with many baseline scenarios. We request that the lagoon/digester cleanout be optional, and if one occurs, it should be modeled in the month when the cleanout takes place.

Thank you very much in advance for addressing our concerns.

Best regards,

Laura Verduzco, D.Sc.

Subject Stop California from Incentivizing MORE Factory Farms in the Midwest!

Comment

There are many negative consequences that come from this illogical
and counterintuitive proposal, and here are two of the big ones:
Incentivizing by commoditizing factory farm pollution and paying
145.1 factory farm corporations for the methane they produce would fuel
MORE factory farms, causing MORE methane and greenhouse gases, MOR
water and air pollution, and MORE corporate consolidation.
This proposal would create additional overproduction of pork and
dairy, pushing market prices even further down for independent
family farms. Currently, overproduction of pork and dairy and
resulting low prices have been devastating for independent family
farm livestock producers.

In this climate crisis we must do all we can to protect our land &
water resources & the air we breath. Corporate Farms have no
145.2 interest in doing this, they ravage the land & take all the water
then walk away with profits leaving these areas devastated. As
well as causing harm to family farmers & we all suffer from their
destruction!
Please stop helping them!

Subject	Including factory farm gas in California Low Carbon Fuel Standard

Comment

I grew up in California's central valley in the 50s and 60s but I now live in the Midwest in the heart of factory farming. In addition to the below reasons, I will add that so called "green biogas" is anything but. It is methane, a dangerous greenhouse gas that is just as harmful to the atmosphere as the fossil kind. Thes farms also harm water quality and property values by their concentrated feeding operations production of concentrated odors and runoff. Please deny this misguided attempt to export your own emissions through carbon credits. Here's what it will do:
Incentivize more corporate factory farms, harming family farmers, rural communities, and our environment.
Create more corporate consolidation in the U.S. livestock industry.
146.1
Commoditize methane production, which would fuel more methane producing practices.
Create additional overproduction of commodities, pork and milk, increasing supply and further pushing down market prices paid to independent family farms.
Pay foreign multinational meatpackers, like Chinese-owned Smithfield and Brazilian-owned JBS, for their pollution.
Create incentives for the public (taxpayer dollars through government subsidies) to fund anaerobic digesters to capture factory farm gas.

REPUBLIC SERVICES

Sustainability in Action

February 16, 2024

California Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: Republic Services Comment Letter Regarding Proposed Changes to California's Low Carbon Fuel Standard (LCFS)

Staff of the California Air Resource Board:

Republic Services is committed to sustainability and shares the California Air Resource Board (CARB) mission of taking action to improve the communities we serve. Through our climate leadership initiative, we are on track to meet our science-based target goals of 35% reduction in Scope 1 and 2 emissions and working toward improvements in circular economy and renewable energy goals. We are proud of our electric vehicle (EV) fleet deployment in California and the contributions of these vehicles to the LCFS program goals.

It is important that changes to the LCFS program properly align incentives with fleet and infrastructure transition timelines. Our review of the draft regulation indicates that staff has arrived at the proper balance between supporting investments in low carbon fuels that have been made over the past decade while continuing to incentivize participation and investment in ZEV fleets.

Our comments are brief and related to verification of quarterly fuel transaction reports.

Section 95500(c)1E - Verification of Quarterly Fuel Transaction Reports

Republic Services welcomes improvements that enhance the integrity of the LCFS and continuation of processes serving to validate credits that are part of the program. It is clear CARB views third party verification (3PV) of EV credit pathways as an essential addition to the program. However, our view is that the proposed rule may create an unnecessary administrative and financial burden on EV participants.

147.1 Our proposal would be for CARB to re-evaluate the 3PV requirements as they apply to EV pathways and simplify the administrative responsibilities of participants in the program. We believe that CARB can obtain the level of confirmation they are seeking while ensuring that the 3PV process does not unduly burden entities that are pro-actively pursuing the emissions reduction goals that have been set forth.

REPUBLIC SERVICES

Sustainability in Action

For example, our EV charging is reported through BP and Shell's software platforms who review our data for accuracy and consistency relative to consumption data. Verifying our data through an established review process will continue to promote the integrity of the LCFS and correspondingly reduce our administrative burden. While there are reduced requirements below the 6,000 credit level under §95500(c)(2)(B), our expenses related to a 3PV utilizing the two year deferment could still outstrip proceeds from credit revenue.

It will be important to arrive at a suitable level of oversight considering the requirements and expense related to EV infrastructure installation, the premium associated with EV vehicle purchases and record keeping associated with utility projects. A balance of flexibility in 3PV site visit requirements while maintaining integrity to the program will be critical to incentivizing early and long-term participation in the EV space. The 3PV requirements as proposed may disincentivize participation in the program for early adopters and impact rates to customers which in turn would hinder the goals of reducing GHG emissions through the LCFS.

A potential means of achieving these goals is the implementation of a desktop remote audit every 2-3 years with site visits being subsequently required if discrepancies beyond a defined threshold
147.1 cont are identified. Our organization is willing to explore the concept of two-way data access (ie. API – Application Programming Interface). This construct and platform is in use with utility incentive programs we are currently involved in and has proven to be a very suitable replacement for time consuming and costly field verifications.

Considering the number of charging centers that will require 3PV in the near term and certainly the extended term, it seems inefficient to have this verification process be in person versus other more streamlined methods that are currently in use. As a point of reference, at full buildout Republic alone will have an estimated 35-40 charging centers that under the current draft language would cost $10,000 each per quarter to comply. Our company would rather place those funds towards infrastructure and EV purchases versus in person 3PV that could be accomplished in a more efficient manner.

We appreciate your consideration of our requested changes and look forward to continued dialogue on the LCFS final rulemaking. We commend CARB leadership and staff on the overall draft regulation that has been put forth and appreciate the opportunity to participate.

Very Best Regards,

Mike Caprio

Re: Comments on Proposed Low Carbon Fuel Standard Amendments 2024

Dear Dr. Laskowski,

Thank you for the opportunity to offer our input regarding 2024 Proposed Low Carbon Fuel Standard (LCFS) Amendments. We appreciate the workshops and meetings and all the staff work that has culminated in these proposed amendments.

We urge you to change critical aspects of the Proposed LCFS Amended program that undermine California's climate goals and that directly harm historically disadvantaged, low income and frontline communities.

We urge CARB to:

1. **End the flawed policy of giving credits for "avoided methane emissions" in 2024 and limit the LCFS carbon intensity scores to no less than zero.**
2. **Cap lipid-based biofuels since they lead to tropical deforestation and result in food insecurity as they compete with land for food production.**
3. **End the crediting of Carbon Capture and Storage projects that use captured carbon for enhanced oil recovery as this conflicts with statewide prohibitions in SB 1314 (Limón 2022) and SB 905 (Caballero 2022).**

148.1 1. **End the flawed policy of giving credits for "avoided methane emissions" in 2024 and limit the LCFS carbon intensity scores to no less than zero.**

Under the current LCFS regulations, producers of livestock biomethane are given a large negative carbon intensity score, since it is assumed that anaerobic digesters capture all the emitted methane. However, a recent study[1] by Food and Water Watch, as outlined in their report 'The Proof is in the Pluming' (January 2024), reveals substantial methane leaks originating from these anaerobic digesters. The plumes of leaked methane are so large that, by Carbon Mapper's definition, the digesters qualify as super-emitters. This is deeply troubling, underscoring the direct contradiction between the current flawed LCFS carbon intensity assignments and California's Clean Energy and Air Quality objectives.

This policy distortion results in an inequitable and socially inefficient distribution of credits favoring compressed natural gas (CNG) trucks over zero-emission vehicles (ZEV), granting more credits to methane-based, polluting hydrogen than to zero-emission green hydrogen, and allocating LCFS credits to large Concentrated Animal Feeding Operations (CAFOs) over smaller more sustainable farms.

Since the economic value of LCFS credits increases with a more negative carbon
intensity measure, it is imperative for California to reevaluate its practice of awarding
148.1 cont credits for "avoided methane emissions." The existing flawed accounting method, which
assigns a carbon intensity range of -102.79 to -790 for factory farm gas, makes no
sense compared to the carbon intensity of zero for an electric car powered by solar
panels. This calls for a thorough reconsideration of the current approach. To ensure the
148.2 alignment of incentives with environmental priorities, CARB must discontinue its
practice of crediting dairy biogas in the LCFS.

The current CARB proposal is to continue with negative crediting of dairy biogas used directly in the LCFS until 2040[2] and until 2045 if used for hydrogen fuel cells.

This provision must be changed and the crediting for avoided methane emissions discontinued this year.

2. **Cap lipid-based (vegetable oil) biofuels since they lead to tropical
148.3 deforestation and global food insecurity, resulting from competition for
land with food production**

[1] https://storymaps.arcgis.com/stories/4b708bdc0d2d419ba34cb352ca79b6e3

[2] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf

A recent insightful blog post[3] by Dr. Jeremy Martin from the Union of Concerned Scientists, emphasizes the critical need for a cap on lipid-based biofuels to stabilize and strengthen California's Low Carbon Fuel Standard.

Currently the LCFS market is in crisis with low credit prices due in part to a surplus of credits resulting from the excessive use of these biofuels. The interaction between the LCFS and the Federal Renewable Fuel Standard (RFS) intensifies the influx of biofuels into California contributing to the surplus of credits. In addition, increases in the consumption of biofuels, such as soy oil, intensifies the competition for land resources used for food production, thereby worsening global food insecurity and raising food prices. Unchecked growth in the biofuel market poses a significant risk of increasing global deforestation, especially as there are limits on waste oil collection and reuse, necessitating expanded production of soy oil and other oil substitutes like palm oil.

148.3 cont Dr. Martin argues that increasing the stringency of the LCFS, as proposed by CARB, is unlikely to alleviate these adverse effects and may, in fact, lead to more detrimental outcomes. He highlights the urgency of transitioning away from vegetable oils to more scalable feedstocks. We strongly agree and support the implementation of a cap[4] on the use of vegetable oils to provide better incentives to move the LCFS toward feedstocks that do not have such harmful impacts on tropical forests and food production.

148.4

3. **End the crediting of Carbon Capture and Storage projects that use captured carbon for enhanced oil recovery, as this conflicts with statewide prohibitions in SB 1314 (Limón 2022) and SB 905 (Caballero 2022).**

As explicitly stated clearly in SB 1314[5] (Limón 2022):

> **SECTION 1.** The Legislature finds and declares that the purpose of carbon capture technologies and carbon capture and sequestration is to facilitate the transition to a carbon-neutral society and not to facilitate continued dependence on fossil fuel production.

This legislation unequivocally recognizes the incompatibility of enhanced oil recovery (EOR) with California's carbon neutrality policies. SB 905 (Caballero 2022), addressing carbon sequestration, also prohibits the use of carbon capture and storage for EOR.

---

[3] https://blog.ucsusa.org/jeremy-martin/a-cap-on-vegetable-oil-based-fuels-will-stabilize-and-strengthen-californias-low-carbon-fuel-standard/

[4] https://theicct.org/wp-content/uploads/2022/08/lipids-cap-ca-lcfs-aug22.pdf

[5] https://leginfo.legislature.ca.gov/faces/billNavClient.xhtml?bill_id=202120220SB1314

148.4 cont EOR poses harm[6] to nearby communities, causing toxic air pollution, impairing groundwater, and presenting a risk of blowouts. In line with these legislative prohibitions, CARB should exclude EOR projects both inside or outside California from receiving LCFS credits.

To fulfill CARB's commitment to integrating environmental justice[7] into its rulemaking, policy development, and implementation activities, including the LCFS, it is critical to disallow EOR from receiving LCFS credits. This action will provide essential safeguards for historically disadvantaged, low income, and frontline communities.

Finally, we wish to point out that Professor Michael Wara[8] and colleagues from Stanford University presented modeling results in the May 31st CARB LCFS Virtual Community meeting that clearly showed CARB can improve the integrity of the LCFS by eliminating credits for avoided methane by 2024 and putting a cap on crop-based biofuels. These are the prescribed changes 1 and 2 that are recommended in this letter. Furthermore, the modeling results show that these changes to the program will not adversely affect the LCFS credit price. Indeed, the concluding bullet from the Stanford presentation reads:

> *"Stanford modeling suggests EJ scenario could achieve ARB goals while lowering impacts to EJ communities and potentially improving climate outcome"*

It is perplexing to note that this important result and presentation did not get consideration in any of CARB's LCFS proposals. We urge CARB to incorporate these important findings and act on them to improve the climate and community impact outcomes for California.

Thank you for the opportunity to provide feedback and comments on the 2024 LCFS proposals.

Respectively Submitted,

Ellie Cohen
Chief Executive Officer
The Climate Center

SORGHUM CROP INPUTS AND GREENHOUSE GAS MODELING ASSUMPTIONS
Prepared by National Sorghum Producers
February 16, 2024

Background

Over the past 15 years, a large amount of sorghum crop input data have been collected. The sources for these data are highly varied and include statistically significant surveys of sorghum farmers, biodiversity programs with wildlife NGOs, lifecycle analyses conducted at land grant universities as well as extension hybrid trials. This document summarizes this information and provides it in reference form for future citations as all this information is publicly available. Figure 1 includes an overview of the data sources and Figure 2 includes a data summary.

Figure 1. Data Sources.

Data Source	Abbreviation	Years Covered	Relevance
SGS North America[1]	SGS	2008-2011	Statistically significant third-party survey of sorghum farmers
Strategic Marketing Research & Planning (first survey)[2]	SMRP1	2017-2019	Statistically significant third-party survey of sorghum farmers
Strategic Marketing Research & Planning (second survey)[3]	SMRP2	2019-2021	Statistically significant third-party survey of sorghum farmers
Strategic Marketing Research & Planning (third survey)[4]	SMRP3	2021-2023	Statistically significant third-party survey of sorghum farmers
Sustainable Environmental Consultants[5]	SEC	2020-2022	Data for biodiversity program with key wildlife NGO
Kansas State University[6]	KSU	2011	Third-party lifecycle analysis
Land Grant University Extension Hybrid Trials[7]	Trials	2008-2022	Fifteen years of scientific trials at seven universities across 31 locations and 5,181 observations

Potassium	g/bu	20.24	18.09	10.12	-	-	0.00	0.36	9.76
Herbicide	g/bu	27.23	-	-	-	-	7.77	-	17.50

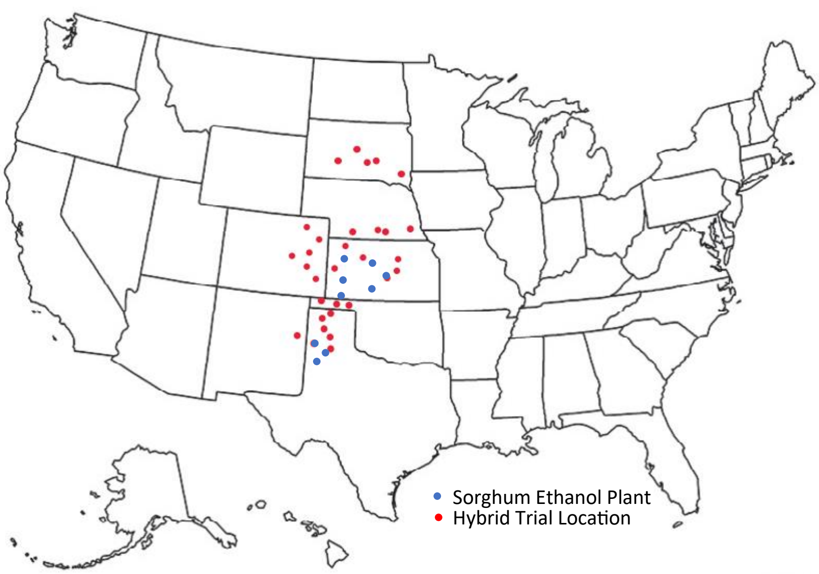
*Given this study was an LCA, it was assumed that it covered the equivalent of one acre.

**Given these were land grant university hybrid trials, it was assumed that each observation covered the equivalent of one acre.

Base Assumptions

The total area covered by the seven data sources was 173,384.28 acres. Note, however, that KSU and Trials were much lower. KSU was a lifecycle analysis, so it was assumed that it covered the equivalent of one acre. Similarly, Trials included 15 years of scientific hybrid trials at seven universities across 31 locations and 5,181 observations, so it was assumed that each observation covered the equivalent of one acre. With both KSU and Trials, this is a reasonable assumption as these values will scale. Figure 3 includes a map of the 31 locations represented in Trials overlaid with sorghum ethanol plants for reference. Each of the six other data sources were also based on production within the confines of this region, which includes more than 85 percent of U.S. sorghum area and produces 100 percent of U.S. sorghum ethanol.

Figure 3. Trials and Sorghum Ethanol Plant Locations.



Energy Inputs

Average diesel usage in British thermal units per bushel across the seven data sources was 4,969.02. In SGS, SMRP1, SMRP2, SMRP3 and SEC, diesel usage was calculated using fuel consumption data from Virginia Cooperative Extension[8] per this equation:

$$D = [\sum (N_{share} * N_{diesel} + R_{share} * R_{diesel} + C_{share} * C_{diesel} + R + P + S + H)] / n$$

Where D is average diesel usage in British thermal units per bushel, N_{share} is the percentage of acres in no-till systems, N_{diesel} is the amount of diesel used in no-till systems, R_{share} is the percentage of acre in reduced till systems, R_{diesel} is the amount of diesel used in reduced till systems, C_{share} is the percentage of acres in conventional till systems, C_{diesel} is the amount of diesel used conventional till systems, R is the amount of residual diesel used, P is the amount of diesel used for planting, S is the amount of diesel used for spraying and H is the amount of diesel used for harvesting. Diesel usage was given in KSU, and residual diesel, gasoline, natural gas and electricity usage were given in SGS. For each fuel type, energy usage associated with field activities, trucking and storage are included in the combined value.

Fertilizer Inputs

Average nitrogen, phosphorus and potassium applications in grams per bushel were 408.21, 133.45 and 9.76, respectively. If applicable, these values were given in all seven data sources.

Herbicide Inputs

Average herbicide usage across the seven data sources was 17.50 grams of active ingredient per bushel. Pesticide usage was given in SGS in gallons per acre. To convert to grams of active ingredient, a weighted average active ingredient factor was calculated based on the pesticide program assumed by the GREET model. This program includes atrazine,[9] metalochlor,[10] acetochlor[11] and cyanazine.[12] This is a realistic program and results in a calculated pesticide usage value for SGS near that of GREET. Pesticide usage in active ingredient volume was given in KSU.

Nitrous Oxide Emissions

Given the U.S. sorghum ethanol industry is located entirely in a dry climate as defined by the 2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories,[13] we have undertaken a significant amount due diligence to confirm the assertion that dry climates will see lower nitrous oxide (N_2O) emissions. According to the 2019 refinement, “dry climates occur in temperate and boreal zones where the ratio of annual precipitation:potential evapotranspiration < 1.” Figure 4 includes a map of the relationship between precipitation and potential evapotranspiration overlaid with sorghum ethanol plants for reference. According to USGS,[14] geographies to the left of the blue line lost more moisture to evapotranspiration than they received from precipitation on average from 1971 through 2000.

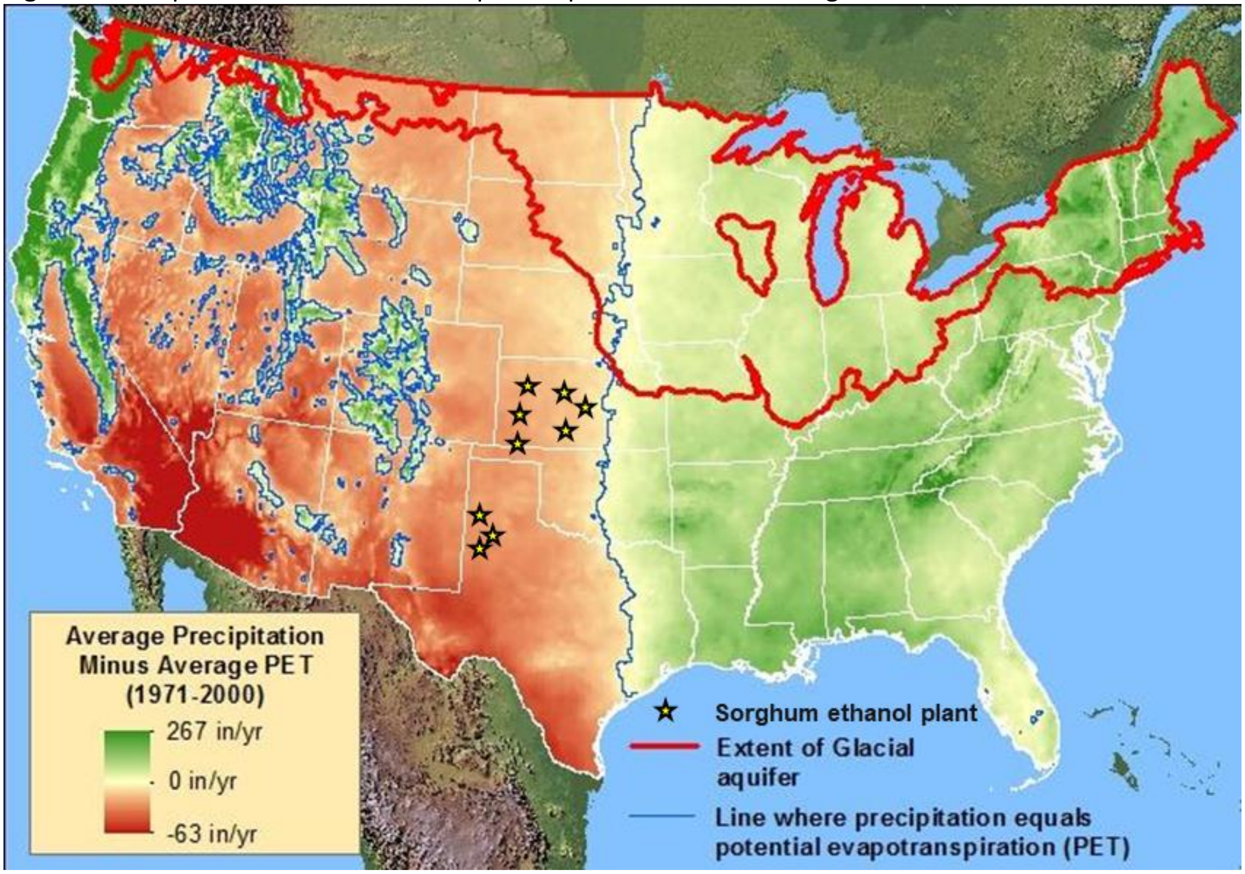
14 https://www.usgs.gov/media/images/map-gridded-values-1971-2000-avg-precipitation-minus-avg-pet

Figure 4. Precipitation and Potential Evapotranspiration as well as Sorghum Ethanol Plant Locations.



The 2019 refinement goes on to reference a map of dry climates: "cf. Figure 3A.5.1 in Chapter 3 of Vol. 4 provides a map subdividing wet and dry climates based on these criteria." This map[15] can be found in Figure 5. Note that much of western North America is now considered a dry climate by IPCC. Available scientific literature confirms the assertion that dry climates will see lower N_2O emissions. According to the 2019 refinement, the N_2O emissions factor should be 0.0050 in dry climates. In the 2006 guidelines[16] the default factor was double, or 0.0100 for all climates. For the wheat-based rotations common to the U.S. Sorghum Belt, Dusenbury, Engel, Miller, Lemke and Wallander (2008) suggested a 0.0023 emissions factor compared to the IPCC default mean of 0.0125.[17] Gehl, Haag, Warren, Sharma and Tomlinson (2020) reached a similar conclusion in a long-term study of sorghum fields in western Kansas, where the emissions factor was found to be 0.0026.[18] Based on the 2019 refinement and the support provided by these studies, we recommend emissions factors of 0.0050, matching the refinement.

Conclusion

The sources for the data presented in this document are highly varied and include statistically significant surveys of sorghum farmers, biodiversity programs with wildlife NGOs, lifecycle analyses conducted at land grant universities as well as extension hybrid trials. They are all publicly available, third-party

California Air Resources Board
Low Carbon Fuel Standard Program
Docket: lcfs-wkshp-feb23-ws

Re: Comments on Proposed Amendments to LCFS Regulation

PineSpire appreciates the opportunity to provide the following perspective on the proposed amendments to the LCFS Program in the Proposed Regulation Order as well as the Purpose and Rationale for LCFS Amendments and other associated documents.

Summary of Issues

We have provided specific examples and issues to consider in the implementation of proposed changes below, and summarized the main issues for your consideration:

- The proposed changes to CI targets, proposed AAM, and updates to pathway evaluations are steps in the right direction, but do not go far enough to create a sustainable, viable marketplace.
- The proposed reduction of the EER in forklifts is not reflective of the forklift fleet in California or the remaining gap of electric conversion. This change would make participation of forklifts financially infeasible in light of additional proposed amendments.
- We support the move to metering of forklifts; however, we urge CARB to consider the many complications of developing and deploying devices that can accomplish this and to allow a gradual timeline to transition from estimation method to metering.
- The proposal to shift credit generation from forklift owner to operator would not resolve the issues that currently create complex registrations. Further work is needed to find a solution that supports accuracy as well as aligning the incentives with the entity making the investment in the hardware.

Strengthen Carbon Intensity (CI) Targets and Auto-Acceleration Mechanism (AAM)

150.1 PineSpire appreciates CARB's recognition of the importance of strengthening CI standards to provide long-term stability and viability to the LCFS program. However, as currently proposed and as evidenced in the market value trends, the proposed updates to CI targets and the AAM are not strong enough to achieve those goals and maintain a viable marketplace. PineSpire strongly suggests accelerating the proposed
150.2 targets and speed at which the AAM functions.

Oppose the EER reduction for Forklifts as Untenable

150.3 The proposed reduction in EER, paired with metering requirements, will make it untenable for nearly all forklifts to participate. Unlike other EV chargers that have built in 'smart' capabilities and other financial incentives (i.e. fees for charging) to measure energy usage, the incremental cost to install metering devices, connect to the cloud, and extract energy usage data from forklift chargers, would very likely exceed the value of the credits if the EER is reduced as proposed.

PineSpire recommends CARB remove Class III lift truck eligibility to address the issues in the analysis instead of cutting the EER for all lift trucks. This would be a more accurate and precise adjustment than the proposed 50% reduction, which is unclear how it was calculated. Furthermore, it would be more aligned with the previous analysis and methodology used to develop the forklift EER.

PineSpire has concerns about the EER analysis and provides the following perspectives that may not have been included:

150.4

- California Specific Industries: The ITA data is a nationwide value that does not reflect the unique and very significant agriculture industry in California, which traditionally relies on propane due to varied indoor-outdoor working environments and seasonal demands for non-stop operations. It is not clear that this dataset is reflective of the sales and industries in California.

150.5

- Class V Lift Truck Replacement: Class V lift truck replacement is still relatively low because electric lift truck options that can effectively replace Class V trucks are a relatively recent technological advancement. The Class V truck is critical to several industries, particularly agriculture and food processing (as mentioned above). The proposed amendments focus on lift truck capacity as a metric for prevalence of internal combustion lift trucks, which overlooks the wide-spread use of internal combustion Class V trucks that typically have a capacity of 5,000lbs-6,000lbs. The current methodology and data provided do not account for the importance of conversion in this sector.
- Electric lift trucks are still being heavily innovated and evolving quickly, which keeps the cost of adoption higher (compared to the drop in prices in electric cars, for example). For example, many higher capacity electric forklifts were originally a conversion of an internal combustion machine, which came with the performance issues of a retrofit. Companies have now invested in developing electric options from the ground up, making them more efficient and effective at replacing the internal combustion option. However, this research and development, as well as innovations in battery chemistry, has kept the upfront cost of electric lift trucks significantly higher than their internal combustion alternatives.

Effectively eliminating the ability of these lift trucks to participate through the reduced EER, paired with metering requirement, erodes the financial return on investment needed to encourage low carbon equipment choices. Further, it discourages participation in the LCFS program by a wide range of critical California businesses.

Metering Implementation

150.6

PineSpire understands CARB's goal to move forklifts towards increased accuracy and into alignment with other EVs by requiring metering of the energy usage. However, we urge CARB to be aware of the significant time and resources required to make this shift, and to provide adequate lead time for the transition. An abrupt transition would likely disenfranchise the vast majority of forklift owners from the opportunity to participate for several quarters; PineSpire recommends CARB to continue to allow participation of e-forklifts through the estimation method during a reasonable transition timeline.

To support this request, we have summarized some of the forklift-specific limitations on data collection that set this vehicle class apart from other types of equipment in the LCFS program:

Current limitations:

- Nascent technologies: The data collection industry for forklifts is in its early stages, unlike the more established on-road EV charger technology. Current telematics solutions remain under development to be able to reliably deliver the level of data and detail that would be required for LCFS reporting. Additional time is needed to deploy and scale financially viable solutions across the California forklift fleet.
- Unique Aspects of Forklift Metering: Typical metering solutions seen in other vehicle classes are unlikely to apply to most forklift operations for several reasons.
    - Unlike other vehicle classes, the cost of implementing energy measurement must show a reasonable return on investment solely from LCFS credits, as there are no fees for charging in this vehicle class.
    - Existing telematics solutions are prohibitively expensive, with upfront costs in the many hundreds of dollars per unit and ongoing monthly subscription fees. Additionally, some require costly technician site visits for manual data downloads. High upfront costs, ongoing fees, and limited functionality currently make the financial justification for adopting the telematics technology challenging.

150.6 cont

    - Installing metering on the AC side is prohibitively expensive as it requires electricians, downtime to operations, and more costly hardware. As mentioned, forklift chargers are frequently distributed throughout facilities, not on a single AC circuit. And the AC circuits have the potential to serve other non-charging usage, thus requiring submetering.

Implementation challenges:

These implementation challenges are based on our experience deploying meters across forklift chargers at a range of facilities in Oregon.

- Hardware: Current monitoring options may require essential hardware modifications to accommodate the diverse range of forklift chargers, unlike the more standardized EV charger hardware. For example, there is a wide range of voltage and frequencies at which forklift chargers operate, both of which have the potential to 'fry' electric components of meters. Ensuring safety and functionality of new hardware, as proven in a range of test environments, is key before requiring widespread deployment.
- Connectivity: Reliable data connectivity requires site-specific troubleshooting and ongoing refinement. Additionally, successful implementation requires working with individual facilities to ensure all use of connectivity technology is secure. The one-off nature of this issue requires more time to implement than a universally designed charging network.
- Software complexity: Frequent software updates are needed to comply with varying state reporting and registration requirements, while maintaining historical data accuracy. This translates to significant lead times and resource allocation for the engineering and manufacturing updates of measurement devices.
- Evaluation burden: Developing hardware quotes, connectivity plans, and completing ROI analyses require time and resources for each individual site and its equipment team. This would be further complicated by the changes the proposed Amendments may have on LCFS values and the associated

150.6 cont financial analysis. Allowing entities time to put together this information, after other proposed amendments have been addressed and their market impact demonstrated, is appropriate.

Additional Considerations:

- Consistency with other CARB regulations: Fleet owners and operators are simultaneously responsible for complying with other CARB regulations, such as the proposed Zero Emission Forklift rule. CARB's zero-emission rules typically rely on a phased-in approach for adoption and implementation, as an acknowledgment of the cost and resources required for compliance. This phase-in approach also ensures a smoother transition for all parties by providing a more gradual 'ramp up' of metering. Using a phased-in approach with metering in the LCFS would be consistent and appropriate.
- Agriculture and Processing Industry Issues: Agricultural, food processing, wine, and beverage industries have several operational constraints relevant to developing hardware, connectivity solutions, and deploying meters. For example, many post-harvest and food processing facilities operate equipment within environments with a high level of dust that may require specific hardware enclosure designs. Similarly, cold storage facilities may challenge typical hardware specifications and require time to adapt specifications. Additionally, during harvest/post-harvest seasons (which can last one to two quarters), many facilities operate around the clock and do not have staff resources nor fleet down-time that would be required to deploy meters. Many of these facilities are large and forklift charging equipment is dispersed at many locations; it is common for facilities not to have reliable Wi-Fi reach throughout these dispersed locations, meaning that additional time and cost is required to deploy routers solely for use by energy measurement devices.

PineSpire represents dozens of agricultural and food processing businesses across California, responsible for thousands of acres of farmland, and millions to billions of dollars of food production. If CARB has specific questions for these types of facilities, we are happy to put you in touch with facility managers to discuss further.

Forklift Credit Generator: Owner <> Operator

PineSpire represents many forklift rental companies, with thousands of locations and several thousand forklifts across their fleets. We understand CARB's concerns with the complications of registering rental
150.7 forklifts for each location where they are used, however we have serious concerns about the disenfranchisement of credit generators under the proposed changes. If CARB has additional questions on this issue you'd like to gather information on, we are happy to facilitate conversation(s) with rental fleet owners.

Concerns with proposed changes, including Operator providing energy usage data:

- Investing in electrification: Rental fleet owners are continually investing in maintaining and updating their electric rental fleet, including upgrading to expensive lithium batteries, updating charger hardware, and purchasing newer forklifts. These investments by rental fleet owners increase the likelihood of fleet managers to use electric equipment as rentals, often serving as a stepping-stone for purchasing electric. Changing the credit generator to the operator would also contradict the draft Zero Emission Fleet (ZEF) regulations, which place extensive requirements on rental fleet owners.

- 150.7 cont Long-term commitment vs. short-term rentals: Participating in the LCFS program requires sustained resource investment (understanding the program, compiling registration information, regular reporting updates, etc.). Rental forklifts are frequently a short-term business solution for operators. The long-term investment in the purchase, maintenance, repairs of a rental forklift is made by the rental fleet owner, therefore the long-term benefits that come from the LCFS program should also accrue to the owner.
- Data Management: In the current framework, the "credits generator" is the facility owner (i.e., the rental operator) who may not have permission to add metering to chargers or forklifts, even in the rare long-term rental case where it makes financial sense. This mismatch creates issues with the ability to implement metering, access data, and reporting for most rental forklifts as proposed under the amendment.
- Does not achieve CARB's stated goal of eliminating registration burdens: The reality of forklift ownership and operation is that a significant portion of all facilities operate both owned and rented equipment simultaneously. For example, the majority of rental lift trucks come with a rental charger that would not be picked up by the fleet operator's metering. We recommend reconsidering options for modifying registration requirements that better align with the realities of mixed-fleet ownership, and metering implementation. We do appreciate there are a range of scenarios of ownership and operation, however we caution against moving ahead with updates that would not reduce the registration burdens.

Updates to eTRU registration

150.8 PineSpire strongly supports the proposed updates to eTRU credit generation to align with the realities of eTRU operations and ownership. TRUs are more similar to on-road EVs, moving continually from site to site and frequently not having a direct contractual relationship with their charging location, therefore the proposed changes are the most practical solution to enable wider participation in this sector.

Multi-Family Residential

150.9 PineSpire supports the proposed updates to the classification of multi-family residential charging as commercial in order to align with how these chargers are often financed and deployed, and making these LCFS incentives more widely accessible.

Thank you for your consideration of our comments.
Sincerely

Ryan Huggins

RE: Comments on the Proposed Low Carbon Fuel Standard Amendments

Dear Chair Randolph:

Suburban Propane writes with regard to the Proposed Amendments to the Low Carbon Fuel Standard (the "Proposed Amendments"). Suburban Propane has served customers for more than 95 years and is the nation's third-largest propane retailer with operations in 42 states. In California, we currently have 266 employees at 71 locations, serving more than 55,000 customers.

Suburban Propane supports the Low Carbon Fuel Standard (LCFS) program and believes its technology-neutral, market-driven approach makes it one of the most effective policies in the country in reducing carbon emissions in the transportation sector. Given that the carbon intensity of California's transportation fuel pool decreased faster than CARB initially forecast and the state of the credit market, we understand the need to tighten carbon intensity (CI) benchmarks and reform the LCFS.

However, there are two specific provisions in the Proposed Amendments that we urge the Board to change: increase the flexibility of the Automatic Acceleration Mechanism by accelerating the CI benchmark reduction proportional to how much the credit bank exceeds the proposed trigger threshold up to one full year; and remove the biomethane credit phaseouts.

Automatic Acceleration Mechanism

As currently drafted, the Proposed Amendments create an Automatic Acceleration Mechanism (AAM) that tightens the annual CI benchmarks if two conditions are met: "(1) when the pool of outstanding credits (the credit bank) exceeds three quarters of average annual deficits generation, and (2) when the number of credits generated each year exceeds the number of deficits generated each year."[1] If those conditions are met, the AAM "would advance the entire benchmark schedule by one compliance period, increasing the stringency of the regulation for all subsequent years relative to what it otherwise would have been."[2]

151.1 Requiring acceleration of the benchmark reduction schedule by an entire year gives CARB too little room to maneuver. If the credit bank just barely reaches the threshold required to trigger the AAM, the benchmark reduction schedule leaps forward by an entire year, instead of considering a minor adjustment to maintain the credit market's stability. This could lead to CARB overtightening the benchmark reduction schedule, leading to a saturation of deficits and more market volatility.

Instead, we recommend the AAM create more flexibility by allowing CARB to proportionally accelerate the benchmark reduction schedule based on how much the credit bank exceeds the trigger threshold, up to the CI benchmark for the following year. This would help maintain the stability of the credit market and thwart any potential overcorrection, which contributes greatly towards supporting long-term investment in transportation decarbonization.

Biomethane Crediting

With a CI score as low as -532.74, biomethane, also known as renewable natural gas (RNG), is one of the most powerful tools in decarbonizing the transportation sector. The Initial Statement of Reasons for the Proposed Amendments acknowledges that "[b]iomethane has played a role in contributing to the overall decrease in carbon intensity of the transportation fuel pool" and [c]apturing methane from California's methane sources (e.g., landfills, dairies, and wastewater) is critical for achieving California's climate targets."[3]

However, notwithstanding the benefits RNG brings to California's transportation fuel pool, the Proposed Amendments seek to phase out crediting for RNG. As currently drafted, for projects that break ground after December 31, 2029, RNG pathways, along with avoided crediting, would be phased out after December 31, 2040. Fuel pathways for RNG with avoided methane used to produce hydrogen would be phased out after December 31, 2045.

151.2 Phasing out RNG pathways is shortsighted and stymies the LCFS's effectiveness by removing a carbon-negative fuel source from the program. CARB argues for the phaseout because natural gas transportation fuel demand "is only about 3% of overall natural gas demand in California, and achieving deep GHG reductions will have to include displacing fossil gas in sectors of the economy beyond transportation."[4]

[3] See https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf.
[4] *Id.*

151.2 cont

This type of reasoning is antithetical to the spirit of the LCFS program, which is to incentivize the increased use of low-carbon energy sources and spur innovation in the production of even lower carbon transportation fuels. According to the U.S. Department of Energy, since the beginning of the LCFS in 2011, natural gas fuel consumption in California's transportation jumped from approximately 211.5 million gasoline gallon equivalents (GGEs) in 2011 to 403.7 million GGEs in 2021.[5] If those gallons were replaced with carbon-negative RNG, it would accelerate the decarbonization of the transportation sector. Further, the availability of RNG pathways under the LCFS led to increased production of RNG. In fact, the potential of securing more LCFS credits was one of the factors that led Suburban Propane to invest in RNG. We created a new subsidiary, Suburban RNG, specifically to acquire assets and increase production of RNG.

Phasing out these pathways removes a key low-carbon and carbon-negative energy source from the LCFS. We ask that CARB remove the RNG pathway phaseout provisions from the Proposed Amendments.

Conclusion

For the reasons above, we urge the Board to consider two changes to the Proposed Amendments: increase flexibility of the Automatic Acceleration Mechanism by accelerating the CI benchmark reduction schedule proportional by how much the credit bank exceeds the trigger threshold, up to one full year; and remove the biomethane pathway phaseout. We would appreciate the opportunity to discuss these changes, as well as other ways to reduce greenhouse gas emissions, with CARB staff. Thank you for your consideration.

Sincerely,

/s/ Paul M. Rozenberg

Board Comments Home

USRED

February 19, 2024

Chair Liane Randolph and Members of the Board
California Air Resources Board
1001 I St.
Sacramento, CA 95814

Subject: **Comments on the Proposed Amendments to the Low Carbon Fuel Standard**

Dear Chair Randolph and Members of the Board:

US Renewable Energy Development Capital, Inc. ("USRED") are investors in and advisors to bioenergy and renewable power project development companies in the United States. The purpose of my letter to you today is to offer USRED's input on proposed amendments to the California Low Carbon Fuel Standard.

Strengthen Carbon Intensity (CI) Targets

152.1 - We are in favor of a strong CI reduction target for driving down GHG emissions in the transportation sector, reducing reliance on petroleum fuels, and transitioning to electronic vehicles where feasible.

-

Don't Phase Out Avoided Emission Credits

- We do not support the phase out of avoided emission credits.
152.2 - Avoided methane emissions are a critical part of science-based, life cycle assessments, and their inclusion in carbon intensity scores is consistent with internationally recognized standards of carbon accounting.

-

Clarify and Support Book-and-Claim and Delivery Requirements

152.3 - We recommend that CARB allow biogas to electricity projects to utilize book-and-claim anywhere in the Western Electricity Coordinating Council (WECC), as is already the case in Oregon under their Clean Fuels Program.
152.4 - We believe CARB should allow biogas-to-electricity projects, where electricity generation and biogas production are not co-located, should be eligible to participate in the LCFS
152.5 - We feel that CARB should provide clarification that biomethane may utilize book-and-claim.
152.6 - We recommend that book-and-claim for biomethane to electricity remain unconstrained by timeline restrictions.

152.7 - We request that the deliverability requirement language be removed from the proposal to allow for further stakeholder engagement in support of a clear and actionable plan for consideration in a subsequent rulemaking.

True-up Provisions Should be Formalized

152.8 - We believe the proposal must be carried over and applied to temporary and provisional CI's as fuel providers may rely on these CI's for months, or even years, as a more refined pathway is evaluated and subsequently approved by CARB.

152.9 - Credits should be awarded based on real-world operational experience and therefore adjusted accordingly when the temporary CI which is applied understates the benefits.

New Markets Are Evolving Requiring CARB's On-Going Pathway Inclusion

152.10 - We feel CARB should remain mindful of the success of the historical framework of the program and continue to apply it to newer pathways and technologies, including the use of avoided emissions and book-and-claim.

152.11 - We ask that CARB begin to think about the framework and guardrails needed to achieve the 80% goal set forth in the Scoping Plan and leverage all of the tools available to the vehicle market, such as book-and-claim and avoided emissions accounting, to make this goal a reality.

152..12 As an active member of the American Biogas Council (ABC) we are in support of and agreement with ABC's positions on all matters pertaining to State of California Low Carbon Fuel Standard policies and practices. Thank you for your consideration.

Sincerely,

James Lavelle

Chief Executive Officer

Subject	Comments on Proposed Low Carbon Fuel Standard Amendments

Comment

Dear California Air Resources Board:

Thank you for the opportunity to provide comments on the Californi
Air Resources Board (CARB) Proposed Low Carbon Fuel Standard (LCFS
Amendments. Penske Truck Leasing Co., L.P. ("Penske") is a nationwide leader in low-emission transportation with a company-wide commitment to a comprehensive transition to zero-emission vehicles (ZEVs). We share CARB's greenhouse gas reduction goals and federal air quality objectives; therefore, we are excited to offer our expertise and insights into these propose
amendments.

Please see our attached comments responding to the draft LCFS amendments, including changes in EV third party verification, infrastructure crediting, and forklift reporting criteria. Our comments underscore the challenges and opportunities inherent in the transition to ZEVs, and we hope to continue partnering with agencies to streamline requirements and goals across multiple programs to better support this critical technology.

Sincerely,
Andrew Cullen
Senior Vice President - Fuels and Facility Services, Penske

RE: Comments on Proposed Low Carbon Fuel Standard Amendments

Dear California Air Resources Board:

Thank you for the opportunity to provide comments on the California Air Resources Board (CARB) Proposed Low Carbon Fuel Standard (LCFS) Amendments. Penske Truck Leasing Co., L.P. ("Penske") is a nationwide leader in low-emission transportation with a company-wide commitment to a comprehensive transition to zero-emission vehicles (ZEVs). We share CARB's greenhouse gas reduction goals and federal air quality objectives; therefore, we are excited to offer our expertise and insights into these proposed amendments.

Fundamentally, Penske is committed to zero-emission transportation technology, a commitment reflected by our significant investments over the last five years in numerous medium- and heavy-duty (MHD) electrification demonstration and deployment projects. As a rental and leasing company, Penske plays a unique role in accelerating the greater adoption of zero-emission vehicles by enabling fleets to test, iterate, and ultimately adopt ZEVs. Penske understands the necessity of collaboration for success, having worked closely with agencies such as CARB, the California Energy Commission (CEC), national utilities, major vehicle manufacturers, charging infrastructure manufacturers and developers, battery providers, and customers in the deployment and operation of new battery-electric transportation services across the entire supply chain.

We believe there are very few, if any, large transportation providers doing more than Penske to advance zero-emission and infrastructure technology. Penske currently operates one of the largest commercial fleets of MHD ZEVs and offroad ZEVs in the United States; our fleet includes battery electric powered trucks and offroad equipment from multiple OEMs, including Freightliner, Volvo, Navistar, Ford, Roush, Kalmar, Orange EV, and many others. These ZEVs operate on a nationally growing network of electric vehicle (EV) charging infrastructure. In addition to our current sites, we are actively working to equip our owned sites throughout the country with charging equipment that will allow us to comprehensively advance our shared zero-emission goals.

Penske's ever-expanding familiarity with ZEVs, coupled with our comprehensive and incomparable understanding of charging infrastructure and real-world commercial fleet applications, uniquely positions us to be a resource for CARB. Our front-line experience on the availability, use, and application of ZEVs allows us to serve as a partner in CARB efforts to amend the LCFS regulations.

On behalf of the entire Penske team, we want to thank CARB and your staff for the time to hear our comments, insights, and concerns while advancing effective regulations and programs that both address real-world concerns while also achieving critical zero-emissions progress.

Recently, CARB released draft language for LCFS amendments. Based on our experience as a leader in commercial ZEVs, Penske offers the following comments for consideration as your agency amends the regulation.

Andrew Cullen
Senior Vice President – Fuels and Facility Services

Electric Vehicle (EV) Third Party Verification

Penske is supportive of the need for validated, auditable LCFS pathways. The long-established third-party verification (3PV) requirements have allowed for the liquid and gaseous low carbon fuel markets to thrive by developing trust between producers and counterparties. The strength of the LCFS is built on consistency and transparency of the program, ensuring confidence by participants in the validity of claims made in the program. However, existing 3PV rules were written specifically for liquid and gaseous low carbon fuels. We ask that any proposed changes develop approaches that are also specific to EVs, to allow for continued growth in that critical sector.

153.1 Penske encourages CARB to reconsider proposed 3PV requirements related to electricity pathways. The existing 3PV framework will create an undue administrative burden on ZEV operators participating in the LCFS program, if implemented as written. In turn, this will slow growth in a unique sector with immense potential to propel the state towards its greenhouse gas (GHG) reduction goals. Current 3PV rules hinder participants' ability to participate in the program and invest in further electrification by burdening them with outsized administrative costs. Specifically, the proposed changes would require electric fuel supply equipment (FSE) owners to verify quarterly an annual data through third party verifiers, site visits, and other requirements originally designed with large volume fuel production facilities in mind. Fleets, the LCFS program, and the state of California will all benefit by addressing 3PV for electricity in a manner that is tailored to the practicalities of the EV market. Without a structure that either aligns with existing documentation or considers the expense associated with a facility-based 3PV approach, CARB risks decreased EV participation in the program.

153.2 To ease this burden, this rule change could be an opportunity to synchronize with existing and planned audit and reporting structures for fleet electrification. For example, the CEC is currently developing Proposed Regulations for Electric Vehicle Charger Inventory, Utilization, and Reliability Reporting. A recent workshop walked through the CEC's draft proposal to require select operators of EV charging stations to report the number, utilization, and reliability of charging stations to the CEC. Validated, reliable charging data under one California regulation, alongside validated utility data that is regulated by the California Public Utilities Commission (CPUC), could serve as an important and streamlined mechanism for verifiable LCFS EV reporting. Similarly, as CARB determines how to implement Senate Bill 253 (California Climate Corporate Data Accountability Act) protocols should align and be streamlined to support holistic GHG reporting and LCFS accounting requirements. By aligning LCFS 3PV with existing and planned audit and reporting structures, CARB can help ensure EV participation in the LCFS program.

With regard to specific requirements in the proposed verification structure, a streamlined process is recommended for electric FSE that report only under Lookup Table pathways. In this case, verification could be limited to:

1) Confirmation that the FSE are operational through review of completed building permits, utility permission to operate, or site photographs. This would eliminate the need for costly site visits while providing verification that FSE has been installed.
2) Verification of charging data through review of charge session data in a charger management portal and/or review of the associated utility meter data. This would allow for confirmation of the accuracy of the reported data (charging energy).
3) Sites that generate 6,000 credits per year or more. Proposed rules would allow for deferral of initial verification requirements for two years but would not eliminate these requirements or reduce the frequency of the verification requirement. Alternatively, CARB could set a lower threshold for exemption from verification requirements, recognizing that per-site verification costs could easily exceed $10,000 per year. At current LCFS credit prices, these verification costs would represent an additional administrative cost of

Penske Transportation Solutions

gopenske.com

PENSKE

Andrew Cullen
Senior Vice President – Fuels and Facility Services

ten percent or more for sites generating less than 2,000 credits per year. Establishing this lower threshold for exemption and allowing for reduced frequency of reporting for sites falling under the 6,000 credit threshold would balance administrative costs with verification.

Zero Emission Vehicle (ZEV) Infrastructure Crediting

Penske is supportive of expanded eligibility for ZEV infrastructure crediting, which allows for increased public and private investment in low carbon fuels. Given the high cost of EV charging equipment, installation, and vehicle
153.3 investment, infrastructure funding support is essential to keep the program on track toward GHG reduction goals. We encourage CARB to continue supporting incentives which expand the availability of low carbon transportation charging options for fleets across the state. In developing these incentives, we especially encourage CARB to consider the unique needs and access points of the MHD ZEV sector.

Presently, even with existing rebates and incentive programs, the pathways for MHD fleets and operators to access ZEVs are difficult, especially for smaller fleets. Many small businesses do not have the capacity to take advantage of incentive programs or the capital to invest in new refueling infrastructure. Further, a transition to ZEVs requires a fundamental shift in business operations, as businesses must consider new challenges, such as including charging time in operation schedules, ensuring charging is accessible enroute, and solving for the inherent inconsistencies associated with emerging technologies. By aligning infrastructure, vehicles, and maintenance into a publicly available package without significant upfront costs, short-term rental and leasing offer a critical avenue for small businesses to affordably incorporate ZEVs into business operations. Thus, as CARB continues to support incentives to expand low carbon transportation charging options, we encourage CARB to recognize the unique needs of the MHD ZEV sector. Specifically, we encourage CARB to consider supporting infrastructure serving multiple fleets through publicly available rental and lease offerings as publicly accessible infrastructure, a practice that aligns with other funding agencies. In doing so, we believe the LCFS can more comprehensively be a major force of change incentivizing the essential transition to low carbon options.

Changes to Forklift Reporting Criteria

Forklifts have been an important participant in the LCFS and continue to provide valuable GHG reductions for California. By ending the estimation methodology reporting technique, CARB improves the accuracy of credit generation, but creates an additional cost burden to install "direct metering" equipment at existing participants facilities. The cost of this additional metering equipment may decrease participation in the program and eliminate a
153.4 revenue source that was part of the fleet's procurement plan. It is understood that better quantification methods are necessary for forklifts, and we propose an intermediary step be taken to allow for a transition period of three (3) years to phase out the use of the estimation methodology for already registered FSE, rather than requiring an immediate transition. Such an intermediary measure would allow for continued recognition of emissions reductions from EV forklifts that were procured and registered under the current program requirements. We further propose that any changes to forklift reporting criteria be aligned with CARB's proposed Zero-Emission Forklift Regulation, allowing companies to onboard new ZEVs and infrastructure that could also meet the goals of the LCFS quantification on the
153.5 same timeline. The proposed Zero-Emission Forklift Regulation has scheduled phaseouts of MY 2025 forklifts beginning in 2028, aligning with the suggested transition period of three (3) years. This would allow fleets the ability to support LCFS goals while strategically preparing for the Zero-Emission Forklift Regulation in a way that causes minimal disruption to operations and maximizes adoption and emissions reductions.

Penske Transportation Solutions

andrew.cullen@penske.com
gopenske.com

Andrew Cullen
Senior Vice President – Fuels and Facility Services

Conclusion

Penske is appreciative of the opportunity to comment on CARB's proposed LCFS amendments. CARB's GHG reduction and zero-emission goals deeply resonate and align with our own, and we hope we can be a source of value as these programs and regulations are adopted. Our experience underscores the challenges and opportunities inherent in the transition to ZEVs, and we hope to continue partnering with agencies to streamline requirements and goals across multiple programs to better support this critical technology.

We believe zero-emission rentals and leasing enable more rapid rollouts of ZEVs via lower-risk leasing, maintenance, outsourcing, and charging efforts. These market--leading efforts will also help define and refine secondary market pathways, residual value calculations, and long- term maintenance planning. We share CARB's goals of lower GHGs and emissions and hope our experiences provide insight into more effective LCFS revisions. Thank you for this opportunity to comment on the proposed regulation amendments. We look forward to engaging CARB on the issues raised herein.

Sincerely,

Andrew Cullen
Senior Vice President – Fuels and Facility Services, Penske

February 19, 2024

Liane Randolph, Chair
Members of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Chair Randolph and Members of the Board,

I retired from the California Air Resources Board (CARB) two years ago. During my 13-year career at CARB, I worked almost exclusively on the Low Carbon Fuel Standard (LCFS), including over a year as Branch Chief overseeing the program.[1] I helped develop and enthusiastically support the LCFS. A strong LCFS is critical to helping California achieve its zero emission transportation goals. I begin this letter with five high-level recommendations for the Board to consider, two of which are described in much greater detail in attachments. I then convey my thoughts on the history of the LCFS, the power of special interests over the program, and the importance of thoughtfully considering the rapidly increasing cost of the regulation to low-income Californians. I finish the letter by briefly describing several focused recommendations. I do hope that you will read this letter in its entirety and please feel free to reach out if you have questions or would like to further discuss comments that resonate with you.

154.1 First and foremost, I highly encourage the Board to cap and ultimately phase out the use of crop-based diesel and aviation fuel in California. The use of crops such as corn and soy as feedstock to produce liquid diesel and aviation fuel is not a sustainable means of reducing GHG emissions and may actually increase emissions as compared to fossil fuels. Moreover, using crops to produce biofuels is expensive and exacerbates tropical deforestation and global hunger. **In fact, a portion of the GHG emission reductions that CARB is attributing to crop-based biofuels directly results from the most food insecure populations in the world eating less.** CARB's promotion of these fuels is not in line with its reputation as a global leader in environmental policy. For further discussion, please see Attachment A.

154.2a Second, rather than simply claiming that all potentially significant impacts are unavoidable, require staff to think creatively and reevaluate which impacts can be mitigated or avoided through LCFS requirements. Throughout the Draft Environmental Impact Analysis (EIA), CARB frequently made the determination that the impacts associated with expected compliance responses are Potentially Significant and Unavoidable. Based on this determination, CARB staff will request that the Board issue a Statement of Overriding Considerations. CEQA places the burden on the approving agency to affirmatively show that it has considered feasible mitigation and alternatives that can lessen or avoid identified impacts through a statement of findings for each identified significant impact. I do not believe that CARB has adequately demonstrated that they have considered feasible mitigation and alternatives that could lessen or avoid

[1] I am writing this comment letter on my own behalf as a private citizen.

154.2b

several potential impacts on air quality. Moreover, there are several faulty assumptions in CARB’s analysis that result in the overestimation of GHG and air quality benefits of the Proposed Amendments in the Draft EIA. These faulty assumptions also lead to the incorrect conclusion that the Proposed Amendments scenario is more cost effective and provides more air quality benefits than Alternative 1.[2] For further discussion, please see Attachment B.

154.3

Third, direct staff to immediately begin a rulemaking for dairy methane. Avoided methane crediting for dairies is unique under the LCFS. No other industry is treated as if their methane pollution is naturally part of the baseline and then lavished with large financial incentives for simply reducing their own pollution.[3] Oil companies are not awarded large LCFS incentives for avoiding methane emissions at oil fields and refineries. Instead, they are regulated and penalized for their emissions. Likewise, landfill operators are not awarded large, avoided methane incentive for capturing methane escaping from landfills, rather they are regulated and required to do so. Excessively rewarding an industry for poor historic environmental performance is troubling in the least and furthermore, doing so only through a transportation fuels program distorts the market against the consideration of less costly and more sustainable methane mitigation options. Every effort should be made to regulate methane emissions from the dairy industry and limit any subsidies to the bare minimum necessary to resolve the problem. As it is, avoided methane crediting for dairies acts as an LCFS offset program, allowing oil companies to generate or purchase large amounts of credits while displacing very little or no fossil fuel.[4] It is no wonder that oil companies are investing heavily in dairy digesters, as it allows them to comply with the LCFS, make a profit doing so, and retain their market share for fossil fuels.

154.4

Fourth, I recommend resetting the LCFS price cap and encourage the Board to set credit multipliers for high priority fuels and projects. Currently the price cap for LCFS credits is $253 and by 2045 will likely be more than $400. As shown in Table 1 later in this document, the pass-through cost increases substantially over time if the credit price is at or near the ceiling. To help prevent excessive pass-through costs in the latter years of the program, I recommend resetting the price cap to $200 and removing the annual inflation adjustment. Moreover, if the Board believes that $200 is not sufficient to incentivize high priority fuels or emission reduction projects, then the Board should adopt credit multipliers that are specific to those fuels or projects. Using credit multipliers will allow the Board to fine tune the regulation to provide extra incentive for high priority fuels and projects without unnecessarily overcompensating other credit generators in the program. Some stakeholders will hypocritically cry out “blasphemy” at such a suggestion and that the LCFS must be “fuel neutral” or that credit multipliers will create an “unlevel playing field”. The truth of the matter is that transportation fuels

---

[2] Alternative 1 includes a limit on total credits from diesel fuels or sustainable aviation fuel produced from virgin oil feedstocks and a complete phase out of light-duty battery electric forklifts from the program.

[3] At an LCFS credit price of $200, dairy digester gas generates approximately $80 per MMBtu in value from the LCFS and currently receives about $40 per MMBtu in value from the federal Renewable Fuel Standard. The commodity price for natural gas is approximately $5 per MMBtu.

[4] Much of the current dairy gas is not displacing fossil fuel, but rather displacing landfill gas.

policy in California has never been a level playing field because the LCFS subsidy is allowed to stack on top of federal subsidies. This is particularly true for the heavy-duty and aviation sector where the LCFS stacking on the RFS, Biodiesel Blenders Tax Credit, and 40B tax credit for sustainable aviation fuel creates an unlevel playing field tilted heavily toward renewable diesel, biodiesel, sustainable aviation fuel, and renewable natural gas. A relatively low, fixed price cap with credit multipliers for high priority fuels and projects will allow the Board to truly establish a level playing field and equitably promote California's zero-emission transportation goals.

154.5 Finally, I highly encourage you to follow the recommendation made by Earthjustice to hold a non-voting Board hearing prior to the Board vote. Staff made significant changes to the proposal at the last minute that were not discussed at workshops or informational Board hearings, nor were they included in modeling that staff performed for the ISOR and Draft Environmental Impact Analysis.[5] Moreover, staff have been surprisingly non-transparent in the amount of information included in the rulemaking materials, which is a change from prior LCFS rulemakings.[6] It is so important to provide stakeholders with the opportunity to convince Board members, as a group and in a public setting, to change course prior to the voting meeting. I strongly urge you not to shortcut this process.

Before providing detailed comments, I believe it is important to understand the history of the LCFS and the power that wealthy special interests have exerted over the program. Throughout these comments, I urge the Board to adopt many of the recommendations from the Environmental NGO and Environmental Justice Communities. Industrial stakeholders will lead you to believe that these recommendations are a radical departure from the history and philosophy of the LCFS. The truth is that most of the LCFS provisions and credit generating opportunities that the environmental community wants to eliminate, phaseout, or amend were not allowed in the original regulation. Under the original LCFS regulation adopted in 2009,

- Dairy projects did not receive avoided methane credit and would have been assessed approximately the same carbon intensity as landfill gas,
- RNG projects (e.g., landfills and dairies) were not allowed to "deliver" biomethane to California using an accounting ledger,
- Oil producers and petroleum refiners could not receive credit for emission reduction activities at their facilities,
- Offset credit could not be generated for direct air capture (DAC),
- Credit could not be generated by unused hydrogen stations and EV chargers,
- Credit could not be generated by forklifts,
- Alternative jet fuel could not participate as an opt-in credit generator,

[5] Confirmed by email with CARB staff.

[6] When contacted by stakeholders to provide more comprehensive data, assumptions, and calculations that were relied upon in making the determination that the Proposed Amendments scenario is superior to each of the Alternative scenarios, staff refused to provide the information, requiring at least one stakeholder to submit a Public Record Act request. Unfortunately, this information will not be available in time to inform comments during the 45-day period.

- Average Midwest corn ethanol did not generate credits but rather generated deficits in year one of the regulation, and
- Soy biodiesel and renewable diesel were only marginally better than fossil diesel and included a very large land use change penalty that more accurately reflected the likelihood that using soy oil to produce fuel indirectly contributes to tropical deforestation.

The original LCFS was designed to radically transform California's transportation sector by helping fund the transition from internal combustion to zero emission vehicles and accelerate the commercialization of advanced renewable biofuels, primarily produced from waste cellulosic feedstock. Over the next 10 years this vision slowly changed and the LCFS was revised to provide additional and unnecessary support to landfills and first generation crop-based biofuels, to mitigate the methane problem created by the dairy industry itself, to provide support for big oil to reduce emissions from their own facilities and more easily comply with their Cap-and-Trade obligations, and to provide support for direct air capture, a technology that has no direct relationship to transportation fuels. Many of us have witnessed this transition from an innovative regulation into a swag bag for venture capitalists, big oil, big agriculture, and big gas, increasingly coming at the expense of low- and moderate-income Californians. The LCFS is an extremely complicated program, which provides powerful special interest groups with a distinct advantage, as they can afford to pay for lawyers, lobbyists, former CARB staff, and research designed to promote their self-interests. Unfortunately, the same cannot be said for the lower-income consumer of gasoline. Powerful special interest groups will argue that changes to the regulation were objective, data driven, and made to reflect evolving science. I disagree. I believe many were subjective policy and modeling decisions, made not with the best interest of the California consumer and California's long-term transportation goals in mind, but rather with the intent to placate these powerful special interests and to achieve policy outcomes outside of transportation decarbonization. At this point, the LCFS gravy train has gained so much momentum that the only recourse from the staff's perspective is to quickly ramp up the targets, risking large costs to low-income gasoline consumers and public backlash. However, there is another option. Restoring many aspects of the original regulation would better focus the program on achieving California's long-term zero-emission transportation goals and at a much lower cost to the California consumer.

154.6 **Do not ignore the problem of pass-through cost to gasoline consumers.** In both 2015 when CARB readopted the regulation and in 2018 when the targets were extended to 2030, staff estimated the maximum pass-through cost of the amendments to consumers of gasoline and transparently conveyed this information to the public. For the current rulemaking, CARB staff provided similar calculations and rationale in the SRIA.[7] The estimation of pass-through cost uses the target CI reduction (converted to deficits generated per gallon of gasoline) multiplied by the estimated future market price for credits.[8] A basic rule of thumb says that a 1 percent reduction in carbon intensity at $100 credit price adds slightly more than 1 cent to the cost of gasoline. So, in late 2023

[7] See pages 55-59

[8] See the discussion and calculation for pass-through cost on pages 48-50 of the 2018 SRIA.

with a target CI reduction of 11.25 percent and a credit price of $75, the pass-through was a modest 9 to 10 cents per gallon. Table 1 below shows future estimates of the pass-through cost under the amended regulation at a range of reasonable credit prices. These costs are in addition to the pass-through cost for the Cap-and-Trade program which could exceed $1 per gallon in 2030 and reach $1.50 per gallon in 2035.[9] **To put the pass-through cost in perspective, at a $200 credit price, the LCFS could cost gasoline car drivers approximately $250 a year in 2025, rising to whopping $1150 a year by 2045.[10]**

Table 1: Estimated LCFS Pass-Through Cost to Gasoline ($ per gallon)

Year	Percent CI Reduction	$150 Credit Price	$200 Credit Price	Credit Price at Ceiling[11]
2025	18.75	$0.30	$0.41	$0.54
2030	30	$0.49	$0.65	$0.95
2035	52.5	$0.85	$1.13	$1.84
2040	75	$1.22	$1.62	$2.90
2045	90	$1.46	$1.94	$3.84

However, in the current staff report, staff disavowed this calculation of pass-through cost and focused instead on total fuel costs to all California consumers.[12] CARB staff wrote "retail fossil fuel prices are strongly influenced by many factors beyond LCFS credit prices (e.g., global events, holiday weekends, seasonal fluctuations, refinery disruptions and decisions about production that affect supply, refinery pricing decisions, seasonal fuel blends, taxes) and fossil fuel producer pricing strategies are complex and reflect local and regional market conditions…Predicting how LCFS credit price changes impact these complex pricing strategies and the per gallon gasoline and diesel prices paid at the pump in the future by consumers is beyond the scope of this work."

I reached out to Danny Cullenward, Senior Fellow with the Kleinman Center for Energy Policy and Vice Chair of California's Independent Emissions Market Advisory Committee, to get his take on the change in CARB's approach. Here is an excerpt from his response: "With respect to how much of the cost impact is passed through to consumers, I appreciate that it is difficult to assess this kind of question empirically, but I've also been skeptical of views that claim a substantial portion is paid for by the refiners. I don't see the reasoning for why refiners would choose to pay much or any of the total cost, especially not when operating in islanded market (for CARBOB) that is designed, in part through the free allocations to in-state producers in the cap-and-trade program, to be relatively hostile to refined product imports. I'd also flag that arguments that refiners may be exercising market power — e.g. the "mystery gasoline surcharge" identified by Severin Borenstein, and the broader concerns around "price gouging" issues that led to the new oversight function at the CEC — would suggest conditions under which refiners would pass 100% of the costs through. Point is, the market

---

[9] See Cap and Trade workshop: slide 34 of November 16, 2023 workshop presentation

[10] Estimates assume 15,000 miles annual driving in a vehicle getting 25 miles per gallon.

[11] The credit price at the price ceiling was estimated assuming inflation of 3% in 2023 and 2% for all future years.

[12] See middle of page 82 to top of page 84 of the ISOR

structure for CARBOB in particular would suggest more market power for refiners, rather than less, and that implies most or all of the costs getting passed through."

Data reported by refiners to the California Energy Commission under SB 1322 further supports the likelihood that the full cost of the LCFS (and Cap-and-Trade) is being passed on to consumers. As indicated in this data, California refiners reported an LCFS cost of 9 to 10 cents per gallon of gasoline in late 2023, the same as the maximum pass-through cost calculated above.

In the staff report, CARB also wrote "the program has a price ceiling to ensure credit prices do not go unchecked. This further ensures that the cost pass-through is managed and unnecessary costs of the program are not passed on to consumers." Table 1 above shows estimated pass-through costs at the price ceiling. I'll leave it up to the Board to decide if the price ceiling provides appropriate management of costs.

CARB's about-face and focus in the ISOR on total fuel costs to all California consumers instead of pass-through costs is a diversion and reminds me of an old joke:

> Question: Why did CARB paint the elephant's toenails red?
> Answer: So they could hide the elephant in a cherry tree!

The calculation of total fuel cost to all California consumers results in an average cost per mile travelled that encompasses both the higher cost to gasoline consumers and the lower cost to ZEV owners. Focusing on this metric rather than the pass-through cost to gasoline completely misses the point for two reasons. First, the total fuel costs to all California consumers does not isolate the effects of the LCFS, but rather encompasses the effects of all transportation policies in California including the ACC and ACT regulations, which are the most important policies driving the adoption of EVs. Second, because EVs are disproportionally being purchased by wealthier individuals, consumers of gasoline will increasingly become, on average, lower and lower income. Through higher prices of gasoline at the pump, gasoline consumers pay the cost of subsidizing the alternative fuels and projects that receive LCFS credit, and over time, this cost per gallon of gasoline is expected to grow substantially. It is important to understand and acknowledge this regressive nature of the LCFS. **CARB should not be avoiding the discussion of pass-through costs, but rather should be considering all possible**
154.6 cont **means to minimize the pass-through cost while preserving those credit generating opportunities that achieve real, additional emission reductions and/or accelerate the transition to zero emission transportation in California.** In voting on these amendments, you as Board Members are deciding how much you believe future California gasoline consumers should be paying for subsidies to combustion biofuels that exacerbate global hunger and may not reduce GHG emissions at all, for subsidizing dairies to mitigate their own pollution, for subsidizing out-of-state landfill and dairy gas projects, for helping oil companies reduce their Cap-and-Trade obligation through implementing non-innovative emission reduction projects, and for subsidizing out-of-state direct air capture projects which don't help California achieve AB32 GHG reduction goals. As an example, if you approve the amendments as written and credit

prices increase to $200[13], lipid-based biofuels will generate approximately $3 billion of LCFS subsidy in 2025 and out-of-state landfills and dairy digesters will likely generate about $1 billion. Are the benefits of renewable diesel and biodiesel worth this cost to California gasoline consumers? Should California gasoline consumers continue to foot the bill for out-of-state RNG projects to the tune of a billion dollars per year? Could we better use $4 billion each year on projects that help achieve California's long-term zero-emission transportation goals? Balancing the cost of the LCFS against the desire to achieve emission reductions and placate powerful special interests presents many difficult choices, which do not go away by trying to hide the elephant.

Fortunately, there are many actions that CARB can take to reduce the pass-through cost to consumers of gasoline. These actions involve limiting credit generation that does not advance California's long-term zero-emission transportation goals, eliminating excessive credit generation, eliminating LCFS subsidies that do not result in additional global GHG emission reductions beyond what would already occur through other State and Federal programs, and minimizing the potential for credit price spikes. Cutting out unnecessary and ineffective credit generation will allow for less stringent targets and lower pass-through costs, without sacrificing real, additional GHG reductions achieved by the program. In addition to a cap on crop-based biofuels and resetting the price cap, I outline several recommended actions in the discussion below.

Eliminate double counting of emission reductions from direct air capture (DAC): In several provisions of the LCFS regulation amendments (e.g., book-and-claim electricity, book-and-claim RNG, book-and-claim hydrogen, renewable or low-CI process energy), the regulation text prohibits generating LCFS credits if the RECs or environmental attributes are "being claimed in any other voluntary or mandatory program with the exception of (insert list of programs where stacking is allowed)". However, such language is conspicuously absent from section 95490 for DAC or other CCS projects. It is public knowledge that Oxy 1PointFive is already preselling future emission reductions in the voluntary carbon market for its first DAC project and intends to bundle DAC emission reductions with crude oil being marketed as "carbon neutral crude" or "net zero oil". See:

154.7
- 1PointFive announces agreement with Airbus for purchase of 400,000 tonnes of carbon removal credits
- Amazon makes first investment in direct air capture climate technology | Reuters
- Oxy teams with Macquarie to deliver the world's first carbon-neutral oil from Permian basin to India

While I agree that the LCFS value for CCS and DAC should stack with Federal 45Q tax credit, generating LCFS credit for emission reductions that are also sold to other entities in the voluntary carbon market and/or bundled with crude as "net zero oil" is a clear instance of double or maybe even triple counting of emission reductions. If your

[13] After the previous rulemaking to adjust targets in 2018, credit prices quickly increased to $200 and remained at this level for nearly two years. See figure 4 of the LCFS Dashboard.

intention is to allow double or triple accounting, then that should be transparently stated and discussed in a public forum.

154.8 Remove Enhanced Oil Recovery (EOR) as an Eligible Sequestration Method: California SB 1314 prohibits the use of EOR as a sequestration method for CCS projects in California. Section 1 of SB 1314 reads "The Legislature finds and declares that the purpose of carbon capture technologies, and carbon capture and sequestration is to facilitate the transition to a carbon-neutral society and not to facilitate continued dependence upon fossil fuel production." CO_2 EOR is a tertiary oil production method that is only used when oil field production has declined to the point that it is no longer profitable to continue producing using secondary production methods such as waterflood. As such, use of EOR results in the recovery of oil that otherwise would not be produced. The LCFS program should not be providing incentive to squeeze additional oil from these fields. Let's leave this oil in the ground! Out of consistency with California requirements, I strongly encourage the Board to remove EOR as an eligible sequestration method under the LCFS. This can be done by setting a grandfather date (e.g., 2028) after which projects using EOR cannot be certified.

154.9 Place a cap on out-of-state DAC projects: Based on press releases, DAC projects are expected to be massive, resulting in credit generation of up to one million MT annually for each project. At a credit value of $200, a single out-of-state project may result in approximately $200 million leaving the California economy annually, while providing no jobs for Californians, displacing no fossil fuels in California, resulting in no air pollution benefits to California communities, and not even counting toward California's AB32 emission reduction goals. Therefore, not only will Californians be paying for a large out-of-state project that provides no immediate benefit to the state, but they will also have to pay again for separate emission reductions that do count toward the State's goals. In effect, these DAC projects would act as "LCFS offsets", allowing oil companies to comply with the LCFS without affecting their fossil fuel sales. Credit generation for out-of-state DAC projects should either be quickly phased out through a grandfather date or tightly capped as is done in the Cap-and-Trade program for offsets. If left uncapped, a proliferation of DAC projects[14] could result in repeated triggering of the Auto-Acceleration Mechanism leading quickly to excessive pass-through costs to California consumers.

154.10 Stop receiving new petroleum project applications in 2025 and phase out crediting by 2030: The innovative crude and refinery investment projects that have been approved to date are certainly not innovative and are excessively subsidized. These projects should not be credited through the LCFS. All projects certified under the innovative crude provision are for solar electricity, which is cost effective without LCFS credit value. Likewise, the refinery investment credit project certified for the Chevron refinery in Richmond is providing approximately 60,000 credits annually for a hydrogen plant upgrade that Chevron was planning to do before the LCFS was even adopted.[15] These

[14] Oxy 1PointFive has announced a goal of completing 70 DAC projects by 2035.
[15] See https://ccpulse.org/2014/07/31/richmond-approves-stalled-modernization-plan-at-chevron-refinery-2/

are certainly not additional emission reductions. In effect, the LCFS is subsidizing oil companies to meet their Cap-and-Trade obligation.

154.11 <u>Stop overcompensating dairy digester projects:</u> It is my understanding that capital financing for dairy digester projects is commonly paid off in ten years, after which only maintenance and operating costs remain. While dairy digester operators may reasonably argue that they need full avoided methane credit for the first ten years while paying of capital costs, having full avoided methane credit for the next twenty years is gross overcompensation. **Moreover, after paying off capital costs for the digester, it is no longer appropriate to assume a baseline of methane emissions to the atmosphere.** With avoided methane crediting, a dairy digester project generates approximately $70 to $125 per MMBtu in total value from the LCFS, RFS, and gas sales.[16] The operating and maintenance costs for a digester project are about $25 per MMBtu ($35 per MMBtu if trucking of the gas is required).[17] In other words, digester projects getting avoided methane credit are generating about 100 to 400 percent annual profit after paying off the digester. To avoid this needless overcompensation, I recommend assigning a fixed CI value of zero g/MJ for the remaining 20 years of LCFS crediting.[18] At a CI value of 0 g/MJ, the dairy digester project would generate a combined value of approximately $40 to $60 per MMBtu, which is much more in line with the operating and maintenance costs.

154.12 <u>Do not allow dairy projects to get more credit for increasing the herd size:</u> Avoided methane credit should be capped based on the historic herd size before LCFS certification. This would prevent dairy projects from receiving additional credit for growing the herd size and exacerbating local air quality problems.

154.13 <u>Apply biomethane deliverability requirements for all biomethane pathways:</u> In a last-minute revision, staff decided to grandfather all RNG projects that break ground prior to 2030 from proposed deliverability requirements, and projects breaking ground in 2030 or later will only be affected by deliverability requirements starting in 2040. I recommend the Board direct staff to revert to the original concept discussed in workshops and apply deliverability requirements for all pathways starting in 2028. As an exception, I recommend that dairy digester projects that break ground prior to 2025 be allowed to complete their first 10-year crediting period under current deliverability requirements. These dates will provide sufficient time for out-of-state RNG projects that do not meet the deliverability requirements to contract with fleets outside of California and continue receiving value from the RFS. This timing will also allow these digester operators sufficient time to work with their own state legislatures to provide additional funding if necessary to avoid potential stranded assets. Gasoline consumers in

---

[16] At an LCFS credit price of $100 to $200, dairy digester gas generates approximately $40 to $80/MMBtu in value from the LCFS, $26 to $40/MMBtu in value from the federal Renewable Fuel Standard, and about $5/MMBtu for the gas for a total value of approximately $70 to $125/MMBtu.

[17] See calculation details at https://asmith.ucdavis.edu/news/digester-update

[18] This recommendation should be made together with a phase out of book-and-claim accounting for landfill gas.

California have jump started the dairy digester industry in these states, they shouldn't be asked to fund these projects in perpetuity.

Quickly phase-out book-and-claim accounting for landfill gas: Landfills do not need LCFS credit as the RFS incentive for these projects is already excessive. Moreover, over 98 percent of the landfill gas generating credit under the LCFS is from out-of-state sources. Producing landfill gas for transportation is estimated to cost approximately $10
154.14 per MMBtu[19] but these projects currently receive about $40 per MMBtu in incentive from the RFS. In other words, the LCFS providing incentive for these projects does not result in additional global GHG reductions, only more profits. I recommend eliminating book-and-claim accounting for landfills in 2028, which will provide sufficient time for out-of-state landfill gas operators to find a different purchaser for their gas.

Phase out crediting for light-duty and heavy-duty forklifts: Staff took a step in this direction by reducing the EER for light-duty forklifts but should go a step further and set
154.15 phase out dates of 2030 for light-duty forklifts and 2040 for heavy-duty forklifts. With limited exceptions, all forklifts will be required to be zero-emission by 2040.[20]

Return to the Board if the Auto-Acceleration Mechanism (AAM) is triggered repeatedly: The AAM is designed to automatically increase the stringency of the program if there is a chronic excess of credit leading to a buildup of the credit bank and reduction of credit prices. In discussing the rationale for the AAM, CARB wrote "The existence of an AAM is expected to decrease market volatility and increase market confidence, which will promote low-carbon technology investments." However, in the staff report, CARB staff made no effort to assess the impact of this mechanism on the credit price or even qualitatively discuss the implications as part of the scenario analysis. For example, in the Proposed Amendments scenario, CARB staff estimate average credit prices ranging from $76 to the price cap, but they do not discuss whether this large volatility in the
154.16 market is reasonable given the addition of the auto-acceleration mechanism to the proposal. Will the AAM effectively set a credit price floor that is well above $76? Will unexpected credit generation result in multiple triggers of the AAM and unexpectedly high pass-through costs? Because of the uncertainty surrounding the impact of the AAM on credit price and pass-through cost, I recommend requiring that a rulemaking be initiated if the AAM is triggered twice in any six-year period. Moreover, this rulemaking should be completed before a third acceleration is allowed. Repeated triggering of the AAM indicates market conditions that staff and the Board did not anticipate when approving these amendments. Staff should be required to investigate and return to the Board with amendments to establish new compliance targets and address the cause(s) of the market imbalance, if necessary.

Address the potential for the AAM to overcorrect the market: I suggest not allowing an acceleration to occur in either 2031 or 2032 as the rate of CI decline for the benchmarks

[19] See https://www.erm.com/globalassets/documents/mjba-archive/issue-briefs/rngeconomics07152019.pdf
[20] See workshop materials for the forthcoming Zero-Emission Forklifts Regulation.

is already doubling and an acceleration that occurs in either of these years would quadruple the rate of target CI decline. Here are the scenarios of concern:[21]

154.17

- The AAM is triggered in May of 2030. This trigger has occurred because the market is generating too many credits based on an annual benchmark decline through 2030 of 2.25 percent. In 2031, the rate of benchmark decline is already scheduled to double to 4.5 percent. An acceleration in 2031 would quadruple the rate of benchmark decline to 9 percent.
- The AAM is triggered in May of 2031. Again, this trigger has occurred because the market is generating too many credits based on an annual benchmark decline through 2030 of 2.25 percent. In 2031, the benchmark has already declined by 4.5 percent, which may itself correct the market. However, in 2032, an acceleration will occur increasing the target CI reduction another 9 percent.

Either of these scenarios may result in an overcorrection with the credit price going to the ceiling, at which it may be stuck for many years. Under the above scenarios, credit price at the ceiling will result in a pass-through cost of approximately $1.30 per gallon of gasoline. Such a pass-through cost would be politically untenable for the program.

Withhold LCFS credits for violating other State and Federal requirements: Apparently, CARB has not been too serious about holding credit generators responsible for complying with other State and Federal requirements, as there do not appear to be any enforcement actions taken against entities for non-LCFS violations.[22] If the Board is truly intent on requiring regulated parties to comply with these requirements as a condition for generating LCFS credits, then I recommend that the Board direct staff to make the following amendments:

154.18

- Clearly define what types of State and Federal requirements (e.g., environmental, safety, labor, tax) are of concern and the repercussions for violating these requirements.
- Require regulated parties to report all violations and require third-party verification bodies to verify compliance with this reporting requirement.
- Investigate regulated parties with violations and withhold credits from entities with serious and/or repeated notices of violation.

If you have read this far, I do thank you for engaging with me😊.

Best regards,
Jim Duffy

---

[21] I wrote these scenarios assuming that the AAM has not already been triggered prior to 2030. If the AAM has previously been triggered, then the years of concern will advance by one year. In other words, I suggest not allowing an acceleration to occur in either of the two years following the transition from a 2.25% rate of decline to a 4.5% rate of decline.

[22] See LCFS Enforcement webpage for a listing and description of settlements and account balance adjustments since the inception of the program.

Attachment A: Cap on Crop-based Biofuels

I most strongly urge the Board to **cap and ultimately phase out the use of crop-based diesel and aviation fuel in California**. The use of crops such as corn and soy as feedstock to produce liquid diesel and aviation fuel is not a sustainable means of reducing GHG emissions and may increase emissions as compared to fossil fuels. Moreover, using crops to produce biofuels is expensive and exacerbates tropical deforestation and global hunger. CARB's promotion of these fuels is not in line with its reputation as a global leader in environmental policy.

<u>If the rest of the world follows California's example, the demand for virgin vegetable oil will be enormous:</u> Just last year CARB issued a news release celebrating the accomplishment that the LCFS has resulted in renewable diesel and biodiesel replacing 50% of diesel. CARB often prides itself on providing an example for the world to follow. **So, what would happen if the rest of the world follows California's lead and replaces over 50% of its diesel fuel with renewable diesel and biodiesel?** Currently, the world annually produces 200 million metric tons of vegetable oil, a majority from the tropical countries of Indonesia, Malaysia, and Brazil. Replacing 50% of diesel worldwide would require an additional 600 million metric tons, necessitating a fourfold increase in worldwide production of vegetable oil. It doesn't take a scientist to know that the impact of such an increase in vegetable oil production on agricultural commodity prices, global hunger, tropical deforestation, and biodiversity would be enormous, especially in a world that is expected to add another 2 billion people by 2050. **Which leads me to ask: Are you really being a leader if the world would be much better off not following?**

<u>Crop-based biofuels are not sustainable:</u> Many studies, including work performed by CARB[23], show that full life cycle emissions, including emissions from increased fertilizer application and land use change (LUC), are significant, highly uncertain, and appreciably or entirely negate the carbon benefit of using biogenic feedstock. In fact, a recent assessment of GHG emissions resulting from corn ethanol production in the U.S. found that total life cycle emissions for corn ethanol exceed those of gasoline.[24] And a recent Model Comparison Exercise conducted by the US Environmental Protection Agency highlights the deep uncertainty underlying the modeled climate benefits attributed to soybean oil-based biofuels.[25] Another recent research study published in Nature Sustainability shows that the pace of tropical deforestation has more than doubled over the first two decades of this century, the same time period over which biofuel production has significantly increased in response to state and federal policies.[26] This study also shows that most (82%) of the forest carbon loss is at some stages associated with large scale commodity or small-scale agricultural activities, particularly in Africa and Southeast Asia.

Producing crop-based biofuels increases food prices and exacerbates global hunger: As indicated by the research quoted above and multiple other research studies[27,28], diverting crops from human and animal feed markets to produce biofuels results in an increase in agricultural commodity prices as compared to the counterfactual without biofuel production. This increase in food prices results in increased hunger, especially amongst the most vulnerable populations of the world. According to Tom Hertel, professor at Purdue University and author of several studies on LUC impacts of biofuels (including original modeling work performed for CARB's LCFS), **"reduced food consumption is an important market-mediated response to increased biofuels production. While lower food consumption may not translate directly into nutritional deficits among wealthy households, any decline in consumption will have a severe impact on households that are already malnourished"**.[29] The biofuel industry wrongly claims that the LUC CI penalty for crop-based biofuels negates any food price increases and food consumption impacts and therefore CARB does not need to impose any additional limits on biofuel consumption beyond the current LUC CI penalty. However, according to Hertel et al., if food consumption were held constant in the CARB LUC model (instead of allowing food consumption to decrease as is done in the actual LCFS modeling), twice as much forest conversion to agriculture would be predicted and the LUC CI penalty would increase by 40%. **In essence, a portion of the emission reductions attributable to crop-based biofuels under the LCFS is the result of the most food insecure populations in the world eating less.**

Crop-based renewable diesel, biodiesel, and aviation fuel is an extremely expensive means of reducing GHG emissions: Renewable diesel, biodiesel, and aviation fuel receives monetary incentives from the federal RFS, the federal Biodiesel Blenders Tax Credit, and the California LCFS. These incentives stack and adding the incentive values of these three programs resulted in a total societal cost in 2023 of nearly $4 per gallon and a GHG cost effectiveness (or ineffectiveness) of more than $600 per metric ton of GHG emission reduction, a value that greatly exceeds any reasonable estimate of the social cost of carbon.[30] Considering that emission reductions from crop-based biofuels are highly uncertain, one can only conclude that policies incentivizing these biofuels are a costly and risky means of spending limited consumer dollars on climate change mitigation. Moreover, because of the RFS volume mandate, renewable diesel and biodiesel would have been produced and consumed in the U.S. without the LCFS incentive. Stacking the smaller LCFS incentive on top of the larger federal incentives merely results in the shuffling of the lowest CI renewable diesel, biodiesel and ethanol to California. **Essentially, California consumers are paying a significant cost to support combustion fuels that achieve very little real global GHG reduction,**

[30] Cost effectiveness estimated by dividing the total incentive value by the estimated GHG emission reduction for soy renewable diesel under the LCFS.

money that would be much better spent helping California transition to zero emission transportation.

In conclusion, emissions associated with producing crop-based biofuels are highly uncertain and may, in fact, be greater than fossil fuels on a full life cycle basis. Moreover, these fuels are very expensive and exacerbate tropical deforestation and global hunger. Because of these issues, the European Union has taken steps to restrict the use of biofuels produced from food and feed crops, and mainstream environmental organizations such as International Council on Clean Transportation, Natural Resources Defense Council, Union of Concerned Scientists and Earthjustice, as well as UC Davis Institute for Transportation Studies are urging CARB to limit the use of vegetable oil-based biofuels under the LCFS.[31,32] **Promoting the use of these fuels is not in line with California's role as a global leader in environmental policy, and I highly encourage the Board to direct staff to cap and ultimately phase-out the use of crop-based biofuels in California**.

Postscript: In lieu of a cap on crop-based biofuels, CARB could acknowledge that the RFS and Biodiesel Blenders Tax Credit are responsible for setting the total volumes of ethanol and biomass-based diesel consumed in the US, and only award LCFS credit for achieving reductions in excess of RFS requirements. For example, the RFS requires a CI reduction of 50 percent for biomass-based diesel to qualify for RINS. The LCFS could have a separate benchmark table for biomass-based diesel that starts at a 2010 baseline CI of 54.88 g/MJ (i.e., a 50 percent reduction) and declines to a 2045 CI target of 5.29 g/MJ (i.e., a 90 percent reduction from the 2010 baseline CI). Likewise, the RFS requires a CI reduction of 20 percent for ethanol to qualify for RINS. The LCFS could have a separate benchmark table for ethanol that starts at a 2010 baseline CI of 79.32 g/MJ (i.e., a 20 percent reduction) and declines to a 2045 target CI of 7.93 g/MJ. The major advantage of this approach as compared to a volume cap is that it doesn't create two separate markets for credits and can be seamlessly incorporated into the LRT-CBTS without major modifications to the software.

Attachment B: Comments on the Draft Environmental Impact Analysis

Throughout the Draft EIA, CARB frequently makes the determination that the impacts associated with expected compliance responses are Potentially Significant and Unavoidable. Based on this determination, CARB staff will request that the Board issue a Statement of Overriding Considerations. CEQA places the burden on the approving agency to affirmatively show that it has considered feasible mitigation and alternatives that can lessen or avoid identified impacts through a statement of findings for each identified significant impact. I do not believe that CARB has adequately demonstrated that they have considered feasible mitigation and alternatives that could lessen or avoid several potential impacts on air quality and agricultural and forest resources. For example:

154.19
- Trucking of biofuel feedstock and finished product, trucking of manure or food and green waste to a centralized digester, trucking of biomethane from digesters to the pipeline injection point, trucking of hydrogen from production facilities to dispensing stations, and trucking of carbon dioxide from the capture facility to the sequestration point are all reasonably foreseeable compliance responses resulting in local air quality impacts. As an example, the conversion of the Paramount refinery to renewable diesel production by World Energy results, by their own calculations, in an estimated 125 tpy increase of NOx emissions for transport of feedstock and finished product.[33] These emissions could be mitigated by requiring these LCFS participants to use zero emission trucks as a condition for generating credit.

154.20
- Converting biogas to electricity using internal combustion generators is a reasonably foreseeable compliance response resulting in local air quality impacts that could be avoided by requiring LCFS participants to use non-combustion alternatives such as fuel cell generators as a condition for generating credit. In fact, CARB staff in the air quality calculations assumed that dairy electricity projects would use fuel cells even though the regulation does not require it. I suggest making it official.

154.21
- Continued siting of new fuel production facilities in overburdened communities is a reasonably foreseeable compliance response which exacerbates entrenched air quality problems that could be avoided by requiring LCFS participants to site all new production facilities in locations receiving a CalEnviroScreen score of "X" or lower as a condition for generating credit.

154.22
- Continued methane leaks from dairy digester projects are reasonably foreseeable and could be avoided by requiring LCFS participants to employ periodic leak detection and repair at digester facilities and transport equipment.

154.23
- Increasing dairy herd size to generate additional LCFS credit is a reasonably foreseeable compliance response resulting in local air quality impacts that could be mitigated by capping avoided methane credit based on the historic herd size before initial LCFS certification.

---

[33] See page 2-41 of the AltAir EIR
https://www.paramountcity.com/home/showpublisheddocument/8001/637811424787470000

- 154.24 Increased biofuel feedstock production is a reasonably foreseeable compliance response resulting in land use change and global hunger impacts that are not being mitigated or avoided by the existing land use change CI penalty. Future impacts could be avoided by placing a cap on use of crop-based feedstocks to produce biofuels.

The Board should require staff to take a step back and think creatively when determining which potentially significant impacts can be mitigated or avoided rather than simply claiming that all impacts are unavoidable.

Moreover, there are several faulty assumptions in CARB's analysis that result in the overestimation or inaccurate portrayal of GHG and air quality benefits of the Proposed Amendments. These faulty assumptions also lead to the incorrect conclusion that the Proposed Amendments scenario is more cost effective and provides more air quality benefits than Alternative 1. These faulty assumptions include:

- 154.25 CARB staff are not using the latest data on tailpipe PM emissions from vehicles consuming renewable diesel. The ISOR and Draft EIA attribute health benefits to increased use of renewable diesel in California, especially associated with reduced PM2.5. This is based on a 2011 analysis, and ignores a more recent 2021 study prepared for CARB that looks at the NOx and PM from Biodiesel and Renewable Diesel Emissions in Legacy and New Technology Diesel Engines. The key finding in this more recent study is that air quality benefits from older engines are not observed in new technology diesel engines, which are now required in California for the on-road fleets. This undercuts one of the main justifications offered to reject limits on renewable diesel and results in an inaccurate portrayal of the criteria pollutant emission benefits of the proposed amendments in the Draft EIA. Ironically, because renewable diesel does offer PM reductions in older trucks that are still in use elsewhere in the US, concentrating most of US renewable diesel in California does not help Californians but it does harm others across the United States, many of whom reside in overburdened communities. A large percentage of renewable diesel currently consumed in California originates from a region of Louisiana known as Cancer Alley. Residents of Cancer Alley suffer from the additional pollution emitted by newly constructed or expanded renewable diesel refineries but do not benefit from the reduced tailpipe emissions that would occur if the renewable diesel were consumed locally instead of being shipped to California.

- 154.26 CARB incorrectly attributes 100 percent of the GHG emission reductions associated with consuming biofuels to the LCFS. Setting aside the argument that the CI values CARB calculates for crop-based biofuels are highly uncertain and likely significantly underestimated, CARB staff have changed the assumptions they use in attributing GHG emission reductions to the LCFS for biofuel. In the rulemaking for the 2018 amendments (see Attachment F page F-14), staff acknowledged that the federal Renewable Fuel Standard (RFS) and Biodiesel Blenders Tax Credit are primarily responsible for driving the production of biofuels. Through its design, the RFS essentially creates a volume mandate for biofuels, and therefore the total volume produced in the United States is effectively fixed by the RFS. In other words, if the LCFS ended today, the same amount of biofuel would be produced in the US. Because of this, the LCFS subsidy does not result in more production of biofuel beyond that incentivized by the RFS and blenders tax credit, but rather provides incentive to incrementally reduce the CI and shuffle the lowest CI production to California. Under the RFS, corn ethanol is required to achieve a 20 percent CI reduction and biomass-based diesel is required to achieve a 50 percent CI reduction to qualify for the subsidy. Therefore, in the 2018 LCFS rulemaking, staff gave credit to the federal programs for a CI reduction of 20 percent for corn ethanol and 50 percent for biomass-based diesel, and only gave credit to the LCFS for CI reduction in excess of these values. For example, under these more appropriate assumptions, the LCFS took some credit for lower CI of fuels made from used cooking oil and tallow which have CI reductions of about 60 to 80 percent but took no credit for emission reductions from fuels made from soy and canola oil which have CI reductions of about 50 percent. Conversely for the 2024 amendments, staff appears to be crediting the LCFS for the full CI reduction (see page 38 of ISOR), effectively ignoring the contribution of the federal programs. This change in assumption results in an overestimation of the GHG benefits of the Proposed Amendments scenario in the Draft EIA.

154.27

- CARB staff makes a flawed assumption that inflates the GHG and criteria pollutant benefits associated with displacing fossil diesel. In the GHG and air quality analysis presented by CARB, staff assume that a reduction in the consumption of fossil diesel in California will result in a proportional reduction in oil production in California. Staff then attribute the reduced criteria pollutant and GHG emissions associated with the oil production decline to the LCFS (see page B-1 of the SRIA for equations). I see several issues with this logic.

    - First, CARB totally disregards the fact that crude production in California is in terminal decline and has been for the past 40 years (see page 7). CARB's calculations assume a static baseline at 2019 crude production levels, rather than a dynamic baseline that accounts for the long-term historical rate of decline in production. In other words, CARB assumes that crude production in California would remain constant at 2019 levels without CARB regulations, when it will likely decline to near zero by 2045 based exclusively on naturally declining production from quickly maturing oil fields. If we want to understand the benefits or costs of an action or regulation, it should be measured against counterfactual case where the action or regulation did not happen. In either world, California oil production is dropping.
    - Second, even if CARB properly assumes a declining baseline for the calculations, I don't see evidence for a relationship between California oil production and fossil fuel demand in California, especially given the fact that California crude makes up only 25 percent of oil supply to California

refineries. Changes to the “rate of oil production decline” in California are largely the result of global oil price, California wholesale NG price, and approval of new well drilling. In other words, California oil production declines more rapidly when global crude prices are low and NG prices are high, and oil production declines less rapidly when crude prices are high and NG prices are low.[34] Changes in California fossil fuel demand will not significantly affect this dynamic because these changes are too small to significantly affect global oil prices. California refineries will much more likely respond to reduced demand for fossil fuels by reducing crude imports first, as is clearly evident by dramatically reduced imports during the pandemic (see the LCFS Dashboard Figure 8 which shows that imports of crude oil declined by nearly 100 million barrels between 2019 and 2020 while California production declined by only 6 million barrels). Moreover, if there were a link between California crude production and fossil fuel demand in California, one would expect to see California crude production increase after the pandemic in response to the rebound in gasoline and diesel consumption. Instead, California crude production continued its relatively steady annual decline and imported crude volume increased.

- Third, CARB is assuming that a reduction in fossil fuel demand will result in a proportional reduction in refining capacity in California. Although this is probably the strongest assumption CARB makes, it is in no way assured. California refiners may simply respond to reduced demand in California by exporting excess production, especially given the legal fights and costs associated with cleanup that will ensue after shutdown. In other words, will California refineries continue to operate and sell barely profitable fuels to satisfy increasing consumption in Asia or will they shut down and incur extremely expensive cleanup costs?

- CARB staff is significantly underestimating criteria pollutant emissions at renewable diesel, renewable gasoline, and sustainable aviation fuel production facilities. Staff assumes that these facilities have similar emissions to a simple oil
154.28 refinery and estimate emission factors of 0.058 and 0.022 tons per million DGE for NOx and PM2.5 emissions respectively.[35] Environmental Impact Reports for the AltAir and Phillips 66 refinery conversions indicate emission factors of 3 to 4 times these values. For the AltAir facility, data indicates emission factors of 0.152 and 0.090 tons per million DGE for NOx and PM2.5 emissions respectively.[36]

---

[34] California oil producers have been injecting steam to recover oil for over 50 years and the remaining oil is getting much harder to extract as indicated by the increasing amount of steam injected per barrel of oil produced. The rate of California oil production is largely dependent on the amount of steam that the oil field operators can afford to inject. During periods like 2011 – 2014 when global crude prices were high (above $100 per barrel) and NG prices low, oil companies could afford to inject more steam and oil production remained nearly constant (see figure 2 on page 8 and figure 6 on page 10). When global crude prices dropped in 2015, California oil production resumed its decline.

[35] See page B-2 of https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/appc-1.pdf

[36] See pages 2-37 through 2-46 for estimated project emissions for the AltAir facility https://www.paramountcity.com/home/showpublisheddocument/8001/637811424787470000

For the Phillips 66 facility, data indicates emission factors of 0.249 and 0.082 tons per million DGE for NOx and PM2.5 emissions respectively.[37]

- CARB staff assume that all future dairy to electricity projects will use fuel cell electric generators even though there is no requirement that project operators use fuel cells rather than combustion generators.[38] This assumption results in extremely low NOx and PM2.5 emission factors for these projects and therefore underestimates potential emissions.

- As discussed previously, CARB appears to be allowing future CCS and DAC projects to receive LCFS credit for emission reductions that will also be sold to other entities in the voluntary carbon market and/or through the marketing of zero-emission crude oil. If this is the case, the GHG emission reductions claimed for the LCFS in the Draft EIA are significantly overestimated as the same emission reductions are also being sold to parties not participating in the LCFS.

The net result of all these assumptions is that CARB is significantly overestimating the criteria pollutant and GHG reduction benefits associated with biofuel production and consumption, dairy electricity projects, as well as CCS and DAC projects, which results in an inaccurate portrayal of the benefits of the amendments in the Draft EIA.

Finally, CARB did not update the CATS model, rerun the Proposed Amendments scenario, and update the economic and air quality analyses between the submission of the SRIA to DOF in September and release of the rulemaking package in January.[39]
154.29 During this period, a few changes were made to the proposed amendments. The most significant of these changes were to grandfather all pre-2030 dairy and swine projects from the proposed phaseout of avoided methane and to grandfather all pre-2030 RNG projects from the proposed deliverability requirements. Therefore, the economic and air quality analyses presented in the ISOR and Draft EIA do not reflect the actual LCFS amendments proposal.

Comments on Proposed Changes to the LCFS Regulation

Dear California Air Resources Board (CARB) Low Carbon Fuel Standard Program Staff:

Thank you for the opportunity to provide comments in response to the draft proposed changes to the Low Carbon Fuel Standard (LCFS) and associated Initial Statement of Reasons (ISOR) published on December 19, 2023. We appreciate CARB hosting workshops and soliciting stakeholders' input on a variety of forward-looking concepts for the future of the LCFS. Taking decisive action to bolster the LCFS market will help ensure the long-term viability of the program and the accomplishment of the state's carbon reduction objectives. SkyNRG Americas ("SkyNRG") is pleased to be able to provide comments on several areas of proposed LCFS policy.

Since 2009, SkyNRG has been building sustainable aviation fuel (SAF) production capacity to support the aviation industry's 2050 net-zero commitments. SkyNRG will be among the first producers of SAF and renewable diesel (RD) at scale from cellulosic feedstocks such as biomethane. Together with our existing technology partners, our production process converts biomethane to SAF and RD at an integrated production facility. SkyNRG's plans necessitate withdrawing biogas from common carrier pipelines on a book-and-claim basis, similar to producers of hydrogen, compressed natural gas (CNG), or liquid natural gas (LNG). Beginning in 2019, SkyNRG has invested in the development of dedicated SAF production facilities in the U.S. and Europe to support the aviation industry's transition to SAF from fossil jet fuel. Critically, SAF is one of the few cost-effective and scalable tools for decarbonizing aviation in the near- to medium-term. As such, SAF is one of few viable solutions for mitigating aviation emissions in the foreseeable future.

While aviation emissions currently comprise a relatively small percentage of California's total greenhouse gas (GHG) footprint, its share of the state's emissions inventory will increase through 2035 and beyond as road transportation modes electrify. The aviation sector is one of the most difficult industries to decarbonize due to unique operational and safety requirements that necessitate energy dense-fuels, highlighting the critical role of low carbon liquid fuels for the future of the aviation sector.

SAF is an essential contributor to achieving Governor Newsom's goal of 20% clean fuels for the aviation sector by 2030. However, delaying supportive low carbon policies now will jeopardize the industry's ability to scale SAF production in the timeframe needed to meet the Governor's goal. SAF production facilities can take five to seven years to move from development to operation; consequently, construction of new projects (or expansions of existing facilities) must begin now to enable availability of these solutions by 2030.

Strengthen the 2030+ CI Targets

The LCFS has been extremely successful in encouraging market investment in low carbon fuels and lowering transportation fuel pool emissions in the past decade. To help ensure a healthy LCFS credit

market that can keep pace with these investments, we strongly support CARB's plans to strengthen the
existing emission targets for 2030 and beyond. As such, CARB should revise the 2030 compliance target
155.1 to achieve at least a 35% reduction in GHG emissions for diesel and gasoline and implement more
stringent carbon intensity (CI) targets for jet fuel. We encourage CARB to make an appropriate
adjustment to reflect the strong market supply scenario to ensure development of novel markets, like
SAF.

We support the introduction of an auto-acceleration mechanism (AAM) to strengthen CI reduction
targets and respond to growth in the low carbon fuels sector. By recognizing and rewarding
overperformance in the program, California benefits from the latest in low carbon fuel technologies. As
155.2 the rule is currently written, it is essential that the AAM functions properly in tandem with the CI
adjustment. Private industry has signaled that it is ready to exceed stated goals well ahead of the
established targets. Considering the achievement of 2024 goals in 2022 and strong credit bank builds
each quarter, we believe the AAM should not be restricted to an every-other-year frequency. This allows
the AAM to respond to market conditions as they emerge rather than potentially two years behind
schedule.

CARB Should Expand, Not Restrict, Book-and-Claim Opportunities for Biomethane

As we have stated in previous comments to CARB, expanding opportunities for biomethane to be used as an input for additional transportation fuels such as SAF and RD will be critical to achieving the more stringent targets introduced during previous workshops. The share of LCFS credits generated for biomethane-based fuel, primarily renewable CNG, has steadily grown over the last decade thanks in large measure to the ultra-low CI scores attainable for feedstocks such as dairy and livestock wastes. This trend may be unsustainable long-term, however, if biomethane opportunities are not encouraged beyond their current applications due to the limited scale of on-road heavy duty natural gas vehicle (NGV) fleets. Existing LCFS regulations heavily incentivize the use of biomethane in renewable CNG and LNG applications, and for renewable hydrogen production, by offering the flexibility of indirect accounting of biomethane injected into pipeline systems connected, sometimes at great distance, to downstream production or dispensing locations (referred to as "book-and-claim"). This is a highly effective way to rapidly decarbonize transportation fuels, and we encourage this to be expanded to SAF and RD as it has been applied to other transportation fuel end uses like, hydrogen, CNG and LNG.

The U.S. biomethane industry has evolved with existing regulatory programs at both the federal and
state levels that reasonably recognize that most sources of biomethane do not justify co-location of fuel
production. To accommodate this challenge, book-and-claim accounting is an indispensable ingredient
155.3 to incentivizing the development of biomethane resources and unlocking their emission reduction
potential to materially reduce emissions.

Under the current regulations, SkyNRG (and others) would be unable to participate in the expansion of biomethane resources because there are no provisions allowing book-and-claim accounting for offsite biomethane utilized as feedstock to produce SAF and RD. We are discouraged that CARB introduced deliverability requirements for biomethane that restrict availability of this valuable feedstock, rather than expanding its availability. Geographic and deliverability limitations would almost certainly stifle investment in biomethane resources and reduce opportunities for the state to achieve its LCFS-specific climate goals. Respectfully, we believe that CARB's stated goal to harmonize book-and-claim policies for low-CI electricity and biomethane limits growth because it fails to recognize the fundamental difference of biomethane as a feedstock.

Additionally, we take issue with the Renewables Portfolio Standard (RPS) deliverability requirements that are specific to electricity generation. In the proposed rule and accompanying ISOR, CARB staff explains intentions to align deliverability of biomethane in the LCFS with the California Energy Commission's (CEC) RPS by requiring common carrier pipelines to physically flow toward California 50% of the time on an annual basis. Considering the RPS requirements are specific to electricity generation, we take issue with relying on this standard for biomethane as a transportation fuel or feedstock. Given the variety of uses of this valuable low-CI feedstock, the RPS alignment is limiting the potential for biomethane to reduce CI of other hard-to-decarbonize sectors, like aviation. Considering the goal of growing SAF's share of California's aviation fuel supply, these unique characteristics need to be considered. By allowing the book-and-claim of biomethane feedstocks, CARB ensures a steady supply of SAF to meet its programmatic goals. Electricity and SAF do not compete for the same investments, resources, or customers. Neither is advantaged over the other under the current regulatory regime, so harmonizing requirements would at best be an unnecessary change, and at worst, it could severely disrupt both existing and future investments.

155.3 cont

Earlier this year, the U.S. Environmental Protection Agency (EPA) recognized the potential for biomethane as a feedstock in the production of renewable fuels. In its 2023 rulemaking, the EPA established a regulatory framework allowing the use of biomethane as a "biointermediate," paving the way for producers like SkyNRG to make renewable, low carbon fuels like SAF and RD from products derived from biomethane under book-and-claim accounting (once finalized). Critically, the EPA's regime leverages indirect accounting of pipeline injection and offtake at separate points consistent with LCFS book-and-claim procedures. In CARB's ISOR for the proposed rule change, the need to align with federal support for SAF proliferation is specifically highlighted as a guiding principle of the rule change. The LCFS program has long been compatible with federal incentives, including the Renewable Fuel Standard (RFS) and numerous tax credits. The creation of additional federal incentives through the Inflation Reduction Act (IRA) and Infrastructure Investment and Jobs Act (IIJA) only increases the opportunity for the LCFS program to align with and leverage federal investments to accelerate decarbonization. While the SAF market is growing, these incentives are greatly needed and have outsized impacts in supporting the industry's maturation. CARB should ensure that the LCFS program aligns with the treatment of SAF feedstocks under the RFS to avoid creating a bifurcated RNG market.

155.3 cont

In summary, we implore CARB to expand eligibility for book-and-claim of all sources of biomethane as feedstock to produce transportation fuels like SAF and RD. Doing so will create new opportunities to utilize biomethane to make low, or even negative, CI transportation fuels that are suitable for sectors that are hard to decarbonize. This will directly contribute to Governor Newsom's ambitious goals for expanded production and use of low carbon, renewable aviation fuels. With appropriate oversight (including the verification and validation procedures CARB already requires), we believe that any compliance risks can be effectively managed as they are today for CNG, LNG, and hydrogen production. By recognizing the potential of RNG as an SAF and RD feedstock, CARB acknowledges its strong value to a maturing industry and instills confidence in investment communities. Failing to expand book-and-claim eligibility for biomethane feedstocks is a critical issue that may significantly negate California's ability to benefit from the next generation of low carbon fuels.

Further Study on Changes to Avoided Methane Emissions Credits is Necessary

As SkyNRG works to build SAF production capacity, the company will continue to explore a wide range of biomethane feedstock opportunities from organic waste streams, including food waste, yard and landscaping waste, industrial and wastewater sludge, and a variety of animal wastes. Many untapped waste streams are novel as it relates to LCFS pathways, but nonetheless can readily be converted to transportation fuels through technologies that are commercially proven and readily suitable for producing low carbon fuels from biomethane pathways.

155.4 CARB should encourage the capture and productive repurposing of emissions from organic waste streams processed through anaerobic digestion, regardless of the source of the waste stream. To this end, CARB should avoid making changes in the present amendments that limit opportunities to include avoided emissions in CI calculations. We do not believe that a premature sunset is appropriate in achieving LCFS success. Therefore, we believe that this warrants further study from CARB to avoid any unnecessary consequences as currently proposed.

The GHG emission reductions resulting from CNG fleets being the default for many medium- and heavy-duty applications are attributed, in part, to the incentives of the LCFS and has resulted in improved air quality for constituents. SAF is at a similar crossroads. By allowing for avoided methane crediting for biomethane as a feedstock, CARB has the potential to see SAF become the default fuel for aviation, much like the transition in the CNG fleet space. Biomethane has continued potential to reduce GHG emissions in California, and recognizing its potential as a feedstock is essential to the continued success of the program.

155.5 We further implore CARB to study the success of Europe's Renewable Energy Directive (RED), which has long recognized the avoided methane benefits when assessing the lifecycle CI of various RNG pathways. The RNG to SAF pathway presents a unique opportunity to scale-up low carbon fuels in the aviation sector to align with California's recently stated goals of obligating jet fuel within the LCFS.

Fossil Jet Participation in LCFS

155.6 Inclusion of fossil jet in the LCFS is a first step in recognizing the impact of aviation on the state's GHG emissions and the benefits of SAF for the state's climate ambitions. Given current technologies and feedstocks, SAF represents a major opportunity to decarbonize this hard-to-abate sector. With the encouraging language in the proposed rule, SkyNRG further encourages CARB to expand the scope of fossil jet regulation to include int**er**state flights.

Current regulations under the LCFS are already regulating interstate fossil fuel for on-road vehicles refueling in California before leaving the state. It was through this scheme that the state has benefited from immense growth in liquid fuel innovation and the current boom in RD production and end use. This major paradigm shift in fuel technology was due in part to visionary leadership by CARB staff. By expanding the scope of fossil jet regulation in the LCFS, the state could further benefit from similar growth in the SAF sector. Furthermore, by regulating all fossil jet fuel uplifted in California, CARB would benefit from a streamlined regulatory process and reduced risk of legal challenge.

155.7 Additionally, we support accelerating the obligation to 2025 instead of 2028. CARB states that the proposal to delay the elimination of the exemption for fossil fuel jet fuel until 2028 is meant to provide "sufficient time for potential producers of alternative jet fuel to add capacity for the anticipated increased demand of alternative jet fuel." However, such a delay is unnecessary, and we urge CARB to consider an earlier implementation date. We note that British Columbia has already added an obligation for all fossil jet fuel beginning in 2026, coupled with a volumetric SAF mandate beginning in 2028. Given that CARB is only proposing an obligation for jet fuel and not an actual SAF requirement, consistent with the LCFS, there is technically no need for lead time to increase SAF production capacity because the structure of the LCFS program allows for compliance via credits generated outside of aviation, credits which are readily available today. In addition, CARB has already provided a five-year window for growth since making SAF an opt-in credit generator in 2019, during which time SAF volumes recorded under the LCFS have increased five-fold, despite a global pandemic and the continued regulatory disadvantages for SAF producers under both the LCFS and the Cap-and-Trade program. Nevertheless, SAF continues to lag far behind similar ground transportation fuels under the LCFS. This gap should not be misinterpreted as a signal that the SAF market or SAF technologies are insufficiently mature to support an obligation for aviation, but rather should serve as evidence that the lack of an LCFS obligation for aviation has steered producers toward more lucrative opportunities serving road transportation.

Thank you for the opportunity to comment on the proposed changes to the LCFS. SkyNRG applauds CARB staff for taking action to drive innovation and growth of low carbon fuel technologies. Through careful consideration of impacts of this rule change to a developing industry, we believe SAF can take the LCFS to new heights. We look forward to continuing the legacy of emissions reductions spurred on by this groundbreaking regulation.

Sincerely,

John Plaza

ENHANCING OPPORTUNITIES FOR INNOVATORS

February 19, 2024

Chair Randolph and Members of the Board
California Air Resources Board
1001 I St.
Sacramento, CA 95814

RE: AJW Comments on the Proposed Amendments to the Low Carbon Fuel Standard

Dear Chair Randolph and Members of the Board,

AJW appreciates the opportunity to submit comments on the proposed amendments to the Low Carbon Fuel Standard (LCFS). AJW applauds the California Air Resources Board (CARB) and is encouraged to see that the proposed amendments are designed to increase overall program stringency and set forth a blueprint to achieve 90% reduction in carbon intensity (CI) of California's transportation fuels by 2045. First and foremost, a strong carbon intensity target is critical to ensure that the LCFS continues to drive down greenhouse gas (GHG) emissions in the transportation sector and decrease the state's reliance on fossil-based fuels.

More specifically, AJW would like to provide the following comments on the Auto Acceleration Mechanism (AAM). Throughout 2023, AJW engaged in a stakeholder process to develop and socialize the concept of an acceleration mechanism – a self-adjusting tool that would complement existing mechanisms to avoid credit shortfalls, a strong 2030 CI target, and a one-time step-down in program stringency. An AAM would aim to keep innovation, investment, and emission reductions on track when there is sustained overperformance of the program. From that stakeholder process, AJW developed a white paper with recommendations for CARB on how to successfully design and implement the mechanism.[1] AJW is
156.1 pleased to see that much of what was proposed by CARB staff is aligned with the recommendations in our white paper and strongly supports the overall concept and inclusion of the mechanism into the LCFS. However, with the benefit of weighing and modeling the proposed design details against the 2030 target and step-down as proposed by staff, we are updating our recommendations on a few design elements.

As proposed in the draft regulation, the first year that the AAM could influence program stringency is 2028 (triggered from 2026 data), but a fundamental principle of the mechanism is to be able to respond to overperformance of the program in a timely manner. We have observed quick market reactions to CARB's Standardized Regulatory Impact Assessment (SRIA) and initial proposal. This stands at odds with the implicit year of waiting before the first proposed AAM assessment. The additional year that staff proposed is presumably designed to allow for the market to fully adjust to the new LCFS targets after implementation in 2025, but this stepped approach does not appear necessary with the immediacy of market response. Thus, **AJW recommends that CARB pull forward the date for triggering the AAM by one year.** In the event the cumulative credit bank continues to grow in 2025, in spite of the step-down and new compliance targets, we believe it is appropriate for a first assessment in 2026, with a change in
156.2 benchmark in 2027. In fact, 2025 is the most important year for CARB to consider, as it will be imperative to make any adjustments to the compliance target before an oversized credit bank deters further investment into alternative fuels and vehicles. Using this approach, the AAM could potentially be utilized in 2027 and 2029, which will yield more opportunities for potential emission reductions and still give

[1] AJW White Paper on Designing an Acceleration Mechanism. Submitted in response to CARB's May 23, 2023, LCFS Workshop. https://ww2.arb.ca.gov/form/public-comments/submissions/3701

ample lead time for deficit and credit generators to adjust their operations to anticipate a stricter compliance curve.

156.3 Additionally, AJW encourages CARB to reassess the proposed threshold when considering the credit bank to average quarterly deficit ratio formula, which is currently proposed at 3.0 (i.e., three quarters of credits in the credit bank). This, when combined with the threshold of 1.0 for the credit generation to deficit generation formula (i.e., credits are continuing to contribute to a growing cumulative bank), is an overly conservative proposal as it would not allow for the AAM to trigger in situations where there is general consensus on the overperformance of the program. For example, looking at recent LCFS history, this 3:1 ratio the AAM would not have been triggered even in 2022 despite most stakeholders observing that the LCFS was overperforming and needed adjustments to program stringency to course correct. After backcasting recent LCFS activity, **we are instead recommending the average quarterly deficit ratio should be 2.0.** The impact of this threshold would mean that the credit bank is able to cover one-half a year of deficits. Today, that would mean that credit production would need to fall by 50% to create that level of demand. Given this, a threshold of 2.0 appears ample, when taken in combination with the consideration of whether credits are continuing to outperform deficit generation.

Backcasting Recent LCFS Activity with CARB-Proposed AAM Triggers							
Year	Formula	Trigger	2018	2019	2020	2021	2022
Cumulative Credit Bank	(B)		8,918,202	8,439,052	8,343,187	9,568,451	15,393,990
Total Credits	(C)		11,310,472	14,934,921	15,364,400	20,186,741	26,871,733
Total Deficits	(D)		12,366,566	15,487,415	15,488,232	18,864,647	21,233,457
Credit Bank to Avg Quart Deficit	(B/ (0.25 x D)	>3.0	2.885	2.180	2.155	2.029	2.900
Annualized Credits to Deficits	(C/D)	>1.0	0.91	0.96	0.99	1.07	1.27

156.4 Lastly, AJW recommends increasing the size of the step-down. A 5% step-down is a good start at beginning to address the size of the cumulative credit bank, however, it does not go far enough. The cumulative credit bank is anticipated to increase its rate of growth throughout 2024 and a 5% step-down will not sufficiently address the problem considering current market conditions. Thus, as stated in previous AJW comment letters, **we encourage staff to increase the step-down to at least 7%** while staying within the boundaries of the existing environmental and economic analysis. Even though a 7% step-down will not completely resolve the problem of the cumulative credit bank, this one-time adjustment will set the program down a path of course correction – one where hopefully the AAM will not be required to make continuous adjustments.

AJW supports CARB's work to improve the LCFS and ensure its long-term viability. We encourage CARB staff to address the recommendations listed above and for the Board Members to adopt the finalized amendments. Doing so will accelerate technological innovations and investments in fuel decarbonization options, increase LCFS credit availability, and secure market stability for years to come.

Sincerely,

Mary Solecki

Questions/Comments to LCFS 2023 Amendment

Name: Tadashi Ogitsu
Affiliation: Lawrence Livermore National Laboratory
Title: Staff scientist, PhD in Materials Science

Disclaimer

Opinions expressed in this document are entirely my own and nothing to do my employer. This study was conducted exclusively during my personal time.

Questions/Comments:

I would like to hear the CARB's responses to the following questions and comments at the hearing on 3/21/2024.

In page SRIA – 16, "3. Fuel Pool Demand, d) Light-Duty Zero Emission Vehicles", it is stated that

Highlight is from commenter

"*By 2031, staff assumed that BEVs would no longer have a substantial range or **charging-time disadvantage** compared to gasoline-powered LDVs and would therefore achieve 100% of the ICE vehicle VMT*."

157.1

1. 5 min charging of 80kWh battery (size of battery used in long range BEVs such as Tesla Model 3/Y) requires 1MW even without considering Joule heating loss and if energy loss is taken into consideration, it will require 10MW electricity supply capacity with 90% energy loss (explained later).
   i. **Question 1-1**: Can CARB elaborate how charging time disadvantage is going to be resolved?
   ii. **Comment 1-1**: 90% loss means that the effective CI will be 10X of the CI of grid electricity, therefore, if the grid cannot achieve 1/10 of current CI by 2031, CO_2 emission from electricity used by BEVs will increase.
   iii. **Question 1-2:** Majority's adaptation of BEVs will require more than 1000 such DCFCs. 1000 of 10MW DCFC will require 10GW low CI on-demand electricity supply. Could CARB explain how are we going to realize this?
   iv. **Comment 1-2:** Solar and wind are NOT on-demand power supplies. Nuclear power plant is baseload (constant output). Therefore, significant amount of buffering capacity (temporal storage) is needed for our future low CI power supplies. DCFC must rely on such a buffer.
   v. **Question 1-3:** Could CARB explain what is the assumed buffering method to address intermittency of solar and wind or inflexibility of nuclear? How much does the solution cost per household?
   vi. **Comment 1-3:** Please keep in mind, $/kWh of stationary battery is about 100X of underground hydrogen storage.

2. LDV hydrogen fuel cell vehicles have been available from 2014 in California, which have always been capable of 5 min charging for 300+ mile driving range. I assume CARB is aware of this fact.
    i. **Question 2-1:** is CARB LCFS standard ***technology agnostic*** and focusing on decarbonizing transportation sector?
157.2
    ii. **Comment 2-1:** assuming the CARB's answer to 2-1 is yes (LCFS is technology agnostic) and considering the CARB's awareness on relevance of charging time and driving range for public acceptance, it is extremely puzzling that CARB assumes overwhelmingly higher rate of public acceptance of BEV over FCEV such as seen in Figures 3, 4, 10.
    iii. **Question 2-2:** could CARB elaborate *why there is no mentioning of LDV-FCEVs* in the section 3 Fuel Pool Demand, d) Light-Duty Zero Emission Vehicle (page 16)?

In the followings, I will provide information relevant to above questions and comments. In my view, these are the critical factors perhaps in the blind spot of CARB staffs.

1. Specification of DCFC necessary to achieve 5 min charging of a long range BEV

Currently, the industry leading long range BEVs can be represented by Tesla Model 3/Y long range models that use 80kWh battery. In order to charge 80kWh of electricity in 5 min, the DCFC must be able to provide at least 80 kWh x 60/5 = 960 kW, which is about 1MW. This does not include energy loss due to Joule heating. In the past, a Tesla expert informed me that current state of art Tesla Supercharger has very impressively low 6% energy loss to achieve one hour charging. In order to achieve 5 min charging, 12 times higher current needs to pass through the circuit. Assuming the resistance of circuit (DCFC and the BEV) is the same, the corresponding Joule heating loss becomes 144 times higher since Joule heating loss goes I^2R (current square multiplied by resistance). 144 x of 6 percent is 864%.

In order to reduce the Joule heating, resistance of the circuit, *R*, must be reduced significantly. I'm not aware of any conductor that offer orders of magnitude lower resistivity than copper. Therefore, I assume reducing *R* by 100x will require 100x larger diameter of cable. Or else, we will need supercoducting material which is affordable and does not consume significant amount of electricity to keep operational.

I must therefore conclude that 5 min charging of 80kWh battery in 2031 at DCFCs that are ubiquitously available for general public is extremely unlikely to take place..

The other possibilities: a significant improvement on the vehicle efficiency, in other words, significant reduction on the required size of battery. Factors of consideration: air drag (major source of loss on highway) and air conditioning (nonnegligible loss in cold winter/hot summer).

Air drag is proportional to (drag coefficient) x (cross sectional area) x velocity^2 . Unfortunately it is extremely unlikely that drag coefficient could be reduced by 100x. Needless to say the cross section of car cannot be reduce by order of magnitude since the driver and passengers need to fit into the car.

Air conditioning: it is said that about 20% of driving range will be reduced by using air conditioning when it is hot (90~100F) or cold (20-30F). In other words, 80% was used to move the BEV. Let's say the vehicle efficiency (moving) gets 100x efficient, we still use 0.2 x 80kWh = 16kWh for air conditioning. Unless battery consumption for air conditioning can be reduce by order(s) of magnetite, total vehicle efficiency cannot be improved that much.

2. Common misconception about the well-to-wheel efficiency of BEV and FCEV

It is often argued that the well-to-wheel efficiency of BEV is much higher than that of FCEV. This argument completely ignores the cost for necessary amount of storage to address intermittency of solar and wind. One can download the supply and demand time profile data in California from caiso.com and simulate how much storage may have been necessary if we are to eliminate fossil power plant by, for example, installing more solar. All what one has to do is integrate demand over one year (or multiple years), then adjust solar supply data in such a way that total demand matches with total supply. Then calculating cumulative loss/gain between supply and demand over the period will give you the ballpark estimate on the necessary storage.

Next is to estimate the cost of storage. This is very simple: look up $/kWh values of available storage solutions and multiply it with the necessary storage capacity. One may also consider the round trip efficiency (RTE). I usually use 0.4 for hydrogen and 0.8 for stationary battery. Then, we may normalize the cost for per-household (about 13M household in California). At last, we need to take the lifetime of such storage solutions to estimate how much all of us need to pay. I used 30 years for hydrogen underground storage and 10 years for stationary battery.

With this, one can estimate the cost/household/year for each storage solutions.

My conclusion was hydrogen underground storage will cost about one hundred dollar per household per year. Stationary battery will naturally cost more than two orders of magnitude higher than hydrogen underground storage, which is not affordable for majority.

Take home message: claimed high well-to-wheel efficiency of BEV (over FCEV) is ***<u>economically unattainable</u>*** with intermittent power sources such as solar/wind.

I had series of debates on this issue with Mr. Michael Liebreich, who popularize the notion that LDV-FCEV is inefficient compared to BEV therefore governments should not support H2 station deployment. I had pointed him out that the claimed high well-to-wheel efficiency of BEV is economically unattainable due to intermittency of solar and wind.

His response to my comment was overproduction.

I hope CARB staffs understand critical flaw in his argument. Overproduction means system waste either produced electricity or the production capacity *by design*. One cannot claim high well-to-wheel efficiency, while the underlying infrastructure is designed to waste significant portion of produced electricity or the production capacity. Hydrogen solution, while RTE (round trip efficiency) may be much lower, enable us to fill the supply-demand gap created by intermittency of solar and wind and/or inflexibility of nuclear (constant output) in an affordable way for majority.

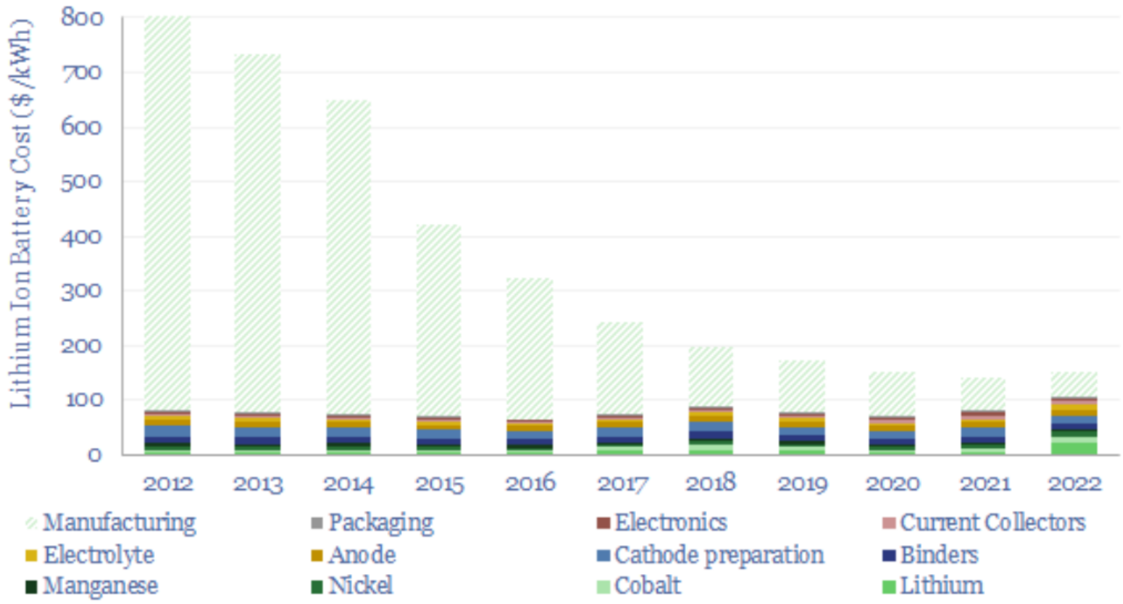
Can innovation bring the cost of battery down to resolve this issue?

Most likely no. The reason is the cost of material necessary for these storage solutions.

Amount of materials necessary for gas (or liquid) storage is proportional to the surface area (R^2), while that for battery is proportional to the volume (R^3). Therefore, for the limit of large storage size, gas storage offers greater economy than stationary battery as witness in about two order of magnitude difference in $/kWh values between hydrogen underground storage and stationary battery.

I also hear some people arguing mass production will reduce the cost of battery. Please remember, it is usually the process cost that could be reduced significantly by mass production. Material cost depends on accessibility and abundance of the chemical species. The material cost could be increased as the consequence of mass production (demand exceeds supply).

For instance, according to https://thundersaidenergy.com/2023/11/18/grid-scale-battery-costs-kw-or-kwh/, recent trend of cost breakdown looks as below. As you can see, manufacturing cost decreased significantly to the point that material cost became dominant. On the other hand, material cost has not come down (as expected). Therefore, I conclude that significant reduction of $/kWh value of stationary battery is very unlikely to take place.



Lithium ion battery costs breakdown between materials and manufacturing

Figure 1: Cost breakdown of battery from https://thundersaidenergy.com/2023/11/18/grid-scale-battery-costs-kw-or-kwh/

At last, I highly encourage the CARB staffs to revisit The Periodic Table and look for the combination of chemical species that could be used to store energy via electrochemical process. What are the abundance of such chemical species?

I hope you do not overlook the first candidate, hydrogen, which is the most abundant chemical species in the universe and is known to produce electricity via electrochemical process with oxygen (fuel cell). One can produce hydrogen out of water (electrolysis). These processes do not produce any harmful chemical species.

Lithium is after hydrogen and helium. Is there any reason to ignore hydrogen?

3. Business sustainability of DCFC and the area coverage of LDV-BEV

It is well known that 90% of charging of BEVs is done at home overnight. In other words, DCFC business market size will be less than 10% of the gas stations. This indicate that number of DCFC stations that is profitable will be about 10% of number of gas stations. Could the area coverage of LDV be kept in a similar level with the current gasoline car and gasoline stations?
We know that the area coverage can be retained with hydrogen fuel cell cars due to the quick fueling time and long driving range that are comparable to gas cars. LDV-FCEV will rely on hydrogen fueling stations so it is very likely that hydrogen fueling station business could simply replace gas stations.

20 February 2024

Subject: Comment Submittal on **Proposed Amendments to the Low Carbon Fuel Standard** as outlined in the Staff Report: Initial Statement of Reasons (ISOR), March 21, 2024

Audi of America

1950 Opportunity Way
Reston, VA 20190
+1 248 754-5000
www.audiusa.com

Audi of America (Audi) welcomes the opportunity to submit comments to CARB on the evolution of this important climate policy. California's Low Carbon Fuel Standard (LCFS) is a vital tool that uniquely leverages market incentives to drive reductions in Greenhouse Gas (GHG) emissions.

To maximize the potential of achieving this core environmental objective, the entities within the primary LCFS value chains, those that can indeed react to the market signal, need to have an explicit participatory role in the program. Program design should be aligned accordingly.

The LCFS can and should serve as a key mechanism in accelerating the transition to zero emissions technologies. Audi views the continued evolution of this fuels policy as vital to supporting our company's goal of completely transforming our vehicle portfolio to plug-in battery electric vehicles (BEVs) over the next decade. In fact, Audi launches its last new internal combustion engine vehicle in 2026. Thus, we are counting on programs like California's LCFS to increasingly leverage the market mechanism it created to support the transition to all-electric vehicles, particularly in the light duty segment which dominates the state's roadways.

What makes the LCFS policy particularly powerful is its ability to incentivize the *utilization* of zero-emission battery electric vehicles (i.e., more eVMT and more GHG reductions) and not just the initial sale of those vehicles.

Thus, an LCFS policy framework that facilitates automakers serving as LCFS base credit generators, alongside electric utilities, indeed provides that direct incentive that will drive further technology innovation, new consumer-facing programs, and further strengthen the market pull for deploying more BEVs, and more *utilization* of those BEVs, in the state of California.

Incentives are important!

In the LCFS ISOR, refenced in the above Subject line, CARB states, "The State is working to rapidly increase the numbers of zero-emission vehicles on the road…"

As was noted in the recent LA Times investigation by Russ Mitchell, demand for EVs from California's vehicle buyers is starting to show signs of weakening.[1] While Audi remains bullish on the long-term prospect of the BEV market here in California, purchase incentives, like that previously provided under the LCFS **Clean Fuels Reward (CFR)** program are becoming even *more* crucial to bringing in hesitant mainstream vehicle buyers into the BEV market. While there are no doubt multiple factors that influence consumer demand, there is ample evidence that purchase incentives drive increased consumer consideration in EVs and ultimately increased sales.

As was noted in the LA Times piece, "…federal incentives have become scarcer and harder to understand." This directly impacts consumer demand.
A reliable, simple, and widely available purchase incentive is sorely needed.
A restructured light-duty CFR would certainly help in this regard. Again,
gauging the need for an incentive against California's stated objective to,
"rapidly increase the number of zero emission vehicles on the road" points
158.1 towards a reconsideration of a light-duty CFR.

Automakers are uniquely well positioned to carry forward a revamped CFR that is much more effective, resilient to credit price fluctuations, and with dramatically lower overhead costs by virtue of our existing expertise in administering these sorts of programs. We look forward to working with CARB to revamp a future CFR that, as noted above, will be increasingly necessary to meet the challenge of achieving higher rates of EV adoption.

Stringency

Audi supports CARB's interest in exploring LCFS design elements that will
158.2 underpin a market incentivizing LCFS credit price. This is most directly and
favorably impacted by ensuring sufficient program stringency and we would
encourage CARB to consider increasing stringency mechanisms accordingly.

[1] https://www.latimes.com/environment/story/2024-02-15/falling-ev-sales-raise-worries-over-california-climate-plan

Cross-Subsidization

158.3 We would respectfully ask CARB to examine the principle of rate class cross-subsidization in the staff proposal; namely, to explore the validity of taking resources (LCFS credits) generated by and within the residential light-duty vehicle segment and transferring those assets over to another rate class (commercial) and different vehicle class altogether. This asset transfer should be examined both within the context of existing deposits of LCFS credits (and credit sales revenues) generated by residential light-duty EV charging as well as any future residential credit generation.

This takes on additional importance when examining the extent of the need to accelerate light-duty EV adoption, as CARB's staff note, "…with just over 20 years to transition from today's significant fossil fuel usage to a future of clean fuels and technology."

A reminder of First Principles

To enable the aforementioned rapid transition, the private sector must continue to be incentivized to innovate and improve both the customer-facing attributes of EVs as well as the core low-carbon "fuel" technology that sits at the core of an EV.

As CARB notes, the top-level objective of the LCFS program is, "…to decrease the carbon intensity of California's transportation fuel pool and provide an increasing range of low-carbon and renewable alternatives, which reduce petroleum dependency and achieve air quality benefits."[2] This is echoed by the Purpose statement of regulation itself, "…[to] reduce the full fuel-cycle, carbon intensity of the transportation fuel pool used in California,…"[3]

It is now abundantly clear that battery electric vehicles are the dominant technology pathway for the light duty segment in California[4] and the principal path for further advances and further decarbonization (more eVMT) depends on investments in new innovations in battery system design (chemistry, core format, thermal management, power electronics, etc.).

---

[2] https://ww2.arb.ca.gov/our-work/programs/low-carbon-fuel-standard
[3] https://ww2.arb.ca.gov/sites/default/files/2020-07/2020_lcfs_fro_oal-approved_unofficial_06302020.pdf
[4] https://www.energy.ca.gov/data-reports/energy-almanac/zero-emission-vehicle-and-infrastructure-statistics/new-zev-sales

In other words, the LCFS program offers the *potential* for a unique and increasingly powerful incentive to automakers to offer more (and more capable) EVs in California – to advance and accelerate the most foundational and "first principle" elements of the LCFS policy. LCFS base credit generation, alongside our electric utility partners, creates the additional market pull to accelerate these advances and deploy more EVs in the state.

Data and Methodology Validation

158.4 There is the additional benefit realized by CARB connected to the data submittals it requires of automakers to generate LCFS credits. Those data allow CARB to check and validate the methodology and algorithms it uses to award LCFS residential EV charging credits in the first place. Without automaker participation, those valuable data submittals would not be available. These data are widely recognized as vital to the program given the understanding that EV usage and charging behaviors continue to evolve rapidly.

Use of Credit Proceeds

In addition to the opportunity of launching a revamped CFR as described above, automakers will also be central to implementing other programs identified by CARB staff in the ISOR (and elsewhere) as important to supporting transportation electrification, such as, "smart" managed EV charging programs (including demand response), improvements in EV charging convenience and efficiency, Vehicle-to-Home and Vehicle-to-Grid technologies, approaches for mitigating battery degradation, etc. All of these programs have a clear and central role for automakers and thus justify a significant allocation of base credits to fund these activities alongside those allocated to the electric utilities for similar purposes.

158.5

The current structure, restricting automakers to Incremental Credit generation only, with the low and decreasing market value of those class of credits (along with the proposed increased costs to register those credits), will lead to automakers abandoning the LCFS program altogether.

158.6 Audi supports annual reporting to CARB around the use of LCFS credit proceeds by automakers commensurate with the requirements of other LCFS credit generators.

Conclusion

Audi again appreciates the opportunity to provide input into the proposed LCFS Amendments.

We view the program design choices CARB is considering not an “either/or” proposition, but rather, an opportunity to maximize program efficacy and decarbonizing potential. By aligning the intrinsic incentive that LCFS credit generation provides with the entities that sit directly within the core value chain of delivering the key enabling technologies.

This can be achieved by a considerate apportionment of base credit generation opportunities, combined with a sufficient program stringency and design that supports a robust credit market. This will allow CARB to realize the core environmental outcomes of the LCFS program while achieving its other stated program objectives.

In addition to the above comments, Audi of America supports the comments submitted by the Alliance for Transportation Innovation (AFAI).

Thank you again for the opportunity to comment on this important policy.

Sincerely,

W. Spencer Reeder
Director, Government Affairs & Sustainability
Audi of America, Inc.

Chair Lianne Randolph
California Air Resources Board ("CARB")
1001 I Street
Sacramento, CA 95814
Via Online Submission

Re: Comment on proposed LCFS Amendment

Dear Chair Randolph and CARB LCFS staff,

Weaver and Tidwell, L.L.P. ("Weaver") appreciates the opportunity to comment on the proposed amendment to the LCFS, as set forth in the ISOR dated December 19, 2023, and appended documents, including Appendix E: Purpose and Rationale for Low Carbon Fuel Standards Amendments (updated January 2, 2024), hereafter referred to as the "Proposed Amendment".

Originally founded in 1950, Weaver is a full- service public accounting firm offering assurance, tax and advisory services. The firm has six offices in California, seven in Texas, as well as offices in Washington, D.C., New York, Oregon, Louisiana, Oklahoma, and virtually. With more than 1,700 employees, Weaver is ranked among the top 35 public accounting firms in the U.S. by Inside Public Accounting.

Weaver's Energy Compliance Services ("ECS") group is dedicated to helping businesses navigate compliance with evolving regulations. Transportation fuels regulations governed by CARB, the U.S. EPA, Environment and Climate Change Canada, and other governing agencies are a substantial focus of the practice. We help companies of all sizes understand their regulatory requirements and maintain compliance. We have over 120 professionals within the ECS practice that have a wide variety of backgrounds, including accounting, business, chemistry, engineering and law.

Weaver is an LCFS verification body accredited by CARB and has two dozen accredited lead verifiers on staff. In addition to consulting and validation/verification services under the LCFS, we provide advisory services to many clients in connection with the U.S. Renewable Fuel Standard and to the fuels sector in general. For example, we assist many clients with EPA attest engagement services in the U.S. with over 200 clients served annually in this capacity. We are one of the select few firms approved by EPA to provide Quality Assurance Plan ("QAP") services, and we assist many clients with registration and engineering reviews. Weaver completes EPA-approved QAP procedures for over 150 renewable fuel facilities on a quarterly basis.

Weaver also maintains a related advisory practice focusing on the fuel sector, which provides consulting, reporting and EPA Moderated Transaction System (EMTS) assistance, and due diligence and compliance audit services to a broad-based array of clients, including major oil companies, independent refiners, biofuel and biogas producers, and product marketers, distributors, and importers.

Given our experience as an accounting firm and our in-depth knowledge of the LCFS, as well as our extensive experience in performing attest and QAP engagements, Weaver is well-qualified to provide comment on the validation and verification provisions of the LCFS.

Specifically, we comment here on the verification body/verifier rotation requirements set forth in §95500 (g) entitled "*Verification Body and Individual Verifier Rotation Requirements".* Subsection (g*)* currently requires a fuel pathway applicant to use a different verification body and individual verifier(s) to perform validation and verification services after six consecutive years of such services. However, our clients and other market participants have expressed to us that this provision is highly disruptive and expensive. We therefore recommend that, instead of requiring a change of verification body and individual verifiers after six years, CARB amend 95500 (g) as follows:

159.1 "(g) ***Lead Verifier and Independent Reviewer*** *Rotation Requirements.* An entity that is required to contract for validation or verification must not use the same **lead verifier or independent reviewer** to perform validation and verification services under this subarticle for a period of more than six consecutive years. [Emphasis added.]

The six-year period **for such lead verifier or independent reviewer begins on the execution date of the Notice of Verification Services for validation or verification services for the entity required to contract for such services under this subarticle and ends on the date the final verification statement for such entity is submitted for such validation or verification**. The six-year limit does not reset upon a change in ownership or operational control of the entity required to contract for validation or verification services. [Emphasis added.]

The entity may re-engage **a previous lead verifier or independent reviewer** only after three years, except in the case of a set-aside of a validation or verification statement as specified in section 95501. An entity required to contract for validation or verification services must, in time for the next verification, replace a verification body that has a suspended or revoked Executive Order pursuant to MRR section 95132(d), and included by reference in section 95502(a)." [Emphasis added.]

In support of our position, we refer to the rotation requirements for auditors contained in Chapter 11, Securities and Exchange Commission (SEC), § 210.2-01, Qualifications of accountants, of Title 17 of the U.S. Code of Federal Regulations (CFR), Commodities and Securities Exchanges. The mission of the SEC is three-fold: protecting investors, maintaining fair, orderly, and efficient markets, and facilitating capital formation. The first two are analogous to the purpose of the LCFS validation and verification requirements.

Like LCFS validations and verifications, SEC audits are typically accomplished by a team whereby you have a lead partner, Engagement Quality Reviewer, and team of accountants. Please note that "Section 210.2–01 is designed to ensure that auditors are qualified and independent of their audit clients both in fact and in appearance". While everyone in an accounting firm is required to be independent of SEC audit clients, lead partners are required to rotate off a client's auditing team after five years, not the entire firm. A "lead partner" for purposes of § 210.2-01 is defined as the "lead or coordinating audit partner having primary responsibility for the audit or review", and therefore occupies a role analogous to a LCFS lead verifier. This same five year rotation requirement applies to the Engagement Quality Reviewer, with this role being similar to that of an independent reviewer under the LCFS validation and verification requirements.

It is essential to the functioning of the U.S. system of capitalism that auditors are independent and are perceived to be independent. Therefore, if CARB were to adopt a rotation requirement analogous to the SEC's in its LCFS validation and verification provisions, it can be confident that verification bodies and individual verifiers will similarly be independent and be perceived to be independent in exercising their roles in the verification process.

Weaver appreciates this opportunity to comment on the proposed amendment to the LCFS. If you should have any questions, please feel free to contact Wade Watson at wade.watson@weaver.com or (832) 320-3262.

Weaver and Tidwell, L.L.P.

Ms. Rajinder Sahota
Deputy Executive Director – Climate Change and Research
California Air Resources Board
1001 I Street
Sacramento, CA 95812

RE: Proposed 2024 LCFS Amendments

Dear Ms Sahota,

Thank you for the opportunity to comment on the Proposed Low Carbon Fuel Standard Amendments, published on December 19, 2023. Camco is a developer and operator of low carbon fuel projects, with a focus on biogas to RNG and biogas to EV projects.

160.1 Camco supports the changes ARB have made from earlier regulatory text to remove deliverability requirements and crediting period renewals for biogas projects beginning before 2030. The proposals as previously drafted would have restricted the development and operation of projects producing biogas for use in the transportation sector. However, we are concerned about ARBs proposed 2030 deadline for biogas to CNG and EV projects which would only be able to account for their avoided emissions benefits until 2040. Provided there are no applicable regulations requiring methane capture on dairy and swine farms, digester projects should be eligible to receive credit for avoided emissions. As a leader in developing programs and policies to lower emissions, California's exclusion of these projects from 2030 and the requirement to physically deliver gas, sends a signal to other jurisdictions, which have launched or are in the process of launching LCFS programs, to exclude these types of projects as well.

160.2 We support the introduction of a credit true-up mechanism under 95488.10(b). For developers and operators of low CI fuel projects, the current regulatory language provides little flexibility to account for variability in project operations and feedstock supply and increases the administrative burden on regulators and operators by requiring repeated adjustments to a projects' CI score. For reasons outlined below, we would like to see the credit true-up concept extended to also include the periods between a project starting and receiving a provisional CI score and between a provisional CI score and certified CI score.

Project developers are seeing waiting times of between 18 and 24 months from project commencement to provisional CI approval. Even using book-and-claim this can result in a low-CI project foregoing a year's worth of LCFS credits. Allowing credit true-ups through the provisional and initial certification would reduce pressure on staff and developers to process applications and updates as quickly as possible and reduce uncertainty for project owners and developers and LCFS credit counterparties. ARBs penalty mechanism as proposed under 95486.1(g) would discourage projects from over

Camco International Group, Inc.

Castle Rock, Colorado 80104
Phone: 720-279-2408
www.camcorenewables.com

crediting and in the event a project over credited and was unable to surrender sufficient credits to match its over credited amount the credit buffer account could be used to ensure the program's environmental integrity.

If ARB does not agree with a true-up for projects undergoing provisional and initial certification we suggest that it considers doubling the book-and-claim period from three quarters to six quarters for projects that have received provisional pathways but have not yet received final certified pathways. Oregon, for example, permits electricity projects to use up to a six-quarter book-and-claim period.

160.3 Currently there is no temporary pathway for electricity generated from dairy or swine manure. The LCA inputs for this type of project are very similar to biomethane CNG and LNG from dairy and swine manure, which received a temporary pathway of -150 in the 2018 updates. As of January 2024, there were 24 dairy manure-to-electricity Tier 2 pathways with certified CIs of between -353 and -790. It should be possible for ARB staff to follow the methodology outlined in Appendix E: Purpose and Rational for LCFS Amendments, page 74 and determine a pathway of -330 gCO2/MJ for electricity from dairy and swine manure. Project owners commencing new manure to electricity projects may have to wait two years for provisional CI pathway approval resulting in significant lost revenues (see previous comment). Permitting these projects to use a temporary pathway while waiting would help to mitigate this impact, remove a disincentive to generate electricity versus CNG from animal waste and support the continued growth of the EV sector.

As always, we welcome the opportunity to have further dialogue with ARB staff on changes to the LCFS program so that it can continue to drive emissions reductions in California's transportation sector and provide a model for the country as a whole.

Sincerely,

Charles Purshouse
Vice President, Camco International Group, Inc.

Advanced Biofuels Canada
Biocarburants avancés Canada

February 20, 2024

California Air Resources Board
1001 I Street Sacramento, CA 95814

RE: Support for LCFS inclusion of jet fuel; suggestions for aligning with British Columbia's approach

Dear California Air Resources Board,

Advanced Biofuels Canada is the Canadian national trade association for advanced biofuels and renewable synthetic fuels. ABFC members produce a portfolio of liquid low-carbon fuels (including alternative jet fuels), sustainable feedstocks, and intermediary products. Our members operate over 34 billion litres of low carbon fuel production capacity globally and are significant suppliers to renewable and low carbon fuel regulations in Canada, the US, and worldwide. Many of our members have operations in both the United States and Canada.

Regarding the subject consultation:

162.1 **ABFC is strongly supportive of CARB's proposal to remove the exemption for intrastate fossil jet fuel use under the LCFS.** Including intrastate jet fuel as a debit-generating fuel under the regulation is an important step towards encouraging more Alternative Jet Fuel (AJF) use in California.

162.2 **ABFC suggests that California expand its ambition towards jet fuel and, to the extent possible, align with the approach enacted in British Columbia that (1) obligates all jet fuel sold under the regulation, (2) prescribes minimum volumetric AJF use requirements, and (3) prescribes carbon intensity (CI) reduction requirements for jet fuel.**

The British Columbia regulations containing the jet fuel requirements are located here: Order in Council 699/2023 (gov.bc.ca)

To summarize, British Columbia's updated LCFS statute:

- Was approved on December 11, 2023 and enacted on January 1, 2024.
- Requires 1% AJF by volume in 2028, 2% in 2029, 3% in 2030.
- Requires a 2% CI reduction from a fossil jet baseline of 88.83 gC02e/MJ in 2026, 4% in 2027, 6% in 2028, 8% in 2029, and 10% in 2030.

We note that the CI reduction requirements for jet fuel are lower than that of gasoline and diesel fuels. Gasoline has a 5% renewable content requirement and a 30% CI reduction requirement by 2030 (below 2010 levels); diesel has a 4% renewable content requirement and is subject to the same 30% CI reduction requirement by 2030. (We note that the CI reduction requirements for any fuel can be met by overcompliance in other fuel types).

162.3 **Addressing aviation emissions should be a strong area of regional collaboration under the Pacific Coast Collaborative.** ABFC recognizes that California and British Columbia are members of the Pacific Coast Collaborative[1] and are leading LCFS jurisdictions in North America. Aligning on clear and stringent approaches to addressing emissions from petroleum jet fuel is an opportune area of continued policy collaboration.

Thank you for this opportunity to provide comments.

Yours truly,

Advanced Biofuels Canada

[1] The Pacific Coast Collaborative, British Columbia, Washington, Oregon, California, and the cities of Vancouver, Seattle, Portland, San Francisco, Oakland, and Los Angeles are working together to build the low carbon economy of the future. We share ambitious goals for reducing greenhouse gas emissions at least 80 percent by 2050.

By connecting jurisdictions at the regional level — and connecting states and provinces with cities in the region — the Pacific Coast Collaborative (PCC) facilitates collaboration on issues that cross borders and jurisdictional boundaries, such as grid integration, a comprehensive electric vehicle charging network, and responding to ocean acidification. We pool policy and technical expertise, share strategies to curb greenhouse gas emissions while growing the economy, and work together to implement them. Dear Ms. Sahota:

Re: Crop-based Fuels Guardrails

Chevron appreciates the opportunity to review and comment on the subject Low Carbon Fuel Standard rulemaking proposal.

Chevron is a major refiner and marketer of petroleum products and renewable fuels in the state of California and a regulated party under the Low Carbon Fuel Standard (LCFS). Chevron, through its Renewable Energy Group subsidiary, is an international producer of lower carbon intensity fuels with a global integrated procurement, distribution, and logistics network and 11 biorefineries in the U.S. and Europe. to help California reduce transportation greenhouse gas emissions particularly in the hard-to-electrify heavy-duty sectors. As the second largest domestic producer of biodiesel and renewable diesel, our company uses waste fats, oils, and greases as well as virgin crop-based feedstocks.

Chevron is submitting multiple letters on key topics under the 2024 LCFS rulemaking. Following are our comments on the crop-based fuels guardrails proposed.

Key Messages

- Eligibility for RFS credit generation is a reliable alternative to the proposed LCFS sustainability criteria.
- Data related to land use in the United States contradicts the theoretical concerns voiced by advocates for a crop-based fuels cap.
- Indirect land use factors are already in place to address theoretical concerns about international impacts.

A Cap on Crop-based Fuels is Not Needed

164.1 Chevron appreciates that the proposal does not seek to implement an unnecessary and over-reaching cap on crop-based fuels. There are effective measures already in place that provide for proper balance in feedstock usage. These measures include the federal Renewable Fuel Standard (RFS) and the new tax incentive structure in the Inflation Reduction Act, that will transition the federal biodiesel tax credit from the existing $1/gal for all eligible biodiesel to a sliding scale incentive based on the fuel's carbon intensity. Further, the LCFS already provides appropriate 'guardrails' through life cycle analysis that incorporates direct and indirect land use

Chevron Products Company
A Division of Chevron U.S.A., Inc.

dgilstrap@chevron.com

change (LUC) factors in products' carbon intensity (CI) scores. These LUC scores provide a conservative view of the potential impact from the use of agricultural feedstocks in fuel production. Illustrating the conservative nature of these factors, Figure 1 below shows that potential land-use change impacts have been declining for decades.

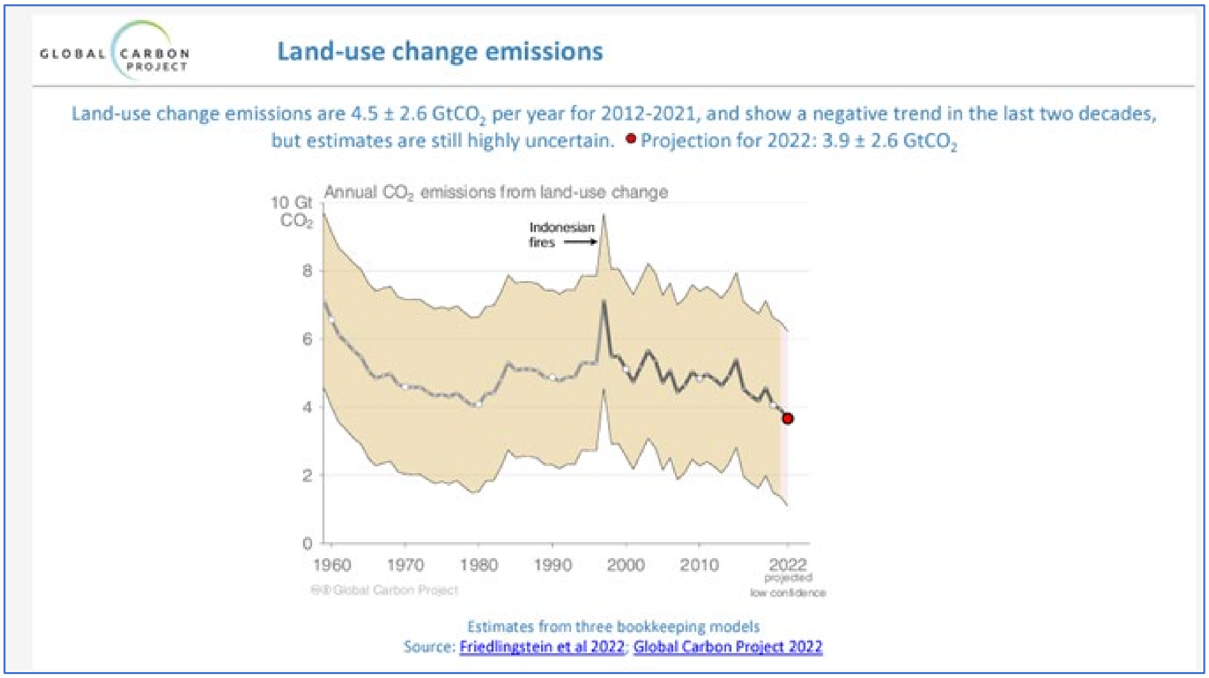

Figure 1, [1]

<u>The RFS Includes Traceability Requirements</u>

It is important to note that the federal Renewable Fuel Standard (RFS) offers safeguards against potential adverse effects owing to land use change. Efforts to include similar traceability
164.1 cont requirements in the LCFS would be duplicative of federal requirements. The RFS requires that land must have been in productive use as of December 19, 2007, to demonstrate that land use has not changed because of the RFS. Biofuel producers sourcing crop-based feedstock in the U.S. and Canada are not required to submit traceability documentation to the point of origin so long as the total crop acreage in a given year does not exceed total acreage determined in 2007 (the first year of compliance for the RFS). In setting the annual renewable volume obligations, U.S. Environmental Protection Administration (EPA), in collaboration with the U.S. Department of Agriculture (USDA), determines the amount of crop acres each year. In no year since the RFS was established has crop acreage exceeded that of 2007. The RFS requires "map and track" traceability requirements for biofuel producers sourcing crop-based feedstocks cultivated outside of the U.S. and Canada. Crop-based biofuels that participate in the LCFS also participate in the RFS and would be subject to federal traceability.

Our Family of Brands
Chevron Products Company
A Division of Chevron U.S.A., Inc.
6001 Bollinger Canyon Rd, San Ramon, CA 94583
925 842 8903
dgilstrap@chevron.com

164.3 In addition, the RFS prohibits the use of certain feedstocks and fuels derived from these feedstocks from participating in the program. The RFS defines what feedstocks may be considered sources of renewable biomass and what fuels derived from renewable biomass may be eligible to participate. Through this process, fuels derived from certain feedstocks, such as palm oil and palm oil derivatives, are ineligible to generate biomass-based diesel RINs. Relying on the federal definition of renewable biomass, and the eligibility of fuels derived from these feedstocks to participate in the program, would preclude the need for an exhaustive list of eligible feedstocks under the LCFS program.

If CARB implements any new guardrails, then to avoid conflicts with the national program, any fuels participating in the RFS program should be exempted.

Specified Source Feedstock Attestations Are Unnecessary

Both the RFS and LCFS currently require significant documentation for feedstock sourcing, including detailed chain-of-custody records, in addition to third-party audits. The RFS specifically requires point of origin documentation for these feedstocks. Additional attestation requirements are duplicative.

164.4 As written, these new requirements have the potential to add considerable burden to feedstock supply chains. It is not clear which feedstock producers, distributors, or users would be required to maintain attestations or which operating conditions require them. It should also be made clear that this would be a recordkeeping requirement only and not akin to a product transfer document. We urge CARB to forego these added requirements or at least work more closely with feedstock producers and suppliers to clarify the purpose and nature of these new requirements.

U.S. Crop Acreage is Declining

There is little evidence that biofuels policies are linked with land use change in the United States. Recent USDA research indicates that total crop acreage has declined since 2007, illustrating that land use change owing to biofuel production is not occurring. Modest expansion of corn and soybean acres has been facilitated by the conversion of hay and wheat acres and land coming out of the conservation reserve program.[2]

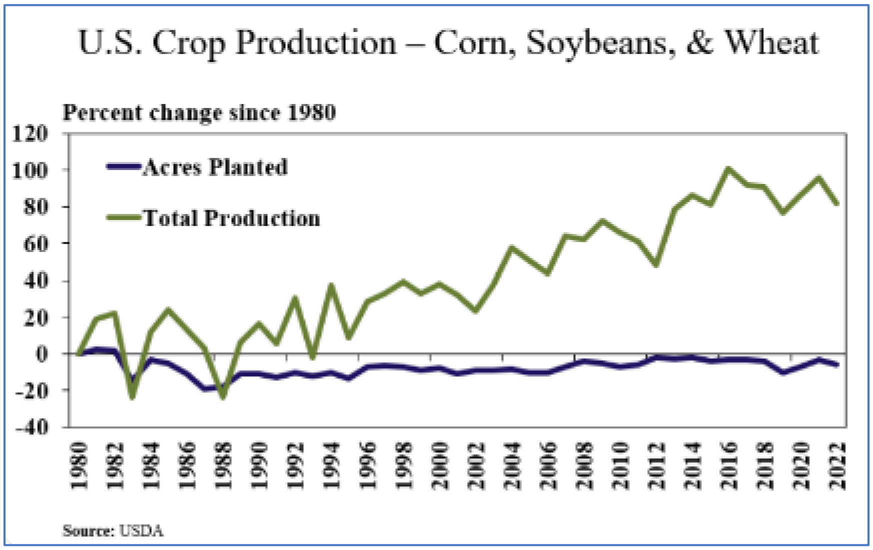

Figure 2 [3]

The 2022 Census of Agriculture recently released by USDA concludes that the U.S. has lost 21 million acres between 2017 and 2022 and lost 63 million acres since 1997. According to America's Farmland Trust, urbanization is a leading cause of lost crop acreage in the U.S. [4] Meanwhile, yields from U.S. soybean cultivation (the leading crop-based feedstock used to produce biomass-based diesel) have increased, indicating that more crops may be produced for a given area of land. According to the USDA, soybean yields, measured by bushels per acre, expanded by 35% between 1989 and 2020.[5] In summary, the United States grows more crops on less land every year.

dgilstrap@chevron.com

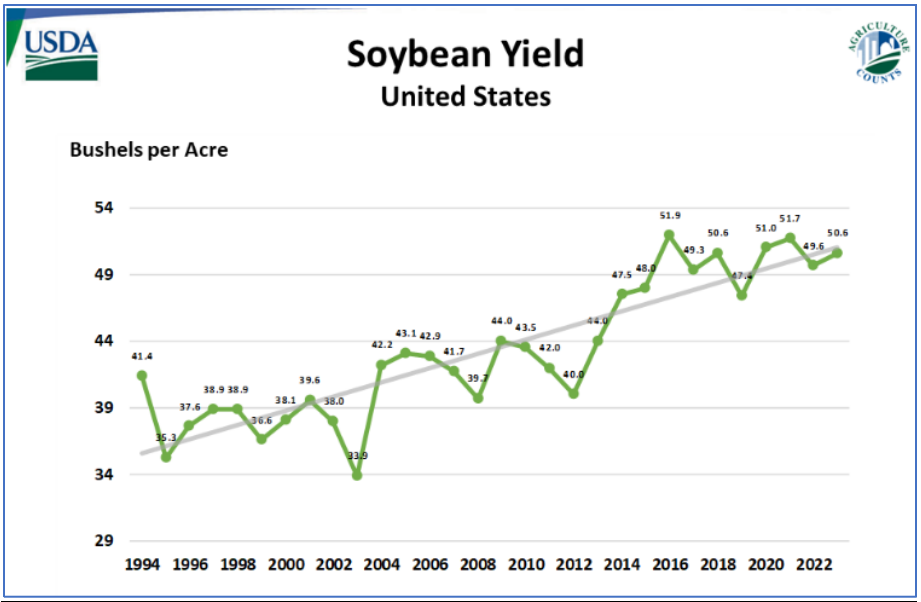

Figure 5, [8]

<u>Conclusion</u>

Additional traceability requirements are unnecessary under the LCFS program. As nearly all crop-based biofuels produced or imported into the U.S. participate in the federal RFS program, the aggregate compliance approach under the RFS offers effective assurance that biofuels policy is not linked to land use change. This approach also requires traceability requirements for feedstock sourced outside of the U.S. and Canada and imported biofuels produced from these feedstocks. Data provided in these comments demonstrates that crop land in the U.S. is declining owing largely to urbanization while yields on many crops are expanding. Thanks to agricultural innovations and smart farming practices we can grow more feedstocks on a diminishing amount of land to meet both biofuel and food demands.

Sincerely,

Sacramento, CA 95814

Dear Ms. Sahota:

Re: Technical Amendments

Chevron appreciates the opportunity to review and comment on the subject Low Carbon Fuel Standard rulemaking proposal.

Chevron is a major refiner and marketer of petroleum products and renewable fuels in the state of California and a regulated party under the Low Carbon Fuel Standard (LCFS). Chevron is also an international producer of lower carbon intensity fuels with a global integrated procurement, distribution, and logistics network and 11 biorefineries in the U.S. and Europe.

Chevron is submitting multiple letters on key topics under the 2024 LCFS rulemaking. Following are our comments on the technical amendments proposed.

Key Messages

- The Automatic Acceleration Mechanism (AAM) should not act as a substitute for future rulemakings.
- The pathway true up language does not address fundamental process issues with fuel pathway applications.
- Sunsetting project-related credits runs counter to the goals of the LCFS.

Periodic Rulemakings Are Necessary to the Health of the LCFS

165.1 Understanding that CARB is introducing the AAM to enable the LCFS to adjust more rapidly to strong performance, it is important that CARB continues to conduct rulemaking's every few years to allow technical adjustments in the recognition of improvements and modeling. Since the original proposal for rulemaking changes in 2022, there have been several legislative bills and executive orders passed affecting the transportation market in California alone, not to mention the hundreds of policy proposals made nationally and internationally. The assumptions made by CARB regarding the future of the transportation market, including both the vehicle market and fueling, should be continually reviewed. It would also be valuable to establish more frequent stakeholder engagement to hear concerns and recommendations well ahead of preparing for the next rulemaking.

The Credit True Up Language Needs Adjustment

Chevron supports the addition of true up language under §95488.10(b) as a means of recognizing demonstrated carbon intensity reduction. However, this language fails to address the extended period that often occurs between approval of a temporary pathway for a facility and the approval of a provisional pathway. Currently, it often takes several months or even years to move from temporary status to an approved provisional pathway. Fuel Pathway Reports are not required until a provisional pathway has been approved. Because the true up language was written so adjustments are only made after verification of an annual pathway report, the loss of credits incurred during extended operation under a temporary pathway is not addressed.

CARB's public comments on this topic indicate that it was not CARB's intention to leave the temporary pathway period out of the True Up process. This unintentional oversight can be remedied with small changes to the new language (see below). CARB may prefer to include separate equations for the two true up types as well. It would also be appropriate to replace the word "may" with "shall" in the first sentence.

165.2

(a) Credit True Up after Annual Verification or Application Validation. Beginning with the 2025 annual Fuel Pathway Report data reporting year, the Executive Officer ~~may~~ shall perform credit true up for a fuel pathway that has a lower verified operational CI upon receiving a positive or qualified positive verification statement for the associated annual fuel pathway report and quarterly fuel transactions reports, notwithstanding the prohibition on retroactive credit generation in section 95486(a)(2). A true up will also be performed for provisional pathway applications that receive a positive or qualified positive validation report. To implement this true up, the Executive Officer will calculate an equivalent number of credits representing the difference between the reported CI and the verified or validated operational CI from annual Fuel Pathway Reports and Provisional Pathway Applications for each fuel pathway code reported with non-liquid transaction types and with the following liquid fuel transaction types "Production in California," "Production for Import," and "Import" during a compliance year, and place those credits in the account of each appropriate fuel reporting entity after August 31 for the prior compliance year. For true ups from temporary pathways to provisional pathways, the true up shall apply to all quarters reported since the first approval of the temporary pathway. The credits will be calculated according to the following equation:

Process Issues Still Remain

While the true up language addresses a major symptom of the extended time it takes to approve fuel pathways, there are several procedural changes needed. CARB considers exportability of the LCFS to other jurisdictions to be a critical goal. Unfortunately, the complexity of the LCFS and the resources required to support the program are frequently cited by states reluctant to implement similar programs. Fuel pathway applications are one of the most resource-intensive elements, involving a significant number of handoffs between parties and considerable delays with each step. Considerable time could be saved if CARB's completeness
165.3 review and duplicative engineering review were eliminated. Applicants could have their pathway materials validated prior to submittal to CARB and the CARB-approved verifiers should be trusted to do the bulk of the analysis needed to ensure accuracy and completeness. We urge CARB to conduct a comprehensive review of the pathway application process with producers to

look for opportunities for streamlining, including measures that emphasize third-party review of applications. CARB staff are currently over-burdened, and certifying third-party engineering firms to review and endorse pathway applications would not only free up constrained staff resources, but also allow for the work to adapt to the growth rate of low-carbon industries.

Project-Related Credits Encourage Real GHG Reduction

165.4 Chevron opposes the phaseout of project-related credits proposed in this rulemaking. This is a counterproductive approach to targeting greenhouse gas reduction in transportation. While recognizing that reduced reliance on fossil fuels is a stated goal of the state, eliminating recognition of emission reductions in the production of those fuels while still part of the transportation fuel mix misses an opportunity to achieve real incremental change during the transition. Emission reductions today have a cumulative effect that should not be discouraged. Further, project-related crediting has not presented a threat to alternative fuel growth since its introduction but has incentivized several projects explicitly focused on emissions reduction.

The Proposed Penalties for CI Variations are Extreme

165.5 CARB has proposed to quadruple the penalization of carbon intensity scores that exceed the previously approved level. The language proposed makes no allowance for unplanned events that may impact a facility's score and would penalize good-faith operations that happen to see moderate changes in energy inputs and outputs. The LCFS already contains provisions to adjust credit balances based on such exceedances and CARB has the authority to pursue enforcement actions should a producer's actions demonstrate irresponsible behavior or ill intent. The proposed language seems intended to punish good actors for unplanned impacts, given that CARB already has sufficient authority to take action against bad actors.

Further Improvements to Verification Procedures Are Encouraged

165.6 CARB has proposed to allow credit generators for electric vehicle charging to forego site visits following a positive or qualified positive verification result. This is a disproportionate allowance given to a single credit source. CARB should extend this same allowance to all producers who receive a positive or qualified positive result. Now that the LCFS has several years of verification history, such a change is warranted. This is particularly true given the limited number of available verification firms and the growing number of LCFS and Cap-and-Trade style programs in place. This is another critical factor in the exportability of the program.

165.7 Limited rotation requirements for verifiers would also improve the flexibility of the LCFS. The LCFS already contains conflict of interest criteria that exceed those of other programs. We believe the rotation requirement to be unnecessary. Absent removal of the requirement, we recommend that CARB provides an exemption for CPA firms that provide verification services. Such firms are subject to considerable licensing requirements that exceed the independence goals of the LCFS. This would reduce the burden on regulated parties and encourage more firms to apply for CARB certification.

Thank you for the opportunity to comment on these matters. If you have any questions regarding our comments, please contact me at (925) 842-8903 or DGilstrap@chevron.com.

Subject	Concerns Regarding LCFS Eligibility and Claims by the Phillips 66 and Marath

Comment

From: Charles Davidson, Sunflower Alliance and the Rodeo Citizens Association. Hercules, CA
To: California Air Resources Board (CARB)
Date: February 20, 2024
Re: Concerns Regarding LCFS Eligibility and Claims by the Rodeo Phillips 66 and Martinez Marathon Refineries

Dear Chair Liane Randolph, CARB Members, and Hon. Dr. Steven Cliff,

I write to express urgent concerns about claims made by the Phillips 66 San Francisco Refinery in Rodeo and the Martinez Marathon Refining Company regarding their renewable diesel projects' eligibility under CARB's Low Carbon Fuel Standard (LCFS) Their claims misrepresent the eligibility criteria and carbon greenhouse gas footprint requirements of renewable diesel, but als exploit regulatory loopholes, potentially violating CARB regulations. Specifically, these LCFS violations regard both the use of virgin food oil non-waste feedstock for renewable diesel ar the fact that renewable diesel refining is profoundly energy intensive.

Existing lax GHG auditing by CARB, allows the refineries to misuse generous State and Federal low-carbon subsidies for projects that are financially dependent on using unearned LCFS certifications. For LCFS-accredited CO2 greenhouse gas reduction projects for renewable diesel, there is an urgent need for rigorous guardrails and pre- and post-project per barrel GHG auditing.

KEY ISSUES:
1.   Misallocation of LCFS Exemptions: Both refineries are inappropriately claiming LCFS tailpipe GHG exemption allowances fo renewable diesel from virgin food oils, traditionally reserved for waste-based feedstocks. Tailpipe CO2 emissions from fuel combustic represents 75% of total lifecycle GHGs, whether from renewable diesel or petroleum diesel. Removing tailpipe GHG emissions from LCFS GHG accounting for virgin food oil feedstock, promotes a massive, unjust food-to-fuels conversion pipeline. According to CARB's own documents, tailpipe CO2 exemption allowances should onl be reserved for rendered waste fats, oils and greases (ie, FOGs), not virgin food oils, because:

The CO2 emitted from vehicles during [used cooking oil] biofuel combustion is considered carbon neutral...as the carbon released was uptaken from the atmosphere within a short timeframe by the plant that produced the oil. [A. Low Carbon Fuel Standards (LCFS) p.19. CARB.
https://ww2.arb.ca.gov/sites/default/files/2020-09/basics-notes.pd

2. Lack of Carbon Intensity Reduction Evidence: There is no substantial evidence to demonstrate a reduction in carbon intensit per barrel of renewable diesel produced (compared to the pre-project petroleum baseline). Instead, both project's Environmental Impact Reports (EIRs) clearly demonstrate a large (post-project) increase in per barrel hydrogen production and the resultant large increase in per barrel GHG emissions. (1)

3. Inadequate CARB Oversight: The refineries' claims have been locally approved without sufficient scrutiny, despite public comment on these matters. The mere fact of CARB not auditing these GHG-related discrepancies in LCFS qualification scoring, highlight critical oversights in CARB's lifecycle GHG assessment capabilitie for renewable diesel projects dependent on substantial GHG-reduction subsidies.

IMPLICATIONS:
The Phillips 66 Rodeo Renewed Project and Marathon's Martinez Renewable Fuels Project, being among the largest hydrogen-based renewable diesel initiatives globally, involve significant financial and reputational stakes. Yet, both refineries' environmental claims stand on shaky ground, with potential loopholes allowing continued use of high-emission petroleum-refining processes.

What has been lost amongst the public promotion of renewable diese and the Rodeo Renewed Project, is that Phillips 66's Environmenta Impact Report maintains a little-known backdoor loophole that wil allow the refinery to continue to use their high GHG-emitting, massive bottom-of-the-barrel petroleum-refining Delayed Coker complex.

RECOMMENDATIONS:
Reevaluate LCFS Eligibility: CARB must closely examine and rectif

the misapplication of LCFS exemptions for high-GHG virgin food oil-sourced renewable diesel, that is extremely expensive, requir subsidies and always has critical supply constraints that make its unrestricted use for transportation fuel a potential national security issue

Implement Rigorous GHG Accounting: It's imperative to introduce stringent, project-specific GHG accounting, hydrogen accounting ar auditing measures to ensure the veracity of claimed environmental benefits and prevent greenwashing.

Promote Transparency and Sustainability: By addressing these issues, CARB can reinforce its commitment to environmental stewardship and truly sustainable energy solutions.
I trust CARB will take these concerns seriously, ensuring that LC certifications and subsidies genuinely contribute to reducing GHG emissions and advancing sustainable practices.

Sincerely,

Charles Davidson

PS: FOOTNOTES
1) INCREASE IN REFINERY-LEVEL CO2 GHG EMISSIONS PER BARREL:
% Increase, estimated based on EIR-provided information, relative increase from petroleum baseline, ie, refinery-wide, yearly Mt CO divided by yearly product amount. (Mt CO2; million tons of CO2e GHGs).

Phillips 66: ~54-76% (relative increase from baseline) -- (2.147 / 2.171 Mt CO2 = 0.99) ÷ [(67/105 bpd = 0.64)-to-(67/120K(capacity) bpd = 0.56) = ~ (1.54-to-1.76)/1.00
Marathon: ~77% (relative increase from baseline) -- (2.169 / 1.14 MtCO2= 0.53) ÷ (48K / 160K(capacity) bpd = 0.3) = 0.53 / 0.3 = ~ 1.77/1.00

LIMITATION OF RENDERED WASTE FEEDSTOCK SUPPLY: By 2030, the combined renewable diesel feedstock needs of Phillips 66 and Marathon, alone, will be 97.3 % of CARB's projected amount of tot California waste oil (FOG) feedstock available, until 2045 (neith including, nor considering, CARB's ambitious SAF aviation target goals).

CONSEQUENCES OF THE ABOVE LIMITATIONS: If the renewable diesel fr only the Phillips 66 and Marathon were combined, ~ 43% of ALL US soybeans would go to renewable diesel (or fungible edible food-quality alternatives, IF there were no waste FOGs used in their manufacture). This would equal an area planted entirely wit soybeans, row-by-row, the size of the State of Michigan planted border-to-border. "To produce 100 percent of 2022 US diesel fuel consumption in the transportation sector would require more than 160 million metric tons (MMT) of feedstock, which is 10 times US production of vegetable oils in 2022 or 80 percent of global vegetable oil production in 2022" Everything You Wanted to Know About Biodiesel and Renewable Diesel. (Jan. 10, 2024) The Union o Concerned Scientists.
https://blog.ucsusa.org/jeremy-martin/all-about-biodiesel-and-ren

SUPPLY INSTABILITY EXACERBATING THE ABOVE LIMITATIONS: Foreign sources of soybeans have profoundly decreased since the war in th Ukraine began and most recently, because the collapse of soybean production in Argentina (a major global soybean producer) due to drought. Specifically, noting that "in the 2022/23 season, Argentina had a historical crop failure caused by hot, dry conditions enhanced by a third consecutive La Niña. The USDA estimated Argentina's 2022/23 production at 25 million metric ton the smallest since 1999/00, with a 43% drop from the previous yea Local sources such as the Buenos Aires Grains Exchange went even lower, putting last year's production at 21 million metric tons." Beginning over one year before the invasion of Ukraine and since, the rate of inflation for global virgin food oils has increase at faster rate than all other major food items.

In stating their reasons for limiting renewable diesel production the Union of Concerned scientists state the following need "to be realistic about where they come from, and limit feedstocks to sustainable resources used at a reasonable scale to avoid turning helpful tool into a harmful dead end. The realistic potential for biofuel conversions is quite small because of the limited availability of suitable feedstocks. Exaggerated hype about potential for refinery conversions to biofuel production amounts greenwashing that distracts from more scalable solutions."
[Everything You Wanted to Know About Biodiesel and Renewable

Diesel. Also, see: The overlooked hub of South American: New Trase data on Argentina's soy supply chain highlights how indirect soy supply in South America could be hiding deforestation in global supply chains. Soy. (Aug. 11. 2022) https://trase.earth/insights/argentina-the-overlooked-hub-of-south

SUMMARY: Virgin food oil supply is becoming increasingly limited for various geopolitical, climate change, market structure and other reasons. The first step towards limiting the misuse of valuable virgin food resources is limiting their being misused for LCFS accreditation and government subsidies. The method to achieve LCFS truthfulness would be a loophole-free auditing of lifecycle CO2 GHGs for renewable diesel, on a per barrel basis with the full accounting of hydrogen production metrics and tailpipe emissions.

Att.: **California Air Resources Board (CARB)**
Topic: **Written comment to the *"Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments"***

February 20, 2024

Nel Hydrogen (NEL) appreciates the opportunity to provide input to the CARB on the *"Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments"* (LCFS)[1].

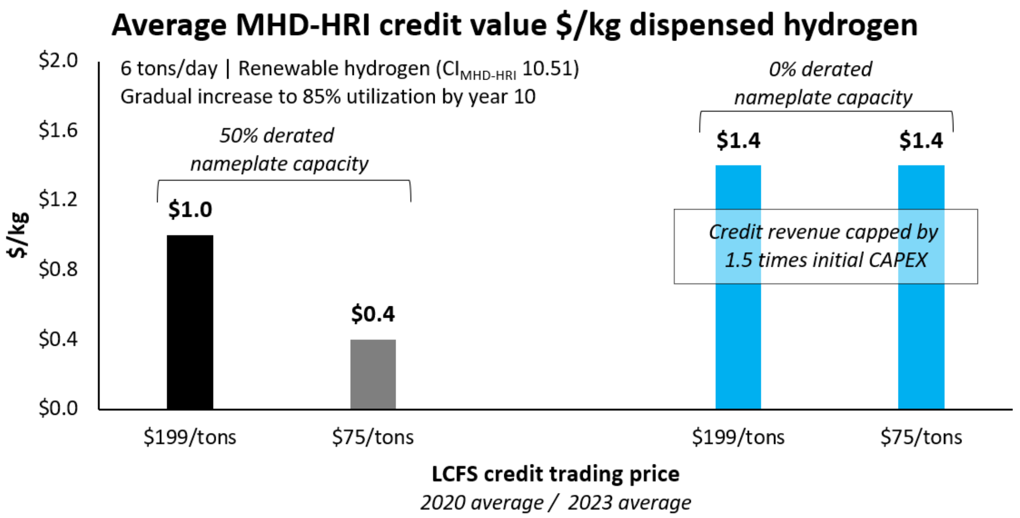
NEL is a leading manufacturer of hydrogen production and fueling equipment and have delivered equipment and provides services to multiple stations in California offering fueling to both Light Duty Vehicles (LDV) and Heavy Duty Vehicles (HDV) on a daily basis.

Foremost NEL would like to complement the CARB for proposing inclusion of both Medium and Heavy Duty Vehicles (MHD) in the LCFS regulation, in addition to the current LDVs only.

Whereas the CARB proposed inclusion of MHD into the LCFS[2] provides a good basis – NEL would like to convey some concerns regarding the following proposed new mechanisms:

167.1
- 50% derating of Nameplate capacity for Shared MHD-HRI stations
- Capping of cumulative credit value at 1.5 times initial capital expenditure.
- Shortening of Crediting Period from 15 years to 10 years.

The impact of the above mechanisms will significantly reduce the achievable credit value per kg hydrogen dispensed, as illustrated in the graph below.



The graph shows calculations of MHD-HRI credit value per kg hydrogen dispensed for a 6 tons/day Shared MHD-HRI station using renewable hydrogen. The average LCFS trading price during 2020 of $199/tons[3] and the average during 2023 of $75/kg are used as they represent the all-time high and low during the past 10 years. Station is assumed operated for 10 years, and with a gradual annual increase of utilization reaching 85% by year 10.

[1] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/lcfs_notice.pdf
[2] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/appa-2.pdf
[3] Based on LCFS credit trading prices as reported on www.arb.ca.gov/fuels/lcfs/credit/lrtcreditreports.htm

Nel Hydrogen
2389 Verna Court
San Leandro, CA 94577
E info@nelhydrogen.com
W www.nelhydrogen.com

167.1 cont The 50% derating of Nameplate capacity results in an average credit value of only $0.4 - $1.0 per kg of hydrogen dispensed during the 10 years Crediting Period.

Without derating of the capacity, the average credit value would be $1.4/kg, almost regardless of the credit trading price, as the value is capped by the cumulative credit revenue limit of 1.5 times the initial capital expense for the MHD-HRI station.

In 2020 a California Energy Commission report[4] assessed that an average LCFS credit value of ~$3/kg in 2030 ($150/tons CI=35) would bring hydrogen dispensed costs within the range of $6-8/kg required for gasoline price parity in LDVs.

However, achieving diesel price parity for MHD vehicles will require an even lower cost of hydrogen dispensed, likely in the range of $4-5/kg. Achieving MHD diesel price parity in 2030 would thus require an LCFS credit value higher than the $3/kg sufficient for LDVs.

As shown in the credit value calculations above, the cap on cumulative credit revenue on 1.5 times the initial CAPEX indirectly limits the maximum credit value to only $1.4/kg – and the 50% derating reduces this even further down to between $0.4 to $1/kg. The proposed 10 years Crediting Period, compared to the current 15 years, also reduces the overall credit value generated.

As a result, the achievable credit value $/kg will most likely not be sufficient for enabling MHD-HRI stations to achieve diesel price parity by 2030.

According to the LCFS amendment Appendix E[5] the CARB rationale for the 1.5 times CAPEX limit, 10 years crediting period and the derating of capacity, is to incentivize a sufficient number of stations to accommodate anticipated MHD hydrogen fuel demand.

Deployment of sufficient number of stations is definitely needed to accommodate MHD vehicle deployments. However, if the potential LCFS credit value does not enable diesel price parity, this will negatively impact the attractiveness of MHD vehicles and may challenge the actual vehicle deployments and emission reductions achieved.

NEL would therefore encourage CARB to:

- Consider removing the 50% Nameplate Capacity derating for Shared MHD-HRI stations
- Consider either removing or increasing the cumulative credit value cap of 1.5 times initial capital expenditure
- Consider keeping the 15 years Crediting Period as in the current LCFS regulation
- Aim of the above should be to enable credit values ($/kg) where diesel price parity is within reach for MHD-HRI stations

Thank you for considering the input from NEL.

RE: Roeslein Alternative Energy Comments on the Proposed Amendments to the Low Carbon Fuel Standard

Dear Chair Randolph and Members of the Board,

Roeslein Alternative Energy (RAE) appreciates the opportunity to comment on the proposed amendments to the Low Carbon Fuel Standard (LCFS). Biogas systems protect our air, water, and soil by recycling organic material, like food waste and manure, into renewable energy and soil products. Biogas systems are, at their heart, a biological means to capture methane that would otherwise be emitted into the atmosphere for use as a renewable fuel. This process specifically decreases baseline methane emissions by converting methane back into carbon dioxide. All of this is an effort to protect our air, water, and soil – crucial parts of the solution to the challenges the California Air Resources Board (CARB) seeks to address. The scientifically based design of the LCFS recognizes the benefits of projects that collect biomethane that would otherwise be emitted to the atmosphere making it available for use in transportation. As a result, millions of gallons of petroleum-based diesel fuel have been replaced with clean biomethane over the past several years delivering substantial reductions in greenhouse gas (GHG) emissions as well as other co-benefits (e.g., reductions in emissions of particulate matter). Furthermore, in August 2023, CARB announced that in Q1 2023 clean fuels replaced more than 50% of the diesel used in the state for transportation purposes, equating to nearly two billion gallons of avoided fossil diesel use in 2022.[1] This further underscores the success of the program and continued need for the LCFS to deliver GHG reductions from the transportation sector.

Over the past year and a half, CARB staff have held numerous public workshops to gather feedback on potential changes to the program, where RAE participated, and we are pleased to see that the rulemaking is nearing completion. RAE would like to underscore the importance of concluding this rulemaking as soon as possible. Any further delay to the rulemaking diminishes the necessary signal the market needs to facilitate and encourage continued investments in clean fuels. Without a strong policy signal, the state risks missing opportunities to further reduce GHG emissions from transportation fuels. Thus, RAE urges CARB staff and the Board to finalize this rulemaking no later than the end of Q2 2024.

Strengthening Carbon Intensity (CI) Targets

RAE applauds CARB and is encouraged to see that the proposed amendments aim to set more ambitious carbon intensity (CI) targets. A strong CI reduction target is a critical component for driving down GHG emissions in the transportation sector, reducing reliance on petroleum fuels, and transitioning to electric vehicles where feasible. However, we believe that there is both room and need to go further. Using the numbers from CARB's Quarterly Summary Report and averaging the rate of credit growth over the past five available quarters, it shows that the current scale-up in the production of clean fuels will continue to generate credits with the cumulative bank likely eclipsing 25 million by the end of 2024.[2] The proposed increase in stringency falls short of what the market can deliver, and as a result, is missing an opportunity to deliver millions of additional tons of

[1] California Air Resources Board, *For the first time 50% of California Diesel Fuel is replaced by clean fuels*. August 23, 2023. https://ww2.arb.ca.gov/news/first-time-50-california-diesel-fuel-replaced-clean-fuels
[2] California Air Resources Board, *LCFS Data Dashboard Figure 3 – Quarterly Summary Report*. https://ww2.arb.ca.gov/resources/documents/lcfs-data-dashboard

reductions in GHG emissions called for in statute and further underscored in the update to the state's Scoping Plan as approved by the Board in December 2022.

Roeslein Alternative Energy believes that there are two key adjustments that CARB can make to the stringency as part of the 15-day change process that do not require new economic or environmental analysis as they fall within the scope of the work CARB has already included in the Initial Statement of Reasons (ISOR). Specifically, by increasing the step-down as well as pulling forward the effective date for triggering the Auto Acceleration Mechanism (AAM) CARB can "recapture" reductions in GHG emissions that will otherwise be lost with the current proposal. Doing so will also send a clear, supportive market signal to continue investments in clean fuels that would otherwise be constrained by the current proposal. The description below provides additional detail on these two recommendations.

While we believe that the proposed 5% step-down in stringency is a good start at course-correcting the market, it simply does not go far enough considering the size of the cumulative credit bank, which is anticipated to increase its rate of growth as new clean fuel projects that have been or are being constructed bring more clean fuels to market. Within the boundaries of staff's
168.1 existing environmental and economic analysis, the step-down must be increased by at least 7%, which, for perspective,
translates into a 2030 target of at least 32% reduction in the CI relative to the 2010 baseline. While a 7% step- down (20.75% CI target) will still leave many credits in the cumulative credit bank, this single adjustment will translate into millions of additional tons of GHG emission reductions that would've otherwise gone unaddressed. RAE would like to emphasize that a 7% step down should be the minimum considered, and that it is possible, based on recent modeling by ICF, for CARB to be more aggressive with the step-down, noting that a step-down of 11.25% (25% CI target) is feasible, and would sufficiently address the excess credits in the cumulative credit bank.[3]

As designed, the first year that the AAM could impact program stringency is 2028---four years from now! The concept and need for the AAM is to respond to clear overperformance of the program and to send an unambiguous market signal to investors that the program is nimble and will respond to opportunities to deliver additional GHG reductions rather than "add to" an excessively large credit bank that is at odds with the objectives of the program. Waiting four years is too long, and RAE recommends pulling the date for triggering the AAM forward. The AAM should be based on 2025 data with the trigger assessment occurring in May 2026, and the AAM being applied in 2027 providing the applicable conditions are met, thus increasing the program stringency for 2027. Relying on 2025 as the first eligible year for triggering the AAM is appropriate as
168.2 one of the main objectives of the step-down is to bring the program into balance. Therefore, assessing the impact of the step-
down on the market based on 2025 data, including the cumulative bank and the rate of credit to deficit generation, is aligned with the principles of the program. With this approach, the AAM could theoretically increase the stringency of the program in 2027 and 2029 (i.e., triggered twice prior to 2030 providing the conditions for the triggering the AAM are satisfied), better ensuring that potential emission reductions are not left on the table in the event the program continues to overperform following the Board's adoption of the amendments. Furthermore, it is important to note that the proposed 3:1 ratio (i.e., cumulative bank/average quarterly deficits) that would trigger the AAM is likely inadequate. For example, in 2022, a year where there is
168.3 general stakeholder consensus that the LCFS was overperforming, the AAM would not have triggered using CARB's current
proposal. Updated ICF modeling shows that changing the cumulative credit bank to average quarterly deficit ratio threshold from 3 to 2.5 or lower would position the AAM to be more responsive to overperformance of the program, thus delivering additional reductions in GHG emissions.[4]

Avoided Emission Crediting

The proposed amendments seek to phase out avoided emission pathways for projects that break ground after December 31, 2029, for biomethane used as a transportation fuel through 2040 and for biomethane used to produce hydrogen through 2045. While we understand that CARB's intention here is to begin to transition biomethane away from the transportation sector, the underlying rational is being construed by some as science-driven rather than a policy decision concerning the phase out of
168.4 combustion in transportation. RAE does not support the phaseout of avoided emission credits.

[4] ICF, *Analyzing Future Low Carbon Fuel Targets in California*. February 2024. https://static1.squarespace.com/static/5b57ab49f407b4a7ffa44ffa/t/65cd3c74d1a72f445cdc7a7e/1707949173143/ICFReport2024.pdf

168.4 cont

Avoided methane emissions are a critical part of science-based, life cycle assessments, and their inclusion in carbon intensity scores is consistent with internationally recognized standards of carbon accounting. The science is robust and recognizes that the baseline includes methane emissions that would otherwise be released into the atmosphere. As stated in our previous comment letters to CARB, recognizing avoided methane emissions and its role as a short-lived climate pollutant, while incentivizing its removal from the atmosphere, has proven highly successful in supporting the reduction of millions of metric tons of carbon dioxide equivalents. We strongly encourage CARB to continue its longstanding commitment to a science-driven framework that utilizes proven science including Argonne National Laboratory's GREET model. In the event CARB maintains its plans to phase out eligibility for avoided methane in vehicle fuels, we encourage CARB to be clear that it is a policy decision associated with CARB's efforts to transition biomethane into non-vehicle sectors (e.g., residential, commercial, and industrial uses). CARB should be explicit that the policy decision to discontinue recognition and eligibility of avoided methane emissions in vehicle pathways should not be interpreted as a departure from the established rigorous science of accounting for the benefits of avoiding methane emissions which continues to be appropriate for non-vehicle sectors. RAE does, however, recognize that avoided emission credits for biogas to electricity projects remain, and applaud CARB for recognizing the value of these projects by proposing to retain this aspect of the program.

168.5

Book-and-Claim and Deliverability Requirements

Book-and-Claim has allowed the LCFS to evolve by supporting investments in clean fuels that have helped the program remain one of the most influential and successful transportation decarbonization policies in the country. To date, CARB's approach to indirect accounting in the program has been pivotal in its success, including its principles of driving GHG emissions down, facilitating investments and production of clean fuels, and in supporting increased clean fuel options for consumers.

While CARB's proposal clearly outlines recommendations related to book-and-claim for biomethane as directed to end use fuel consumption and hydrogen production, it does not adequately address biogas and biomethane as directed to electricity production. There are three key areas that CARB should address to ensure that biogas and biomethane can support electricity production in support of transportation decarbonization. The first is to allow biogas to electricity projects to utilize book-and-claim anywhere in the Western Electricity Coordinating Council (WECC), as is already the case in Oregon under their Clean Fuels Program. Currently, the LCFS requires electricity to be physically delivered to California. This would eventually result in regulatory consistency for projects with the same feedstock (i.e., biomethane) once the deliverability requirements for that fuel are realized. Second, biogas-to-electricity projects where electricity generation and biogas production are not co-located should be eligible to participate in the LCFS. This is in-line with the California Renewable Portfolio Standard's (RPS) treatment of "directed biogas" and allows greater project penetration by supporting optimal siting of both the biomethane source and the electricity generator rather than forcing co-location. Third, notwithstanding the preceding constraints, there are clear guidelines and requirements for how electricity, as a LCFS fuel, can utilize book-and- claim to move electricity from point of generation to end use. There is not, however, clear information on how biogas or biomethane can utilize book-and-claim to move RNG to electricity generation. RAE recommends that CARB provide clarification that biomethane may utilize book-and-claim in this context. Further, we recommend that book-and-claim for biomethane to electricity remain unconstrained by timeline restrictions proposed for biomethane to end use and biomethane to hydrogen production. We believe this is appropriate to support zero-emission vehicle aspirations beyond 2030.

168.6

168.7

168.8

168.9

168.10

Roeslein Alternative Energy is also requesting CARB provide further guidance on the proposed deliverability requirements. The proposed amendments aim to adopt the California RPS requirement of ensuring biomethane injected into a common carrier pipeline physically flows towards California 50% of the time. This referenced RPS framework does not, however, provide clarity on how those biomethane molecules can be traced to California, how a 50% average flow toward California may be modeled, nor expected geographical indications of regions anticipated to remain eligible for book-and-claim accounting. Moreover, limiting book-and-claim to physical deliverability requirements risks the LCFS becoming a less effective decarbonization program and undermines California's interest in rapidly ramping up the production and use of renewable hydrogen—a foundational principle in establishing ARCHES, which is at odds with CARB's proposal, to implement deliverability requirements for hydrogen projects utilizing biomethane.

168.11

It remains to be seen if and how the proposed deliverability requirements can be harmonized with the California Public Utilities Commission's (CPUC) SB 1440 program, as suggested. It has been clear over the past year that CARB was exploring potential deliverability requirements. However, throughout that process an actionable plan outlining the strategy and evidence necessary for imposing delivery requirements never emerged. Rather, stakeholders continued to raise concerns about the lack of a feasible plan which continues with the ambiguity of the proposed amendments.

Therefore, RAE recommends that the deliverability requirement language be removed from the proposal to allow for further stakeholder engagement in support of a clear and actionable plan for consideration in a subsequent rulemaking.

True-up Provisions

The proposal includes true-up provisions where verified operational CI's are drawn on to potentially adjust the credits based
on certified CI's. The proposal indicates that a shortfall (i.e., a verified operational CI that is higher than the certified CI upon
which project credits were generated) is subject to a "penalty" that is 4 times the spread for the applicable volume of fuel. The
168.12 rationale for a 4X spread is unclear as a smaller spread (e.g., 2X) serves as a significant disincentive to producers for being
overconfident in their analysis. Further, the language indicates that in the event the operationally verified CI is lower than the
certified CI (i.e., it failed to generate as many credits as it could have) the Executive Offer (EO) "may" make the appropriate
168.13 adjustment (true-up) by awarding additional credits to the applicable fuel reporting entity. The word "may" should be deleted.
If the operationally verified CI, including an affirmative verification statement, is lower than the certified CI that was the basis
for credit generation, the EO "must" award the supplemental credits supported by the underlying documentation.

The concept of adjustment to credits based on operationally verified CI's is sound. However, limiting the proposal to certified CI's is a significant oversight. The proposal must be carried over and applied to temporary and provisional CI's as fuel providers may rely on these CI's for months, or even years, as a more refined pathway is evaluated and subsequently approved by CARB.

168.14 Temporary CI's have been an important option under the program, but applicants can be reluctant to use them given the heavy credit discounting relative to facility-specific provisional CI's. Correcting for any under (or over) crediting while a temporary CI is used will help streamline and simplify the program as well as send a stronger signal to the market that investments in clean low-CI fuels will be rewarded. Further, including temporary CI's as part of the true-up process will reduce the pressure on CARB from developers to process LCFS applications quickly which has been an ongoing and growing challenge under the program. The concept of adjusting the awarding of credits based on operationally verified CI's is a key principle that supports innovation and must be reflected from project initiation, where a temporary CI is used, throughout the project's lifetime to properly account for and reward the associated reductions in greenhouse gas emissions. Credits should be awarded based on real-world operational experience and therefore adjusted accordingly when the temporary CI which is applied understates the benefits.

New Markets

As the technology in the transportation sector continues to evolve and advance towards lower carbon alternatives, RAE is following suit and are ready to serve these new markets, such as alternative jet fuel (AJF), low-CI hydrogen, as well as exploring opportunities where biomethane can be utilized outside of transportation. As these markets continue to grow, the RAE asks CARB to remain mindful of the success of the historical framework of the program and to continue to apply it to newer pathways and technologies, including the use of avoided emissions and book-and-claim.

If CARB's goal is to transition biomethane out of the vehicle sector, RAE strongly encourages CARB to ensure there continues
to be a market for low-CI biomethane as it is an important decarbonization tool, especially in sectors that are hard to
decarbonize. For example, the CPUC's SB 1440 program creates a biomethane procurement mandate for the state's largest
utilities, however, the program excludes dairy biomethane due to the credit it currently receives in the LCFS.[5] With CARB's
intention of phasing out all biomethane crediting for transportation fuel by the end of 2040, it makes sense for the CPUC to
168.15 integrate dairy biomethane into the SB 1440 program which will allow for more market choice and volumes of renewable fuel
for utilities to procure. The industrial sector is also another area where biomethane can help significantly reduce emissions,
particularly at facilities that are large natural gas users and where electrification is not currently feasible. However, there isn't
one, all-encompassing policy that drives biomethane, and other low-CI clean fuels, towards that use case. Thus, RAE
recommends that CARB, starting with the 2024 amendments to the LCFS, send a clear policy signal that biomethane is a
necessary and effective decarbonization strategy in these other sectors (e.g., residential, commercial, industrial) that are
fundamental to the state meeting its ambitious GHG reduction targets.

---

[5] California Public Utilities Commission, *Decision Implementing Senate Bill 1440 Biomethane Procurement Program: R.13-02-008*, page 4. https://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M453/K954/453954308.PDF

Roeslein Alternative Energy would also like to extend its support for CARB's proposal of eliminating the exemption for intrastate
168.16 fossil jet fuel from the program starting in 2028. This will allow for continued and increased momentum for AJF production and
use and will help drive down GHG emissions in the aviation sector. Furthermore, the 2022 update to the Scoping Plan calls for
80% of aviation fuel demand in 2045 to be met by AJF.[6] The growth of AJF use is a new market opportunity for biomethane as
it can be an important input for the fuel, helping it achieve lower CI's. The magnitude of ambition the state has called for will
require the industry to significantly scale-up production and use of AJF, and for that reason, the ABC requests that CARB begin
168.17 to think about the framework and guardrails needed to achieve the 80% goal set forth in the Scoping Plan and leverage all of
the tools available to the vehicle market, such as book-and-claim and avoided emissions accounting, to make this goal a reality.

Conclusion

The LCFS continues to be a flagship policy that drives investments in low carbon fuels and is delivering millions of tons of reductions in greenhouse gases to meet California's statutory commitments. The program is also protecting communities throughout the state by transitioning from petroleum to much cleaner fuels, including biomethane. The LCFS is the hallmark of effective environmental policy in that it: 1) sets clear, science-based targets; 2) establishes clear regulations for program implementation; and 3) provides the market with the flexibility to innovate. There is a clear reason that other states and nations model their efforts on California's LCFS. RAE is proud to help build on this success story and is committed to CARB's efforts to continue to drive down emissions from transportation fuels.

Thank you for the opportunity to comment on the proposed amendments, and we look forward to engaging with CARB staff on these topics.

Sincerely,

Chris Roach
President, Renewables

Board Comments Home

February 20, 2024

Chair Liane Randolph and Members of the Board California Air Resources Board
1001 I St.
Sacramento, CA 95814

RE: Newtrient LLC Comments on the Proposed Amendments to the Low Carbon Fuel Standard

Dear Chair Randolph and Members of the Board,

Newtrient appreciates the opportunity to comment on the proposed amendments to the Low Carbon Fuel Standard (LCFS). Newtrient was founded by leading milk cooperatives and organizations, representing 20,000 dairy farmers producing approximately half of the nation's milk supply. Newtrient delivers solutions to environmental and economic challenges, including advancing manure management technologies and products. Through a team of credible technical experts in manure management systems, nutrient recovery, renewable energy, and environmental asset markets, Newtrient helps dairy farms and the dairy industry reduce its environmental footprint.

Newtrient applauds the leadership the California Air Resources Board (CARB) is taking on climate change and appreciates being a part of this important dialogue surrounding potential changes to the Low Carbon Fuel Standard (LCFS). The dairy industry has answered the call to action and is embracing environmental responsibility - from family farms in California, to farms across America. By installing and utilizing biogas systems, farms are offering practical solutions to the challenges CARB seeks to address.

Two programs directed by the California Department of Food and Agriculture (CDFA) have been particularly vital to the progress California has made. According to the 2023 CARB Mid-Year Data Update report on the cumulative progress of the California Climate Investments Program (CCIP), the Dairy Digester Research and Development Program (DDRDP) and the Alternative Manure Management Program (AMMP) have received a total of $309.1 million in funding and have reduced 23.2 million $MTCO_2e$. The funding for these programs represents 1.86% of the

California Climate Investments program as of May 31, 2023, but the GHG reductions from these two programs represent 23.69% of the total for all California Climate Investments programs[1].

There are 78 subprograms listed in the 2023 CARB Mid-Year Data Update report on the cumulative progress of the California Climate Investments Program as of May 31, 2023. Only one of these subprograms, the DDRDP, has produced a GHG reduction at a cost of less than $10 per $MTCO_2e$. The DDRDP program has the largest GHG reductions of any single subprogram (22.1 million $MTCO_2e$) and represents the single most effective program in the overall strategy to achieve the ambitious climate goals set by the State of California.

In December of 2022, researchers at UC Davis published the study, *Meeting the Call: How California is Pioneering a Pathway to Significant Dairy Sector Methane Reduction* in which they stated "…analysis shows that continued implementation and commitment to the incentive-based climate smart solutions that are currently driving voluntary dairy methane reduction in California should, by 2030, achieve the full 40 percent reduction in dairy methane sought by state regulators without the need for direct regulation."[2]

With our support of CARB and the LCFS in mind, Newtrient would like to offer the following suggestions for improving the proposed amendments to the Low Carbon Fuel Standard:

Strengthening Carbon Intensity (CI) Targets

Newtrient applauds CARB and is encouraged to see that the proposed amendments aim to set more ambitious carbon intensity targets. A strong CI reduction target is a critical component for driving down (GHG) emissions in the transportation sector, reducing reliance on petroleum fuels, and transitioning to electric vehicles where feasible. However, we believe that there is both room and a need to go further. Using the numbers from CARB's Quarterly Summary Report and averaging the rate of credit growth over the past five available quarters, it shows that the current scale-up in the production of clean fuels will continue to generate low carbon

[1] California Climate Investments Program: *2023 CARB Mid-Year Data Update* (May 31, 2023), (https://ww2.arb.ca.gov/sites/default/files/auction-proceeds/cci_2023mydu_cumulative_statistics.pdf)
[2] Kebreab, Ermias, Ph.D., Mitloehner, Frank, Ph.D., and Sumner, Daniel A., Ph.D., Meeting the Call: California is Pioneering a Pathway to Significant Dairy Methane Reduction (December 2022), available at: https://clear.ucdavis.edu/news/new-report-california-pioneering-pathway-significant-dairy-methane-reduction

fuel standard credits with the cumulative bank likely eclipsing 25 million by the end of 2024.[3] The proposed increase in stringency falls short of what the market can deliver, and as a result, is missing an opportunity to deliver millions of additional tons of reductions in greenhouse gas emissions called for in statute and further underscored in the update to the state's Scoping Plan as approved by the Board in December 2022.

Newtrient believes that there are two key adjustments that CARB can make to the stringency as part of the 15-day change process that do not require new economic or environmental analysis as they fall within the scope of the work CARB has already included in the Initial Statement of Reasons (ISOR), specifically, by increasing the step-down as well as pulling forward the effective date for triggering the Auto Acceleration Mechanism (AAM) CARB can "recapture" reductions in GHG emissions that will otherwise be lost with the current proposal. Doing so will also send a clear, and supportive market signal to continue investments in clean fuels that would otherwise be constrained and subdued by the current proposal. The below description provides additional detail on these two recommendations.

169.1 While we believe that the proposed 5% step-down in stringency is a good start at course correcting the market, it simply does not go far enough considering the size of the cumulative credit bank, which is anticipated to increase its rate of growth as new clean fuel projects that have been or are being constructed bring more clean fuels to market. Within the boundaries of staff's existing environmental and economic analysis, the step-down must be increased by at least seven percent (7%), which, for perspective, translates into a 2030 target of at least 32 percent (32%) reduction in the CI relative to the 2010 baseline. While a 7% step-down will still leave many credits in the cumulative credit bank, this single adjustment will translate into millions of additional tons of greenhouse gas emission reductions that would've otherwise gone unaddressed.

169.2 As designed, the first year that the AAM could impact program stringency is 2028---four years from now! The concept and need for the AAM is to respond to clear overperformance of the program and to send an unambiguous market signal to investors that the program is nimble and will respond to opportunities to deliver additional GHG reductions rather than "add to" an excessively large credit bank that is at odds with the objectives of the program. Waiting four

[3] California Air Resources Board, LCFS Data Dashboard Figure 3 – Quarterly Summary Report. https://ww2.arb.ca.gov/resources/documents/lcfs-data-dashboard

years is too long, and Newtrient recommends pulling the date for triggering the AAM forward.
169.2 cont The AAM should be based on 2025 data with the trigger assessment occurring in May 2026, and the AAM being applied in 2027 providing the applicable conditions are met, thus increasing the program stringency for 2027. Relying on 2025 as the first eligible year for triggering the AAM is appropriate as one of the main objectives of the step-down is to bring the program into balance. Therefore, assessing the impact of the step-down on the market based on 2025 data, including the cumulative bank and the rate of credit to deficit generation, is aligned with the principles of the program. With this approach, the AAM could theoretically increase the stringency of the program in 2027 and 2029 (i.e., triggered twice prior to 2030 providing the conditions for the triggering the AAM are satisfied), better ensuring that potential emission reductions are not left on the table in the event the program continues to overperform following the Board's adoption of the amendments.

Avoided Emission Crediting

169.3 The proposed amendments seek to phase out avoided emission pathways for projects that break ground after December 31, 2029, for biomethane used as a transportation fuel through 2040 and for biomethane used to produce hydrogen through 2045. Newtrient believes that this is inconsistent with the incentive-based approach outlined in SB 1383 and currently being implemented in California. Moreover, eliminating or phasing out the avoided methane crediting in the dairy sector would lead to an inability to meet the state's targeted methane reduction goals and result in significant dairy methane emissions leakage. Avoided methane crediting is a key component of dairy methane reduction incentives that has achieved significant reductions to date and as stated previously, is one of the most effective tools to meet California's GHG goals.

According to a UC Davis analysis:

> . . . misguided efforts to change course by forced coercion to pasture-based operations, direct regulation of dairy farms, or limitation on dairy digesters incentives will not only fail to achieve the desired greenhouse gas emissions reductions but will exacerbate the problem by causing significant emissions leakage. Revenue streams that incentivize investment in biogas capture and beneficial use are critical. Phasing out of avoided methane crediting in the dairy sector would jeopardize existing projects, making them

169.3 cont uneconomic in the long-term, and dry up investment capital for the additional digester projects sought by CARB to achieve the state's ambitious and aggressive targets.[4]

The ultra-low carbon indices within the dairy Anaerobic Digestion (AD)/Biogas sector are real and well-vetted within the national laboratory-developed Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model. As such, anyone who values science must appreciate their role in meeting GHG and climate goals, and not selectively replace them with non-scientific reasoning.

The low carbon intensity of these projects arises from a combination of well-to-wheels carbon gains plus the methane offsets from baseline methane emissions from manure management, storage, and application. Methane offsets from baseline emissions are a legitimate accounting practice as baseline, pre-AD/biogas systems emissions exist, and are largely removed through the installation of the AD/biogas system.

CARB has carefully and correctly set the boundaries of animal agriculture and clearly defines the baseline scenario of California dairies by providing a diagram of the LCFS boundaries and indicating the project related components in the Compliance Offset Protocol for Livestock Projects Capturing and Destroying Methane from Manure Management Systems Adopted: November 14, 2014.

Some groups misrepresent the dairy industry and, as in the case of the comments submitted and made during public input sessions, misrepresent the benefits of the use of anaerobic digestion and renewable energy production on dairy farms. Anaerobic digestion systems have scientifically supported GHG reductions. By calling the scientifically supported GHG reductions achieved by AD systems "artificially inflated," they show that they are not willing to discuss the science and the significant impact of AD on reducing GHG emissions from farms, but instead label and denigrate these projects with their own unscientific opinions.

Revenue streams that incentivize investment in biogas capture and beneficial use are critical. Phasing out of avoided methane crediting in the dairy sector would jeopardize existing projects, making them uneconomic in the long-term, and dry up investment capital for the additional

[4] Kebreab, Ermias, Ph.D., Mitloehner, Frank, Ph.D., and Sumner, Daniel A., Ph.D., Meeting the Call: California is Pioneering a Pathway to Significant Dairy Methane Reduction (December 2022), available at: https://clear.ucdavis.edu/news/new-report-california-pioneering-pathway-significant-dairy-methane-reduction

169.3 cont digester projects sought by CARB to achieve the state's ambitious and aggressive targets.

Avoided methane emissions are a critical part of science-based, life cycle assessments, and their inclusion in carbon intensity scores are consistent with internationally recognized standards of carbon accounting. The scientific evidence for this is robust and recognizes that the baseline includes methane emissions that would otherwise be released into the atmosphere. Recognizing methane and its role as a short-lived climate pollutant, while incentivizing its removal from the atmosphere, has proven highly successful in supporting the reduction of millions of metric tons of carbon dioxide equivalents. We strongly encourage CARB to continue its longstanding commitment to a science-driven framework that utilizes proven science including Argonne National Laboratory's GREET model.

169.4 In the event CARB maintains its plans to phase out eligibility for avoided methane in vehicle fuels, we encourage CARB to be clear that it is a policy decision associated with CARB's efforts to transition biomethane into non-vehicle sectors (e.g., residential, commercial, and industrial uses). CARB should be explicit that the policy decision to discontinue recognition and eligibility of avoided methane emissions in vehicle pathways should not be interpreted as a departure from the established rigorous science of accounting for the benefits of avoiding methane emissions which continues to be appropriate for non-vehicle sectors.

Book-and-Claim and Deliverability Requirements

Book-and-Claim has allowed the LCFS to evolve by supporting investments in clean fuels that have helped the program remain one of the most influential and successful transportation decarbonization policies in the country. To date, CARB's approach to indirect accounting in the program has been pivotal to its success, including its principles of driving greenhouse gas emissions down, facilitating investments and production of clean fuels, and in supporting increased clean fuel options for consumers.

169.5 Newtrient is requesting CARB provide further guidance on the proposed deliverability requirements. The proposed amendments aim to adopt the California Renewable Portfolio Standard (RPS) requirement of ensuring biomethane injected into a common carrier pipeline physically flows towards California 50% of the time. This referenced RPS framework does not, however, provide clarity on how those biomethane molecules can be traced to California, how a 50% average flow toward California may be modeled, nor does it provide the expected geographical regions that will remain eligible for book-and-claim accounting. Moreover, limiting

169.5 cont book-and-claim to physical deliverability requirements risks the LCFS becoming a less effective
decarbonization program and undermines California's interest in rapidly ramping up the
production and use of renewable hydrogen—a foundational principle in establishing California's
initiative to accelerate renewable hydrogen projects and the necessary infrastructure now
known as the ARCHES program---despite CARB proposing to implement deliverability
requirements for hydrogen projects utilizing biomethane five years later than projects using
biomethane for CNG vehicles.

It remains to be seen if and how the proposed deliverability requirements can be harmonized
with the California Public Utilities Commission SB 1440 program, as suggested. It has been clear
over the past year that CARB was exploring potential deliverability requirements. However,
throughout that process an actionable plan outlining the strategy and evidence necessary for
imposing delivery requirements never emerged. Rather, stakeholders continued to raise
concerns about the lack of a feasible plan which continues with the ambiguity of proposed
amendments. Therefore, Newtrient recommends that the deliverability requirement language
be removed from the current amendments to allow for further stakeholder engagement to
support a clear and actionable plan for consideration in a subsequent rulemaking.

True-up Provisions

The proposal includes true-up provisions where verified operational CI's are drawn on to
potentially adjust the credits based on certified CI's. The proposal indicates that a shortfall (i.e.,
a verified operational CI that is higher than the certified CI upon which project credits were
generated) is subject to a "penalty" that is 4 times the spread for the applicable volume of fuel.
169.6 The rationale for a 4X spread is unclear as a smaller spread (e.g., 2X) serves as a significant
disincentive to producers for being overconfident in their analysis. Further, the language
indicates that in the event the operationally verified CI is lower than the certified CI (i.e., it
failed to generate as many credits as it could have) the Executive Offer (EO) "may" make the
169.7 appropriate adjustment (true-up) by awarding additional credits to the applicable fuel reporting
entity. The word "may" should be deleted. If the operationally verified CI, including an
affirmative verification statement, is lower than the certified CI that was the basis for credit
generation, the EO "must" award the supplemental credits supported by the underlying
documentation.

The concept of adjustment to credits based on operationally verified CI's is sound. However,
169.8 limiting the proposal to certified CI's is a significant oversight. The proposal must be carried
over and applied to temporary and provisional CI's as fuel providers may rely on these CI's for

169.8 cont months, or even years, as more refined pathways are evaluated and subsequently approved by CARB.

Temporary CI's have been an important option under the program, but applicants can be reluctant to use them given the heavy credit discount relative to facility-specific provisional CI's. Correcting for any under (or over) crediting while a temporary CI is used will help streamline and simplify the program as well as send a stronger signal to the market that investments in clean low-CI fuels will be rewarded. Further, including temporary CI's as part of the true-up process will reduce the pressure on CARB from developers to process LCFS applications quickly which has been an ongoing and growing challenge under the program. The concept of adjusting the awarding of credits based on operationally verified CI's is a key principle that supports innovation and must be reflected from project initiation, where a temporary CI is used, throughout the project's lifetime to properly account for and reward the associated reductions in greenhouse gas emissions. Credits should be awarded based on real-world operational experience and therefore adjusted accordingly when the temporary CI which is applied understates the benefits.

New Markets

As the technology in the transportation sector continues to evolve and advance towards lower carbon alternatives, Newtrient members and the rest of the dairy industry and are ready to serve these new markets, such as alternative jet fuel (AJF), low-CI hydrogen, as well as exploring opportunities where biomethane can be utilized outside of transportation. As these markets continue to grow, Newtrient asks CARB to remain mindful of the success of the historical framework of the program and to continue to apply it to these newer pathways and technologies, including the use of avoided emissions and book-and-claim.
If CARB's goal is to transition biomethane out of the vehicle sector, Newtrient strongly encourages CARB to ensure there continues to be a market for low-CI biomethane as it is an important decarbonization tool, especially in sectors that are hard to decarbonize. For example, the CPUC's SB 1440 program creates a biomethane procurement mandate for the state's largest utilities, however, the program limits dairy biomethane due to the credit it currently receives in the LCFS.[5] With CARB's intention of phasing out all biomethane crediting for transportation fuel by the end of 2040, it makes sense for the CPUC to integrate dairy

[5] California Air Resources Board, *2022 Scoping Plan Update*, page 73. https://ww2.arb.ca.gov/sites/default/files/2023-04/2022- sp.pdf

biomethane into the SB 1440 program which will allow for more market choice and volumes for utilities to procure. The industrial sector is also another area where biomethane can help significantly reduce emissions, particularly at facilities that are large natural gas users and where electrification is not currently feasible. However, there isn't one, all-encompassing policy that drives dairy biomethane, and other low-CI clean fuels, towards that use case. Thus, Newtrient recommends that CARB, starting with the 2024 amendments to the LCFS, send a
169.9 clear policy signal that dairy biomethane is a necessary and effective decarbonization strategy in these other sectors (e.g., residential, commercial, industrial) that are fundamental to the state meeting its ambitious GHG reduction targets.

Conclusion

Over the past year and a half, CARB staff have held numerous public workshops to gather feedback on potential changes to the program, where Newtrient participated, and we're pleased to see that the rulemaking is nearing completion. Newtrient would like to underscore the importance of concluding this rulemaking as soon as possible. Any further delay to the rulemaking diminishes the necessary signal the market needs to facilitate and encourage continued investments in clean fuels. To continue the significant and unprecedented progress made by CARB and the dairy industry of California under the guidance and support of the CDFA, Newtrient urges CARB staff and the Board to finalize this rulemaking no later than the end of Q2 2024.

Thank you for the opportunity to comment on the proposed amendments, and we look forward to engaging with CARB staff on these topics.

Sincerely,

Mark Stoermann

Comment

I'm speaking today as a resident of rural America, one who has
lived in the shadow of factory farms and biogas digesters. Despit
170.1 all the promises from DNR, local elected officials, and experts
over the years that this farm/biogas digester wouldn't hurt our
water quality or way of life....that has not aged well in Emerald,
Wisconsin.

I watched several in my neighborhood lose their drinking water -
the Town Hall's well which originally had nitrates at 6.9 ppm just
a few years ago - now has nitrates consistently near 40 ppm and ha
spiked to 52 and 62 ppm.

This farm keeps getting larger. We've seen the implementation of
biogas digesters become a rationale for increasing herd sizes....
yet our drinking water is not getting cleaner - but actually much
worse. The biogas digester exploded and burned up after a few
years and wasn't replaced, but the damage was already done, and ou
water has not improved.

My neighbors watched the nitrates rapidly increase over the same
time in their private wells, many of which don't drink their water
anymore - some won't even give it to their pets. Well drillers
have said "we can dig you a well, but we can't guarantee you
drinkable water." One neighbor experienced that firsthand when
selling his home - a new well 200 feet deep well was still testing
at 17 ppm for nitrates. He had to install a reverse osmosis syste
to get the property sold - but then the new family, with small
children, moved away within a year because they were concerned
about the water quality.
E.coli has also been found in several wells in our neighborhood
over the years - which made turning on my faucet every day a "crap
shoot" in my mind. That led to the heartbreaking decision my
husband and I finally made to leave our acreage in Wisconsin for
safer spaces in Minnesota - a place where we can drink the water
and serve it to family and friends without fear.

Clean water is the only driver of economic development in rural
areas. No one wants to locate a home, subdivision, or business if
clean drinking water is not available. To incentivize manure
production over milk production is damaging to our environment.
There is no way our soils can absorb that concentrated nutrient

170.1 cont

load from digestate when they are already 5-6x higher in phosphoru
than what is recommended by University of Wisconsin for growing
crops. TMDLs are common in many agricultural parts of Wisconsin -
green rivers, streams, and lakes by the 4th of July. Nitrates in
groundwaters are still rising per a 10-year study in St. Croix
County, Wisconsin.

I make the analogy that this feels like these energy companies hav
come in and raided our kitchens, make a disastrous mess, and
leaving us to clean it up and deal with the consequences.

As a resident of the St. Croix River Valley for over 25 years (a
Wild & Scenic River, part of the National Park System), I ask that
you look at the long-term picture - plan for the next generation
and not just the next years' dollars.

As a farmer's daughter, I get that farming has changed....but what
has not, or will EVER change, is our need for clean drinking
water.

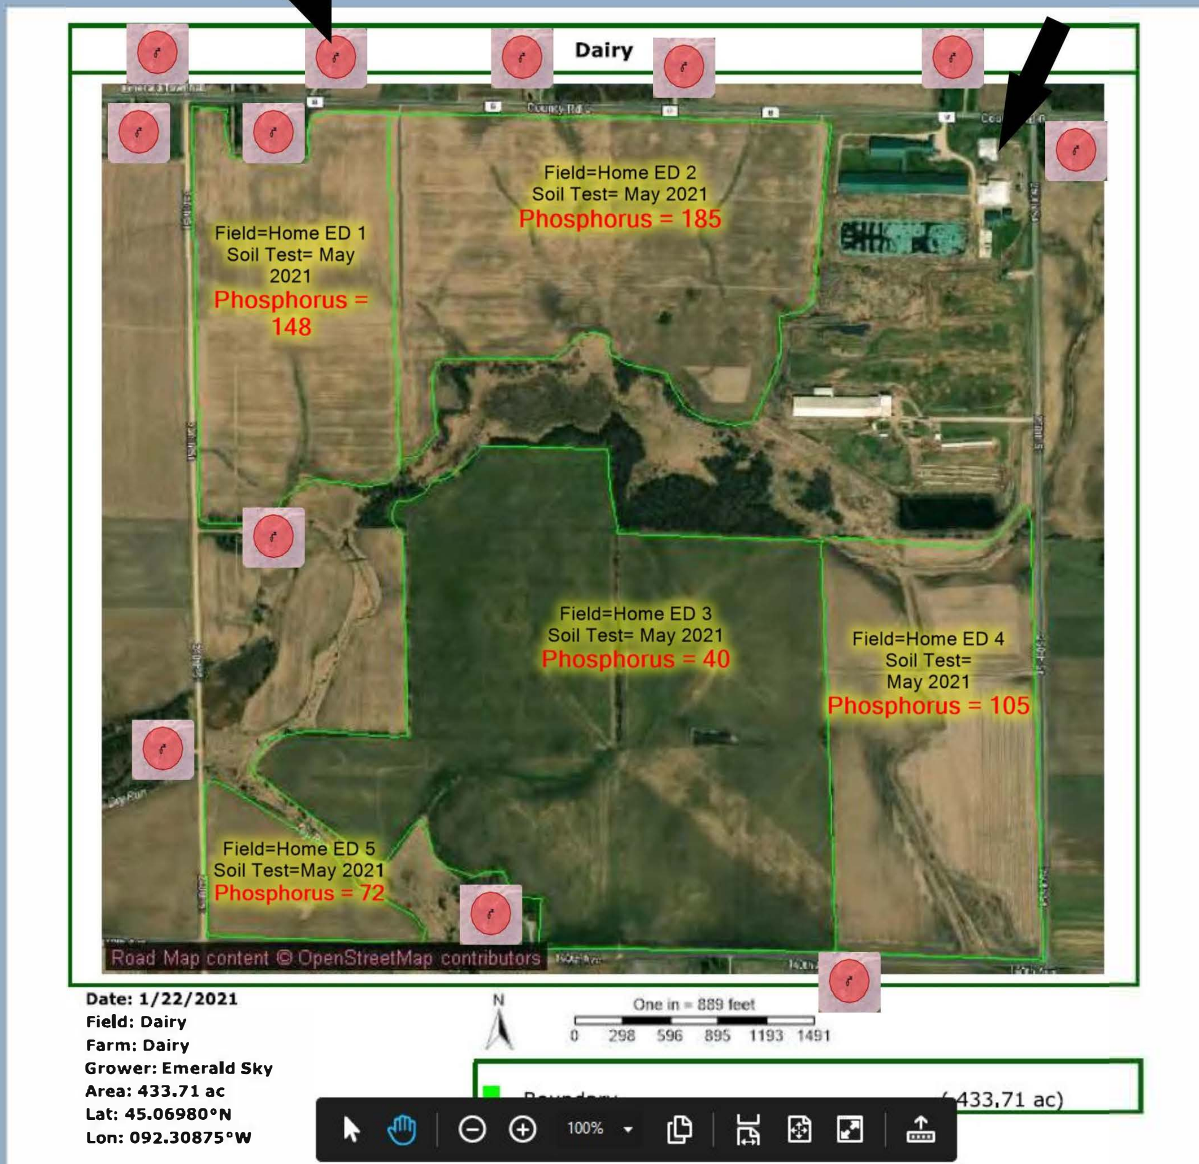
5x higher than Public Health
safety standard

= Drinking water well

Emerald Sky Dairy
production area



Note 1: Soil test Phosphorus levels for most agronomic crops in Wisconsin are considered "excessively high" at 35+ ppm. Once levels reach 200 ppm - DNR must give written permission to continue with manure spreading since it takes over 50 years of NO spreading to resture the soil.

"Optimum" soil P levels are generally between 16 ppm and 25 ppm and are considered (interpreted) by UW-EX as "economically and environmentally the most desirable soil test category." Further, "the Wisconsin program defines the critical level as the cutoff between the optimum and high soil test levels. If the nutrient supply drops below the critical level, growers face economic losses from reduced yields or poor crop quality.

If the supply exceeds the critical level, there is an increased risk of mobile nutrients moving into the groundwater and surface water. In addition, there is no profit in applying nutrients that will not be used."

RENEWABLE FUELS ASSOCIATION

February 20, 2024

The Honorable Liane Randolph
Chair
California Air Resources Board
1001 I St
Sacramento, CA 95814

Re: Proposed Low Carbon Fuel Standard Amendments

Dear Chair Randolph and Members of the Board,

The Renewable Fuels Association (RFA) appreciates the opportunity to comment on the proposed amendments to the Low Carbon Fuel Standard (LCFS). The RFA is the leading trade association for America's ethanol industry. Our mission is to drive growth in sustainable renewable fuels and bioproducts for a better future.

The RFA supports the LCFS and looks forward to continued engagement in this process to strengthen and extend the program beyond 2030. The RFA is also working around the country in collaboration with other stakeholders to develop and implement clean fuel programs in other states.

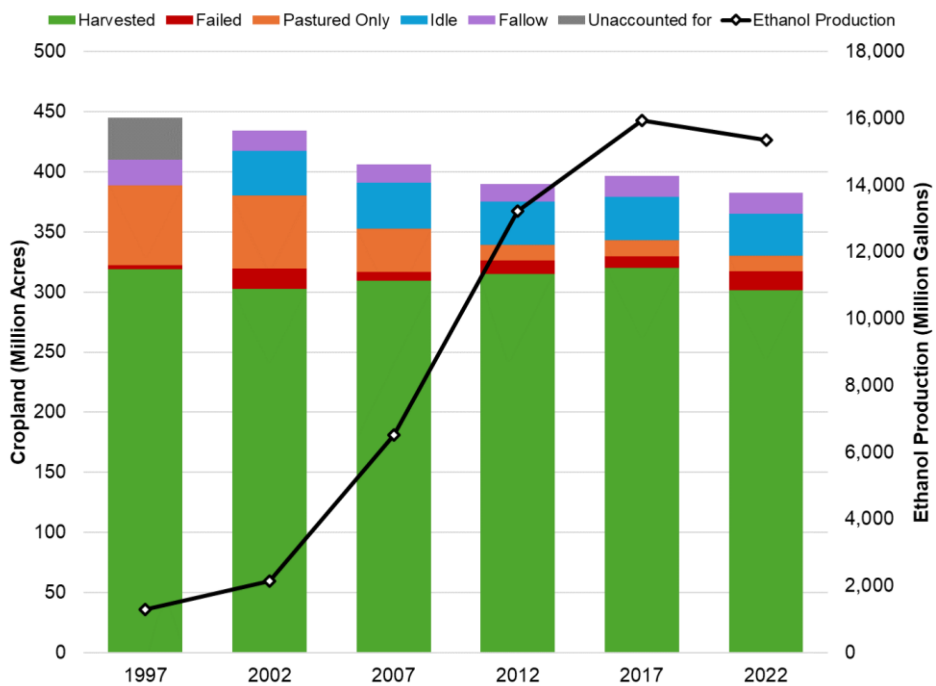
The RFA has commented extensively over the last two years during the California Air Resources Board's (CARB) process of modifying and updating the LCFS program. We will not reiterate those comments here, but are attaching them to this letter, in order to enter them into the public record for the LCFS rulemaking and to encourage further refinement of the LCFS. To date, most of our substantive comments have not received adequate responses from staff. Our comments here address new items introduced in the rulemaking package and some further elaboration of earlier comments.

The proposed sustainability requirements for crop and forestry feedstocks are vague, overreaching, and unnecessary for U.S.-produced biofuel feedstocks.

171.1 The proposed amendments to the LCFS released at the end of 2023 include a sustainability certification program which is a new concept that has never been introduced or discussed at any public workshop or hearing during the two years of the LCFS modification process. It is problematic from a public process perspective to introduce a concept with wide-ranging policy implications and cost burdens to feedstock and clean fuel producers with no corresponding clear justification or demonstrated benefits of such a program.

In CARB staff's Initial Statement of Reasons, the rationale for a feedstock certification program is a stated concern over deforestation or adverse land use change resulting from a rapid increase in biofuel production. As was documented in the RFA comments of August 8, 2022, the total acreage of cropland in the U.S. has steadily declined for decades, including since the beginning of both the federal Renewable Fuel Standard (RFS) in 2005 and the LCFS in 2011. This was reinforced by the 2022 Census of Agriculture released by USDA just last week, which showed that the amount of cropland in the U.S. fell by an additional 14 million acres, or 4%, since the prior Census in 2017. The decline in cropland area has occurred even as ethanol output increased substantially from the modest volumes of the early 2000s (Figure 1).

Figure 1: U.S. Cropland Area Compared to Ethanol Production



Sources: U.S. Dept. of Agriculture, Census of Agriculture (cropland area); U.S. Energy Information Administration (ethanol production)

As also documented in our prior comments, significant increases in biofuel production have been made possible by continuous crop yield and biofuel production efficiency improvements. From 1997 to 2022, three-quarters of the increase in U.S. corn production was attributable to rising yields, while only one-quarter came from higher acreage, based on an RFA analysis of Census data.[1]

It should be emphasized that the RFS already contains provisions to protect against any expansion of cropland for biofuel feedstock production from a 2007 baseline.

[1] https://ethanolrfa.org/media-and-news/category/blog/article/2024/02/ag-census-confirms-cropland-decline-adoption-of-environmental-practices

171.1 cont Imposing a third-party verification system for feedstock certification places an extreme audit burden on feedstock suppliers and biofuel producers without any clearly defined benefit. The audit report summaries would need to be designed so that their publication does not result in the disclosure of sensitive or confidential business information.

It is difficult to understand what is being proposed, as even the term "sustainability" is not defined in the proposed amendment. Moreover, the requirement that the certification system include social criteria could take it far afield from being an environmental safeguard and could introduce subjectivity regarding the criteria that are included.

This provision needs extensive stakeholder engagement and analysis before being considered for inclusion in any amendment to the LCFS program. At least for U.S.-sourced feedstocks and biofuel production, there is no substantiable reason to impose this vague, yet cumbersome system.

Consistency across transportation fuel technologies is another issue with the sustainability provisions in the LCFS proposed amendments. If feedstocks for biofuels are to be examined across yet-to-be-defined sustainability criteria, then so should other raw materials and technologies. For instance, with the projections for a massive increase in new electric vehicles, what are the sustainability considerations for the corresponding massive increase in the amount of mining for lithium, cobalt and other metals involved in battery production?

A precedent close to what is being suggested for sustainability requirements is the Land Use and Biodiversity (LUB) provisions of Canada's recently adopted Clean Fuel Regulation (CFR). Based on analysis provided to Environment and Climate Change Canada, the agency implementing the CFR, the U.S. was granted feedstock recognition on November 9, 2023, certifying that U.S. feedstocks comply with the LUB criteria covering all bio-based diesel and ethanol shipped to Canada from the U.S. If California moves ahead with any feedstock certification program, there should be a provision comparable to the Canadian CFR to designate all U.S.-produced biofuels as being in compliance with the program so long as aggregate cropland acreage in the U.S. does not expand beyond a given baseline.

The RFA and many other stakeholders have commented repeatedly on the need to develop farm level crediting for carbon-reducing agricultural practices such as cover cropping, no till, and lower carbon inputs. There is a tremendous opportunity to incentivize carbon reductions in agricultural production which would meaningfully contribute to lower carbon intensity from the biofuels that continue to be a critically important contributor to the success of the LCFS. Any consideration of sustainability certification should include the opportunities for farm level crediting of lower-carbon farming practices.

171.2 **Higher blends of ethanol are an immediate option for maximizing carbon intensity reductions, lowering criteria emissions, and reducing consumer costs in the LCFS. Concurrent with adoption of LCFS amendments, CARB should initiate a rulemaking to certify E15 blends in California.**

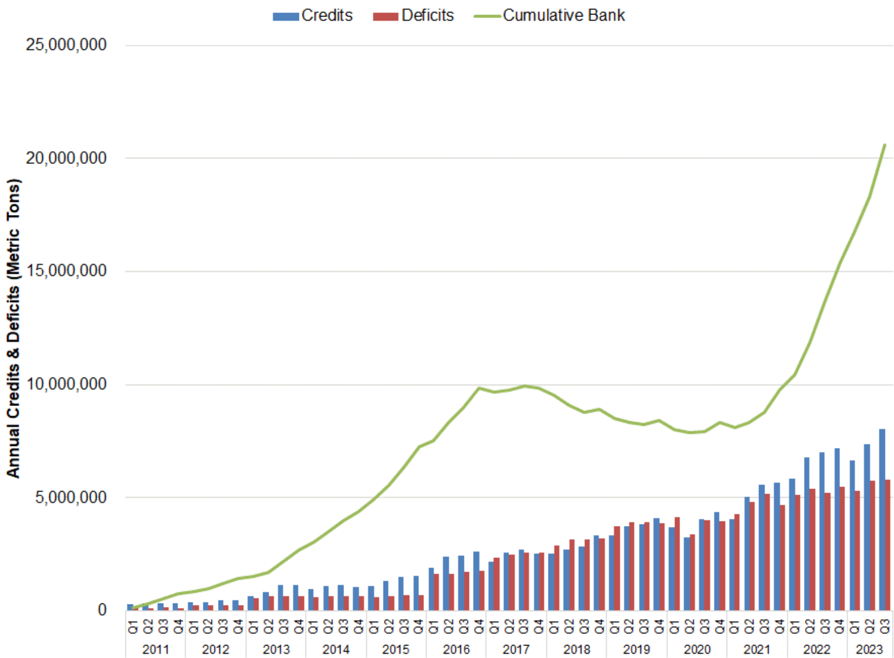
With Montana's approval of E15 in December of 2023, California is now the only state not recognizing the blend as a legal fuel. Decarbonizing the liquid fuels that will be in the market for decades to come is a critically important complement to electrification in achieving the goals of the CARB Scoping Plan. Science informs us that time is of the essence to achieve maximum GHG reductions now. E15 is the leading opportunity under the LCFS to immediately and significantly further reduce GHG emissions while at the same time reducing criteria pollutant emissions and consumer costs. Higher ethanol blends in California will not lead to substantial increases of ethanol in the California fuels market, but rather utilize existing supplies to displace more petroleum as gasoline consumption in California declines, meeting both decarbonization and petroleum displacement goals.

Ethanol has been a workhorse of the LCFS program generating one-quarter of the credits program to date. Opening the LCFS to higher blends of ethanol supports a more stringent compliance curve resulting in greater GHG and criteria pollutant reductions. A vehicle emissions study co-funded by CARB demonstrated remarkable air quality benefits when increasing the blend of ethanol from 10 to 15 percent. E15 as the standard fuel in California would result in an additional annual reduction of two million metric tons of GHGs while reducing the cost of gasoline to consumers.

RFA is part of the broad coalition of clean fuel suppliers who have documented through analysis by ICF that carbon reductions of over 40 percent by 2030 are readily achievable. E15 is a significant contributor to these additional carbon reductions. The ICF analysis has been shared with CARB Board members and staff.

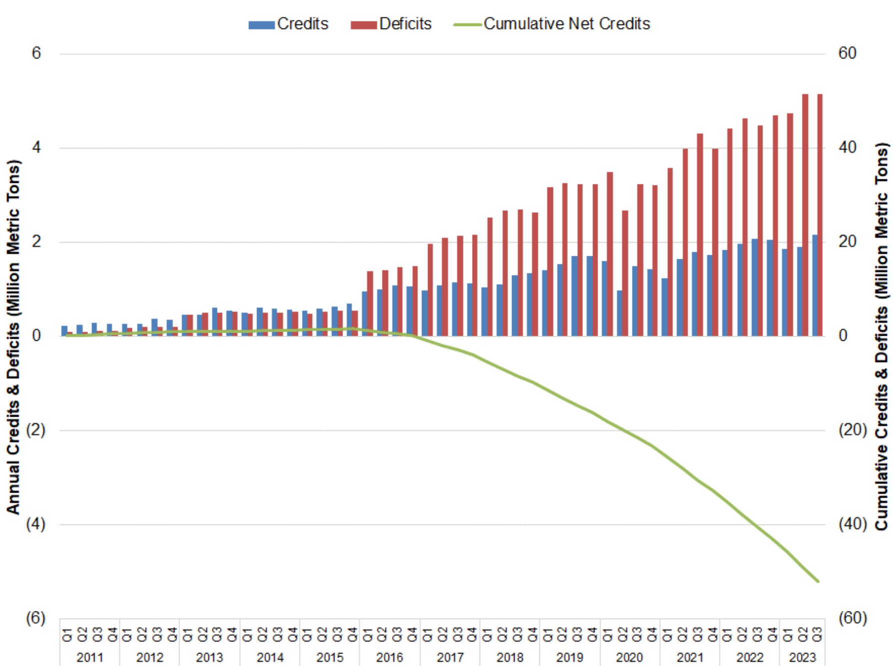
Additional credit generation in the gasoline pool is critical in the near term to reverse the growing and alarming trend of large deficit balances in the light duty transportation sector. Figure 2 and Figure 3, which are updated from prior RFA comment letters, show the credit surpluses in the overall LCFS program due to large credit generation from RNG and bio-based diesel (now 60 percent of total diesel consumption) contrasted with the large deficits in the gasoline pool, where ethanol is limited to ten-percent blends (E10) and petroleum continues to be the dominant source of fuel.

Figure 2: Total California LCFS Credits and Deficits for All Fuels



Source: California Air Resources Board

Figure 3: Net Credits (Deficits) Generated by Gasoline, Ethanol and Charging of On-road Electric Vehicles, Excluding Heavy-duty Vehicles



Source: RFA Analysis of California Air Resources Board data

171.2 cont The Department of Finance was correct in responding to the SRIA by questioning the assumption that E10 would be the standard ethanol blend through 2045 when the consequence is greater dependence on liquid petroleum fuel, which runs counter to stated CARB policy. The response by CARB to the Department of Finance in defending the E10 assumption was misleading. The Multimedia Working Group (MMWG) process evaluating E15 blends has been ongoing for over three years and is nearly complete, merely waiting for finalization by CARB staff to then refer to the Environmental Policy Council for a final recommendation.

Due to California leading underground tank policies, all underground tanks in California are legally required to be compatible with E15 and higher blends as of January 1, 2024. Virtually all the cars on the road are approved by EPA for E15 use and virtually all the new dispensers sold are warrantied for at least E15 blends. With E15 approval by CARB, fuel marketers will have the option of providing a lower cost and cleaner fuel choice to consumers.

CARB has expressed interest in leveraging federal support in meeting LCFS and climate neutrality goals. The Inflation Reduction Act (IRA) of 2022 allocated $500 million to the High Blend Infrastructure Incentive Program (HBIIP) to support the building of new infrastructure for the distribution of higher blends of both ethanol and biodiesel produced from agricultural products. The first round of $50 million in HBIIP funding is committed with $450 million still available over the next several years. This program is available to California businesses to invest in new infrastructure for dispensing E15 and higher ethanol blends.

SB 32, which extended the goals of California's groundbreaking AB 32 legislation, is clear in the mandate for CARB to adopt rules and regulations to "achieve the maximum technologically feasible and cost-effective greenhouse gas emissions reductions." California's exemption from the Clean Air Act to implement its own clean air programs is predicated on the state's regulations going further than the federal government on improving air quality and human health. Expeditiously approving E15 use in California is consistent and necessary for CARB to comply with both state and federal clean air policies.

As commented by the RFA from the beginning of this process, E15 certification should be part of the current LCFS rulemaking. We respectfully ask that the CARB Board direct staff to expedite the simple gasoline specification change allowing for (not mandating) E15 to facilitate greater emissions reductions, petroleum displacement and cost savings as soon as possible to advance the success of the LCFS program.

171.3 **Allowing the Auto Acceleration Mechanism (AAM) to be triggered as early as 2026 and to apply to consecutive years would be more effective in supporting a robust LCFS.**

RFA supports the AAM and the conditions proposed to trigger a pulling forward of the compliance schedule by one year. The current proposal prohibits the AAM from starting before 2027 and being triggered in two subsequent years, requiring a one-year break before it can be triggered again even if in that subsequent year the conditions are met. To support a robust LCFS compliance curve, we support the AAM implementation in 2026 and dropping the skip-year requirement. Carbon markets are efficient in responding to supply/demand imbalances. Delaying implementation of the AAM until 2027 or a waiting an extra year if the market is out of balance will create inefficiencies and undermine the objective of the LCFS to maximize carbon emission reductions.

Indirect accounting for low carbon intensity hydrogen production through
171.4 **purchase power agreements (PPAs) should be extended to the production of all low- to zero-carbon biofuels.**

In the interest of both technology neutrality and maximizing renewable electricity production and carbon emission reductions, the use of PPAs for book-and-claim accounting should be extended beyond just hydrogen. RFA supports the concepts for PPA accounting to ensure new or expanded capacity, delivery to local balancing authorities and quarterly matching. Extending these concepts to biofuel producers supports further increases in renewable electricity production and further decreases in the carbon intensity of liquid biofuels.

RFA reiterates its support in prior comments for book-and-claim accounting to also be extended to the use of biogas delivered to a pipeline for displacing fossil natural gas in the production of liquid biofuels. This could be subject to the same additionality, deliverability and balancing measures being proposed under the PPA construct.

The LCFS and Scoping Plan have an overarching objective to maximize carbon reductions as quickly as possible to achieve carbon neutrality no later than 2045. Appropriately and consistently extending indirect accounting for both renewable electricity and biogas for liquid biofuel production is a valuable and necessary tool in achieving the state’s aggressive climate targets.

The carbon intensity of ethanol is falling faster than any other low carbon fuel supplied to California and RFA ethanol producers have committed to zero carbon ethanol production before 2050. While RFA supports the LCFS, the current proposed amendments to the LCFS program are falling short of maximizing technologically feasible and cost-effective greenhouse gas emission reductions that are possible when utilizing higher blends of ethanol and indirect accounting for renewable process energy incorporation in ethanol production.

171.5 **The proposed credit true-up for entities achieving a lower verified operational CI is a reasonable step to recognize GHG emissions reductions that have been achieved. However, the deficit multiplier for a verified CI exceedance is disproportionate.**

RFA supports the proposal to allow credits to be placed in the account of a fuel reporting entity that achieves a lower verified operational CI for a fuel pathway, as this will provide additional incentive to reduce GHG emissions. However, the proposed measure to allocate deficits to entities with a CI exceedance is disproportionate to the treatment of entities achieving a lower verified operational CI and is unnecessarily punitive, as the number of deficits is four times the difference between the verified operational fuel pathway CI and the reported CI, multiplied by the quantity of fuel. A more equitable treatment of these mirror-image cases would be merited, and the deficit multiplier should be eliminated or greatly reduced.

171.6 **The requirement that there be rotation of verification bodies/individual verifiers every six years should be revised.**

The prohibition against the same verification body or individual verifier performing validation and verification services for more than six consecutive years is not newly proposed, but the January 1, 2026 date when entities that are required to use these services would start having to change providers is fast approaching and would occur during the timeframe covered by the proposed amendments. Such changes would be disruptive and costly, and CARB's objectives can be accomplished through less-rigid means. Specifically, it would be sufficient to require that the person(s) leading the verification organization's services for a client be rotated every six years.

Thank you again for the opportunity to submit these comments. RFA looks forward to working with CARB staff and other stakeholders to strengthen and extend the successful LCFS program.

Sincerely,

Scott Richman

Chief Economist

ATTACHMENTS

RENEWABLE FUELS ASSOCIATION

June 6, 2023

Ms. Cheryl Laskowski, Branch Chief
Transportation Fuels Branch
California Air Resources Board
1001 I St
Sacramento, CA 95814

Re: Low Carbon Fuel Standard Workshop May 23, 2023

Dear Ms. Laskowski,

The Renewable Fuels Association (RFA) appreciates the opportunity to comment on the workshop regarding the consideration of potential Acceleration Mechanisms to the Low Carbon Fuel Standard (LCFS) program held on May 23, 2023. The RFA supports the LCFS and looks forward to continued engagement in this process to strengthen and extend the program beyond 2030. The RFA is also working around the country in collaboration with other stakeholders to develop and implement LCFS and other clean fuel programs in other states.

The RFA has commented extensively on the key issues of the LCFS modifications in our letter of August 8, 2022, following the July 27, 2022 LCFS workshop, our letter of December 20, 2022, following the November 9, 2022 LCFS workshop, and our letter of March 15, 2023 following the February 22, 2023 workshop. These new comments should be considered in combination with the earlier comments and are responsive to CARB staff's request at the most recent workshop for stakeholder input on the topics of a potential stepdown in the compliance curve and acceleration mechanisms.

A stepdown in the compliance curve in 2024 is the single most important step CARB can take to strengthen the LCFS.

The LCFS program's outstanding success has resulted in overcompliance, ballooning the credit bank and undercutting credit prices. This is dampening new investment in low- to zero-carbon fuels. A stepdown of at least five percent from the current compliance curve will send the right long-term price signal, while also facilitating a significant strengthening of the 2030 target from the scheduled 20 percent to greater than 40 percent. The RFA is working with a broad coalition of fuel providers who have commissioned ICF to demonstrate both a central and higher ambition case to CARB on what the clean fuels industry is prepared to deliver by way of carbon intensity reductions.

Higher blends of ethanol are a cost-effective and immediate option for maximizing carbon intensity reductions in the LCFS. CARB should include E15 approval in the upcoming LCFS rulemaking package.

At the most recent workshop, the CARB presentation identified the objectives of the new LCFS rulemaking: to support increased low-carbon fuel supply, provide long-term price signals and increase regulatory clarity to support deeper transportation decarbonization, and to leverage new federal programs with complementary LCFS policies.

Consistent with these objectives, CARB should include with the rulemaking an approval of E15 as a legal fuel in California. If E15 had been used in California in 2022 rather than E10, that alone would have allowed the LCFS compliance target to be nearly 2 percent lower. Migration of the market to E15 over the course of this decade would enable a 2.5 percent reduction of the current 2030 target against the 2010 baseline, based on a combination of the expected improvement in ethanol's carbon intensity and the forecast decrease in finished gasoline consumption resulting from the Advanced Clean Cars II regulation. (Please see our calculations at the bottom of this comment letter.)

When the E10 cap is removed from the CATS model, the model immediately selects usage of E15 as a cost-effective way to achieve additional carbon reductions. California and Montana are the only two states not recognizing E15 as a legal fuel. The recently passed IRA includes billions of dollars to support the significant lowering of the carbon intensity of ethanol through CCS, climate smart ag and other efficiency improvements. Not including E15 certification in the current LCFS rulemaking would be inconsistent with the stated goals of the LCFS, sending a contradictory and confusing message to the market on what carbon reduction goals are possible.

It is also important to note that increasing the ethanol blending rate will not result in large increases in ethanol consumption in California but will displace larger volumes of fossil energy use and increase the market share of renewable liquid fuels as overall gasoline volumes decline rapidly with continued electrification. Projected out to 2045 when California has committed to carbon neutrality, there will still be billions of gallons of liquid fuels in the market and these fuels must be ultra-low to zero carbon to achieve that goal. In the gasoline pool, ethanol is the only commercially available fuel that meets this test. Even in emerging renewable gasoline blends, ethanol will still be needed to help raise octane, dilute sulfur, increase oxygen content and provide other desirable properties (e.g., Chevron's new renewable gasoline blend contains 15% ethanol[1]).

[1] https://www.chevron.com/-/media/chevron/newsroom/2023/Q2/renewable-gasoline-blend-factsheet-may-2023.pdf

A properly constructed Acceleration Mechanism is helpful for sending a consistent market signal for innovation and investment in additional supplies of low carbon fuels.

The current low credit prices under the LCFS are clearly inhibiting new investment in low carbon fuel production. The long period of time (up to three years) to update the LCFS given the regulatory process in California is creating uncertainty as to the longer-term trajectory of the program. In combination with an immediate stepdown of the LCFS program in 2024, an Acceleration Mechanism could address this problem. RFA generally agrees with the concepts presented by AJW and believes that an acceleration formula should incorporate ratios of credit and deficit generation as well as ratios of such generation to the overall size of the credit bank.

It is critically important for CARB to move quickly and concisely in strengthening the LCFS program. Timely and accurate modelling and scenario development, with input from the coalition of stakeholders that are supporting the ICF analysis, is an important and valuable tool in this regard.

Ethanol is a top generator of credits in the LCFS program, accounting for three of every 10 credits generated since the program's inception. But constraining ethanol's use to E10 is sacrificing additional carbon reductions possible today. We urge CARB to include E15 approval as part of the regulatory package for the current LCFS modifications under consideration, which will allow the ethanol industry to help displace more fossil fuel in California and lower carbon emissions now.

An accurate modelling of ethanol's benefits and an integration of CARB fuels policy to incentivize higher ethanol blends will result in immediate reductions of GHG emissions and criteria pollutants while lowering the cost of compliance to obligated parties and California consumers.

RFA looks forward to working with CARB staff and other stakeholders to strengthen and extend the successful LCFS program.

Sincerely,

Scott Richman

Re: Low Carbon Fuel Standard Workshop February 22, 2023

Dear Ms. Laskowski,

The Renewable Fuels Association (RFA) appreciates the opportunity to comment on the workshop on potential changes to the Low Carbon Fuel Standard (LCFS) program held on February 22, 2023. The RFA supports the LCFS and looks forward to continued engagement in this process to strengthen and extend the program beyond 2030. The RFA is also working around the country in collaboration with other stakeholders to develop and implement LCFS and other clean fuel programs in other states.

The RFA commented extensively on the key issues of the LCFS modifications in our letters of August 8, 2022 (in response to the July 27, 2022 LCFS workshop) and December 20, 2022 (regarding the November 9, 2022 workshop). These new comments should be considered in combination with the earlier comments and are responsive to CARB staff's request at the most recent workshop for stakeholder input on specific topics.

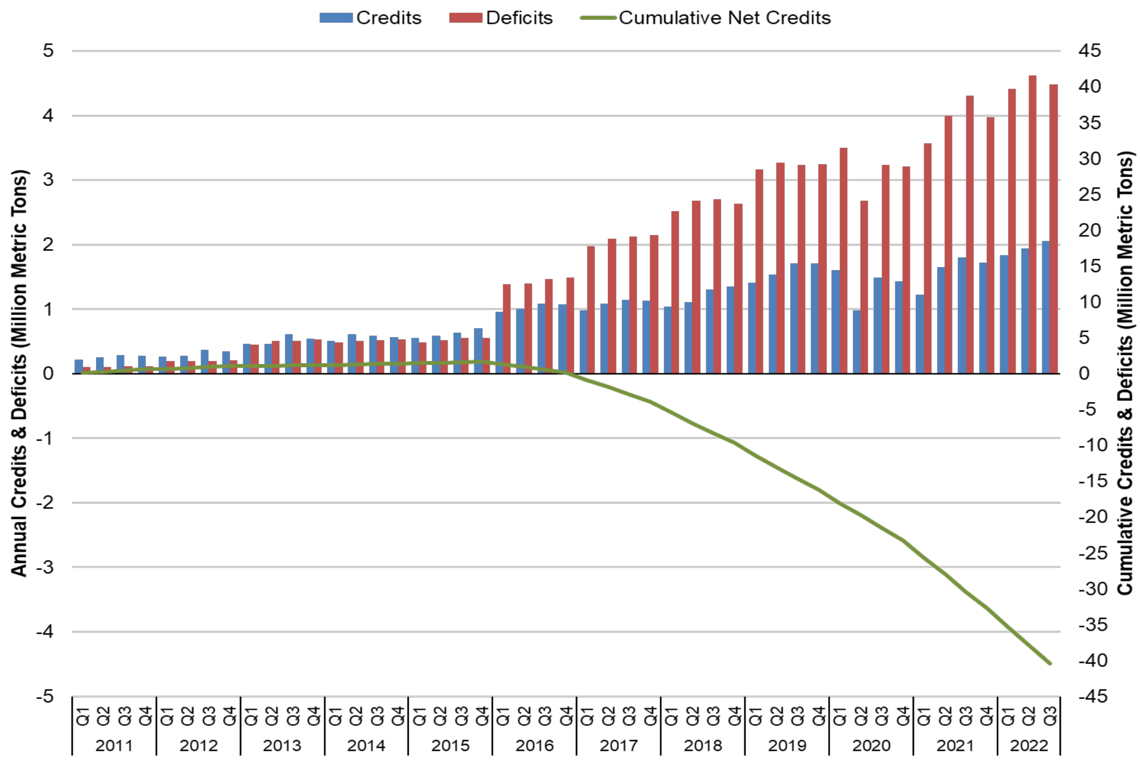
Since the earlier workshops were considered informal workshops, and the February workshop is considered the first formal workshop for the proposed LCFS modifications rulemaking, we are including the earlier comments with this comment letter to ensure that they are included in the formal rulemaking record.

Higher blends of ethanol are necessary to meet the goals of the newly adopted CARB Scoping Plan.

The CARB presentation at the last workshop identified the current *Decade of Action* to achieve the near-term statewide goal of achieving a 48% reduction of GHG emissions below 1990 levels by 2030 and a rapid transition away from fossil fuels in the transportation sector. In addition to aggressive electrification goals, higher blends of low- to zero-carbon ethanol are a critical component of achieving the 2030 targets on the path to carbon neutrality by 2045. CARB has all the data to support the immediate approval of E15 for use in California. Migrating all E10 to E15 in California today would result immediately in approximately 2 million metric tons annually of additional GHG reductions while also reducing criteria pollutants and toxics, all at a lower cost to California consumers.

As RFA has commented before, while the overall LCFS program has resulted in a significant credit surplus (currently over 13 million metric tons with the most recent third quarter report of 2022), the deficit generation in the gasoline pool continues to grow rapidly with a current deficit balance of 40 million metric tons and accelerating as shown below.

LCFS Credits/Deficits Associated with Finished Motor Gasoline and Onroad EV Charging
Q1 2011-Q3 2022



The RFA and a preponderance of stakeholders support both strengthening the 2030 carbon reduction target to at least 30 percent and a stepdown of the current compliance curve starting in 2024. Without addressing the growing deficit generation in the gasoline pool, such a robust strengthening of the compliance curve will not be possible. With a greater inclusion of higher ethanol blends in the California gasoline supply, RFA believes that the 2030 target reduction could be moved to as much as 35 percent. Oregon has strengthened their Clean Fuels Program compliance target to 37 percent by 2035, and the modelling to support this includes both a transition of gasoline blends to E15 and significant growth in the E85 market.

Beyond 2030, intermediate blends above 15 percent and continued growth of E85 are needed to further displace fossil fuels and achieve carbon neutrality. The Scoping Plan includes a large volume of "bio-based gasoline" in achieving carbon neutrality. Ethanol is the only commercially practical and affordable "bio-based gasoline" substitute in the market today, and the LCFS and other CARB policies must clear unnecessary regulatory hurdles to its increased use. Simply stated, by not encouraging higher blends of low- and zero-carbon ethanol in the transportation market today, CARB would be abdicating its own stated goal of maximizing GHG reductions as soon as possible.

Further modify the CATS model to better reflect current and projected ethanol economics, carbon intensities and volumes.

RFA appreciates the revisions in version two of the CATS model that were partially responsive to our comments on carbon intensities and carbon capture and sequestration (CCS), but we believe further revisions would more appropriately reflect the current market and future trends in the ethanol industry.

The updated CATS model incorporates the average carbon intensity (CI) of ethanol in the market today and assumes that CI improvements will continue in the future. Yet, it also assumes that the CI of ethanol produced at facilities using CCS will remain at a constant 35 gCO_2e/MJ through 2045. Given trends in agricultural practices and in the processing of both corn starch and corn fiber ethanol, which were well documented in the RFA comment letter of December 20, 2022, it is reasonable to expect substantial reductions in the CI of ethanol over the next two decades. Accordingly, for ethanol produced using CCS, the model should be modified to assume the CI will decline to zero CI by 2045. This is consistent with recent research and the 2021 pledge by RFA's producer-members to ensure that ethanol achieves net zero lifecycle GHG emissions, on average, by 2050 or sooner.[1]

Additionally, the CATS model baseline should reflect rapid adoption of E15 starting in 2024 for the reasons discussed above, and CARB should consider loosening the binding constraint on E85 usage. RFA would also draw attention to the comments in our December 20, 2022 letter regarding corn price, ethanol conversion costs, E85 infrastructure costs and corn distillers oil, which have not yet been addressed or, in the case of conversion costs, were adversely revised in the latest version of CATS, apparently without referencing available survey-based data.

Regarding E85, the CATS model assumes a 2022 volume of 49 million gallons of E100 equivalent, which translates to approximately 62 million gallons of E85, a volume similar to that reported for 2021. While CARB has not yet published E85 sales for 2022, our market sources would suggest that the E85 number is closer to 100 million gallons. The success of the LCFS and attractive pricing of E85 in California (selling for $1.50 to

[1] https://ethanolrfa.org/pledge

$2.00 per gallon less than gasoline) has resulted in approximately 60-percent increases in E85 demand annually over the last two years. The CATS model should be adjusted to the actual number for E85 sales in 2022. E85 is an extremely effective GHG reduction strategy in California and should be further incentivized in the LCFS program.

RFA is available to provide CARB staff with information on the topics raised regarding the CATS model. With updated and more accurate assumptions, CATS will "choose" more low- to zero-carbon ethanol as one of the most cost-effective ways to lower GHG emissions now and out to 2045 and reduce the pervasive LCFS deficits generated by the gasoline pool.

An Acceleration Mechanism is appropriate for sending a consistent market signal for innovation and investment in new supplies of low carbon fuels.

The current low credit prices under the LCFS are clearly inhibiting new investment in low carbon fuel production. The long period of time (up to three years) to update the LCFS given the regulatory process in California is creating uncertainty as to the longer-term trajectory of the program. Some form of an Acceleration Mechanism could address this problem.

Of the concepts advanced by CARB, RFA believes that a mechanism based on some ratio of credit to deficit generation on an annual basis would be the preferred approach for triggering a compliance mechanism. This is a preliminary assessment, and we look forward to working with CARB staff and other stakeholders in building longer-term market certainty into the LCFS modifications.

It is critically important for CARB to move quickly and concisely in strengthening the LCFS program. Timely and accurate modelling and scenario development through the CATS model and other analyses is a valuable tool in this regard.

Ethanol has generated the single largest volume of credits in the LCFS program, accounting for roughly four of every 10 credits generated since the program's inception. But constraining ethanol's use to 10 percent blends is sacrificing additional carbon reductions possible today. We urge CARB to move quickly to adopt regulations approving E15, which will allow the ethanol industry to help displace more fossil fuel in California and lower carbon emissions now.

An accurate modelling of ethanol's benefits and an integration of CARB fuels policy to incentivize higher ethanol blends will result in immediate reductions of GHG emissions and criteria pollutants while lowering the cost of compliance to obligated parties and California consumers.

RFA looks forward to working with CARB staff and other stakeholders to strengthen and extend the successful LCFS program.

Sincerely,

Scott Richman

Re: Low Carbon Fuel Standard July 7th , 2022 Workshop

Dear Ms. Laskowski,

The Renewable Fuels Association (RFA) appreciates the opportunity to comment on the workshop on potential changes to the Low Carbon Fuels Standard (LCFS) program held on July 7, 2022. The RFA supports the LCFS and looks forward to continued engagement in this process to strengthen and extend the program beyond 2030. The RFA is also working around the country in collaboration with other stakeholders to develop and implement similar programs in other states.

These comments update many of the RFA comments in our letter of January 7, 2022, following the December 2021 LCFS workshop, and are responsive to CARB staff's request at the most recent workshop for stakeholder input on specific topics.

The integrity of the LCFS depends on maintaining technology neutrality.

The hallmark of success of the LCFS is its market-based, technology-neutral approach that is driven by the carbon intensity scores of all fuels whether generating credits or deficits. The RFA supports California's goal of carbon neutrality by 2045. This is an aggressive, but achievable goal that will require a broad portfolio of low- and zero-carbon fuel solutions. The LCFS is a centerpiece policy in California's decarbonization efforts and modifying and extending the LCFS regulation beyond 2030 is necessary to achieve carbon neutrality. Any new policies that are introduced to incentivize new innovations and technology development should be equitably available to all low carbon fuels.

A cap on crop-based biofuels is not necessary, would be inconsistent with the technology-neutral design of the LCFS, and would chill investment in lower-carbon fuel technologies.

During the workshop, CARB staff noted that some stakeholders had expressed concern about the LCFS increasing demand for lipid-based feedstocks for biofuels. While this discussion was focused primarily on lipid-based feedstocks for renewable diesel and biodiesel, RFA believes capping any low-carbon fuels under the LCFS is contrary to the successful market-based and technology-neutral design of the LCFS. The inclusion of substantial land use change emissions factors in the program's carbon intensity scoring framework already serves to constrain the use of certain feedstocks and biofuels under the LCFS. And as discussed in these comments, and as documented in studies and data analysis, the iLUC factor in the LCFS for corn ethanol is overstated and should be adjusted downward. The use of ethanol is also already constrained by federal and state regulations that allow only 15% ethanol (E15) to be used in conventional light-duty automobiles.

California is one of only two states that does not yet allow the sale of E15. If some LCFS stakeholders feel it is necessary to take credit generation pressure off lipid-based biofuels like renewable diesel, the easiest and fastest way to do that would be to approve the use of E15.

Further, capping the use of certain feedstocks (like corn) for ethanol production would have no impact whatsoever on consumer food prices or food price inflation rates. Indeed, it has been very well established that the primary driver of food price inflation is energy price inflation (i.e., since energy is used at every step in the food production supply chain). Thus, programs like the LCFS that encourage greater use of lower-cost, lower-carbon alternatives to petroleum play a role in fighting the effects of petroleum market volatility on food inflation. Capping the use of biofuels would only exert more pressure on petroleum markets, drive petroleum prices higher, and spur additional food price inflation.

U.S. ethanol production peaked in 2018 at approximately 16 billion gallons. The pandemic, structural marketplace changes (e.g., more fuel-efficient cars, higher gas prices, higher sales of electric vehicles and increased working from home) have suppressed gasoline consumption and by extension, the usage of ethanol. The EIA forecasts only negligible growth in domestic ethanol production and consumption between 2023 and 2030 and increases in corn productivity (i.e., yield per acre), are generally expected to outpace any increases in the use of corn for ethanol over the next decade.

Meanwhile, modest increases in ethanol production combined with the allowance to sell higher blends can help accelerate the decline in gasoline consumption in California that will be necessary to achieve carbon neutrality by 2045. Given the volume of petroleum fuels that will continue to be in use in 2040 and beyond, accelerated carbon removal is essential in achieving carbon neutrality. This is fully recognized in California's Draft 2022 Scoping Plan.

Ethanol has the unique ability to combine low carbon fuel production with carbon removal through CCS. Two ethanol plants in the US have already commercialized CCS, and the industry is poised for widescale adoption of CCS as long as the appropriate federal and state policy signals remain in place. Capping crop-based biofuels in the LCFS would send the wrong signal to a biofuels industry that is making significant investment in low- and zero-carbon technologies and represents the most immediate and economic path to CCS.

US farmers have supported the significant growth in biofuel production while continuing to supply growing food, feed, and fiber markets. We are attaching to this letter an RFA presentation that goes into more detail on this topic. In summary, due to productivity gains in agricultural production and processing, U.S. farmers have easily satisfied demand growth in all market segments on less crop acreage than in 2007 when the RFS2 regulations were implemented.

Feed corn is the primary feedstock for U.S. ethanol. The production process converts the starch in the corn kernel to ethanol, while concentrating the feed value in the form of high protein feed (DDGS) and the industry continues to fraction off more valuable components of the corn kernel such as corn oil that is an ultra-low carbon input for renewable diesel production and fiber that can be converted to cellulosic ethanol.

Processes to further concentrate the protein for higher value protein markets also increases the corn oil yield. Today, there is over 150 million gallons per year of cellulosic corn fiber ethanol delivered to California and this amount could grow significantly over the next several years with the right market signals provided by the LCFS in California and similar programs in other states. Capping crop-based biofuel production would be the wrong market signal for an industry that continues to grow and innovate in meeting food, feed, fiber, and fuel markets.

RFA supports CARB staff's consideration of stronger LCFS compliance curves before and after 2030.

Strengthening the compliance curves is appropriate to harmonize the LCFS with the goal of carbon neutrality by 2045, and it sends the long-term market signal necessary to encourage the significant new investment in innovative technologies required to meet decarbonization goals. In the early years of the LCFS, political and market uncertainty resulted in low LCFS credit pricing which dampened investment in lower carbon fuels. But following the "readoption" of the LCFS in 2015, credit prices reacted in a way that stimulated investment and growth in low-carbon fuels. From 2018 through the first half of 2021, credit prices held steady around $200 per metric ton, stimulating new investments in growing supplies of lower carbon biofuels, electrification, and refinery improvements. In the last year, credit prices have dipped to below $100 per metric ton, and there is a real risk of not attracting sufficient new investments for the large volumes of low carbon fuels needed to meet future compliance targets. Prices have drifted lower due to the success of the program, with projections of over-compliance and a significant build in the credit bank balance over the next several years absent a significant adjustment to the compliance curve.

Specifically, RFA supports strengthening the 2030 target from a 20 percent reduction to between a 25 and 30 percent reduction. We would suggest that post 2030 targets be set in a linear fashion to be close to 100 percent reductions by 2045. Quickly moving to a steeper and longer-term compliance curve will send a strong market signal that the ultimate success of the LCFS depends on continued innovation and new investments. RFA members have committed to achieving net-zero carbon ethanol production by 2050. A recent study by Informed Sustainability Consulting identified five distinct pathways to net-zero corn ethanol based on a set of 28 emissions reduction actions that were considered. It concluded that "the industry can achieve net-negative (carbon intensity) ethanol by adopting near term technologies and expanding best practices in corn farming." [1]

However, if CARB were to proceed with an ill-advised cap on crop-based biofuels, it would not be feasible to substantially strengthen the compliance curve—and CARB's vision of achieving carbon neutrality by 2045 would be put in grave danger.

Higher ethanol blends are necessary to meet a more aggressive LCFS compliance schedule and carbon neutrality goals.

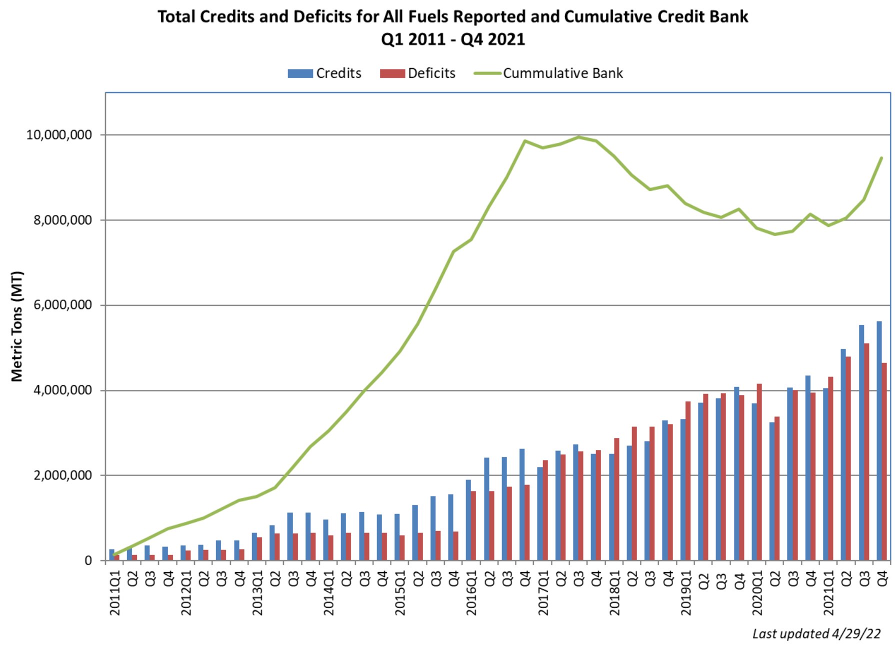
Higher blends of low-carbon ethanol in the current gasoline pool represent the nearest term and most affordable path for immediate reductions of GHG emissions from the light duty fleet. Higher ethanol blends are also necessary to meet the longer term need to decarbonize the liquid fuels that will be in the California transportation system for decades to come.

The University of California's Institute of Transportation Studies report, "*Driving California 's Transportation Emissions to Zero"* (April 2021) clearly documented this challenge and pointed repeatedly to the need for the LCFS and complementary policies to drive the substantial volume of liquid fuels remaining in the system to near zero carbon. To date, ethanol has contributed approximately 30 percent of all LCFS credits, with the vast majority from 10 percent ethanol blends (E10).

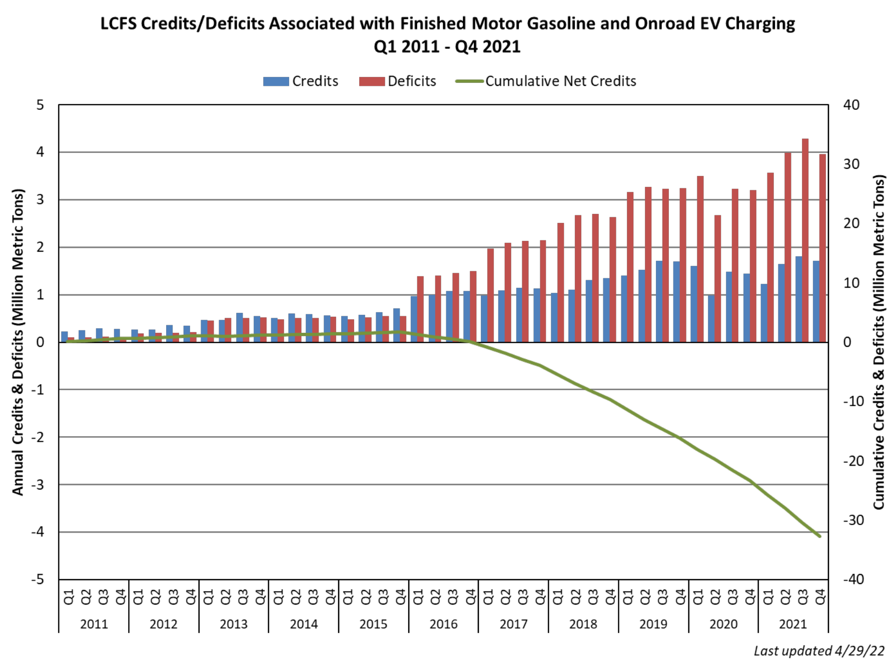
Complementary policies to allow for higher blends of ethanol, E15-E100 are a critical component to the future success of the LCFS. Even with ethanol contributing the single largest share of LCFS credits in the program, limiting ethanol to a 10 percent blend has swamped the gasoline pool with net deficits. The first chart shown below is for all fuels showing a net credit surplus of nearly 10 million metric tons to date as reported by CARB.

---

[1] *Pathways to Net-Zero Ethanol: Scenarios for Ethanol Producers to Achieve Carbon Neutrality by 2050;* Emery, I., February 2022; https://ethanolrfa.org/file/2146



However, looking at the gasoline pool separately, as shown in the chart below, a different picture emerges. Ethanol and electricity combined (i.e., the only current replacements for gasoline) are not even close to covering the deficits generated by CARBOB, resulting in a large and growing net deficit of over 30 million metric tons program to date.



Source: California Air Resources Board. Included CARBOB, ethanol and electricity for on-road light and medium duty vehicles

The rapid growth of renewable diesel has provided the excess credits in the program to cover the gasoline deficits. This is not sustainable, as new supplies of renewable diesel are needed to further displace conventional diesel and gasoline substitutes will need to cover gasoline deficits in a transportation system moving toward carbon neutrality. Also, as mentioned above, if some LCFS stakeholders feel it is necessary to take credit generation pressure off lipid-based biofuels like renewable diesel, the easiest and fastest way to do that would be to approve the use of E15.

Achieving carbon neutrality will only be possible with the widespread deployment of low to zero carbon ethanol at blends above 10 percent, along with electrification and other bio-based gasoline substitutes. An important first step is to immediately approve the use of E15 in California. The LCFS should also work in tandem with other CARB polices to encourage, require, or incentivize future ICE engines that can run on very high levels (i.e., 85-100 percent) low to zero carbon biofuels. The Advanced Clean Car Regulation should require that all ICE engines sold starting in 2026 are flex fuel (FFV) capable.

Biofuel producers should qualify for book and claim credits for RNG in the pipeline utilized to substitute for natural gas in the biofuel production process.

This modification to the LCFS would be consistent with the principles of technology neutrality and further incentivizing private investment in low carbon fuels. It is also analogous with the book and claim accounting that is currently allowed for hydrogen producers utilizing pipeline RNG in the manufacturing process of hydrogen for fuel. To ensure fairness, consistency, and neutrality across all low carbon fuel pathways, CARB should allow all low-carbon fuel producers to use the same accounting procedures. Combining RNG for process fuel with carbon capture and sequestration (CCS) projects that are now in the planning stages at many ethanol facilities, moves the industry to the production of ultra-low to zero to negative carbon ethanol. The right policy support from the LCFS facilitates this valuable contribution in meeting the state's climate goals.

RFA strongly supports allowing low-carbon fuel producers to incorporate site-specific agricultural factors and inputs into fuel pathways.

A significant portion (roughly half) of the full life cycle carbon intensity of ethanol is from the agricultural production of the feedstocks. With the increasing employment of no-till, cover cropping, and other modern precision agricultural practices, farmers have quantified the ability to significantly lower the carbon intensity of feedstock production while also increasing soil carbon levels. These practices result in carbon scoring well below the current averages employed in the CA-GREET model. Currently, the CA-GREET model treats agricultural feedstock production practices as "one size fits all" and does not allow ethanol producers to incorporate lower-carbon agricultural practices into their pathway carbon intensity scores. Allowing fuel producers to provide site specific input agricultural data will further incentivize carbon efficient agricultural practices, resulting in lower carbon ethanol production and contributing to a more successful LCFS. More detailed recommendations for recognizing soil carbon sequestration and other carbon efficient ag practices within CA-GREET are provided in a comment letter from the Low Carbon Fuels Coalition, which was signed and endorsed by RFA. We look forward to working with CARB staff and other agricultural and academic stakeholders to systematically address CARB's questions regarding verification and permanence.

A combination of a high concentration of low to zero carbon ethanol combined with more efficient engines is an opportunity to define new Energy Economy Ratios (EERs).

The high-octane rating of ethanol combined with a higher-compression ratio internal combustion engine offers a significant fuel efficiency improvement and lifecycle carbon intensity reduction. However, the LCFS currently does not provide any opportunity to recognize and encourage these GHG benefits. The use of a high-octane fuel with higher renewable content in a plug-in hybrid with a higher compression ratio engine qualifies as a ZEV and represents an opportunity for defining a new EER. Specifically, our analysis has shown that the use of a high-octane (98 RON) blend containing 30 percent ethanol in a high-compression ratio engine would result in a drivetrain energy efficiency improvement of 11 percent, equating to an EER of 1.11. We encourage CARB to include an EER for high-octane fuels used in high compression ratio engines in both conventional and plug-in hybrid vehicles.

The land use change (LUC) values used by CARB to determine CI scores should conform to updated analytical and empirical data.

A recent analysis by a collaboration of researchers from Environmental Health Engineering, MIT, Tufts, and Harvard concluded that a LUC (direct and indirect) emissions value for corn ethanol of 3.9 g/MJ represents the most credible evolution of the science on the topic.[2] Oregon's Clean Fuels Program uses the Argonne GREET model values of 7.8 g/MJ. These lower values are supported by recent analyses of land use patterns by Purdue University, the U.S. Departments of Energy and Agriculture, University of Illinois, and other institutions. Both values are well below California LCFS value of 19.8 g/MJ, which has not been updated since 2014.

The Argonne GREET model is the basis for the entire life cycle analysis in the LCFS, so it is consistent to use Argonne GREET for land use change values as well. Argonne updates its model regularly (typically on an annual basis) to incorporate the best

[2] *Carbon Intensity of Corn Ethanol in the United States: State of the Science:* Scully, M. et al., January 2021; https://iopscience.iop.org/article/10.1088/1748-9326/abde08

science on all variables. Additionally, in the interest of technology neutrality and with the rapid increase in battery-electric vehicles, the land use impacts of mineral extraction for battery production should also be evaluated [3], along with the land use implications of expanded wind and solar electricity generation [4].

There are several other data sources and studies that should be considered in the analysis of crop-based biofuels.

Responsive to CARB staff's request for other data sources and studies to take into consideration, following are other important and recent studies that should be reviewed on the topics of ethanol's climate and land use change impacts.

- *Retrospective Analysis of the U.S. Corn Ethanol Industry for 2005-2019; Implications for Greenhouse Gas Emission Reductions;* Lee, U et al., May 2021; https://onlinelibrary.wiley.com/doi/10.1002/bbb.2225. The study, conducted by Argonne National Laboratory researchers, found that the carbon intensity of corn ethanol shrank by 23% over the 2005-2019 timeframe, from 58 to 45 gCO2e/MJ (not including the land use change value of 7.4 gCO2/MJ). By 2019, corn ethanol reduced lifecycle emissions by 44-52% compared to gasoline. The researchers determined that corn ethanol reduced transportation related greenhouse gas (GHG) emissions by a cumulative 544 million metric tons CO2e over the study timeframe. Notably they demonstrated that there has been a "downtrend in simulated (land use change) emissions" that the stated "is a result of better developed and calibrated economic models and better modeling of GHG emissions."

- *GHG Emissions Reductions due to the RFS2: A 2020 Update*; Unnasch, S. & Parida, D., February 2021; https://ethanolrfa.org/file/748. The Renewable Fuel Standard (RFS) as expanded in 2007 has resulted in significant reductions in GHG emissions, with cumulative carbon dioxide savings of 980 million metric tons to date. Most of the savings have been associated with the use of ethanol.

- *The California Low Carbon Fuel Standard: Incentivizing Greenhouse Gas Mitigation in the Ethanol Industry*; Lewandrowski, J., Hohenstein, B., & Pape, D., November 2020; https://www.usda.gov/sites/default/files/documents/CA-LCFS-

[3] See, for example, International Energy Agency. "*The Role of Critical Minerals in Clean Energy Transitions.*" May 2021. The report shows highly variable EV carbon intensity based on the minerals used. Mining and processing of cobalt sulfate, for example, is four times more carbon intensive than mining and processing of zinc. https://www.iea.org/reports/the-role-of-critical-minerals-in-clean-energy-transitions

[4] A recent study published in Nature, for example, found that the land cover changes, including indirect effects, associated with significant expansion in solar "…will likely cause a net release of carbon ranging from 0 to 50 gCO_2/kWh [0-180 g CO2/MJ], depending on the region, scale of expansion, solar technology efficiency and land management practices in solar parks." See: van de Ven, DJ., Capellan-Pérez, I., Arto, I. *et al.* The potential land requirements and related land use change emissions of solar energy. *Sci Rep* **11,** 2907 (2021). https://doi.org/10.1038/s41598-021-82042-5

Incentivizing-Ethanol-Industry-GHG-Mitigation.pdf. The assessment, which was conducted by researchers from the USDA and ICF, concluded that the value of credits toward California's Low Carbon Fuel Standard (LCFS) provides a strong financial incentive for ethanol facilities to implement GHG-reducing technologies and practices. A series of interviews with ethanol facility managers indicated that the LCFS and other policies, including the RFS, were large drivers of decisions to proceed with plant upgrades, such as process efficiency improvements, process energy modifications, changes to co-product production, and enzyme enhancements.

- *Response to Comments from Lark et al. Regarding Taheripour et al. March 2022 Comments on Lark et. al. Original PNAS Paper*; Taheripour, F. et al., May 2022; https://greet.es.anl.gov/publication-comment_environ_outcomes_us_rfs2. Researchers from the Department of Energy's Argonne National Laboratory, Purdue University, and the University of Illinois system thoroughly assessed the paper by Lark et al. "Environmental Outcomes of the US Renewable Fuel Standard," and they refuted key findings of the work. They showed that indirect land use change was overestimated, and land transitions were misinterpreted; additionally, there were significant issues with the calculation of GHG emissions associated with purported land use change. The authors concluded, "The overestimated emission factors and overestimated land conversion in Lark et al. led to overestimated [land use change] emissions for corn ethanol."

- *A Cautionary Tale: A Recent Paper's Use of Research Based on the USDA Cropland Data Layer to Assess the Environmental Impacts of Claimed Cropland Expansion*; Pritsolas, J. & Pearson, R., June 2021; https://ethanolrfa.org/file/1833/SIUE-Rebuttal-on-USDA-CDL-Use.pdf. A study by Zhang et al. assessed the environmental impacts of cropland expansion in the Midwest between 2008 and 2016, building on previous research that used the USDA Cropland Data Layer (CDL) to estimate the conversion of grassland to cropland. A review of the two studies determined, "The cropland expansion claimed … has a high potential of being false change due to poor classification certainty in the earlier CDL." This occurred since the earlier CDLs underestimated cropland area and grossly overestimated non-cropland area, but both were mapped more accurately as the CDL improved over time. The reviewers pointed out that the USDA has warned about "very low classification accuracy" of pasture and grass-related land cover categories in the CDL.

- *Response to "How Robust Are Reductions in Modeled Estimates from GTAP-BIO of the Indirect Land Use Change Induced by Conventional Biofuels?"*; Taheripour, F., Mueller, S., & Kwon, H., May 2021; https://www.sciencedirect.com/science/article/abs/pii/S0959652621016504. The paper was a response to criticisms by Malins et al. regarding the Global Trade Analysis Project model for biofuel analysis (GTAP-BIO) and the Carbon

Calculator for Land Use Change from Biofuels Production (CCLUB). The authors compared early versus recent results of GTAP-BIO, discussed the treatment of cropland pasture, the yield-to-price elasticity and harvest frequency in the model, and they commented on the CCLUB emissions model. They asserted that as data and models have improved over time, estimates of the emissions associated with induced land use change from biofuels have decreased. It was noted that in the past, the "exclusion of market mediated responses, poor characterization of agricultural supply responses, poor reflection of real-world data, and using models and data not well-suited for addressing ILUC-related questions contributed to over-estimation of land use changes due to biofuels".

- *Effects of Ethanol Plant Proximity and Crop Prices on Land-Use Change in the United States*; Yijia, L., Miao, R., & Khanna, M., December 2018; https://onlinelibrary.wiley.com/doi/10.1093/ajae/aay080. The analysis showed that land use is inelastic to changes in corn ethanol production capacity. A 1% increase in the effective ethanol capacity in a county led to an increase in corn acreage in that county by about 0.03% to 0.1%, and an increase in total acreage of only 0.02% to 0.03%. The effect of the corn price and aggregate crop price on acreage change from 2008 to 2012 was more than twice as large. The results implied that the effect of changes in corn price on land use was largely at the intensive margin rather than at the extensive margin. Corn prices are influenced by a number of factors, not only ethanol, and it was noted that the effect of crop prices on land use was largely reversed as a result of the downturn in prices after 2012 and was close to negligible by 2014 relative to 2008.

- *Carbon Calculator for Land Use Change from Biofuels Production: Users' Manual and Technical Documentation*; Dunn, J. et al., December 2017; https://greet.es.anl.gov/files/cclub-manual-r4. The Carbon Calculator for Land Use Change from Biofuels Production calculates carbon emissions from land use change for ethanol production pathways, including corn ethanol. It is used in connection with Argonne National Laboratory's GREET model. For corn ethanol, land use change emissions were estimated to be 7.8 g CO_2e/MJ.

- *Lessons Learned from US Experience with Biofuels: Comparing the Hype with the Evidence*; Khanna, M., Rajagopal, D., & Zilberman, D., March 2021; https://www.journals.uchicago.edu/doi/pdf/10.1086/713026. The paper reviews projections that were made about the impacts of biofuels during the initial expansion in the 2000s and presents empirical evidence and modeling results about the effects of increased production on crop and fuel prices, land use change and GHG emissions. Biofuels were one of several significant factors that contributed to the increase in agricultural commodity prices through 2012, but the impact has dissipated over time. Regarding indirect land use change, the authors concluded that "the high initial estimates of the effect of biofuels on ILUC were driven largely by stringent model assumptions and have not been supported by either recent models (that have more advanced features) or the empirical evidence that has emerged over time."

- *Economic Impacts of the U.S. Renewable Fuel Standard: An Ex-Post Evaluation*; Taheripour, F., Baumes, H., & Tyner, W., June 2020; https://www.frontiersin.org/articles/10.3389/fenrg.2022.749738/full. The GTAP-BIO model was used to evaluate the extent to which the RFS and other factors affected commodity markets in the medium to long run, focusing on two time periods: 2004-2011 and 2011-2016. The analysis determined that coarse grain prices were 0.6% higher during the first time period and 0.9% higher during the second period due to the RFS. This was supplemented with a partial equilibrium model, which determined that on a short-term basis the price of coarse grains was 6.7% higher during the second period due to the RFS. Overall, the study concluded that the RFS made major contributions to the agriculture sector, raising U.S. annual farm incomes by $1.4 billion in the first period and by $2.4 billion in the second period. In both periods, the long-run effects of biofuel production and policy on food prices were negligible.

- *Food Versus Fuel: An Updated and Expanded Evidence*; Filip, O. et al., August 2019; https://www.sciencedirect.com/science/article/pii/S0140988317303742. The study was segmented into three time periods, centering around the commodity price escalation that occurred during the second half of the 2000s. The analysis determined that ethanol did not affect agricultural commodity prices prior to June 2008, that it explained approximately 15% of the variance in corn prices and 5% of the changes in other commodity prices from July 2008 to February 2011, and that it contributed to approximately 10% of the variance in commodity prices from March 2011 to May 2016. The authors concluded that the results served as an ex-post correction of early studies that found biofuels had more substantial effects.

- *The Impact of Ethanol Industry Expansion on Food Prices: A Retrospective Analysis*; Informa Economics IEG, November 2016; https://ethanolrfa.org/file/975/Retrospective-of-Impact-of-Ethanol-on-Food-Prices-2016.pdf. A retrospective statistical analysis determined that retail food prices were not impacted in any demonstrable way by the expansion of U.S. corn ethanol production under the RFS. In fact, the study found that food price inflation actually slowed during the "ethanol era." While corn prices were positively impacted by ethanol expansion, the link between corn prices and consumer food prices was shown to be weak.

Making higher blends of ethanol available to consumers promotes equity.

Ethanol reduces GHG emissions, criteria pollutants[5] and lowers cost to the consumer. Life cycle modelling has clearly demonstrated that ethanol reduces GHG emissions compared to gasoline by approximately 50 percent. Corn fiber ethanol production reduces GHG emissions by roughly 70 percent and as discussed, the ethanol industry continues to drive ethanol production toward net zero carbon offering an affordable and viable path for decarbonization in transportation alongside vehicle electrification.

The recent emissions testing on E15, sponsored and supported by CARB, showed significant reductions in most criteria pollutants compared to E10. This can help improve the air quality today in front line communities that have a disproportionate exposure to today's air pollution.

Historically, ethanol has sold at a discount to gasoline. Currently, E85 is typically selling in California at over a $2/gallon discount (or more) to regular gasoline.[6] E85-capable vehicles (flex fuel vehicles) cost the manufacturer just $50-100 more to produce than conventional gasoline-powered vehicles and are significantly less to produce (and purchase) than current electric vehicles. Providing policy support for E15 and flex fuels like E85 helps meet California's ambitious environmental goals while providing consumer choice and lower cost options for California citizens.

RFA applauds CARBs commitment to support the exportability of the LCFS.

Many other jurisdictions across the country are now considering LCFS type programs and California is the leader. The successful policy framework of the LCFS is an excellent model for developing new programs outside of California, but its attractiveness to other jurisdictions depends on maintaining a technology neutral, market-based structure. RFA believes that protecting the integrity of a performance based standard and working on incorporating site specific agricultural inputs improves the exportability of the LCFS program.

RFA urges CARB staff to move expeditiously to make these modifications to the LCFS. The most recent UN IPCC report and subsequent COP 26 meeting in Glasgow make alarmingly clear the imperative of further reducing GHG emissions immediately. The recent rash of extreme heat events, wildfires and flooding around the world are painful reminders of the consequences of the climate crisis and the urgency to act now.

---

[5] See, for example, the results of recent emissions testing supported by CARB and conducted by the University of California Riverside. https://ww2.arb.ca.gov/resources/documents/comparison-exhaust-emissions-between-e10-carfg-and-splash-blended-e15

[6] See, for example, https://twitter.com/EthanolRFA/status/1554149931325300741?cxt=HHwWioC9hZvIuZErAAAA

The cumulative impacts of not reducing GHG emissions as soon as possible can be catastrophic. When coupled with the ongoing decrease in the carbon intensity of ethanol, higher ethanol blends like E15 and flex fuels like E85 present a practical and cost-effective opportunity for both immediate and long-term GHG reductions under the LCFS.

RFA looks forward to working with CARB staff and other stakeholders to strengthen and extend the successful LCFS program.

Sincerely,

Kelly S Davis

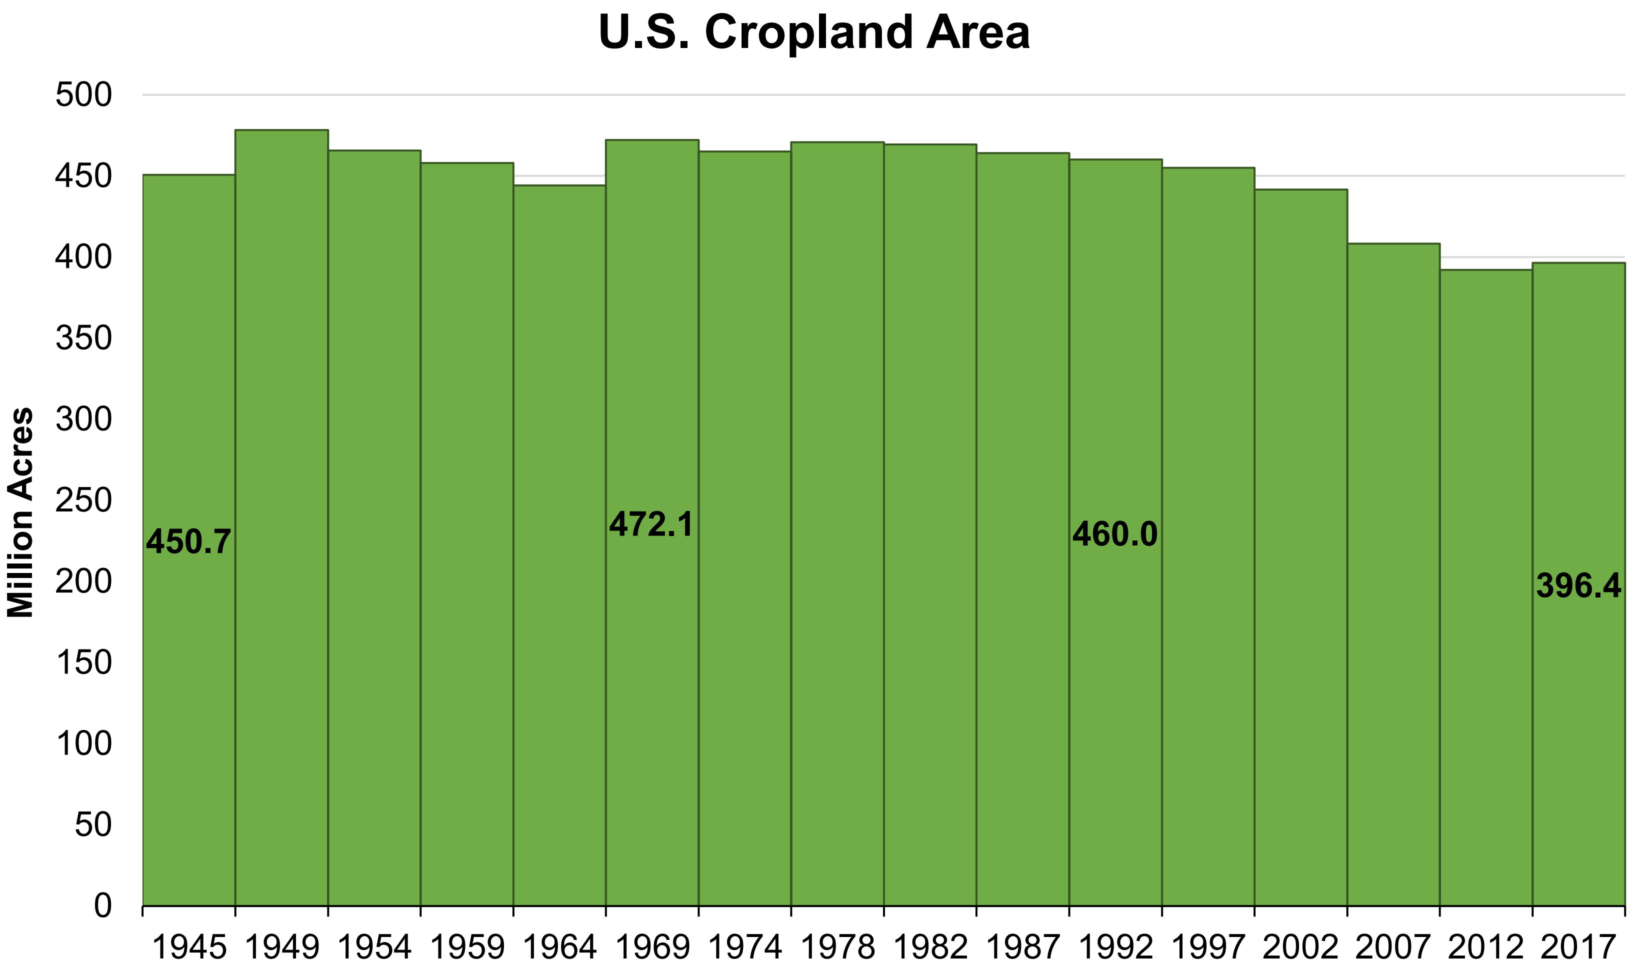
VP of Regulatory Affairs

Thinking Clearly About Agricultural Land Use, Productivity Gains, and the Impact of Ethanol Expansion

Renewable Fuels Association

July 2022

The amount of U.S. land dedicated to crop production continues to shrink

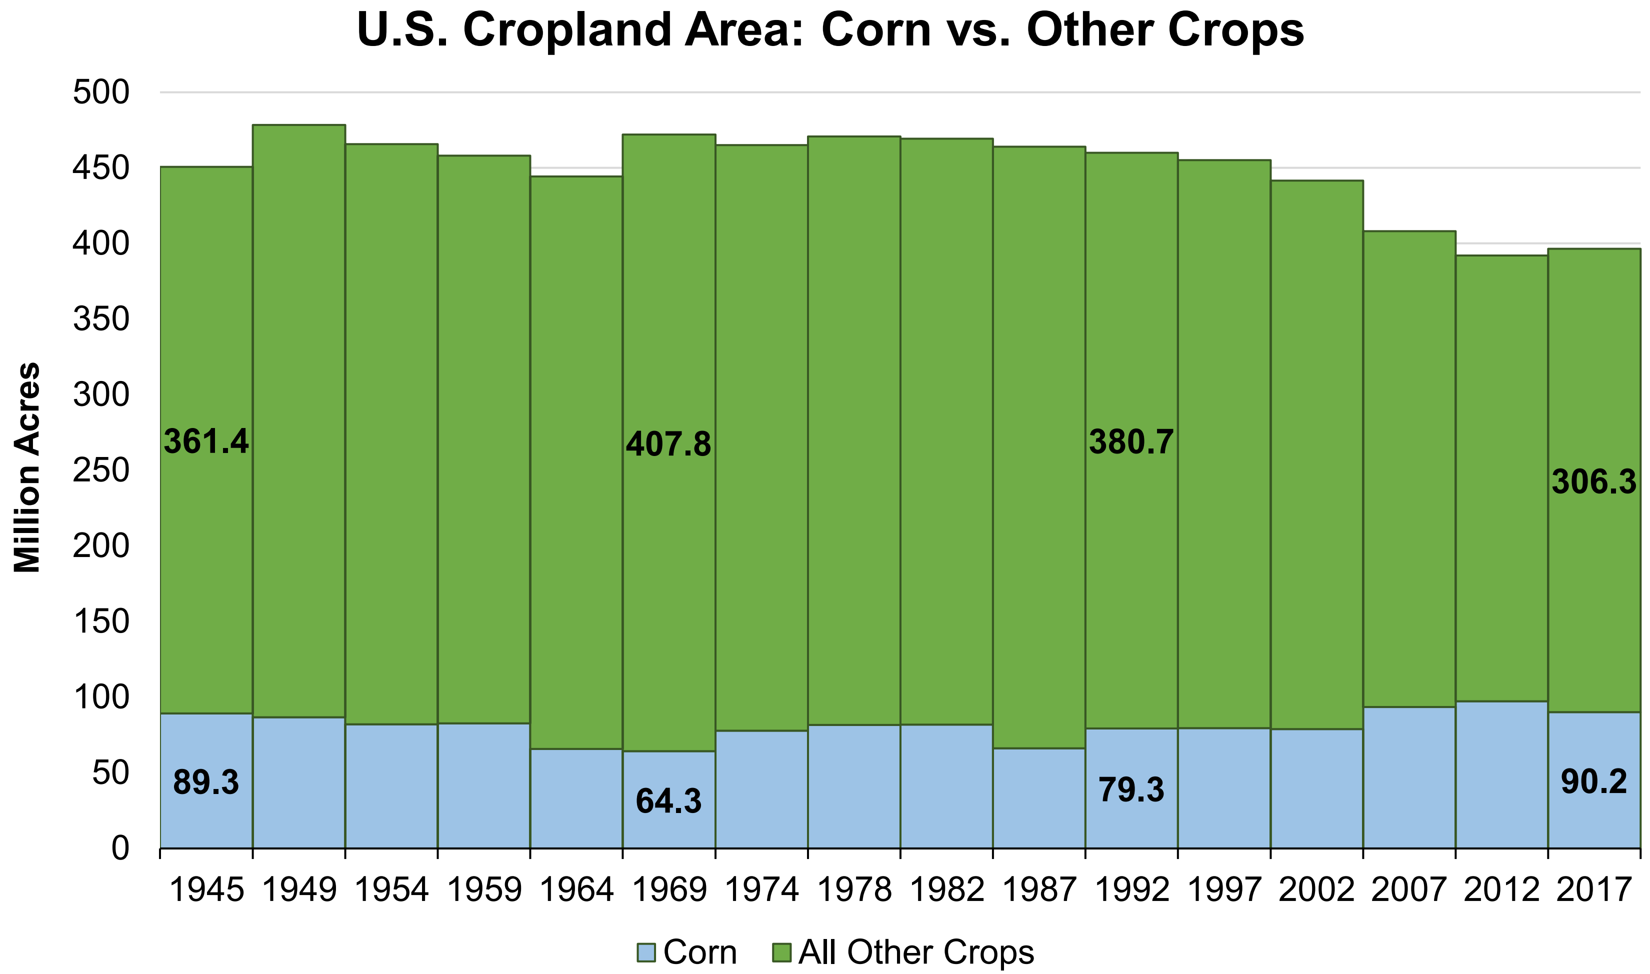


- Since the late 1960s, U.S. land dedicated to crop production has continued to shrink.
- Between 1969 and 2017, U.S. cropland fell 16%, or 76.7 million acres—an area the size of New Mexico, our fifth-largest state.
- U.S. cropland has remained under 400 million acres since 2008.

Source: USDA Census of Agriculture (2022 data not yet available)

RENEWABLE FUELS ASSOCIATION

Total cropland is shrinking, even as corn acreage is flat or slightly increasing

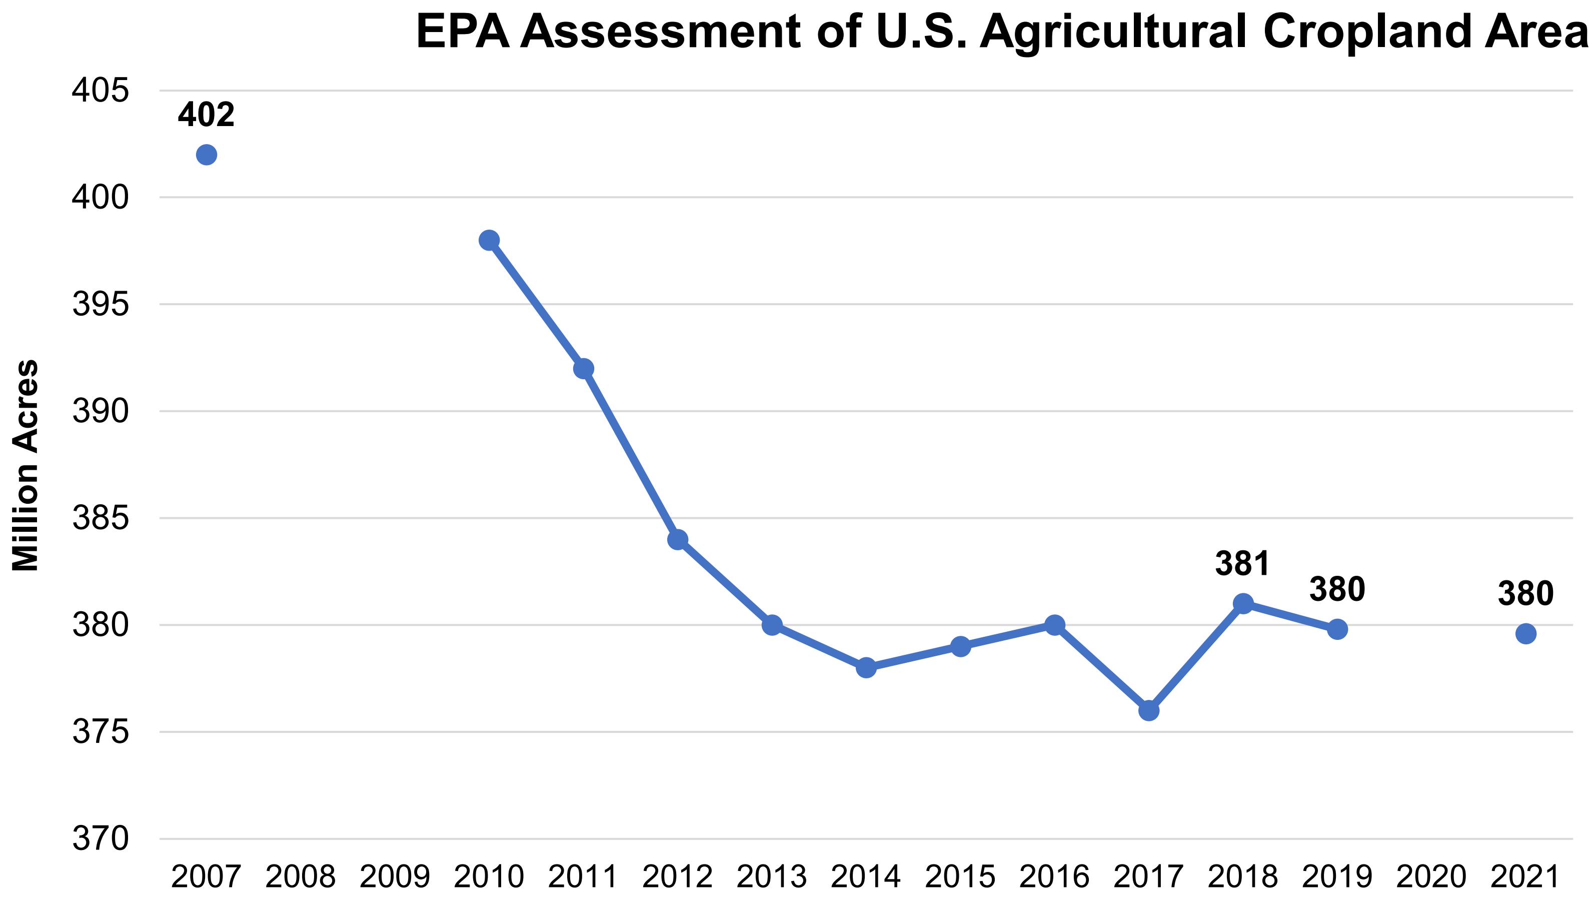


- In recent years, corn has accounted for roughly 20% of U.S. cropland.
- Acres planted to corn in 2017 were nearly identical to the amount of land planted to corn in 1945 (less than 1 million acres difference).
- Acres planted to wheat, cotton, oats, sorghum, barley and other crops have trended lower as increased yields and lower demand have reduced land requirements.

Source: USDA Census of Agriculture (2022 data not yet available)

RENEWABLE FUELS ASSOCIATION

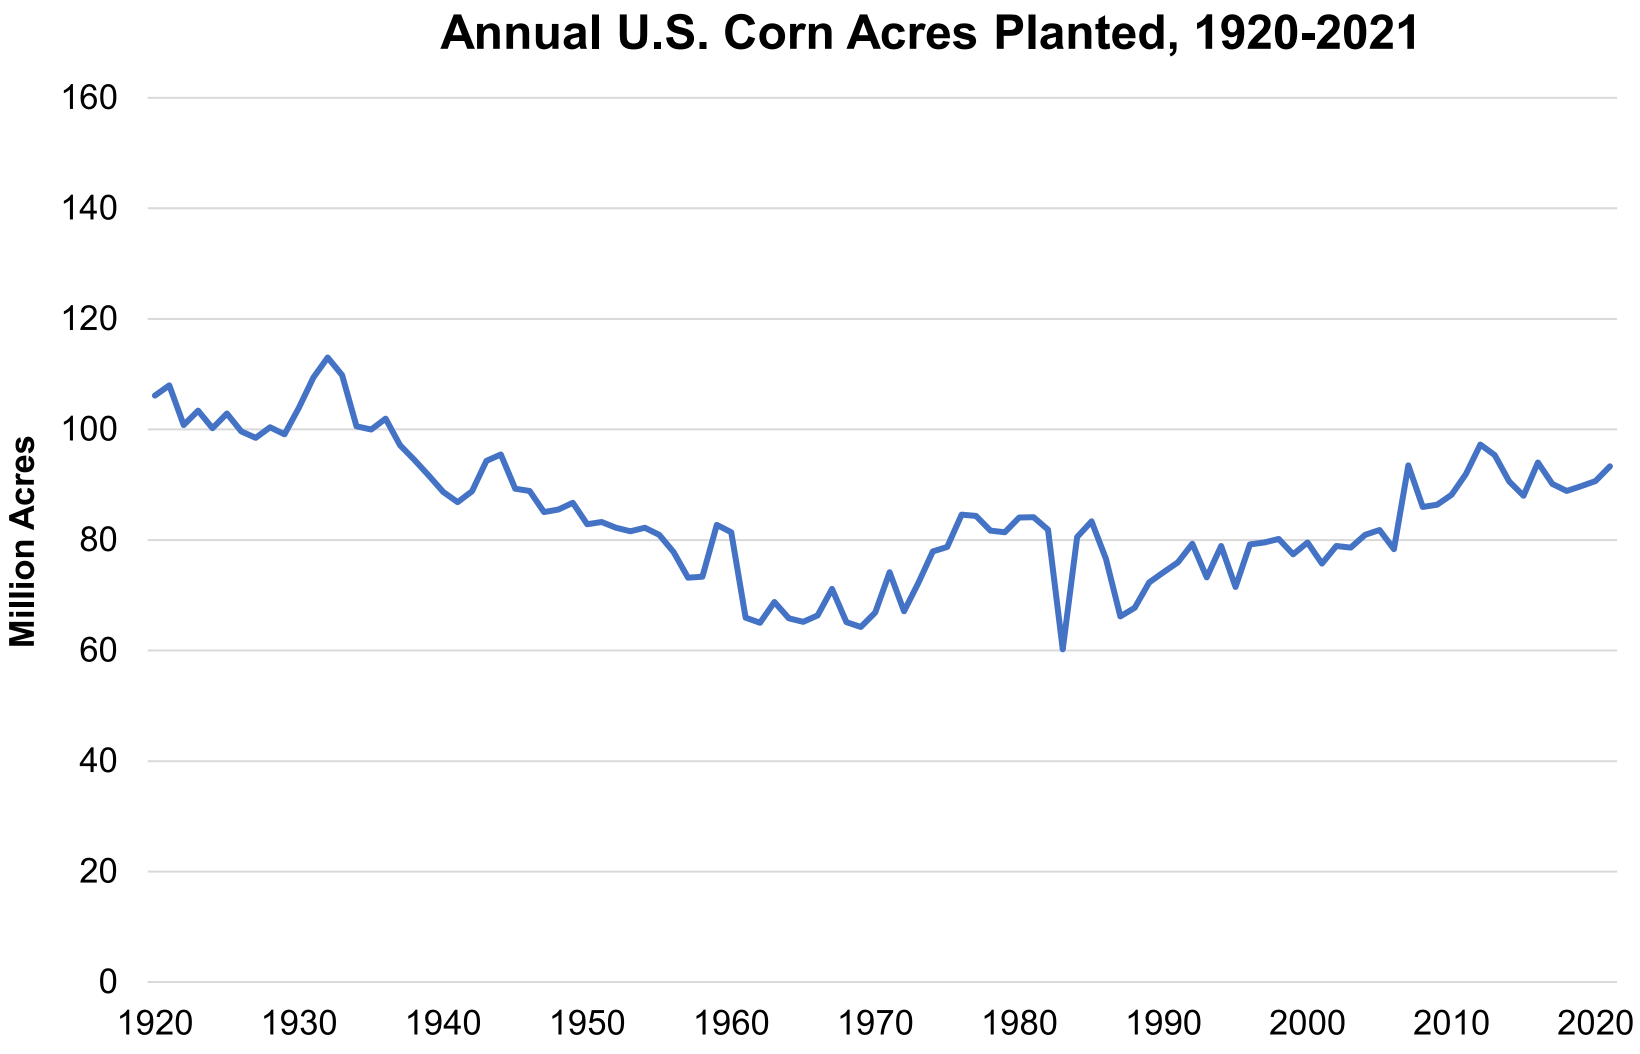
EPA data show nearly 25-million-acre reduction in agricultural cropland since 2007



- The 2007 law establishing the expanded RFS **prohibits** ethanol producers from using corn or other feedstocks from new cropland “cleared or cultivated” after 2007.
- To ensure compliance, U.S. EPA tracks agricultural cropland area annually using USDA data. The data show **no expansion** of U.S. cropland from 2007 levels.
- In fact, U.S. EPA analysis shows a **decrease** in agricultural cropland of 20-25 million acres (roughly 6%) between 2007 and 2017-2021.

Source: U.S. EPA

Fewer corn acres today than in 1920s-1930s

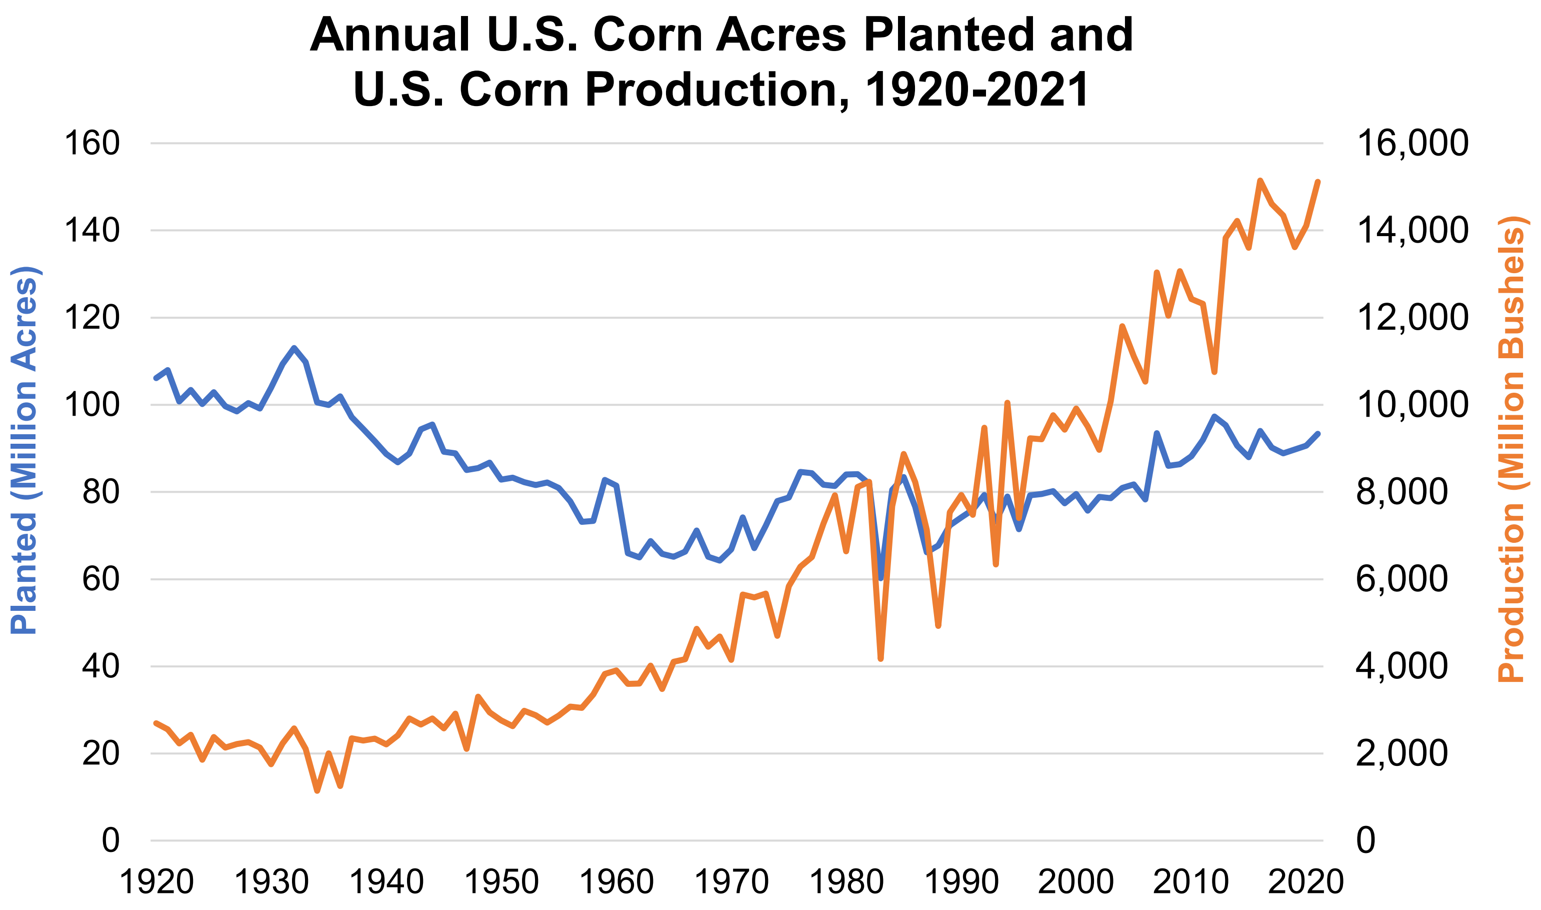


Source: USDA

- Over the past 100 years, acres planted to corn have averaged less than 85 million annually.
- Corn acres were well over 100 million in the 1920s and 1930s, peaking at 113 million in 1932.
- Corn acres have generally been in the 85 to 95-million-acre range since the RFS was expanded in 2007, as profitability returned to corn farming.
- Corn acres have been trending downward since 2012, as stocks were rebuilt and prices gravitated lower.

RFA
RENEWABLE FUELS ASSOCIATION

Corn acreage trending downward, while production up nearly 600% since 1920s

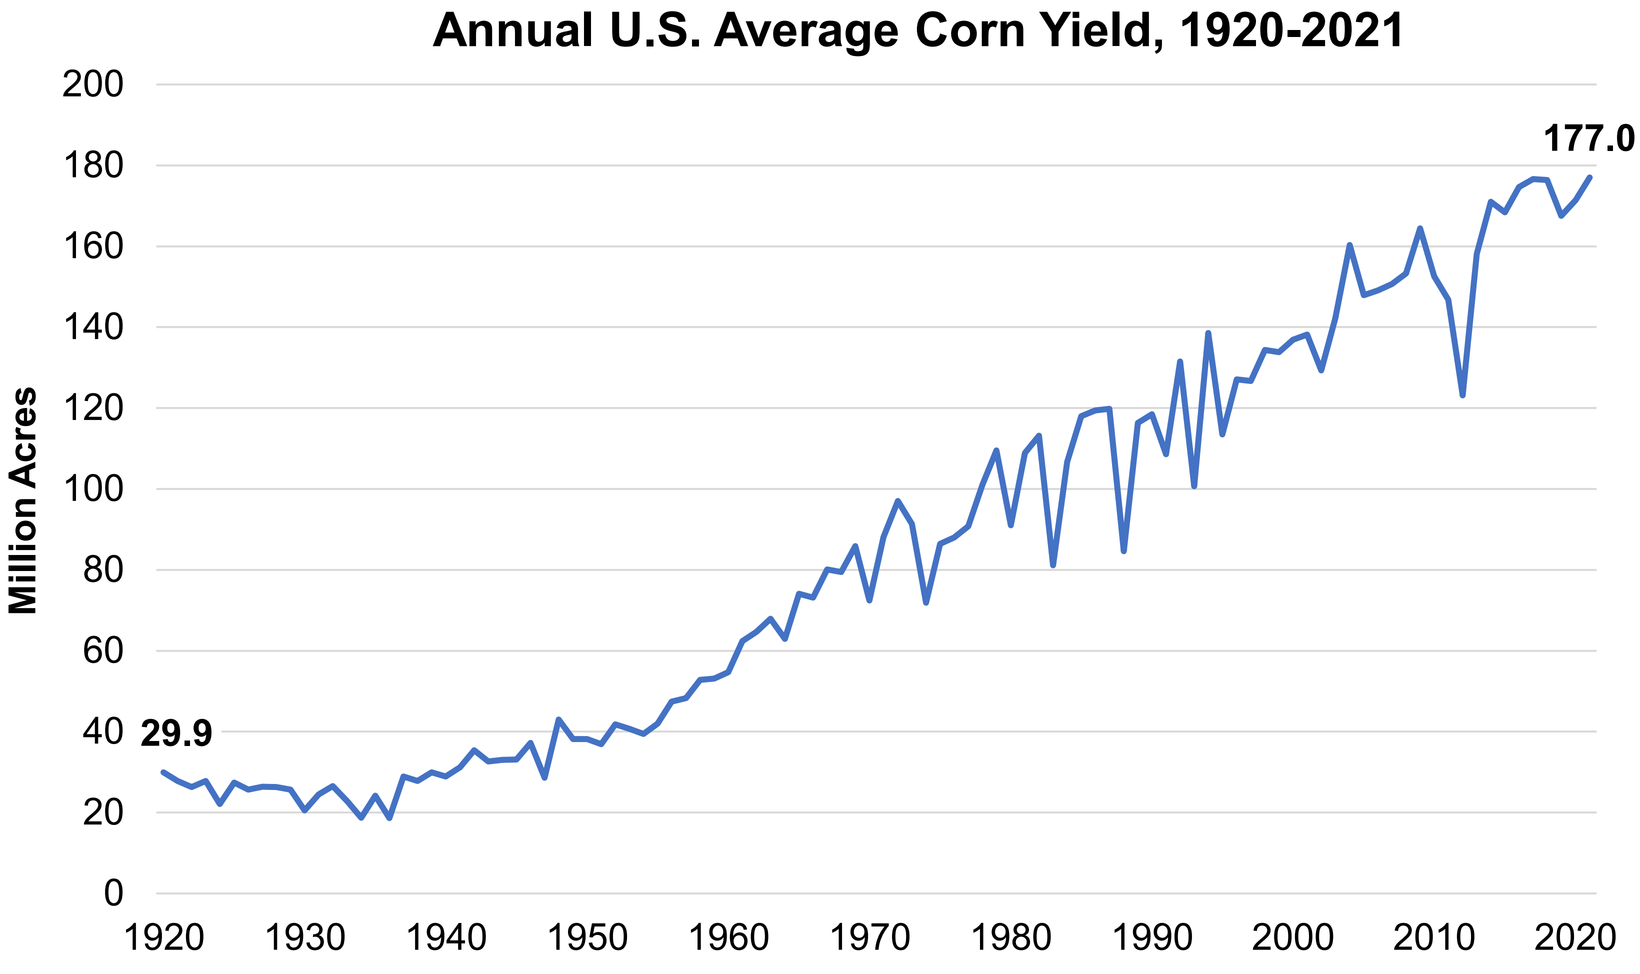


- While corn acres have been relatively flat over the past century, corn production has increased **six-fold**.
- In the 1920s-1940s, annual corn production averaged roughly **2.3 billion bushels** and planted acres averaged 98 million.
- In the 2000s, annual corn production averaged **11 billion bushels** from 82 million acres.
- Since 2010, annual corn production has averaged **13.7 billion bushels** on an average of 92 million planted acres.

Source: USDA

RENEWABLE FUELS ASSOCIATION

Corn output per acre continues to trend higher; up nearly 600% over past century



Source: USDA

- The average amount of corn produced per acre ("yield") has increased nearly **600%** over the past 100 years.
- A new record average yield of **177.0 bushels per acre** was established in 2021. Each bushel of corn weighs 56 pounds.
- Since 1970, yields have grown an average of **2.8% per year**.

RENEWABLE FUELS ASSOCIATION

Ethanol biorefineries are also seeing gains in productivity and output per unit of input

Transportation Fuels Branch
California Air Resources Board
1001 I St
Sacramento, CA 95814

Re: Low Carbon Fuel Standard Workshop November 9, 2022

Dear Ms. Laskowski,

The Renewable Fuels Association (RFA) appreciates the opportunity to comment on the workshop on potential changes to the Low Carbon Fuel Standard (LCFS) program held on November 9, 2022. The RFA supports the LCFS and looks forward to continued engagement in this process to strengthen and extend the program beyond 2030. The RFA is also working around the country in collaboration with other stakeholders to develop and implement LCFS and other clean fuel programs in other states.

The RFA commented extensively on the key issues of the LCFS modifications in our letter of August 8, 2022, following the July 27, 2022, LCFS workshop. These new comments should be considered in combination with the earlier comments and are responsive to CARB staff's request at the most recent workshop for stakeholder input on specific topics.

RFA supports strengthening the current LCFS compliance schedule before and after 2030, in conjunction with other regulatory improvements that will make more stringent targets achievable.

The RFA supports both strengthening the 2030 carbon reduction target to 30 percent and steepening the trajectory of the compliance curve starting in 2024. At the workshop the staff presentation outlined that over-compliance with the program has resulted in LCFS carbon credit pricing of around $60 per metric ton, chilling investments in new technologies and innovations.

The science as summarized in the most recent UN IPCC report points to the urgent need to make immediate and large-scale reductions in GHG emissions in this decade to avoid catastrophic consequences of climate change. Approving E15 as a legal fuel and further incentivizing flex fuels like E85 (through the value of carbon credits) provides a significant new opportunity for credit generation, supporting a much stronger carbon reduction compliance curve. However, without complementary action (e.g., E15 approval and promotion of E85 and flex fuel vehicles), more stringent future LCFS requirements may be very difficult to achieve.

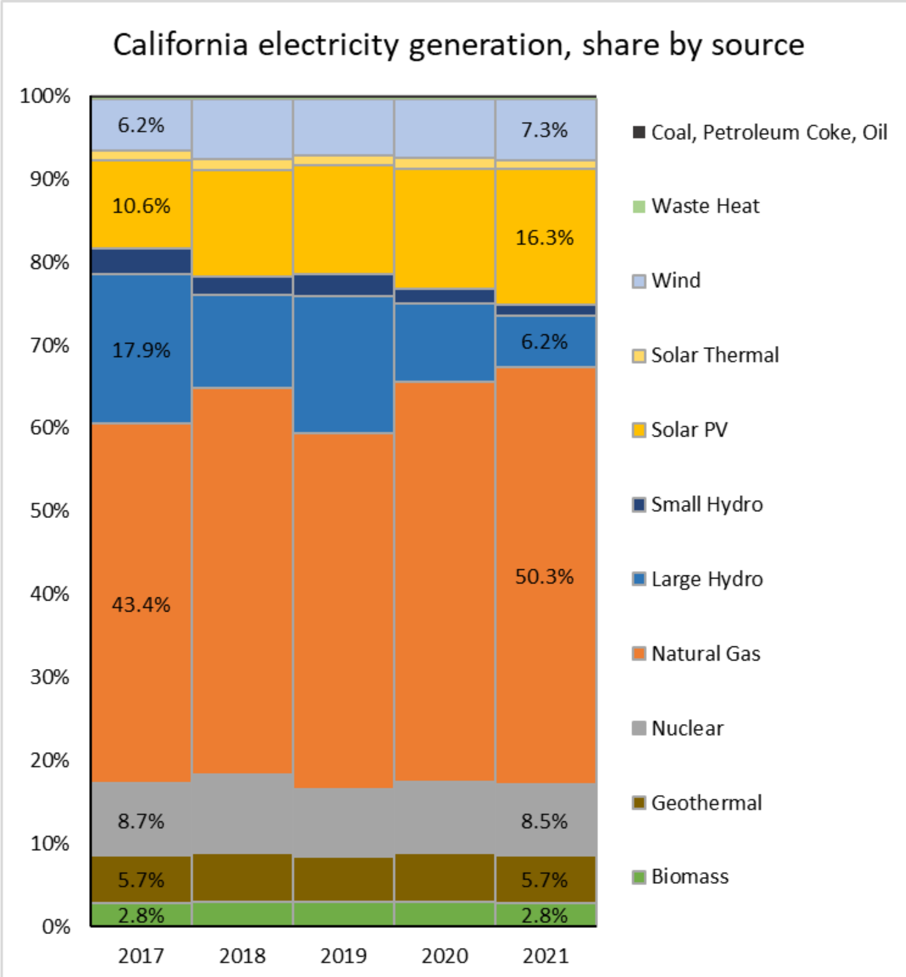
Modify The CATS model to better reflect current and projected ethanol economics, carbon intensities and volumes.

RFA appreciates the release of the CATS model and believes that with the proper assumptions, the model could be a helpful tool for understanding technically and economically viable strategies for improving the LCFS program. Unfortunately, the model was not made available in a timeframe and manner sufficient to facilitate in-depth stakeholder review and input.

Based on the posted CARB Presentation, CATS Model Technical Documentation, CATS Summary Inputs and Supplemental FAQ Documentation, RFA submits for consideration the following comments:

- The CATS model assumes a static 66 gCO_{2e}/MJ (g/MJ) carbon intensity (CI) for ethanol without carbon capture and sequestration (CCS) and a 35 g/MJ CI for ethanol with CCS. The average CI for ethanol in the California market today is 58 g/MJ and has steadily fallen since the inception of the LCFS.[1] The actual values in the market should be used as the starting point and there should be a curve representing the decreasing CI over time for ethanol. RFA members are committed to net zero carbon ethanol production no later than 2050 and have outlined concrete plans and pathways to achieve this result.[2] Using a declining future trend for ethanol CI would be consistent with both the historical (observed) trend analysis and the model's treatment of electricity, where a declining CI over time is built into the CATS model assumptions. Notably, the model's assumed declining CI for electricity is not necessarily consistent with recent observed trends in California's electricity generation. As shown in the chart below (based on data from the California Energy Commission), the share of California electricity generated from natural gas has increased in recent years, while increases in the solar and wind share of generation have been largely offset by decreases in hydro-electric generation.

[1] https://ww2.arb.ca.gov/resources/documents/low-carbon-fuel-standard-reporting-tool-quarterly-summaries
[2] https://d35t1syewk4d42.cloudfront.net/file/2146/Pathways%20to%20Net%20Zero%20Ethanol%20Feb%202022.pdf



- The CATS model assumes an E10 blend in conventional gasoline. Given the significantly lower CI of ethanol relative to CARBOB, and the results of the recent CARB-supported emissions study showing significant criteria pollutant reductions from increasing the blend to E15, the model should run a scenario on higher blends. E15 represents a key strategy for an early acceleration of the LCFS compliance curve.

- E85 represents another significant opportunity for carbon reductions from the light duty vehicle fleet. Given the lower CI of E85 and the fuel's distinct price advantages, California E85 volumes have been increasing at an annual growth rate of approximately 50-60 percent in recent years. From the Technical Documentation, the CATS model is assuming additional costs associated with bringing E85 to market relative to E10 to be reflected by D6 RIN prices ($1.13 per gallon in the model). This assumption is greatly overstated given the modest costs of converting existing E10 distribution to E85. We are happy to work with staff to better understand these costs.

- Market prices are used for modelling biofuels, but for electricity the social marginal cost is used; however, the document referenced in the footnote states that "the marginal cost is vastly lower than current rates." With the need to more than double total electrical production in California to meet state climate objectives and the assumption that the grid CI is dropping, market pricing with some escalation over time seems to be a more appropriate assumption. This would also be more consistent with the treatment of other alternative fuels in the CATS model.

- For ethanol with CCS, the CATS model assumes that the CO2 captured would be used or stored in oil and gas fields qualifying for the $60 per metric ton 45Q federal tax credit. As a matter of fact, most of the announced ethanol CCS projects will be geologically sequestering the CO2 and qualifying for the higher $85 per metric ton 45Q credit. The model should be adjusted accordingly.

- A $7 per bushel corn price assumed in the CATS model is not a representative long-term price for corn. Current corn prices around $6.50 per bushel are at a multi-year high due to the Russia-Ukraine war and general worldwide commodity price inflation. USDA forecasts that prices will fall to $4.30 per bushel by 2026 and then remain at that level as shown in the U.S. Feed Grains file in the recent USDA Baseline Projections.[3]

- The model's conversion cost for ethanol appears to be higher than actual observed costs. Typical operating costs for ethanol producers are in the public domain and should be used to validate or modify the results of the regression analysis. For example, the Center for Agricultural and Rural Development (CARD) provides weekly updated margin reports that document corn ethanol conversion costs.[4]

- Corn distillers oil from ethanol producers is a coproduct of the production process and is an inedible corn oil (ICO). Consequently, it should not be included on the list of virgin oils. The distillers oil extracted at dry mill ethanol plants is strictly an industrial product and has no human food application. The FAQ supplement stated that it was not included as a waste oil because it had alternative uses as a feed. The same is true of the tallow and used cooking oil, which also have feed market opportunities.

[3] https://www.usda.gov/oce/commodity-markets/baseline
[4] https://www.card.iastate.edu/research/biorenewables/tools/hist_eth_gm.aspx

It is critically important for CARB to move quickly and concisely in strengthening the LCFS program. Timely and accurate modelling and scenario development through the CATS model and other analyses is a valuable tool in this regard.

Ethanol has generated the single largest volume of credits in the LCFS program, accounting for roughly four of every 10 credits generated since the program's inception. But constraining ethanol's use to 10 percent blends is sacrificing additional carbon reductions possible today. We urge CARB to move quickly to adopt regulations approving E15, which will allow the ethanol industry to help displace more fossil fuel in California and lower carbon emissions now.

An accurate modelling of ethanol's benefits and an integration of CARB fuels policy to incentivize higher ethanol blends will result in immediate reductions of GHG emissions and criteria pollutants while lowering the cost of compliance to obligated parties and California consumers.

RFA looks forward to working with CARB staff and other stakeholders to strengthen and extend the successful LCFS program.

Sincerely,

Kelly S. Davis
VP of Regulatory Affairs

SUBJECT: Proposed Low Carbon Fuel Standards Regulations and Its Impact on Bank Size and Credit Prices

Dear Respected Members of the California Air Resources Board,

We are writing this letter to share with you some of our concerns regarding the proposed LCFS regulation as it relates to the growing credit bank size, its impact on credit prices, and the ability to reach CARB's emission reduction goals.

First and foremost, we would like to thank the CARB team for putting in the effort to update the LCFS regulations, which are intended to help move the fuel pool mix toward being cleaner and more diversified. We would like to recognize that ensuring the alignment of the proposed regulations with California's goals, as well as having minimal impact on all of California's stakeholders, cannot be easy.

172.1 That being said, we strongly feel that the proposed regulation, as it stands, would fall short of achieving CARB's goals in terms of diversifying the fuel pool mix as well as providing support for the LCFS credit prices. In fact, we have run some simulation scenarios using CARB's input file and incorporated the proposed step-down CI values as well as any potential trigger of the Automatic Acceleration Mechanism (AAR). We have also included some plausible scenarios that may alleviate these limitations. Note that we have only focused on the period of 2024 through 2030 as we strongly believe that the market will not price future projections past this time frame.

1- Scenario 1 – Proposed Regulation: 5% CI Step-down in 2025 and AAR in 2028

We believe that CARB underestimated the growth of renewable diesel (RD) and biomethane, which has led to a large credit bank and depressed credit prices. As of Q3 2023, renewable diesel filled almost 60% of the state's liquid diesel pool and generated roughly 50% of all new LCFS credits. In fact, we expect 80% of the diesel complex to be made up of RD by early 2025. This has undermined the LCFS's support for electrification and more scalable low-carbon fuels. The LCFS credit current prices saw high 50's, which did not inspire much in terms of investment. As the bank continues to grow, prices will continue to drop.

While stepping down the CI target by 5% in 2025 should create more demand for LCFS credits, this will not be enough to curb the rapid growth of the LCFS credit bank and its downward pressure on credit prices. We have used CARB's input file, along with the present CARB data (Q3 2023), to model the size of the bank throughout Q4 2030, as shown in Fig. 1. We assumed that the AAR will be triggered in 2027 and the CI target will be updated in 2028. Under this scenario, the credit bank will grow to 91 million credits by Q4 2030. As the bank continues to grow, prices will continue to drop. It is important to note that current RD capacity utilization is in the high 60% and low 70%, and capacity in the pipeline is expected to double; the bottleneck is how quickly paperwork can get signed to have the fuel find its way into California.

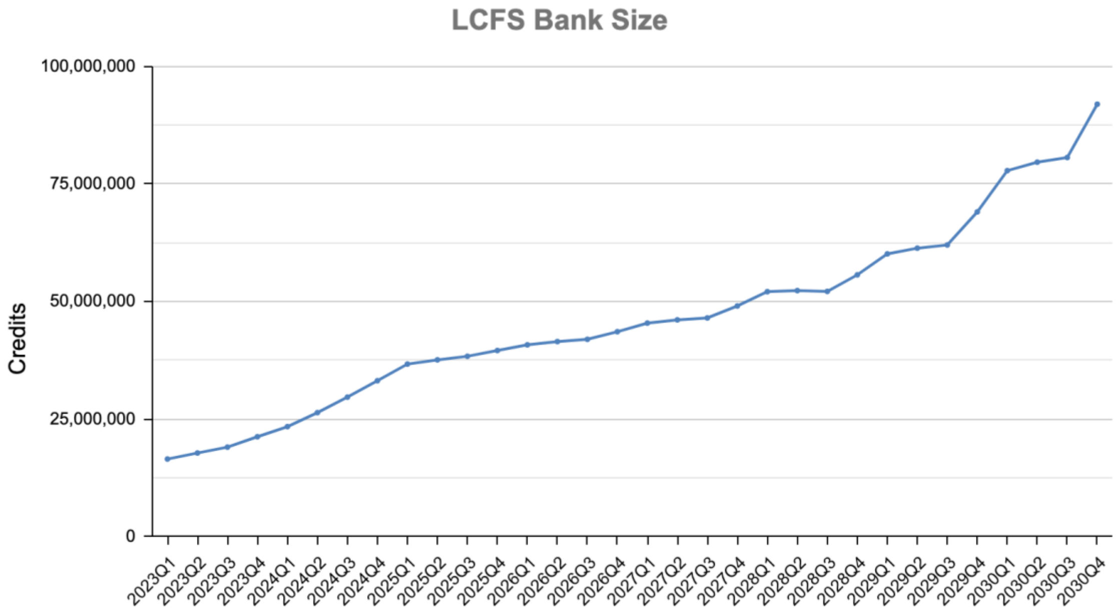

Fig. 1: Projected Bank Size Under Current Proposed Regulations (AAR in 2028)

2- **Scenario 2 – Incoming legislation + Stronger step-down to 21%**

In this scenario, we propose stepping down the CI target to **21% in 2025** while keeping the same rules in the proposed regulation. Under this scenario, the AAR isn't triggered until 2030, and the resulting credit bank will be shown in Fig. 2.

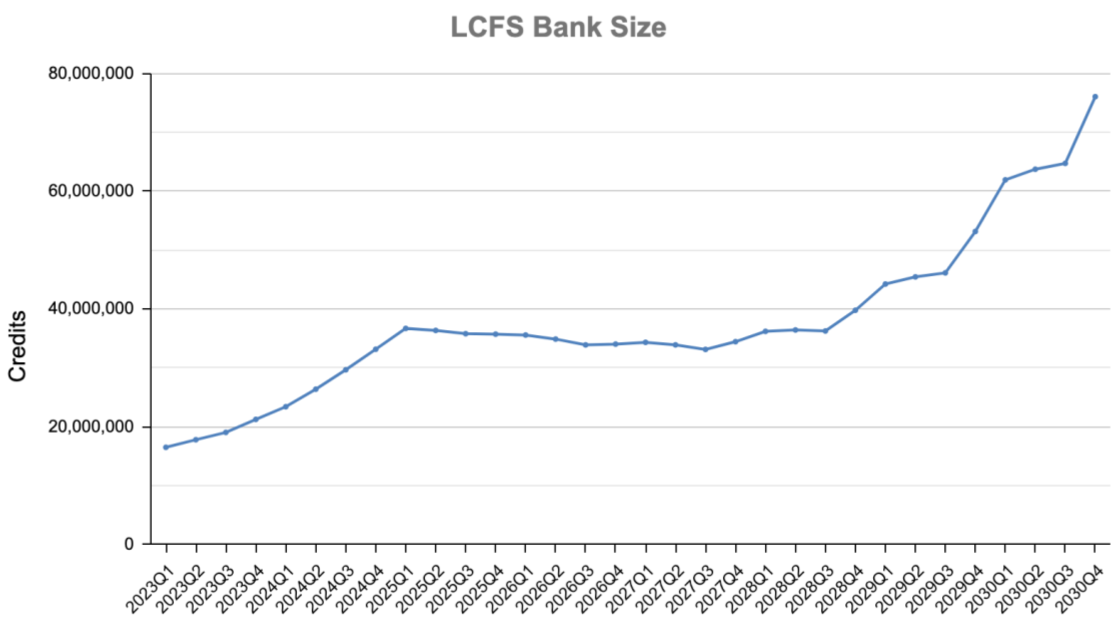

Fig. 2: Stronger step-down in 2025 to 21%

The impact of this would initially be positive between 2025 and 2028 as it would draw down the bank almost immediately. This may send a signal to the market, which can result in supporting LCFS credit prices. This change in CI step-down CI schedule can be easily implemented, allowing CARB to maintain the proposed regulation. CARB can then monitor the bank and assess whether a stronger action would be needed. However, it is important to note that the draw on the bank is relatively weak, so its impact on price levels may not be sufficient. The model predicts that the bank will resume rising in late 2028 and reach almost 77 million by the end of 2030.

3- **Scenario 3 – Incoming legislation + Stronger step-down to 23.5%**

In this scenario, we propose a bigger step down to 23.5% by 2025. This larger step down would quickly draw down the bank and correct prices. While the bank would rise starting in 2029, the size of the bank will be below the projected levels by the end of 2024. In addition, as the number of deficits grows, the bank's acceptable size can also become larger. In addition, the AAR may be triggered in subsequent years (past 2030) to address growing bank size and falling prices.

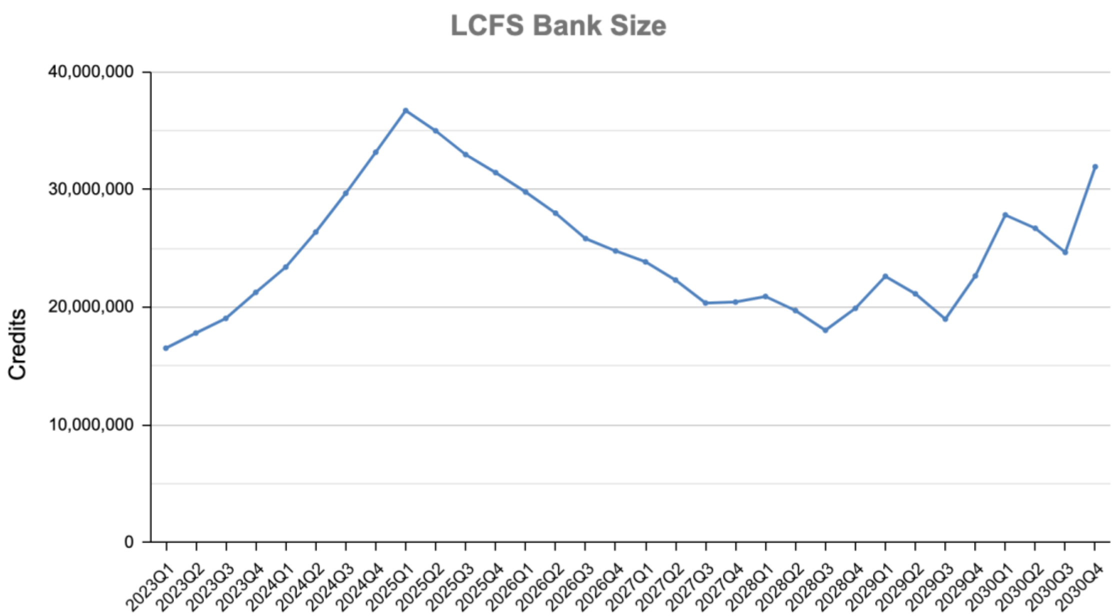

Fig. 3: Stronger step-down in 2025 to 23.5%

172.1 cont In summary, the current proposed regulation, as is, will not result in any measurable impact on the rapid growth trajectory of the credit bank and will almost eliminate any clean fuel technology, other than renewable diesel, from being competitive. We have presented some alternatives that may help stabilize the growth in the credit bank and stabilize LCFS credit prices. CARB can also put caps on RD and other biofuels to help other clean technologies get established and allow investments to flow into them.

We are committed to helping California reach its target CI reduction goals and hope the board will push CARB to address the above concerns to ensure the success of the LCFS program.

Respectfully,
/s/

Submitted electronically through CARB Portal

RE: Comments of Diamond Green Diesel, LLC on 2024 Proposed Low Carbon Fuel Standard Amendments

Dear Ms. Sahota:

Diamond Green Diesel, LLC ("DGD"), a joint venture between subsidiaries of Darling Ingredients Inc. and Valero Energy Corporation, submits these comments regarding the 2024 proposed Low Carbon Fuel Standard ("LCFS") amendments. DGD is a leading producer of renewable diesel in the United States, with a total production capacity of approximately 1.2 billion gallons annually. We are also well underway on a project to upgrade approximately half of the new Port Arthur facility's production capacity to produce sustainable aviation fuel ("SAF"). Upon commissioning of this project, currently planned for early 2025, we are poised to become one of the largest SAF producers in the world.

As one of the nation's leading producers of renewable diesel and as a trailblazer in SAF production, we are proud to have played a leading role in helping California achieve the LCFS goal of reducing the carbon intensity of the transportation fuel pool. Our growth owes much to the strong market signals created by the LCFS, and we look forward to helping CARB continue to improve the program so that it can remain the premiere market-based regulatory program supporting innovation in low-carbon fuels. With that goal in mind, we offer the following comments.

Feedstock Considerations

DGD appreciates that CARB does not propose to implement a cap on biofuels made form crop-based feedstocks, because doing so would have been impractical to implement, could have created market uncertainty, and may have led to legal challenges. However, DGD has some concerns regarding the proposed specified source feedstock attestation letter requirement because they will increase the annual verification burden for pathway holders without
173.1 any associated "value add" to the program. If it is the intent of the provision that upstream suppliers be held accountable through the pathway holder, then it is duplicative of the currently effective provisions requiring chain of custody documentation. CARB should consider an approach consistent with the International Sustainability and Carbon Certification ("ISCC") requirements.[1]

[1] International Sustainability and Carbon Certification, *ISCC EU 201 System Basics*, at pp. 25-28, available at: https://www.iscc-system.org/wp-content/uploads/2024/01/ISCC_EU_201_System_Basics_4.1_January2024.pdf ("The collecting point is the first element that must be individually certified. Points of origin can be covered under the certificate of the collecting point but may also receive an individual or group certification.")

Diamond Green Diesel LLC • One Valero Way • San Antonio, Texas 78249-1616
Post Office Box 696000 • San Antonio, Texas 78269-6000 • Telephone (210) 345-2000

DIAMOND GREEN DIESEL

Likewise, DGD requests that CARB provide greater clarity on the definition of "crop-based" and "forestry-based" biofuels. Currently, it is unclear which feedstocks Subsection 94588.9(g)(1) would apply to. DGD reiterates its
173.2 previous comment that distiller's corn oil ("DCO") used to make renewable diesel is inedible and not fit for human consumption.[2] Additionally, it is produced as a byproduct of the ethanol production process. Because corn is not grown to provide DCO, it should not be considered a "crop-based" biofuel, subject to additional sustainability requirements that are ostensibly designed to inhibit land-use change.

To address these issues, DGD suggests that CARB schedule workshops with the affected parties for any sustainability requirements, as was previously done with the CI stringency and AAM provisions. There are numerous international approaches to supply chain declarations that CARB can study and more seamlessly implement, with
173.3 appropriate stakeholder feedback. At a minimum, CARB should reconsider the length of time allowed for verification and/or allow for less intensive verifications, as has been done with fuel reporting entities reporting only electricity transactions. The recent announcement to postpone the Board's consideration of the rule may provide an opportunity to further develop this issue.

Feedstock Emission Factors

a. Feedstock Emission Factor for Tallow Rendering

The emission factor for tallow rendering used in the draft HEFA Tier 1 calculator is almost 2.5x the value in Argonne's GREET 2022 model (286 gCO2e/lb oil vs 119 gCO2e/lb oil). The draft HEFA Tier 1 calculator and CA-GREET 4.0 appear to use the same values for energy consumption in the tallow rendering process as CA-GREET 3.0, which
173.4 was based on GREET 2016. Since the publication of GREET 2016, Argonne has updated their tallow rendering data and emission factors multiple times based on updated industry data. CARB should update the tallow rendering values in CA-GREET 4.0 to reflect the most current Argonne GREET 2022 model, to ensure consistency with the other feedstocks and processes that CARB has updated in CA-GREET 4.0.

b. Feedstock Emission Factor for UCO Rendering

Similarly, CA-GREET 4.0 uses a UCO rendering emission factor of 87 gCO2e/lb oil, compared to Argonne GREET
173.5 2022's UCO rendering emission factor of 81 gCO2e g/lb. CARB should update CA-GREET 4.0 consistently with GREET 2022 to reflect current industry practices for all feedstock and fuel production processes, regardless of technology.

Increasing Stringency of Annual Carbon Intensity Benchmarks

In light of CARB's recent announcement that the Board hearing on the proposed amendments will be postponed pending staff's reconsideration of the proposed carbon intensity benchmarks, DGD will reserve specific comments regarding the stepdown and AAM at this time and will look forward to participating in the workshops planned for mid-April. DGD agrees in principle with the near-term step down in order to send a clear message that CARB is committed to using the LCFS to promote transportation decarbonization and to help stabilize the unprecedentedly high credit bank.

[2] Comments of Diamond Green Diesel LLC on February 2023 CARB LCFS Revisions Workshop, March 13, 2023.

DIAMOND GREEN DIESEL

173.6 Additionally, we note that the proposal to extend the program for ZEV infrastructure credits to medium- and heavy-duty ZEVs could potentially work counter to the proposed increased stringency of the targets. Because vehicle manufacturers and fleet owners face regulatory mandates to transition the medium- and heavy-duty vehicle fleets to ZEV technology, incentives already exist for affected parties to provide for infrastructure to support these technologies. Providing additional incentives in the form of LCFS credits may lead to credit price dilution, thus further weakening the credit market and reducing incentives for development of all low-carbon transportation fuels. It is not clear that CARB has modeled both of these phenomena in conjunction, and staff may not have a clear indication of how the market will emerge and continue to drive innovation and investment in low-carbon transportation fuels.

We greatly appreciate your consideration of our comments. If you have any questions or would like to discuss any of the points discussed in this letter, please do not hesitate to contact us.

Sincerely,

Sandra Dudley

RENEWABLE FUELS NEBRASKA

Ensuring the growth of the renewable fuels industry in Nebraska

February 20, 2024

California Air Resources Board

1001 I St.

Sacramento, CA 95814

Re: Comments from Renewable Fuels Nebraska on California's Low Carbon Fuel Standard

Chair Randolph and Members of the California Air Resources Board,

I write today to urge you to reconsider proposed changes to the Low Carbon Fuel Standard.

Specifically: On behalf of the hundreds of thousands of farmers, ranchers, producers,
and workers here in Nebraska who help feed and fuel the world — and for the sake of
our shared goal of reducing greenhouse gas emissions — we respectfully request for
174.1 you to adopt a more technology-neutral, market-based approach that ensures that
biofuels can contribute on a level-playing field to a cleaner, more efficient energy
future in California and across the country.

In addition to general concerns that the proposed changes as currently envisioned would pick winners and losers among renewable energy alternatives, there are several specific factors to note as you continue the regulatory process.

These include our inability to provide more detailed comments with regard to the
sustainability requirement proposal for crop- and forest-based biofuels without more
174.2 information. Details such which third-party verifiers would be involved and what
information said third-party verifiers would require are necessary, both to ensure
equitable application in the real world and to ensure that interested stakeholders are
able to provide informed feedback as soon as possible.

More broadly, the proposed changes to the Low Carbon Fuel Standard risk doubling down on California's inexplicable decision to effectively reject cleaner fuels and lower emissions through the failure to permit the use of E15.

174.3

For instance, if E15 had replaced E10 in California cars as recently as 2022, the Golden State would have enjoyed an additional greenhouse gas savings of 2.2 billion metric tons (CO2e) that year alone.[1] And California residents could have joined drivers

[1] Letter from Renewable Fuels Association, October 3, 2023.

[1] Renewable Fuels Association study, April 2023.

174.3 cont nationwide in saving an average of more than 25 cents per gallon when filling up their tanks.[2]

Yet, despite the substantial greenhouse gas emissions benefits associated with E15 — and the significant financial savings to consumers — California continues to abstain from this commonsense step towards a better and cleaner energy future. And that hurts California residents from all walks of life both financially and environmentally.

We urge CARB to reconsider its approach towards the Low Carbon Fuel Standard before it makes the same kind of mistake again.

And we remain committed to working with you and other dedicated stakeholders to pave a better path forward that appropriately balances strident goals and the incredible technologies available to us today to help achieve them.

Sincerely,

Dawn Caldwell

Comment

February 20, 2024

Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Chair Randolph and Honorable Members of the Board,

Thank you for your continued dedication to enhancing air quality i the Golden State through the proposed updates to the Low Carbon Fuel Standard Program (LCFS). We commend your decision to further encourage and not restrict the use of crop-based feedstocks withi the proposed LCFS amendments under consideration.

The proposed accounting requirement for crop-based feedstocks, to trace their origin and undergo independent certification, aligns with the California Air Resources Board's commitment to ensuring crop-based feedstocks do not contribute to adverse impacts associated with land use change or limiting food supply. This proactive approach addresses concerns raised by the Environmental Justice Advisory Committee (EJAC) regarding "expanse of global deforestation, unsustainable land conversion, or adverse food supply impacts."

Our company, Global Clean Energy, stands ready to assist CARB in achieving this important goal. As a California-based renewable fu innovator with offices in Torrance and a renewable fuels producti facility in Bakersfield, we work tirelessly to ensure renewable fuels that we produce can have the lowest possible carbon intensity. What sets us apart is our focus on producing ultra-low carbon renewable fuels using Camelina sativa (camelina), a crop that alleviates the foregoing concerns.

Unlike other renewable fuel feedstocks, camelina is nonfood. Camelina is quick to mature, is tolerant to drought, promotes biodiversity, sequesters carbon as it is grown, and provides soil health benefits similar to those of cover crops. Importantly, camelina does not displace food crops when grown. Instead, it gro on existing farmland during the fallow between crop cycles -

providing a new revenue source to farmers and rural agricultural communities while also strengthening our domestic energy supply. With these unique traits, camelina has the potential to be the lowest carbon intense renewable fuel feedstock on the market.

Labeled as an "Intermediate Crop," camelina falls under a new classification of biofuel and renewable fuel feedstocks. "Intermediate Crops" act as harvestable cover crops that can reach maturity during an idle or fallow period on existing farmland, which does not cause land use change or adversely impact food supply. Intermediate crops like camelina can help California and our nation reach our renewable fuel and SAF goals responsibly through biomass.

As you endeavor to create an accounting mechanism to track feedstocks to their point of origin and develop the independent feedstock certification process recommended within your proposed LCFS rule, we encourage you not to recognize the importance of emerging crops like camelina. By incentivizing the further adoptic of "Intermediate Crops" like camelina among growers and renewable fuel producers, we can help ensure land use change is prevented, soil health is protected, and renewable fuel feedstock demand can be met responsibly.

As new crops, education and incentives are vital to ensure "Intermediate Crops'" continued adoption and future success. Recognizing that newer feedstocks lack the resources of traditiona commodities like soy or corn, we recommend that accounting rules should not place "Intermediate Crops" like camelina at a financia disadvantage as they establish themselves within the market.

As experts in this emerging field of "Intermediate Crops" we stanc ready to work with CARB staff and others to lend data and provide guidance in the development of an accounting mechanism addressing GHG and air pollution emissions associated with feedstock production pathways.

We look forward to working together to ensure Intermediate Crops are supported while these accounting criteria are developed. Thank you for taking the time to consider our comments.

RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

EcoEngineers appreciates the opportunity to submit comments regarding the Proposed Low Carbon Fuel Standard Amendments.

EcoEngineers is one of the nation's leading auditing, verification and consulting firms for renewable fuel and clean energy technologies. We are accredited under the EPA Renewable Fuel Standard (RFS), the California Low Carbon Fuel Standard (LCFS) and the Washington and Oregon Clean Fuel Standards. We are also accredited by the American National Standards Institute (ANSI) National Accreditation Board (ANAB), in accordance with the International Organization for Standardization (ISO) standards ISO/IEC 17029:2019 and we are in the process of becoming accredited by the Canadian Government for the Clean Fuel Standard. We appreciate the opportunity to share some of our thoughts and comments on the proposed amendments.

EcoEngineers strongly supports the advancement of policies, regulations and programs that address the global reduction of greenhouse gas (GHG) emissions across all sectors. The LCFS program continues to be a vital tool that can assist California and the US in meeting their climate reduction goals. This program serves as an example to jurisdictions around the world looking to decarbonize their transportation fuel sector and as such, should continue to strive towards ambitious targets while closely considering market dynamics.

EcoEngineers presents the following comments on the Proposed Low Carbon Fuel Standard Amendments.

1- Compliance, Program Benchmarks, and Credit Generation

176.1 Strengthening the carbon intensity benchmarks throughout 2045 and including fossil jet fuel are 176.2
necessary steps to ensure continued reductions in GHG emissions while providing industry with the regulatory certainty required to develop and grow low carbon fuel alternatives.

The inclusion of a "step-down" mechanism is a key element of this proposal. If implemented
176.3 correctly, the mechanism could help stabilize the credit market. EcoEngineers recommends CARB
implement a more active "step-down" mechanism that annually balances rates of production with

requirements. EcoEngineers also suggests including a “step-up” mechanism that can address potential credit surpluses.

Finally, EcoEngineers recommends that CARB provide clarity as to the stackability of CORSIA and
176.4 LCFS credits. Similar to US Renewable Fuel Standard RINs, CORSIA credits in conjunction with
LCFS credits would help facilitate uptake of SAF. This will also provide industry with additional
clarity as they develop capital intensive SAF projects.

2- Equity-Focused Improvements

Even with the “step-down” mechanism as proposed, current EcoEngineers’ modeling shows credit prices in the near term will remain within the current range. The main factor driving price outlook is the near-term oversupply of credits versus the schedule, primarily from renewable diesel. Historic data and refinery planning indicate that renewable diesel use will continue to grow with current credit pricing till 2030. However, the modeling also shows a potential undersupply of credits toward the end of the decade without improvements in electric vehicle (EV) sales.

EcoEngineers believes that zero emission vehicle (ZEV) (includes battery electric vehicles (BEV)
and fuel cell electric vehicles (FCEV)) uptake is a critical element of the LCFS program. There is
clear evidence that point-of-sale and home charging economic incentives for ZEV purchases
increase ZEV uptake. EcoEngineers suggests that CARB implement vehicle based LCFS ZEV credit
accounting in conjunction with infrastructure credits. By having an accounting system based off
vehicular data, OEMs would eventually be able to discount their ZEV sale prices by future LCFS
credit generation. This would be similar to the approach adopted by the USEPA in the proposed
176.5 RFS eRIN rules.

The proposed focus and increased investment on increasing the accessibility of ZEVs in disadvantaged, low-income, rural, and tribal communities coupled with the expansion of ZEV crediting to the medium and heavy-duty sector will be positive additions to the LCFS program.

3- Fuel Pathway Applications and CI Determination

EcoEngineers fully supports updating LCA modeling tools and emission factors to ensure the
176.6 modeling is reflective of the most up-to-date scientific, evidence-based information. The update
of the GREET model will help ensure the LCFS remains at the forefront of science-based GHG
reductions including the addition of a Tier 1 Calculator for hydrogen.

EcoEngineers also supports sustainability requirements for crop and forestry-based feedstock.
176.7 These requirements should be clearly defined, and sufficient time should be given to ensure
industry can incorporate the necessary changes to meet the requirements.

4- Verification Program

EcoEngineers supports the proposed addition of third-party verification on hydrogen and
176.8 electricity data types and deferral thresholds as well as on applications for project-based
crediting. Third-party verification continues to be a reliable method of validating applicant
information to ensure the integrity of the program.

February 20, 2024

Thank you once again for the opportunity to comment on the proposed amendments and please do not hesitate to contact me for more details. We look forward to continuing to work with the LCFS on implementing a successful program.

Sincerely,

Lisa Hanke,

Director, Regulatory Engagement
EcoEngineers

California Air Resources Board
1001 I Street
Sacramento, CA 95814
RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

As a renewable fuel producer and participant in CARB's LCFS program, my team and I value the partnership and mission shared with you and your state to reduce the carbon intensity of transportation fuels.

I am writing to share our company's perspective on several key program areas for your consideration. These requests address the topics of **CCS protocols, Low-CI Electricity, LCFS modeling & crop-based biofuels, and Verification**.

Fuels Produced Using Carbon Capture and Sequestration

177.1 We support and encourage CARB to approve fuel pathway applications from entities utilizing the CCS Protocol dated August 13, 2018 so that they may receive credits associated with net GHG reductions from CCS projects.

Low-CI Electricity

CARB Staff proposes to update language in Sections 95488(i)(1), 95490(b)(8), and 95491(d)(4)(D) related to modifications to book-and-claim accounting of low-CI electricity to produce hydrogen used as a transportation fuel and for process electricity in direct air capture projects. The rationale in Appendix E states that the process of capturing CO2 directly from the atmosphere has higher electricity demand, which makes it financially challenging and may drive the need for additional electricity load. The proposal permits low-CI electricity with quarterly demonstration of trackable deliverability to be used for hydrogen production for hydrogen used as a transportation fuel as well as at a direct air capture facility, which aligns with the requirement for renewable or low-CI process energy (section 95488.8(h)(1)(C)). On page 34 of the ISOR, CARB staff also recommends allowing for power purchase agreements but can only be from new or expanded capacity for low CI hydrogen production.

177.2 We would like to highlight that adding the process of carbon capture from controlled, high CO2 concentration sources (e.g. fermentation vessels at an ethanol plant) also require a higher electricity demand and may also need additional electricity load, which makes it financially challenging. Therefore, we **request CARB treat all CO2 capture and sequestration activities similarly and allow the book-and-claim accounting for low-CI electricity or the expanded use of PPAs for carbon capture facilities with fuel pathways claiming CCS credits by producers of alternate transportation fuels**.

LCFS Modeling & Crop-Based Biofuels

To reduce the risk that rapid expansion of biofuel production and biofuel feedstock demand could result in deforestation or adverse land use change, CARB staff are proposing additional guardrails on the use of crop-based feedstocks for biofuel production. CARB staff are proposing to require pathway holders to track crop-based and forestry-based feedstocks to their point of origin and require independent feedstock certification to ensure feedstocks are not contributing to impacts on other carbon stocks like forests. As crop-based biofuel producers may have field level information to comply with this provision, we **request that**

177.3 **LCFS modeling be granular and allow the inclusion of on-the-farm carbon accounting and factor lower carbon intensity grain associated with climate smart and regenerative agriculture farming practices.**

Verification - Firm Rotation

The existing regulations within the LCFS verification program stipulate a mandatory rotation of audit firms every six years to assess participants' carbon intensity (CI) and fuel quantities compliance.

Our request is that CARB amend the mandatory firm rotation regulation to include an exception for licensed CPA firms. Of the 30 approved LCFS verification bodies, there are only four licensed CPA firms.

An approved verification body, that is also a licensed CPA firm, exceeds the standards in place for verification bodies and is already subject to additional

177.4 ***oversight on the entity's quality control system in accounting and auditing practices through the required AICPA peer review process.***

Due to the increased regulatory oversight, we suggest a CPA firm not be subject to the audit firm rotation but would instead adhere to a Lead Verifier rotation after six consecutive years.

A licensed CPA firm differs from other consulting agencies by adhering to more rigorous standards and oversight at a state and national level. If a verification body were to violate a Lead Verifier rotation requirement, it would put the firm license at risk. The firm license is required for all services provided by the firm, not just the LCFS verification services, thereby ensuring adherence to requirements.

Licensed CPA firm requirements

- A licensed CPA firm must be comprised of over 50% of the ownership being licensed CPAs.
  - To earn the accreditation to be a CPA, one must pass a rigorous four-part CPA exam, accumulate education hours, and in many states, one must fulfill 1-2 years of work experience.

- 3-year peer review audit
  - Each licensed CPA firm must enroll in an approved peer review program with reviews conducted every 3 years. The peer review requirement is a requirement of the American Institute of Certified Public Accountants (AICPA)

and is an external review of a firm's quality control system in accounting and auditing practices. CPA firms' peer review results can be found on AICPA's website under the Peer Review Public File Search.

- State Boards of Accountancy (SBOA) are found in each state's statute to aid state governments in the licensing and regulation of the public accounting profession.
    - SBOAs provide further oversight on CPA firms by evaluating CPA licensees' examinations and regulatory oversight to ensure a firm is practicing within their statutory scope.

The audit quality and efficiency improve as the auditor becomes more familiar with our company's processes. In addition, with the limited number of firms available as verification bodies and a five-year lookback period in place, it is proving difficult to identify a quality verification body that is not also working with our facility in other consulting capacities. The number of people available with the proper expertise to assist us in design and development of projects and to reserve for verification purposes has proven even more limiting, which is also why we request a Lead Verifier rotation rather than a full firm rotation.

Less Intensive Verification

Regarding less intensive verification, we noted in Appendix E staff's proposal for less intensive verifications for when electricity is used as a transportation fuel, allowing verification bodies to skip site visits if they visited the site in the last two years and issued a positive verification statement.

The rationale for this proposed change states, "there is little change of operation from reporting period to reporting period thus reducing the benefit of annual site visits." Additionally, staff rationale states, "There is no or little risk to the integrity of the LCFS program to allow for less intensive verification services without a site visit in the annual verifications for the following two years. This should reduce the cost of verification services which is often passed on to program participants."

Currently, the proposed language limits this allowance for less intensive verifications to QFTR third-party verification bodies for fuel reporting entities only reporting electricity transactions.

We agree with the staff's stated rationale, but **we request for less intensive verification to**
177.5 **be extended as an option for verification bodies on all validations and annual**
verifications for any reporting entities.

In CARB's MRR program (section 95130), less intensive verification is applied without prejudice to verification services by accredited verification bodies.

We agree with staff that less intensive verification leads to little to no risk to the integrity of the LCFS program and that there is little change in operation from reporting period to reporting period, while also providing cost savings to verification providers and passed on to our company as program participants.

We acknowledge the importance of adhering to CARB's specified conditions that necessitate comprehensive verification services. These conditions include the issuance of an adverse verification statement or a qualified positive verification statement in the preceding year and the occurrence of a change in operational control of the reporting entity in the previous year.

Thank you for your time and consideration. Please reach out to us if you have any questions.

Sincerely,

Don Gales
CEO

Re: *SCE Support for Low Carbon Fuel Standard Regulation Amendments with Some Proposed Modifications and Clarifications*

Southern California Edison (SCE) appreciates the opportunity to comment on the California Air Resources Board's (CARB's) staff proposal to amend the Low Carbon Fuel Standard (LCFS) regulation (Proposed Amendment), which CARB posted on December 19, 2023. The LCFS Regulation has been instrumental in helping California move towards a decarbonized economy and SCE appreciates staff's willingness to consider and collaborate on opportunities to strengthen and provide clarity within the regulation.

178.1 Among other things, SCE supports the Proposed Amendment's recommendations to: (1) establish an automatic acceleration mechanism (AAM); (2) adjust the minimum contribution of
178.2 large investor-owned utilities (IOUs) towards the Clean Fuel Reward program to 50% of their base residential credit proceeds; (3) list and provide detailed examples of pre-approved uses for 178.3
utility Holdback credit proceeds; and (4) include Vehicle Grid Integration (VGI) and workforce development as pre-approved Holdback projects. 178.4

178.5 SCE also understands the need for a brief postponement of the public hearing to consider the amendments, given the number of items that require staff's attention and time to address. However, to ensure the timely implementation of important modifications to stringency, the statewide Clean Fuel Reward program, and utility Holdback project requirements, SCE requests that the extension not extend beyond the end of Q2 2024.

In addition to SCE's general support, SCE proposes that CARB (1) combine the separate holdback project lists proposed for equity and nonequity projects; (2) specify that utilities have discretion to select the most appropriate projects for their customers and require the large investor-owned utilities (IOUs) to fund at least three program options; (3) retain the 10% administrative cost cap for Holdback programs because 5% is insufficient; (4) align the administrative cost cap for the statewide Clean Fuel Reward Program with other large utility incentive programs; (5) update vehicle eligibility for the Statewide Clean Fuel Reward Program to conform to CARB's goals; and (6) reject the 1-mile requirement for capacity credits in favor of greater flexibility.

I. CARB Should Combine the Separate Holdback Project Lists Proposed for Equity and Non-equity Projects

As mentioned above, SCE appreciates the staff's proposed amendments expanding the list of LCFS Holdback projects and activities but recommends that the final amendments do not contain separate lists for (1) Holdback Credit Equity Projects - for projects that are for the primary benefit of or primarily serving a defined list of underserved individuals and/or communities[1] and (2) Other Holdback Projects – for activities are not considered as equity Holdback projects.[2] As currently drafted, the Other Holdback funding list limits the IOUs' spending on non-equity projects to three project types: (1) vehicle grid integration (VGI), (2) investments in grid-side distribution infrastructure necessary for EV charging, and (3) hardware and software that decrease the costs of or avoid updates to infrastructure, including load management software or outlet splitting. Such limits are not consistent with broader CARB objectives and may contribute to confusion. For example: because VGI projects are found only on the "Other Holdback (aka non-equity)" list of projects in the proposed draft language, the proposed amendment, if adopted, would not authorize the IOUs to use LCFS funds to support a VGI program that could minimize charging costs for a low-income EV driver or equity
178.6 communities.

SCE therefore supports the "one list" approach that a CalETC and the other IOUs' shared with CARB staff. CalETC's proposal proposes to authorize the IOUs to use LCFS holdback funds for any pre-approved LCFS Holdback projects for all types of customers and communities. To meet the proposed equity spending requirements, SCE supports a proposal to require the utilities to demonstrate that they distributed the funds to one of the defined underserved individuals or communities (*e.g.*, rebates issued as part of an income-qualified program, or public charging stations installed in a rural community, etc.). This streamlined approach enables utilities to deploy any of the projects and solutions when and where they are best for their service areas, while maintaining the requirement for utilities to direct funding to equity-focused activities.

II. CARB Should Specify that Utilities Have Discretion to Select the Most Appropriate Holdback Program Option(s) for their Customers and Require the Large IOUs to Fund At Least Three Program Options

California has a diverse mix of electric utilities, with differing customer needs and requirements.
178.7 There are the large IOUs, like SCE, and smaller publicly owned utilities that serve customers across the state. Because individual utilities will have different needs and require different solutions to ensure an affordable and equitable transition to electrified transportation for their

[1] Proposed Amendments to LCFS Regulation, § 95483(c)(1)(A)(5)(a)
[2] Proposed Amendments to LCFS Regulation, § 95483(c)(1)(A)(5)(b)

178.7 cont customers, CARB should update the LCFS Regulation's *Restrictions on Use of Holdback Credits* section[3] to clarify that CARB does not require or prefer any particular program option, so long as the large IOUs use LCFS credit revenues for multiple categories to support their diverse customer classes.

Specifically, SCE requests that CARB's final amendment clearly state that "utilities have discretion to select the most appropriate Holdback program option(s) for their customers, within the established requirements." Additionally, the regulation should require the "large IOUs to use their Holdback credit revenues to fund a minimum of three program options." Using funding for at least three program options will ensure that the IOUs meet diverse customer needs.

III. CARB Should Retain the 10% Administrative Cost Cap for Holdback Programs Because 5% Is Insufficient

178.8 The Proposed Amendments propose to reduce the allowed administrative costs on utility Holdback programs from 10% of total portfolio costs to 5%. This reduction in allowable administrative costs on utility Holdback programs will make it extremely difficult, if not impossible, to administer these programs given that these programs are designed to reach the most underserved individuals and communities. As Table 2 below shows, while SCE was able to operate its Clean Fuel Reward Program (CFRP) Rebate in years 2017-2020 with administrative costs at 5% or below, the moment SCE converted its program to a used EV rebate program with a targeted low-income rebate in 2021, SCE's administrative costs nearly tripled. While some of the 14% administrative cost in 2021 is the product of a combination of close-out costs from CFRP and launch costs from SCE's Pre-Owned EV Rebate (POEV), it required just under 11% administrative costs to implement POEV in 2022.

Table 2: SCE's LCFS Holdback Program Administrative Costs over Time

	2017	2018	2019	2020	2021	2022
Administrative Costs	$461,428	$339,590	$489,074	$1,678,204	$1,091,169	$1,002,251
Total LCFS	$10,554,478	$14,881,205	$28,876,538	$32,210,342	$8,037,704	$9,274,919
Administrative % of Total	4%	2%	2%	5%	14%	11%

SCE files the data in Table 2, which is public, in April of each year with both CARB and the California Public Utilities Commission (CPUC). While SCE has not compiled its calendar 2023 report, the administrative costs for SCE's LCFS Holdback programs from Q1-Q3 of 2023 were 8-9%. The targeted requirements of utility Holdback programs necessarily make them more expensive to operate than broad, unrestricted incentive programs. Thus, CARB should reject the Proposed Amendment's 5% cap and instead retain the 10% allowable administrative costs for utility Holdback programs, as authorized in the current version of the LCFS Regulation.

[3] Proposed Amendments to LCFS Regulation, § 95483(c)(1)(A)(5)(a -b).

IV. CARB Should Align the Administrative Cost Cap for the Statewide Clean Fuel Reward Program with Other Large Utility Incentive Programs

As the Program Administrator for the statewide Clean Fuel Reward Program since 2019, SCE can attest that not only is reducing the allowable administrative costs on the statewide Clean Fuel Reward from 10% to 5% an impediment to operating the program, but also does not comport to cost controls on other large utility programs. For example, the IOUs energy efficiency program portfolios, which have administered billions of dollars of incentive funds throughout the state with oversight from the CPUC, are operated under guidelines established in the Energy Efficiency Policy Manual (Version 6 published in April 2020 at this link). As shown in Table 3 below, Appendix C of the Energy Efficiency Policy Manual lists the cost caps (hard requirements) and targets that the CPUC established for the operations of these programs.

178.9

Table 3: Energy Efficiency Policy Manual APPENDIX C Cost Category Caps

Budget Categories	**Cap**	**Target**
Utility program administrative costs	10%	
Third-party / Gov't partnership administrative costs		10%
Marketing & outreach costs		6%
Direct implementation non-incentive (DINI) costs		20%
Evaluation, measurement & verification (EM&V) costs	4%	

In addition to being separate from ME&O costs, administrative costs, as defined in the Energy Efficiency Policy Manual, explicitly exclude third party implementer fees, ME&O costs, and also exclude *direct implementation non-incentive (DINI) costs* (which include activities such as software licenses, rebate processing, contractor training, etc.). By comparison, the Statewide Clean Fuel Reward program currently counts *all* of these costs towards its 10% Administrative and ME&O cost cap.

When the CPUC authorized SCE to administer the Statewide Clean Fuel Reward program in Resolution E-5015, it found that "A 10% cap of administrative funds is generally within the range of spending for other customer programs the utilities implement," and ordered SCE to "administer no more than 10% of the total Clean Fuel Reward program budget on administrative and marketing, education, & outreach spending, which must include all administrative spending related to the Clean Fuel Rewards program."

A 10% administrative cap on utility LCFS programs aligns utility LCFS programs with other similar utility programs and ensures the programs can operate as effectively as they will need to in order to help the state achieve its ambitious transportation electrification objectives.

V. CARB Should Update Vehicle Eligibility for the Statewide Clean Fuel Reward Program to Conform to CARB's Goals

178.10 SCE, as the Program Administrator for the statewide Clean Fuel Reward Program, supports CARB's proposed amendments to transition the statewide program from an incentive for all new passenger EVs to one that will support the adoption of electric MDHD vehicles in the coming decade. However, it is necessary that CARB make minor changes to the vehicle eligibility in the draft amendments to ensure that that next iteration of the program can effectively implement CARB's ambitious plans for the commercial vehicle sector.

178.11 For example: in *Appendix E: Purpose and Rationale of Proposed Amendments for the Low Carbon Fuel Standard Requirements,* CARB Staff states that the "Clean Fuel Reward will change from a universal new light-duty EV rebate to be focused on new and used rebates for medium- and heavy-duty trucks" because this " will jumpstart the transition for a harder to transition segment." However, the draft amendments define the Clean Fuel Reward as "a statewide program established by EDUs to provide a reduction in price on purchases or leases for new medium- or heavy-duty electric vehicles." SCE believes that CARB unintentionally omitted the word "used" from the draft amendments and recommends CARB add it to the final language.

178.12 Additionally, the definitions for *medium-or-heavy duty vehicle* in the draft amendments need updating to align with CARB's intentions. While CARB defines medium-duty vehicle in the Definitions and Acronyms as "MDV means a vehicle that is rated between 8,501 and 14,000 pounds GVWR," there is no accompanying definition for HDV, though HDV is reference in several locations throughout the Regulation as the acronym for *heavy-duty* vehicle. CARB should add the weight classification for completeness.

178.13 More significantly, that the combination of defining MDV and HDV solely by weight class and the proposed definition of the Clean Fuel Reward as "a statewide program established by EDUs to provide a reduction in price on purchases or leases for new medium- or heavy-duty electric vehicles" means that the program may be required to provide incentives for *all* vehicles that have a GVWR greater than or equal to 8,501, which includes many passenger vehicles such as the Rivian line of products, the extended range Ford F-150 Lightning, the electric Chevrolet Silverado, and the electric Hummer. Based on CARB Staff's published rationale, the Clean Fuel Reward should only provide incentives for these vehicles if the purchaser obtained them for *commercial* use. This distinction is important not only for the goals of the Clean Fuel Reward, but also the operations of the program, as implementing a program that is accessible to all commercial customers plus a narrow segment of the retail (passenger vehicle) market would be administratively challenging. Therefore SCE, as the Clean Fuel Reward Program Administrator, recommends that CARB revise the definition for the Clean Fuel Reward program as follows:

> *"Clean Fuel Reward" is a statewide program established by EDUs to provide a reduction in price for new* ***and/or used commercial*** *electric vehicles, greater than or equal to 8,501 GVWR, that are not subject to the High Priority and Federal Fleets requirements as specified in, title 13, California Code of Regulations, section 2015(a)(1) in California. The Clean Fuel Reward is funded exclusively through LCFS proceeds generated by EDUs from electricity fuel.*

For the avoidance of doubt, SCE also recommends that CARB add *commercial vehicle* to the definitions in the LCFS Regulation now that the CCFR is explicitly incentivizing them. HVIP is an established and well understood definition that SCE recommends CARB adopt for the LCFS Regulation Definitions and Acronyms section:

> *"Commercial vehicle" for the purposes of this program means any vehicle used by a business, public or governmental agency, or non-profit to carry people, property, or hazardous materials.*

VI. CARB Should Reject the 1-Mile Requirement for Capacity Credits in Favor of Greater Flexibility

SCE commends Staff for including the new capacity crediting (FCI) provision for public and shared-private medium-duty and heavy-duty (MDHD) charging stations. The MDHD FCI provision is critical in assisting the deployment of these charging stations by allowing developers to recover a portion of their LCFS crediting potential while their utilization grows as the electric MDHD vehicle market matures. However, SCE is concerned that the requirement that these sites be located within one mile of an Alternative Fuel Corridor (AFC) creates incentives for developers to impose arbitrary constraints on the electric grid that may stall overall MDHD vehicle electrification.

178.14

An examination of SCE's public-facing Grid Needs Assessment (GNA) Load Capacity maps illustrates this point. In 2025, SCE expects to have a total of 12,921MW of carry capacity available on its system over a total of 4,285 circuits, with 75% of that carrying capacity located within one mile, and 95% of the capacity located within ten miles, of the AFC routes. However, MDHD charging stations are much larger than typical interconnection requests – usually greater than 5MW and often greater than 10MW. When applying this filter, only 36% of SCE's available circuit capacity is located withing one mile of AFC routes for circuits that can handle at least 5MW of additional load, and that value increases to only 45% when the radius is expanded to ten miles.

Because incentives drive market participant behavior, SCE is concerned that the strict geographic restrictions proposed in the draft amendments for MDHD FCI credits will cause developers to attempt to locate sites in areas that do not have immediately available circuit capacity. This scenario creates undue costs on SCE's ratepayers and delays the deployment of critical MDHD charging infrastructure that is necessary to achieve the state's decarbonization targets. For this reason, SCE recommends that CARB reject the 1-mile requirement and allow for greater flexibility in allowable locations for sites seeking to claim MDHD FCI credits.

Thank you for considering SCE's comments and recommendations.

Sincerely,

/s/ *Rosalie Barcinas*

California State Association of Counties®

February 20, 2024

California Air Resources Board
1001 Street
Sacramento, CA, 95814

Subject: Concerns on the proposed Low Carbon Fuel Standards Rulemaking

Dear Members of the California Air Resources Board:

On behalf of the California State Association of Counties (CSAC), representing all 58 counties in the state, I write to express concerns on the regulatory proposal by the California Air Resources Board (CARB) to regulate jet fuel under the Low Carbon Fuel Standard (LCFS) program.

CSAC is committed to environmental stewardship and recognizes airports' critical role in a balanced transportation system. We are proud of our county airports' advances towards reducing their carbon emissions. Although we recognize how these proposed regulations support the State's broader goals for sustainability and environmental protection, the proposal to regulate jet fuel usage presents several challenges that could disproportionately affect county airports. Many county airports are not equipped with the infrastructure necessary for Sustainable Aviation Fuel (SAF) and Jet A blending, nor do they have the financial resources to undertake such significant upgrades. Implementing these upgrades will negatively impact their operations and services, exposing them to be in violation of federally mandated grant assurances and Federal Aviation Administration (FAA) policy.

We recognize and appreciate California's leadership in adopting SAF. However, we are concerned that the proposed regulations do not account for the significant infrastructure upgrades required for SAF and Jet A blending, particularly at general aviation airports. The logistics of transportation and storage for SAF, which differ from conventional jet fuel, pose additional challenges. Implementing this proposal could impose substantial operational burdens on county airports, potentially disrupting the progress toward our state's sustainable aviation future.

179.1

County airports play a vital role in the state transportation system and support numerous ancillary industries, it is imperative to consider the operational implications of this regulation carefully, not to mention the risk of losing federal entitlement monies by being in violation of federal grant assurance policies. We must avoid creating an aviation environment within our State where regulatory compliance costs undermine the viability of county airports. County airports are a vital part of the transportation system and delivery of emergency fire services in communities across California.

We urge CARB to reconsider this proposal, given the unique circumstances of county general aviation airports. Instead of a one-size-fits-all approach, we advocate for a strategy that includes grants for infrastructure upgrades and a phased implementation plan that allows county airports to transition to SAF usage without compromising their federal obligations and operational or financial stability.

In conclusion, we respectfully request that CARB preserve the existing opt-in approach for SAF, collaborate with county airports to address the complexities of SAF integration and focus on realistic policies that facilitate a smooth transition to a greener aviation future in California.

Thank you for your attention to this critical matter.

Sincerely,

Mark Neuburger
Legislative Advocate
California State Association of Counties

RE: Low Carbon Fuel Standard: 2024 Proposed Amendments

General Motors LLC (GM) appreciates the opportunity to offer comments on CARB's Low Carbon Fuel Standard (LCFS) Proposed Amendments for 2024.

If you have any questions, please contact me at +1-202-775-5071.

Sincerely,

Hon. David Strickland
Vice President
Global Regulatory Affairs and
Transportation Technology Policy
General Motors LLC

EXECUTIVE SUMMARY

General Motors LLC ("GM"), headquartered in Detroit, MI, is a global automotive manufacturer committed to positively impacting the communities where its customers live and work. As of December 2023, GM employs roughly 163,000 employees, operates 120 facilities, delivers over 2 million vehicles annually, and works with more than 5,000 suppliers.[1]

GM is focused on advancing toward a zero emissions future that is inclusive and accessible to all.[2] Battery Electric Vehicles ("BEVs") are key enablers of our vision for a world with Zero Crashes, Zero Emissions, and Zero Congestion.[3] GM regularly reports on sustainability metrics,[4] and endeavors to track and report emissions inventory.[5] GM has set science-based targets consistent with the goals of the Paris Agreement to support this vision.[6]

GM appreciates the opportunity to provide its insight as a BEV manufacturer to CARB's Proposed Amendments to the Low Carbon Fuel Standard, particularly on aspects of the proposal related to EV charging. This proposal clearly signals CARB's intention to further pursue reductions in carbon-based fuel impacts to the environment by incentivizing BEV deployment lower carbon intensity electricity. GM generally supports CARB's proposed updates to the LCFS framework, with recommendations on specific aspects of the revised program.

GM supports CARB's framework proposal to tighten carbon intensity stringency, adopt an acceleration mechanism and introduce a step down in stringency for 2025.

The LCFS program is among the most successful regulatory programs, delivering significant reductions in carbon intensity of fossil fuels and promoting adoption of lower carbon intensive transportation modes. As such, the market is oversupplied with credits, thereby reducing their value and potential to reinvest in California's EV infrastructure development. CARB's plan to
180.1 increase stringency for the LCFS market will tighten market conditions, thereby bolstering the market and further decreasing carbon intensity in liquid fuels.

The proposed amendment to require a 30% reduction in carbon intensity benchmarks by 2030 is appropriate for market compliance conditions. Adding additional flexibility to the regulation with the adoption of a near-term step-down and an automatic acceleration mechanism will strengthen the LCFS market long-term. Using two credit market ratio signals as the triggers for the acceleration mechanism is appropriate to address the specific problem that the proposal is intended to address.

Credits generated from light-duty electric vehicles should be reinvested into the still developing light-duty electric vehicle market.

While California leads the US in EV sales having reached 25% market share, the EV transition is
180.2 far from complete. Substantial progress is needed to meet CARB's complementary regulatory

[1] https://www.gm.com/company/usa-operations
[2] https://news.gm.com/company/about-us
[3] *Id*.
[4] https://www.gmsustainability.com/esg-resources-and-downloads.html
[5] https://www.gmsustainability.com/data-center.html
[6] https://www.gmsustainability.com/_pdf/resources-and-downloads/GM_2021_SR.pdf (pages 11, 16-17)

180.2 cont programs, which will require 51% ZEV sales in 2028 leading to 100% by 2035 under Advanced Clean Cars II. Infrastructure access for light-duty vehicles must be addressed to achieve EV market growth to meet regulatory and climate expectations. Funding generated from residential EV credit generation should be directed to the light-duty EV market by investing in infrastructure deployment, vehicle incentives and public education.

GM recommends that CARB reinstate Clean Fuel Rewards for light-duty EV adopters. Light-duty EV adopters represent the best opportunity for reducing carbon intensive transportation applications, including the harder to transition used vehicle market. Residential light-duty EV charging funds the Clean Fuel Reward program and this program is highly incentivizing to light-duty EV purchasers as it is available at the time of purchase as an “on the hood” incentive. It is paramount that the Clean Fuel Reward program is mechanized reliable for light-duty vehicle purchasers. We urge CARB to reconsider its proposal to allocate the Clean Fuel Reward to medium and heavy duty electric vehicles.

GM looks forward to reviewing details on CARB’s proposal to add third-party verification provisions to electricity transaction types.
GM recognizes and supports provisions designed to enhance integrity of regulatory programs, while streamlining regulatory compliance and costs. Based on CARB’s proposed regulatory text, CARB’s expectation for how third-party verification should be managed for metered residential EV charging are unclear.

180.3

In §95500(c)(1) Applicability, entities submitting Quarterly Fuel Transaction Reports are expected to obtain the services of an accredited verification body, including required site visits. It would be ideal to understand CARB’s expectations for a “site” under this verification requirement, as this definition could be widely interpreted as it pertains to residential EV credit generation and may require considerations to address consumer privacy protections. Finally, third-party verifiers for regulatory programs tend to slow market conditions due to limited accreditors, at least in the near term. We look forward to working with CARB to come to a practical solution for both parties to demonstrate validity of EV residential charging events for the final amendment update.

INCORPORATION BY REFERENCE

180.4 GM contributed to the development of comments through the Alliance for Automotive Innovation and provides its support for the positions established therein.

CONCLUSION

GM supports CARB’s proposed framework for the 2024 updates to the low carbon fuel standard. As a one of the key stakeholders in low carbon electricity within the LCFS program and its administration, GM would be glad to provide further support for any of the above topics and looks forward to continued collaboration on the development of the LCFS program.

Re: Comments of Bloom Energy - Proposed Amendments to the Low Carbon Fuel Standard

Dear Chair Randolph,

Bloom Energy appreciates the opportunity to submit comments in response to the December 19, 2023 Staff Report regarding proposed amendments to the Low Carbon Fuel Standard (LCFS). Acknowledging the complexity and far-reaching nature of the program, we thank the Air Resources Board for steady management over the years while balancing a broad range of interests and stakeholders.

Bloom Energy is a manufacturer of solid oxide fuel cell (SOFC) technology that utilizes an electro-chemical process to power non-combustion microgrids as well as high efficiency electrolyzer systems designed to convert renewable electricity into renewable "green hydrogen." Bloom Energy's solid oxide fuel cells and electrolyzers are designed in a modular fault-tolerant format that provides mission critical reliability with no downtime for maintenance. The company has installed over 1000 of its non-combustion solid oxide fuel cell systems for customers in thirteen U.S. states as well as in Japan, South Korea, India and Italy. Bloom Energy's emission reducing systems have proven resilient through outages caused by hurricanes, winter storms, earthquakes, forest fires, and other extreme weather and natural disasters.

Bloom Energy's modular design, high efficiency, and ability to utilize biogas without the significant upgrading required for pipeline injection, allows for smaller and remotely located biogas projects to make the most efficient use of this valuable form of renewable energy, producing more electricity for equivalent volumes of biogas than other available technologies. Its electrochemical process produces far fewer criteria pollutants than competing technologies that rely on combustion. Our SOFCs also require virtually no water during operation, mitigating water supply concerns in many areas across the country.

Based on our experience developing projects that consume or generate renewable fuels, we offer the following comments on a few key aspects of the proposal and Staff Report.

Avoided Methane Crediting

Bloom Energy does not support a phaseout of avoided emission credits for biogas to electricity projects, and commends CARB for recognizing the value of these projects by proposing to retain this aspect of the program.

181.1

Converting biogas into electricity through scalable, efficient, non-combustion technologies provides outsize environmental benefits by eliminating methane emissions and generating reliable clean, firm, renewable electricity. As a short-lived climate pollutant and potent greenhouse gas, methane is a core contributor to climate change and often a difficult pollutant to mitigate. Phasing out avoided methane credits would have the unintended consequence of leaving small or remote methane sources

Bloom Energy Corporation
4353 North First Street, San Jose, CA 95134
408 543 1500
www.bloomenergy.com

181.1 cont undeveloped, creating stranded resources that emit methane with no mitigation options. Because small or remote farms or digesters are not biomethane project candidates due to their size and distance from pipelines for injection, in many cases biogas-to-electricity is the only viable option for emissions reductions. In addition, non-combustion biogas-to-electricity projects that supply EV chargers directly serve CARB's goal of improving air quality by reducing vehicle tailpipe emissions through increasing market penetration of Zero Emission Vehicles (ZEVs). As noted in the Staff Report, "[r]educing criteria pollutants and toxic emissions from fuel combustion in line with California's air quality goals requires deploying ZEVs and ensuring the availability of fueling infrastructure to support ZEV deployment."[1] Supporting extremely low carbon intensity (CI) renewable energy to power ZEVs serves both climate and local air quality objectives.

As highly efficient, non-combustion and modular electricity generation systems, fuel cells meet the needs of these small/remote sources. Developing biogas to electricity projects in these locations would deliver critical methane reductions and valuable clean, firm electricity that can be delivered to meet transportation energy demand around the clock. Avoided methane credits are critical to leveraging these resources and developing such projects. And the carbon benefits are not just theoretical; as of this writing, Bloom has three operational non-combustion solid oxide fuel cell biogas-to-electricity projects operational at dairy farms in California. The first project, located in Kerman, CA, received a CARB-certified CI score of -790, the lowest CI score in the history of the LCFS program.[2]

Book-and-Claim

181.2 Currently, biogas-to-electricity projects under the LCFS must physically wheel the power into California, while RNG projects may be located anywhere in North America and utilize book-and-claim accounting to demonstrate use for LCFS compliance. We acknowledge CARB's proposal to limit book-and-claim accounting for RNG starting in 2040 but that is a long time away. We believe that the most efficient, cost-effective way to ensure that the LCFS program enables the most beneficial projects is to maintain a level playing field for pathways that rely on the same feedstock. A major step towards aligning requirements for projects with the same feedstock, and unlocking the untapped emissions reductions of biogas-to-electricity, would be to allow such projects to utilize book-and-claim accounting anywhere in the Western Electricity Coordinating Council (WECC), as is already the case in Oregon under their Clean Fuels Program. This, coupled with the proposed sunset for national book and claim available for RNG projects, would eventually result in regulatory consistency for projects with the same feedstock.

181.3 Additionally, Bloom recommends changes that allow biogas-to-electricity projects to qualify when electricity generation and biogas production are not co-located. This is in-line with the California RPS's treatment of "directed biogas" and allows greater project penetration by supporting optimal siting of both the RNG source and the electricity generator rather than requiring co-location. Specifically, where electricity generation is used for on-site EV charging, the project should be permitted to utilize directed biomethane as a power generation fuel provided that the biogas source and the electricity generator are located within the WECC. This additional flexibility would allow many more biogas to electricity projects to participate and would provide for greater deployment of biomethane-fueled microgrids at EV charging stations, which, as noted above, would further CARB's efforts to promote vehicles with zero tailpipe emissions. Of course, this would also bolster California's efforts to address the significant grid capacity

[2] Application No. B0490, available at: https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/fuelpathways/comments/tier2/b0490_cover.pdf

issues associated with large scale deployment of charging infrastructure across the State by enabling renewable generation to be deployed where it is most needed, rather than where the fuel is generated.

Consideration of Total Environmental Impact

Furthermore, Bloom Energy encourages CARB to reward market participants in the LCFS Program for achieving environmental results beyond carbon reductions. Environmental benefits such as reduced criteria air pollutant emissions in particular warrant consideration as part of the calculation methodology.

181.4 An increasing body of research has found the economic and health benefits associated with reducing NOx and PM emissions often exceed the economic and health benefits of reducing GHG emissions on a per ton basis.[3] Currently, while biogas combustion narrowly serves LCFS program objectives, the associated air pollution runs counter to CARB's broader new and long-standing air quality goals. Alternatively, non-combustion biogas-to-electricity projects meet LCFS objectives while also reducing local air pollution and furthering air quality objectives.

Over the past several years, research has shown that local combustion-related air pollutants are far more harmful to human health and the environment than previously understood. Some key findings that demonstrate the need for clean energy programs to value these impacts include:

- Combustion related air pollution may be as harmful to human lungs as smoking cigarettes;[4]
- Combustion related air pollution increases preterm birth risk;[5]
- Particulate matter (PM) is the largest environmental health risk factor in the nation, and the resulting health impacts are borne disproportionately by disadvantaged communities.[6]

This information is not new to CARB. In fact, the benefits of reduced criteria pollutant emissions are well documented in the Staff Report. To the extent that the proposed amendments do already reduce these emissions, the report states, "[t]he total statewide health benefits derived from criteria emissions reductions is estimated to be approximately $5 billion, with $4.9 billion resulting from reduced premature cardiopulmonary mortality and $85 million resulting the reductions in other adverse health impacts."[7]

The following table shows the different environmental impacts of non-combustion via a solid oxide fuel cell versus combustion uses of biogas.

Table 1: Comparison of NO_x and SO_2 Emissions

	g/MMBtu		
	Non-combustion SOFC[1]	**Engine[2]**	**% reduction**
NO_x	0.402	385.55	99.9%
SO_2	0.00039	0.27	99.8%

1. From source testing
2. AP-42 Chapter 3 Section 2 for 2SLB engines

58,000 MMBtu/year of biogas equates to roughly a 1 MW Bloom solid oxide fuel cell system, or 7,900 MWh/year. Using the emissions factors above for an illustrative biogas-to-electricity project and utilizing the corresponding emissions for EPA's Co-Benefits Risk Assessment Health Impacts Screening and Mapping Tool (COBRA),[8] results in $1.3 to $3M of air quality driven health benefits for non-combustion fuel cell over combustion-based generation or flaring. The illustrative 1 MW Bloom project in the above example emits roughly 3,000 MT CO_2e/yr. At the midpoint of the COBRA health benefits calculation ($2.4M), the additional air quality-driven health benefits of the project equate to roughly $800/MT. While the LCFS credit market generally values carbon abatement at anywhere from ~$50 to ~$200/MT, it does not value air quality benefits at all.

In order to value these significant benefits, Bloom strongly encourages CARB to include a mechanism that appropriately considers criteria air pollutant emission reductions when evaluating electrical generation from biogas and natural gas, across all pathways. One possibility is to include an LCFS credit multiplier such that, when utilizing the same fuel, a project that does not exacerbate air quality issues generates more credits than one that does. Under this model, we recommend setting an emissions threshold of <0.1g/MWh NO_x and <0.01g/MWh SO_2, below which projects receive a credit multiplier of 1.5.[9] At current and expected LCFS credit prices, this results in far less additional value than the $800/MT shown above and would be a modest but direct acknowledgement of the societal benefits of improved air quality.

Tier 1 Calculator for Biogas-to-Electricity

For certain fuel pathways the LCFS currently provides Tier 1 CI calculators that help to streamline the application review and validation process. As part of the proposed amendments, Staff proposes to update the calculators to increase usability and further reduce administrative burden on applicants and agency staff. Additionally, the proposed amendments would create a new Tier 1 CI calculator for hydrogen. While
181.5 the Staff Report justifies the existing Tier I option due to extensive experience reviewing certain pathways,
no such claim can be made of hydrogen, which is relatively new and still emerging. This acknowledges the benefits of streamlining without risking the integrity of an existing and robust process.

Bloom supports both of these proposals and the Tier 1 calculators in general. Additionally, we respectfully request that a Tier 1 calculator or other streamlining option be made available for biogas-to-electricity projects. Given the fact that this option is already available for RNG, this would help to provide equal treatment for pathways dependent on the same feedstock.

[8] https://www.epa.gov/cobra

[9] Note that the emission rates shown in Table 1 are represented in terms of grams per MMBtu.

GREET Model Treatment of CO2 Storage

With the emergence of various forms of above ground permanent CO_2 storage, such as manufacturing
181.6 products (including concrete, plastics, etc.) from captured CO_2, we encourage CARB to broaden the
definition of permanent CO_2 storage beyond the limited "underground" storage definition currently used.
This will incentivize more projects to capture and sequester CO_2, thus achieving even lower carbon
intensities and furthering CARB's goals of aggressive decarbonization of the transportation sector.

A Broader Clean Fuels Standard Will Support Industrial and Commercial Sector Decarbonization

Notwithstanding all of the above, Bloom Energy also wishes to point out that a broader Clean Fuels Standard is necessary to support industrial and commercial sector decarbonization. These sectors have proven hard-to-decarbonize and remain a significant source of GHG emissions that must be addressed to achieve the State's carbon neutrality goals. As the adopted 2022 Scoping Plan recognizes, changes in fuel use are also critical to reducing GHG emissions from these sectors and biomethane use in these sectors is critical to meeting both 2030 and 2045 Scoping Plan goals.

CARB could and should expand the LCFS program outside of transportation or use the LCFS program as an
example to develop and adopt a broader Clean Fuels Standard that would complement the LCFS. Such a
standard could impose a decreasing, rate-based target on regulated entities, allowing these sectors to
achieve emission reductions in a technology neutral manner by choosing between electrification,
procuring low- and zero-carbon and carbon-negative fuels, and/or improving energy efficiency. Such a
181.7 standard would achieve significant reductions at least cost by enabling compliance flexibilities and
harnessing technological innovation. The current LCFS program is providing critical support to the RNG
market. Because a significant amount of RNG usage today is occurring in the transportation sector, the
LCFS program holds continued importance as the State explores opportunities to incentivize RNG use in
other sectors. Competitive pricing and availability of supply will be critical when looking to expand RNG
usage to other hard-to-abate sectors. For these reasons, Bloom Energy continues to recommend that
discussions about the potential expansion of LCFS or the potential development of a broader standard
should happen in parallel with ongoing support provided to the RNG market through the current LCFS.

Bloom Energy appreciates the opportunity to provide comment on this important proceeding. Please do not hesitate to contact the undersigned if we can provide additional information. We look forward to further engagement as stakeholders collaborate to strengthen the LCFS program.

Sincerely,

/S/Jordan Garfinkle

RE: Low Carbon Fuel Standard Potential Amendments

The Western Propane Gas Association (WPGA) is pleased to submit its comments in response to the Low Carbon Fuel Standard (LCFS) proposed amendments. Aligned with our recent meeting with CARB staff on February 1, 2024, the focus of our letter is on the value of renewable propane as an eligible fuel for LCFS.

As mentioned in our previous letters, we would like to thank CARB staff for recognizing the value of renewable propane in decarbonizing "hard-to-electrify" segments of California, and for justly calculating a lower Carbon Intensity (CI) of conventional propane under the GREET4.0 proposed model (Lookup Table Pathways, Pg 24)[1].

<u>CORRECTING CI OF CONVENTIONAL PROPANE IN GREET MODEL</u>
However, WPGA also supports adjusting the baseline CI for propane further based upon corrected assumptions and modeling. Please see our letter submitted on April 29, 2023[2] for detailed CI calculations.

In short, WPGA proposes that CARB update its modelling of the CI for conventional propane within the lookup table to result in **80.06 gCO2eq/MJ** due to corrections on:

182.1
- Upstream combustion emissions – from a CI of 64.84 to 64.58 (determined by existing GREET 2021 model updates for school buses),
- Assumptions regarding refining source – from 75% oil/25% natural gas mixture for conventional propane to 59.5% oil/40.5% natural gas within California per Argonne National Laboratory reporting[3], and
- Transport distance for delivery – fewer than 100 miles traveled for final delivery, based upon industry reporting and best practices.

<u>AIR & WATER QUALITY BENEFITS OF TRANSITIONING TO PROPANE</u>
The current CI of renewable propane ranges from half- to one-quarter of the CI of California's current electric grid – and new sources keep going lower still. Like traditional propane, renewable propane has no methane and therefore does not suffer leakage issues or fugitive GHG emissions like natural gas. Likewise, it does not run the risk of groundwater or soil intrusion from spills like liquid fuels or degrading electronic waste, such as batteries or solar panels.

[2] WPGA, Comment Letter, RE: GREET4.0 – Propane Carbon Intensity Calculation, Submitted to CARB April 29, 2023
[3] Backes, S. E., Beath, J., Sebastian, B., & Hawkins, T. R. (2020, September). Sources of Propane Consumed in California. Chicago; Argonne National Laboratory.

There would be a significant air quality benefit to transitioning from fuels with significant air emissions like CARBOB (California gasoline blend), natural gas, and diesel to the no-SOx, no-black-carbon, and ultra-low-NOx solution of renewable propane. To meet 2022 Scoping Plan goals and other emission reduction mandates such as the State Implementation Plan (SIP), renewable propane serves as the bridge fuel to meet timeline goals in fuel sectors where using electric technology is not yet affordable nor feasible. It is the perfect fuel for hard to decarbonize areas and sectors of the state, like off-road and heavy-duty transportation. Renewable propane can be prioritized in underserved communities where electric infrastructure is not afforded to them or where service is intermittent due to power shutoffs or natural disasters.

TRANSPORTATION EMISSIONS AND BOOK & CLAIM

Acknowledging that the transportation of fuel is included in the CI, ideally renewable propane production would be in California. There are already facilities in the state producing renewable propane, with additional sources coming rapidly online. One of them is Global Clean Energy, which utilizes the energy-rich cover crop camelina seed; currently qualified as an LCFS compliant fuel. While many renewable diesel and sustainable aviation fuel (SAF) plants produce renewable propane, it is currently being utilized onsite to lower the CI of other existing LCFS-compliant fuels. This limits the amount of renewable propane on the market.

182.2 WPGA proposes that CARB apply its Book & Claim and avoided emissions reporting to renewable propane. While renewable propane is currently only deliverable in California by truck or rail, CARB, through amendments, has the capacity to generate enhanced distribution and use of renewable propane. Given renewable propane's low CI score, CARB could, through adopting its Book & Claim and avoided emissions framework, play an instrumental role in lowering the CI score in California and increasing production to offset fuels with larger air quality or GHG emissions footprints.

182.3 Similar to its provisions pathway for renewable biomethane, CARB could develop a provisional pathway for avoided emissions for renewable propane.

- One pathway would involve booking propane produced outside of California, and exchanged for renewable propane produced in California, allowing a lower CI score to and to avoid the added CI for transmission.
- A second proposed provisional pathway would account for reduced or nominal CI additions for renewable propane shipped by rail or truck, as renewable propane should not be excluded by a failure of useful infrastructure.

CARB has a unique potential to both stimulate renewable propane production and demand, while lowering CI scores and improving environmental justice communities, all by providing for Book & Claim and avoided emissions accounting for renewable propane. Through this process, CARB can ensure the best available fuel for particular communities and uses, while at the same time lowering the CI score of the fuel utilized.

STREAMLINE PATHWAY APPROVAL PROCESS FOR DELIVERY MODELS

Alongside Book & Claim efforts, there are other steps that CARB can take that would improve the supply and usage of renewable propane within California.

182.4 WPGA proposes that CARB adopt a streamlined approval process for the following additional delivery models of fuel:

1) Pathways that would incentivize production of electricity used in the charging of battery electric vehicles: Currently, renewable and conventional propane can be used in fast-

182.4 cont charging mobile or stationary applications to charge battery electric vehicles across many classes. Offering a streamlined pathway to incorporate the delivery of already-approved renewable propane to these charging applications is directly in line with existing LCFS intent and will provide greater reliability for electric vehicle charging networks within California.

2) Updated GREET model (and/or pathways) that incorporate the usage of renewable fuels or technologies within the transportation of renewable propane for delivery. In-state transportation emissions could further be reduced by using renewable propane to fuel the vehicles involved in transportation and delivery. WPGA is working with vendors to bring ultra-low-NOx renewable propane-powered Autogas vehicles to the California market to supplant diesel. CARB could create a streamlined process to incorporate those reductions in the CI of transportation within the CI of the fuel itself.

CONCLUSION

With approximately 15% of all propane used in transportation being renewable today, the industry has a goal of reaching 100% renewable propane across California's propane transportation market by 2035 or sooner. WPGA remains committed to transitioning its fuel within California and bringing additional resources to the non-transportation markets served by our members.

WPGA appreciates the opportunity to submit feedback on the LCFS potential amendments. We will continue engaging with CARB staff to support a path for the continued development of renewable propane.

Sincerely,

Krysta Wanner

LOS ANGELES AREA
CHAMBER OF COMMERCE

February 13, 2024

Liane M. Randolph, Chair
California Air Resources Board
P.O. 2815
Sacramento, CA 95812

Re: Opposition to California Air Resources Board Proposal to Regulate Jet Fuel

Dear Board Chair Randolph,

The Los Angeles Area Chamber of Commerce is writing to share our serious concern and opposition to the recent California Air Resources Board (CARB) proposal to regulate jet fuel under its Low Carb Fuel Standard (LCFS) program.

The Los Angeles Area Chamber of Commerce represents the interests of a broad spectrum of organizations across the private, non-profit, academic and public sector, including the business community, job creators, and innovators in the Los Angeles region. Our mission is to design and advance opportunities and solutions for a thriving regional economy that is inclusive and globally competitive. As the oldest and largest business association in the region, the Chamber has a long standing history of convening business leaders, communities, and policy makers to promote a vibrant economy.

The U.S. airline industry plays a vital role in California's economy. Furthermore, the industry is committed to reducing its climate impact and achieving "net zero" carbon emissions by 2050. Transitioning to Sustainable Aviation Fuels (SAF) is core to this commitment, and the industry has pledged to work with governments and other stakeholders to make three billion gallons of SAF available in the United States by 2030. Achieving these goals requires new and additional policy incentives, streamlined permitting processes, and close collaboration among airlines, fuels industry, manufacturers, environmental organizations and governments, among others.

With respect to SAF, California has established itself as an early leader in attracting investment, production, and use of SAF through the existing Low Carbon Fuels Standard (LCFS) Program, which provides an opt-in credit for SAF that helps reduce the price difference between SAF and conventional jet fuel. This voluntary regulatory structure has been successful in enabling the growth of the SAF market in California and across the country. CA has the most viable market for SAF today in the United States and as airlines increase their demand for SAF the market continues to grow.

350 S. Bixel St. | Los Angeles, CA 90017 | P: 213.580.7500 | F: 213.580.7511 | lachamber.com

Aviation accounts for 2.6% of the US GHG emissions but 5% of US GDP and 4.1% of CA's GDP. There are 380 thousand employees of US Commercial aviation firms based in California, with an overall economic impact of $194 billion[1]. Aviation is critical to driving California's economy and it's rank as the 5th largest economy in the world, enabling $114 Billion in annual trade flows and underpinning the of many of the rest of California's biggest economic drivers such as agriculture, tourism, manufacturing, banking, technology and small business. Ensuring a healthy and vibrant aviation industry is essential to California's future, and leveraging CARB's early leadership on SAF can enable California leadership in the emerging SAF production industry, creating new jobs and economic development opportunities.

With this context, we express our serious concern with a new proposal by the California Air Resources Board (CARB) to regulate jet fuel as an obligated fuel under the LCFS Program. CARB's proposed changes to the LCFS program include a proposal to eliminate the existing exemption for conventional jet fuel use for flights within the state of California. This proposed change is unlikely to result in increased SAF production, availability, or use in California, but would lead to higher jet fuel prices. The primary impediment to increased SAF production and availability in California remains the higher cost of SAF for producers and buyers relative to conventional jet fuel and renewable diesel. The CARB proposal would not meaningfully address this fundamental challenge and therefore unlikely to meaningfully increase SAF supply or use.

183.1 The proposal seeks to regulate jet fuel and reduce emissions from aviation, both of which are pre-empted under federal law a fact that CARB recognized when it exempted jet fuel in 2018.[2]. Aviation has unique circumstances, that go beyond considerations of interstate commerce, for the safe operation and maintenance of aircraft that the federal government has recognized in the EPA's Clean Air Act and the jurisdiction of the FAA. These statutory authorities establish clear and broad federal authority for regulating jet fuel and aircraft engine emissions that pre-empts California from regulating jet fuel under the LCFS program.

Moving forward with eliminating the fossil jet fuel exemption and implementation of a new obligation will likely result in litigation that will be lengthy, costly and do nothing to advance the mission of more SAF production and uplift. Engaging in litigation will divert resources from the state and the aviation industry that would be better spent enabling greater SAF production. Our mutual interest is to increase SAF production, availability, and use and the most effective way to accomplish this is to continue the positive,

[1] The Economic Impact of Civil Aviation on the U.S. Economy, State Supplement, US Department of Transportation, November 2020

[2] CARB stated that "[s]ubjecting aircraft fuels to annual carbon intensity standards would raise federal preemption issues" *available at* https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2018/lcfs18/isor.pdf?_ga=2.259407882.1202437490.1641231788-253234234.1573227006

collaborative approach represented by the existing “opt-in” mechanism developed by CARB and the aviation community.

Based on these considerations, we urge CARB to reconsider and withdraw the proposal to remove the exemption for jet fuel for intrastate flights and instead preserve the existing opt-in approach for SAF and partner with the aviation sector and stakeholders across the emerging SAF ecosystem on new policies and approaches to rapidly increase the availability of SAF in California. We urge CARB to focus on the ultimate goal – how to get more SAF into planes in California by reducing barriers to production, availability and use.

For more information, please contact Elissa Diaz at ediaz@lachamber.com.

Sincerely,

Maria S. Salinas

Comment 193 for Proposed Low Carbon Fuel Standard Amendments (lcfs2024) - 45 Day.

First Name	Lisa
Last Name	Whelan
Email Address	lisa@iowacci.org
Affiliation	Iowa Citizens for Community Improvement
Subject	Reform the LCFS

Comment

Iowa Citizens for Community Improvement urges the Air Reso
Board to grant the recent Petition for Rulemaking to Exclude All Fuels Derived from Biomethane from Dairy and Swine Manure and amer the LCFS accordingly. Iowa CCI is a statewide organization with a communication base of 15,000 everyday Iowans working to win socia environmental, economic and racial justice. We want to reform our food and farm systems to work for farmers, workers, eaters, and tl planet. Amending the LCFS to exclude fuels from methane captured from factory farms is an important step toward this critical reform.

The current flaws in the LCFS, such as "avoided methane cı and inaccurate life cycle assessments, not only enable pollution but disproportionately harm low-income communities and communitie of color. Factory farms, predominantly situated in these marginalized areas, inflict severe damage on air, water, public health, rural economies, and overall quality of life.

We urge you to consider and prioritize the following refo the LCFS:

1. Eliminate "avoided methane crediting" in 2024.
2. Address inaccuracies in the Life Cycle Assessment that ignore associated up and downstream greenhouse gas emissions from factor farm gas production.
3. Remove the 10-year "grace period" for factory farm gas producers.
4. Stop double counting by allowing factory farm gas projects pai for and claimed by other programs to sell LCFS credits as well.

We are extremely concerned that the LCFS, which the ARB a with the intention to reduce greenhouse gases from California transportation fuels, will perversely incentivize more and larger hog and dairy confinements in Iowa. Over the last several decades the number of permitted livestock facilities has increased dramatically from 722 (93% hog) in 2001 to over 10,000 in 2017. Bu recently, the Iowa legislature exempted confinement operations fr a permitting requirement for operations greater than 8,500 animal units if an operation installs an anaerobic digester system to capture biogas. The Cedar Rapids Gazette reports that nine Iowa dairies have applied for permits for anaerobic digesters, seven a expanding herd sizes as part of the process, and two are utilizin the exemption because their herd sizes will exceed 8,500 animal units.

The LCFS program has drawn significant interest from fact in California and other states with many factory farms taking advantage of lucrative LCFS credits. We do not want to see your transportation fuel policy entrench and enrich corporations like Iowa Select, Smithfield, Tyson, JBS, and Prestage Farms at the expense of our communities, land, air, and water. Even worse, we are extremely concerned that the value of LCFS credits for biomethane from hog and dairy waste will incentivize expansions a even more confinement operations. Right now, Iowa agricultural runoff is contributing approximately 30 percent of the nitrogen load feeding the Gulf Dead Zone off the coast of Louisiana, and that amount has been increasing. And this runoff is polluting ou drinking water as well. Turning Iowa factory farms into sources credits to offset California transportation fuel emissions will inevitably generate more incentives to increase more manure which will further degrade our communities and water quality.

We hope that you recognize the consequences that your pol choice has inflicted and will inflict. We urge you to amend the LCFS to stop utilizing out-of-state factory farms as a source of offsets for your pollution trading scheme. We also ask that, at a minimum, you amend the LCFS to correct the over-valuation of manure-based credits to include all climate pollution associated with the factory farm system and ensure that credits from non-additional reductions do not continue.

Instead of pitting our states and residents against each should be working together to implement real solutions that prote our communities, our farmers, our workers, and our planet. Thank you for considering these comments.

From: Lisa Whelan, Iowa CCI Executive Director on behalf of Iowa CCI members

Date: February 20, 2024

Re: Reform the LCFS

184.1 Iowa Citizens for Community Improvement urges the Air Resources Board to grant the recent Petition for Rulemaking to Exclude All Fuels Derived from Biomethane from Dairy and Swine Manure and amend the LCFS accordingly. Iowa CCI is a statewide organization with a communication base of 15,000 everyday Iowans working to win social, environmental, economic and racial justice. We want to reform our food and farm systems to work for farmers, workers, eaters, and the planet. Amending the LCFS to exclude fuels from methane captured from factory farms is an important step toward this critical reform.

The current flaws in the LCFS, such as “avoided methane crediting” and inaccurate life cycle assessments, not only enable pollution but disproportionately harm low-income communities and communities of color. Factory farms, predominantly situated in these marginalized areas, inflict severe damage on air, water, public health, rural economies, and overall quality of life.

I urge you to consider and prioritize the following reforms to the LCFS:

184.2 1. Eliminate "avoided methane crediting" in 2024.
184.3 2. Address inaccuracies in the Life Cycle Assessment that ignore associated up and downstream greenhouse gas emissions from factory farm gas production.
184.4 3. Remove the 10-year "grace period" for factory farm gas producers.
184.5 4. Stop double counting by allowing factory farm gas projects paid for and claimed by other programs to sell LCFS credits as well.

184.6 We are extremely concerned that the LCFS, which the ARB adopted with the intention to reduce greenhouse gases from California transportation fuels, will perversely incentivize more and larger hog and dairy confinements in Iowa. Over the last several decades, the number of permitted livestock facilities has increased dramatically from 722 (93% hog) in 2001 to over 10,000 in 2017. But recently, the Iowa legislature exempted confinement operations from a permitting requirement for operations greater than 8,500 animal units if an operation installs an anaerobic digester system to capture biogas.[1]

[1] Iowa Code § 459.206(2)(c).

184.6 cont The Cedar Rapids Gazette reports that nine Iowa dairies have applied for permits for anaerobic digesters, seven are expanding herd sizes as part of the process, and two are utilizing the exemption because their herd sizes will exceed 8,500 animal units.[2]

The LCFS program has drawn significant interest from factory farms in California and other states with many factory farms taking advantage of lucrative LCFS credits. We do not want to see your transportation fuel policy entrench and enrich corporations like Iowa Select, Smithfield, Tyson, JBS, and Prestage Farms at the expense of our communities, land, air, and water. Even worse, we are extremely
184.6 concerned that the value of LCFS credits for biomethane from hog and dairy waste will incentivize expansions and even more confinement operations. Right now, Iowa agricultural runoff is contributing approximately 30 percent of the nitrogen load feeding the Gulf Dead Zone off the coast of Louisiana, and that amount has been increasing.[3] And this runoff is polluting our drinking water as well.[4] Turning Iowa factory farms into sources of credits to offset California transportation fuel emissions will inevitably generate more incentives to increase more manure which will further degrade our communities and water quality.

We hope that you recognize the consequences that your policy choice has inflicted and will inflict. We urge you to amend the LCFS to stop utilizing out-of-state factory farms as a source of offsets for your pollution trading scheme. We also ask that, at a minimum, you amend the LCFS to correct the over-valuation of manure-based credits to include all climate pollution associated with the factory farm system and ensure that credits from non-additional reductions do not continue.

Instead of pitting our states and residents against each other, we should be working together to implement real solutions that protect our communities, our farmers, our workers, and our planet. Thank you for considering these comments.

Comments to Proposed Low Carbon Fuel Standard Amendments

Umwelt Energy ApS ("**Umwelt Energy**") appreciates the opportunity to provide feedback on the California Air Resources Board's ("**CARB**") proposed amendments to the Low Carbon Fuel Standard ("**LCFS**") regulation.

As detailed below, our comments pertain to Section 95482(d)(2) of the current LCFS regulation, which exempts ocean-going vessels from the LCFS.

In particular, these comments propose the basis for revisions to the regulatory text, so fuels for ocean-going vessels — as a minimum — are treated the same way as aviation fuels.

We believe revisions are warranted, as they would significantly incentivize the scale-up of Californian low-carbon fuels, which are regarded as the most promising pathway to decarbonize the maritime sector, a significant (indirect) contributor to California's emissions.

Umwelt respectfully requests that CARB include these proposed revisions in its forthcoming LCFS amendments.

➢ Background: Umwelt Energy

Umwelt Energy develops industrial-scale e-fuel projects in green industrial hubs that further the green energy transition by enabling deep decarbonization of hard-to-abate industries. We believe that addressing emissions from all sectors, including maritime shipping, is crucial to achieving California's ambitious climate goals.

Our projects combine renewable power generation, the production of green hydrogen via electrolysis, and e-fuel synthesis plants. Using proven technologies that can operate flexibly on-grid or off-grid, the e-fuels we produce include green methanol, ammonia, and kerosene, with off-takers primarily in the maritime and aviation sectors. In addition to serving as feedstock for e-fuels, our projects can help local communities by decarbonizing heavy Californian industry like the glass, steel, and cement[1], which are major contributors to in-state greenhouse gas ("**GHG**") emissions. Hence not only do our projects reduce emissions directly in California, but they also reduce California's GHG footprint outside the state.

➢ California as World-Leading on Climate ctions

"185.1" Umwelt Energy currently have projects in different stages of development in the US, with several projects specifically located in California. However, regulatory hurdles, including limitations within the LCFS, hinder our ability to contribute fully to the state's ambitious climate goals.

A critical shortcoming is the current exemption for ocean-going vessels from the LCFS. This exclusion undermines California's potential for comprehensive GHG reduction, considering the global shipping industry's 2-3% share of global emissions[2]. As California ascends to become the world's fourth-largest economy while simultaneously claiming the "*most ambitious set of climate goals*

[1] California's seven cement plants are major contributors to the state's greenhouse gas emissions, spewing out 7.8 million metric tons of carbon dioxide equivalent in 2019 alone. This accounts for a staggering 8.8% of all industrial sector emissions, highlighting the urgent need for cleaner alternatives in this critical industry (https://ww2.arb.ca.gov/events/second-workshop-sb-596-cement-sector-net-zero-emissions-strategy#:~:text=The%20seven%20cement%20plants%20currently,sector%20GHG%20emissions%20in%20California.)

[2] https://www.globalmaritimeforum.org/getting-to-zero-coalition

"185.1 cont." *of any jurisdiction in the world*[3] this inconsistency becomes particularly glaring.

Thousands of ships traverse the world's oceans, transporting goods to and from California, virtually all reliant on fossil fuels that generate significant GHG emissions. Overlooking these emissions, with their undeniable Californian footprint, is counterproductive. While the latest LCFS amendment addresses important areas, it fails to consider this major contributor to the state's climate challenge.

Therefore, we urge CARB to include ocean-going vessels within the LCFS scope. This crucial step would not only align with the state's climate goals but also incentivize the adoption of clean e-fuels in the maritime sector, ultimately contributing to a cleaner future for California and beyond.

"185.2"

➢ Low Carbon Fuels for the Maritime Sector

Ocean-going vessels are undeniable contributors to climate change and local air quality concerns, not just through their 2-3% share of global GHG emissions, but also by spewing significant air pollutants. While geographically, much of this occurs outside California's immediate jurisdiction, the impacts of climate change and degraded air quality transcend borders, significantly affecting the state.

Including ocean-going vessels within the LCFS presents a unique opportunity to leverage California's leadership role in environmental progress. Such a bold move would not only address a significant source of emissions directly linked to California's economy and environment, but also set a powerful precedent for stricter regulations on a global scale. This precedent could pave the way for the wider adoption of cleaner technologies and practices, driving meaningful change in a problem with undeniable global implications.

Furthermore, incorporating ocean-going vessels into the LCFS aligns with the rising tides of stricter regulations being implemented by both the European Union (EU) and the International Maritime Organization (IMO). By taking this step,

[3] https://ww2.arb.ca.gov/news/california-releases-final-2022-climate-scoping-plan-proposal

UMWELT energy

California would not only be leading by example but also aligning itself with the progressive efforts of these influential bodies, potentially accelerating the pace of positive change in the maritime sector.

As an example, bio-methanol and e-methanol hold significant potential as future shipping fuels. They have emerged as a major pathway for achieving maritime decarbonization goals and offer one of the most promising solutions for reducing emissions in the marine industry.

Methanol is an organic chemical used in various products and as a fuel. When burned, it produces lower amounts of CO_2, particulate matter, and sulfur emissions compared to heavy fuel oil ("**HFO**") or marine gas oil ("**MGO**"). Naturally, CO_2 is emitted as well in the process (1.4 kilograms per kilogram of methanol versus 3.1 kilograms per kilogram of fuel oil[4]. However, as the bio-methanol and e-methanol is produced from captured biogenic or unavoidable CO_2, and for e-methanol, combined with green hydrogen generated from renewable electricity sources, these fuels ultimately represent carbon-neutral fuels.

Leading shipping companies, including A.P. Møller-Maersk, CMA CGM, COSCO, Methanex Waterfront Shipping, and Stena, have already chosen marine methanol as the near-term low carbon future fuel[5]. Therefore, California also needs to support the immediate development of a greener future for the maritime sector by making these low-carbon intensity fuels available at a competitive price. This can be achieved by including ocean-going vessels in the LCFS program.

Additionally, deploying bio-methanol and e-methanol as a marine fuel dramatically lowers emissions of sulfur oxides, nitrogen oxides, and particulate matter compared to HFO or MGO.

"185.3" ➢ Leveraging the Amendment to the Intrastate Aviation Fuel Precedent

[4] https://www.man-es.com/discover/methanol-fueled-ships
[5] https://www.methanol.org/wp-content/uploads/2023/05/Marine_Methanol_Report_Methanol_Institute_May_2023.pdf

The proposed amendment to include intrastate sustainable aviation fuel ("**SAF**") in the LCFS sets a crucial precedent for holding all transportation sectors accountable for emissions reduction. Exempting ocean-going vessels creates an inconsistency that undermines California's leadership in environmental action and sends a message of unequal treatment of GHG emitters.

Expanding the LCFS to encompass – as a bare minimum - intrastate marine fuels for ocean-going vessels demonstrates policy coherence and continuity. It builds upon the established framework for regulating intrastate fuel sources and sends a clear message of comprehensive decarbonization efforts across all transportation modes.

In addition, the 2028 start date for SAF LCFS regulation reflects anticipation of technological advancements and infrastructure development for cleaner fuels. Similarly, including ocean-going vessels in the LCFS incentivizes investments in low-carbon intensity fuel production and infrastructure, is alligned with expected advancements in the timeframe of technological advancements for low-carbon marine fuels.

"185.4"

- Benefit of including ocean-going vessels to section 95482(d)(2)

Incentives created by including ocean-going vessels to the LCFS could spur the development and adoption of clean technologies like bio-methanol and e-methanol, generating economic opportunities across the state of California. This shift away from fossil fuels wouldn't just benefit the environment, but also enhance the competitiveness of Californian fuel infrastructure, ports and shipping companies through their leadership in sustainability.

In addition, including ocean-going vessels in the LCFS creates a fair environment for players who invest in green technologies. Companies choosing cleaner fuels would gain a competitive edge in the global market, accelerating the transition towards a sustainable maritime industry, which ultimately reduce the climate impact on California.

"185.5" We must also address, that communities living near Californian ports and heavy industries suffer disproportionately from air pollution. By including ocean-going vessels in the LCFS, California can demonstrate its commitment to environmental justice, ensuring all communities benefit from cleaner air and a healthier environment.

As the world's fourth-largest economy with ambitious climate goals, California has a unique responsibility to address its maritime emissions. A phased approach starting with vessels operating within Californian waters can lay the groundwork for broader inclusion.

- Final Remarks

California can cement its global leadership in climate action by including ocean-going vessels in the LCFS. This bold step would not only address a significant source of emissions directly linked to the state, but also set a powerful precedent for stricter regulations, incentivize clean technologies, and ultimately contribute to a cleaner future for California.

- Align with ambitious climate goals: Including ocean-going vessels in LCFS aligns with California's commitment to tackling all sectors contributing to emissions.
- Leverage California's economic power: Incentivize investments in low-carbon fuels like bio-methanol and e-methanol, generating economic opportunities across the state and strengthening the competitiveness of California.
- Level the playing field: Create a fair environment for players who invest in clean technologies, accelerating the transition towards a sustainable maritime industry with tangible benefits for California's climate impact.
- Address environmental justice concerns: Protect communities disproportionately impacted by air pollution from ocean-going vessels and demonstrate California's commitment to environmental justice and ensuring cleaner air for all.
- Build upon existing framework: Leverage the precedent set by including amendments to intrastate SAF in the LCFS, demonstrating policy coherence and continuity toward comprehensive decarbonization.

Umwelt Energy stands ready to contribute to this critical initiative by developing low-carbon e-fuels projects for the maritime sector. We urge CARB to seize this opportunity to make a meaningful impact on California's future by including ocean-going vessels in the LCFS.

oooOOOooo

Thank you for your consideration of our comments. Please do not hesitate to contact me Lasse Moelgaard-Nielsen (las@umwelt.energy), if you have any questions.

I want to stress in closing that we would be pleased to meet or otherwise engage with your staff on any aspect of our comments.

Sacramento, CA 95812

Re: Proposed Amendments to the Low Carbon Fuel Standard Regulation

Submitted to https://ww2.arb.ca.gov/applications/public-comments

Dear Chair Randolph and Honorable Board Members:

CalETC appreciates this opportunity to SUPPORT the Low Carbon Fuel Standard (LCFS) regulation and provide feedback for CARB Board member consideration. As discussed in detail below, CalETC largely supports the proposed draft regulation order ("draft order"), however, we are urging CARB to make some modifications to ensure that the utilities will be able to effectively administer the programs funded by LCFS proceeds. These changes are critical to ensuring the success of the LCFS program.

CalETC is a non-profit association committed to the successful introduction and large-scale deployment of all forms of electric transportation including plug-in electric vehicles of all weight classes, transit buses, port electrification, off-road electric vehicles and equipment, and rail. Our board of directors includes Los Angeles Department of Water and Power, Pacific Gas and Electric, Sacramento Municipal Utility District, San Diego Gas and Electric, Southern California Edison, Northern California Power Agency, and the Southern California Public Power Authority. Our membership also includes major automakers, manufacturers of zero-emission trucks and buses, developers and operators of charging stations and other industry leaders supporting transportation electrification. CalETC supports and advocates for the transition to a zero-emission transportation future to spur economic growth, fuel diversity and energy independence, ensure clean air, and combat climate change. This letter is submitted on behalf of the CalETC board of directors and covers issues specific to the utility interests in LCFS.

Over the past few years, the CalETC board has worked closely with the CARB LCFS staff to provide suggested amendments to the LCFS regulations. We appreciate the tremendous effort and accessibility of CARB staff during the extensive public process regarding this regulation.

I. Executive Summary of CalETC Utility Comments

CalETC requests specific changes to the draft order to ensure that the utilities will be able to
effectively administer programs funded by LCFS proceeds. These changes include: (1) ensuring that
"186.1" the cap on administrative costs for both holdback programs and the statewide California Clean
Fuel Reward (CCFR) program is clearly defined and set at a reasonable amount; (2) simplifying and
"186.2" clarifying the language in the proposed regulation pertaining to utility "holdback" (holdback)
"186.3" programs; (3) clarifying that Publicly Owned Utilities must spend 50% of holdback funds on equity
"186.4" projects, as opposed to 75%; (4) clarifying that San Diego Gas and Electric is a "medium-sized"
"186.5" utility under the regulation; (5) making edits to the regulation that will assist smaller utilities,
"186.6" potentially allowing them to participate in LCFS; (6) modifying the utility reporting requirements to
better track deployment of funds to impacted communities, align with the reporting framework
required by the California Public Utilities Commission (CPUC), and simplify reporting for smaller
"186.7" utilities; (7) requesting that the regulation allow the Executive Officer to approve certain
modifications to the CCFR that can improve program responsiveness and efficacy; and (8)
"186.8" requesting implementation assistance on the Credit Clearance Market (CCM). All of these
modifications are discussed in Section II, below.

CalETC supports many provisions in the draft order including, but not limited to: (1) the current program design with utilities generating the "base" LCFS residential credits; (2) the provision of more credits to the utility holdback programs; and (3) the establishment of a statewide medium-and-heavy-duty electric vehicle rebate program for new and used vehicles. A detailed description of the rationale behind CalETC's support positions is included in Section III, below.

II. CalETC Requests the Following Important Changes to the Draft Order

CalETC respectfully requests that the following changes be made to the Draft Order:

186.1 *(1) CalETC opposes the proposed 5% cap on administrative costs for both holdback programs and the statewide California Clean Fuel Reward and recommends that the cap remain at 10%*

Based on how utilities currently track and report program administrative costs, the reduction of allowable administrative costs for utility holdback programs from 10% to 5% in the proposed amendments will make it extremely difficult, if not impossible, to administer these programs. Given their focus on addressing the most underserved individuals and communities, utility holdback programs are necessarily more expensive to operate than broad, unrestricted incentive programs given higher levels of customer support and additional expenses like income verification needed to ensure the funding is reaching the people that most need it. Additionally, smaller utilities may only be able to implement a portfolio of small programs that will never benefit from the economies of scale that larger programs achieve. While there is an option in the Regulation that allows the utilities to exceed the administrative cost caps with advanced approval from the Executive Officer, this is likely to create administrative challenges for CARB and utility staff if each utility must make a request each year that they expect to exceed the proposed 5% cap.

CalETC acknowledges, however, that there may be differences in how CARB Staff and the electrical distribution utilities (EDUs) interpret "administrative costs" as this is not a defined term in the Regulation. While CARB Guidance 20-03 does provide some insight into what might be considered administrative costs, it appears to be inclusive only of the utility's administrative staff costs (salary, benefits, training, travel, etc.) and does not mention other program-specific costs that have typically been reported as "administrative costs" in past and current utility LCFS programs to CARB and the CPUC . These include critical program activities such as third-party administrative costs, rebate processing fees, applicant and income verification costs, website licenses and fees, and other direct, but non-incentive, program costs. It has been customary for the IOUs to report all these additional costs as "administrative costs" to both CARB and the CPUC in their annual LCFS reports based on the history of discussion in various CPUC Decisions and their experience with other customer programs.[1]

So, while it may be possible to implement utility Holdback programs with a 5% administrative cost cap under the narrow definition considered in Guidance 20-03, CalETC recommends that, with the exception of small EDUs that have annual electricity sales of less than 2000 GWh, the cap on equity holdback administrative costs should revert to 10% as allowed in the current Regulation, and that the definition should be expanded to include all associated program administrative costs, with the exception of start-up costs and education and outreach costs. Start-up costs, defined as set-up costs that occur before any incentives can be paid, are already excluded from the CCFR. Because costs before program launch are almost 100% administrative, it is nearly impossible to meet any administrative cap in the year a program is being set up. For small EDUs, CalETC proposes that they are not subject to a cap on administrative costs. To this end, CalETC has proposed a definition of EDU Program Administrative Costs in the Appendix that should be included in the Definitions and Acronyms section of the Regulation.

For small EDUs, CalETC proposes that they are not subject to a cap on administrative costs, or are subject to a higher cap, such as 20%. While Small EDUs are able to design and implement programs specifically tailored to their community needs, administrative costs for these EDUs may naturally result in a higher percentage of costs due to the small scale of programs and the utility's limited staff resources, particularly if the definition of administrative costs is expanded. The 2000 GWh exemption makes sense as a natural break in utility sizes when looking at 2022 CEC data on total electricity sales. While there is a process for EO approval of administrative costs exceeding 10%, the process would place yet another administrative burden on small EDUs to go through the process annually and require additional LCFS Staff time. Furthermore, the process requires a contract with a community-based organization, which is limiting. Many small EDU equity projects incorporate partnerships and collaboration with a CBO without a formal contract.

[1] See D.14-12-083, D.20-12-027, and CPUC Resolution E-5015.

To further illustrate how other program operating costs are different than the definition of administrative costs in Guidance 20-03, consider the investor-owned utilities (IOUs) energy efficiency program portfolios, which have administered billions of dollars of incentive funds throughout the state with oversight from the CPUC, are operated under guidelines established in the Energy Efficiency Policy Manual[2]. As shown in the Table below, Appendix C of the Energy Efficiency Policy Manual lists the cost caps (hard requirements) and targets that the CPUC established for the operations of these programs.

Appendix C Table: Energy Efficiency Policy Manual APPENDIX C Cost Category Caps

Budget Categories	Cap	Target
Utility program administrative costs	10%	
Third-party / Gov't partnership administrative costs		10%
Marketing & outreach costs		6%
Direct implementation non-incentive (DINI) costs		20%
Evaluation, measurement & verification (EM&V) costs	4%	

In addition to being separate from ME&O costs, administrative costs, as defined in the Energy Efficiency Policy Manual, explicitly exclude third party implementer fees, and also exclude direct implementation non-incentive (DINI) costs (which include activities such as software licenses, rebate processing, contractor training, etc.). CalETC's request to expand the definition of administrative costs to include things such as third-party implementer costs and DINI costs while imposing a cap of 10% is more conservative than the requirements of the Energy Efficiency Policy Manual while still allowing the utilities the budgets needed to effectively operate their LCFS-funded programs.

CalETC has confirmed with CARB staff that ME&O costs for holdback are not included as part of administrative costs in any LCFS guidance document. In addition, as noted above, the CPUC does not include ME&O as part of administrative costs for other programs, including current LCFS programs. We recommend that ME&O should be excluded from administrative costs in the new LCFS regulation to reduce uncertainty and improve clarity. See the Appendix for our proposed amendments.

With this expanded definition of administrative costs, CalETC also recommends that the allowable cost cap for the statewide Clean Fuel Reward, which currently includes ME&O costs, be reverted to 10% from the 5% that is in the proposed regulation. While CARB Staff have expressed reasonable concerns that the potential size of the Clean Fuel Reward could allow for very large administrative and ME&O budgets, it should be noted that these same concerns were addressed when the CPUC authorized the utilities to implement the Clean Fuel Reward in 2019, finding that "a 10% cap of administrative funds is generally within the range of spending for other customer programs the utilities implement," and ordered SCE in Resolution E-5015 to "administer no more than 10% of the total Clean Fuel Reward program budget on administrative and marketing, education, &

[2] Version 6 located at 6442465683-eepolicymanualrevised-march-20-2020-b.pdf (ca.gov)

outreach spending, which must include all administrative spending related to the Clean Fuel Rewards program." The CPUC found that including ME&O in the 10% cap was reasonable for a program of this size; the potential scale of the Clean Fuel Reward is no larger today than it was in 2019 and the same rationale should apply today. Further, we do not believe that either the Clean Fuel Reward or holdback programs will grow so large in the near term that the administrative costs will be too large . CARB will be doing another LCFS rulemaking in a few years and should closely monitor administrative costs and address if there is a problem.

Therefore, the proposed amendment's 5% cap should be rejected, and instead should revert to 1) the 10% allowable administrative costs for utility equity holdback programs, excluding startup costs and ME&O, as this is currently accepted by both CARB and the CPUC, 2) the 10% cap on allowable combined administrative and ME&O costs for the Clean Fuel Reward programs, as authorized in the current version of the LCFS Regulation and concurrent CPUC Resolutions, and 3) a more expansive definition of administrative costs that explicitly excludes ME&O should be added to the regulation. CalETC has provided recommended language for the relevant sections of the Regulation in the Appendix that implement these recommendations. Additional details on administrative costs should continue to be in an updated guidance document.

186.2 *(2) CalETC recommends simplifying and clarifying the language in the proposed regulation pertaining to utility holdback programs*

CalETC supports the staff's efforts to develop a recommended list in the proposed regulation of activities for holdback projects to make it easier for all stakeholders (e.g., the CPUC, CARB Staff, municipal utility governing boards, and utility program developers) to have a clear understanding of how CARB intends utility LCFS Holdback funds to be used. While we appreciate that many new project types have been included in the proposed amendments at the recommendation of CalETC and its members, several updates to the Holdback project list in the proposed amendments are needed for the sake of simplicity and to provide clarity on what is or is not considered a holdback equity project while also providing consistency of interpretation through the regulation itself.

The proposed amendments contain two lists: one which CARB Staff has indicated must be used for equity projects and another which are "good ideas" for non-equity projects. However, this makes it unclear if a utility could implement a project on the "equity" list – such as deploying charging stations at a multifamily property – as part of its non-equity project spending, and it also implies that a project on the "good ideas" list – such as optimized EV charging – could not be considered as counting towards a utility's equity spending requirements even if that project was directly reducing the energy bill of a low-income customer. Further uncertainty exists around the incentivization of medium- and heavy-duty (MDHD) vehicles: should projects supporting MDHD electrification only be considered equity projects if the vehicles are domiciled, or fueling located in, impacted communities, or always be considered equity projects since the pollutants from these vehicles disproportionately impact equity communities (i.e., disadvantaged rural, tribal and low-income communities) regardless of where they are domiciled or fueled?

CalETC recommends that the two lists be consolidated into one and that project spending be considered towards the utilities' equity allocation compliance requirements if it benefits the communities and individuals defined in the equity holdback section. To ensure that the utilities are only deploying projects that CARB supports for equity communities and individuals, CalETC recommends that the single project list must be used for equity projects and may be used for non-equity projects in addition to other non-equity projects that further transportation electrification in California as defined by 95491(e)(5). This approach is more straightforward, minimizes opportunity for conflicting interpretations, and provides certainty on expectations around CARB's priorities while still allowing flexibility for utilities to propose non-equity programs that are best suited to their specific service areas and customers. CalETC also recommends that any project that furthers the deployment of electric MDHD vehicles be considered as an equity project, as the electrification of trucking almost always benefits low-income individuals and disadvantaged communities with criteria pollutant and GHG reductions even when the primary charging / ownership location is outside of the disadvantaged community, low-income community, tribal area, or rural area (*See* CalETC's comments on the definition of rural in bullet 8 below).

Additionally, CalETC recommends several smaller changes to the proposed regulation below with proposed amendments in the Appendix:

1. The regulation should include a requirement for large IOUs (SCE and PG&E in CalETC's comments below) to utilize their holdback credit revenues to fund a minimum of three program options as there are increasingly diversified needs in transportation electrification over large service areas. Including this requirement to fund a minimum of three program options will help ensure that the large IOUs consider the diverse needs of their customers and are not compelled by stakeholders to focus on a single project.
2. While we agree with the proposed regulation's deletion of broad-based ME&O (e.g., television and radio), the regulation, rather than Guidance Document 20-03, should clearly allow ME&O for specific projects.
3. The project list should explicitly allow for upgrades to electric panels, which are prerequisites to transportation electrification for many customers living in older buildings that have not had recent updates. Upgrades to panels can have other benefits but are primarily to enable transportation electrification.
4. For simplicity and clarity, the project list should be consolidated on the recommended projects for electric mobility solutions as there are two list items that appear to overlap regarding mobility alternatives.
5. The project list should preserve a narrowly-focused project category for direct multilingual education and outreach serving equity communities. The preservation of this category is not intended to include general marketing or advertising. It is only intended to allow for multilingual education and outreach to equity communities.
6. The list of agencies that may be consulted in the creation of workforce development projects should be expanded to include other pertinent entities, such as California Community Colleges, community-based organizations, and publicly-owned utilities (POUs) Governing Boards.
7. CalETC thanks CARB Staff for harmonizing the definitions of equity communities and individuals in the proposed amendments with those detailed in AB 841 and CPUC Decision

D.20-12-027. However, the language requires a slight modification. AB 841 defines this as "a community located on lands belonging to a federally recognized California Indian tribe."[3] The proposed amendments include "state and federally recognized".

8. The definition of "rural" needs to be updated as the U.S. Census Bureau no longer reports rural percentages for census tract population. The Census Bureau now defines rural as "all population, housing, and territory not included within an urban area."[4]
9. "Off Road Vehicle" should be defined for clarity because it is not obvious that vessels, aircraft, and other transportation qualify under that term. CalETC has provided recommended edits to this section of the proposed amendments in the Appendix to this letter.

186.3 *(3) CalETC requests clarification that POUs must spend 50% of holdback funds on equity projects, as opposed to 75%*

CalETC notes a discrepancy between the proposed LCFS requiring 75% of holdback funds for equity projects compared to Appendix E "Purpose and Rationale for Low Carbon Fuel Standards Amendments," which calls for 50% for POUs. We recommend that POUs have a 50% requirement for equity holdback. We understand there are almost 30 POUs that have opted into LCFS and potentially another fifteen could opt in. The POUs are very diverse and represent specific and limited territories within the State, with a wide variety of populations, EV densities, rural/urban splits, percentages of DACs and community needs. POUs are also uniquely in tune with local needs. Designing and implementing effective transportation electrification programs for low-income, rural and/or disadvantaged communities can be challenging, and the uptake and timing of projects is difficult to predict. In addition, there will be natural fluctuations in program spending year-to-year, and an annual requirement of 50% allows for better planning to maximize the impact of equity spending. In addition, we recommend the 50% equity requirement for the three small IOUs (instead of the 75% in the proposed LCFS). These small IOUs are not opted into LCFS, and a 75% equity holdback requirement creates practical challenges at start up that make it difficult for them to opt-in to LCFS.

186.4 *(4) CalETC requests clarification that San Diego Gas and Electric is a "medium-sized" utility under the regulation*

CalETC notes that the regulatory package has conflicting information regarding the size of San Diego Gas and Electric (SDG&E) and its requirements under CCFR and holdback programs. Specifically, in *Appendix E: Purpose and Rationale of Proposed Amendments for the Low Carbon Fuel Standard Requirements*, CARB staff states, "San Diego Gas & Electric is re-defined to have a comparable contribution to the statewide program to similarly sized public utilities." However, this change is not in the proposed regulation. In discussion with CARB staff, we understand that

[3] Bill Text: CA AB841 | 2019-2020 | Regular Session | Amended | LegiScan at 1601.(e)(5)

[4] See https://www.census.gov/programs-surveys/geography/guidance/geo-areas/urban-rural.html

that they intend to categorize SDG&E as the same size as Los Angeles Department of Water and Power based on their similar total 2022 electricity sales (annual GWh). CalETC supports these two utilities having the same contribution to the CCFR in the final LCFS, as their size is very similar, and SDG&E is substantially smaller than the two large IOUs. This change will allow SDG&E to have more meaningful holdback programs.

CalETC may have further comments on the definition of EDUs based on annual GWhs in the future, as we understand that staff plans to propose amendments to these definitions (e.g., improved data, new thresholds for large, medium, and small EDUs) in an upcoming 15-day comment period.

186.5 *(5) CalETC requests edits to the regulation that will assist smaller utilities, potentially allowing them to participate in LCFS*

CalETC requests the LCFS include a program to encourage small EDUs who have not opted-into LCFS to do so and expand programs by small EDUs who have recently opted in. There are over 50 EDUs in California, and we understand from staff that about thirty have opted in to LCFS. Our proposal would support approximately twenty small rural utilities who cover about one percent of California.

We propose that the LCFS have new regulatory language that allows the CCFR Steering Committee to work with the Executive Officer to design one-time grants to incent the small, mostly rural EDUs that have not yet opt into the LCFS to opt-in and also to provide additional funding to EDUs that have recently opted in. The goal of the program would be to have almost all California utilities participate in the LCFS and provide holdback programs to provide better coverage in underserved areas.

Specifically, we request funding for our recommended program to come from funds that non-opt in EDUs have been providing to the CCFR since 2020 per Section 95486.1 (c) (1) (A) paragraph 2.[5] Our informal survey of these small EDUs found that they often only have a handful or a few hundred EVs which is not enough to justify a program. Under our proposal, a start-up grant would be enough for a small EDU to start or expand a basic program to help their customers and CARB would provide approvals and oversight to the CCFR Steering Committee and Program Administrator. Our recommended amendment is in the Appendix.

186.6 *(6) CalETC requests the regulation modify the utility reporting requirements to better track deployment of funds to impacted communities, align with the reporting framework required by CPUC, and simplify reporting for smaller utilities*

CalETC appreciates the areas where CARB Staff have made efforts to harmonize the regulatory and reporting requirements of the LCFS Regulations with other regulatory bodies, such as the

[5] All base credits for any EDU that is not eligible to receive base credits pursuant to this provision will be allocated to the Clean Fuel Reward program pursuant to section 95486.1(c)(1)(A) paragraph 2.

CPUC. One such area was increasing the equity allocation requirement of utility Holdback programs for the Large IOUs from 50% to 75%. Yet, while increasing the equity requirement to 75% appears to align with the CPUC's requirements in D.20-12-027, CARB and the CPUC currently measure this metric in very different ways. CARB counts percent of proceeds earned in a calendar year, which was clarified by guidance document 20-03 to include percent of proceeds either spent or encumbered (i.e., budgeted or set aside) to an equity program. The CPUC, however, counts spending that occurs during the calendar year, regardless of when the credits were earned. This is subtle but, as a result, the IOUs are often reporting entirely different data to demonstrate compliance to each agency in their annual reports[6].

Tracking compliance against the percentage of annual proceeds creates many operational difficulties. For example, if the combination of on-road EV charging and credit prices-- both of which are beyond the utilities' control – evolve over a year such that a utility generates double the proceeds it expected to generate, then a utility may be faced with two options to maintain compliance based on percent of annual proceeds: double the spending of its in-market programs or encumber those funds, without actually spending them, in some combination of those programs. The first may not be practical as it is difficult to increase operational capacity of a program in real time; the second achieves compliance but it does not necessarily allow the utility to assess where it should best allocate its holdback funds in the coming calendar year as they will have been encumbered to a specific program for the sake of compliance.

Tracking on how LCFS proceeds are actually returned to Californians, is a more effective metric to track how LCFS dollars actually flow to benefit underserved communities over time and is consistent with the metric used by the CPUC to ensure compliance[7]. However, in recognition that the balance between equity and non-equity spending may necessarily vary in a given year, the regulation should specify that any "underspend" in annual equity spending will carry over to the next calendar year(s) in the form of increased equity spending requirements.[8] The recommended language has been provided in the Appendix as part of the updates to the holdback program section.

Compliance based on spend, when coupled with the rollover of any "underspending" on equity in a given year, also helps smaller utilities, by providing an option, to save up holdback proceeds for several years to accumulate a large enough bank to implement a program without "pre-deciding" how to allocate their funds into a program until they are ready to spend them, in addition to the option of saving up for large equity spending projects through the rollover provision. Further, compliance based on spend makes it easier to account for the reality of utility programs, which often have both equity and non-equity recipients, as the utilities can

[6] See Decision D.14-12-083 Ordering Paragraph 4, requiring reporting on annual expenditures.

7 Decision D.20-12-027 Ordering Paragraph 1

[8] For example, if a large IOU spent $10 million in one year, $7.5 million of that would be required for equity. However, if only $7 million was spent on equity (70%), the $500,000 underspend would be added to the following year's compliance such that they would need to spend 75% plus $500,000.

simply report how much of the annual spend went to each type of recipient in a calendar year, rather than managing set asides in intra-program budgets.

Therefore, CalETC recommends that the utility holdback project equity allocation requirements be updated to percent of annual spend rather than percent of annual proceeds. Further, CalETC proposes that if a utility underspends on equity projects in a given year, the amount that it underspends will be carried forward to the next year. This aligns the LCFS Regulation's requirements with the obligations that the CPUC has already placed on the IOUs, improves tracking of how LCFS funding is actually being deployed into impacted communities, and simplifies accounting for CARB, CPUC, and utility staff. CalETC has proposed language that would implement these recommendations in the Appendix to this letter as part of its other recommendations for updates to the holdback section.

186.7 *(7) CalETC requests that the regulation allows the Executive Officer to approve certain modifications to the CCFR that can improve program responsiveness and efficacy*

The LCFS is a powerful tool for incentivizing the adoption of low carbon technologies to support the technologies called for in the 2022 Scoping Plan. Because the Scoping Plan calls for the adoption of new zero emission technologies, the LCFS regulatory framework must allow for some flexibility in response to changing market conditions and needs. As such, CalETC respectfully requests that the final regulation allow the Executive Officer to make modifications to the electricity provisions of the LCFS, including the ability to add tools other than rebates or new technologies (such as financing assistance) to the statewide Clean Fuel Reward program if requested by the Clean Fuel Reward Steering Committee. CalETC also respectfully requests that such exception requests to the Executive Officer be handled expeditiously, and staff be adequately resourced to handle these exceptions.

186.8 *(8) CalETC requests implementation assistance on the Credit Clearance Market (CCM)*

CalETC's members include large EDUs who will be impacted by the CCM. We respectfully ask for a guidance document (or, if appropriate, a user guide or FAQ) on the mechanics of the CCM. For example, what do deficit/credit holders functionally do once a CCM / Advanced Crediting phase is declared? Also, given the proposed increase from ten million to thirty million credits in the CCM, we request further discussion regarding possible practical issues down the road if only a small number of EDUs are trying to transact such a large volume in a mandatory compressed timeframe.

III. CalETC largely supports the proposed order

CalETC applauds CARB's efforts to amend this important and complicated regulation. In particular, CalETC supports the following provisions of the proposed order:

(1) CalETC supports the continued allocation of base residential charging credits to the electric distribution utilities (EDUs) which fund important statewide and individual utility programs

CalETC strongly supports the continued allocation of the residential base credits generated by electricity used to fuel electric vehicles to the electric utilities. This is appropriate and leads to the most efficient, equitable, and market-stimulating distribution of the proceeds.

1. *The utilities are subject to extensive regulatory oversight, ensuring that the proceeds are spent in a manner that aligns with the state's goals.*

The electric utilities are subject to extensive reporting and compliance requirements, ensuring that the distribution of LCFS proceeds is open and transparent. Furthermore, the utilities have a duty to serve all customers, including populations that have been slower to adopt EVs including those residing in disadvantaged communities (DAC), low-income renters and multi-unit dwellings (MUD). Residents of DACs and MUDs are utility customers, and as such the utilities are incentivized to assist those customers in transitioning to electric transportation. The electric utilities can use the proceeds gained from base residential credits to establish holdback programs that enable charging at MUDs, for renters, and in equity communities. Similarly, utilities can leverage credits generated across the entire customer base to fund programs incentivizing adoption in DACs and low-income communities. Utilities are the only entity able to use credits generated from residential light-duty EV charging to support heavy-duty or off-road vehicle electrification, an increasingly urgent issue in decreasing the transportation sector's air pollution and greenhouse gas emissions.

California's electric utilities are uniquely positioned to support and enable additional load from electric vehicles because electric vehicle load is flexible and when used off peak makes more efficient use of the electric system which puts downward pressure on electric rates for all other customers. Because of this, California's electric utilities are the only entities that have the primary goal of ensuring accessible infrastructure and affordable electricity, making them uniquely positioned to receive and manage base residential credits.

2. *The electric utilities have been a long-time partner in the state's decarbonization efforts and are by definition located in California.*

Unlike other entities, the electric distribution utilities (EDUs) must always be located locally, within California, to provide a critical and essential service. The size of utilities varies dramatically, with the larger utilities having the staff and resources necessary to work cohesively with the other EDUs to efficiently run statewide programs. Some examples of efforts to collectively enable market transformation include programs in energy efficiency, renewable energy and most recently, the California Clean Fuel Reward. The utilities are equipped to handle the very large-scale proceeds generated by the LCFS. They are experienced, efficient administrators and have a long history of designing large-scale, stable successful programs and have shown they can quickly implement statewide and individual utility programs.

Additionally, all Californians have an electric utility provider and are used to working with their utility to support their energy needs. This name recognition and familiarity is necessary for getting reluctant customers to adopt new technologies. Finally, the electric utilities have provided service to their customers for decades and will continue to serve their territories for many decades to come, providing the stability needed to positively contribute to the wholesale market transformation required by the switch to electrified transportation.

3. *Electric utilities are able to implement programs that address the needs of all aspects of electric vehicle adoption and at the scale needed to support CARB's scoping plan.*

Unlike other important players in the electric vehicle industry, electric utilities can administer programs involving all aspects of the transportation electrification ecosystem. The utilities can provide rebates for chargers, rates designed to incentivize adoption, vehicle incentives, grid upgrades to support increased beneficial electrification, and have decades of experience implementing programs targeted to benefit lower-income and disadvantaged customers. Having the ability to address all aspects of electric vehicle adoption allows for flexibility in how the money is spent. Furthermore, a properly designed program can afford the utilities the ability to act quickly and to adjust program design when external factors change. This is increasingly important as state, local and federal funding sources and tax breaks tend to shift over time.

Electric utilities also provide service to all electric vehicle segments and classes. The utilities serve light, medium- and heavy-duty vehicles, individually owned vehicles, last-mile vehicles, and fleets. With the increase of electrification, upgrades to the electric grid will be necessary. Utilities will need information about the location of all electric vehicles so that they can adequately upgrade the grid and provide vehicle/grid integration services. Finally, serving all vehicle classes allows the electric utilities to provide programs for both the light-duty and medium-and-heavy-duty sectors. This allows the utilities to utilize the funding from the sectors that are first to electrify (light-duty) to incentivize and support the sectors that are harder to electrify (e.g., medium-and-heavy-duty).

Allowing the utilities to receive the residential base credits also supports individual utility programs which are necessary for meeting local needs and hard-to-reach markets such as medium- and heavy-duty EVs, off-road EVs and infrastructure for renters (homes, apartments, etc.) that are identified in the Scoping Plan, Advanced Clean Cars, and Advance Clean Fleets. Individual utility programs can be nimble and respond to the complex, ever-changing incentive landscape for EV and infrastructure incentives.

4. *Keeping the current structure prevents a complicated system where both utilities and non-utilities receive base residential credits.*

The current structure supports large-scale, statewide programs linked to the State's equity and climate goals. Diluting the credits coming to utilities makes both individual utility and large-scale statewide programs very difficult to implement and harder for CARB to regulate. Also, the current structure enables and funds active utility involvement, especially for small POUs, and encourages more small EDUs to join LCFS and create custom programs to support their customers. The current LCFS is a well-crafted system that allows site-hosts, automakers, charging providers and utilities to all receive LCFS credits.

CalETC also supports the proposed provision requiring entities "generating credits from electricity to use all credit proceeds to further transportation electrification efforts in California and include in their annual compliance report an itemized summary of efforts and costs associated with meeting this requirement." Ensuring that all the proceeds from the electricity LCFS credits are put back into programs and projects that incentivize the adoption of transportation electrification is essential to effectuating the goals of CARB's Scoping Plan.

(2) CalETC supports staff's proposal for EDUs to spend more of their LCFS proceeds on holdback programs

Under the proposed order § 95483(c)(1)(A)(2), the required contribution to CCFR and remaining allocation to holdback programs would be changed as follows:

EDU Category	Holdback Allocation (%)	
	Proposed	Previous
Large Investor-owned Utilities	50	33
Large Publicly Owned Utilities	75	55
Medium Investor-Owned Utilities	75	75
Medium Publicly Owned Utilities	90	75
Small Publicly Owned Utilities and Small Investor-owned Utilities	100	98

CalETC strongly supports these changes, with the exception discussed above regarding San Diego Gas and Electric. Funding from base residential credits for holdback programs and CCFR are directly linked. With the proposed regulation increasing holdback funding percentages, the percentages allocated to the CCFR will decrease. This change is appropriate because the proposed CCFR is for the much smaller market of medium- and heavy-EVs vs. the larger light-duty market in the current CCFR.[9] Similarly, removing very small EDUs from contributing to the CCFR is appropriate because a two percent contribution is not meaningful and results in administrative inefficiencies for both the CCFR Program Administrator and the very small EDUs.

(3) CalETC supports the proposed shift in the California Clean Fuel Reward (CCFR) from being a reduction in the purchase or lease price of new light-duty electric vehicles (EVs) to being a reduction in the purchase of lease prices of new electric medium- and heavy-duty EVs

CalETC supports CARB's proposed amendments that will transition the statewide Clean Fuel Reward program from an incentive for all new passenger EVs to one that will support the adoption of electric MDHD vehicles in the coming decade. We also agree that the new Clean Fuel Reward

[9] The California Energy Commission anticipates that the adoption of medium- and heavy-duty vehicles as follows: 27,000 by 2025, 155,000 by 2030 and 377,000 by 2035. *See* Assembly Bill 2127 Second Electric Vehicle Charging Infrastructure Assessment Revised Staff Report.

should be in line with the needs of CARB's Scoping plan - and primarily benefiting equity communities - and believe the new proposal[10] achieves this goal. However, as the Clean Fuel Reward Program Administrator (SCE) has commented, minor updates to the vehicle eligibility in the proposed amendments are needed to ensure that that new Clean Fuel Reward program can effectively implement CARB's ambitious plans for the commercial vehicle sector.

For example, in *Appendix E: Purpose and Rationale of Proposed Amendments for the Low Carbon Fuel Standard Requirements*, CARB Staff states that the "Clean Fuel Reward will change from a universal new light-duty EV rebate to be focused on new and used rebates for medium- and heavy-duty trucks." However, the proposed amendments define the Clean Fuel Reward as applying only to new vehicles. CalETC believes that "used" was accidentally omitted from the proposed amendments and has provided recommended language that includes used vehicles in the Appendix to this letter.

Additionally, CalETC is concerned that definitions for medium-or-heavy duty vehicle in the proposed amendments do not necessarily align with CARB's stated intentions. Defining these solely by weight class, as the current proposed amendments do, means that the Clean Fuel Reward program may be required to provide incentives for all vehicles that have a GVWR greater than or equal to 8,501, which includes many passenger vehicles such as the Rivian line of products, the extended range Ford F-150 Lightning, the electric Chevrolet Silverado, and the electric Hummer to name few. Based on CARB Staff's published rationale, CalETC believes these vehicles should be incentivized by the Clean Fuel Reward only if they are purchased for use as commercial vehicles. CalETC agrees with the Program Administrator's proposal that the definition of Clean Fuel Reward be updated to specify that it is for commercial vehicles only, and the Regulation should also include a definition for commercial vehicle in the Definitions and Acronyms section for clarity and completeness. For consistency, CalETC proposes that the LCFS Regulation adopt the same definition for commercial vehicles utilized by the Hybrid and Zero-Emissions Truck and Bush Voucher Incentive Project (HVIP). Both these definitions are included in the Appendix to this letter, and CalETC believes that these minor modification to the proposed amendments will empower the new Clean Fuel Reward program to be a vital tool in the state's efforts to decarbonize heavy-duty trucking.

CalETC appreciates the opportunity to provide comments on this important regulation. If you have any questions, please do not hesitate to contact me at any time.

[10] "Clean Fuel Reward" is a statewide program established by EDUs to provide a reduction in price on new light-duty EV purchases or leases for new medium- or heavy-duty electric vehicles that are not subject to the High Priority and Federal Fleets requirements as specified in, title 13, California Code of Regulations, section 2015(a)(1) in California.

Best,

Laura Renger
Executive Director

Appendix

New or updated Defined Terms to be added to the Regulation's Definitions and Acronyms

[New term] "EDU Program Administrative Costs" are all costs associated with implementing LCFS-funded programs incurred by an EDU to pay for its staff, 3rd party implementers, non-incentive implementation costs (rebates processing, application verification, etc.) websites, application portals, and other direct program costs required to operate the program. EDU Program Administrative Costs do not include marketing, education and outreach costs.

[Updated term] "Clean Fuel Reward" is a statewide program established by EDUs to provide a reduction in price ~~on new light duty EV~~ ~~purchases or leases~~ for new and/or used commercial medium- orheavy-duty electric vehicles that are not subject to the High Priority and Federal Fleets requirements as specified in, title 13, California Code of Regulations, section 2015(a)(1) in California. The Clean Fuel Reward is funded exclusively through LCFS proceeds generated by EDUs from electricity fuel.
[New term] "Commercial vehicle" for the purposes of this program means any vehicle used by a business, public or governmental agency, or non-profit to carry people, property, or hazardous materials.[11]

"Rural Area" means a census tract ~~with~~ ~~*at least 75 percent of its population*~~ *identified as* ~~*rural*~~ *non-urban* *by the latest US Census data.*

[new term] "Off road vehicle" is a piece of equipment that is moved over distances in order to transport goods or people from one physical location to another and is not primarily operated on roads established for automotive transport (e.g. fields, waterways, construction sites, airports, airways, etc.).

Recommendations for edits to the holdback program

5. *Restrictions on Use of Holdback Credits.* Documentation of adherence to the following restrictions must be included inthe annual report submitted pursuant to section 95491(e)(5)(A).

    a. *Holdback Credit Equity Projects.* Effective January 1,202~~2~~5, at least 75 percent ~~in year one, 40 percent in year two, and 50 percent in subsequent years~~ of holdback credit ~~proceeds~~ annual spending for large and medium investor owned EDUs and 50 percent of holdback credit annual spending for all other EDUs must be used to support transportation electrification for underserved individuals and communities. Any project from sections 95483(c)(5)(a)(i), (viii), or (xi)

---

[11] HVIP FY22-23 Implementation Manual, Definitions, page 52 HVIP-FY22-23-Implementation-Manual.pdf (californiahvip.org)

shall be considered a holdback credit equity project; all other projects described in this paragraph may be considered holdback credit equity projects provided they are for the primary benefit of or primarily serving disadvantaged communities and/or low-income communities and/or rural areas or low-income individuals eligible under California Alternative Rates for Energy (CARE) or Family Electric Rate Assistance Program (FERA) or the definition of low-income in Health and Safety code section 50093 or the definition of low-income established by a POU's governing body or a community in which at least 75 percent of public school students in the project areaare eligible to receive free or reduced-price meals under the National School Lunch Program, or a community located on lands belonging to a ~~state and~~ federally recognizes California Indian tribe.

If an EDU fails to spend the required percentage on equity projects in a calendar year, the shortfall of spending, in dollars, will be added to their total equity spending requirement for the following year.

~~a.~~

~~b.~~ EDUs must use their holdback credits to implement additional projects that further transportation electrification efforts in California. Project costs may include incentives; infrastructure installation; administration; marketing, education, and outreach (ME&O); evaluation; and other cost categories as needed. Equity projects as defined in this paragraph must be selected from the options of projects listed in i-x below. Non-equity projects may be selected from the options on this list or any alternative provided the EDU meets the requirements of 95491(e)(5) without further CARB approval. The large investor-owned utilities must implement at least three different holdback projects. Equity holdback project options are listed below: ~~These projects may include:~~

~~i. Electrification and battery swap programs for school or transit buses.~~

~~ii.~~ i. Electrification of drayage trucks as well as other medium-, heavy-duty, or off-road vehicles including school and transit buses.

~~iii.~~ ii. Investment in public EV charging infrastructureand EV charging infrastructure in multi-family residences.

~~iv.~~ iii. ~~Investment in electric mobility solutions, suchas EV sharing and ride hailing programs.~~

~~v. Multilingual marketing, education, and outreach designed to increase awareness and adoption of EVs and clean mobility options and including information about: the environmental, economic, and health benefits of EV transportation; basic maintenance and charging of EVs; electric rates designed to encourage EV use; and local, state, and federal incentives available for purchase of EVs.~~

~~vi.~~ [*Revised Subsection v. renumber as iii*] Multilingual ~~marketing, education, and outreach~~ community education events located within communities listed in 95483(c)(1)(A) designed to increase awareness and adoption of EVs and clean mobility options, and outreach in coordination with community-based organizations, including but not limited to neighborhood canvasing, community listening sessions, and needs assessments, focused in communities listed in 95483(c)(1)(A), to inform the development of projects and programs tailored to community needs. ~~including information about: the environmental, economic, and health benefits of EV transportation; basic maintenance and charging of EVs; electric rates designed to encourage EV use; and local, state, and federal incentives available for purchase of EVs.~~ Education and outreach do not include general marketing or advertising campaigns.

~~vii.~~

~~viii.~~ ~~Iv~~iv. Additional rebates and incentives ~~for low-income individuals~~ beyond existing local, federal and State rebates and incentives ~~including the Clean Fuel Reward~~ for: purchasing or leasing new or previously ownedEVs; installing EV charging infrastructure in residences, including panel and service upgrades; ~~promoting use of public transit andother clean mobility solutions;~~ and offsetting costs for residential or nonresidential EV charging.

v. Investing in, or promoting the ~~Promoting~~ use of, ~~and additional incentives foruse of~~ public transit and other clean mobility solutions~~, via charging equipment or infrastructure for the following categories~~ such as:

I. EV sharing and ride hailing programs,

II. Electrification of public transit and school buses, including battery swap programs, and

III. Use or ownership of neighborhood electric vehicles, eBikes, eScooters, eMotorcycles, and other micromobility solutions.

IV. Charging equipment or infrastructure for any of the above.

vi. Re-skilling and workforce development for transportation electrification and electric vehicle infrastructure applications, developed in coordination with the California Workforce Development Board, ~~or~~ local workforce development agencies~~.~~, a community-based organization, a California Community College, or a workforce strategy adopted by the Board of a POU.

vii. Investments in grid-side distribution infrastructure necessary for ~~medium- and heavy-duty~~ EV charging.

viii. Transportation Electrification projects that are identified in, or consistent with, a Community Emission Reduction Plan created in response to AB 617.

ix. Support for vehicle-grid integration with projects such as:

I. Encouraging the optimization of EV charging through education in the following areas: peak demand, rate pricing, grid emergencies, potential power shutoffs, infrastructure deferral, renewable integration, and/or other signals and grid needs to provide grid and customer benefits.

II. Providing program incentives to encourage driver participation in monitored/managed charging, demand response, or vehicle-to-load / vehicle-to-grid applications.

III. Supporting the deployment and installation of bidirectional charging equipment.

IV. Other innovative approaches to promoting and managing EV charging and discharging that provides benefits to customers and the grid.

x. Hardware and software that decrease the cost of or avoid updates to infrastructure, including load management software or outlet splitting

~~vii.~~xi. Alternatively, EDUs, in coordination with local environmental justice advocates, local community-based organizations, and local municipalities, may develop and implement other projects that promote transportation electrification in disadvantaged and/or low-income communities and/or rural areas or for low-income individuals. These alternative projects are subject to approval by the Executive Officer. Applications submitted to theExecutive Officer must include, and will be evaluated for approval based on, a complete description of the project, demonstration that the project promotes transportation electrification in disadvantaged and/or low-income communities and/or rural areas orprovides increased access to electric transportation for low-income individuals, and evidence that the project was developed in coordination with local environmental justice advocates, local community-based organizations, and local municipalities.

b. ~~*Additional Reporting Requirements for Holdback Credit Equity Projects.* As part of annual reporting required pursuant to section 95491(d)(3)(A)5., EDUsmust include a discussion on how their portfolio of holdback credit equity projects is consistent with the findings and recommendations of the SB 350 Low-Income Barriers Study, Part B report prepared by CARB (rev. Feb. 2018), incorporated herein. This discussion must include, as applicable, a description of how the projects: support increased access to clean transportation and mobility options; consider, and to the extent feasible, either complement or buildupon existing CARB, other State, or local incentive projects to diversify and maximize benefits from statewide investments; demonstrate partnership and support from local community-based organizations; and meet community-identified clean transportationneeds.~~

~~b. *Other Holdback Projects.* Holdback projects that arenot specified in subsection 95483(c)(1)(A)6.a. mustfollow the requirements specified in 95491(e)(5). Below are examples of pre-approved uses for these other holdback credit proceeds:~~

~~i. Investments in grid-side distribution infrastructure necessary for EV charging.~~

~~ii. Support for vehicle-grid integration with projects such as:~~

~~I. Encouraging the optimization of EV charging through education in the following areas: peak demand, rate pricing, grid emergencies, potential power shutoffs, infrastructure deferral, renewable integration, and/or other signals and grid needs to provide gridand customer benefits.~~

~~II. Providing program incentives to encourage driver participation in monitored/managed~~

~~charging, demand response, or vehicle-to-load / vehicle-to-grid applications.~~

~~III. Supporting the deployment and installation of bidirectional charging equipment.~~

~~IV. Other innovative approaches to promoting and managing EV charging and discharging that provides benefits tocustomers and the grid.~~

~~iii. Hardware and software that decrease the costof or avoid updates to infrastructure, including load management software or outlet splitting.~~

b. Administrative Costs of Holdback Credit Equity Projects. With the exception of EDUs with annual sales of less than 2000 GWh, EDU Program administrative costs to support the ~~development and~~ implementation of holdback credit equity projects excluding start-up costs (those costs associated with setting up the program and incurred prior to issuing incentives),must not exceed 10~~5~~ percent of total spending on holdback credit equity projects annually unless the EDU contracts with a community-based organization, and the exceedance is approved in advance by the Executive Officer. The request for administrative cost exceedance for a calendar year must be submitted by September 30~~th~~ of the prior year. The request must include, and will be evaluated for approval based on, a complete description of the equity projects planned by the EDU, an estimate of total administrative costs relative to total spending on the projects, and evidence that the community-based organization is a non-profit organization focused on serving disadvantaged and/or low-income groups.
Within 30 days of receiving a request for higher administrative costs, the Executive Officer will inform the EDU of its decision in writing. If the request is rejected the Executive Officer will provide a rationale for the decision. If the rejection is due to insufficient information, the EDU may resubmit the request after addressing the deficiencies identified in the Executive Officer decision.

Recommended amendments on Administrative cost

§95483(c)(1)(A)(4) Combined ~~A~~administrative and marketing, education and outreach costs, excluding start-up costs (those costs associated with setting up the program and incurred prior to issuing rewards), to support any Clean Fuel Reward program funded by LCFS credit proceeds may not exceed ~~5~~10 percent of LCFS credit proceeds contributed to the Clean Fuel Reward program annually, unless approved in advance by the Executive Officer.

§95483(c)(1)(A)(4)(a) A request to exceed ~~5~~ 10 percent administrative and marketing education and outreach costs must be submitted by the administrator of the Clean Fuel Reward program to the Executive Officer by September 30 of the prior year.

Recommended amendments for a new Small EDU program
[New provision – exact location TBD] §95483(c)(1)(A) XXXX Proceeds from non-opt-in EDU base credits that were allocated to the Large EDUs beginning with the deposit of Q2 2019 credits through the deposit of Q2 2024 credits and the transferred to the Clean Fuel Reward program pursuant to section 95483 (c)(1)(A) may be transferred by the Clean Fuel Reward Program Administrator to small EDUs opted in to the LCFS program by March 31, 2025. Any base credit proceeds reallocated in this manner must be spent by the recipient small EDU in accordance with sections 95491 (e)(5) and 95483 (c)(1)(A).The Executive Officer must approve the Clean Fuel Reward Program Administrator's plan for distribution of previously unallocated base credit proceeds prior to any transfers.

The Honorable Liane M. Randolph, Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Gevo, Inc.'s Comments on "Proposed Amendments to the Low Carbon Fuel Standard"

Dear Chair Randolph:

Thank you for the opportunity to comment on the California Air Resources Board's (CARB) Proposed Amendments to the Low Carbon Fuel Standard (LCFS).

Gevo, Inc.'s (Gevo) mission is to produce low-carbon, renewable energy-dense liquid hydrocarbons for drop-in transportation fuels such as gasoline, jet fuel, and diesel. Gevo's alcohol-to-hydrocarbons production process uses a combination of decarbonization technologies and sustainably farmed feedstock to produce fuels with substantially reduced carbon intensity (CI) compared to fossil fuel equivalents. We broke ground on our first alternative jet fuel (AJF)/sustainable aviation fuel (SAF)[1] production facility, "Gevo Net-Zero 1" (NZ1), in Lake Preston, South Dakota, in September 2022. This facility will use a three-part strategy to produce low-CI SAF: 1) use locally-sourced corn feedstock from farmers engaged in sustainable agriculture to both reduce on-farm greenhouse gas (GHG) emissions and sequester CO_2 in the soil; 2) decarbonize the fuel production process by replacing conventional fossil fuel inputs with wind energy, renewable natural gas, and green hydrogen; and 3) use carbon capture and sequestration (CCS) technology to reduce emissions from the production process further. The Gevo approach is aimed at decarbonizing every step in our SAF's life cycle,

[1] Gevo typically uses the term "sustainable aviation fuel" or "SAF" to refer to our fuel. This fuel meets the definition of "alternative jet fuel" (AJF) as set forth in the LCFS regulations. Accordingly, our references to SAF in this comment letter should be deemed synonymous with AJF.

which we track all the way from the farm field through to the aircraft using our Verity Tracking platform.

Gevo intends to submit a Tier 2 LCFS Provisional Pathway application for the SAF, renewable diesel, and renewable naphtha fuels produced at the NZ1 facility, utilizing our field corn starch feedstock and alcohol-to-jet (ATJ)/alcohol to hydrocarbons production process.

I. Overview of Gevo's Comments

Gevo greatly appreciates the role that the LCFS is playing in reducing GHG emissions by incentivizing the replacement of fossil fuels with low-carbon alternatives. We currently are participating in the LCFS through our production of renewable natural gas (RNG) and, given our prospective SAF offtake agreements with major airlines operating in California, we expect to deliver SAF into the state from our NZ1 facility and sequential net-zero SAF facilities in the future. Our comments on the current LCFS proposal are focused accordingly. Although we provide detailed comments below keyed to specific sections of the proposal, we note the following by way of summary:

187.1
- Gevo strongly supports CARB's intent to strengthen the overall compliance curve. CARB's analysis clearly shows that this is needed to support California's emission goals. While we support CARB's proposal of a 30% reduction in fuel CI by 2030 and a 90% reduction in fuel CI by 2045 from a 2010 baseline at a minimum, as detailed below, we believe CARB can and should adopt an even more aggressive curve.

187.2
- Gevo also supports CARB's proposal for a CI stepdown in 2025 and for adoption of an Automatic Acceleration Mechanism (AAM). However, as detailed below, we urge CARB to consider a significantly greater stepdown than the 5% that has been proposed and to further strengthen the AAM.

187.3
- In various places in the proposed regulations, CARB proposes to enumerate certain feedstocks and/or production processes, rather than retaining the feedstock- and technology-neutral approach that has typically been taken under the LCFS. In our comments, Gevo raises concerns with these proposed changes, as they imply unnecessary barriers to feedstock and technological innovation.

187.4
- Gevo supports the "true-up" concept for all pathways, although, as detailed below, we recommend that this be expanded to include true-ups between temporary and provisional pathways.

187.5
- While Gevo supports CARB's recognition of the important role that crop-based biofuels play in reducing GHG emissions and we are committed to strong

sustainability and tracking provisions, we have significant concerns regarding CARB's current open-ended proposal to require third-party "sustainability certifications" for crop-based feedstocks. In our comments below, we encourage CARB to convene a stakeholder process to flesh out an appropriately tailored approach to sustainability certifications for feedstocks that would include crediting the emissions reductions from climate-smart agriculture.

187.6
- Gevo strongly supports avoided methane crediting recognizing RNG project benefits that reduce global methane emissions regardless of location or end use. In our comments, Gevo recommends changes to the current RNG proposals so the LCFS can continue to deliver emissions benefits and maintain project developer and investor confidence in continuing to advance these important methane abatement projects.

- Gevo also provides comments on several compliance-related and administrative provisions set forth in the proposal.

Also, in addition to providing our own comments, Gevo is a member of and supports
187.7 and incorporates by reference the comments of the Coalition for Renewable Natural Gas
(RNG Coalition) and the Low Carbon Fuels Coalition (LCFC).

II. Gevo's Detailed Comments on the Proposal

<u>§ 95484 "Annual Carbon Intensity Benchmarks" (i.e., Compliance Curve), Stepdown, and Automatic Acceleration Mechanism</u>

a. Gevo supports strengthening the overall compliance curve

CARB affirmed rigorous emissions reduction goals in the 2022 Scoping Plan update.
CARB's analyses and that of various outside parties, including ICF,[2] have confirmed not
only that the LCFS is a critical tool for emissions reduction in the State, but that the
LCFS carbon intensity (CI) benchmarks and compliance curve therefrom must be
strengthened to in order for the State's emissions goals to be met. Accordingly, Gevo
187.8 supports CARB's proposal to update the annual CI benchmarks through 2030 and
establish more stringent post-2030 benchmarks in alignment with the 2022 Scoping
187.9 Plan. Notably, the analysis undertaken by ICF demonstrates that CARB could go even

[2] ICF's prior analysis, captured in the report, "Analyzing Future Low Carbon Fuel Targets in California," was previously submitted to CARB by the Low Carbon Fuels Coalition. *See* Letter from the Low Carbon Fuel Coalition to CARB Chair, Liane Randolph (Sept. 28, 2023) (attaching the ICF report).

187.9 cont. farther, as ICF's LCFS analysis found that a 2030 target for the program greater than 40% is achievable, when all low carbon fuels are allowed to contribute fully under the program's technology-neutral, performance-based design.[3] Thus, while supporting CARB's benchmarks/compliance curve proposal, we urge CARB to view the proposed targets as a minimum, and to continue to consider ways to further advance emissions reduction through LCFS emissions targets.

187.10 cont.

b. The proposal for a stepdown in 2025 and for the auto accelerator mechanism are warranted and support California's emissions reduction goals, though CARB should further strengthen these proposed mechanisms

In addition to adjusting the overall compliance curve, CARB has also proposed a near-term, one-time 5% stepdown of the CI benchmark in 2025 and an Automatic Acceleration Mechanism (AAM). While Gevo supports the adoption of these mechanisms, we urge CARB to adopt a greater stepdown than proposed and to further strengthen the AAM.

The LCFS is clearly a successful program, exceeding its initially projected carbon reductions through what CARB has referred to as "overperformance." Although the LCFS has supported the production of a greater quantity of low-carbon fuels during a certain timeframe than originally projected, Gevo notes that labelling this phenomenon as "overperformance" is a bit of a misnomer. In actuality, given the State's aggressive carbon emissions reduction and climate goals, and the challenges associated with meeting them, the situation might better be referred to as underperformance of the CI targets and implementing mechanisms. As CARB has recognized, because the volume of low-carbon fuel has exceeded projections, the credit prices have been reduced and the credit bank is unduly large, thereby threatening continuing success. Implementing an appropriately calibrated near-term CI stepdown and automatic acceleration mechanism alongside the compliance curve/benchmarks revisions can address this. Indeed, a near-term CI stepdown can provide near-term market improvements while the accelerator mechanism will provide California with the tools to monitor the LCFS program and adjust it when needed. In addition, the accelerator mechanism will also help meet the State's interest in spurring additional emissions reductions from SAF by supporting expansion of SAF production (and other renewable fuels) by providing investors and industry with confidence that the LCFS can support the crediting of additional gallons without the long delays that would be required by future rulemakings.

---

[3] ICF, "Analyzing Future Low Carbon Fuel Targets in California," (September 2023).

187.11 While Gevo supports adoption of these mechanisms, we are concerned that setting the stepdown at the proposed 5% level will be insufficient to achieve the intended results. As established in the ICF report accompanying comments submitted by the Low Carbon Fuels Coalition,[4] a stepdown in 2025 of at least 6.5% appears necessary to ensure that the LCFS credit bank does not continue to build. And that analysis also shows that a stepdown of at least 10.5% in 2025 likely is needed to ensure that the credit bank reverses and is drawn down to the level necessary to continue to incentivize LCFS-driven emissions reductions, i.e., with the credit bank holding approximately two to three quarters' worth of deficits. By contrast, ICF's analysis indicates that if CARB retains the proposed 5% CI stepdown for 2025, the credit bank will build in 2025, 2026, and 2027, with the credit bank reaching 45-50 million credits in 2027. In turn, this would trigger the AAM in 2028 and again in 2030, and yet the AAM would not be able to sufficiently adjust to correct the imbalance.

187.12 While ICF's analysis demonstrates that a greater 2025 stepdown is needed, it also demonstrates that this should be done in tandem with an adjustment to the proposed threshold for triggering the AAM so the AAM will be triggered when the credit bank is more than 2.5 times greater than the quarterly deficits generated in a given year. These changes would result in a tighter credit-deficit balance and would provide sufficient flexibility to respond to market conditions in the near-term future (pre-2030), while enabling California to achieve its long-term GHG reduction targets. Accordingly, Gevo recommends that CARB revise the stepdown and AAM proposals consistent with this analysis.

§95481(a): Revised Definitions of "Renewable Diesel" and "Renewable Naphtha"

187.13 Gevo is concerned about the proposed revision to the definition of "renewable diesel" and the proposed definition of "renewable naphtha" in the LCFS package. CARB's proposals would import specific feedstocks and production pathways (i.e., hydrotreated lipids and biocrudes or from gasified biomass that is converted using the Fischer-Tropsch process and portions from co-processing) into these definitions. As written, the proposed definitions would presumably exclude feedstocks and production pathways that are not enumerated. We urge CARB to reconsider this approach and to instead revert to the technology and feedstock neutral approach for these definitions.

---

[4] See, ICF "Analyzing Future Low Carbon Fuel Targets in California: Response to Staff Report," February 2024, available at https://www.lcfcoalition.com/comment-letters-reports (tagged there as "ICF Analysis: Updated Results for Accelerated Decarbonization, Initial Statement of Reasons (ISOR) Case").

187.13 cont.

With specific respect to Gevo, our production process – the alcohol-to-hydrocarbons conversion process – apparently would be excluded from these definitions, as would our feedstock, corn starch (or other such biomass not expressly included in the proposed definitions).[5] Yet, renewable diesel and renewable naphtha are hydrocarbon fuels that are produced alongside our SAF (i.e., alternative jet fuel) in alcohol-to-hydrocarbons production facilities. There is no rational reason for excluding such truly renewable naphtha and diesel from the CA-LCFS program and to do so would unnecessarily limit the effectiveness of the LCFS. Moreover, by enumerating specific technologies and feedstocks (and in this case, so few), CARB would be creating an administrative barrier to the types of innovations the State wants to encourage, as regulatory revisions would have to be made each time a new feedstock or production process (or new combination thereof) were introduced. Accordingly, as noted, we urge CARB to make these definitions neutral as to non-petroleum feedstocks and production processes.

§95488.1(d)(4): Tier 2 Classification

187.14

As discussed above with respect to the proposed renewable diesel and naphtha definitions, we believe it is critical that CARB include – or not appear to exclude – the alcohol-to-hydrocarbon conversion process from LCFS eligibility. While Gevo understands that the Tier 2 pathway classification is not limited to the production processes listed in this section of the proposed regulation, we are concerned that the omission of the alcohol-to-hydrocarbon conversion process might be misread as an exclusion. Therefore, for clarification and transparency, we suggest revising the language associated with Tier 2 classification to explicitly mention alcohol-to-hydrocarbon conversion technology, as follows (proposed addition underlined and bolded, while the strikethroughs are in CARB's proposal):

> *(4)Drop-in fuels (~~renewable~~ biomass-derived hydrocarbons using processes such as gasification and pyrolysis, synthetic hydrocarbons,* ***and alcohol to hydrocarbon conversion****) except for renewable ~~diesel~~ hydrocarbon fuels produced from feedstocks described in section 95488.1(c)(3). This category includes fuels produced from low carbon feedstocks co-processed with fossil feedstocks in petroleum refineries;*

§95488.8(h)(2): Renewable or Low-CI Process Energy

In this section of the LCFS package, CARB has proposed the following physical limitation on biogas/biomethane: "Biogas or biomethane must be physically supplied directly to

[5] In addition to our NZ-1 facility, Gevo is planning additional facilities that would employ the alcohol-to-hydrocarbons process and there are other companies that also use such processes.

the production facility. The applicant must submit the attestation set forth below in section 95488.8(i)(2)(C)2."

The proposed requirement for physical delivery of biogas or biomethane, i.e., RNG, to a production facility would add significant cost burden and environmental impact as truck transport of RNG apparently would be required to decarbonize thermal energy. In addition to unduly burdening RNG suppliers like Gevo, it would be counterproductive to the State's emissions reduction goals.

187.15

To avoid these results, we encourage CARB to allow for biogas or biomethane to be supplied as process energy using the book-and-claim provisions under the regulation. This will bring the CA-LCFS into alignment with the recent changes in the Renewable Fuel Standard (RFS) Biogas Regulatory Reform – which now allows for biogas to be delivered via commercial natural gas pipelines and used to decarbonize thermal demands.

CARB recognizes the benefits of the book-and-claim approach and provides for book-and-claim of biomethane for hydrogen production/use in a production facility. As CARB has confirmed that book-and-claim approaches work well under the LCFS, such an approach should be authorized for natural gas thermal heating.

§95488.9(b) Temporary Fuel Pathways

187.16 Gevo applauds CARB's proposal to include alternative jet fuel (i.e., SAF) temporary pathways in Table 8. This will allow new ATJ production facilities to send initial batches of fuel to the State while awaiting approval of a provisional pathway.

187.17 We respectfully request that CARB expand the ATJ temporary pathways to include corn starch feedstock processed using an alcohol-to-hydrocarbon production process. As noted above, the alcohol-to-hydrocarbon pathway is well established, with multiple ATJ/SAF facilities using this production process coming online. Inclusion of the corn starch feedstock to alcohol-to-hydrocarbon process as a temporary ATJ pathway will further incentivize its production, helping to meet the State's emissions reduction goals and will avoid the delay that would be occasioned by deferring its addition until later.

§ 95488.10(b): "Credit True Up after Annual Verification"

187.18 Gevo supports a credit true up in the LCFS program for all pathways and believes it should be expanded to also include true ups between temporary pathways and provisional pathways.

Temporary LCFS pathways offer production facilities an opportunity to generate LCFS credits while awaiting full provisional pathway approval. While these temporary pathways are vital to supporting the start-up and build out of new production facilities, the credits generated are much more conservative than actual carbon intensity reductions the fuel is offering to California.

187.18 cont. *Example: RNG Pathways*

We note that the RNG temporary pathway score of -150 CI for swine and dairy manure biomethane projects is more than 50% higher than the actual CI of Gevo's operating facility. Provisional pathways undergo the same rigorous validation and verification process as operational pathway CI scores undergo. By allowing "true ups" between temporary and provisional CI's, CARB would be supporting the successful start-up of these production facilities and recording actual GHG emission savings as part of the program.

A significant amount of capital is invested to ensure the success of methane emissions abatement through RNG projects. RNG projects are critically important because they mitigate methane (a potent GHG) from entering the atmosphere that would normally be released through standard agricultural operations. Yet the lack of a true-up mechanism between temporary and provisional pathways results in significantly discounting the real emissions reduction value of an RNG project simply due to regulatory process and associated timelines, thereby disincentivizing such projects. By contrast, a true-up mechanism would allow operators like Gevo to be rewarded for the entirety of their project and the real-world climate value these projects bring, thereby supporting and promoting investment in climate mitigating projects like Gevo's.

§ 95488.9(g): "Sustainability Requirements for Crop-Based and Forestry-Based Feedstocks"

Gevo is committed to providing low-carbon, sustainable SAF, which starts at the field and goes all the way into the aircraft. As noted, we plan to source sustainably-grown, low-CI field corn from the Lake Preston, South Dakota area and use Verity Tracking to measure and verify carbon intensity and all farm activities to the field level. The Gevo Growers' Program is already enrolling farmers under our $30 million USDA Climate-Smart Commodities grant, which allows us to pay farmers more for implementing climate-smart agriculture practices such as cover crops, reduced tillage, organic fertilizers, and nutrient management.

187.19 These practices are critical to producing sustainable feedstock. In addition to sequestering carbon in soil, they provide significant additional ecosystem benefits such as better soil health, better water quality, higher water use efficiency, more resilient crops, and long-term land fertility. These practices are a significant component of Gevo's approach to sustainable SAF production and we fully support crediting them under the LCFS.

Gevo also supports and is committed to fully meeting appropriate sustainability criteria.
187.19a Unfortunately, what CARB has proposed misses the mark. CARB has not set out specific sustainability requirements that it would expect to be met, instead deferring to unspecified third-party schemes. CARB's failure to set out specific requirements calls into question not only how one might comply, but also whether CARB has the legal and regulatory authority to import into the LCFS undefined substantive provisions within outside schemes.

Indeed, the provisions under (1)(B) are too vague to be implemented appropriately and consistently across production facilities and by various certification bodies. For example,
187.20 the provision that "the certification must consider environmental, social, and economic criteria" could be interpreted in a variety of ways. It is unclear from the proposed language which specific environmental, social, and economic criteria would be deemed essential for the CA-LCFS program and how they might align with program goals. Further, CARB's failure to establish clear criteria calls into question why the current analytical, science-based methodologies used by CARB are assumed to be insufficient to provide the necessary controls on crop-based (and forestry) feedstocks to ensure environmental integrity.

Moreover, it is unclear why crop and forestry-based fuels are being singled out for meeting social and economic criteria, which have implications for any fuel pathway
187.21 participating in the program. These additional criteria have the potential to add substantial administrative burden to both farmers and fuel producers, potentially creating barriers to participation in the LCFS, and as such should be carefully considered in the context of what the program hopes to achieve with these criteria.

187.22 Accordingly, we implore CARB to remove this section from the rulemaking and continue to mature the development of specific program requirements with multi-stakeholder input and workshop feedback to align whatever substantive requirements CARB might impose with specific LCFS goals and to make the provisions practicable. Critically, this stakeholder input must bring farmers and others who work in agriculture to the table. Farmers are more often than not omitted from the development of program standards,
187.23 despite being the most critical actors in implementation of those standards. Specifically, while we are members of and work with the Roundtable on Sustainable Biomaterials (RSB) and the International Sustainability and Carbon Certification (ISCC) initiative, in our experience, despite being well intentioned regarding stakeholder input, these entities have not actively included farmers in the development of standards and only seem to consult such stakeholders after standards have already been formalized, if at all.

187.24 Notably, in establishing specific sustainability criteria that are expected to be met for crop-based feedstocks, CARB should include provisions that allow for climate-smart agriculture practices to be credited under the LCFS. These practices represent significant additional effort on the part of the farmer to implement and are a departure from business-as-usual feedstock production. Moreover, these practices can bring significant GHG emissions reductions, as recognized by the U.S. Department of Agriculture, the National Academy of Sciences, the IPCC, and others.[6][7][8] Hence, they should be incentivized through crediting to drive adoption of these important practices.

187.25 By focusing in on what the State of California seeks to achieve through additional sustainability criteria, and delineating those criteria with appropriate inputs, CARB can ensure that program requirements are fit for purpose, clear, transparent, applied fairly across feedstocks and fuel production processes, properly credit GHG emissions reductions from agricultural feedstocks, and align with LCFS-specific program goals. And such a process need not take long, as CARB could set up a process with a specified time frame (e.g., six months) as it has in other instances where program requirements need to be refined.

Biomethane Projects

187.26 Gevo applauds CARB for progressing the LCFS to encourage the mitigation of GHG emissions, increase the production and consumer optionality of clean fuels, and facilitate investments of such clean fuels. To continue to meet those objectives, Gevo urges CARB to continue its progressive stance on biomethane projects, rather than create limitations for methane avoidance projects. Accordingly, Gevo recommends that CARB continue to support biomethane projects that benefit the climate, regardless of location, pipeline flow directionality or end-use, thereby providing a level playing field

187.27 for projects that provide the same GHG mitigating practices. Much like carbon capture and sequestration (CCS) is not limited by its location in the U.S. and is judged by the

fact that GHG emissions are removed from the atmosphere, these same principles should be applied to biomethane projects throughout the U.S., without the limitations proposed in the current round of LCFS revisions and as outlined below.

Book-and-Claim and Deliverability Requirements

§ 95488.8. Fuel Pathway Application Requirements Applying to All Classifications.

§ 95488.8.(i)(2)(B)(1) Book-and-Claim Accounting for Pipeline-Injected Biomethane Used as a Transportation Fuel

187.27 cont.

Gevo urges CARB to continue to expand book-and-claim and deliverability requirements within the LCFS in general, and to not place book-and-claim (or other) restrictions on biomethane projects. CARB's proposals in the LCFS package that would place restrictions on biomethane projects risk the LCFS program's ability to decarbonize through biomethane projects. In particular, Gevo opposes CARB's proposal for biomethane projects breaking ground after December 31, 2029, which would mandate that "[s]tarting January 1, 2041…the entity…must demonstrate that the…pipelines along the delivery path physically flow from the initial injection point toward the fuel dispensing facility at least 50 percent of the time on an annual basis." Instead of singling out certain biomethane projects for such restrictions, Gevo supports consistency in LCFS pathways and believes biomethane projects be evaluated and credited on the science-based merits of GHG emissions reduction, rather than the project location or directionality of biomethane flow in U.S. pipelines.

Gevo supports CCS projects across the U.S. for the GHG reducing merits and believes this same concept should apply to existing and future biomethane projects. In the same way that carbon dioxide does not have to be transported and injected into California's geologic pore space to provide value to the climate, biomethane projects should not be geographically limited. In sum, Gevo supports the expansion of book-and-claim accounting mechanisms, rather than restrictions, promoting the tangible reductions in GHG reductions that result from this type of program flexibility.

Crediting Periods – Avoided Methane Emissions

§ 95488.9(f): "Carbon Intensities that Reflect Avoided Methane Emissions from Dairy…Manure…"

§ 95488.9(f)(3)(A) Crediting Periods

187.28

As noted, Gevo strongly believes that RNG projects that remove methane, a potent GHG, from the atmosphere should not be limited in their eligibility or approval within the LCFS program, for existing or future projects. To realize the level of emissions

187.28 cont. benefits needed to meet California's climate targets, all projects that bring demonstrable emissions benefits should continue to be credited on a performance basis. Thus, Gevo urges CARB to decline to adopt the limits on the crediting periods that it has proposed under the LCFS.

Missing Data Provisions

§ 95491.2. Measurement Accuracy and Data Provisions.

CARB, like many regulatory bodies, has recognized the use of "reasonable temporary methods" to address data gaps, recognizing that operational realities result in such gaps and can be reliably filled in alternative ways. Accordingly, Gevo urges CARB to continue to allow those participating in the LCFS to be able to use "a reasonable temporary
187.29 method," rather than being shoehorned into the limited data substitution tactics specified under 95491.2(b)(2)(B)'s Table 13. CARB has not provided a reasoned basis for eliminating the "reasonable temporary method" option, which provides needed flexibility to Gevo and others with current and anticipated pathways in locations that are remote and with intermittent communication outages. While Gevo typically does not experience significant outages, we appreciate flexibility in filling in for missing data periods using the data immediately before and after an outage period, which has been established as a statistically valid approach to addressing such data gaps. And such flexibility is important for RNG and other renewable fuel facilities because such operations tend to have variability in operations. For example, Gevo's RNG facility has variability due to cow herd counts, associated manure volumes, drastic changes in weather conditions that can drive utility usage, and cold weather events that can cause occasional freezes/shutdowns.

The data immediately before and after an outage is able to account for such operational variability and would be expected to be more accurate than averages across a 30-day before/after-, year-to-date- or two-year- period, as would be required under 95491.2(b)(2)(B)'s Table 13. As another example, the amount of natural gas Gevo uses in the summer is nominal to what Gevo will use in the winter on a 0-degree Fahrenheit day. In such cases, incorporating averages outside of the missing data period as apparently would be required under Table 13 often would not align accurately with actual operations.

Thus, Gevo advocates for maintaining flexibility in approach and supports the current approach of being able to use a "reasonable temporary method." Gevo currently documents our "reasonable temporary" methods thoroughly and has confirmed their reliability. Indeed, this approach allows for unique downtime events to be addressed with realistic data directly before and after the event. Additionally, being forced to utilize Table 13 would be expected to negatively – and unduly – impact Gevo's CI score as the substituted values would not be representative of operational events around

187.29 cont. each missing data event. Due to the operational parameters described above, the values that would fall in the 10th or 90th percentile or the highest and lowest values in a given year or two would be *too* conservative to reflect actual operations. This would have a significant negative impact on Gevo's actual CI score by forcing much higher or lower values compared to real operating values during missing data events.

Lastly, Gevo believes even if we were able to resort to an "Executive Office approved alternate method," this would pose a significant burden on not only Gevo, but on CARB, as CARB will be called on to review each unique method for approval. Gevo is also concerned that this proposed approach will unnecessarily delay pathway certification. In our experience, verifiers are well qualified to ensure that data substitution under "reasonable temporary" methods are robust. Accordingly, we encourage CARB to retain this option for data substitution.

§ 95491.2(b)(2)(C) Force Majeure Events

187.30 Gevo respectfully requests that CARB provide more definition and specificity around "Force Majeure Events," especially regarding what might be deemed a "facility shutdown" or "disruption drastically affecting production." As noted above, alternative fuel production facilities can face shutdowns and disruptions (and typically more frequently than their petroleum-based counterparts) given the expected variability in bio-feedstocks and processing conditions. Thus, to the extent that CARB seeks to impose further requirements for what it defines as "shutdowns" and "disruptions," it will be critical to Gevo and other alternative fuel producers that these terms are fleshed out and understood.

Overall, Gevo believes the types of events CARB is implying in this section are already captured in shutdown logs provided to the verification body along with the data captured during the events (typically null or zero values). Thus, it seems unnecessary and unduly burdensome to require special reporting for such events within 90 days, given the remote nature and geographic location of many alternative fuel facilities and especially given that production during these events is minimal to zero, which is readily captured in the reported dataset(s).

Tier 1 CI Calculator for Dairy and Swine Manure Biomethane: Retention Time and Drainage

Gevo reasserts here the comments we submitted on July 12, 2023, regarding the proposed changes to the "Biomethane from Anaerobic Digestion of Dairy and Swine Manure" Tier 1 calculator. As before, CARB has proposed a change regarding the "Retention Time and Drainage" instructions for Tier 1 calculators. Currently, an applicant can select from the options that are applicable to their farms in the "Manure-to-Biogas (LOP Inputs)" tab without having to select a particular month where the system is completely emptied. CARB has now proposed a standardized requirement that: "If there is no regular storage/treatment system clean schedule, must select 'System Emptied in This Month' each September. The applicant only needs to select one 'System Emptied in This Month' for each year."

187.31 Gevo appreciates what we perceive to be CARB's approach to standardize the Tier 1 Calculator's inputs for swift processing. Nonetheless, we are concerned that by setting this specific "System Emptied" timeframe, this requirement can result in a forced increase in the CI of a project, causing a penalty to farms that retain a certain level of volatiles in their storage system throughout the year. Accordingly, we urge CARB to retain the current approach rather than adopting this amendment.

In any event, although the proposal appears to seek to standardize, and only apply to, Tier 1 applications, to the extent CARB proceeds with the proposed change, we respectfully request that CARB continue to assess site-specific optionality in Tier 2 applications. This will ensure unnecessary penalties aren't assessed for farm-specific circumstances in which the farm does not completely empty their storage systems in any year.

Removal of "business days" and overall shortening of response timelines

187.32 In several sections of the rulemaking proposal, CARB has proposed shortening the fuel pathway applicant response timeline from "business" days to "calendar" days, effectively reducing the amount of time allowed for responses. In some sections response time has been reduced even further (for example: reduction from 15 business days to 14 calendar days). This includes sections:

- §95488.5(c) Completeness Check for lookup table fuel pathway applications
- §95488.7(d) Certification process for Tier 2 pathway applications

Although the proposed changes might seem trivial to CARB, in application the reduction in response times will put significant additional strain on compliance program staff dedicated to supporting LCFS pathway compliance. And yet there is no compelling reason for CARB to make these changes. Accordingly, we recommend that CARB maintain the current regulatory language and timelines, including specifying "business" days and providing appropriate and needed time for fuel applicant response.

Tier 1 and Tier 2 application data interval requirements

187.33 With respect to the proposed application data intervals, Gevo recommends specifying a six (6) month timeline, rather than a three (3) month timeline as outlined below.

The LCFS proposal has added language in the following sections:

- *§95488.6(a)(1) "Tier 1 applications must not have an interval of greater than 3 months between the end of the reported operational data month and the date of submission"*
- *§95488.7(a)(1) "Tier 2 applications must not have an interval of greater than 3 months between the end of the operational data month and the date of submission."*

187.33 cont.

The process to collect data, prepare the Tier 1 or 2 calculator and supporting documentation package is significant and, in our experience, requires the support of dedicated internal staff resources and outside consultants. Imposing a three-month timeframe on the preparation and submission of an LCFS application package will cause a significant cost burden and may not be feasible for all projects. In addition, there does not appear to be a compelling reason for limiting the intervals to only three months. Thus, Gevo recommends that CARB specify six (6) month timelines instead.

III. Conclusion

Thank you for the opportunity to comment on the "Proposed Amendments to the Low Carbon Fuel Standard." Please let us know if you have any questions regarding our comments. We look forward to continuing to participate in this program with our RNG and as Gevo begins commercial scale production of SAF and other biofuels.

Respectfully,

Kent Hartwig
Director of State Government Affairs

Nancy N. Young

Re: SUPPORT Proposed Amendments to the Low Carbon Fuel Standard Regulation

Submitted to https://ww2.arb.ca.gov/applications/public-comments

Dear Chair Randolph and Honorable Board Members:

The Electric Vehicle Charging Association (EVCA) and CalETC appreciate this opportunity to SUPPORT the Low Carbon Fuel Standard (LCFS)regulation and provide feedback for the California Air Resources Board (CARB) Board member consideration. This letter largely supports the proposed draft regulation order and provides some suggested modifications for consideration. We also appreciate the tremendous effort and accessibility of CARB staff during the extensive public process leading up to this hearing.

EVCA is a not-for-profit trade organization of twenty leading EV charging industry member companies and two zero-emission autonomous fleet operators. The association was established in 2015 to comprehensively represent the entire EV charging value chain and provide a collective industry voice for decision makers.

CalETC is a non-profit association committed to the successful introduction and large-scale deployment of all forms of electric transportation including plug-in electric vehicles of all weight classes, transit buses, port electrification, off-road electric vehicles and equipment, and rail. Our board of directors includes Los Angeles Department of Water and Power, Pacific Gas and Electric, Sacramento Municipal Utility District, San Diego Gas and Electric, Southern California Edison, the Northern California Power Agency, and the Southern California Public Power Authority. Our membership also includes major automakers, manufacturers of zero-emission trucks and buses, developers and operators of charging stations and other industry leaders supporting transportation electrification. CalETC supports and advocates for the transition to a zero-emission transportation future to spur economic growth, fuel diversity and energy independence, ensure clean air, and combat climate change. Please note that the views and comments reflected in this letter represent the positions of the CalETC board of directors and some, but not all, of the members of CalETC.

Over the past 10 years, the LCFS has been tremendously successful in supporting the transition from petroleum to cleaner transportation fuels including electric fuel. Clean low-carbon fuels have replaced a percentage of petroleum and, in doing so, have reduced climate change pollutants as well as a myriad of air and toxic pollutants that adversely impact communities. The LCFS has served as a catalyst for billions of dollars of investments in clean fuels and infrastructure.

The most recent Intergovernmental Panel on Climate Change (IPCC) report along with countless studies cannot be clearer on what science tells us. We must act decisively with an amplified focus on mitigation if we are to limit the most severe impacts of climate change—impacts that will be disproportionately borne by those least equipped to adapt. The Governor and the Legislature's leadership to address the threat that climate change poses to the health of Californians and the economy is emphatic and reflected in a series of actions including statutorily mandated greenhouse gas reduction targets and an unprecedented budget commitment.

The 2022 update to the Scoping Plan is the state's response to the need for a holistic strategy to achieve legislatively mandated greenhouse gas reduction targets including achievement of carbon neutrality by 2045. The 2022 Scoping Plan is built on science and robust analysis, presenting an irrefutable case for ramped-up mitigation and public investment relying heavily on strengthening programs that have been effectively implemented for years. In short, there is no path to achieve the state's climate goals without strengthening the LCFS.

We have been participating in staff workshops for several years and have had several constructive conversations with staff in that time. We very much appreciate their accessibility and commitment to LCFS.

For a summary of our comments, please see the Executive Summary, immediately below. Thank you again for the opportunity to provide CalETC's feedback on this important program.

Executive Summary of CalETC's Comments

EVCA and CalETC largely support the proposed amendments to the LCFS (also referred to as draft regulation order). However, we have many significant concerns and requests for amendments. A summary of our support positions and requests for changes is as follows:

188.1 1. EVCA and CalETC recommend the hearing on the new LCFS be no later than 2nd Quarter 2024,
188.2 2. EVCA and CalETC support the proposed carbon intensity targets in Table 1 (e.g., 30% in 2030 and 45% in 2045),
188.3 3. EVCA and CalETC appreciate the proposal to extend the existing Fast Charge Infrastructure (FCI) program for light duty EVs at public charging locations, but the proposed size and rules governing this program are inadequate to meet California's needs for 83,000 public DC fast chargers by 2035 needed to support the Advanced Clean Cars II (ACC II) regulation,
188.4 4. EVCA and CalETC appreciate the proposal to create a new FCI program for medium-, and heavy-duty EVs (eMHDVs) at public, fleet, and shared depot locations but the proposal includes several limiting parameters that will undercut its effectiveness in supporting

California's Advanced Clean Truck (ACT) and Advanced Clean Fleet (ACF) requirements. EVCA and CalETC oppose the geographic limits and prescriptive site limits and specifications included in the proposed LCFS. A larger, more flexible program is needed to meet industry needs, accelerate deployment, reduce costs, and align with California's truck electrification ambitions,

188.5 5. EVCA and CalETC oppose the proposed requirements for parties to pay for visits to individual charging stations by third-party verifiers to check for accuracy at public and private charging stations for light -, medium-, and heavy-duty EVs and incremental residential credits when reviewing quarterly fuel transaction reports. Instead, we recommend parties pay for desk-top reviews by third-party verifiers at central data locations that do not duplicate existing accuracy regulations established by the California Department of Food and Agriculture's Division of Measurement Standards and the California Public Utilities Commission (CPUC) and that generators of small numbers of non-residential credits be exempted from these requirements,

188.6 6. EVCA and CalETC recommend at least an immediate 7% step down in carbon intensity (CI) to better account for historical overcompliance and push the market to greater levels of emission reduction and attract the private capital needed to meet state requirements and goals,

188.7 7. EVCA and CalETC support the proposed automatic acceleration mechanism but recommend that the mechanism can be triggered as soon as 2027,

188.8 8. EVCA and CalETC continue to recommend the new LCFS create a level playing field for emerging transportation electrification end-uses in airports, agriculture, mining, marine, aviation, and recreation by adding conservative default EER of 2.0. while excluding certain end-uses such as golf carts and indoor sweeper/scrubbers that are already electric,

188.9 9. EVCA and CalETC support the proposal for all sizes of electric forklifts to remain in LCFS,

188.10 10. EVCA and CalETC support expanding LCFS to new sectors. We support expanding LCFS to include new types of transportation (e.g., sea and air transport). Including new types of transportation will further necessitate increasing the stringency of LCFS. The Low Carbon Fuel Standard is a successful tool for decarbonizing transportation and should be expanded to other types of transportation given the climate crisis.

EVCA- CalETC Comments on the January 2024 LCFS Draft Regulation Order

EVCA and CalETC appreciate this opportunity to comment on the proposed LCFS amendments. Our comments focus on the electricity-related provisions.

188.1 *1. EVCA and CalETC recommend the hearing on the new LCFS be no later than the 2nd Quarter 2024.*

The first CARB workshop on amending the current LCFS was in late 2020. We previously recommended the new LCFS go into effect in January 2023 if not sooner. The market participants need a new LCFS in effect by the end of this year at the latest.

188.2 *2. EVCA and CalETC support the proposed carbon intensity targets in Table 1 (e.g., 30% in 2030 and 45% in 2045).*

EVCA and CalETC applaud staff for aligning the proposed Table 1 requirements with CARB's Scoping Plan vision and providing industry and stakeholders with the certainty needed for LCFS to be successful to planners, implementers, and investors.

Currently the LCFS is overperforming as the carbon intensities are too easy for the market to meet, leading to low credit prices that are undermining investment in electric cars, trucks, buses, and charging infrastructure, as well as infrastructure for other low-carbon fuels. Multiple models support increasing the stringency of the LCFS to a minimum 30 percent reduction in carbon intensity by 2030. It is essential that the stringency be increased expeditiously and be implemented as soon as possible to ensure the LCFS continues to contribute substantially to the state's clean air, climate change, and zero-emission transportation requirements and goals. The LCFS has been a highly successful program as part of a broad package of regulations and incentives to address climate change. For the LCFS program to continue to be successful, the annual compliance requirements on regulated parties should be strengthened and extended. Currently, the LCFS credit market suffers from credit oversupply issues. When the 2030 standard was adopted, the CARB Board made it clear the standard could be adjusted if market circumstances called for adjustment. CARB must expeditiously address this market supply issue; increasing the overall stringency of the LCFS regulation is one way to accomplish this.

While there are impacts to retail gasoline prices from LCFS compliance, the correlation between LCFS prices and gasoline prices is not nearly as significant as global macroeconomic factors that play a much larger role in price swings of this global commodity. The impact of increased LCFS stringency on gasoline prices is overshadowed by other factors. This makes it difficult to determine how the regulated oil industry is responding to increased stringency in LCFS with respect to consumer pricing of gasoline and diesel. The graph below[1] does not show a direct, quantifiable link between quarterly LCFS prices and the price of gasoline. Further, as gasoline faces competition from low-carbon fuels in the next decade, it is likely that any price impact between LCFS stringency and gasoline prices will be further muted.

188.3 3. *EVCA and CalETC appreciate the proposal to extend the existing Fast Charge Infrastructure (FCI) program for light duty EVs at public charging locations but the proposed size and rules governing this program are inadequate to meet California's needs of 83,000 public DC fast chargers by 2035 to support ACC II.*

The proposed LCFS would create a new light duty vehicle FCI program 2026-2030 where the cap on prior quarter deficits is 0.5% (instead of the current 2.5% cap) and limit FCI projects to disadvantaged communities (DACs) are rural areas only instead of the entire state like the current light duty (LD) FCI.

EVCA and CalETC support the following aspects of an FCI program. The current FCI program (which ends in 2025) is a well-designed program that has been effective in helping attract capital to build public DC fast charge stations in California by helping to de-risk investment and, if not for the pandemic, would have been even more successful. One of its most attractive aspects is that it results in charging plazas and refueling stations being able to exit the FCI program and transition to traditional LCFS credits. Put another way, both FCI and hydrogen refueling infrastructure (HRI) capacity credits decrease over time as the utilization of the stations increases and the station generates more traditional LCFS credits.

Recommendations. The proposed LD-FCI program has limits, caps and rules that are very different than the current program and that are inadequate to support the infrastructure needed for the ACC II regulation. In summary, we recommend the existing light duty FCI program be continued to 2035 with only a few modifications to the existing program.

- Changes to the existing program that we support. The proposed regulation makes the LD FCI credit life 10 years instead of five years and the formula for calculating LD FCI credits to be linear rather than exponential. Both of these changes make LD FCI have rules that align with the proposed LD HRI. The proposed regulation removes requirements on connectors and raises the minimum charger kW from 50 to 150 kW.
- Keep the existing program rather than the proposed changes. The existing LD FCI program has a 2.5% cap on prior quarter deficits, but the proposed regulation lowers this to 0.5%. The existing LD FCI does not have geographic limits on public DCFC locations, but the proposed regulation does. The existing regulation caps sites at 2.5 MW with exceptions allowed up to 6 MW, but the proposed regulation caps sites to 1 MW and four connectors per site which encourages 250 kW chargers. We discuss these issues in detail below.
- Other recommended changes. The proposed LD FCI should allow applicants to have zero carbon electricity just like the proposed LD HRI does, and few exceptions should be allowed for DCFC projects in cities and towns that serve apartments and condominiums with DCFC located at curbside or in public, private and non-profit parking lots outside of the apartment or condominium. We discuss these recommendations in detail below.

Keep in the new LD FCI the current 2.5% cap on prior quarter deficits: The CARB Scoping Plan, ACC II, and the AB 2127 report by the California Energy Commission (CEC) all call for or inherently require rapid build-out of DCFC infrastructure to support the light duty vehicle electrification for all use cases. However, the 0.5 percent cap for light duty FCI in the proposed LCFS does not reflect the widespread demand and need for fast charging to meet state requirements.

With the adoption of the ACC II regulation requiring 100 percent of new vehicle sales be battery EVs, fuel cell EVs and plug-in hybrid EVs with 50-mile all-electric range in 2035, California is requiring a dramatic increase in sales of light-duty ZEVs. The rapid deployment of ZEVs accessible to all Californians and the success of ACC II depends upon substantially more access to ZEV fueling infrastructure than currently exists. Therefore, it is counter to the state's ZEV requirements and goals and the commensurate need to build out sufficient fueling infrastructure to reduce the capacity credit generation cap to 0.5 percent for the LD FCI program and 0.5 percent for the LD HRI program. This is particularly true in 2026-2035, when the state anticipates massive ZEV sales increases and a commensurate build out of public fueling infrastructure. It is too early to declare "mission accomplished" on light duty electric vehicle charging. In the technology adoption life cycle, we are now past the early adopters and into the mainstream of car buyers. These buyers tend to be more risk-adverse and more concerned with the availability of charging infrastructure. It is crucial that we continue to maintain a 2.5% cap to create a positive charging experience for these mainstream customers and use the FCI program to build infrastructure in advance so that we can continue to advance the ACC II towards 100 percent of new car sales.

While an increase in battery EV sales will likely lead to greater utilization of DCFC in a manner that reduces the need for FCI credit generation in certain areas, DCFC usage is not uniform across the state; regrettably, a more restrictive cap on light-duty FCI credits will adversely affect DCFC deployment opportunities in communities with less favorable station economics, which may include rural, low-income, and disadvantaged areas of the state which need more DCFC than a 0.5 percent cap can provide.

Moreover, light-duty FCI credits are also critically important for supporting ongoing operating costs for fast chargers and help enhance station reliability. With charging experience topics emerging as a state and national priority, EVCA and CalETC assert that maintaining broad pathways for light-duty FCI credits will be important for driving consumer confidence in EVs and charging technology – particularly at stations that have yet to achieve robust levels of utilization.

According to the modeling done by Southern California Edison using the Bloomberg New Energy Finance model, the impact of a ten percent cap on prior quarter deficits for capacity credits (light-, medium and heavy duty for both FCI and HRI programs) to the overall LCFS out to 2030 is manageable and the lower cap in the proposed LCFS is not needed.[2] Furthermore, as shown by the CEC (with the National Renewable Energy Lab), 37,000 public DCFC will be needed to support 8 million EVs in 2030,[3] and 83,000 public DCFC will be needed to support the nearly 14 million EVs expected in 2035 under the ACC II regulations.[4] In fact, data from the CEC and NREL confirm that substantially more DC fast chargers will be needed than the Governor's prior Executive Order.[5] CARB's new LCFS should be aligned with the needs of ACC II. Absent further analysis from CARB demonstrating materially adverse effects from preserving the current light-duty FCI credit structure, EVCA and CalETC recommends that CARB maintain the size of the light-duty credit pool at 2.5 percent of prior quarter deficits.

Keep in new FCI the eligibility of LD FCI sites statewide. The proposed regulation's limit on LD capacity credit generation to fueling infrastructure located in low-income, rural, or disadvantaged communities (DAC) does not align with the state's efforts to reduce impacts in those communities, nor does it ensure benefits to those communities. While there may be situations where a low-income or disadvantaged community benefits from fueling infrastructure located in the community, alternatively some communities may prefer that the preponderance of fueling

[2] See SCE's letter December 21, 2022 on the LCFS workshop docket, pages 12-13.
[3] Figure 1. Final AB 2127 report from the California Energy Commission (CEC) 2020.
[4] Comments by NRDC on ACC II regulation, page 5.
[5] Governor's Executive Order is 10,000 DC fast chargers by 2025.

infrastructure be primarily located outside the community to limit the traffic flow within the community. DAC residents travel beyond their communities and benefit from DC fast chargers outside of the DACs. Also, there may be fueling infrastructure facilities that serve light-, medium-, and heavy-duty ZEVs. And as explained above, the need is so great to meet ACC II that public DCFC are needed in all parts of the state.

The proposed regulation has a restriction that effectively limits LD FCI stations to rural areas because it limits FCI stations to be no closer than ten miles from an existing DCFC station. We oppose this because it is not workable to develop LD FCI stations and check federal maps (e.g., Alternative Fuel Data Center) on a daily, monthly, or even quarterly basis to see if the planned station remains within ten miles of some other public DCFC station.

If our recommendation for no geographic restrictions is not acceptable, we recommend the new LCFS use the term "rural area" instead and it be defined to align with the new definition used by the US Census Bureau. Specifically, we recommend the following edits to Section 95481: "Rural Area" means a census tract ~~with at least 75 percent of its population~~ identified as ~~rural~~ non-urban by the latest US Census data. This definition aligns with the United States Treasury Department and Internal Revenue Service (IRS) guidance on station eligibility for the 30C alternative fuel vehicle fueling property tax credit, which was designed to support the deployment of EV charging infrastructure in non-urban (rural) communities across the US and updated in the Inflation Reduction Act.[6] The U.S. Department of Energy has also published a clear mapping tool that shows which census tracts meet IRS definition of non-urban census tracts.[7] The federal definition of non-urban census tracts is easily understood, stable, and remains in effect through 2030 until the Census Bureau updates determinations of urban and non-urban areas.[8]

We also recommend that the FCI program should be slightly modified in order to address the "chicken and egg" infrastructure problem associated with placing public-access DCFC in cities and towns to serve EV drivers who live in apartments and condominiums and where the DCFC is placed in locations such as curbside of a street or in public, non-profit or private parking lots. Building charging at multifamily residences is a well-recognized challenge and placing level 2 chargers on site is not always attractive or in many cases even possible. CARB has an opportunity with this LD FCI program to address this problem by encouraging DCFCs at nearby locations that will work not only for residents of apartments and condominiums but also for

[6] https://www.irs.gov/pub/irs-drop/n-24-20.pdf

[8] https://www.irs.gov/pub/irs-drop/n-24-20.pdf and https://www.census.gov/programs-surveys/geography/guidance/geo-areas/urban-rural.html

residents of single-family homes in denser urban areas where off-street parking is limited. We recommend the following three changes to the proposed regulation:

- The 24-7 requirement for public access should, at minimum, be slightly modified so that non-profit and private locations in our proposal do not run into problems with rights-of-way laws. For example, a site such as a church or a bank needs to close their parking lot for at least one day a year in order to not lose their property rights. Ideally, CARB should also accommodate, through an exception process, other times that access could be blocked for a few hours (e.g., neighborhood festivals).
- CARB should allow less than 150 kW chargers through an exception process (applications to the Executive Officer). An example: adding two 25 kW DC fast chargers curbside is possible next to underground vault transformers in an urban area.[9] While this may not be a common application, it is a worthy experimental program that could be easily added to the new LCFS.
- Finally, if CARB keeps the proposed geographic restrictions in the proposed LCFS, we recommend that the geographic restriction be lifted for our proposal above to serve those EV drivers who mostly live in apartments and condominiums anywhere in California.

Keep in the new FCI the current rules allowing a 2.5 MW per site cap with exceptions allowing up to 6 MW and more chargers per site. Also, encourage 150 kW rather than 250 kW chargers. To reach the infrastructure needs of ACC II charging sites discussed above much larger than 1 MW sites limited to four connectors per site are needed. The NEVI minimum standards, which CARB uses to justify the increase to 150 kW, state that four ports are the *floor* not the ceiling for eligible NEVI sites.[10] If CARB's intent is to align with NEVI, then CARB should not artificially cap site size if we are trying to build larger sites that EV drivers want. Further, CEC and Caltrans are strongly encouraging NEVI applicants to build corridor sites on I-5 and I-15 that exceed four ports per site. CARB should better align with CEC/Caltrans plans for rural/corridor charger buildout and not artificially restrict site size.[11] We strongly recommend returning to the current rules allowing 2.5 MW per site with exceptions to go higher and the only limit on chargers per site would be based on a 150-kW charger minimum. Charging developers are fast moving to 350 kW which also shows that 1 MW is an inadequate cap. Further, charging developers need flexibility to meet consumer demand and the different use cases at DCFC sites where they may want or need 150 kW chargers.

---

Align the new LD FCI more closely with the proposed LD HRI program. We support having the 2026 – 2030 LD FCI program be more closely aligned with the 2026 to 2030 LD HRI program in the proposed regulation, and three recommendations make this alignment closer: 1) keeping the 2.5 MW per site cap in the current LD FCI and not lowering it to 1 MW is very similar to the proposed HRI, 2) allowing use of zero carbon intensity electricity in the FCI formula which is the same as zero CI hydrogen allowed in the proposed HRI formula, and 3) removing the limit of four charging connectors per site. (See our detailed explanation in the next section on this topic).

Extend the new LD FCI to 2035. We recommend that this program extend to 2035 and not sunset in 2030. We are in a challenging phase of light duty EV adoption as the market needs to capture more skeptical mainstream buyers to meet the "hockey stick" ramp inherent in the ACC II requirements. The light duty FCI remains a very elegant and desirable tool to address the chicken-and-egg problem of how to accelerate EV infrastructure and EV adoption. Without the changes we recommend to the light duty FCI the pace of DCFC build-out could dramatically slow which makes meeting ACC II much more challenging. Now is not the time to scale back this program. CARB can take a no-regrets approach to supporting the light-duty fast charging market by adopting a 2.5% cap with no geographic restrictions. While the addition of more credits into the market can lower credit prices several factors can counter this including the new acceleration mechanism.

188.4 *4. EVCA and CalETC appreciate the proposal to create a new FCI program for eMHDVs at public, fleet, and shared depot locations but the proposal includes several limiting parameters that will undercut its effectiveness in supporting California's ACT and ACF requirements. EVCA and CalETC oppose the geographic limits and prescriptive site limits and specifications included in the proposed regulation. A larger, more flexible program is needed to meet industry needs, accelerate deployment, reduce costs, and align with California's truck electrification ambitions.*

The FCI program, as demonstrated by the existing FCI for light duty EV charging, is an incredibly elegant tool to solve the "chicken and egg" problem that EVs and EV infrastructure face. We truly thank CARB for creating an FCI to 2030 for eMHDVs and support the addition of fleets and shared depot locations as eligible, as well as the addition of more corridors. However, as proposed the MHD FCI is simply not workable for most industry use cases (e.g., shared charging depots and fleets for drayage, short-haul, and delivery trucks), especially in the near term with uncertainty around utilization and truck deployment timelines. It also does not meet the infrastructure needs of CARB's ACT and ACF regulations.

The proposed new FCI program for MHDVs, which starts when the new LCFS begins and ends December 31, 2030, includes a 2.5% cap on prior quarter deficits and restricts FCI locations to public truck stops and shared depots within one mile of existing and pending corridors on the federal highway administration map as well as locations that are "on or adjacent to a property used for medium or heavy-duty vehicle overnight parking or has received capital funding from a State or Federal competitive grant program that includes location evaluation as criteria." It allows projects built after January 1, 2022, to earn credits once the new LCFS begins, limits how many credits a single firm can earn per quarter, requires the minimum charger size to be 250 kW and for public chargers requires acceptance of "all major fuel, credit, or debit cards." "Private" fleets would not receive as much FCI credit as public truck stops and shared depots. In addition, its rules focus on encouraging 1 MW chargers at truck stops for long-distance travel because the proposal only allows ten chargers per site and has a 10 MW per site cap not just for truck stops but for fleets and shared depots too.

In summary our recommendations are:

1. Remove the geographic restrictions completely; if that is not acceptable, expand the corridor boundary from one mile to five, clarify language around parking, and consider local funding along with state and federal when determining eligibility,
2. Remove the cap of ten chargers per site, and if that is not acceptable, remove this for shared depots and fleets or raise this to 100 chargers per site,
3. Lower the 250-kW charger minimum size to 150 kW, and if that is not acceptable, apply a 150-kW minimum only to shared depots and fleets. If lowering the 250-kW charger minimum is not acceptable, we request that LCFS exempt projects that began design and construction after Jan. 1, 2022, and before the start date of the new LCFS from the 250-kW charger size requirement,
4. Increase the cap the proposed 2.5% of prior quarter deficits on MHD FCI to 5%,
5. Increase the 10 MW cumulative charger nameplate capacity credit generating cap for sites to at least 15 MW or alternatively allow an exception by the Executive Officer for up to 24 MW,
6. Allow zero carbon intensity electricity just like the proposed HRI program,
7. Change the requirement for payment to be done by all major fuel cards to a single fuel card,
8. Include land costs for new sites as an eligible cost, as these stations are extremely difficult to site and new locations are often needed,
9. Clarify what is meant by networking requirements, and
10. Clarify that "private MHD-FCI stations" includes fleets owned by entities in the government, private and non-profit sectors.

Geographic restriction. The market will necessarily prioritize public truck stops in the most heavily trafficked freight routes. Adding additional geographic restrictions will undermine the program, slow charger deployment, and increase costs. EV charging infrastructure for trucks has different siting requirements than other types of liquid or gaseous fueling infrastructure. EV charging can be located closer to the point where vehicles are domiciled and used, which may not be on or near highway corridors for many of the vehicle fleets that must be electrified.

It is difficult and expensive to find suitable sites for truck charging due to scarcity of land in urban areas (owning or 10-year leases), zoning restrictions, lease restrictions and, most importantly, the challenge in finding 5-20 MW (sometimes more) of grid capacity.[12] The Venn diagram overlap of these needs is small. Restricting FCI to sites within one mile of a corridor is unnecessary and exacerbates the challenges around infrastructure buildout. Expanding eligibility to a limited subset of sites with overnight parking will help in some cases, but greenfield sites with overnight parking will also be needed given fleet operational needs and constraints. Similarly, expanding eligibility to sites that have won specific state or federal grants is directionally helpful but insufficient to cover the broad array of sites the state will need to meet electrification goals.

As broad an area as possible would be helpful to expand opportunities as many shared depots and public access trucks stops will need between 5-20 MW.[13] Many types of trucks will need shared depots which need to be closer to where the vehicles are domiciled. For example, short-haul trucks or trucks operated by independent-owner operators, which often need shared depots, are often not domiciled near corridors. Truckers who operate local routes need safe overnight parking with full charge in the morning with schedulable charging sessions for top-ups during the day. The focus on corridors in the proposed MHD-FCI may make sense for long-haul trucks, but the proposed LCFS's seeming focus on long-haul trucks versus other segments such as drayage, short-haul and delivery trucks is inappropriate given ACF and the nascent stage of the electric truck market. While single user fleets and shared depots have been added as eligible locations in the proposed FCI, their locations are not concentrated near corridors according to developers.[14]

Retaining the one-mile requirement could unintentionally trigger additional utility upgrades because developers will be incentivized to prioritize corridor proximity over existing grid capacity when making siting decisions. This then brings additional costs and delays with the energization and grid upgrade process. Removing the one mile from corridor restriction will open up locations where fleet needs intersect with existing grid capacity, resulting in faster and lower cost infrastructure deployment.

It is important to note that the financial incentives of the proposed FCI MDHD program are not enough to incentivize building the charging infrastructure at a

[12] As an example of the challenge of finding available grid capacity see Southern California Edison's new tool. https://drpep.sce.com/drpep/

[13] See Figure ES-1 at https://www.nationalgrid.com/document/148616/download Much more is needed after 2035.

[14] Conversations with Forum Mobility, EV Realty, Carbon Solutions and Tesla.

location that is not likely to see sufficient utilization. As with the light duty FCI program, developers will continue to build in locations that are expected to see utilization as the market matures. The geographic limits are therefore unnecessary from the standpoint of avoiding stranded assets. We recommend completely eliminating the geographic restriction to maximize the benefits of this program. However, if CARB must put a restriction in this new 2024 LCFS, we recommend expanding the corridor boundary from one mile to five from the existing and pending corridors in the Federal Highway Administration map.[15] We also recommend clarifying the language to explicitly allow greenfield sites with overnight parking to support evolving fleet operations, and we recommend consideration of local funding sources (e.g., local air districts) in addition to state and federal as a trigger for eligibility. Overly restricting location for MHD-FCI sites will create adverse impacts on the grid, delay deployment, adversely impact meeting the ACT and ACF regulations and increase overall cost.

In order to address the siting challenges and considerations outlined above, we recommend completely striking section §95486.3 (b)(1)(B)2. Alternatively, increase flexibility with the following changes to the proposed LCFS:

2. *Located within ~~one mile~~ five miles of a ready~~ing~~ or pending electric vehicle Federal Highway Administration Alternative Fuel Corridor or on or adjacent to a property that allows ~~used for~~ medium or heavy-duty vehicle overnight parking at the time credits are claimed, or has received capital funding from a local, State or Federal competitive grant program. ~~that includes location evaluation as criteria.~~*

Ten chargers per site. The proposed regulation caps the numbers of chargers at an applicant's site at 10 chargers.[16] This is a huge problem that will severely restrict the usefulness of this important program. Many depots being designed around the state today serve upwards of one hundred trucks. At larger sizes, economies of scale deliver lower costs. Artificially restricting the size of eligible depots will not only slow deployment, but also raise costs – both of which are counter to the state's interest.

Also, the proposed limit on ten chargers per site and 10 MW per site implies the proposed MHD FCI is designed to encourage 1 MW chargers. The challenge with this is threefold. First, 1 MW chargers do not yet exist at broad commercial levels. Secondly, there are no trucks currently commercially available that can take 1 MW. Third, there is actually a strong policy interest in charging as low and slow as possible: doing so will maximize the utilization of the existing distribution network and thereby minimize rate impacts.

[15] https://hepgis-usdot.hub.arcgis.com/apps/5c4d9e173301473688468fc7cf6dbe19/explore

[16] "The number of FSEs. The total number for all FSEs claiming MHDFCI credit owned by a single applicant within ¼ mile of an MHD-FCI site cannot exceed ten. The nameplate power rating (kW), connector type(s), and model for each FSE. The total nameplate power rating for all FSEs claiming MHD-FCI credit owned by a single applicant within ¼ mile of an MHD-FCI site cannot exceed 10 MW."

The requirement in the proposed regulation for claiming credits on not more than ten chargers per site was never workshopped nor mentioned in our conversations with staff last year. For many large government, non-profit, and private fleets and for most shared depots, much larger sites are needed. For example, many developers are building sites with upwards of one hundred chargers – larger sizes bring down costs and make key reliability functions, such as security and technical support staff, economically viable. There is a trade-off between speed of charging and cost, and this is something that market participants should decide.

Minimum charger capacity. Instead of the requirement for a 250-kW minimum capacity for a DC fast charger, we recommend affording more flexibility to industry by setting a 150-kW minimum, and if that is not acceptable, have a 150-kW minimum only for shared depots and fleets. This supports the State's interest in helping electrify Class 2b to Class 8 trucks that are included in ACT and ACF regulations and in better utilizing grid resources with lower and slower charging. Higher capacity fast charging that seeks to replicate liquid fueling times for combustion vehicles is neither necessary nor desirable in all cases, and unduly increases costs and grid impacts. In addition, there is a lot of variation between Class 2b and 8 trucks in use cases for charging times. An analogy is how CNG trucks found early success with cherry picker trucks (Class 5), transit buses (Class 7), and garbage trucks (Class 7). Similarly, with a shift to 150-kW minimums MHD FCI can better serve many use cases and classes of trucks. For example, small independent truckers will be heavily reliant on shared depots that offer many different kW levels so they can slowly charge overnight or top-off during the day. Our members tell us that their customers are price sensitive. Forcing super-fast charging in all circumstances, regardless of whether it can be served by cheaper and less impactful alternatives, is the equivalent of eliminating level 1 home charging and requiring DCFC for light-duty EV home charging. CARB should provide flexibility to charging developers and their customers instead of picking a certain technology.

As stated above, some fleet consumers and shared depot customers prefer the lower costs associated with 150-kW charging. While we understand the desire to ensure a positive customer charging experience, we do not believe our recommendation will negatively impact public truck stops because the developers and operators of these locations will be subject to market pressures to do what their customers want and will naturally gravitate toward higher kW as this is demanded. If this approach is not acceptable to CARB, we recommend allowing only private and shared fleets to have a minimum DC charger size of 150 kW in order to save costs and provide customers with choices.

In addition, we recommend that the 250-kW requirement for chargers not be applied to stations that began development prior to the start of the new LCFS. (Note: the proposed LCFS allows stations that started development in 2022 to be eligible for FCI.) Doing so would be very expensive for a developer who already has stations (typically with 180 kW chargers) under development and would require re-engineering the project and potentially starting again in the queue for energization of the location by the local utility.

Cap on prior quarter deficits. The MHD-FCI program is limited to 2.5% of the previous quarter deficits. At 2025 deficit levels, we estimate this would support as little as 635 MW of capacity from MHD FCI credits, depending on utilization, uptime, and other assumptions.[17] According to the CEC's AB 2127 analysis, the state will need about 2,900 MW of charging from eMHDVs by 2025 and 11,600 MW of charging from eMHDVs by 2030.[18] Additional support is needed to attract the scale of private capital required, particularly at this nascent stage of the market with less than 1,000 MHD trucks and vans on the road and with both fleets and OEMs citing infrastructure as a primary limiting factor.

We recommend increasing the 2.5% cap on prior quarter deficits, particularly in the early years of the program, to kickstart the zero-emission truck market especially for near-term trucks applications in the drayage, short-haul, medium-haul, and delivery segments. As momentum builds, CARB might consider reducing the cap in a future rulemaking. We recognize that there are tradeoffs and that the "right" cap depends on perspective. However, we are at a critical launch point for both ACT and ACF and believe a higher cap – we recommend 5% based on the above need - is warranted to begin deploying a network that will enable the market to take off. Solving the chicken-and-egg infrastructure problem by using FCI to build infrastructure in advance of vehicle adoption is critical to the success of ACF, ACT and the Scoping Plan.

California will need to deploy charging infrastructure in advance of vehicle deployment to keep pace with the need to install over 50 MHD chargers per day every day through 2030.[19] MHD FCI is a crucial tool to encourage charging

[17] This calculation was derived leveraging the formulas from Appendix A-2 Proposed Regulation Order, section § 95486.3.(b)(2)(G) and section § 95486.3.(b)(5)(G) with the following assumptions: previous quarter deficits = 8,082,115 MT (based on CARB CATS model 2025 forecast); shared MHD-FCI charging site model selection; 85% uptime; and 5% utilization.

[18] The California Energy Commission's AB 2127 report uses the HEVI-load model to forecast the number of depot and public chargers required for MHD charging under the AATE3 primary scenario. This forecast predicts the number of chargers and their respective power ratings that will be required in 2025 and 2030, as seen in Appendix-H, Table H-1. The sum of the total MHD charging capacity based on this forecast was calculated to be 2,900 MW and 11,600 MW by 2025 and 2030, respectively, by taking the sum-product of the number of chargers and their respective power rating.

[19] Based on the more recent CEC AB 2127 report available at: https://www.energy.ca.gov/publications/2023/second-assembly-bill-ab-2127-electric-vehicle-charging-

infrastructure deployment in advance of vehicles – thereby removing a frequently cited barrier to electrification overall and ACF in particular. Encouraging the early adopters (e.g., shared depots and some fleets) to build the infrastructure to accommodate full electrification is critical even if the initial vehicle deployments are lower. This will help expedite the time frame for increasing the fleet's adoption rate of electric trucks. In the near future, turnaround time for new electric truck orders will be measured in weeks and the lack of infrastructure will delay adoption. Helping fleets move early will allow them to quickly add to their fleet after gaining comfort with the technology.

As mentioned above, the state will need about 11,600 MW of MHD charging by 2030 but we estimate the proposed MHD-FCI will only provide about 600 MW. The chart below also illustrates the size of the need for DC charging infrastructure and the pace of installation needed.[20] As for the impact of our recommendation on credit prices, see our points above in the LD-FCI section.

Table 27 - HEVI-LOAD Infrastructure Results for 112,000 BEVs in 2030 and 289,000 BEVs in 2035[105]

Charger Power Level	2030			2035		
	Number Chargers (% Depot / % Public)	Charging Energy (%)	Charging Time (%)	Number Chargers (% Depot / % Public)	Charging Energy (%)	Charging Time (%)
19; 25 kW	9,509 (100 / 0)	2.74	21.69	24,638 (100 / 0)	2.29	19.94

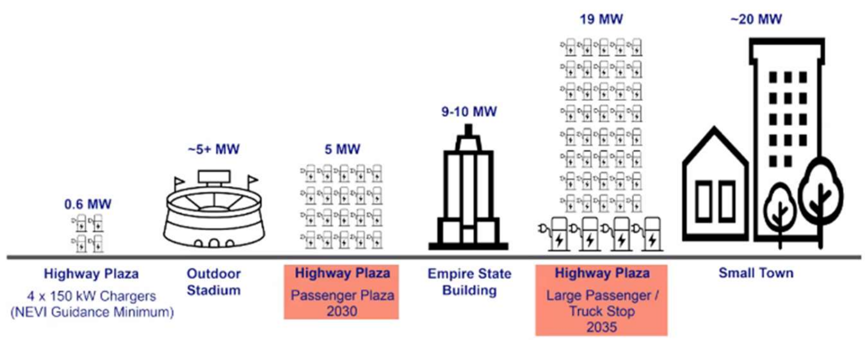
infrastructure-assessment, to support medium- and heavy-duty plug-in electric vehicles, California will need about 109,000 depot chargers and 5,500 public chargers for 155,000 vehicles in 2030, and 256,000 depot chargers and 8,500 public chargers for 377,000 vehicles in 2035. **For 2030:** 114,500 chargers divided by 2146 days (from today) = 53 chargers a day through 2030 needed. What is the baseline of current chargers? 2000? that would bring it to fifty-two chargers a day. **For 2035:** 264500 chargers divided by 3972 days - 67 chargers a day; if we assume a baseline of 2000, then 66 a day through 2035.

[20] https://ww2.arb.ca.gov/sites/default/files/2022-01/Draft_2022_State_SIP_Strategy.pdf

10 MW cap per location. We recommend either raising the MW cap on cumulative nameplate charging capacity eligible for credit claiming per location to 15 MW or alternatively, allowing up to 24 MW with Executive Officer approval. The later recommendation is 4 times the current LD-FCI which is capped at 2.5 MW per location with up to 6 MW with Executive Officer approval. In addition, this approach is similar to the MHD HRI provisions which are five times larger than the current LD HRI. The chart below also helps illustrate the MW size of MHDV charging.[21]

Infrastructure – Readying for Future Deployments

Figure 21. Comparative Peak Loads for Illustrative Sites and Other Major Users[35]



Source: Electric Highways: Accelerating and Optimizing Fast-Charging Deployment for Carbon-Free Transportation (2022 – National Grid, Calstart, RMI)

Allow zero carbon intensity (CI) electricity just like the proposed HRI program. The proposed regulation gives preferential treatment to hydrogen stations over electric vehicle charging stations when assigning the CI for capacity credits. Hydrogen stations utilizing the HCI pathway receive a CI of the "Company-wide weighted average CI for dispensed hydrogen during the quarter or 0 g/MJ, whichever is greater." DCFC stations utilizing the FCI receive a CI of the "California average grid electricity carbon intensity" regardless of whether the EV charging company is utilizing 0 CI RECs for the rest of their charging. We encourage CARB in the new LCFS to harmonize Hydrogen refueling and EV charging by allowing EV charging FCI capacity credits to be generated off of a 0 CI if the company is using renewable energy credit (REC) matching for the rest of their charging.

Payment. We recommend a slight change to the payment requirements. We support the requirements for all major credit and debit cards for publicly accessible chargers but oppose the requirement for all major fuel cards to work for payment. Fuel cards for gasoline / diesel stations do not have this interoperability of station branded

[21] See Figure 21 at https://www.nationalgrid.com/document/148616/download

payment cards. For example, a Shell branded refueling station card does not work with every other brand of gasoline/diesel stations. The same is true for light duty EV charging stations even though there are a few peer-to-peer agreements. For at least ten years, the light duty EV charging industry has tried to achieve payment interoperability between the cards offered by charging station brands but has not succeeded and nor has CARB's Electric Vehicle Equipment Supply Standards required this. In addition, we seek clarification that providing contactless payment is sufficient and there is no need for the older technologies (chip cards, magnetic swipe cards or toll-free phone numbers).

Networked chargers. CARB proposes a networking and communication requirement we request clarification around the data to be shared and the rationale. The proposed language states "Each FSE must be networked and capable of monitoring and reporting its availability for charging." This can be read to require public reporting of availability, which would not necessarily be relevant for shared chargers such as those found in multi-fleet charging depots with defined customers and reservations.

Other provisions we support: We support both HRI and FCI credits for MHDVs lasting 10 years as one way to make the two programs more similar and fairer. We support having fewer credits for single user fleets and appreciate CARB proposing to include this use case as eligible to generate credits as they also face challenges and risks in developing DCFCs.

188.5 *5. EVCA and CalETC opposes the proposed requirements for parties to pay for visits to individual charging stations by third-party verifiers to check for accuracy at public and private charging stations for light -, medium-, and heavy-duty EVs and incremental residential credits when reviewing quarterly fuel transaction reports. Instead, we recommend parties pay for desk-top reviews by third-party verifiers at central data locations that do not duplicate existing accuracy regulations established by the California Department of Food and Agriculture's Division of Measurement Standards and the California Public Utilities Commission (CPUC) and that generators of small numbers of non-residential credits be exempted from these requirements.*

The proposed regulation requiring site hosts to pay for third party verifiers for metered incremental residential credits, non-residential, and FCI credits for charging of light duty EVs and eMHDVs will result in high costs and a chilling of market development by site hosts, automakers, and charging developers. Section 95501 (b)(3) seems to indicate that site visits to each facility with a charging station is required (we see no mention of risk assessments or sampling affecting the number of site visits in the proposed regulation). We believe this requirement represents a massive time investment and cost for extraordinarily little benefit.

Metered electricity fuel credit generators are widely distributed, unlike other fuel providers that generate LCFS credits. Electricity is also economically regulated, unlike other transportation fuels. While there are approximately 10,000 gasoline / diesel stations in California, electricity is fundamentally different, with already 10,000 public DCFC, about 90,000 public level 2 charging stations, many thousands of fleet charging stations, and nearly one million residential charging stations. Soon these numbers will need to grow by a factor of eight or nine, as the ACC II, ACT, ACF and other regulations ramp up their compliance requirements. The sheer number of charging stations and their distributed nature makes travel to even a fraction of these an exorbitant cost.

Additionally, this requirement is not needed as EDUs have meter accuracy requirements that cover tens of millions of meters in private and commercial locations and a process to deal with inaccuracy complaints.[22] Moreover, the California Department of Food and Agriculture's Division of Measurement Standards (DMS) regulates EV chargers for metering accuracy as well as many other consumer protection requirements,[23] and inspections to enforce this regulation are conducted by each California county's Department of Weights and Measures and paid through device registration fees paid to the counties.[24] Adding a requirement for site hosts to pay for third-party verification for data that is already aligned with the proposed measurement accuracy requirements in §95491.2(a)(1)(B) in Appendix A-2 Proposed Regulation Order[25] may cause smaller fleets or properties like multifamily residences to forego participating in the LCFS program and the sectors CARB more broadly wishes to support. We recommend that the new LCFS does not require site visits to the charging stations and defers to existing CPUC and DMS metering accuracy regulations.

Requiring third party verification for residential metered charging is particularly concerning, as there are already hundreds of thousands of EVs being reported to CARB in order to generate incremental residential LCFS credits with kWh measurement via EV telematics or a charging station. Conducting site visits to even a fraction of those sites will be tremendously expensive. It is also unclear how the verifier would check the EV's telematics data and engage with the EV owner. We see

---

[22] Utility Meters are certified to ANSI C12 standards by Nationally Recognized Testing Labs (NRTLs). Here is a SMUD example on meter accuracy. For example, https://www.smud.org/-/media/Documents/Going-Green/EVs/Engineering-Specification-T017---Electric-Vehicle-Chargers-Rev-0---3-6-18.ashx. And https://www.smud.org/-/media/Documents/Rate-Information/Rates/Rule-2-17.ashx Utilities have processes to respond to high bill complaints and this can be escalated to the CPUC's Consumer Affairs Branch: https://www.cpuc.ca.gov/consumer-support/file-a-complaint/utility-complaint.

[23] https://www.cdfa.ca.gov/dms/pdfs/regulations/EVSE-OAL_EndorsedLetter-and-FinalText.pdf

[24] https://www.cdfa.ca.gov/dms/docs/publications/2023/2023_Combined_BPC.pdf

[25] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/appa-2.pdf

no corresponding benefit and recommend that site visits by a verifier to the EV or residential charger not be required.

EVCA and CalETC propose that for incremental residential credits, FCI credits, and non-residential charging of light, medium- and heavy-duty EVs, that the only requirement is for desk top reviews to be done by third-party verifiers to check the accuracy of the calculations, except where a risk-based assessment reveals a reasonable concern about accuracy.

EVCA and CalETC appreciate that the proposed regulation allows for a deferment in verification for small entities with fewer than 6,000 credits per year, but we do not think this goes far enough for the many small locations that are just entering LCFS. We recommend that any entity with fewer than 2,000 credits per year be exempted from all verification and that those applicants with 2,001 to 6000 metric tons of credits per year be eligible for deferment of paying for a verifier to visit the central data location. Our intent is to avoid a chilling impact that verification requirements will have on recent and new sites and to have a better cost -benefit ratio for these sites. Fleets, workplaces, multifamily buildings, grocery stores, small utilities and other businesses are often just one or two locations and only generating a handful to a few thousand credits per year.[26] We believe our proposal is reasonable to prevent the costs of verification from removing the financial benefits of generating credits or even discouraging the adoption of charging stations so needed to make ACC II, ACT, ACF, Innovative Clean Transit, Clean Miles Standard, Zero-Emission Airport Shuttle and other regulations effective.

Also, as noted below, we are recommending that many emerging EVs in agriculture, airports, mining, and recreation be allowed to be in LCFS immediately. We recommend these new TE end-uses be subject to the same deferment and exemption thresholds as listed above, and any site visits be determined by a risk-based assessment that considers whether there is a reasonable risk of inaccuracy from the meter or charging equipment itself rather than the calculations and reporting.

Finally, CARB staff indicated that base residential credits should not count toward a 6,000-credit cap for deferment of verification (or our proposed 2,000 credit cap for exemption). However, the current regulation language simply references credits in the LCFS Reporting Tool and Credit Bank & Transfer System (LRT-CBTS). Almost all of the utilities' LCFS credits come from base residential credits calculated by CARB (and therefore not subject to verification). However, the current LCFS LRT-CBTS does not differentiate between a utilities base residential credits and other metered credits.

[26] Medium and heavy-duty trucks and buses are often generating several thousand credits annually when they are starting out.

CARB should clarify that only credits subject to verification count towards the credit cap for deferment or exemption.

We recommend that CARB avoid the creation of duplicative reliability requirement as part of the proposed verification provisions on electricity. The CEC is in the process of drafting a reliability standard for publicly funded charging stations pursuant to AB 2061 (Ting). We recommend that CARB work closely with the CEC to understand how the CEC's reliability standards would affect Level 2 charging stations and DC fast chargers participating in the LCFS. It is important for CARB and CEC to align these standards, as harmonizing technical requirements for reliability will result in a more consistent charging experience across the state.

188.6 6. *EVCA and CalETC recommend at least an immediate 7% step down in carbon intensity (CI) to better* account for historical overcompliance and push the market to greater levels of emission reduction.

EVCA and CalETC support the proposed immediate "step down" in stringency to deliver additional near-term pollutant reductions. The step down in 2024 and the proposed automatic acceleration mechanism would not replace the need for increasing the overall stringency of the program as proposed in Table 1 (e.g., 30 percent reduction in CI by 2030). Rather, the stringency and step-down provisions would complement the increased compliance requirement on traditional high-carbon fuels industry both in the near- and mid-term. That said, we remain concerned about overcompliance creating an oversupply of credits that limit motivation for additional low carbon fuels investment and recommend at least a 7% step down instead of 5%. For additional details regarding this position, please see the letter submitted by AJW on this topic.

188.7 *7. EVCA and CalETC support the proposed automatic acceleration mechanism but recommend that the start date for the mechanism be 2027 instead of 2028.*

The LCFS includes several features designed to mitigate excessive costs for the petroleum industry by ensuring against potential shortages of credits. These features include:

- Unlimited banking
- No expiration date on credits
- Fungible use of credits to mitigate deficits irrespective of the deficit-generating fuel
- Credit clearance mechanism (CCM) with a price cap
- Mechanism to pull utility electric vehicle credits forward if the CCM is activated, and
- Ability to carry over deficits in the event credits are unavailable.

From the LCFS program's inception, minimal attention has been directed at effectively protecting clean fuel providers by providing some certainty and market stability against the potential for a market glut of LCFS credits and very low credit prices. Specifically, the results of the current LCFS continue to stifle investment in electrification of the transportation sector, investment in charging infrastructure, and investment in all clean fuels. This is likely due to exceeding the CI reduction compliance targets resulting in a significantly reduced credit value and adding to a growing credit bank that now stands at over twenty million credits.[27] The historical response to market perturbation and glut of credits, which unfortunately means the full emission reduction benefits of the LCFS are not being realized, has been to implement amendments that increase the stringency of the program. However, anticipating the magnitude of innovation associated with developing progressively cleaner fuels and vehicles, like electricity fuel and electric vehicles, is exceedingly difficult. The market has consistently exceeded the CI reduction targets under the program and waiting for a new round of amendments has resulted in missed opportunities to reduce millions of tons of climate change pollutants and accelerate the transition to a zero-emission transportation future. In short, the problem is a suboptimal stringency requirement without a timely mechanism to correct it resulting in suboptimal climate change and other pollutant reductions, investment in innovative solutions, and/or investment by low carbon fuel providers. For these reasons, we support the adoption of an acceleration mechanism.

The acceleration mechanism will dynamically respond in the event of future sustained and significant innovation supporting a rapid escalation in credit generation by further tightening the stringency. Together with the proposed CI targets in Table 1, the acceleration mechanism in the new LCFS will provide greater certainty for clean fuel providers and customers, and better ensure that opportunities to deliver additional reductions of climate change pollutants, traditional (e.g., ozone-forming pollutants, PM2.5) air pollutants, and toxic emissions are not foregone. We believe the acceleration mechanism proposed in this regulation utilizes transparent metrics that trigger adjustments to the program's stringency and the necessary certainty for clean fuel providers to plan accordingly. An acceleration mechanism keeps innovation, investment, and emission reductions accelerating faster than they would otherwise. By incorporating a responsive acceleration mechanism into the regulation, the program will provide the market with a clearer signal that investments in clean fuels will be rewarded, and that California will not leave climate change pollutant reductions "on the table" in the future.

CARB, with the credit clearance market and other features listed above, provided price and risk certainty to the oil industry. We believe that now is the time for CARB

[27]https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/dashboard/quarterlysummary/Q3%202023%20Data%20Summary_013124.pdf

to adopt an acceleration mechanism, which would provide similar certainty to the low-carbon fuels industry, consumers, and society.

We support the proposed details of the acceleration mechanism except we recommend that the start date of the acceleration mechanism be 2027 instead of 2028 for the reasons that are provided in the letter submitted by AJW on this topic.

188.8 8. *EVCA and CalETC continue to recommend that the new LCFS create a level playing field for emerging transportation electrification end-uses in airports, agriculture, forestry, mining, marine, aviation, and recreation by adding a conservative default EER of 2.0, while excluding certain end-uses such as golf carts and indoor sweeper/scrubbers that are already electric.*

While LCFS supports many types of transportation electrification, it does not support emerging EVs used in agriculture, airports, mining, forestry, rail, warehouses, water transportation and recreation. This needs to be fixed so these hard-to-reach applications of EVs can easily participate in LCFS. The last 10 years have shown that these emerging EV industries do not have the wherewithal to develop the current LCFS requirement for a scientific study needed in a Tier 2 pathway to prove their Energy Economy Ratio (EER) which is their efficiency compared to gasoline or diesel. To solve this problem, we propose the new LCFS allow these industries to use a conservative default EER that is much less than other EVs. If they want a more realistic EER, these industries can do the full scientific study and the process outlined in Section 95488.7 (a)(3): *Tier 2 Pathways for EER-Adjusted Carbon Intensity*.

In other words, EVs which do not have an EER in the proposed Table 5 should be able to receive a default, conservative EER of 2.0 and allow them to compete with other low-carbon fuels which already earn LCFS credits. However, to address staff's concerns about applications that are mostly electric, we further propose that CARB does not allow this default EER for golf carts, indoor mobile sources such as walk-behind and ride-on sweepers, scrubbers and burnishers, airport heating and air conditioning units, conveyer belts and lawn and garden equipment. We believe this is a realistic compromise to the current situation that still provides an incentive for emerging TE industries to apply for a better EER via the Tier 2 pathway process. The Low Carbon Fuel Standard is a successful tool for accelerating the market for ZEVs and should be expanded to include all ZEVs given the climate crisis and the state's very ambitious regulations.

188.9 *9. EVCA and CalETC support the proposal for all sizes of electric forklifts to remain in LCFS.*

Previously, CalETC expressed many concerns with the staff's proposal to remove most electric forklifts from LCFS because this proposal was arbitrary. We argued that many fuels and end-uses of low-carbon fuel technologies are regulated and/or already exist in the market (not just electric forklifts), and that any criteria for removal of a fuel or technology from LCFS eligibility should be fuel and technology neutral, transparent, support the state's requirements and goals to decarbonize transportation fuel and the transportation sector, complementary to existing regulations, and approved by the CARB Board.

The new proposal to keep all sizes of electric forklifts in LCFS but grant different EERs to forklifts with different lift capacities is an acceptable compromise. We also support the proposed LCFS provisions to remove estimation of kWh for electric forklifts and require metering and third-party verifiers.

We appreciate the opportunity to comment on these important changes to the LCFS regulation. Thank you for your consideration.

RE: SRECTrade Comments on Proposed Low Carbon Fuel Standard (LCFS) Amendments

Dear Ms. Sahota:

SRECTrade appreciates the opportunity to comment on the Proposed LCFS Amendments. SRECTrade is the largest aggregator of EV charging stations under the LCFS, helping the nation's leading EV charging networks, EV fleet operators, and others participate in and benefit from this valuable incentive program.

We appreciate your consideration of our comments:

189.1

1. **Increase the 2030 carbon intensity reduction targets to at least 40%**. SRECTrade supports the findings in the analysis conducted by ICF which indicated that a target above 40% target is achievable based on expected carbon intensity reductions.[1] LCFS has long been a powerful driver of low carbon fuels precisely because of the clear, consistent market signal it provides. However, the transportation fuel economy has outperformed expectations set during the last rulemaking in 2018. CARB now has an opportunity to challenge the entire sector yet again, and in doing so align with the ambitious goals set by the 2022 Scoping Plan.

189.2

2. **Modify the auto-acceleration mechanism (AAM) to be triggered in consecutive years.** The AAM will be a valuable tool to adjust carbon intensity targets to market conditions without the need of a rulemaking. The triggers for the AAM should be attuned to prevailing market conditions and not be unnecessarily restricted.

189.3

3. **Phase-in the implementation of forklift metering requirements to give fleet operators time to install metering solutions**. SRECTrade supports aligning reporting requirements for forklifts with other electricity applications and strongly encourages CARB to provide fleet operators at least one year to install metering solutions. During the one-year phase-in period, fleet operators should be able to continue to use the estimation methodology by demonstrating that they are in the process of installing metering solutions. SRECTrade also encourages CARB to consider a broad variety of reporting technologies for forklifts, including vehicle telematics.

189.4

4. **Grant verification bodies discretion to conduct site visits when verifying quarterly fuel transactions reports for EV charging**. SRECTrade is supportive of expanding the scope of third-party verification to include electricity transactions. However, site visits can be costly given the volume of charging stations and may provide little to no benefit to the

[1] ICF Resources, L.L.C. (2023). *Analyzing Future Low Carbon Fuel Targets in California*. Available here.

verification of quarterly fuel transactions if the data collection process is centrally managed. SRECTrade recognizes that not all EV charging applications or underlying technologies are the same, therefore a verifier should be given the discretion to determine whether a site visit is necessary and be required to document the decision in the verification report.

189.5 5. **Remove the U.S. Commodity Futures Trading Commission registration requirement for Clearing Service Providers operating spot exchanges**. SRECTrade supports CARB's efforts to enable a robust cleared spot market for LCFS credits. Exchange-traded spot markets create transparent marketplaces with better price discovery and confidence with secured clearing and settlement. The current requirement that a Clearing Service Provider (CSP) maintain a derivative clearing organization license is prohibitive for operators of spot exchanges where no such licenses are required or relevant. The requirement should be removed or clarified so that it only applies to futures exchange operators.

Sincerely,

Evan Rosenberg

Sacramento, CA 95814

RE: National Corn Growers Association (NCGA) Comments on the Proposed Amendments to the Low Carbon Fuel Standard

Dear Chair Randolph and Members of the Board,

The National Corn Growers Association (NCGA) values the opportunity to provide comments on the proposed amendments to the Low Carbon Fuel Standard (LCFS).

NCGA represents 40,000 dues-paying corn growers and more than 300,000 farmers who contribute to corn promotion programs nationally. Along with its 50 affiliated state associations and checkoff organizations, NCGA works to protect and advance the interests of corn growers. NCGA recognizes CARB staff's leadership in continuing to refine the LCFS program to support California's ambitious climate goals and serve as an example to encourage similar programs elsewhere.

NCGA would like to provide the following comments in response to the proposed amendments to the LCFS:

190.1 **2030 Target**

NCGA is encouraged to see CARB's proposal of a 30% reduction in carbon intensity (CI) by 2030. This target can be reached at an accelerated pace through the implementation of fuel blends with up to 15% ethanol (E15) in California. NCGA urges CARB to adopt E15 due to the
190.2 immediate benefits it can help achieve as a lower carbon and lower cost fuel which is readily available. Ethanol has a low-CI and can help reduce greenhouse gas (GHG), criteria, and toxic pollutant emissions. Compared to E10, E15 can reduce annual GHG emissions by 2 million metric tons.

Notably, California is the last state that has not approved E15 despite gasoline-ethanol blends having a long history of being used in the state.[1] Today, almost all gasoline sold in California

[1] Montana Becomes 49th State to Approve the Sale of E15

WWW.NCGA.COM
NATIONAL OFFICE

uses blends of up to 10% ethanol (E10). As California looks to electrify much of its transportation, higher ethanol blends are a complementary solution, especially for hard-to-abate sectors and heavy-duty applications. California has long been a leader in championing progressive climate policies, with the LCFS being one of them. With more jurisdictions looking to introduce their own clean fuels programs, the lack of approval for E15 in California will be a significant obstacle to exporting the program as E15 helps garner agricultural support.

The ethanol industry and CARB have invested significant resources in conducting the proper analyses to get E15 approved in California. Among these efforts is the Multimedia Evaluation (MME) of E15, which is in the final stages.[2] In the Tier II Report for the MME, the ethanol industry and CARB jointly funded vehicle emission testing conducted by the University of California Riverside which found significant air quality improvements (see results in the table below).[3] Throughout the MME process, ethanol stakeholders have been responsive and collaborative with CARB to ensure the evaluation could move at a quick pace.

190.2 ctd

E15 is a readily available and affordable solution which can swiftly enable additional CI reductions in the LCFS. Approving E15 in California will allow for the LCFS to be even more ambitious in setting targets and achieving California's transportation decarbonization goals.

Pollutant	Reduction %	Statistical significance
NOx	3%	Not significant
THC	5%	Significant
NMHC	8%	Marginally significant
CO	17%	Significant
CO_2	1%	Marginally significant
PM	18%	Significant
Solid Particle	12%	Significant

Figure 1, E15 Tier II Report – Vehicle Emission Testing Results, UC Riverside

Sustainability Requirements

NCGA asks CARB to reconsider the proposal for crop-based biofuel sustainability requirements. Requiring credit generators to track feedstocks back to their point of origin will impose an extensive regulatory burden with unclear benefits. Despite this proposal adding more responsibility and costs to farmers, it does not address our members' requests for on-farm credits to reward better agricultural practices. Our members are already dedicated to improving their agricultural practices by continuing to advance and incorporate increased efficiencies in land, water, and energy use. [4] In working towards these goals, U.S. corn growers are committed to reducing GHG emissions per bushel by 13% from 2020 to 2030.[5]

190.3 We suggest CARB take a step back from the proposed framework and instead explore a more sophisticated approach that would balance on-farm crediting with sustainability tracking and low carbon ag practices. Also, CARB should be weighing the incremental benefit of this additional

[5] NCGA 2030 Corn Environmental Sustainability Goals

data against information that is already collected and reported. For instance, Argonne's Feedstock Carbon Intensity Calculator examines the CI variations of different farming practices for growing crops used for biofuel production.[6] This tool uses data from key farming inputs from the Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) fuel-cycle model. In understanding the data and resources that are already available, this can better inform CARB's concerns in verifying sustainability standards while preventing duplicative efforts and reporting for credit generators.

Figure 2, NCGA's 2030 Goals

NCGA appreciates the opportunity to provide feedback on the proposed amendments for the LCFS. We look forward to continuing our engagement with CARB both in the completion of this rulemaking and those to come.

Sincerely,

Harold Wolle, Jr.
President, National Corn Growers Association

Re: Proposed Low Carbon Fuel Standard Amendments

California Air Resources Board:

The U.S. Canola Association (USCA) appreciates the opportunity to comment on the California Air Resources Board's (CARB) Proposed Low Carbon Fuel Standard Amendments issued on December 19, 2023.

The U.S. Canola Association (USCA) is a non-profit commodity organization whose mission is to increase domestic canola production and promote the establishment and maintenance of conditions favorable to growing, marketing, processing and utilization of U.S. canola. Canola has multiple uses and markets and is one of numerous feedstocks used to produce clean burning, renewable biomass-based diesel (BBD) and is a potential feedstock for sustainable aviation fuel (SAF).

The BBD industry is an important market for canola producers, utilizing approximately 1.2 billion pounds of canola oil in 2021. The BBD market provides a valuable outlet for surplus canola oil not utilized for food production.

Consistent with the intent of the LCFS, BBD from canola provides significant benefits to our national energy security, the environment, and the economy. Canola BBD contributes to the expansion and diversification of U.S. fuel and energy production, reduces emissions and improves air quality, and provides jobs and additional economic benefits, especially in rural communities. The canola and BBD industry have provided these benefits without significant disruption or adverse impacts to consumers.

Currently, U.S. canola production is primarily in the Northern Plains and Pacific Northwest region of the country. It is predominantly a Spring planted crop harvested in the Fall and grown as part of a beneficial crop rotation on diversified farms that grow five or more different crops. Canola production has grown modestly, but steadily over the past few decades, reaching over 2.3 million acres in 2023. There is potential for continued expansion of canola production in the U.S., including as a winter and double crop option in the Pacific Northwest, Great Plains, and

Southeast regions. This winter canola and double crop production provides additional vegetable oil feedstock from existing cropland and fallow land.

Crop-Based Biofuels Sustainability Criteria

191.1 The USCA believes CARB can utilize existing programs and data sources, such as the federal Renewable Fuel Standard (RFS) and USDA crop production data and statistics, to certify that feedstocks grown in North America that are used in the production of BBD are produced sustainably and meet CARB's proposed criteria.

The proposed amendments state that CARB staff are proposing additional guardrails on the use of crop-based feedstocks for biofuel production. Specifically, CARB staff are proposing to require pathway holders to track crop-based and forestry-based feedstocks to their point of origin and require independent feedstock certification to ensure feedstocks are not contributing to impacts on other carbon stocks like forests. The USCA does not believe that CARB needs to impose additional feedstock tracking and certification requirements. There is no evidence to suggest that deforestation is occurring in the U.S. due to land being converted to agricultural production. Expanded agricultural production is occurring through yield increases, improved agronomic practices, double cropping and use of previously fallow land that benefits environmentally from having "cover" crops.

The federal RFS already includes protections against land conversion to cropland for biofuel feedstock production. To be eligible for the RFS, feedstocks have to come from land that was non-forested and in production prior to December 19, 2007. EPA set a national baseline for eligible cropland in 2007 of 402 million acres. If cropland in subsequent years exceeds that baseline, biofuel producers would be required to track and trace where its feedstocks were grown. There is also a threshold of 397 million acres which, if exceeded, would trigger investigation and reassessment of the aggregate compliance program. Neither of these thresholds have been exceeded since 2007. We would also note that the most recent Census of Agriculture data released by USDA on February 13, 2024 shows a 2% decline of total farmland in the United States since 2017. We believe CARB could utilize the existing federal protections and monitoring of land conversion instead of imposing additional, unnecessary compliance burdens.

The USCA urges you to recognize that fuels produced and certified under the federal RFS meet CARB's proposed sustainability criteria. Additional requirements would place an unnecessary burden on the fuel and feedstock providers as well as on CARB's staff and resources for LCFS implementation and enforcement. This additional burden would increase costs without providing any additional environmental benefit.

We would also point out that, as noted in the proposed amendments issued in December, the California LCFS already accounts for land use change emissions in its life cycle methodologies. Additional certification requirements would be redundant and create unnecessary burdens and expenses that could increase costs and reduce the amount of renewable fuel available to achieve the LCFS targets.

Again, the USCA appreciates the opportunity to comment on the Proposed Low Carbon Fuel Standard Amendments and looks forward to supporting your efforts to implement an effective LCFS program.

Sincerely,

Andrew Moore
President

Subject	Stop rewarding mono-cropping, and factory farming/ranching

Comment

192.1 What we need to stop is pollution, whether it be from private jets yachts, McMansions, golf courses, the military, industry and factory farming. The predatory class, industry and the military cause the vast majority of the pollution that poisons us and our environment, yet they are all exempt from the ridiculous "carbon" standards foisted on the rest of us, and yet our tax dollars subsidize what little mitigation is actually done toward cleanup. There is no reason why Air Force One should run 24-7, which create gawd-knows how much pollution.

If anyone in government or our regulatory agencies (mostly staffed by a revolving door of executives and lobbyists), actually cared about us (they don't), our tax dollars would subsidize regenerative, humane, organic, biodynamic, local, small-scale farming and ranching, which would go a long way to restoring the soil and cleaning up the environment. And, we would severely punish industrial polluters, where the executives would be criminally prosecuted and spend time with rank and file criminals in prison, and not some Club Fed where they play golf all day.

Subject Suggested LCFS Amendments (2024)

Comment

Dear Board:

We are thankful for the opportunity offer-up our suggestions towards deploying the LCFS to meet the aims of SB 596 (Becker), namely empowering the deployment of zero-carbon low-energy electrification technologies.

The Annex demonstrates that with minimal rule changes, the LCFS could be easily innovated to support Title XVII by way of example If you require the Annex in Word format, please advise.

Thank you again for the opportunity to submit.

Yours faithfully

Denizhan Baytug

Innovating the Low Carbon Fuel Standard Regulation ("LCFS") for SB596

Dear California Air Resources Board:

We write in response to CARB's invite, encouraging "members of the public to bring to the attention of staff in advance of the hearing any suggestions for modification of the proposed regulatory action", our having noted that despite SB596's clear mandate—and Senator Becker's address to the UNFCCC at COP 26 heralding its purpose—nonetheless SB596 is not mentioned once in the documentation supporting CARB's proposed regulatory action. Even Appendix D, Attachment A ("Environmental and Regulatory Setting For the Proposed Low Carbon Fuel Standard Regulation") fails to mention SB596.

Context in Brief

This letter is sequential to our public letters to CARB dated 09.04.23 (**here**|PDF **here**) and 11.01.23 (**here**|PDF **here**). By our November 2023 letter, we requested an LCFS rule-innovation having in mind SB596's clear and present impetus, in the context of the *energy paradox* identified by the U.S. EIA (**here**) and California's energy supply.

We believe a fair reading of California's *primary* statutes confirms that CARB shoulders a number of specific duties formed from express demands over cement and concrete's decarbonization. Moreover, the LCFS has evolved into a flexible tool to deliver legislators' Climate Action priorities. Our November 2023 request was made in that context only and this letter demonstrates *why*. After all, by comparing our own EPD (**here**) with the PCA's (**here**), at its intended capacity EMC California would save >1.87 TWh energy annually, across LCA Zones A1-A3. That's before energy-intensive CCS is factored-in that will *at least* double those savings!

Purpose and Structure of this Letter

We respect the work and commitment of CARB in meeting its statutory duties. Having noted the many comments made already in this 45-day process, it is clear there is a sense of urgency. For example, we note the exhortations per the January 11, 2024 letter endorsed by over 2,600 individuals (**here**):

> "The world has changed a lot since the implementation of the LCFS in 2009. Unlike the 2000s, we have a north star goal for our climate and the air we breathe: zero emissions transportation. Continuing to invest the billions in revenue from the LCFS into harmful and polluting biofuels that end up combusted, instead of electric vehicles powered by clean energy, hampers our efforts to fight the climate crisis while enriching oil companies and industrial agriculture."

We agree: much *has* changed since 2009! So, what is the "North Star goal"? This letter will not engage in pages of legal argument to assert our answer, as we believe the opportunity speaks for itself. Instead, the purpose of this letter is to lay-out the basis for the annex that sets out our "suggestions for modification of the proposed regulatory action". **First**, we set out a succinct compendium to record various Californian legal sources having in mind Title XVII's 2021 innovations (per 42 U.S. Code §16513, **here**) and the DOE LPO's recent rule changes (**here**) in the context of California's §38561.2 Health and Safety Code (b)(6) set out below at line number 73. **Second**, we set out a brief digest. **Finally**, we set out a brief conclusion.

Californian Code: A Succinct Compendium *(grouped thematically)*

The Global Warming Solutions Act of 2006 (AB32), required California reduce its greenhouse gas emissions to 1990 levels by 2020. This has been missed. The current 2030 target is 40% below 1990 levels.

CARB Statutory authority per AB32/Global Warming Solutions Act of 2006 (**here**):

- 38510. The State Air Resources Board is the state agency charged with monitoring and regulating sources of emissions of greenhouse gases that cause global warming in order to reduce emissions of greenhouse gases.
- 38560. The state board shall adopt rules and regulations in an open public process to achieve the maximum technologically feasible and cost-effective greenhouse gas emission reductions from sources or categories of sources, subject to the criteria and schedules set forth in this part.

Macro CO2 Reduction Targets:

- Executive Order S-3-05: 1 of 2006 (**here**):

  That the following greenhouse gas emission reduction targets are hereby established for California: by 2010, reduce GHG emissions to 2000 levels; by 2020, reduce GHG emissions to 1990 levels; by 2050, reduce GHG emissions to 80 percent below 1990 levels;

- Executive Order B-30-15 of 2019 (**here**):
  1. A new interim statewide greenhouse gas emission reduction target to reduce greenhouse gas emissions to 40 percent below 1990 levels by 2030 is established in order to ensure California meets its target of reducing greenhouse gas emissions to 80 percent below 1990 levels by 2050.
  2. All state agencies with jurisdiction over sources ofgreenhouse gas emissions shall implementmeasures, pursuant to statutory authority, to achieve reductions of greenhouse gas emissions to meet the 2030 and 2050 greenhouse gas emissions reductions targets.

LCFS enabling:

- Executive order S-01-07 for LCFS (**here**):

  WHEREAS greenhouse gas ("GHG") emissions pose a serious threat to the health of California's citizens and the quality of the environment; and

  WHEREAS Assembly Bill 32 (Chapter 488, Statutes of 2006) requires a cap on GHG emissions by 2020, mandatory emissions reporting, identification of discrete early action measures, achievement of the maximum technologically feasible and cost-effective emission reductions from sources, and authorizes the development of a market-based compliance program; and

  WHEREAS California's dependence on a single type of transportation fuel whose price is highly volatile imperils our economic security, endangers our jobs, and jeopardizes our industries; and

  WHEREAS alternative fuels can provide economic development opportunities and reduce emissions of greenhouse gases, criteria pollutants, and toxic air contaminants.

LCFS (**here**):

- § 95481. Definitions and Acronyms.

  (150) "Transportation Fuel" meansany fuel used or intended for use as a motor vehicle fuel or for transportation purposes in a non-vehicular source.

- § 95484. Annual Carbon Intensity Benchmarks.

  (f) Carbon Intensity Benchmarks for Biomass-Based Diesel Fuel. The benchmark for diesel fuel, set forth in section 95484(c), applies to biomass-based diesel fuel is used or intended to be used in any:

  (1) light-, medium-, or heavy-duty vehicle;

  (2) off-road transportation application;

  (3) off-road equipment application;

  (4) locomotive or commercial harbor craft application; or

  (5) non-stationary source application not otherwise specified in subsections (1) through (4) above.

SB 596:

- Generally, see, CARB (**here**):

  "In September 2021, Governor Newson signed Senate Bill 596 (Becker), which requires CARB, by July 1, 2023, to develop a comprehensive strategy for the cement sector in California to achieve a greenhouse gas (GHG) emissions intensity 40% below baseline levels by 2035 and net-zero GHG emissions by 2045. The bill also requires CARB to establish interim targets for reductions in the GHG intensity of cement used within the state relative to the average GHG intensity of cement used within the state during the 2019 calendar year, with the goal of reducing the GHG intensity of cement used within the state to 40% below the 2019 average levels by December 31, 2035."

- Bill (**here**):

  (a) The Legislature finds and declares all of the following:

  (1) Climate change is an urgent threat to the health and well-being of California's residents and economy.

  (2) California is a global leader on climate action and has committed to achieve carbon neutrality as soon as possible, and no later than 2045, in line with the latest climate science.

  (3) Achieving this objective will require advance planning, coordination, outreach, and development of a robust set of policies tailored to the needs and opportunities of every major emitting sector, including cement and concrete.

  (5) A wide range of commercially available technologies and practices exist to reduce and remove emissions of greenhouse gases throughout the lifecycle of cement and concrete production and use, but these technologies and practices face a series of market and regulatory barriers hindering their deployment.

  (6) Implementing complementary strategies to both reduce the greenhouse gas intensity of cement production and grow the demand for low-carbon concrete will also reduce air pollution and improve public health in California communities.

  (7) Positioning California's cement and concrete sector to thrive in a low-carbon economy will enhance the sector's long-term competitiveness, support high-quality jobs, and enable resilient infrastructure development.

  (b) It is the intent of the Legislature that attaining net-zero or net-negative emissions of greenhouse gases from the cement and concrete sector in a manner that enhances California's competitiveness, supports high-paying jobs, improves public health, and aligns with local community priorities becomes a pillar of the state's strategy for achieving carbon neutrality.

- Statute: Section 38561.2 Health and Safety Code (**here**)

  (b) In developing the comprehensive strategy pursuant to subdivision (a), the state board shall do the following:

  (1) Define a metric for greenhouse gas intensity and evaluate the data submitted by cement manufacturing plants to the state board for the 2019 calendar year and other relevant data about emissions of greenhouse gases for cement that was imported into the state to establish a baseline from which to measure greenhouse gas intensity reductions.

  (2) Assess the effectiveness of existing measures, identify any modifications to existing measures, and evaluate new measures to overcome the market, statutory, and regulatory barriers inhibiting achievement of the objectives described in this section.

  (3) Identify actions that reduce adverse air quality impacts and support economic and workforce

development in communities neighboring cement plants.

(4) Include provisions to minimize and mitigate potential leakage and account for embedded emissions of greenhouse gases in imported cement in a similar manner to emissions of greenhouse gases for cement produced in the state, such as through a border carbon adjustment mechanism.

(6) Prioritize actions that leverage state and federal incentives, where applicable, to reduce costs of implementing greenhouse gas emissions reduction technologies and processes and to increase economic value for the state.

(7) Evaluate measures to support market demand and financial incentives to encourage the production and use of cement with low greenhouse gas intensity, including, but not limited to, consideration of all of the following measures:

(A) Measures to expedite the adoption for use in projects undertaken by state agencies, including the Department of Transportation, of Portland limestone cement and other blended cements.

(B) Measures to provide financial support and incentives for research, development, and demonstration of technologies to mitigate emissions of greenhouse gases from the production of cement with the objective of accelerating industry deployment of those technologies.

(C) Measures to facilitate fuel switching.

(D) Measures to create incentives and remove obstacles for energy efficiency improvements and waste heat recovery at cement manufacturing facilities.

Academic:

Farrell, A. E; Sperling, D.; Arons, S.; Brandt, A.; Delucchi, M.; et al. (2007). A Low-Carbon Fuel Standard for California Part 1: Technical Analysis. UC Berkeley: Transportation Sustainability Research Center (**here**), at p.175:

"Jackson (2005) evaluated two applications at ports: the use of shore power instead of ships' engines for electricity and heat (a practice called "cold ironing") and the use of electric-drive cranes instead of diesel-powered cranes. Two truck-related electric applications were also evaluated: electric truck refrigeration units (e-TRUs) instead of diesel-powered devices, and the supply of electricity at truck stops as a substitute for engine idling. Large off-road vehicles include airport ground service equipment, electric forklifts (class 1 and 2), and tow tractors/industrial tugs. Small off-road vehicles include small electric lawn and garden equipment, electric golf carts, electric sweepers/scrubbers, burnishers, electric forklifts (class 3), electric personnel and burden carriers, and turf trucks. Jackson (2005) does not consider light rail, high-speed rail, electric freight rail, electric trolley buses, electric boats, electric bikes, commercial walk-behind mowers, riding mowers, leaf-blowers or other applications."

Digest

"If CCUS is applied on an industrial scale, the power demand of cement manufacturing will increase significantly. As described, carbon capture technologies will require high power consumption to e.g. supply consumables like oxygen, pump solvents, operate power driven separation devices like membrane or cryogenic units and purify and compress the CO_2 in order to meet the required conditions of downstream processes. **Therefore, CCUS will *increase* power consumption by 50 to 300% at plant level.**"

ECRA | State of the Art Cement Manufacture: Current Technologies & Future Development (2022) | **here**

This letter's purpose is not to set out the *minutiae* of Title XVII's requirements. Instead, let us focus on this gnawing simplicity: an EMC plant delivering 1mn tonnes annual CO_2 abatement will likely yield upwards of 1.87 TWh savings when compared to a PCA-declared cement plant (**here**). This is equivalent to more than 375,000 Californian apartments that on average each use 5 MWh/yr (**here**). Even if CCS only *doubled* the energy needs of Portland cement production as it stands now (which is likely *conservative* according to ECRA's conclusion above), that number would balloon to 750,000 Californian apartments.

To assert our request, we had noted especially the assorted text as highlighted per the Compendium section above. Simply: on our reading, the LCFS is a powerful wide-ranging Climate Action tool, now modified through the years. It now includes provision for CCS (and DAC) and (separately) also fuels made from such CCS systems. Per our 11.01.23 letter, as the rules are currently formulated a DAC plant can be installed anywhere on the planet to make its LCFS claim. Having in mind the controlling statutes empowering CARB—and that the primary legislation has been *turbocharged* per SB596—we assert the following points in support of our request:

- Noting our LCA diagram and EPD for California (**here**), in transportation terms an EMC plant can be justified also as a *transportation device* per LCA boundaries A2–A3. For example, as our LCA diagram confirms, Zone A3 is an all-electric *linear* transportation device. It will span over 1000 ft and hence will be of a dimension similar to the guide-rails of a portside crane.
- All of our Zone A3 could be powered by diesel. Indeed, when in 2014 we were asked by Cameroon's government to investigate an EMC installation there, such are the limitations of West African electricity supply, any such EMC plant would have used diesel across its entire A3 transportation device so as to cause both the necessary drying and processing. Instead, we demurred.
- Just like a portside crane, our Zone A3 plant is *captive*. It does not move from its intended site. Only the intended substrate is transported: again, just like a portside crane.
- §95483(c)(4) LCFS (**here**) rewards the usage of electric forklifts. LCFS Credits flow directly to the "fleet owner". Clearly, a forklift is also *captive*: it is not intended to move beyond its operation site.
- The LCFS' definition of "transportation fuel" speaks for itself and *per se* has no requirement for a device to be non-stationary. Per lines 25–26 above, the term "non-vehicular" is expressly included. UC Berkeley's 2007 technical report confirms non-vehicular equipment, including leaf blowers.
- Further, that same definition places no restriction for such *equipment* only to cause *transport*. Equally, that same definition makes no attempt to rank transport as the fuel's primary purpose. Simply put: the "transportation fuel" definition is agnostic in all such regards.
- In confirmation of such agnosticism, per lines 30–31 above, the LCFS expressly introduces the terms "off-road transportation application" and "off-road equipment application".
- The highlight at line 88 confirms the inclusion of portside electric cranes: *i.e.,* yet another type of wholly *captive* device.

Conclusion: Zero CO2 | Low Energy | Electrification

> "Though going from an 80% reduction to a 100% reduction might seem incremental, the effort to decarbonize the economy gets harder the closer we get to 100%. To deliver on the much more ambitious goal, CARB needs more technologies in the mix. The "net-zero" part is acknowledgement that, for some sectors of the economy, such as air travel, we won't have cost-effective solutions to cut emissions...CARB realized the technologies weren't sufficiently developed and needed government support to get there...any entity that captures and sequesters a ton of CO2 from the air (which traded at an average price of $160 in 2018), can claim a credit from California. And because it doesn't matter where the CO2 is captured and stored, any entity in the world can apply for the credit."
>
> **Akshat Rathi, Quartz** | A Tiny Tweak in California Law is Creating a Strange Thing: Carbon-Negative Oil (2019) | **here**

Per line 73 above, §38561.2(b)(6) expressly includes the word "prioritize". To such ends, our LCA diagram confirms A3's processing of raw material is impossible unless it is *transported*. Simply: transport is both inherent and necessary in absolute terms to an EMC's production. Today, the LCFS is a wide-ranging Climate Action toolkit. However, it has always comprised the means to directly deliver the *electrification* of legacy fossil-fuel transportation and equipment *applications*. Equally, a Portland cement plant is a legacy application that is both fossil-fuel intensive and requiring its substrate to be transported in a linear fashion by its installed equipment system. Further, vast quantities of cement are used in California's transport infrastructure on which its economy depends. Concrete may not be a product used to power trucks, but without it? Concrete is a vital transportation *material*, whose decarbonization is now a statutory demand.

Our 11.21.23 letter noted that ECRA's CCS cost estimate (~€100/t) is corroborated by Canada's IISD report (**here**). Moreover, the glaring scale of the energy savings we have set out here, is such that the more CCS is progressed in California, the greater California's need for a low-energy solution such as ours. At the very least, and using ECRA's most conservative CCS energy-forecast, 1mn tonnes of electric CCS bolted to a Californian Portland cement plant can only be offset—in energy terms—by 1mn tonnes EMC *Californian* CO_2 abatement (an energy-saving equaling the needs of some 750,000 apartments *upwards*).

This letter demonstrates that the LCFS supports a variety of devices carrying, to whatever degree, some sense of a transportation *dynamic*. A leaf blower transports only a "substrate" (*i.e.*, leaves). A forklift truck is captive. A portside crane transports a variety of loads only within the confines of a rail-system set within the range of an EMC plant's length. Both are captive. Hence, whether a device is "non-stationary" is a red herring. There is no doubt that a hook-up towed conveyor used in (say) forestry management is an "*off-road equipment application*". However, that machine is likely sitting entirely stationary when doing its job — during which the only aspect delivering transportation will be the conveying *mechanism* itself.

SB596 compels innovation. Our future is only about *delivery*. Respectfully therefore, having in mind especially §38561.2(b)(6) and Title XVII, we repeat our request for an LCFS rule-innovation that favors SB596 industrial low-energy *electrification*. We fully accept any new rule must be open equally to others also delivering those same benefits in an SB596 setting. To such ends, we believe the innovations we have suggested could be easily implemented and require minimal change to California's existing code, while being linked expressly to the aims of SB596. Further, the suggestions we have made are designed also to concord with Title XVII, moreover so that only innovative *electrification* technologies may qualify under the LCFS (with the credits generated tied to verified carbon mitigation). Nevertheless, if it is demonstrated objectively that the LCFS cannot be innovated no matter the reasons as suggested by us here, then we would welcome any alternate rule-change given §38561.2(b)(7)'s express requirements, per lines 76–86 above which includes energy-efficiency improvements and "*Measures to facilitate fuel switching*".

Sincerely

Atle Lygren | C.E.O. EMC Cement BV

ENC: Annex

ANNEX

NOTES

The ***New Definitions*** suggested below are taken from 10 CFR 609.2 (here), duly modified.

The terms "ASTM", "Executive Officer", "Primary Product", "Verification Body" are already set out in §95481 and do **not** require modification in the setting as suggested below.

193.1 ***New Definitions:***

"Commercial Technology" means a technology in general use in the commercial marketplace in the United States at the time the application is made to the Executive Officer. A technology is in general use if it is being used in three or more facilities that are in commercial operation in the United States for the same general purpose as the proposed project, and has been used in each such facility for a period of at least five years. The five-year period for each facility shall start on the in-service date of the facility employing that particular technology or, in the case of a retrofit of a facility to employ a particular technology, the date the facility resumes commercial operation following completion and testing of the retrofit.

"New or Significantly Improved Technology" means an electrical technology which produces a Primary Product and is intended to reduce both the generation of high-temperature heat and the greenhouse gas emissions associated from cement production, which that at the time the application is made to the Executive Officer either:

(i) Has only recently been developed, discovered, or learned; or

(ii) Involves or constitutes one or more meaningful and important improvements in productivity or value, in comparison to Commercial Technologies in use in the United States;

provided, always, such technology may still be considered a "New or Significantly Improved Technology" if no more than 6 projects employ the same or similar technology as another project, provided no more than 2 projects that use the same or a similar technology are located in the same region of the United States.

193.2 ***§95483(c)(5) ("For Electricity Used as a Transportation Fuel") amended as follows:***

(5) *Other Electric Transportation Applications.* For electricity supplied to a transportation application not covered in subsection (1) through (5) above, any entity can apply to the Executive Officer to be ~~the fuel reporting entity and~~ the credit generator:

(A) and the fuel reporting entity for electricity supplied as long as it meets the requirements of section 95488.7(a)(3) and 95491;

(B) for any New or Significantly Improved Technology that is not a Commercial Technology at the time the application is made to the Executive Officer, as long as:

1. the deployment of any such New or Significantly Improved Technology meets the reasonable requirements as may be stipulated by Executive Officer;
2. the Primary Product is ASTM compliant; and
3. the carbon mitigation delivered by any such New or Significantly Improved Technology is verifiable by a Verification Body including for the purposes of the Executive Officer meeting the requirements of §95486(a)(3)(A).

Board Comments Home

To: California Air Resources Board

Thank you for the opportunity to comment on the LCFS rule making process. We recognize CARB's long-established leadership in addressing the climate crisis across a broad landscape of innovative policies such as the LCFS program and the State's Cap and Trade program, which implemented stringent forestry offset protocols now being emulated by programs outside of California. We appreciate the opportunity to contribute to the dialog, in particular regarding the forestry practices embedded in the LCFS program.

Allotrope Cellulosic Development Company (ACDC) is a California-based project development company developing a forest residues and agricultural waste derived cellulosic ethanol plant in California. In partnership with a well-regarded, established technology partner as well as other important industry partners, ACDC's plant will produce carbon negative ethanol, which is a critical piece of making Sustainable Aviation Fuel possible. Developing such plants will support many key elements of California's overall strategy to address climate change while lowering the risk of catastrophic wildfire and creating numerous related environmental benefits.

The CARB 2022 Scoping Plan for Achieving Carbon Neutrality establishes a goal of managing and treating 2.3 million acres per year of Natural Working Lands (NWL), a goal that it acknowledges is "ambitious." [1] Near the end of the document, the Scoping Plan addresses "considerations" that "must be addressed when implementing" the plan, one of which is that achieving the ambitious goal of treating 2.3 million acres of NWL will require "significant changes" in forest management.[2] Scoping Plan strategies to scale forest management include expanding biomass processing infrastructure and streamlining permitting in collaboration with State and local agencies.[3] As a project developer working to build a commercial scale cellulosic ethanol plant in Northern California utilizing forest biomass, we contribute to carbon neutrality while improving forest management and expanding biomass processing infrastructure.

Forestry residues from harvests and fire management activities are materials that, at present, are typically left in the woods post-harvest, resulting in heightened fire risk and, ultimately, in emissions/pollution, be it from wildfire, open pile burning or via decomposition. Alternatively, removing this material and utilizing it to manufacture carbon negative cellulosic ethanol meaningfully contributes to combating climate change, while also resulting in improvements in air quality and a reduction in particulate matter, due to the elimination of open pile burning, or wildfires in the worst-case scenario.[4]

[2] Scoping Plan at p. 262 ("Increasing forest management to the degree included in the Scoping Plan Scenario will require significant changes to wood-processing infrastructure, workforce capacity, permitting processes, technical assistance, and other operational constraints.")
[3] Scoping Plan at p. 252.
[4] See Springsteen, Christofk, Eubanks, Mason, Clavin and Storey, "Emissions reductions from woody biomass waste for energy as an alternative to open burning."
https://www.hcd.ca.gov/community-development/disaster-recovery-programs/ndrc-attachment-f/docs/aw_article_pcapcd_20120321.pdf

Cellulosic biofuel projects using forest and agricultural waste biomass offer a variety of benefits to the California communities where they are located, including significant direct employment opportunities[5] and indirect job creation as the biomass supply chain needed to support the ethanol plant grows to meet increased biomass demand. Our first plant requires 300,000 metric tons of forest residue annually, which will support an estimated 25,000 acres of annual forest treatments, advancing sustainable forest management activity at scale and increasing the carbon stock of those forests while reducing the risk of catastrophic fire. Our project supports the long-term growth of forest carbon stocks and also improves the overall water supply. Furthermore, the resulting biofuel produced will have a negative carbon intensity, will displace fossil fuels and will support the long term decarbonization of the State's economy. This project is fully aligned with CARB's approach to Natural and Working Lands that "holistically fosters ecosystem health, resilience, provision of overall climate function, and other co-benefits."[6]

The key operational challenge as a biofuel developer in California is securing a long-term supply of state LCFS and federal Renewable Fuel Standard (RFS) qualified forest biomass. Existing federal rules preclude the use of federal forest biomass and thus require that we source forest biomass from private or State forests only. To that end, we are concerned with the language in the proposed LCFS amendments that makes forest residue biomass derived from private land clearcuts ineligible. If approved, this would result in the elimination of an important, immediately available feedstock that is presently left in the woods, eliminating a critical long-term supply source required to advance renewable fuels projects that also advance broader CARB goals.

Our long-term aim is to add residue from emerging forest management activities to the existing residues, further increasing sustainable long-term biomass contracts for expansion and additional facilities. We are eager to see sustainable solutions that allow for the long-term utilization of additional material and we urge CARB (and other state entities) to support
194.1 continued funding for CalFrame and to support proposed avoided emissions credit programs to help create the appropriate economic structures that support more forest management work and additional residue utilization. We also see opportunity to work with federal authorities to lift the ban on biomass from federal lands. While such longer-term forest management enhancements are developed, we believe that working with existing operations to use waste streams presently left in the woods provides significant value to the forest ecosystem and supports the transition to broader forest management activities.

It's important to note that in California clearcutting is tightly restricted by State regulations in the California Forest Practice Rules, which are set forth in Title 14 of the California Code of Regulations (CCR) at Chapters 4, 4.5 & 10. Specifically, 14 CCR Section 921.3(c) establishes narrow circumstances under which clearcutting may be employed, as well as detailed rules regarding the extent and manner in which it may be used. And it can only "be used when

[5] Each ACDC plant will generate over 500 temporary jobs during construction and fifty well-paid permanent jobs.
[6] Scoping Plan at p. 243.

justified and explained in the plan and found in conformance by the Director" with the requirements of the rule.[7] Given the tightly regulated permitting of clearcutting, there is no chance that allowing the forest residual materials that remain after a clearcut to be utilized as biomass feedstock will create any incentive for additional clearcutting. Instead, it will deliver the many environmental and climate benefits noted above, and thereby improve the overall environmental impact of the limited usage of clearcutting that is allowed today in the State.

194.2 We therefore propose that the language in § 95488.8. Fuel Pathway Application Requirements Applying to All Classifications. section (g) Specified Source Feedstocks (1) (A) subsection 3 be amended to read as follows:

> "~~*Small-diameter, non-merchantable*~~ *Any forestry residues and byproducts removed as part of a forest fire fuel reduction,* ~~*last*~~ *stand improvement or slash/tops from a treatment (including harvests)* ~~*where no clear cutting occurred;*~~ *from forest lands that meet applicable federal, state or local regulations; Municipal solid waste that is diverted from landfill disposal;".*

We respectfully submit that in California any residue from pre-2008 plantations[8] that meets the current California Forest Practice Rules requirements should be eligible for the LCFS program. We note that CARB took a similar approach when it aligned the 2015 Compliance Offset Protocol for U.S. Forest Projects with the requirements of the California Forest Practice Rules.[9] California's Forest Practice Act regulations are the most stringent in the United States[10] and set a standard that assures sustainability, a long term increase in the carbon balance of forests and assures that these forests will not be converted to plantations for energy crops as there are minimum stand age and minimum diameter requirements in place. While other jurisdictions may not be as stringent as California, by aligning its climate and forest management regulations it
194.3 will strengthen the State's leadership role in both areas.[11]

As we seek long term feedstock agreements with forest landowners in the region, we recognize that, while all landowners in California adhere to California Forest Practice Act (CFPA) standards, their forest management practices do vary in practice. When analyzed at a landscape scale, over the longer time frames appropriate for forest and carbon management, CFPA standards assure a growing carbon stock in these regions as well as a healthier and more fire resilient ecosystem. As such, we respectfully submit that the focus should be on landscape scale improvements to forestlands and that compliant clear-cutting practices on individual small

[7] 14 CCR Section 921.3(c)(1).
[8] We believe the definition of pre-existing plantation proposed in Section 95488.9 is appropriate as it is largely consistent with federal definitions used for eligibility requirements for federal RINs.
[9] See Section 5.2.1(e)(1)(D) regarding forest projects in California.
[10] See Goldstein, Crandall and Kelly, "The cost of doing business": Private rights, public resources, resulting diversity of state-level forestry policies in the U.S. Table 1 demonstrates, for instance, that California is the only state that requires licensing for foresters and timber harvest plans/permits before harvest as well as notification requirements before harvest.
[11] Another option would be to do as CARB did in the 2015 Forest Offset Protocol and carve out a specific set of rules for California. Compare Section 5.2.1(e)(1) with Section 5.2.1(e)(1)(D).

stands of pre-existing plantations should be seen within that larger context and not result in the elimination of an important source of feedstock for the biofuels industry in California.

Sincerely,

Robert Hambrecht

3Degrees 235 Montgomery St., Suite 320
San Francisco, CA 94104

February 20, 2024

The Honorable Liane M. Randolph, Chair
California Air Resources Board
1001 I St.
Sacramento, CA 95814

RE: 3Degrees Comments in Response to Proposed Amendments to the Low Carbon Fuel Standard Regulation

Dear Chair Randolph and Air Resources Board (ARB) Staff,

Thank you for the opportunity to provide comments in response to the Proposed Amendments to the Low Carbon Fuel Standard (LCFS) Regulation published December 19, 2023 (updated January 2, 2024). 3Degrees Group Inc. ("3Degrees") is a global climate and clean energy solutions provider and is a strong supporter of the LCFS program. We participate in the program as a designated reporting entity on behalf of a variety of opt-in parties with light-duty electric vehicle (EV) chargers, electric forklifts, hydrogen forklifts, and heavy-duty EV fleets. We are also an active fuel pathway developer.

3Degrees appreciates the time and effort that Staff has put into engaging the public and crafting these updates to the program over the last few years. Our recommendations for the LCFS proposed rule are outlined below. Under each heading, we have organized our comments in order of what we view as the key priorities for this formal rulemaking process.

I. Carbon Intensity (CI) Reduction Targets and Credit Market Mechanisms

195.1a **ARB should impose a more stringent near-term carbon intensity reduction schedule to ensure long-term credit price stability.**

The LCFS program has been highly effective at achieving emissions reductions, and we understand that the final target for this rulemaking needs to be feasible as well as effective. The low carbon fuel industry has consistently exceeded the expectations of this program and with the right market signals, the total decarbonization of the transportation sector could be within reach. However, our market analysis shows that the proposed 30% CI target (§ 95484) is too low to provide the near-term price indicators that are necessary to spur the substantial industry investment in lower-CI projects, fuels, and vehicles required to reach the program's long-term goals.

In our comments during the informal rulemaking process, 3Degrees advocated for at least a 35% CI reduction by 2030 and 90% by 2045 in order to align with the ambition of the 2022 Scoping Plan and other decarbonization objectives in California. With credit prices dropping from ~$67 to ~$55 since the publication of the proposed rule, the market reaction to the proposed CI schedule has evidenced a lack of confidence that the near-term target of a 30% reduction by

2030 will require more than minimal additional credit generation to attain. We therefore reiterate our support for at least a 35% target by 2030.

Our market analysis shows that under the proposed rule the credit bank will continue to grow until it peaks in 2030, followed by a sharp drawdown, potentially depleting the bank by as early as 2034. The auto-adjustment mechanism (AAM) would be triggered twice, making the CI reduction target in 2030 38% and reaching 90% reduction in 2043. We expect that prices will only begin to rise once the bank begins to draw down.

While lower near-term prices may achieve the objective of reducing total program costs, the post-2030 targets will only be achievable through significant investments in the low carbon fuel sector this decade. Low credit prices will not send an adequate market signal to drive the necessary investment. We are generally supportive of the AAM (§ 95484(b)) and 2025 step-down adjustment (§ 95484(d) - Table 1, footnote b), though we would suggest that the AAM should be able to be triggered earlier, in 2026. This design would lead to fewer surplus credits through the late-2020s and likely result in the higher prices needed to drive investment, thus mitigating pricing volatility with a smoother path towards more ambitious targets.

195.1b

II. Changes to Forklift Crediting

195.2 **3Degrees urges ARB to not phase out technology (e.g., zero-emission (ZE) forklifts) or fuel types from the program via energy economic ratio (EER) adjustments.**

Staff's proposal to adjust the EER for forklifts with lift capacities less than 12,000 kg (§ 95486.1(a) - Table 5) to decrease credit generation opportunities for this technology introduces unnecessary regulatory risk to the LCFS program. In the Initial Statement of Reasons (ISOR), Staff explains that this adjustment is based on a re-evaluation of the forklift baseline; because ZE forklifts have replaced many combustion-fuel forklifts in the State, Staff is assuming that approximately 50% of new ZE forklifts purchased will be replacing older ZE forklifts, effectively neutralizing overall ZE forklift adoption rates. However, not only is this crediting limitation ill founded, it sets a precedent for the reduction of other credit generation opportunities that could threaten the ability to meet program targets, especially in the long-term.

In conjunction with the LCFS, other California policies aimed at decarbonizing vehicle types and fuels, such as the Advanced Clean Cars II Regulation, Advanced Clean Trucks Regulation, and Advanced Clean Fleets Regulation, will inevitably lead to similar situations in which some portion of ZEV purchases for those equipment types will be made to replace existing ZEVs. However, depending on the vehicle type, this does not necessarily mean that older ZEVs will be retired. For example, used light-duty ZEVs with a lower price point may replace fossil fuel vehicles that would not otherwise have been retired. The need for ARB to account for this kind of market dynamic while balancing decarbonization goals against program operability underscores the importance of establishing clear criteria for equipment phase outs.

Arbitrarily halving the EER, defined in the regulation as "the dimensionless value that represents the efficiency of a fuel as used in a powertrain as compared to a reference fuel used in the same powertrain," should not be used as the method to discount forklift credit generation, or that of other technologies or fuels. If ARB must phase out any credit generation opportunity, this should only occur via a well-defined, data-driven methodology that accurately accounts for market saturation and other relevant factors. As noted in our comments during the workshop phase of this rulemaking, the LCFS should provide an off-ramp or other provision geared at a smooth and predictable transition out of the program. A lack of clarity on how other equipment types will be treated under the LCFS as they gain traction may result in reduced investment in these technologies, making it more difficult for the Program to achieve its long-term goals.

195.3 **A metering requirement for forklift credit generation calculations should be phased-in so that industry has time to adjust their equipment and processes.**

While 3Degrees understands the benefits to data accuracy that metering provides, in order for the LCFS program to have an effective metered solution in place, facilities with e-forklifts need sufficient lead time to plan, pay for and install the external meters that are required to measure electrical dispensation into their fleets. The LCFS's estimation methodology has been a cornerstone of the forklift credit generation process and businesses have relied on not needing meters for participation in the program for many years. Changing this rule without some provision of an offramp for estimation, coupled with any reduction to the forklift EER as discussed above, would be significantly disruptive to many current participants.

Should ARB move forward with an immediate metering requirement, we respectfully request that Staff consider a delayed effective date for forklifts that are currently registered in the program. This would allow time for owners of fueling supply equipment (FSE) to acquire the capital, engineering reviews, permits, and equipment necessary to comply.

III. Third-Party Verification Requirements

195.4 **ARB should provide clarification within the new verification provisions for hydrogen and electricity transaction types to ensure that site visit requirements are feasible.**

With the introduction of new third-party verification requirements for certain hydrogen and electricity crediting types, it is imperative that ARB does not take a one-size-fits-all approach to the site visit obligation. Although the sampling plan mechanism as described in the proposed rule would reduce the number of FSE that must be surveyed for a particular site, it would not be reasonable to expect individual site visits for the thousands of disparate sites containing FSE, particularly for designated entities. Furthermore, conducting site visits of all metered residential charging poses practical and privacy implications for homeowners that may outweigh assurances gained by a visual inspection of the meter.

The proposed text states that verifiers must "annually visit each facility; and, if different from the fuel production facility, the central records location for which the records supporting an application or report subject to verification are submitted" (§ 95501(b)(3)). We request that ARB make a revision to this section such that in the case of designated reporting entities or entities with more than a certain number of registered FSE, verifiers need only visit the designated reporting entity's central location for recordkeeping plus a subset of facilities based on a carefully-crafted sampling plan. This would be a typical set of requirements for verification bodies to come to a *reasonable* level of assurance - the standard for a positive verification statement - as opposed to seeking an *absolute* level of assurance by visiting every parking lot in the state with a registered FSE. While we understand that ARB desires to apply verification requirements equally to all reporting entities throughout the LCFS program, the nature of EV charging equipment is such that the verification process could require multiple months of continuous travel to achieve 100% visitation of all sites with registered FSE. This impractical requirement would pose serious issues for verification bodies and designated entities alike. In addition, we ask ARB staff to exempt residential charging from site visit requirements. Failing to make these changes would discourage EV participation in the program, especially for entities with a large number of distributed FSE.

We further recommend that § 95500(c)(1)(E)(1) be revised to state, "EV Charging except as specified under 95491(d)(3)(A) *and 95491(d)(3)(B)*" (new text in italic). This captures both the metered and non-metered residential charging provisions under the exemption.

IV. Other Proposed Amendments

195.5 **The deficit generation penalty for exceeding a predetermined CI score will disproportionately penalize the biogas sector and should be adjusted down.**

According to the proposed rule, beginning in 2025, exceeding the CI score of a fuel pathway will result in both deficits being generated and a claw-back of credits, and the number of deficits per volume of fuel will be 4x the difference between the verified CI and the reported CI (§ 95486.1(g)). If this full penalty is enforced, many well-intending pathway operators will observe large swings in performance, particularly in digester-derived fuels processing organic wastes and newly-certified pathway operations that will likely have unavoidably variable CIs.

The proposed combination of credit clawback and 4x deficit generation effectively creates a 5x penalty for CI deviations. Combined with the fact that the LCFS regulation does not allow for retroactive credit generation for overperformance, this creates an incentive for projects with variable CI scores and/or operations to implement a dramatic safety factor that significantly reduces the benefits of the program for these projects. These projects provide real greenhouse gas benefits as compared to sending those organic materials to landfills, and the proposed penalty may discourage these projects from being built, effectively limiting California's realized greenhouse gas emissions reductions.

We propose either (1) reducing the 4x deficit generation policy and replacing with a 1x deficit penalty or (2) implementing a carve-out for all categories of digester-derived pathways that exceed their certified CI only as a result of organic variability in digester performance. A reduced deficit penalty would be a fairer and cleaner means of ensuring that participants make best efforts to meet assigned CI scores. Additionally, accounting for the operational differences that digester projects face as compared to other LCFS activities is critical to maintaining the equitable treatment of fuels within the program.

195.6 **ARB should continue to allow site-specific data to be used in the Tier 1 calculator for Renewable Electricity from Dairy and Swine Manure.**

In the Tier 1 Simplified CI Calculator for Biomethane from Anaerobic Digestion of Dairy and Swine Manure Instruction Manual (DSM Manual), we ask that ARB revert to the original language requiring that site-specific data take precedence over values from Table A.9 of the Compliance Offset Protocol - Livestock Projects (LOP) as an input to the calculator for solid separation equipment. This change made by ARB in Table 2, L1.(1-6).13, Fraction of Volatile Solids Sent to Anaerobic Storage/Treatment System, and similar language in L4.5 and L4.6 of the Proposed Tier 1 Simplified Calculators, will lead to less precise calculations and an underrepresentation of emission reductions achieved.

Pathways that rely on site-specific values result in a far more accurate CI score than the default. Further, the LOP generally prioritizes site-specific data, also in favor of accuracy. 3Degrees has generated CI projections based on this site-specific data which now may suffer a material deterioration of their CI due to this modification of the DSM Manual. If ARB is not willing to revise the Tier 1 instructions, then we support maintaining the ability to utilize site-specific values for solid separation equipment inTier 2 applications as a reasonable alternative.

195.7 **We encourage ARB to add electric ground support equipment (eGSE) as an eligible credit-generating technology.**

3Degrees recommends that ARB use this rulemaking opportunity to explicitly include eGSE as an eligible credit-generating technology type under the LCFS. eGSE are eligible for crediting under the programs in both Oregon and Washington, and incorporating eGSE into the LCFS would serve to incentivize an industry that is in the early stages of electrification. This would help ensure that the California LCFS remains a driving force for new technologies to transition away from fossil fuels. An EER for eGSE can be easily developed using a similar methodology to that of electric cargo handling equipment (eCHE). This category of electric off road equipment charging should, in line with other clean fuels programs, assign the owner of the FSE as the fuel reporting entity and the credit generator.

195.8 **3Degrees recommends aligning the minimum charging capacity requirement for light-duty fast charging infrastructure (LD-FCI) crediting eligibility with current technological capabilities.**

The proposed minimum charging capacity requirement of 150 kW for LD-FCI (§95486.2(b)(1)(D) and (b)(7)(A)) is higher than currently technically feasible for most EVs to charge. While this capacity standard may be forward-looking, 50 kW would be a more appropriate minimum in line with today's technological capabilities. We suggest a gradual increase in the requirement, for example, ARB could institute a 100 kW minimum in a few years, followed by 150 kW once EV technology has evolved to reliably charge at this level.

3Degrees appreciates this opportunity to provide feedback and we look forward to continuing to work with ARB on the success of the LCFS program. Please reach out with any questions or for further discussion.

Sincerely,

/s/ Helen Kemp

RE: 2024 Proposed Low Carbon Fuel Standard Amendments

Dear Chair Randolph:

On behalf of the members of the American Coalition for Ethanol (ACE), I appreciate the opportunity to comment on the California Air Resources Board (CARB) 2024 proposed amendments to the Low Carbon Fuel Standard (LCFS). Our comments will focus specifically on the proposed "sustainability criteria" for crop-based biofuels, the need to approve E15 use in California, and the importance of E85 and flexible fuel vehicles (FFVs).

Crop-Based Sustainability Criteria

Over the past several years, ACE has been leading the effort to ensure ethanol producers and farmers are part of the climate solution. Our work involves development and advocacy for new LCFS policy in Midwest states and validation of the real-world greenhouse gas (GHG) reductions modern-day corn and ethanol production can deliver at scale. The farmer and locally owned ethanol plants which comprise the grassroots membership of ACE are investing in a variety of strategies and technology innovations to supply California with low-carbon ethanol and believe a properly designed and administered LCFS policy incentivizing climate-smart agriculture practices can support increased use of ethanol.

196.1 Nevertheless, we do not support CARB's sweeping "sustainability criteria" approach to regulate ethanol producers and farmers. The broad and burdensome proposal to require pathway holders to track crop-based feedstocks to their point of origin and obtain independent third-party certification will only serve to discourage participation in the LCFS. Instead, we offer a scientifically driven alternative based on real-world farm practices.

Earlier this year, the United States Department of Agriculture (USDA) made a $25 million investment in a Regional Conservation Partnership Program (RCPP) led by ACE. This USDA RCPP project is designed to unlock corn ethanol access to LCFS markets and new tax incentives based on the adoption of climate-smart agricultural practices which reduce GHG emissions.

The USDA funding will help farmers adopt reduced tillage, nutrient management and cover crops on nearly 100,000 acres across 167 counties surrounding 13 ethanol facilities partnering with ACE to implement the project in the 10-state region of Illinois, Indiana, Iowa, Kansas, Minnesota, Missouri, Nebraska, Ohio, South Dakota and Wisconsin. The sites were strategically chosen to provide our project's scientific team with statistically significant data regarding the GHG effect of conservation practices in different soil types and climates.

american coalition for ethanol

ACE and our partners will accomplish three important objectives with this funding support from USDA. First, we will incentivize farmers in 10 states to adopt conservation practices. Three-fourths of the funding will go toward farmer adoption of practices. Second, our team of soil scientists and agronomists will monitor, measure and verify how the conservation practices adopted by the farmers reduce GHG emissions from corn production. The data they collect will be shared with the U.S. Department of Energy who will use it to pressure test existing models such as the Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model to address real and perceived 'information gaps' which currently prevent farmers and ethanol producers from adequately monetizing climate-smart ag practices. Third, our ultimate objective is to empower ethanol producers and farmers with modeling and calculator tools to earn higher tax credits and premium prices in clean or low carbon fuel markets based on climate-smart ag practices.

Our partners, including 13 ethanol companies and team of technical experts, are currently making plans to ensure farmers in the 167 counties are aware of their eligibility and we hope to execute contracts for initial conservation practices following the 2024 fall harvest. This larger project is based on ACE's existing South Dakota RCPP, where we have more than 15,000 acres in seven counties under contract for climate-smart ag practices. Given the progress we have already made with the South Dakota RCPP project, we are in a good place to hit the ground running on this 10-state project.

196.2 While we may share CARB's goal for better understanding the GHG impacts farming practices have on crop-based biofuels, we disagree feedstocks such as corn must be tracked to their point of origin. Rather, some of the models CARB and other regulators use today to penalize corn ethanol for land use change (LUC) and farm-level practices can be improved and modified to assign carbon credits based on climate-smart agriculture practices. Specifically, we believe the GREET model developed by U.S. Department of Energy's Argonne National Laboratory should be used to assign carbon credits from climate-smart ag practices. GREET currently estimates nitrous oxide emissions from fertilizer use, contains a module for estimating LUC penalties through the Carbon Calculator for Land Use Change from Biofuels (CCLUB), and features a relatively new Feedstock-Carbon Intensity Calculator (FD-CIC) module estimating soil carbon emissions and sequestration credits for practices such as conservation tillage and cover crops on corn production.

Scientists and modelers indicate precipitation, soil type, and temperature are essential factors used to determine the GHG benefits of climate-smart agriculture practices. These same modelers and market regulators such as CARB are reluctant to assign carbon credits for farm-level practices without more locally verified data upon which to validate the GHG benefits. Our USDA RCPP project includes an experienced team of scientists from land-grant universities and the U.S. Department of Energy's Sandia National Lab who have developed a proven mechanism to collect data from farmers in the 167 counties. Our scientific team will be able to assess the real-world carbon sequestration and reductions in carbon dioxide, methane, and nitrous oxide emissions from the climate-smart practices and validate them at a high confidence level required by modelers and market regulators.

The result of this USDA RCPP project will be the establishment of a non-proprietary, scientifically verified tool such as a modified GREET for ethanol producers and farmers to use to document the carbon intensity benefits of changes in agricultural practices that are validated with on-farm data at production level scale.

In short, our USDA RCPP project will establish an alternative to CARB's proposed burdensome and costly quantification and verification protocols that would discourage farmers and ethanol producers from reaping maximum benefits from these practices in the future.

The economic potential of capitalizing on climate-smart farming practices to produce corn ethanol for clean fuel markets or new tax incentives is significant. Through the 13 partner ethanol facilities, there's the potential to remove over 2,679,843 metric tons of CO_2 per year, or the equivalent of taking 596,346 cars off the road annually. Across the 10-state project area, this could amount to over $500 million per year in estimated maximum value from clean fuel markets — a $266 per acre benefit for farmers based on the three-year average LCFS carbon credit price. This potential economic value is similar to what the carbon benefits could be worth under a properly implemented 45Z tax credit. To learn more about this project, visit ethanol.org/usda-rcpp.

E15

196.3 Though technically related to CARB's "Advanced Clean Cars" (ACC) proposed amendments, we must take this opportunity to implore you to once and for all approve the use of E15 in California. Afterall, allowing E15 will help reduce the carbon intensity of the state's gasoline supply and also cut emissions of criteria pollutants. In fact, the Center for Environmental Research and Technology at the University of California Riverside found that replacing E10 with E15 in California will significantly improve air quality.[1] It should also be noted E15 is EPA-approved for nearly all vehicles on the road and offers meaningful cost savings, but Californians are currently paying more at the pump because CARB has not yet approved E15.

E85 and Flexible Fuel Vehicles (FFVs)

196.4 While E15 is not yet allowed for use in California, the availability of E85 enables the state to significantly reduce GHG emissions and save drivers of Flexible Fuel Vehicles (FFVs) substantial money at the pump. We specifically reinforce comments and concerns submitted to CARB from Pearson Fuels on January 15, 2024. Pearson is the largest distributor of E85 in California, supplying more than 350 fueling locations and planning more than 150 additional locations in the next 24 to 36 months.

In its January 15 comment letter, Pearson noted E85 use continues to rise in California but the number of FFVs declined from 2021 to 2022 by nearly 4 percent. As Pearson noted, "absent specific federal or state policy changes to motivate automakers to manufacture FFVs, we expect the FFV population will further shrink as automakers reduce model offerings. This will remove a key tool in the state's push to reduce carbon emissions, scale down petroleum usage, and offer consumers affordable fuel." We urge CARB to work with other state agencies, automakers, and the federal government to incentivize manufacturers to produce more FFVs and convert existing gasoline-operated internal combustion engines to operate on E85.

Thank you for your time and consideration of these comments.

RE: Electrify America comments on Proposed Low Carbon Fuel Standard (LCFS) Amendments

Dear Ms. Sahota:

Electrify America appreciates the opportunity to comment on the Proposed Low Carbon Fuel Standard Amendments. Electrify America is the nation's largest open network of DC fast chargers for electric vehicles (EVs), with over 3,900 ultra-fast chargers across 887 locations around the country, and over 1,100 chargers across more than 250 locations open to the public in California.

The electric vehicle sector is at a critical time in California. The market for new electric vehicles was highly successful in 2023, with approximately one quarter of new vehicles deployed in the state being electric. The result has been a surge in demand for public charging that necessitates a rapid expansion of charging infrastructure. In November 2023, Electrify America reported to CARB that dozens of stations in the state are experiencing above 40% utilization, with multiple sites exceeding 50% utilization for the quarter. At 50% utilization, all charging ports at a station are in use, on average, more than 12 hours per day. Now, more than ever, it is critical that California support the installation of additional charging ports to meet the rising customer demand for clean vehicles.

The LCFS has historically been one of the State's most powerful tools for supporting clean transportation in California, including electric vehicle charging infrastructure deployment. As a leading charging infrastructure developer, Electrify America can attest that every dollar generated from LCFS credits goes directly back into operations and efforts to expand access to affordable, reliable EV charging. As highlighted in the SRIA, the LCFS is poised to add nearly $100 billion in value to the EV ecosystem over the next two decades.[1]

However, at a time when charging infrastructure and the EV market more broadly needs to expand rapidly to achieve California's clean air, climate change, and transportation electrification goals, LCFS credits have rapidly declined in value, with credit generation substantially exceeding deficits over the past several years, leading to a reduction in credit prices. Specifically, after many years of relative stability, the excess of banked credits began

[1] SRIA, Table 24.

increasing rapidly around Q3 2021, more than doubling to a total of over 18 million banked credits by Q2 of last year. Furthermore, independent analysis by ICF demonstrates that the proposed amendments to the program may be insufficient to reverse this trend, resulting in a protracted situation of credit oversupply and low credit values that reduces a critical funding stream for development and operations of charging infrastructure.[2]

197.1 The most important thing CARB can do to stabilize the program is quickly amending the LCFS to appropriately strengthen targets, reverse the trend of accumulating excess credits, and return the program to a state where it continues to drive investments in a broad array of low carbon fuels and infrastructure, including EV charging. To achieve these goals, and based on the analysis by ICF,[3] we believe that a 40% reduction target by 2030 is the minimum necessary to stabilize the credit market and ensure that the LCFS program supports a successful transition to electric transportation in California. Given that sentiment and premise, we appreciate your consideration of our comments below.

197.2 **CARB should propose 15-day changes to align with findings from the ICF analysis**

Electrify America has participated in the coalition group working with ICF to analyze market appetite for low carbon fuels and associated appropriate targets for the LCFS. We support the overarching finding of the analysis, that a 2030 target of greater than 40% is appropriate and can be readily supported by the market. A target of at least 40% by 2030 is likely necessary to align with California's climate change goals and Scoping Plan outcomes, as well, which calls for a 40-48% reduction in greenhouse gas emissions by 2030. Given the fact that transportation fuel pathways account for about half of California's greenhouse gas emissions, LCFS targets that align with statewide greenhouse gas reductions are reasonable.

In fact, at least as it relates to electricity-related pathways, we have reason to believe that the assumptions in the ICF analysis are conservative. For example, while the assumptions assume minimum compliance with the Advanced Clean Cars II sales, in fact, EV sales in California consistently outperform regulatory requirements, and we expect that to continue into the future. Already, zero emission vehicle sales comprise about a quarter of California's new vehicle market, a market share not anticipated until the 2026 model year under the Advanced Clean Cars II rules. We also anticipate further innovation and efforts to reduce the carbon intensity of electricity used as transportation fuel in California. For example, Electrify America's network in California is backed by 100% renewable electricity. We expect others will increasingly do the same, reducing the carbon intensity of power for EV charging well below the grid average, and delivering additional LCFS credits into the market.

[2] ICF (2024) Analyzing Future Low Carbon Fuel Targets in California: Response to Staff Report, ICF Resources, LLC, February.

[3] ICF (2023) Analyzing Future Low Carbon Fuel Targets in California: Initial Results for Accelerated Decarbonization, Central Case, ICF Resources, LLC, June. https://ww2.arb.ca.gov/system/files/webform/public_comments/4306/Analzying%20Low%20Carbon%20Fuel%20Targets%20-%20Central%20Case%20Draft%20FINAL%20%28submit%29.pdf

Following the release of the Proposed Amendments, ICF conducted additional analysis to incorporate updated market data, evaluate CARB's proposed targets, and adjust assumptions into the scenario analysis to reflect prevailing assumptions from CARB. Their analysis reinforces
197.3 their earlier findings that CARB's proposed targets are too low, and that the step-down and auto acceleration mechanism as proposed in the 45-day regulatory package are insufficient to flatten or reverse the credit bank and restore market conditions that support ongoing investments in EV charging and other low carbon fuels.

Electrify America supports the findings of the ICF analysis and urges CARB to propose 15-day changes to the regulation that would do the following:

- 197.4 Increase the step-down to 20-25%, and have it take effect as soon as the regulation does in 2024.
- 197.5 Increase the 2030 target to at least 40%, in line with Scoping Plan targets.
- 197.6 Modify the AAM so that it:
    - Would be triggered when banked credits exceed 2-2.5 times quarterly deficits.
    - Can apply to calendar year 2025 data, potentially be triggered in 2026, and the compliance schedule can be potentially pulled forward in starting in 2027.
    - Can be triggered in consecutive years if market conditions warrant.

Comments on additional elements of the Proposed Amendments

Electrify America offers the following comments on other aspects of the Proposed Amendments:

- 197.7 We support the proposed capacity crediting provisions for zero emission vehicle infrastructure, including shifting FCI crediting proposals to medium and heavy-duty vehicles (MHD-FCI) and targeted deployments for light-duty vehicles (LD-FCI).
- 197.8 We support amendments to clarify that the owner of EVSE at multi-unit dwellings that is not serving a dedicated or reserved parking space is eligible to generate credits.

Thank you again for the opportunity to comment on the Proposed Amendments. We appreciate CARB's efforts to support the transition to EVs in California and look forward to continuing to work with CARB through the LCFS amendment process and in other forums to advance the State's transportation electrification and climate change goals. Please do not hesitate to reach out with any questions.

Sincerely,

DocuSigned by:

RE: Electric Hydrogen Comments on Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

Thank you for the opportunity to provide comments regarding the proposed low carbon fuel standard amendments. Electric Hydrogen respectfully submits the following comments and proposed amendments, which are intended to facilitate the adoption of green hydrogen production at scale, as a transportation fuel as well as a feedstock in the production of transportation fuels for conventional and low and zero-carbon liquid transportation fuels (including sustainable aviation fuel, power-to-liquids, and renewable diesel).

With significant facilities, management groups, and employees in California and Massachusetts, Electric Hydrogen manufactures the world's most powerful electrolyzers for critical industries to produce low-cost green hydrogen. Our 100 MW electrolyzer plant is designed to load follow variable renewable energy resources and enable customers to efficiently convert renewable electrical energy into clean molecular energy in the form of hydrogen. Electric Hydrogen's mission is to achieve cost parity with fossil fuels in a timeframe that matters. Put another way, the company exists to make green hydrogen an economic inevitability, giving hard to decarbonize industries, like heavy-duty transportation, aviation, and maritime transport, a viable and cost-effective solution to meet their urgent net-zero climate objectives.

Green hydrogen is a necessary tool in the energy transition to a net-zero economy. The 2022 California Scoping Plan for Achieving Carbon Neutrality notes that for California to achieve its net-zero goal by 2045, California will have to increase green hydrogen production 1700-fold.[1]

Within the transportation sector, green hydrogen has multiple applications for helping lower GHG emissions. In addition to green hydrogen used as a transportation fuel in fuel cell electric vehicles (FCEVs), hydrogen is a necessary feedstock in both conventional petroleum fuels and many low and zero-carbon liquid transportation fuels including renewable diesel, sustainable aviation fuel (SAF), power-to-liquids (PtL), and maritime fuels including methanol and ammonia.

---

[1] California Air Resources Board. *2022 Scoping Plan for Achieving Carbon Neutrality.* December 2022, page 8. https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf

Enabling the adoption of green hydrogen as both a transportation fuel in FCEVs as well as a feedstock in other transportation fuels can drive emissions reductions in both the near and long-term. Low and zero carbon liquid transportation fuels for heavy duty and long-haul transportation applications such as aviation and maritime shipping will be needed for the foreseeable future. CARB's scoping plan calls for meeting 80% of aviation fuel demand in 2045 with sustainable aviation fuel and power-to-liquids—fuels that require hydrogen as a feedstock in their production.[2] The scoping plan acknowledges the role that low-carbon liquid fuels will play for the foreseeable future and calls for continued state support: "the state must continue to support low-carbon liquid fuels during this period of transition and for much harder sectors for ZEV technology such as aviation, locomotives, and marine applications."[3]

Leveraging the LCFS to incentivize liquid transportation fuel producers to switch from gray to green hydrogen can also help the green hydrogen industry scale and in turn reduce the cost of green hydrogen which will enable greater adoption of FCEVs in medium and heavy-duty transportation. California's existing annual hydrogen production capacity is approximately 1.83 million metric tons. However, only about 5000 metric tons (less than 0.3% of current production capacity) is used to fuel FCEVs.[4] While the FCEV market for green hydrogen is expected to grow in the coming years, it will remain small compared to the market for green hydrogen as a feedstock in liquid transportation fuels. Ensuring that developers producing green hydrogen for the FCEV market as well as the liquid transportation fuel market can benefit from LCFS eligibility would accelerate green hydrogen adoption, reduce emissions, and reduce the cost of green hydrogen creating a virtuous cycle enabling greater adoption of FCEVs.

To enable the LCFS eligibility of green hydrogen as a feedstock in liquid transportation fuels, Electric Hydrogen recommends the following three amendments to the LCFS staff draft.

- Allow book-and-claim delivery of low-CI electricity for electrolytic hydrogen production used as a feedstock in liquid transportation fuel.
- Allow book-and-claim delivery of low-CI hydrogen in dedicated hydrogen pipelines outside of California for transportation fuel sold into the California market.
- Allow delivery of low-CI electricity via book-and-claim for electrolytic hydrogen production in the Renewable Hydrogen Refinery Credit Program.

198.1 **Allow book-and-claim delivery of low-CI electricity for electrolytic hydrogen production used as a feedstock in transportation fuel.**

§ 95488.8. subsection (i)(1) restricts the use of book-and-claim delivery of low-CI electricity to electrolytic hydrogen used in FCEVs. This provision artificially limits the market for LCFS

---

[2] California Air Resources Board. *2022 Scoping Plan for Achieving Carbon Neutrality.* December 2022, page 73. https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf

[3] California Air Resources Board. *2022 Scoping Plan for Achieving Carbon Neutrality.* December 2022, page 190. https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf

[4] Justin Bracci, Adam Brandt, Sally M. Benson, Gireesh Shrimali and Sarah D. Saltzer, *"Pathways to Carbon Neutrality in California: The Hydrogen Opportunity",* Stanford Center for Carbon Storage and Stanford Carbon Removal Initiative, February 2022, page 2.

eligible green hydrogen to less than 0.3% of California's current hydrogen market. Refineries and other fuel production facilities that produce the lion's share of hydrogen in this State (whether conventional, SAF, renewable diesel, or power-to-liquids) typically lack both the land and the solar/wind resources necessary to produce the hundreds of megawatts or gigawatts of renewable generation required to turn grey hydrogen production into green hydrogen production. Without amendment, this restriction will unnecessarily limit growth of the green hydrogen market and miss an important opportunity for California to drive emissions reductions in the transportation sector. It is also inconsistent with CARB's scoping plan which, as noted previously, calls for continued state support for low and no-carbon liquid transportation fuels to decarbonize hard to decarbonize transportation modes including aviation, maritime, and heavy and medium duty transportation.

Extending the ability to utilize book-and-claim delivery of low-CI electricity in hydrogen production for liquid transportation fuels would also create a level playing field with hydrogen produced from renewable natural gas (RNG). § 95488.8 subsection (i)(2) of the staff draft allows for the utilization of book-and-claim delivery of RNG, including for RNG used in the production of a liquid transportation fuel. This allowance applies to production of any kind of liquid transportation fuel including both conventional gasoline and diesel as well as low and zero-carbon liquid transportation fuels.

Electric Hydrogen respectfully requests that CARB amend the current staff draft to allow for book-and-claim delivery of low-CI electricity for hydrogen used as a feedstock in any liquid transportation fuel. This approach would maximize the potential for green hydrogen adoption and emissions reductions and match the treatment CARB has extended to RNG. However, if CARB is concerned with extending this policy to green hydrogen used in conventional gasoline and diesel refineries, CARB should at a minimum allow for book-and-claim delivery of low-CI electricity in green hydrogen production used as a feedstock in low and no-carbon liquid transportation fuels including sustainable aviation fuels, power-to-liquids fuels, and renewable diesel.

198.2 **Allow book-and-claim delivery of low-CI hydrogen in dedicated hydrogen pipelines outside of California.**

§ 95488.8 subsection (i)(3) restricts the use of book-and-claim delivery of low-CI hydrogen in dedicated hydrogen pipelines to pipelines physically connected to California. California currently has only 17 miles of dedicated hydrogen pipelines. However, nationwide there are about 1600 miles of dedicated hydrogen pipelines, of which about 1300 miles are concentrated in the Gulf Coast.[5] This existing hydrogen pipeline infrastructure network serves a variety of industrial customers, including both conventional and low-carbon fuel producers selling liquid transportation fuels into the California market. This restriction limits the ability of these fuel producers to utilize green hydrogen to lower the carbon intensity of their liquid transportation fuels. The optimal policy would be to allow book-and-claim delivery of low-CI hydrogen in any dedicated hydrogen pipeline serving as a feedstock in any fuel. However, if CARB is concerned

[5] Justin Bracci, Adam Brandt, Sally M. Benson, Gireesh Shrimali and Sarah D. Saltzer, *"Pathways to Carbon Neutrality in California: The Hydrogen Opportunity",* Stanford Center for Carbon Storage and Stanford Carbon Removal Initiative, February 2022, page 25.

with extending this policy to hydrogen used in conventional gasoline and diesel refineries, CARB should at a minimum allow for book-and-claim delivery of low-CI hydrogen in dedicated hydrogen pipelines when that low-CI hydrogen is used as a feedstock in low and no-carbon liquid transportation fuels such as sustainable aviation fuels, power-to-liquids fuels, and renewable diesel.

198.3 **Allow delivery of low-CI electricity via book-and-claim for electrolytic hydrogen production in the Renewable Hydrogen Refinery Credit Program.**

§ 95488.10 subsection (f) prohibits the delivery of low-CI electricity via book-and-claim for electrolytic hydrogen production in the Renewable Hydrogen Refinery Program. Requiring onsite renewable electricity generation restricts the program to pilot scale projects thereby limiting the efficacy of the program in reducing emissions.

California currently has 20 hydrogen production facilities with 1.83 million metric tons of annual hydrogen production capacity. The median production capacity of the fleet is 226,517 metric tons per year.[6] To fully decarbonize the hydrogen supply at the median-sized facility would require 1.3 GWs of electrolysis capacity assuming a 100% utilization rate and a plant efficiency of 50 kWh/kg H2. A more realistic utilization rate of 50% would increase the requirement to 2.6 GWs of electrolysis capacity. To meet even the 50% utilization rate would require an oversizing of the renewable generation capacity relative to the electrolysis capacity. Hence, to decarbonize even half of the median hydrogen production facility in California would require renewable generation on the scale of the Alta Wind Energy Center in Kern, County, which is the largest wind farm in the United States.

Requiring onsite renewable generation to decarbonize even a portion of a refinery's hydrogen production requires more land than refineries have available onsite. Allowing for the delivery of low-CI electricity via book-and-claim for electrolytic hydrogen production would allow refineries to utilize this program to lower emissions. Without this amendment, this program will likely continue to be underutilized.

<u>Conclusion:</u>

EH2 is committed to helping California meet its climate goals. We appreciate CARB's consideration of the three proposed amendments, and we look forward to continuing to work with CARB on this critically important effort.

Sincerely,

Paul Wilkins

Paul Wilkins
Vice President for Policy and Government Engagement

Hello,
I am submitting comments on behalf of DTE Vantage to Chair Randolp
and Members of the California Air Resources Board. DTE Vantage
appreciates the opportunity to provide the agency with these
comments and commends CARB for its efforts and dedication to this
program and amendment process.

DTE Vantage welcomes any opportunity to meet with the agency or
provide any follow-ups should there be any questions regarding the
outlined recommendations. Thank you for your time and
consideration.

Best,
Jo
On behalf of DTE Vantage

Board Comments Home

DTE VANTAGE

February 20, 2024

The Honorable Liane Randolph
Chair, California Air Resources Board
Low Carbon Fuel Standard Program
1001 I Street
Sacramento, CA 95814

RE: December 19, 2023, Proposed Amendments to California's Low Carbon Fuel Standard

Dear Chair Randolph and Members of the California Air Resources Board,

DTE Vantage (DTE) appreciates the opportunity to provide written feedback on the proposed amendments to California's Low Carbon Fuel Standard (LCFS) program. DTE is a developer, owner, and operator of biomass, co-generation, and landfill gas electricity facilities in California and nationally, supplies renewable natural gas (RNG) to the state, and participates in the LCFS program.

Our company has invested millions of dollars in California's decarbonization goals, in part due to the strong market signal provided by the LCFS program. By spurring investment and innovation, the LCFS has been and can continue to be a critical tool for achieving the state's objectives to reduce the carbon intensity of the transportation sector, while continuing to set a leading example for other states and jurisdictions to follow to drive performance-based emission reductions in the transportation space.

We appreciate the California Air Resources Board's (CARB) efforts to engage stakeholders as it considers changes to the program and respectfully submit the following comments for your consideration.

199.1 **Further Increasing the Stringency of the Program Will Accelerate California's Transportation Decarbonization Goals**

199.2 CARB has an opportunity in this amendment process to enhance the market signal to low carbon fuels and drive further greenhouse gas (GHG) emissions reductions by increasing the program's stringency. DTE strongly supports CARB's efforts to strengthen the LCFS program in this proposal. We are encouraged by the Agency's proposal to increase the 2030 carbon intensity (CI) targets from 20% to 30% by 2030, with a one-time 5% reduction in 2025. However, we urge the Agency to consider even more stringent reduction goals to support California's ambitious climate targets and address the current LCFS market imbalance.

DTE Vantage's internal modeling suggests that the currently proposed changes to the LCFS program are not sufficient to address the growing credit bank. In fact, we predict that the credit bank could increase to over 80MM credits by 2030 absent additional changes to the latest proposed rules. Failing to curb the growing credit bank could undermine necessary investments in low carbon fuels and unwind the clean fuels market needed for California to meet its goals. If the credit bank swells to 2x - 4x its current size, credit pricing may decrease to the point that further decarbonization investments are no longer incentivized and existing projects may be forced to shut down for economic reasons. Our recommended actions will establish a more robust LCFS program that will continue to drive innovation and accelerate GHG emissions reductions.

To CARB's credit, the LCFS program has overperformed in recent years, creating greater reductions than required, and leading to a significant oversupply of credits. The cumulative LCFS credit bank now stands at ~20.6 million surplus credits, while LCFS prices continue to decline, hovering around $65 per ton in January 2024. We encourage CARB to target at least a 40% CI reduction by 2030 to correct its course and address the credit surplus.

Additionally, due to the size of the current credit bank and the ongoing credit surplus, we believe that CARB's proposed 5% step-down in 2025, while helpful, is unlikely to impact the market at the scale needed. DTE encourages the Agency to consider increasing the step-down provision's size to 10% to appropriately address the current state of credit and deficit creation. A decisive step-change reduction in 2025 would provide a signal of strong intent by the Agency to support both short- and long-term investment to meet California's climate goals.

Finally, we applaud CARB's proposal to integrate an auto-acceleration mechanism to increase the stringency of the annual CI targets of the program when triggered by clear criteria. However, like our recommendations above regarding the CI reduction target and the step-down mechanism, we encourage CARB to be more ambitious in its proposal to ensure the greatest progress in achieving the goals of the LCFS. We recommend the agency adopt the auto-acceleration mechanism earlier, as soon as 2025, to allow triggering as early as 2026 and ensure the current surplus is addressed promptly and efficiently. There is no rationale for delaying the implementation of the acceleration mechanism given its triggering criteria, however substantial risk exists if the mechanism is delayed resulting in further growth of the credit bank.

199.3 **CARB's Proposed Remedy of a 4x Penalty for CI Exceedance is Excessive and will Disproportionately Impact Agriculture Facilities**

DTE Vantage incorporates by reference the comments submitted by the RNG Coalition dated February 20, 2024, which reflect our stance on CARB's proposed penalty for CI exceedance.

"We continue to support a full true up to verified actual CI performance for all pathways (temporary, provisional, and fully certified). Dairy Manure Digesters (and other biological systems) experience substantial increases and decreases in gas production due to weather, livestock herd changes, and other uncontrollable factors that are not present in other fuel pathways. Because the carbon intensity of the gas from these systems is calculated against a quantity of avoided methane emissions, these variations in biogas production necessarily result in outsized changes in the digester pathways' carbon intensity (CI) scores every year. Under the current structure of the LCFS (prior to the changes proposed in this rulemaking), all dairy digesters pathways experience the following negative impacts:

1. Substantial underestimation of greenhouse gas benefit (and associated lost revenue) during the project startup (temporary pathway) period.
2. Substantial risk of underestimation of greenhouse gas benefit (and lost revenue) each year during annual verification.
3. Substantial risk of LCFS enforcement, resulting in fines or potential pathway cancellation, due to no fault of the pathway holder.

These consequences are an unavoidable outcome of CARB's overly conservative approach to dairy digester pathways (and some other pathways with biological feedstocks) under the current LCFS structure. As we will describe below, no amount of careful management, conservative pathway assumptions, or other actions can fully protect a digester under the Current Rule—and the Proposed Rule's changes alleviate some, but not all, of these concerns."[1]

DTE Vantage understands CARB's focus on program integrity and the importance of recouping excess credits created by CI scores, adjusted during reviews. However, imposing a 4x penalty for adjustments not resulting from misconduct is unwarranted and unfair. DTE agrees with a party refunding excess credits received (despite the fact that CARB does not award additional credits when a review finds that a lower CI score was warranted) but opposes the 4x penalty. This punitive provision is not justified by any history of problems with the program, and the existing documentation and 3rd party review requirements already provide adequate protection for the program. DTE strongly encourages CARB to eliminate this multiplier penalty. Conversely, providing a true up mechanism whereby excess credits are refunded back to CARB and additional credits are awarded following a review showing that a lower CI score was warranted would be an acceptable solution to the inherent variability in dairy manure digester pathways. DTE Vantage is in agreement with the system proposed by the Coalition for Renewable Natural Gas' comment letter dated 2/20/2024.

199.4 **Reconsider Proposed Concepts Related to Phasing Out Avoided Methane Crediting and Aligning Deliverability Requirements of Biomethane as a Transportation Fuel with RPS and CPUC 1440 Program**

DTE Vantage remains highly concerned with CARB's proposed changes to phase out avoided methane crediting and remove book-and-claim accounting for out-of-state biomethane.

We strongly urge CARB to reconsider its proposed changes to eliminate RNG pathways that rely on book-and-claim delivery mechanisms for pathways associated with projects that break ground on or after January 1, 2030. As identified in previous comment letters in response to the CARB

[1] RNG Coalition's Comments on Low Carbon Fuel Standard Initial Statement of Reasons dated 2/20/2024

LCFS workshops on 2/22/23 and 5/23/2023, DTE's primary areas of concern with this proposal are as follows:

- At present time, there are insufficient outlets available in other markets and end uses to absorb RNG that would otherwise supply the LCFS transportation market.
- Because CARB is proposing to remove the option of a fuel that competes well in the market to continue to enter the fuel mix, credits that otherwise would be generated from out-of-state RNG will presumably be replaced by more expensive alternatives. Thus, the agency's proposal will make compliance more expensive for Californians.

We also urge the agency to continue its avoided methane crediting methodology to preserve and promote meaningful GHG emission reductions for pathways associated with projects that break ground on or after January 1, 2030. Clean fuel providers made significant investments in dairy RNG projects based on the avoided methane crediting construct, which are mitigating fugitive methane emissions on farms. California's SB 1383 targets a 40% reduction in total methane emissions and a 40% reduction in dairy and livestock emissions. To meet these goals, we recommend that CARB reconsider eliminating avoided methane crediting of the LCFS program.

Conclusion

In summary, DTE Vantage appreciates the opportunity to provide the agency with these comments and commends CARB for its efforts and dedication to this program and amendment process. As the Agency looks to finalize this rulemaking, we strongly encourage CARB to implement the following changes:

- At least a 40% CI reduction target in 2030,
- Increase the step-down provision to 10% in 2025,
- Effectuate the auto-acceleration mechanism in 2025,
- Implement symmetrical CI true up mechanism for pathways known to have inherent variability,
- Continue to allow RNG pathways that rely on book-and-claim delivery mechanisms and avoided methane crediting methodology to promote meaningful GHG emissions reductions.

We would welcome the opportunity to meet with the agency should there be any questions regarding our recommendations. Thank you for your consideration of our comments.

Sincerely,

Philip O'Niel

Vice President – DTE Vantage

Board Comments Home

Tuesday, February 20, 2024
California Air Resources Board
1001 I Street
Sacramento, CA 95814
By email: isd@arb.ca.gov, LCFSWorkshop@arb.ca.gov + *submitted via online portal*

To Whom It May Concern:

Attached are the Environmental Justice Advisory Committee's comments from our final 2022 Scoping Plan recommendations, along with the 8 point resolution adopted and discussed during our 2023 and 2024 meetings. While the recommendation language points to the 2022 Scoping Plan, many of the recommendations remain relevant to the rulemaking process, as well as providing foundational context for the resolution. We look forward to receiving direct responses to these recommendations and are hopeful that staff and the board will work to substantively integrate equity considerations into the Low Carbon Fuel Standard.

Sincerely,

Martha Dina Argüello, EJAC Co-Chair, Physicians for Social Responsibility-Los Angeles

Dr. Catherine Garoupa, EJAC Co-Chair, Central Valley Air Quality Coalition

Non-Fossil Fuel Energy Generation	Type of Activity
"CARB should" is implied at the start of every recommendation.	

		Biogas	
200.1	NF41	CARB must acknowledge the significant environmental justice and sustainability concerns around biogas and particularly biomethane, including: (1) the incentivizing of ongoing and expanded, massive dairies and their associated impacts to the air, water, odor, and well-being of local communities; (2) the perpetuation of a polluting natural gas industry via sustained gas infrastructure; and (3) the improper accounting of emissions and emissions reductions from dairies in the state's credit schemes, which additionally allows ongoing oil and gas emissions.	Action/ Analysis
200.2	NF42	CARB and other state agencies must regulate livestock methane starting in 2024 instead of relying solely on incentives to yield dairy methane reductions, and do so in a manner that advances co-equal benefits to local air and water quality, odor, and community well-being.	Interagency Coordination
200.3	NF43	CARB must commit in the Scoping Plan to examining the life cycle impacts of dairy biogas to ensure the state is relying on the most accurate assessments of the technologies and fuels making up California's long term GHG reduction strategy. If a rulemaking is not already underway, the Scoping Plan must commit to addressing the problems and impacts of dairy biogas in a dedicated Low Carbon Fuel Standard (LCFS) rulemaking. LCFS Pathways certifications for dairy biogas should be paused until the conclusion of the rulemaking.	Action/ Analysis
200.4	NF44	Increase LCFS stringency to at least 30%–35% to meet the Governor's stated goal. This will force a more rapid removal of NOx- and black carbon-emitting internal combustion engine (ICE) powered stationary and mobile sources.	Action
200.5	NF45	Exclude polluting fuels like biogas, biofuels, and factory farm gas from the LCFS and any other definition of clean, renewable, and/or zero-carbon energy.	Action
200.6	NF46	Regulate dairies to limit methane instead of producing factory farm gas that benefits oil and gas companies and artificially delays progress to zero emission transportation.	Action
200.7	NF47	The SB 1383 moratorium on regulation expires in 2024, and as the Scoping Plan is a five-year plan, it must include a plan to begin regulating emissions from dairies in 2024. In the alternative, direct the upcoming LCFS rulemaking to address these issues, and pause certification of LCFS pathway applications that include these polluting fuels until the completion of the 2024/2025 rulemaking.	Action
200.8	NF48	Ensure that materials used to produce transportation fuels do not incentivize feedstocks and production practices that result in air quality and water quality degradation. Fuels derived from livestock and dairy manure must be excluded from the LCFS, and the LCFS must be reformed to ensure that its implementation does not negatively impact low-income communities, communities of color, and areas already suffering environmental degradation including areas that are in nonattainment status for state and federal air quality standards.	Action
200.9	NF49	A dramatic increase in alternative fuel production must not come at the expense of a transition to clean electricity, global deforestation, unsustainable land conversion, environmental justice, or adverse food supply impacts, to name a few examples. Staff must continue to monitor scientific findings on these topics to ensure that California	Action

	policies, such as the LCFS, send appropriate market signals and do not result in unintended consequences. AB 32 Environmental Justice Advisory Committee, Draft Recommendations, F1E. *ejacrecsrevised.pdf* (ca.gov).	
NF50 200.10	Accelerate the reduction and replacement of fossil fuel production and consumption in California. AB 32 Environmental Justice Advisory Committee, Draft Recommendations, F3. *ejacrecsrevised.pdf* (ca.gov).	Action
200.11 NF51	Incentivize private investment in new non-polluting and zero-carbon fuel production in California.	Action / Investment
NF52	Invest in the infrastructure to support reliable refueling for transportation such as electricity.	Investment
NF53	Evaluate and propose, as needed, changes to strengthen the Cap-and-Trade Program, including eliminating eligibility for offsets that result in either the perpetuation or increase in local air or water pollution.	Action
NF54 200.12	Initiate a public process focused on options to increase the stringency, integrity, and scope of the LCFS: • Evaluate and propose accelerated carbon intensity targets pre-2030 for LCFS. • Evaluate and propose further declines in LCFS post-2030 carbon intensity targets to align with the Final 2022 Scoping Plan. • Consider integrating opt-in sectors into the program. • Provide capacity credits for electrolytic hydrogen and electricity for heavy-duty fueling. • Evaluate and ensure full life cycle emissions from all LCFS pathways and each LCFS project, including all upstream and downstream • Evaluate and ensure that credits issues pursuant to the LCFS are based additional GHG emission reductions and were not already accounted for through other state or federal funding and incentive programs • Ensure that LCFS pathways and projects do not disproportionately impact communities of color, low-income communities, or communities already disproportionately burdened by environmental degradation and do not conflict with efforts to ensure that regions attain state and federal air quality standards. • Reevaluate the carbon intensity value of livestock and dairy gas based on a full life cycle analysis, an analysis of additionality for each project, and relevant regulatory programs. • Evaluate whether to remove livestock and dairy gas from the LCFS based on the role of the LCFS in incentivizing herd concentration near pollution-burdened communities and in pollution-burdened regions, accurate GHG emissions analyses, and conformity with additionality requirements.	Action / Analysis /
NF55 200.13	Monitor for and ensure that raw materials used to produce low-carbon fuels or technologies do not result in unintended consequences, including allowing for ongoing	Action / Analysis

	pollution in low income communities, communities of color, and environmentally burdened regions and communities.	

Fossil Fuel Industry and Transportation		Type of Activity
	"CARB should" is implied at the start of every recommendation.	
F1	**Transportation / Reducing Vehicle Miles Traveled (VMT)**	
F1E 200.14	**Send a strong signal that CARB plans to amend the Low Carbon Fuel Standard (LCFS) to reflect serious climate and sustainability concerns.** CARB must be clear about the very limited supply of sustainable, carbon-free liquid and gaseous fuels and avoid using them in any sectors where it is feasible to implement solutions that are zero-emission for both air pollution and GHGs. CARB has previously identified these environmental sustainability concerns in the 2018 CARB LCFS Environmental Assessment. Previous PATHWAYS modeling included a biofuels module that chose to exclude purpose-grown crops because of their harmful environmental impacts and climate risks and further limited the biomass used to in-state production in addition to California's population-weighted share of total national waste biomass supply. Without intervention, the majority of renewable diesel and sustainable aviation fuel produced in the state will come from food crop and food system oils, predominantly soybean oil. A chief substitute for soybean oil is palm oil, whose production has been linked to significant deforestation and associated carbon sink loss. After a decade of studies, the European Parliament has voted to restrict use of soybean oil as a feedstock, by providing that it would no longer be counted toward the quota for first-generation biofuels. Belgium has already banned soybean oil-based biofuels as of 2022. Although soy is currently the main feedstock concern, distiller's corn oil is a growing concern as well, with the production of ethanol causing major problems in the corn growing states. At the public EJAC meeting on July 25, 2022, Dr. Maureen McCue from Physicians for Social Responsibility-Iowa described significant environmental problems caused by ethanol (using the Iowa experience because Iowa is the largest producer of ethanol in the U.S), including deforestation, soil and nutrient loss, pollinator extinction, and rising food costs. Additional market disruption results from the fact that distiller's corn oil was has long been used in animal feed, before large amounts of it were diverted to produce biodiesel. The Scoping Plan should make clear that California fuels policy will assess and refrain from supporting fuels associated with soy, corn, and any other feedstocks, either due to CI impacts from ILUC, other environmental harms, or food system disruptions. At the very minimum, CARB should commit to establishing a cap on the availability of the LCFS subsidy for feedstocks such as soybean oil that carry the highest risks of market disruption or Indirect Land Use Change emissions, based on such factors as feedstock availability and California's proportional share of the distillate fuel market; the availability of LCFS credits should be limited in order to deter production of volumes and types of biofuel that are inconsistent with California's climate planning trajectories. (Malins and Sandford. 2022. *Animal, vegetable or mineral (oil)?* Cerulogy. https://theicct.org/wp-content/uploads/2022/01/impact-renewable-diesel-us-jan22.pdf.)	Action

	(“Soy oil set to follow palm as crop faces biofuel feedstock restrictions,” *Biofuels International* July 14, 2022, *available at* https://biofuels-news.com/news/soy-oil-set-to-follow-palm-as-crop-faces-biofuel-feedstock-restrictions/. Achieving Carbon Neutrality in California: Pathways Scenarios Developed for the California Air Resources Board, California Air Resources Board, Energy and Environmental Economics, Inc., footnote 2 at 19-20, *available at* https://ww2.arb.ca.gov/sites/default/files/2020-10/e3_cn_final_report_oct2020_0.pdf).	
F4	**Carbon Capture and Storage (CCS) and Carbon Capture Use and Sequestration (CCUS) on Refineries, ‘Blue Hydrogen’ or ‘Low-carbon Hydrogen)**	
F4.1 200.15 200.16 210.17 200.18	Do not consider any engineered carbon removal for fossil fuel infrastructure in the 2022 Scoping Plan. a. Revisit the LCFS CCS Protocol to clarify the application of rigorous eligibility and application review criteria specific to different types of fossil fuel infrastructure. Currently, the protocol lacks adequate assessment criteria to evaluate the addition of carbon capture technology to different types of CCS capture facilities, as defined in the LCFS CCS Protocol Section A.2(19). Despite inclusion in the system boundary under Section B.1, the substantive Sections B.2 (Quantification of Geologic Sequestration of CO2 Emissions Reductions), and the entirety of Section C (Permanence Requirements for Sequestration), there must be no question which provisions apply to what types of capture facilities themselves, not only injection and sequestration sites. b. Additionally, the permissibility of weak financial assurance instruments in Section C.7 (Financial Responsibility) is unsupportable. c. Revisit regulations governing the Refinery Investment Credit program, title 17, CCR, section 95489(e), which currently fails to consider the range of risks necessary to protect refinery communities; additionally, amend the regulations to reflect initial assessments and findings from the first examples of CCS projects on fossil fuel infrastructure across the globe. d. Do not authorize LCFS credits for CCS infrastructure in EJ communities that would increase net criteria pollution; knowingly incentivizing projects that would increase net criteria pollutant emissions as described in section 95489(e)(1)(c), perpetuates and worsens a long legacy of environmental racism.	Action

EJAC Resolution re: the Low Carbon Fuel Standard

WHEREAS, the Low Carbon Fuel Standard (LCFS) has exacerbated and entrenched air, water, and odor pollution in communities most impacted by environmental injustices;

WHEREAS, The LCFS has worsened environmental injustice issues across the state, nation, and world by increasing and entrenching pollution on the frontlines of industrial agribusiness;

WHEREAS, California Air Resources Board (CARB) has the authority to regulate methane emissions from livestock as soon as January 1, 2024, pursuant to Health and Safety Code section 39730.7(b).

WHEREAS, the LCFS has exacerbated and entrenched harmful pollution in frontline oil refinery communities;

WHEREAS, the LCFS has exacerbated and entrenched harmful pollution from tailpipes by incentivizing combustion fuels;

WHEREAS, the LCFS has exacerbated and entrenched harmful pollution to global communities from deforestation and using food for fuels;

WHEREAS, the LCFS has exacerbated and entrenched harmful pollution in communities near and regions containing large dairies and other confined animal feeding operations by incentivizing the production, storage, and land application of wet manure;

WHEREAS, insofar as the LCFS reduces carbon emissions from the transportation sector, the provision of LCFS credits for carbon removal such as direct air capture eliminates the possibility of reducing commensurate carbon emissions and co-pollutant emissions from the transportation sector through the LCFS;

WHEREAS, insofar as CARB's goal for carbon removal is to be carbon negative, issuing LCFS credits for carbon removal such as direct air capture (DAC) ensures that it will not be carbon negative but rather offset continued burning of fossil fuels;

WHEREAS, the provision of LCFS credits for direct air capture harms frontline communities both directly with harms and risks from capturing and storing the carbon, and indirectly from displaced renewable deployment that could reduce emissions from fossil fuel power plants, as well as from foregone reductions in transportation sector emissions;

Therefore, be it resolved that the EJAC recommends that the CARB board direct staff to address the above risks, threats, and harms to environmental justice communities by incorporating the following changes, referenced throughout as the "Comprehensive EJ Scenario" into the Low Carbon Fuel Standard through the current rulemaking:

1. Conduct and incorporate a full life cycle assessment of all air pollution and greenhouse gas (GHG) emissions for all pathways, and their implications for environmental justice communities.
2. Conduct a full accounting of GHG and air pollution emissions associated with pathways relying on the production of fuel from livestock and dairy manure.
3. Eliminate avoided methane credits effective January 1, 2024.
4. Eliminate credit generation for pathways relying on the production of fuel from livestock and dairy manure for emissions reductions that otherwise would have occurred or were legally or contractually required to occur.
5. Cap the use of lipid biofuels at 2020 levels pending an updated risk assessment to determine phase out timelines for high-risk, crop-based feedstocks.
6. Prohibit enhanced oil recovery as an eligible sequestration method.
7. Do not issue LCFS credits for carbon removal projects such as Direct Air Capture.
8. Consider the inclusion of intrastate jet fuel and marine fuels as a deficit generator and provide analysis of this option as part of the LCFS.

Be it further resolved that the EJAC recommends that CARB formally consider the Comprehensive EJ Scenario as a regulatory alternative in the LCFS rulemaking process.

Be it further resolved that the EJAC recommends that CARB reform the LCFS to strengthen the Low Carbon Fuel Standard's support for zero emission vehicles including mass transit vehicles, drayage duty trucks, and heavy duty trucks.

Be it further resolved that the EJAC recommends that CARB immediately initiate formal rulemaking for the regulation of livestock methane pursuant to Health and Safety Code section 39730.7(b).

Board Comments Home

February 20, 2024

The Honorable Liane Randolph
Chair, California Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Chair Randolph,

As one of California's leading renewable fuels producers, Aemetis is pleased to submit comments to the California Air Resources Board (CARB) in response to the Proposed Amendments (Proposed Rule) to the Low Carbon Fuel Standard (LCFS) and associated Initial Statement of Reasons (ISOR). We appreciate the leadership you have shown as Chair to address the critical environmental issues of our time and look forward to working closely with you and the CARB staff to advance the next stage of California's landmark LCFS program.

Headquartered in Cupertino, California, Aemetis owns and operates a 60 mgy renewable fuel ethanol plant in Keyes, California, has eight (8) operating dairy biogas digesters (with an additional 40 digesters planned), operates 36 miles of biogas pipeline (with 24 additional miles permitted), and has an operating RNG gas conditioning unit and PG&E gas interconnection. Aemetis is also in the final permitting and engineering phase to build a 78 mgy sustainable aviation fuel (SAF) and renewable diesel (RD) facility in Riverbank, California. Finally, in 2023 Aemetis was granted a characterization well permit for the eventual construction of a 1 million ton per year carbon capture and underground sequestration well (CCUS) at the Riverbank facility.

In short, Aemetis has clearly shown a commitment to the production of low or below zero carbon intensity fuels that will help California achieve its ambitious goals as set forth in the LCFS and other climate and air quality policies and programs. Aemetis plans to invest an additional $1.3 billion in production facilities to capture methane, produce sustainable aviation fuel, and sequester carbon dioxide in California.

LCFS credits are a significant portion of the revenues for a wide variety of renewable energy, carbon capture, and energy efficiency projects. A failure of the LCFS price to be near the price cap is directly correlated with a failure to attract lenders and institutional investors.

201.1 If CARB wishes to attract new investment utilizing the LCFS program, then an ambitious mandate that allows the LCFS price cap to be reached quickly and thereby establish a stable LCFS credit market price is the best way to quickly create confidence in the LCFS program. Any mandate short of a clear price signal that the excess credit bank will be quickly reduced to less than 10 million "excess credits" by year-end 2025 is telling the market that there will always be too many credits – so the price should be low for many years to come.

20400 Stevens Creek Blvd., Suite 700, Cupertino, CA 95014 Main (408) 213-0940 Fax (408) 252-8044
www.aemetis.com

As the rapidly accelerating surplus of LCFS credits weighs heavily on the market and market price for credits, we fear that without immediate and dramatic action by CARB, the LCFS will lag well behind the goals envisioned in the ISOR, and the atmosphere for investment in low or below zero carbon projects in California will shift to other states or regions that promise a more fitting economic return. At the present time, California already has a number of well-established sectors that can rapidly advance the LCFS in the near term. Rather than trading existing low or below zero carbon intensity fuels for technologies that will likely take longer to develop wider market acceptance and implementation, CARB can take immediate action to support both the near- and longer-term goals of the LCFS. We urge CARB to avoid
201.1 cont. making false choices or trading today's low or below zero carbon intensity fuels for tomorrow's promise of better solutions. It is not only possible to have both, but also imperative for the overall success of the LCFS.

To that end, we are concerned that the proposed carbon intensity (CI) compliance curve is inadequate in stimulating the market and needs to be significantly strengthened to draw down the excess credit bank which recently hit a new high of over 20 million surplus credits, with ICF forecasting that the program will have an excess credit bank of more than 30 million LCFS credits by the end of 2024.

The LCFS price was $218 in August 2020, driving investment interest in renewable projects by institutional investors that has now almost disappeared as the LCFS credit price crashed to about $60 in 2023 and recently hit a seven year low at only $55.

Without immediate action by CARB, the LCFS credit price will continue to decline, and investment will stall further. <u>A 2025 target of 25% or greater CI reduction below the 2010 Baseline is needed to address the LCFS credit oversupply issue. This step-down should be implemented in Q3 or Q4 of 2024.</u>

Without immediate and meaningful action this year, investors and obligated parties have little or no incentive to accelerate the implementation of low or below zero carbon intensity fuels in California, which will not only damage existing and planned development, but it will also remove the sense of urgency needed to achieve meaningful carbon reduction in the state's transportation matrix.

Aemetis also encourages CARB to adopt a more aggressive CI reduction target than the 30% by 2030 that was put forward in the January 2, 2024, *Proposed Amendments to the LCFS*. <u>We support a 40% CI</u>
201.2 <u>reduction target by 2030</u>. Extensive quantitative modeling by ICF Resources concludes that implementing this strategy would increase the current approximate $55 credit price to $100-$120 by the end of 2025 and maintain at least that price through 2030.

Additional RNG-related changes are needed to improve investor confidence and increase the pace of methane emissions abatement. We strongly urge CARB to implement the following items that are critical to the near and long-term success of RNG as a fuel or feedstock:

- <u>We support a full true-up to verified actual CI performance for all pathways (temporary,</u>
201.3 <u>provisional, and fully certified)</u>. Dairy Manure Digesters experience substantial increases and decreases in gas production due to weather, livestock herd changes, and other factors that are not present in other fuel pathways. Because the carbon intensity of the gas from these systems is calculated against a quantity of avoided methane emissions, these variations in biogas production necessarily result in outsized changes in the digesters' carbon intensity (CI) scores every year. Under the current structure of the LCFS (prior to the changes proposed in this rulemaking), <u>all</u> dairy digester pathways experience the following negative impacts:

1. Substantial underestimation of greenhouse gas benefit (and associated lost revenue) during the project startup period.
2. Substantial risk of underestimation of greenhouse gas benefit (and lost revenue) each year during annual verification.
3. Substantial risk of LCFS enforcement, resulting in fines (NOV) or potential pathway cancellation, due to weather patterns and at no fault of the pathway holder.

201.3 cont.

Currently, pathway approvals require 18 months or more which imposes severe financial hardships on finished projects and those in planning stages. A full credit true-up would allow completed projects to apply their actual CI performance retroactively to the start of operations and thus eliminate the need to store gas. We support the *Proposed Amendment's* inclusion of a "Credit True Up" after Annual Verification. ***However, the Proposed Amendment's true up language requires re-drafting as it appears to not allow true ups during the temporary pathway period.***

When implemented properly, such a concept can ensure that the LCFS program correctly accounts for the full GHG benefits all fuel pathways produce.

201.4

- The Auto Acceleration Mechanism should be allowed to trigger as early as 2026 using data from 2025. This would dynamically respond in the event of future sustained and significant underestimation of CI reduction targets by further tightening the overall stringency of the program, complement existing mechanisms to avoid credit shortfalls, and better ensure that opportunities to deliver additional reductions of carbon and air pollutants are not foregone.

201.5

- We support the revised Tier 1 calculators and urge improving pathway processing times by utilizing the Tier 1 application as the norm for dairy RNG project applications, not the exception. The current initial review delay of over one year has put existing project capital repayment in jeopardy, and if this persists, will stymie future investment in RNG and other zero or below zero carbon projects. Today, each $4 million completed project must endure an 18- to 24-month administrative review to fully certify the project's LCFS pathway. Given the urgent nature of climate change and the need for methane abatement, this delay is completely unacceptable. Certification should be performed in less than a six-month window, as is the norm with most Tier 1 applications.

201.6

- We strongly oppose the phase-out of avoided methane crediting for dairy RNG projects. Given the importance of LCFS crediting in project viability, it is unwise and irresponsible to propose an arbitrary phase-out of avoided methane crediting without a detailed plan for developing a supporting replacement policy. At current LCFS credit prices, a framework without avoided methane crediting may not even cover operating costs for existing agricultural-based projects. Absent some new market that covers the cost of operations, existing digesters will not continue operating after their avoided methane crediting periods expire, leaving the state with billions of dollars of stranded biomethane capture assets and resulting in methane returning to California's environment or, much worse, the cancellation of projects before they are built.

201.7 Finally, Aemetis strongly encourages CARB to approve 15% ethanol blended gasoline (E-15) in California in 2024. E-15 was first approved by the US EPA in 2012, and California remains the only US State not to adopt an E-15 gasoline blend.

201.7 cont. Over the past 12 years, billions of miles have been driven utilizing E-15, and no notable safety, environmental, or vehicle damage concerns have been presented. In 2023, the US EPA approved E-15 for year-round use. California has performed all of the required air and road testing required to adopt E-15, and yet CARB inexplicably refuses to approve the use of E-15.

Beyond the environmental attributes of renewable E-15 (higher octane, lower tailpipe emissions), E-15 will reduce prices at the pump for California residents as ethanol consistently sells at a discount to gasoline. Californians continue to suffer from higher gasoline prices than most states, which creates economic and environmental harm - especially to marginalized and disadvantaged communities. While Aemetis supports CARB's push for increased adoption of ZEVs and alternative fuel vehicles, longer than anticipated adoption rates require interim steps that can provide immediate GHG reductions. E-15 will allow California to pursue aggressive ZEV adoption over the next decade while reaping the benefits of lower tailpipe emissions today. No action on E-15 keeps gasoline prices artificially high and causes more pollution than necessary.

As the world leader in environmental policy, it seems out of character for California to be the laggard as the only US state to support a 90% petroleum gasoline mandate. We urge CARB to fully approve an E-15 gasoline blend immediately. Otherwise, Californians will endure yet another summer of record setting gasoline prices, economic hardship, and increased air pollution.

We appreciate the opportunity that CARB has provided for input on the Proposed Rule/LCFS, and the ongoing dialogue that you have encouraged through workshops, meetings, and written comments. We strongly support the efforts that you and the CARB staff have made to include feedback from all interested parties, and we look forward to working together as this important next step is taken to achieve net carbon neutrality.

Sincerely,

Andy Foster
President
Aemetis, Inc.

Deere & Company
One John Deere Place Moline, IL 61265

Dr. Cheryl Laskowski
Branch Chief, Low Carbon Fuel Standard
California Air Resources Board
1001 I Street, Sacramento, CA 95815

Re: 2024 Proposed Amendments to the Low Carbon Fuel Standard Regulation

Dear Dr. Laskowski,

Deere & Company ("John Deere") appreciates the opportunity to submit these comments in response to the proposed Low Carbon Fuel Standard (LCFS) amendments, published in January 2024, to the California Air Resources Board (CARB).

John Deere's customers play a critical role in producing crop-based feedstocks for California's liquid biofuels and can directly contribute to measurable reductions in carbon intensity (CI) of the state's overall energy mix. The U.S. renewable fuels sector provides thousands of jobs to rural communities, enhances U.S. energy security, provides cleaner-burning transportation fuels to U.S. consumers, and generates additional value for farmers. It is John Deere's hope that, backed by strong clean fuels policies like California's LCFS program, farmers can continue to add positively to our nation's economy and play a key role in reducing emissions within the transportation sector.

202.1 Respectfully, John Deere opposes the "***Sustainability Requirements for Crop-Based and Forestry-Based Feedstocks***" in CARB's latest proposal. These deforestation-focused requirements would create broad, inequitable administrative burdens for the agricultural sector without significant benefits towards the stated goal of minimizing CI associated with biofuel feedstock production. For example, most of the crop-based feedstocks for fuel ethanol used in California are produced by U.S. corn farmers[1], where corn production efficiency improvements have drastically out-paced growth in corn acreage. Specifically, average bushel per-acre yield has seen a 400% increase since the mid-1900s while total harvested acres of corn have increased by less than 25%, according to USDA data[2].

The California LCFS could more effectively meet its sustainability goals by recognizing voluntary farm emissions reductions that contribute to the reduced CI of fuels, allowing biofuel producers to use field-level CI data in their fuel pathways, and enabling farmers to receive a fair share of the economic value generated.

Deere recommends that CARB add voluntary incentives for farmers to leverage sustainable practices and utilize field-level data that demonstrate a reduction in CI instead of the proposed mandatory certification

---

[1] California State Energy Profile, U.S. Energy Information Administration (2023). www.eia.gov/state/analysis.php?sid=CA
[2] USDA, Economic Research Service, National Agricultural Statistics Service (2023). www.ers.usda.gov

laid out in the "***Sustainability Requirements.***" Deere believes the certification requirement for crop- and forestry-based feedstocks is an inefficient and inequitable approach to reducing overall CI of crop-based biofuels and fails to acknowledge and leverage the major technological innovations that characterize today's agriculture operations:

202.2 A. **Efficiency and equity for farmers:** Any sustainability requirements of biofuel feedstock growers should be voluntary and incentive-based, rather than mandatory. Productive engagement and buy-in from farmers that produce crop-based biofuels feedstocks are essential to the success of clean fuels programs and standards. This will only come with meaningful and fair incentive structures that allow farmers to receive compensation from lowering their operation's CI, given that they are already pressed for time and resources throughout the growing season without additional documentation burdens.

Mandatory certifications created by disparate and disconnected sustainability and clean fuels programs ultimately place a burden on farmers without any apparent benefits. Instead, CARB should incentivize traceability and field-level certification of growing practices, rather than mandating sustainability certifications. Several other active and proposed low carbon fuel programs around the world have adopted a strategy that allows farmers to certify their operations by utilizing the same technology and data that already support their decision-making in the field. Importantly, creating demand for field-level data will also increase the adoption of precision technology and sustainable farm management practices, resulting in many benefits including reduced greenhouse gas (GHG) emissions. There are significant opportunities for digital agricultural technologies to improve nitrogen use efficiency and water quality, while restoring soil health and contribute to the overall[3].

202.3 B. **Appropriate use of technology:** Precision technologies and data have made demonstrable contributions to GHG emissions measurement and reduction of U.S. agriculture,[4] with significantly greater emissions reductions still possible[5]. John Deere brings a unique perspective on the use of technology and data, as the leader in precision agriculture equipment and technologies. In 2020, John Deere introduced its Smart Industrial Operating Model to accelerate the delivery of scaled analytics and provide high-quality, usable data, while protecting the proprietary interests of producer customers. Today, John Deere's farm data management system, Operations Center™, has enabled agricultural producers to digitize their operations on more than 388 million acres globally (e.g. digital record of planting rate, fuel use efficiency, fertilizer application, and yield variability within a field).

As more acres are digitally engaged, Deere is focused on empowering farmers with data-driven insights on key sustainability metrics, including nitrogen use efficiency and field-level GHG emissions. The necessary data for voluntary sustainability programs can be verified using the John

[5] Northrup, et al. (2021). doi.org/10.1073/pnas.2022666118

Deere Operations Center today[6]. For example, farmers can opt-in to sharing tillage intensity and cover crop data from their operations with a third party directly via APIs. CARB's approach should ensure that current farm data systems like Operations Center are considered acceptable sources of data to increase accuracy, reduce verification costs, and allow farmers to more easily provide necessary data to meet sustainability goals, if they choose.

We appreciate the opportunity to be an active participant as CARB continues implementation of the LCFS and considers program changes. John Deere supports maintaining a pathway-neutral low carbon fuel program without limits or caps on crop-based feedstocks in California. We also reiterate our offer to work collaboratively with CARB on ways to ensure farmers are included as part of the solution to meet the State of California's climate goals.

For questions or for further information regarding John Deere's comments, please contact John Rauber, Director & Counsel, Federal Affairs at rauberjohnw@johndeere.com.

Thank you for your consideration on this important issue.

Re: Comments on the December 19, 2023 LCFS Proposed Amendments

Submitted electronically

California Air Resources Board
1001 I Street
Sacramento, CA 95814

Thank you for affording our company and other stakeholders the opportunity to comment on proposed amendments to California's Low Carbon Fuel Standard (LCFS). The LCFS has been a landmark policy in greenhouse gas (GHG) reductions, enabling the renewable fuels industry to grow with direction and purpose. The biofuels sector has been a significant contributor to the development of this landmark lower-carbon policy, and likewise, companies such as ADM have led the way in producing fuels that have helped the state reach its goals and sustain its progress on GHG reductions in transportation.

ADM's Low-Carbon Legacy and Commitment to Sustainability

Long before adoption of the LCFS, ADM had significant interest in and contributions to low-carbon energy policy. For more than a century, we have transformed crops into products that serve the energy and food security needs of a growing world. Renewable fuels are a vital part of our business. We first produced ethanol in 1978 and added biodiesel production in 2006. Today in the U.S., we manufacture more than 1.4 billion gallons of corn-based ethanol per year at seven plants in five locations. We also produce or market more than 400 million gallons of biodiesel per year from four North American ADM-owned facilities and one for which we market product. Globally, we also produce biodiesel at facilities in Europe and Brazil. These facilities produce biomass-based diesel from a variety of feedstocks, including soy and canola. Collectively, our current biofuel production operations directly support nearly 4,000 jobs, and indirectly support tens of thousands more. We also are growing our capacity, with additional soybean crush capability now online in Spiritwood, North Dakota, as part of a partnership with Marathon Petroleum to provide feedstock for its renewable diesel operations.

Sustainability is a foundation of ADM's purpose and a pillar of our growth strategy, and we applaud CARB's interest in sustainable fuel production throughout the history of the program, including its most current proposed amendments. With global scale and a value chain that stretches from more than 200,000 farmers to customers, ranging from multinational companies to startups, ADM is a leader in supporting the production of sustainable solutions in categories encompassing food, fuel, and industrial and consumer products.

Our company has made significant global sustainability commitments, updated, published, and highlighted each year in our annual Corporate Sustainability Report. The most recent report is attached for your review. Highlights from last year's report, covering January 1 through December 31, 2022, include:

- Achieving 100% traceability across direct and indirect soybean suppliers in Argentina, Brazil, and Paraguay.
- Disclosing GHG emissions from land use change.
- Introducing a goal to increase low-carbon energy usage to 25% of total energy use by 2035.
- Launching our regenerative agriculture program, re:generations™, and enrolling more than 2 million North American acres in regenerative agriculture programs – which leverage the land's ability to

77 West Wacker Drive
Suite 4600
Chicago, Illinois 60601

312-634-8100

sequester carbon, enhance biodiversity, and help protect and preserve soil and water – in the initiative's inaugural year. We aim to enroll 4 million acres globally by 2025.
- Committing to work with the Science-based Targets Initiative (SBTi) to align ADM's carbon reduction targets with ambitious goals to limit the average rise of global temperatures to 1.5 degrees Celsius.

These metrics indicate the very real progress made by ADM, indicative of the positive change that the entire renewable fuels industry is undertaking.

77 West Wacker Drive
Suite 4600
Chicago, Illinois 60601

312-634-8100

The Biofuels Industry Promotes Food *and* Fuel

Producers such as ADM have the skill, technology, and vision to make the most efficient use of an entire agricultural crop. Indeed, we and our counterparts in the agricultural and biofuels sectors are focused on promoting both food and fuel. Corn and oilseeds like soybeans and canola produce high-protein feed and oil. The protein is used for animal feed and other food products. The oil is used for food ingredients and preparation and a range of industrial uses, including biofuels.

Looking specifically at oilseeds, feedstocks which are driving growth of lower-carbon biodiesel into the California market, U.S. demand over the next five years is forecast to grow 10%. A corresponding growth in vegetable oil supply will occur in tandem. Because per-capita fats and oils consumption across the globe is decreasing, lipid-based biofuels are actually recovering the value of the product that would otherwise had been lost (see Figure 1). This is a benefit to farmers, consumers, and the environment, as more biofuel is being consumed in our transportation system. Said another way, without demand for the oil via biofuels, either farmers would see less profitability or the price of soy protein meal for pork, chicken, and turkeys would have to increase – leading to food inflation.

Figure 1

Suite 4600
Chicago, Illinois 60601

312-634-8100

Further Analysis of Crop-Based Fuels Sustainability Criteria

Given the reality of food and fuel, ADM applauds CARB's decision not to implement a cap on crop-based biofuels in these most recently proposed amendments to the program. Data regularly makes clear that crop-based biofuels do not negatively impact the production of human or animal nutrition. Rather, crop-based fuels such as ethanol and biodiesel produce both food and fuel at affordable prices. And as stated earlier, the biofuels industry has led the way in meeting the LCFS program's goal of reducing GHG and other emissions over time. A cap would be a significant course reversal, for the state, consumers, and the environment.

203.1 While CARB's decision not to propose a cap is promising, significant questions remain regarding its proposed sustainability criteria for crop-based fuels. Given that this proposal had not been previously considered or publicly discussed, we appreciate the additional workshop to be conducted this spring on a number of issues, including sustainability criteria. All stakeholders should be afforded the opportunity to engage and understand how such criteria would be implemented and administered.

The workshop will be instructive in more fully exploring a number of important factors seemingly not yet considered by CARB. For example, existing standards and protocols already achieve the goals these new criteria aim to achieve. Two of the primary crops grown in the U.S. are covered by the U.S. Soybean Assurance Protocol or the U.S. Corn Assurance Protocol. In addition, under the U.S. Renewable Fuel Standard (RFS), sustainability criteria as proposed by CARB are met and in some cases exceeded. The RFS law has been in place for nearly two decades, well exceeding CARB's proposal that applicable sustainability certification programs be in place for at least two years before satisfying these proposed requirements. Additionally, under the RFS:

- Fuel feedstocks must not be sourced from agricultural land cleared or forested after Dec. 19, 2007;
- Environmental, social, and economic criteria are taken into account in developing annual fuel volumes under the program;
- Transparent public review of and comment on proposed annual volumes and changes to the rule are central to the continual development of the program. Proposed changes, public comment, and associated documents are posted on the U.S. Environmental Protection Agency's (EPA's) website to review by stakeholders and the general public.
- Scientific experts within EPA and associated technical advisory panels provide regular input into changes to the program.
- A rigorous audit program via EPA, including high standards, training to ensure competency, and transparency to the public, is maintained.

On each of these and more points, the comprehensive RFS meets or exceeds sustainability certification criteria as proposed by CARB. Moreover, recognizing the RFS in this manner would avoid the burden of duplicative criteria and reporting, allowing the program to stand on firm, proven ground as it pertains to sustainability while ensuring that biofuels producers and feedstock providers are held to account.

As stated, we look forward to a workshop focused on this matter in order for stakeholders in the program to understand key drivers, definitions, implementation planning, and finer points of the requirements not covered in adequate depth as part of the proposed amendments. Key participants in these sessions would be farmers and those who work closely with them, as providing our agricultural community certainty and a straightforward, reliable manner of compliance is critical to their continued growth and success.

77 West Wacker Drive
Suite 4600
Chicago, Illinois 60601

312-634-8100

Finally, ADM welcomes discussions on our global scope of work, including with accrediting bodies currently developing and deploying sustainability models.

203.2 **Protecting and Promoting North American Feedstocks**

The proposed sustainability criteria noted above would place U.S. and Canadian crop-based feedstocks at a disadvantage versus feedstocks coming from other markets, as the RFS recognizes and provides rigorous review of feedstocks from these two countries as part of the program. As mentioned, establishing duplicative criteria would be a burden not only to fuel producers, but also to domestic U.S. and Canadian farmers who fully participate in feed and fuel production. All of this would occur with no commensurate sustainability benefit.

203.3 Further to the point of protecting North American feedstocks, the rise of international used cooking oil (UCO) feedstock imported into the U.S. market has skyrocketed in recent years, after the establishment of more incentives for their use in producing lower-carbon fuel. Much of this UCO also is leveraged for LCFS compliance in the California market, and on a level playing field, this is appropriate. Still, this influx of UCO from overseas raises questions about its sourcing and, at a minimum, calls for greater scrutiny to ensure integrity of the LCFS program and the fuels consumed in the state.

203.4 Finally, North American-grown feedstocks such as corn, soy, and canola are expected to face expanding global competition, including Chinese agriculture which is improving its own production and crop yields, and will be able to supply more feed and fuel to our domestic markets in the coming years. Our industry will lead the way on domestic food and energy security.

Conclusion

As amendments to the LCFS are finalized and implemented, we ask that CARB continue partnering with the agricultural industry as we grow, evolve, and supply California consumers with food and fuels in a sustainable manner. The LCFS program is a key policy to further catalyze our and others' sustainability efforts and associated learnings. A robust LCFS sends a clear signal to the market and supports continued investments in lower carbon feedstocks as well as carbon reduction efforts, including regenerative agriculture practices such as cover crops and improved water and fertilizer management practices.

Thank you for the opportunity to share these comments as the CARB staff and Board complete work on amending the LCFS. We further associate ourselves and align with comments submitted by the California Advanced Biofuels Alliance, Clean Fuels Alliance America, National Oilseed Processors Association, and Growth Energy. Please do not hesitate to contact me or our Vice President – State Government Relations Greg Webb (webb@adm.com) with any questions.

Respectfully,

Greg Morris
Senior Vice President
President, Ag Services and Oilseeds

Re: Low Carbon Fuel Standard

Dear Chair Randolph,

As Senior Vice President of Legal and Government Affairs of the Hexagon Group ("Hexagon"), I am writing to express support for the key proposed amendments to the Low Carbon Fuel Standard (LCFS) and urge the adoption of two additional amendments that will allow the state of California to achieve climate and clean air goals more effectively. We would like to further provide our support for the letters provided by Natural Gas Vehicles for America (NGVA) and California Renewable Transportation Alliance (CRTA). As we respect your time, we will not repeat those arguments here, but incorporate those arguments by reference.

Hexagon is a global leader in clean energy systems and solutions. Hexagon enables the storage and conversion to clean energy in a wide range of mobility, industrial and consumer applications. Further, Hexagon Purus, a business area of Hexagon, is a world leading provider of complete vehicle systems and battery packs for hydrogen fuel cell electric and battery electric vehicles including hybrid mobility applications on light, medium and heavy-duty vehicles, transit buses, ground storage, distribution, maritime, rail, and aerospace. Most importantly, as an alternative fuel company, we are focused across all divisions on displacing diesel and gasoline in transportation and bringing, "clean air everywhere." We do this by leveraging all available alternative fuels, including propane and natural gas, electric and hydrogen. Notably, we have been instrumental in the transportation-related emissions reductions of Amazon, UPS, Waste Management, and many other fleets.

We believe the LCFS is well positioned to encourage billions of dollars of investment into the transportation sector of California but must remain fuel-neutral and supportive of all technologies to do so. Currently, there is a strong bias for zero tailpipe emission vehicles, which is not conducive to carbon reduction of the highest polluting sectors of transportation. Among other reasons, this is because the heavy-duty sector requires internal combustion engines to continue to move volumes of goods cost efficiently in the near term. There is not a sufficient infrastructure in place now or within the next five years to meet the electricity or hydrogen fueling demands of the heavy-duty market[1]. Therefore, we have the following recommendations.

204.1 1. **Increase stringency of carbon intensity (CI) targets for heavy-duty (HD) vehicles.** Increasing CI stringency for heavy duty vehicles will result in the accelerated adoption of CNG engines by fleets currently using diesel engines. Diesel power not only perpetuates the use of higher CI scored fuels, but they are responsible for driving demand for biodiesel which is overproduced and harms LCFS credit prices[2]. If CARB can drive more bio based RNG (landfill and

[1] Electric Vehicle Charging Infrastructure Assessment - AB 2127 (ca.gov)
[2] A Cap on Vegetable Oil-Based Fuels Will Stabilize and Strengthen California's Low Carbon Fuel Standard - Union of Concerned Scientists (ucsusa.org)

dairy/swine) to displace fossil CNG, the CI of California will continue to drop as fugitive methane becomes more valuable to collect and use. Furthermore, this increased reduction will pave the way for hydrogen and electric infrastructure to catch up to the demands of future zero emission vehicles.

204.2 **2. Cap lipids-based biodiesel production volumes.**

Biodiesel and renewable diesel incentives have been an overwhelming success for the LCFS program. Unfortunately, there are situations when too much of a good thing can be bad. The overproduction of biodiesel can easily be viewed as one example.

"Over the last decade, BBD fuels have grown from 0.4% of California's diesel blend in 2011 to 32% in 2021 and this growth is poised to accelerate in coming years. Vegetable oil, waste oil, and animal fats are lipid compounds that can be readily converted to BBD. Although BBD can also be produced from cellulosic

feedstocks such as agricultural and forestry residues, lipid-based feedstocks are the primary materials used to produce fuel for the state's BBD market. These feedstocks will be increasingly drawn from the rest of the United States and the world to meet growing demand. Increased consumption of lipid-based biofuels raises food prices, sustainability issues, and fraud concerns and could undermine the efficacy of the LCFS[3]."

Currently, LCFS credit prices are almost 1/3 of what they were only 3 years ago. This rapid decline not only instills fear in investors, but also undermines future adoption of LCFS standards by other states like New Mexico, who recently adopted an LCFS program but has not yet put it into practice.

Conclusion

There is no more effective and immediate step we can be taking to address climate change now than to aggressively and rapidly reverse emissions of fugitive methane from all sectors, including society's organic waste streams through renewable natural gas (RNG) projects. For all other avenues within the LCFS, there should be a tiered value structure for different volumes of positive CI fuels entering California. Limiting credit values of different production methodologies allows CARB to push for the most efficient CI scored production methodologies and get the most value out of the marketplace. The LCFS must remain fuel-neutral, driven by CARB's science-based analysis, capable of incentivizing real-world investment, and focused on performance-based GHG outcomes. Remaining true to these core concepts will ensure California leads the world in rapid transportation sector decarbonization.

We thank CARB for the chance to comment and appreciate your commitment to keeping California's air clean.

Ashley Remillard

RE: IRFA Comments on Proposed LCFS Amendments

Iowa Renewable Fuels Association (IRFA) appreciates the opportunity to provide comments to CARB regarding potential amendments to the Low Carbon Fuel Standard (LCFS) ("Proposed Amendments" or "Proposal"). The IRFA is the independent state trade association representing ethanol, biodiesel, renewable diesel, and renewable natural gas producers from across Iowa. In total, Iowa has 42 ethanol refineries capable of producing over four and half billion gallons annually, accounting for about a thirty percent of the United States total ethanol production. Iowa is also the largest biodiesel producing state, with 10 plants capable of producing around four hundred million gallons annually or roughly twenty percent of the United States total biodiesel production. Ultimately, California is a major market for each of these low carbon, renewable fuel segments.

Biofuels have been among the largest contributors to the success of the LCFS program to date and are poised to continue to do so with appropriate updates to the program. This includes but is not limited to what third-party verifiers will be looking for or even who are the approved third-party verifiers. In our view, CARB has not provided the public and regulatory community notice or the opportunity for stakeholders to comment on the validity of these new requirements.

205.1

Furthermore, we believe crop-based biofuels, which again currently provide the majority of credit-generating fuels for the LCFS program, are being singled out for more stringent criteria. This is all on top of not allowing crop-based biofuels the ability to include on-farm activities such as cover crops or no till practices that increase sustainability while dramatically lowering crop-based biofuels carbon intensity (CI) score. How is this following the spirit of "technology neutrality" if only crop-based biofuels are penalized and treated unfairly?

205.2 To further proof this point, ethanol gets lumped in with other crop-based and forestry-based biofuels with worse LUC penalties like palm oil proving the unfair application of said sustainability requirements that heavily penalize U.S. corn ethanol. In fact, the benefits of ethanol are routinely proven including recently by [IFP Energies]

nouvelles (IFPEN) which found that “compact” plug-in hybrids that run on E85 (85% ethanol, 15% gasoline), are comparable in carbon neutrality to electric vehicles when accounting for all emissions in connection with the vehicle and its battery as well as the energy used across production, distribution and combustion. Finally, as U.S. airlines look to move to sustainable aviation fuel (SAF), crop-based biofuels like ethanol are one of the few feedstocks that are readily available and in needed quantities to meet this growing demand.

The LCFS has been a major national driver in low carbon fuel use and the push toward net zero energy. However, if the proposed changes are made, we would see a major step backwards from achieving our goal while pushing U.S. energy production away for new energy sources overseas. It would also raise questions about the stability of the LCFS program that could undermine future investments in technologies designed to help reduce carbon emissions from not just on-road vehicles, but aviation as well.

As it stands today, IRFA and its members firmly believe California’s LCFS should encourage, not prohibit, low carbon options for the consumers and while keeping the program truly technology neutral. I think we all can agree that we should let science decide the best route forward. However, this can only be done when there is a level-playing field without the scales being pushed down in favor of one particular technology or energy source.

If you have additional questions, please contact me at mshaw@IowaRFA.org or 515-252-6249. Also, if you or any of your staff would ever be interested in touring an Iowa biofuel production facility, visit an Iowa farm and other aspects of the biofuels supply chain in Iowa, IRFA and its members would love to host you.

Sincerely,

Monte Shaw

Re: CATF Comments on CARB's Proposed Low Carbon Fuel Standard Amendments

Dear Chair Randolph,

Thank you for the opportunity to comment on CARB's proposed amendments to the Low Carbon Fuel Standard (LCFS). Clean Air Task Force (CATF) is a global nonprofit organization working to safeguard against the worst impacts of climate change by catalyzing the rapid development and deployment of low-carbon energy and other climate-protecting technologies. These comments convey our concerns regarding the proposal's treatment of biomethane crediting and bio oil-based fuels, and we recommend constructive actions CARB can take to address these concerns.

Biomethane Crediting Provisions

LCFS credits generated under pathways utilizing biomethane from dairy and swine manure provide valuable incentives to invest in technologies like anaerobic digesters, which can be an effective tool for managing methane emissions from manure. More than half of methane emissions in California are from the livestock sector, with 25% of total methane coming from manure,[1] a consequence of California's predominant large herd production systems and their manure management. While CATF recognizes the need to provide incentives for anaerobic digesters, we are concerned about the LCFS locking in very lengthy crediting periods despite a lack of robust scientific literature on a number of critical topics.

206.1 • Farming Management Practices. There are uncertainties about the current LCFS policy's impacts on farming management practices, such as the risk of subsidies accelerating the rate of consolidation of livestock herds, driving an increase in herd size, and leading to changes in manure management practices.[2] CARB has publicly stated that it has a lack of evidence that the implementation of LCFS is contributing to dairy farm consolidation and increased herd size.[3] However, the UC Davis analysis[4] referenced by CARB used a "cows per farm" statistic, and the study's author advises that further analysis using data from the USDA's Census of Agriculture[5] (released in February 2024) would be better to answer this question. Furthermore, because LCFS subsidies benefit dairies outside of

[4] Are Manure Subsidies Causing Farmers to Milk More Cows? | Aaron Smith (ucdavis.edu)

[5] https://www.nass.usda.gov/AgCensus/

California, analysis of the impacts on farming management practices should also consider farms outside the state.

Clean Air Task Force
114 State Street, 6th Floor
Boston, MA 02109

P: 617.624.0234
F: 617.624.0230

- Increased Methane Emissions. Some changes in manure management, such as transitioning from land application to long-term storage,[6] may increase methane emissions. In addition, increases in herd sizes may also lead to an increase in methane from enteric emissions. Critically, enteric emissions are currently not
206.2 included in the LCFS's lifecycle emissions analysis for biomethane from manure. [7] While CARB does not account for these upstream emissions, if there is an increase in enteric emissions as a direct effect of LCFS policy, progress toward meeting the SB 1383 target for livestock methane emissions reductions may be negatively affected.

Given the long-term commitment in the proposed LCFS amendments to fully credit avoided methane emissions and the lack of robust scientific data about the current LCFS policy's holistic impacts on farming management practices and subsequent methane emissions, CATF strongly recommends CARB take the following actions:

206.3 1. CARB should investigate the avoided methane crediting mechanisms, their potential to affect farm management practices, and the implications of resulting shifts in those practices. CARB should support research that uses data from the 2022 census (just released in mid-February 2024[5]) to investigate whether LCFS policies are accelerating the rate of consolidation in dairies participating in the LCFS in California and outside the state. Further analysis should evaluate if there is a correlation between farmers' intention to expand (based on permitting asks to increase herd size) and participation in the LCFS program. Note that because the LCFS benefits farms outside California, a simple comparison between California versus other states may represent a study bias, and the study design should account for that. These analyses would address some of the concerns around the LCFS credits supporting the deployment of anaerobic digesters in livestock farms. This could be achieved by convening an external working group comprised of experts that meet to review new science and data regarding the impacts of LCFS policy on farm management practices.

206.4 2. CARB should ensure that the final rulemaking documents explicitly provide for the possibility of adjusting crediting periods for avoided methane if future research or data indicates that the LCFS is leading to negative climate consequences such as additional methane emissions (e.g., from enteric or digestate management due to changes in farm management practices) or negative health consequences.

206.5 3. CARB should account for potential unintended increases in emissions at the farm level (from manure management and/or digestate management) and potential risk to accelerate rate-of-farm consolidation in the amendment

Sustainability Concerns Regarding Bio-Oil Based Fuels

CATF has submitted its detailed comments to the docket (see joint comments submitted by CATF and Pacific Environment on February 20, 2024) regarding our concerns about the risks that the LCFS amendments will result in unsustainable consumption of vegetable oil-based biofuels. Below is a high-level summary of the concerns and recommendations conveyed in that comment letter.

Concerns:

- Without adequate safeguards, strengthening and extending LCFS carbon intensity benchmarks will likely accelerate the rapid growth in demand for bio-oil based biofuels, directly and indirectly impacting food markets and increasing emissions from land use changes;

- Including intrastate fossil jet fuel in the LCFS is an important policy signal for decarbonizing the aviation sector, but the current proposal will further increase demand for bio-oil based fuels, given that refining and hydrotreating bio-oils is currently the only commercially viable alternative to fossil jet fuel at scale; and

- The only proposed sustainability requirement for crop-based biofuels is third-party certification that the feedstocks are derived from land that has not been forested since 2008, which is too narrowly scoped to serve as an effective constraint on climate-damaging land use change.

Given these risks, we recommend the following:

206.6 1. CARB should limit the volume of first generation vegetable oil-based fuels that are eligible to generate credits under the program;

206.7 2. CARB should assess on an annual basis the direct and indirect market impacts from fuels obligated under the proposed sustainability requirements; and

206.8 3. CARB should extend the sustainability requirements beyond crop oils to used cooking oil and waste oils.

Conclusion

Thank you for considering the concerns and recommendations expressed above. If you have any questions or would like to discuss these topics further, please contact CATF's U.S. State Climate and Energy Program Director, Jeremy Tarr, at jtarr@catf.us.

Dear Recipient,

I am submitting public comments from members of the Union of Concerned Scientists in response to the *Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments*. **Enclosed are 1,350 messages, 138 of which came from UCS Science Network members who are pursuing advanced degrees in science, public, economics, and engineering. Of the 1,350 comments, 92 were individualized messages 1,258 signed on to the message below**:

> *I am writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards.*

207.1

> *Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.*

207.2

> *I urge the California Air Resources Board to ensure that changes to the LCFS place a cap on vegetable oil-based fuels and reflect our commitment to a sustainable future. Thank you for considering my views on this crucial matter.*

Thank you for your consideration.

Sincerely

Kye Whitmore

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

As a California resident, I believe it is critical that California not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Sincerely,

Richard Dawson
rcdawson@att.net

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

As a Senior living in Los Angeles, I'm writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California does NOT rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses SIGNIFICANT tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Sincerely,

Hilary Hilary

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

207.3

I believe that the most effective way to effect carbon in the atmosphere is a carbon tax with proceeds divided equally to every man woman and child plus a border tax of the same magnitude on products from other countries that do not have a carbon tax. Even with that, we need every known measure and some as yet unknown, to be instantly applied. Hence I am writing to provide input on the most effective way to support the proposed to amendments to the Low Carbon Fuel Standard (wayLCFS). As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am a proud and happy electric vehicle owner. The whole thing thrilled me so much, I ditched my gas-powered lawnmower and bought a cordless electric mower. I went green in areas where it is obtainable for most. I will address the rest of my living space as appliances die. Now, I see that somehow soybean oil diesel has made the cut as environmentally friendly. What! This is far from the truth, so I am writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

Regarding the proposed amendments to the Low Carbon Fuel Standard (LCFS): Allowing a large increase in vegetable-oil-based diesel will result in deforestation due to a greater market for imported vegetable oil. Deforestation harms the environment by both disrupting the forest ecosystem and by contributing to global warming. In addition, diverting vegetable oil to use as fuel instead of food risks impacting food security in vulnerable communities.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

As a California diesel consumer for transportation, I am writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. My exploration of biodiesel over the past two decades has convinced me that it is a useful adjunct and not a base for a sustainable transportation future. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification. As California's consumption of soybean oil-based diesel increases, it fuels the rapid expansion of palm oil cultivation to replace what we use for fuel. California's consumption of soybean oil for fuel is projected to reach 1.3 million metric tons this year, equivalent to 10 percent of the worldwide trade in soybean oil, which will distort the market.

Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification. Insofar as the soybean source is Brazil, this implies deforestation, another major concern. Off subject perhaps, but similarly using corn to produce ethanol by fermentation is a terrible environmental idea (rationale is purely political). Fermentation produces CO2 and the energy content is reduced by 20%

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am writing in regard to the proposed amendments to the Low Carbon Fuel Standard (LCFS). In particular, I urge CARB to reevaluate the amount of subsidies provided to vegetable-oil based diesel and instead focus the program toward supporting vehicle electrification and green hydrogen. California should not be reliant upon soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification. Also overlooked in this process are programs to support the production of green hydrogen. While manufacturers are ramping up production of electric vehicles, the promise of hydrogen fuel cell transportation solutions (non-polluting and much more convenient for consumers) will stall without government support for clean hydrogen production and distribution.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I respectfully ask that you support the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Sincerely,

Jan Charvat

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification. I have added solar panels and a battery to my home and look forward to getting an electric plug in car. We desperately need to move away from oil-based fuels that dirty our air and take away land for fuel burning. We can do so much better using solar energy.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am writing to express my great concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is absolutely critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses some very significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the needed support the LCFS provides for transportation electrification. Electrification really is the best route-especially with our public transportation. That would leave fewer vehicles on the road. Upgrade our transportation from LNG, and filthy fossil fuels to electricity, add more buses & trains, and schedule them to arrive in a timely manner, maybe even add more stops. This would greatly improve our air, soil, and water quality. Thank you for caring about us.

Sincerely,

Kate Considine

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The unprecedented expansion and magnitude of soybean oil-based diesel used in California is harming people, accelerating tropical deforestation, and undermining the state's climate policies. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification. You Board members can mitigate the impact of California's fuel consumption on sensitive ecosystems by aligning our climate action with sustainable practices by capping soybean oil-based diesel and refocusing the LCFS on electric vehicles.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. There are two reasonable alternatives, both based upon Hydrogen: fuel cells and combustion. The residual exhaust is WATER. These are both very attractive for truck transportation and can be phased in over at 7-10 year period, thus not forcing an instantaneous change. The key is that the market in California is so large, if we require this, the rest of the country will follow and in time, the world. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California does NOT rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Sincerely,

Cynthia King

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident and as a public health professional and environmental advocate for 40+ years, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Sincerely,

Nancy Kingston

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification. All fuels for vehicles in California need to be sustainably created and we must rapidly shift to an all electrified fleet of commercial and personal cars and trucks. Long haul trucks need to replace diesel with electric ones where possible as soon as feasible. Air transportation needs to convert to more sustainable and truly renewable fuels such as green hydrogen from renewably sourced electricity.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

Vegetable oil is not the answer. Please amend the Low Carbon Fuel Standard (LCFS)so that vegetable based oils are not diverted from use as food to use as fuel. California should not rely on soybean oil-based diesel to reach our environmental goals. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. Vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I strongly oppose the proposed amendments to the Low Carbon Fuel Standard (LCFS) concerning fuels made from vegetable oil. LCFS must stop promoting production and consumption of diesel made from vegetable oil that exceeds sustainable sources of waste oils and fats. It is worse than counterproductive for CARB policy to encourage the razing of tropical forests to grow vegetable oil for transportation fuel, as deforestation is a major driver of the climate crisis. The flood of vegetable oil-based diesel in California also undermines the our state's efforts to increase transportation electrification.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am expressing my concern about the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California not rely on soybean oil-based diesel to reach our ambitious but essential environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation and the resulting loss of carbon sequestration and loss of important wildlife habitat. The flood of vegetable oil-based diesel in California also undermines the impact the LCFS would otherwise have for expanding the electrification of vehicles.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I write to express my deep concern about and to provide input on the proposed amendments to the Low Carbon Fuel Standard (LCFS). As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Sincerely,

Mary Proteau

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I have been trying to educate myself about the way the Low Carbon Fuel Standard (LCFS) works in California and I am troubled by some of what I have learned. Iam writing to express my concern and to provide input on the proposed amendments to the Low Carbon Fuel Standard. As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I am deeply concerned with the Low Carbon Fuel Standard (LCFS) set by CARB. Biofuels as a clean energy alternative is a myth. The CO2 emissions from planting, fertilizing, harvesting, shipping and processing biofuels are far greater than the slight decrease in the emissions from burning. Your support of biofuels stands in the way of electrification, which is the only true path to zero emissions in the transportation sector. And with the subsidies you're offering to oil refineries, you're simply helping keep them in business. Furthermore, you're supporting U.S. farmers' shift from grow food crops to growing biofuel feedstocks. It's time to rethink the LCFS and stop the proliferation of biofuels in California.

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments

To: California Air Resources Board

I was born and raised in the Bay Area, and I'm very concerned about the LCSF standard and the other impacts and implications of biodiesel. I am writing to express my concern and to provide input on the proposed amendments to the LCFS. As a California resident, I believe it is critical that California does not rely on soybean oil-based diesel to reach our ambitious yet responsible environmental standards. Diverting vegetable oil from food to fuel poses significant environmental harm through tropical deforestation. There are also additional transportation emissions and land-use concerns. The flood of vegetable oil-based diesel in California also undermines the support the LCFS provides for transportation electrification.

Re: Comments in Response to the California Air Resources Board Rulemaking to Amend the Low Carbon Fuel Standard

Friends of the Earth U.S. (FOE), on behalf of our 120,000 members and supporters in California, welcomes this opportunity to provide comments in response to the California Air Resources Board's (CARB) rulemaking to amend the Low Carbon Fuel Standard (LCFS). We echo the calls of California-based organizations and individuals living near industrial dairy operations in California to reform the LCFS and immediately address the egregious environmental injustices in the program.

LCFS is driving the demand for manure biogas — or "factory farm gas" — by allowing concentrated animal feeding operations (CAFOs), or factory farms, to generate credits from installing and operating anaerobic digesters that can be sold to companies to pay for their pollution. It creates a perverse incentive for CAFO operators to generate as much methane — and therefore as much manure — as possible to capitalize on these hefty subsidies the program provides. As a result, the LCFS is exacerbating existing pollution and failing to mitigate animal agriculture's climate impacts by driving the growth of both factory farms and factory farm gas production across the United States.

To achieve California's environmental, public health, climate, and environmental justice objectives,
208.1 CARB must cease the incentives for factory farm gas and stop paying these industrial polluters to capture methane emissions in a dangerous, ineffective approach to address the climate crisis.

Industrial Animal Agriculture's Environmental & Health Impacts on Communities

Industrial animal agriculture operations are a major polluter of the rural communities in which they are located, which are disproportionately communities of color and low-wealth communities such as California's San Joaquin Valley.[1] Today's industrial-scale farms, housing thousands — or sometimes hundreds of thousands — of animals, generate as much as 1 billion tons of manure per year, which contaminates air, drinking water, and surface waters, directly impacting the health of the surrounding communities.[2]

Manure from industrial dairy and hog operations, the main beneficiaries of LCFS' incentives, is typically stored as liquid in giant manure lagoons and periodically applied to spray fields and contains

pathogens, antibiotic-resistant bacteria, and heavy metals.[3] The sprayed, untreated waste can contaminate the soil and run off into waterways, causing harmful downstream effects.[4] The manure also emits hazardous gases and particulate matter, causing toxic air emissions and noxious odor.[5] Studies have shown that people living near factory farms face higher risk and severity of respiratory illnesses, digestive issues, headaches, and other serious health conditions.[6]

As mentioned above, these negative impacts disproportionately affect low-income communities and communities of color because of where CAFOs operate. One study found that of the 15,900 deaths from food production in the U.S., 80 percent, or 12,700 deaths, are attributable to industrial animal production, and the majority of deaths — 12,400 deaths each year — are attributable to ammonia acting as a PM2.5 precursor.[7] Environmental justice communities face a so-called "triple jeopardy" where their proximity to sources of air pollution, disproportionate disease burdens, and psychosocial stressors compound to diminish their quality of life.[8]

In addition to being a major polluter of rural communities, animal agriculture is the top source of U.S. climate changing methane emissions, accounting for 36% of total U.S. methane emissions.[9] Climate change also disproportionately affects communities of color, low-income communities, and other vulnerable populations, which are more likely to live in isolated rural areas, floodplains, coastlines, and other at-risk locations, putting them at risk of exposure to adverse climate change impacts and compounding the harm inflicted by factory farm pollution.[10]

Ultimately, the state of California should be doing so much more to protect these long-suffering communities from both industrial pollution and climate change. The very least it could do is stop rewarding the perpetrators.

Factory Farm Gas Production Fails to Address Environmental and Health Impacts on Communities and Creates New Problems

Not only does producing factory farm gas fail to address the aforementioned public health and safety concerns of communities, producing factory farm gas also generates additional environmental, public

health, and safety concerns for communities living near CAFOs and biogas plants. These include increased production of ammonia pollution from anaerobic digestion,[11] higher concentrations of nutrients digestate that contribute to water pollution,[12] increased disruption and pollution from new pipelines and trucks to transport manure or biogas through communities, and more toxic air pollution from biogas processing than is produced by fossil gas.[13]

For example, as petitioners point out in their *Petition for Rulemaking to Exclude all Fuels Derived from Biomethane from Dairy and Swine Manure from the Low Carbon Fuel Standard*, the Lakeview Dairy Biogas project in Kern County, California, uses two internal combustion engines to produce over 1,000 kW of electricity on-site.[14] Even with the required pollution control technology, this project emits 4.58 tons/year of NOx, 1.98 tons/year of PM10 (fine particulate matter), and 3.18 tons/year of VOC.[15] Compared to a natural gas combined cycle plant in a nearby town, the Lakeview digester project produces much higher levels of NOx, SOx, and VOC emissions per unit of electricity generated.[16] Meanwhile, communities in California's San Joaquin Valley, which are disproportionately Latino and low-income, already suffer some of the worst air and water quality in the country due in large part to the concentration of dairy factory farms. The California Air Resources Board acknowledges that 1,200 residents of the San Joaquin Valley die prematurely each year from PM2.5 pollution alone.[17] Producing and combusting manure biogas onsite leads to even worse air quality, exacerbating public health harms and environmental injustice.

The Low Carbon Fuel Standard is Flawed

The LCFS incorrectly assigns factory farm gas an extremely large negative Carbon Intensity (CI) score, one even better than electric vehicles powered by renewable electricity, and as result, it generates a large subsidy for the CAFOs and biogas operators.[18] This is because CARB gives participating CAFOs credit for both reducing methane emissions from manure under the assumption

that wet, methane-generating manure is an unavoidable byproduct of livestock production, and for replacing fossil fuels with higher CI scores.[19]

208.2 This is flawed for a number of reasons. First, CARB completely disregards the greenhouse gas emissions from the underlying factory farming operations as well as the increased greenhouse gas emissions when operators use and dispose of the digester waste. Second, maintaining massive
208.3 quantities of liquid manure is not a given; it is a choice — one that the LCFS rewards and reinforces.
208.4 There are alternative manure management practices that have lower methane-emissions and are more sustainable.[20] Finally, the LCFS does not prohibit participants in the program from double-counting
208.5 the emissions reductions attributable to anaerobic digesters, with the same purported emissions reductions being counted toward multiple programs, inflating climate progress. Research has shown that the LCFS takes credit for the same emissions reductions as California's state-funded Dairy Digester Research and Development Program.[21]

The LCFS Creates Perverse Incentives

Due to factory farm gas' flawed CI score, the LCFS distorts the market for transportation fuels, boosting fuels derived from manure above truly renewable sources. Perversely, CAFO operators and energy companies are incentivized to produce more manure biogas, in the most methane-emission heavy manner, to receive the lucrative rewards from the false market that has been created. This is done either by consolidating farms, creating an even more unfair playing field for producers, by increasing herd sizes (and the pollution, public health risks, and animal cruelty that comes with expanding CAFOs), or by utilizing the worst (most methane-generating) manure management strategies.

These perverse incentives exacerbate extensive environmental and public health impacts frontline communities are already enduring from CAFOs and undermines the methane-reducing potential of anaerobic digesters.

Reform the LCFS Immediately

Failing to reform the LCFS will entrench our current, inherently unsustainable systems of industrial animal agriculture and fossil fuel energy. Without a change, industrial polluters will continue to reap lucrative benefits at the expense of frontline communities' health and safety, perpetuating the environmental injustice California seeks to address. As such, CARB should prioritize the following changes to the program:

208.1 1. Eliminate "avoided methane crediting" in 2024.
208.2 2. Fix the inaccurate Life Cycle Assessment that ignores upstream and downstream greenhouse gas emissions associated with factory farm gas production.
208.6 3. Eliminate the 10-year "grace period" for factory farm gas producers.
208.5 4. Eliminate credit generation from factory farm gas projects that would have happened anyway due to other programs or investments.

---

[19] *Id.*

[20] It's worth noting that an even more effective approach to mitigating animal agriculture's impact on the climate is for methane emissions from industrial livestock facilities to be monitored, publicly disclosed, and regulated by the state.

[21] Phil McKenna, *Is California Overstating the Climate Benefit of Dairy Manure Methane Digesters?*, Inside Climate News (Dec. 30, 2023), https://insideclimatenews.org/news/30122023/milkingit-california-overstating-climate-benefit-dairy-manure-methane-digesters; Gabriel Petek, Legislative Analyst's Office, *Assessing California's Climate Policies—Agriculture* (Dec. 2021), https://lao.ca.gov/Publications/Report/4483.

We encourage CARB to change course and prioritize the well-being of Californians over industrial polluters and reform LCFS immediately. Thank you for your consideration.

Sincerely,

Molly Armus

SUPPLEMENT TO APPLICATION TO THE EXECUTIVE OFFICER

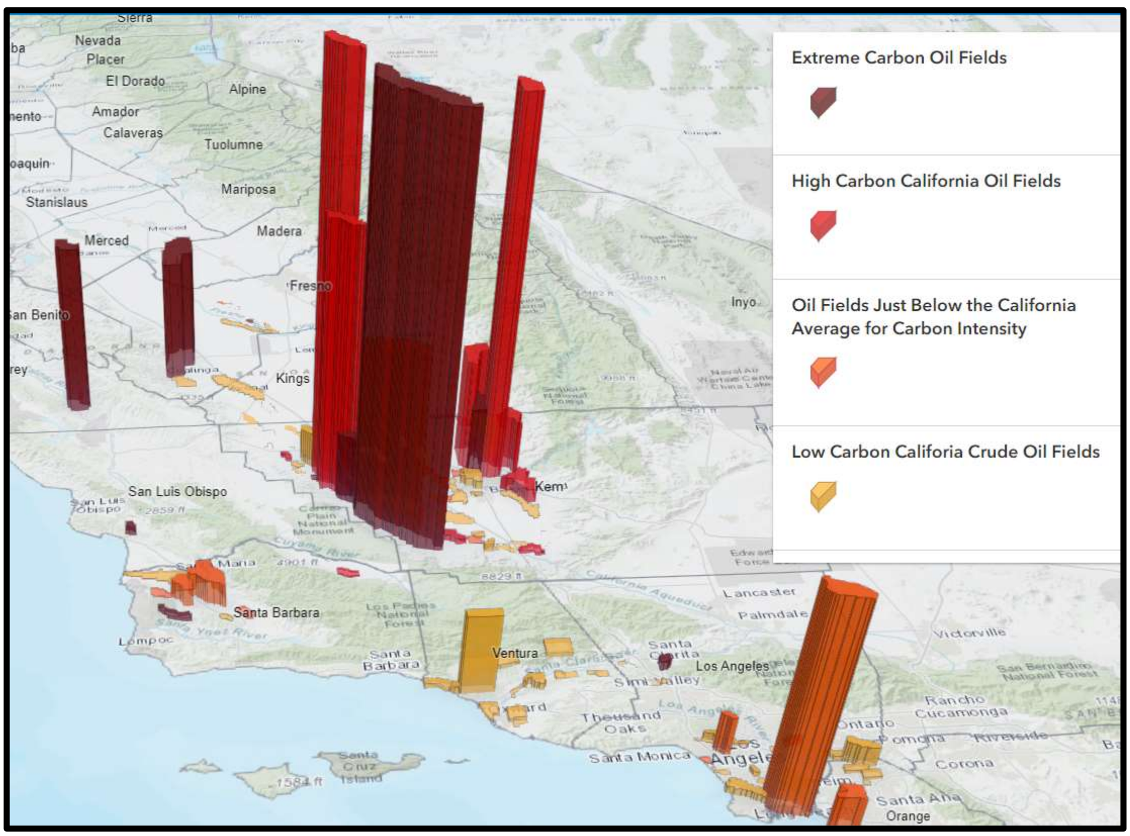
FOR LCFS CREDITS FOR USING INNOVATIVE METHODS FOR CRUDE

PRODUCTION OR TO AMEND §95849(c)(1)(A)

CYCLIC STEAM REPLACEMENT

CLEAN SURFACTANT ENERGY (CRSE) PROJECT

RENEWABLE AND BIODEGRADABLE SURFACTANT



Thermal Heavy Oil Fields, Kern County California

SUPPLEMENT TO APPLICATION TO THE EXECUTIVE OFFICER

FOR LCFS CREDITS FOR USING INNOVATIVE METHODS FOR CRUDE PRODUCTION OR TO AMEND §95849(c)(1)(A)

CYCLIC STEAM REPLACEMENT

CLEAN SURFACTANT ENERGY (CRSE) PROJECT

RENEWABLE AND BIODEGRADABLE SURFACTANT

Recognizing that CARB's world leading LCFS is designed to decrease the carbon intensity of California's transportation fuel pool, Senergy submitted its application for approval of credits for CRSE, an innovation that uses renewable chemistry to eliminate steam in production of crude oil. Senergy's application gives focus to the operational advantages of the innovation. This supplement describes externalities that merit attention in Staff's evaluation.

1. CRSE advances social justice in impacted communities in California.

Where oil is produced in California, the most impacted and least protected communities are near its source and bear the brunt of GHG emissions. Reducing that impact is the priority of CARB. CRSE immediately facilitates significant progress toward that equity goal.

2. CRSE brings economic advantages to disadvantaged communities.

Enabling production of clean oil provides increased local employment in communities that are presently under economic pressure. In turn, CRSE multiplies economic opportunity for local businesses. The CRSE innovation will redress long-standing inequities for communities which are otherwise disadvantaged by the loss of well-paying jobs.

3. CRSE enables decarbonizing around the clock.

Current accredited innovations that reduce emissions from steam do so only during daylight hours, in favorable weather. CRSE, by contrast, enables GHG reduction from the point source of oil production 24/7/365—without land use changes. This is a concrete example of how new technology is better than old technology.

4. CRSE ensures buy-in from the dirtiest industry in the state.

Forcing emission abatement on the oil industry has met with some resistance from recalcitrant operators, and too little active participation even by the most enlightened companies. Burning natural gas to generate steam remains economically attractive. The proposed credit will alter the calculation and incentivize adoption of the CRSE innovation.

CRSE abates emissions and maintains efficient production, eliminating any excuse to delay decarbonizing efforts. By accelerating the production of existing oil supplies, CRSE abbreviates oil production in California, *and* cleans up the fuel pool to advance the energy transition.

5. CRSE eliminates dirty oil in California.

As long as oil is produced in California, CARB should favor production of the *cleanest possible oil*. Awarding credits to companies that adopt efficient abatement measures incentivizes decarbonization. The marketplace will nudge every oil producer in the right direction. Even the most truculent oil producer can appreciate the cost-benefit analysis that will mandate implementation of this innovation.

6. Granting the CRSE application encourages further innovation.

By allowing credits for carbon abatement, CARB acts as a clearing house for the best and brightest advancements in abated emissions in oil production. The potential exists for upstream advancements like CRSE to encourage additional decarbonizing throughout the transportation fuel chain.

CONCLUSION

Senergy wants to express gratitude for everything CARB does to make California a better place to live and work. We remain ready to answer your tough questions about our product and process.

RESPECTFULLY SUBMITTED,

____

Jesse Holman, President, and CEO

February 20, 2024

Chair Liane Randolph and
Members of the Board
California Air Resources Board
1001 I St.
Sacramento, CA 95814

RE: Proposed Low Carbon Fuel Standard Amendments

Dear Chair Randolph and Members of the Board:

The Center for Biological Diversity appreciates the opportunity to comment on CARB's proposed amendments to the Low Carbon Fuel Standard ("LCFS"). There are serious issues with the current iteration of the LCFS: it is misaligned with the California's electrification goals, worsens environmental injustices, and permits a credit excess from biofuels and other "false solutions" that undercuts the credit price. We offer several concerns and suggestions to improve the program in order to better address the state's climate goals and avoid reliance on false solutions that accelerate the climate crisis.

I. CARB Should Use the Time Until the Final Vote to Incorporate Feedback from the Board and the Public.

We appreciate that the Board recently delayed a final vote on the LCFS, given the volume of comments the Board has received. While we are generally skeptical of industry-led attempts to delay implementation of life-saving rules that the Board has adopted in recent years, there were good reasons to delay a vote on this particular proposal. The Board now has time to analyze and incorporate the changes requested in this comment letter, as well as the changes recommended by the Environmental Justice Advisory Committee ("EJAC"), many of which are not reflected in the current proposal.

The LCFS has been trending in the wrong direction in recent months. The current proposal
backtracks in important ways from what staff had outlined in September. For example, the new
210.1 proposal backslides on the previously announced avoided methane policy, allows retroactive
210.2 crediting for pathways that favor non-zero-emission fuels, and adds (inadequate) safeguards on
210.3 crop-based feedstocks. The Board now has time to consider the changes proposed here before the LCFS is finalized. It should use the coming months to revisit some of the fundamental assumptions currently baked into the program, which could have a tremendous impact on whether the program will help meet the state's climate goals.

II. Carbon Capture and Storage Threatens to Derail Climate Goals and CARB Must Respond Accordingly.

210.4

a. CARB must end LCFS credits to out-of-state projects conducting EOR associated with CCS.

CARB must remove its provision allowing credits to projects outside of California that produce oil using captured carbon dioxide ("CO_2"). This provision is at odds with California law. Closing this loophole would not only align with California law, but also reduce opportunities for fossil fuel production, and align with an EJAC recommendation.

In September 2022, Governor Newsom signed Senate Bill 905 (SB 905) into law.[1] Among other provisions, SB 905 prohibits operators in California from utilizing CO_2 from CCS operations in enhanced oil recovery ("EOR").[2]

It's easy to see why the legislature listened to communities in California and banned EOR associated with CCS. EOR involves the injection of fluids and/or gases (such as CO_2) underground to extract fossil fuels.[3] EOR threatens drinking water integrity, yet regulations on EOR activities are decades old and fall short of providing sufficient safeguards for groundwater.[4] In addition, all forms of EOR have some risk of blowouts that can result in leakage and/or surfacing of fossil fuels or injection fluids.[5] And throughout the EOR lifecycle—from construction to injection, production, and waste disposal—there are risks to the environment and communities from air, water, and noise pollution.[6] Adding to this is the contribution to climate change caused by extracting and using more fossil fuels via EOR. One study found that for each ton of CO_2 injected for EOR, 2.7 tons of CO_2 are eventually emitted from burning recovered oil.[7]

Yet while California decidedly took a stand against CCS-associated EOR within the State, CARB's LCFS door remains open to incentivizing this same harmful practice *outside* the State's borders. Under the LCFS CCS Protocol, applicable CCS projects are those "that capture carbon dioxide (CO_2) and sequester it onshore, in either saline or depleted oil and gas reservoirs, *or oil*

[4] *Id.*
[5] *Id.* at 13.
[6] *Id.* at 12.
[7] *Id.* at 23, *citing* Banks, Brian et al., *SaskPower's Carbon Capture Project – What Risks? What Rewards?*, Canadian Center for Policy Alternatives at 16-17 (2015) (noting that this calculation "does not even account for carbon dioxide losses in the course of the injection process: a substantial proportion returns to the surface with the oil.").

and gas reservoirs used for CO_2-enhanced oil recovery (CO_2- EOR).[8] Thus, non-California regulated entities conducting EOR will be compensated by CARB for causing environmental and community health damage elsewhere. This asymmetry is simply wrong and must be corrected by removal of CCS-related EOR from the LCFS.

Closing the out-of-state EOR loophole aligns with the EJAC's recommendation that CARB has yet to address in the LCFS revisions. The EJAC specifically directed CARB staff to "Prohibit enhanced oil recovery as an eligible sequestration method."[9]

The following are possible changes to remove CCS-related EOR:

A. Remove the bolded language below from the LCFS CCS Protocol:
   - The CCS Protocol applies to projects "that capture carbon dioxide (CO_2) and sequester it onshore, in either saline or depleted oil and gas reservoirs, **or oil and gas reservoirs used for CO_2-enhanced oil recovery (CO_2- EOR)."**

B. Update the following regulations:
   - In 17 Cal. Code Regs. section 95490(a)(1) (stating that eligible entities include "Alternative fuel producers, refineries, and oil and gas producers that capture CO_2 on-site and geologically sequester CO_2 either on-site or off-site"), make clear that, to be eligible, capture and sequestration of CO_2 does not include EOR.
   - In 17 Cal. Code Regs. section 95490(a)(2) (stating that "If CO_2 derived from direct air capture is converted to fuels, it is not eligible for project-based CCS credits. However, applicants may apply for fuel pathway certification using the Tier 2 pathway application process as described in section 95488.7."), make clear that CO_2 derived from direct air capture may not be used for EOR.

210.5 **b. CARB must not encourage continued and/or prolonged use of fossil fuels through its petroleum-plus-CCS phase-out loophole.**

CARB is seeking to "encourage existing petroleum facilities to deploy"[10] technologies like CCS and in doing so, to allow these fossil fuel projects to continue to generate credits beyond the phase-out date of December 31, 2040.[11] This amendment creates a dangerous loophole that relies on a so-called climate solution that is anything but; the result will be California incentivizing and perpetuating the climate catastrophe and the health and environmental harms that come with it.

---

[8] CARB LCFS CCS Protocol at 7 (Aug. 13, 2018) (emphasis added). CCS projects are eligible for LCFS participation under the Tier 2 pathway. *See* 17 Cal. Code Regs. § 95488.1(d)(7)(B).

[10] LCFS Proposed Amendments, Appendix E at page 88, Y.8, rationale for proposed §§ 95489(c)(1)(A)2 and 95489(e)(1)(D)1.
[11] LCFS Proposed Amendments, Appendix E at page 93, X.19, proposed for §§ 95489(c)(5), 95489(d)(5)(C), 95489(e)(5)(B), and 95489(f)(5)(B).

Encouraging fossil fuels and exempting their use from phase-out is reckless and derails California's efforts at climate leadership. The Intergovernmental Panel on Climate Change (IPCC) modeled pathway to the best chance of limiting warming to 1.5°C makes no use of fossil fuels with CCS or bioenergy with CCS and limited to no use of engineered CO_2 removal technologies.[12] CCS projects around the world have failed drastically—and repeatedly—to meet their GHG emission reduction promises.[13] For example, in July 2021, Chevron admitted that its self-described "world's biggest CCS project" failed to meet its five-year capture target and was seeking a deal to make up for millions of tons of CO_2 emitted.[14] In another example, the Petra Nova[15] CCS facility which was promised to capture 90 percent of the power plant's total CO_2 emissions only captured 7 percent.[16] Providing a phase-out exemption for fossil fuel projects in California invites failed and under-delivering polluting facilities to continue to pollute communities and the climate, all without any end in sight.

There is also a substantial energy penalty for the use of CCS that reduces any potential climate benefits—especially when that extra energy is sourced from fossil fuels.[17] An energy penalty is defined as the extra energy required to run a capture process or the amount of energy spent when compared to the energy generated.[18] The energy penalty of CCS increases the fuel requirement for electricity generation by 11-40%.[19] Thus, the installation of CCS and its concomitant energy penalty drives even more pollution, which is currently unaccounted for in CARB's Scoping Plan and, seemingly, in the proposed phase-out exemption.

[12] The IPCC-modeled pathway with the best chance of keeping warming at or below the target of 1.5°C makes no use of fossil fuels with CCS. IPCC, Summary for Policymakers in Global Warming of 1.5°C (2018) at 14, Section C.1.1., Figure SPM 3b (Pathway 1); *see also* IPCC SR1.5, at Ch. 2.3.3 and Table 2.SM.12.

210.6 **c. Hydrogen using fossil fuels plus CCS must not be eligible for reducing the CI score or LCFS credits generally.**

As explained later in this comment, the only form of hydrogen that should be considered under any provision in the LCFS is "green hydrogen," or hydrogen made by splitting water into hydrogen and oxygen using 100% solar or wind energy, while adhering to the three pillars. Instead, CARB staff are proposing to allow "hydrogen as an intermediate input to alternative or petroleum fuel production is eligible for reducing the GHG emissions associated with fuel production if hydrogen production is equipped with" CCS.[20]

As reiterated throughout this comment letter, CARB should not be incentivizing and prolonging the use of fossil fuels *in any manner*. This includes fossil fuels plus CCS. Facilities using CCS do *not* capture 100% of their climate-harming emissions, they incur a high energy penalty (meaning more energy use and emissions), and fossil fuel production is rife with environmental and health harms. Phasing out fossil fuels should be a fundamental tenant of any climate-focused policy, but CARB insists on carving out ways for fossil fuels to continue, such as this hydrogen allowance. These carve outs must end.

210.7 **d. CARB must ensure capture-to-injection tracking of CO_2.**

While we do not support the false climate fix that is CCS, we do support CARB's proposal that "additional entities, such as CO_2 transporters, along the supply chain of a CCS project" register as joint applicants and include "how the captured CO_2 passes through the supply chain among various entities."[21] We agree that "it is crucial for CCS projects to track the CO_2 throughout the supply chain."[22] It is important to avoid double-counting and double credits, both at the LCFS level and to the extent this information can be used to avoid double-counting at the federal level with IRS 45Q tax credits, which is rife with this kind of fraud.[23]

We recommend that CARB staff prohibit applicants from claiming confidential business information (CBI) in their applications so that members of the public have insight into the joint applicants involved in the entirety of a CCS project.

210.8 **III. CARB Should Strictly Limit the Use of Crop-based Biofuels.**

210.3 **a. The proposed sustainability criteria for crop-based biofuels are woefully inadequate.**

The proposed LCFS amendments allow for the continued use and expansion of crop-based (lipid) biofuels despite evidence that they are unsustainable and a danger to environmental and

[23] Taxpayers for Common Sense, "45Q Issue Brief – Nearly 90 Percent of Carbon Sequestration Tax Credits Based on Insufficient Reporting and Fraudulent Claims" (Feb. 2023), https://www.taxpayer.net/climate/45q-issue-brief-nearly-90-percent-of-carbon-sequestration-tax-credits-based-on-insufficient-reporting-and-fraudulent-claims/.

public health. The only effort CARB staff propose to address these concerns is to identify and implement a sustainability certification for crop-based biofuels, without defining the criteria that would make a crop-based biofuel viable for use under such a certification. A sustainability requirement that equates to satisfying a certification standard that has yet to be defined is meaningless, and it should not have been proposed without a certification standard already chosen for consideration.

In the absence of CARB-established sustainability criteria, we looked to general definitions of energy sustainability to establish governing principles for biofuels. The result was the following biofuels sustainability criteria: (1) the fuel must be produced using feedstock that is readily available and can be replenished; (2) collecting and processing the feedstock must not cause environmental and social harms; (3) procuring the feedstock must not result in significant land-use change or otherwise hinder land's natural ability to store and sequester carbon; and (4) the lifecycle greenhouse gas emissions from the fuel must be near zero relative to conventional jet fuel.[24] In applying these sustainability criteria, it becomes clear that no crop-based biofuel is sustainable.

210.9 **b. In permitting crop-based biofuels, CARB is allowing climate-damaging emissions.**

Relying on crop-based biofuels results in both direct and indirect land use change emissions that worsen the climate crisis, counter to their intended purpose. For example, in an analysis of 17 potential alternative-fuel pathways looking at different feedstocks, technologies, and world regions, researchers found that using virgin vegetable oil had the highest indirect land-use change emissions because of links to high deforestation and peat oxidation in southeast Asia, driven by palm expansion.[25] Though CARB staff are proposing to remove palm-derived fuels from eligibility under the LCFS, it must be noted that this does not eliminate the threat of CARB's sanctioning of crop-based biofuels leading to palm oil expansion. In the same study, it was found that producing biofuels from any vegetable oil in any region, including corn and soy in the U.S. context, would encourage palm oil expansion and associated peat oxidation in southeast Asia due to substitutions among vegetable oils and international trade.[26] Thus, high indirect land-use change emissions from virgin vegetable oil biofuel pathways undermine some, if not all, of the greenhouse gas savings from these fuels.[27]

[27] Pavlenko, N. and Searle, S., Fueling flight: Assessing the sustainability implications of alternative aviation fuels, International Council on Clean Transportation (2021); Zhao, X. et al., Estimating induced land use change emissions for sustainable aviation biofuel pathways, 779 Science and the Total Environment (2021).

CARB staff state that, "[w]ith continued increased demands on biofuel crops the Proposed Amendments could contribute to increased direct and indirect land use change to accommodate new croplands," but go on to minimize this statement by stating that "the likelihood of this is at least partially (and potentially fully) accounted for by the LUC scores added to crop-derived pathways."[28] However, the reality is that the Proposed Amendments likely will yield additional direct and indirect land use change emissions without any guarantee that these emissions will be fully accounted for. So CARB staff are proposing guidance on crop-based biofuels that could lead to unforeseen climate-harming emissions.

210.10 **c. Crop-based biofuels pose a threat to communities and the environment.**

There could also be unforeseen harms to communities and the environment. One such harm is worsening water scarcity. A 2017 study found that increased production of crop-based biofuels heavily contributes to global water scarcity and is not the best option for bioenergy.[29] Meanwhile, a 2016 study found that biofuels rely on about 2-3% of the global water and land used for agriculture. Based on the food calories used for biofuel production, that amount could feed about 30% of the malnourished global population.[30] Just in the United States, about 140 million people could be fed with the resources for bioethanol, and about 10 million people could be fed with the resources for biodiesel, indicating the threat of crop-based biofuels to global food security.[31] Also, with increased production of crop-based biofuels, there is the potential for increased nutrient and pesticide runoff to surface waters and contamination of groundwater due to crop cultivation.[32]

Another harm from crop-based biofuels is the impact to communities from biofuel refining and resulting criteria pollutant emissions. Crop-based biofuels are most often produced using the Hydroprocessed Esters and Fatty Acids (HEFA) pathway, which reacts crop feedstock with hydrogen at high temperatures and pressures to form fuel.[33] Because of the high temperatures and extremely high pressures, runaway increases in temperature are common, which result in operators flaring refinery gases to bring conditions back under control. However, in doing so, toxic and smog-forming air contaminants are emitted such as particulate matter, sulfur dioxide, and hydrocarbons that worsen air quality. Because HEFA processes require more hydrogen than petroleum refining, it is expected that hydro-conversion-related flaring would be worse with

HEFA refining, along with explosion and fire risk.[34] With refineries most often sited in low-income communities and communities of color,[35] environmental justice harms are exacerbated by the presence of HEFA refining and would worsen with crop-based biofuel expansion.

Biofuel refinery expansion is alluded to by CARB staff: "Potential compliance responses to the Proposed Amendments…include construction and operation of new facilities to produce renewable diesel, biodiesel, and AJF and collection and distribution of feedstock to supply these facilities, or replace existing petroleum refineries."[36] Indeed, attempts are already being made in the Bay Area, for example, to convert existing oil and gas refineries to HEFA refineries, [37] and where low-income communities and communities of color would bear the brunt of air-pollution exposure.

210.11

d. CARB should adopt the EJAC recommendation of a cap on crop-based biofuels.

Given the risks associated with crop-based biofuels, it is disappointing that CARB staff rejected the amendments in the Comprehensive Environmental Justice Scenario proposed by CARB's Environmental Justice Advisory Committee (EJAC). The proposal was to "[c]ap the use of lipid biofuels (commonly known as crop-based biofuels) at 2020 levels, about 855 million gallons, pending an updated risk assessment to determine phase out timelines for high-risk, crop-based feedstocks."[38] The EJ Scenario was rejected because it would purportedly result in higher volumes of fossil diesel being used than any of the other scenarios evaluated. However, capping the use of lipid biofuels could instead spur the development of less deleterious alternatives such as the use of true waste products in biofuel production such as municipal solid waste (mentioned in the amendments),[39] and push the needed transition to battery-electric in shipping and trucking,[40] all while preventing the expansion of crop-based biofuel harms. Instead, crop-based biofuels are treated as the unavoidable alternative to fossil fuels, locking in the threat to communities and the environment.

210.12

IV. CARB Should Add Conventional Jet Fuel as a Deficit-Generator But Add Strong Guardrails on Crop-Based Biofuels.

CARB is proposing to add conventional jet fuel ("CJF") for intrastate flights as a deficit-generator, as opposed to its current status as an opt-in fuel.[41] In including aviation emissions in the LCFS, the Board must walk a fine line between eliminating the exemption for dirty jet fuel while not incentivizing the use of crop-based biofuels, which damage ecosystems and communities.[42]

First, we note that the current language on this issue is weaker than staff had previously suggested, which will delay the potential benefits achieved through this change. The current proposal includes only fuel from intrastate flights, rather than all fuel that is combusted in and over California by all flights, including interstate and international. And it delays implementation until 2028.[43] These limiting factors will needlessly slow the benefits that may come from a transition to a more sustainable aviation industry. CARB should explore whether it can accelerate the implementation of this change and include fuel combusted from international and interstate flights for the portion of their trips that occur within the state's boundaries. If the Board chooses not to explore these avenues in this rulemaking, it should revisit these options at its next opportunity.

Second, it is beyond time to end the unfair advantages given to CJF that perpetuate the industry's use of fossil fuels. Many state policies heavily subsidize the industry's use of carbon-based jet fuels, which works against the state's efforts at decarbonizing the sector and allows this fuel to be under-regulated. For example, fuel used in international flights are exempt from sales and use taxes in California, a practice that was estimated to cost state and local governments nearly $300 million in revenue in 2021-2022.[44] Commercial airlines are also exempt from the excise tax for jet fuel, a tax break that costs the state about $23 million each year.[45] The carveout in the Low Carbon Fuel Standard for conventional jet fuel saves the airlines an estimated $110 to $360 million each year[46] on the cost of that fuel.

Relatedly, the industry continues to push the false solution of so-called Sustainable Aviation Fuels. Rather than accept the true and full climate costs of aviation and invest more seriously in research for zero-emission technologies like electric aircraft, the industry has become enamored with false solutions like carbon offsets or flawed, short-term answers like SAFs. Many sources of SAF feedstock are likely unable to scale up to the industry-wide demand, and particularly

problematic sources of biofuel feedstock like palm oil may create even more problems than they solve. Therefore, CARB should carefully regulate the feedstocks that receive credit for contributing to SAFs.

Third, while ending the exemption for CJF is a welcome first step, it needs to be paired with complementary policies that strictly limit the use of crop-based biofuels, as described above in Part III. The inclusion of CJF in the program at this juncture provides the Board an opportunity to ensure that included fuels meet true sustainability criteria going forward. Relying on crop-based biofuels results in both direct and indirect land use change emissions that worsen the climate crisis, counter to their intended purpose. The Board should therefore choose to allow only feedstocks that have little to no land use effects or indirect emissions, such as municipal solid waste.

In short, the promotion and subsidization of SAFs, without adequate regard for the lifecycle impact and other ecological consequences of different feedstocks, threatens to substitute one problem for a host of others. California should not be in the business of subsidizing an industry's transition to fuels that promote deforestation in other parts of the country and world. Because crop-based biofuels are simply not sustainable, CARB should only incentivize fuels that meet strict and transparent sustainability criteria—a goal the Board has not reached in its current proposal.[47]

210.13
210.14
V. CARB Should Limit the Incentives for Hydrogen and Restrict Crediting to Renewable-Fueled Hydrogen.

210.15
a. The LCFS should only allow hydrogen production that adheres to the three pillars.

According to CARB staff, "[p]otential compliance responses to the Proposed Amendments could include the construction of new or expanded hydrogen production facilities, using steam methane reformation, electrolysis, or gasification technologies."[48] This highlights a grave issue with the proposed amendments since, according to current best science, the cleanest way to produce hydrogen, without drawing much needed renewables from other uses, is to employ the three pillars—hourly matching, deliverability, and additionality—in the process of renewable-fueled electrolysis.[49]

---

[47] *See infra*, Part III.
[48] Appendix D, p. 29.
[49] Ricks, Jenkins, *The Cost of Clean Hydrogen with Robust Emission Standards: A Comparison Across Studies,* Princeton University Zero-carbon Energy Systems Research and Optimization Laboratory (2023), available at https://subscriber.politicopro.com/f/?id=00000187-9bb4-daaa-a5e7-bfbfff120000; Dan Esposito et al., *Smart Design of 45V Hydrogen Production Tax Credit Will Reduce Emissions and Grow the Industry,* Energy Innovation Policy & Technology (2023); and Ben Haley, Jeremy Hargreaves, *Three-Pillars Accounting Impact Analysis,* Evolved Energy Research (2023), available at https://www.evolved.energy/post/45v-three-pillars-impact-analysis.

Specifically, hydrogen production should proceed where hydrogen generators are powered by *new* sources of zero-emissions electricity (additionality or incrementality) that directly supply the grid electrolyzers are connected to (deliverability), within the same hour that generators are running (hourly matching). This is reaffirmed by the IRS's proposed rulemaking in which hydrogen producers could only receive the Section 45V clean hydrogen production tax credit by adhering to the 3 pillars.[50] Yet, CARB staff's proposed amendments would allow the continued use of fossil gas, and the use of problematic feedstocks like dairy biogas and biomass, despite the emissions and environmental burdens these all carry. The only form of hydrogen that should be considered under any provision in the LCFS is "green hydrogen," or hydrogen made by splitting water into hydrogen and oxygen using 100% solar or wind energy, while adhering to the 3 pillars.

210.16 **b. The LCFS should only allow electrolytic hydrogen produced using renewable solar and wind energy.**

"Blue hydrogen" production, or steam methane reformation paired with CCS, and gasification or pyrolysis of biogenic resources (e.g. woody biomass and biogas) should be explicitly excluded because of their associated harms: CCS, on which blue hydrogen production relies, has proven to be ineffective, dangerous, and expensive,[51] with research showing that blue hydrogen can be worse for the climate than burning fossil fuels.[52] Woody biomass, as a feedstock (e.g. in gasification or pyrolysis) or energy source to make hydrogen, harms the climate,[53] communities, and ecosystems with significant emissions of CO_2[54] and criteria pollutants.[55] As the IPCC, the

federal Environmental Protection Agency's Science Advisory Board, and other scientists have established, wood bioenergy should not be assumed to be carbon neutral;[56] Using methane to produce hydrogen increases methane leakage risk, with one biogas plant study finding that leaked methane can be as high as 14.9% of total methane production.[57] There is also a significant pollution burden from biogas facilities near communities.[58] The LCFS should no longer incentivize and subsidize feedstocks that harm the climate and pollute the same communities that have historically borne the pollution burden of our status quo energy portfolio.

c. Hydrogen will only have a limited role in a carbon-free future.

Ultimately, even hydrogen produced using clean, renewable energy should play only a limited role in a carbon-free future, given the risks it carries. First, hydrogen is a potent, indirect greenhouse gas with 100 times the warming power of CO_2 over a 10-year period and 33 times over 20 years.[59] As a small molecule, hydrogen is more leakage-prone than methane, posing climate risks across the production and supply chains. Also, transporting hydrogen through pipelines is more dangerous than transporting methane: it is more likely to explode, burns hotter, and is more corrosive to pipelines.[60] Further, hydrogen production from fossil gas and coal emits dangerous health-harming pollution.[61] And all forms of hydrogen production use massive amounts of water—much more than solar and wind per unit of energy produced—which will put

extra stress on water supplies in areas already suffering from climate crisis-charged drought.[62] At present, about one million Californians lack access to safe, clean, and affordable water adequate for human consumption,[63] begging the question of whether water should be diverted to hydrogen production.

Thus, the use of hydrogen should be limited to those sectors without a viable present-day
210.17 alternative, such as replacing existing dirty gray fossil-based hydrogen, crude oil refineries, or
steel manufacturing.[64] This would effectively exclude the sectors for which the proposed
amendments are most incentivizing hydrogen adoption: light-duty, medium-duty, and heavy-
duty transport. Through the Hydrogen Refueling Infrastructure (HRI) provision, for instance,
CARB is incentivizing the rapid buildout of hydrogen refueling infrastructure.[65] However,
210.18 resources would be better directed to other pursuits given that for light-duty vehicles, battery-
electric is readily available, energy efficient, and lower cost than the hydrogen fuel cell
alternative.[66] Likewise, for heavy-duty vehicles such as those in long-haul trucking, it has now
been shown that battery-electric is competitive and economically advantageous.[67] Whenever
direct electrification can be used instead of hydrogen, as with vehicles, it's the demonstrably
better choice. Electricity made from solar and wind is more efficient, lower cost, lower in CO_2
emissions, and a mature energy resource.[68] The LCFS should be incentivizing full electrification
210.17 rather than hydrogen which is projected to have only a limited role in a carbon-free future.[69]

210.19 **VI. CARB Should Remove Woody Biomass Feedstocks from the LCFS Program.**

CARB's proposed amendments to section 95488.8(g)(1)(A)1 on Specified Source Feedstocks adds "forestry residues" to the list of feedstocks, with some specifications: "Small-diameter, non-merchantable forestry residues removed for the purpose of forest fire fuel reduction or forest stand improvement and from a treatment where no-clear cutting occurred."[70]

We oppose the inclusion of woody biomass feedstocks, including forest and agricultural residues, in the LCFS program due to the significant greenhouse gas pollution, air pollution, degradation of forest ecosystems, and loss of forest carbon storage that come from producing biofuels and hydrogen from woody biomass. CARB's proposed specifications for forest residues are vague and will not meaningfully reduce harms.

210.19 **a. CARB should not include woody biomass, including forest and agricultural residues, as feedstocks in the LCFS program due to the harms to the climate, public health, and forest ecosystems.**

As detailed below, the production of biofuels and hydrogen from woody biomass releases large amounts of planet-heating CO_2 and toxic air pollutants, worsening the climate emergency and harming public health. While the GREET model incorrectly treats forest feedstocks as carbon neutral, scientific research clearly shows that combustion or gasification of trees and other forest material—including residues considered to be "waste"— leads to a net increase of carbon emissions in the atmosphere for decades to centuries. Biomass facilities often concentrate pollution in communities of color and low-income communities in California, worsening environmental injustice.[71] Adding CCS to biomass gasification, pyrolysis, or combustion would still result in significant climate and air pollution and threaten public and safety, given CCS has proven to be ineffective, unsafe, and energy-intensive. Incentivizing hydrogen and biofuels production from forest biomass risks increasing logging and thinning, which degrade wildlife habitat and result in a net loss of forest carbon storage and sequestration, at a time when we must be protecting forest carbon stores. Biofuel and hydrogen production from woody biomass are not part of a clean, just energy future and should not be included in the LCFS program.

i. Gasification and pyrolysis of biomass to produce hydrogen and biofuels produce large amounts of CO_2 and health-harming pollutants.

Gasification and pyrolysis are the primary processes being promoted to produce hydrogen and biofuels from woody biomass such as trees and agricultural materials. The gasification of biomass at high temperatures (800-1200°C) produces a "syngas" containing large amounts of CO_2, as well as methane (CH4), carbon monoxide (CO), and hydrogen (H_2), in addition to liquid hydrocarbons and tar, solid char and ash residues, and a wide array of air pollutants. The pyrolysis of biomass additionally produces pyrolytic oil and larger quantities of char. The biomass fuel, gasifier type, temperature, and gasifying agent (e.g., steam, air, oxygen, oxygen-enriched air) influence the composition of the syngas.[72] Biomass gasification and pyrolysis processes to produce hydrogen are still in the initial development phase, have not been demonstrated at any meaningful scale, are technically difficult, and expensive.

ii. Health-harming pollutants.

Biomass gasification and pyrolysis produce a wide range of health-harming pollutants including fine particulate matter, NOx, SOx, benzene, toluene and xylenes (BTEX), tars and soot, and persistent organic pollutants such as polycyclic aromatic hydrocarbons (PAHs) (e.g., naphthalene), polychlorinated dibenzo-*p*-dioxins and dibenzofurans (PCDD/Fs).[73] Importantly, gasification and pyrolysis of biomass are significant sources of fine particulate matter (PM 2.5) that can penetrate deeply into the lungs, even enter the bloodstream, and cause serious health problems.[74] Fine particulate matter pollution is linked to a higher risk of premature death, heart disease, stroke, and aggravated asthma.[75]

The formation of NOx precursors, including NH_3, HCN and HNCO, during biomass pyrolysis has been widely reported, where NOx damages the respiratory system and contributes to acid

[75] U.S. Environmental Protection Agency, Health and Environmental Effects of Particulate Matter, https://www.epa.gov/pm-pollution/health-and-environmental-effects-particulate-matter-pm.

rain, harming ecosystems.[76] Of the BTEX compounds produced during gasification and pyrolysis, benzene is a known human carcinogen, and toluene and xylenes damage the brain and nervous system, respiratory system, kidneys, and liver.

The formation of liquid tar is an inherent problem in biomass gasification. Tar contains toxic substances such as benzene, toluene, and naphthalene, while tar build-up also lowers energy efficiency, interrupts continuous operation, and increases maintenance costs of gasification processes.[77] Methods to clean tar from equipment would create large amounts of toxic wastewater, with resulting environmental and community harms.[78]

iii. Climate-heating CO_2.

Similar to biomass combustion, gasification and pyrolysis of biomass produce large quantities of CO_2 as well as methane emissions that worsen the climate emergency. Biomass-derived hydrogen and biofuels are often falsely promoted as being carbon neutral or carbon negative (i.e., meaning that they will lead to a net removal of CO_2 from the atmosphere) based on the inaccurate claims that woody biomass is a carbon neutral feedstock and/or that CCS can be used to capture the CO_2 emitted from the process. The claim that woody biomass is a carbon neutral feedstock has been thoroughly debunked,[79] given the lost carbon storage and sequestration from extracting biomass, and the significant CO_2 emissions during biomass processing and gasification, pyrolysis, or combustion.[80] For example, substantial upstream emissions are released from cutting and extracting trees and other vegetation which immediately ends their carbon storage and sequestration; the use of fertilizers and pesticides after cutting; transporting biomass often long distances in diesel trucks; and processing biomass through chipping and drying.[81] The combustion, gasification, and pyrolysis of trees and other forest material—

including residues considered to be "waste"— leads to a net increase of carbon emissions in the atmosphere for decades to centuries.[82]

Furthermore, CCS has consistently proven to be exceptionally ineffective, unsafe, expensive, and targets environmental justice communities.[83] CCS operations are very energy-intensive given the high energy requirements needed to separate, compress, transport, and inject CO_2, typically requiring at least 15-25% more energy, which results in increased greenhouse gas and air pollution emissions.[84] CCS projects around the world have consistently failed to meet their carbon-capture promises, often by large margins.[85] Moreover, 95% of CO_2 captured in the U.S. by CCS is used to pump oil and gas out of the ground in process called enhanced oil recovery,[86] worsening the climate emergency. CCS poses significant new health, safety, and environmental risks from toxic air pollution emitted from CCS facilities, earthquake risks from underground CO_2 injection, and the inevitable ruptures of CO_2 pipelines and leaks from underground CO_2 storage that can sicken and even kill people.[87] In short, putting CCS equipment on biomass gasification and pyrolysis facilities (BECCS) would still lead to significant CO_2 and co-pollutants emissions, endangering communities and the climate.

iv. Environmental injustice.

Biomass gasification and pyrolysis project proposals are targeting communities in the Central Valley already overburdened with pollution. For example, idled Central Valley bioenergy facilities in or near communities, such as the Madera biomass facility, are being proposed for

conversion to biomass gasification or pyrolysis facilities to produce hydrogen, threatening to worsen environmental injustice for these communities.[88] Another recent proposal envisions a massive build-out of 50 to 100 biomass processing facilities—many of them biomass gasification and pyrolysis facilities—that would be concentrated in the Central Valley, paired with a polluting network of CO_2 pipelines, railcars, and trucking, and the injection of 100 million tons of CO_2 underground each year,[89] with inevitable harms from air pollution, water pollution, noise pollution, CO_2 leakage, earthquake risks, and ecosystem damage.

v. High water usage.

Biomass gasification to produce hydrogen has extremely high water usage. One recent study estimated that biomass gasification uses 306 kg water per kg of H_2 produced, which is orders of magnitude more than electrolysis production pathways estimated at 9 to 18 kg water per kg H_2.[90] This would put extra stress on water supplies in areas already suffering from climate crisis-charged drought.

vi. Forest ecosystem harms and lost forest carbon storage and sequestration.

Incentivizing the production and commodification of hydrogen and biofuels from woody biomass is likely to increase forest logging and thinning which degrade wildlife habitat and result in a net loss of carbon storage and sequestration from forests, at a time when we must be reducing deforestation and protecting forest carbon stores.[91] Logging and thinning trees releases their stored carbon to the atmosphere in a triple whammy for the climate: it increases overall carbon emissions, reduces the forest carbon sink, and requires massive public subsidies, taking resources away from truly low-carbon solar and wind energy.

210.20 **b. CARB's proposed specifications for forest residues are vague and will not meaningfully reduce harms.**

CARB's proposed specifications for forest residues are that they are "[s]mall-diameter, non-merchantable forestry residues removed for the purpose of forest fire fuel reduction or forest stand improvement and from a treatment where no-clear cutting occurred."[92] However well-intentioned, these specifications are too vague to limit forest degradation nor will they

[92] Appendix A-1 at 145.

meaningfully reduce the significant harms to the climate, communities and forests detailed above.

Almost all forest logging and thinning projects are done under the justification that they will promote forest health and resilience and/or are needed for fuels reduction. Trees and other forest vegetation of any size can be lopped and masticated into “small-diameter” residues and called “non-merchantable.” Incentivizing the commodification of forest materials under the LCFS will lead to the removal of more biomass from the forest than would happen if these materials were not commodified, threatening forest ecosystems and forest carbon storage. Management practices should instead prioritize leaving residues in the forest to maintain soil organic carbon, retain vital nutrients in the ecosystem, and support wildlife habitat.[93]

Thank you for consideration of these comments.

DARLING INGREDIENTS

February 20, 2024

California Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: Proposed 2024 LCFS Amendments

Dear California Air Resources Board:

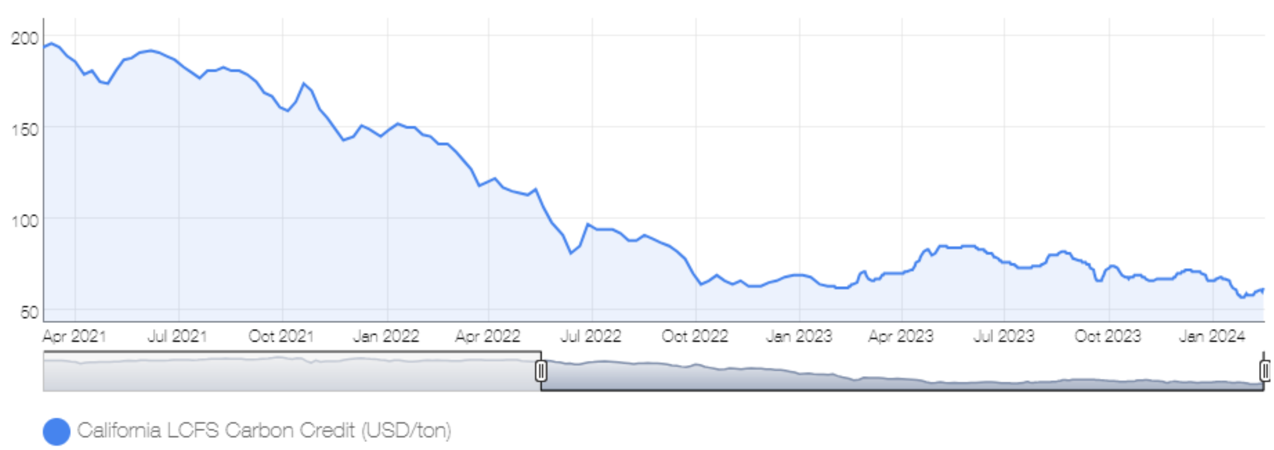
We are writing to provide comments on the Proposed 2024 Low Carbon Fuel Standard Amendments. Thank you for considering our views on this important issue.

Darling Ingredients is North America's largest purveyor of waste fats and oils and is a 50% owner of the nation's largest renewable diesel production facility through a joint venture. Most of the fat that Darling Ingredients processes from its North American factories (used cooking oil and animal fat) are used as feedstocks for domestically produced renewable diesel. We have collection, recycling, and processing operations at several locations in California[1]. According to CARB, our renewable diesel reduces greenhouse gasses (GHGs) by as much as 80%, particulate matter by 30%, NOx by 12%, and is sulfur and benzene free because it is produced from biological – rather than fossil – feedstocks. Renewable diesel is compatible up to 100% in all existing vehicles, equipment, and infrastructure and can be further processed into sustainable aviation fuel (SAF).

After reviewing the regulatory package, we have several comments we would like to share.

<u>Carbon Intensity (CI) Benchmarks</u>

Addressing the persistent decline in LCFS credit values demands more robust measures than have been included in the proposed regulatory package. While the amendments represent progress and a good faith effort to get the program back on track, a 5% step down in 2025 is simply not ambitious enough to
211.1 remedy the ongoing challenges linked to overcompliance and a historically high credit bank. The data depicted in the chart below unmistakably indicate that the credit market lacks confidence in the proposed amendments' ability to rebalance supply and demand effectively.



---

[1] Fresno, Los Angeles, San Diego, San Francisco, Santa Ana, and Turlock.

To address this issue, stakeholders previously recommended that CARB implement the 5% step down beginning July 1, 2024 rather than January 1, 2025. We still believe this would be an effective policy response to help address the current problem. However, in addition, we recommend increasing the 2025 step down from 5% to at least 10.5%. This would help restore the credit bank to levels more consistent with historical averages. For the 2030 benchmark, we recommend a requirement of at least 35%. By implementing these measures, the program would be poised for stability and innovation both in the short and long term.

Exemption for Jet Fuel

Prior to the availability of sustainable aviation fuel (SAF), exempting jet fuel from the LCFS program seemed logical. However, the landscape has changed with new facilities coming online in the very near future. For example, our joint venture project, which will be capable of producing approximately 235 million gallons of SAF annually beginning by approximately the first quarter 2025, underscores the
emergence and wider availability of SAF. In light of this evolving reality, it is disconcerting that the
211.2 proposed amendments continue to exempt intrastate jet fuel until January 1, 2028. Such a delay would
prove severely counterproductive since urgent market signals are needed to capitalize on the
momentum the industry is currently experiencing.

Advancing the repeal of the exemption to January 1, 2025 would offer essential support urgently
needed to transition the aviation sector toward cleaner, more sustainable practices. Furthermore, we
advocate for exempting the obligation on all jet fuel, not solely intrastate, as continuing reliance on
211.3 petroleum jet fuel amidst cleaner alternatives is entirely unnecessary, especially for years 2025, 2026,
and 2027 when our joint venture alone could fulfill the entire SAF obligation for all three years.

Auto Acceleration Mechanism (AAM)

The AAM concept represents an innovative approach to managing the ambition of the LCFS, and we appreciate its integration into the proposed amendments. However, similar to the concerns expressed regarding the exemption of jet fuel, we fail to understand the reasoning behind postponing
implementation until 2028. Should CARB lean toward deferring implementation of the AAM, we
211.4 recommend considering 2027 as a more suitable timeline. The years spanning 2025 through 2027 stand
out as particularly unbalanced during credit bank modeling exercises, demanding more ambition than is
represented in the proposed amendments.

Credit True Up After Annual Verification

211.5 We strongly support the provision that allows the Executive Officer to perform a credit true up for a fuel
pathway that has a lower verified operational CI upon receipt of a positive verification statement for the
211.6 associated annual fuel pathway report. However, we fail to understand why CARB proposes to penalize
CI exceedances by four times the difference in credits between the verified operational fuel pathway CI and the reported CI. Obviously, the agency has regulatory options at its discretion currently, including issuing notices of violation and levying financial penalties. If staff believe an additional deterrent is needed, two times the exceedance would seem more than sufficient to deter such activity. Four times the exceedance is simply unfair to producers and will result in less accurate CI values as well as an entirely different set of administrative challenges.

CARB Leadership

We urge staff and the board to continue embracing CARB's historical role as the global leader on low carbon fuels policy. Under the tech-neutral California program, every alternative fuel and technology has been successful and significantly outperformed expectations. While we are encouraged and optimistic about the future of low carbon programs in other states, the reality is that most other jurisdictions are still in some phase of consideration or in a nascent stage of development. For this reason, continued strong leadership from CARB is needed to ensure continuity of innovation across the broad spectrum of technologies, especially sustainable aviation fuel.

Once again, thank you for considering our comments. If you should have any questions, please feel free to contact me at any time at shelby.neal@darlingii.com.

Sincerely,

Shelby Neal

Comment

Dear California Air Resources Board,

We appreciate the opportunity to share our thoughts on California Air Resources Board's Low Carbon Fuel Standard amendments. The United States Hydrogen Alliance is a non-profit trade association dedicated to building the U.S. hydrogen economy. Our organization represents hydrogen companies actively deploying clean technologie across the country.

We are writing to share our perspective on several key program areas for your consideration. These requests address the light dut hydrogen refueling infrastructure pathway, low carbon intensity electricity, methane pyrolysis, along with recommendations for pyrolysis and renewable hydrogen definitions.

Regarding the new light duty hydrogen refueling infrastructure pathway, we believe the location restrictions to disadvantaged communities, low-income communities, and rural areas is overly limiting. While we respect the intent of these restrictions, we as for removal of the hydrogen refueling station location restrictio to allow alignment with traffic/use forecasts to ensure high usag and maximum societal benefit and to avoid applying a double standard for hydrogen, a zero emission fuel, in comparison to electricity.

New restrictions for low carbon intensity electricity require it t be supplied by new or expanded production, or within three years o a hydrogen production facility or air capture project's creation date. These restrictions resemble "additionality" or "incrementality," and is something the hydrogen industry is oppose to on all accounts. We suggest the removal of the new 100% renewable electricity requirement given the policy bias for electricity against hydrogen, as battery electric vehicles are no required to charge with 100% renewable electricity. Through California's Renewables Portfolio Standard, it is already require for retail electricity to be 100% renewable by 2045; with the gri already moving in this direction, this requirement seems redundan

For the definition of pyrolysis we suggest two amendments, the inclusion of both biomethane and solid carbon. We believe that solid carbon should be considered as a form of carbon capture and sequestration. Methane pyrolysis should also be included in a pathway for flexible access to low greenhouse gas methane sources to reduce both greenhouse gasses and the cost of hydrogen. We also suggest an amendment to the definition of renewable hydrogen to include pyrolysis in section two.

In section § 95490. Provisions for Fuels Produced Using Carbon Capture and Sequestration, we suggest adding the eligibility requirement below:
(3) "Hydrogen producers from methane pyrolysis that capture precombustion carbon in solid form and permanently store it or provide proof of permanent storage. 1kg of solid carbon is equivalent to 3.67kg of avoided carbon dioxide"

We at the United States Hydrogen Alliance thank you for your time and consideration. Please reach out to us if you have any questions.

Respectfully,

Roxana Bekemohammadi
Founder and Executive Director

RE: Proposed 2024 LCFS Amendments

Dear California Air Resources Board,

We appreciate the opportunity to share our thoughts on California Air Resources Board's Low Carbon Fuel Standard amendments. The United States Hydrogen Alliance is a non-profit trade association dedicated to building the U.S. hydrogen economy. Our organization represents hydrogen companies actively deploying clean technologies across the country.

We are writing to share our perspective on several key program areas for your consideration. These requests address the light duty hydrogen refueling infrastructure pathway, low carbon intensity electricity, methane pyrolysis, along with recommendations for pyrolysis and renewable hydrogen definitions.

212.1 Regarding the new light duty hydrogen refueling infrastructure pathway, we believe the location restrictions to disadvantaged communities, low-income communities, and rural areas is overly limiting. While we respect the intent of these restrictions, we ask for removal of the hydrogen refueling station location restrictions to allow alignment with traffic/use forecasts to ensure high usage and maximum societal benefit and to avoid applying a double standard for hydrogen, a zero emission fuel, in comparison to electricity.

212.2 New restrictions for low carbon intensity electricity require it to be supplied by new or expanded production, or within three years of a hydrogen production facility or air capture project's creation date. These restrictions resemble "additionality" or "incrementality," and is something the hydrogen industry is opposed to on all accounts. We suggest the removal of the new 100% renewable electricity requirement given the policy bias for electricity against hydrogen, as battery electric vehicles are not required to charge with 100% renewable electricity. Through California's Renewables Portfolio

USHA
UNITED STATES HYDROGEN ALLIANCE

Standard, it is already required for retail electricity to be 100% renewable by 2045; with the grid already moving in this direction, this requirement seems redundant.

For the definition of pyrolysis we suggest two amendments, the inclusion of both biomethane and
212.3 solid carbon. We believe that solid carbon should be considered as a form of carbon capture and sequestration. Methane pyrolysis should also be included in a pathway for flexible access to low greenhouse gas methane sources to reduce both greenhouse gasses and the cost of hydrogen. We also suggest an amendment to the definition of renewable hydrogen to include pyrolysis in section two.

212.4

In section § 95490. Provisions for Fuels Produced Using Carbon Capture and Sequestration, we suggest adding the eligibility requirement below:

> (3) "Hydrogen producers from methane pyrolysis that capture precombustion carbon in solid form and permanently store it or provide proof of permanent storage. 1kg of solid carbon is equivalent to 3.67kg of avoided carbon dioxide"

We at the United States Hydrogen Alliance thank you for your time and consideration. Please reach out to us if you have any questions.

Respectfully,

K. Bekemohammadi

Roxana Bekemohammadi

THE INTERNATIONAL COUNCIL ON CLEAN TRANSPORTATION
1500 K STREET NW | SUITE 650 | WASHINGTON DC 20005

February 20, 2024

RE: International Council on Clean Transportation comments on the **Proposed Low Carbon Fuel Standard Amendments**

These comments are submitted by the International Council on Clean Transportation (ICCT). The ICCT is an independent nonprofit organization founded to provide unbiased research and technical analysis to environmental regulators. Our mission is to improve the environmental performance and energy efficiency of road, marine, and air transportation, in order to benefit public health and mitigate climate change. We promote best practices and comprehensive solutions to increase vehicle efficiency, increase the sustainability of alternative fuels, reduce pollution from the in-use fleet, and curtail emissions of local air pollutants and greenhouse gases (GHG) from international goods movement.

The ICCT welcomes the opportunity to provide comments on the Air Resources Board's Proposed Low Carbon Fuel Standard amendments. We commend the agency for its technical analysis and interest in continuing to improve the effectiveness of one of its flagship climate programs. Based on the content of the Initial Statement of Reasoning (ISOR) document, the comments below offer a number of technical observations and recommendations for ARB to consider in aligning the program with the goals of the 2022 Scoping Plan.

We would be glad to clarify or elaborate on any points made in the below comments. If there are any questions, ARB staff can feel free to contact Nik Pavlenko (n.pavlenko@theicct.org) and Dr. Stephanie Searle (stephanie@theicct.org).

Stephanie Searle, PhD
ICCT Acting Deputy Director
International Council on Clean Transportation

Summary of Comments

The LCFS program is designed to diversify California's transportation fuel pool and support the state's broader climate targets of economy-wide decarbonization and reducing dependence on petroleum.[1] Since 2011, the LCFS has undergone numerous rounds of revisions that have raised the carbon intensity (CI) reduction target and trajectory, expanded the list of eligible fuel pathways, and supported the expansion of zero-emission fueling infrastructure. The California Air Resources Board (CARB) is now administering another round of revisions to better align the program with the state's 2022 Scoping Plan.[2] These revisions were developed with input from numerous public workshops and engagement with the Environmental Justice Advisory Committee (EJAC) and summarized in an Initial Statement of Reasoning (ISOR) document released in December 2023.[3]

In its latest amendments, CARB has proposed to increase the annual CI reduction target to 30% in 2030 and make other program changes such as setting deliverability requirements on biomethane, phasing out avoided methane emissions crediting beginning in 2030, expanding project crediting for medium and heavy duty zero-emission vehicles, and obligating the volume of fossil jet fuel consumed on intrastate flights. CARB has also proposed introducing an auto-acceleration mechanism (AAM) and step down in the near-term CI target to address low and fluctuating credit prices in recent years. These changes are intended to put California on a path towards its long-term climate goals including an 85% GHG emission reduction target by 2045 and a path towards carbon neutrality.[4] Though we applaud CARB's proposal to extend the LCFS targets, we are concerned with the lack of safeguards to mitigate unintended emissions and market distortions that could undermine the policy's intended effects.

Our analysis finds that the "Proposed Alternative" is insufficient because it does not implement policy safeguards necessary to avoid unintended consequences to the climate impacts and efficacy of the program that were identified by CARB staff during the 2022-2023 Scoping Plan process. Safeguards discussed in previous LCFS workshops such as limiting the contribution of crop-based biofuels were not incorporated in the ISOR proposal, while proposed other safeguards such as phasing out avoided methane emissions crediting and aligning biomethane deliverability requirements with other fuel pathways are pushed far into the future and will have little relevance to the program's operation for over a decade.[5] The Proposed Alternative overestimates the GHG emissions attributable to the proposals and diverges from

[4] https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp-es.pdf
[5] https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/lcfs_meetings/LCFSpresentation_02222023.pdf; https://ww2.arb.ca.gov/sites/default/files/2022-11/LCFSPresentation.pdf

previous LCFS rulemakings. Due to the recent ramp up of the program's CI reduction trajectory, as well as potential interactions with the auto-acceleration mechanism, swift implementation of these safeguards is critically important to avoid unintended consequences of alternative fuel expansion.

Based on our review of CARB's "Proposed Alternative", we find that an alternative scenario is warranted. We recommend that this scenario incorporates elements of Alternative 1 and the Environmental Justice scenarios evaluated by CARB to safeguard against upstream emissions risk and align the LCFS with the goals of the 2022 Scoping Plan.

We recommend that CARB:

213.1

1) Set a cap on the volume of lipid-derived fuels credited under the LCFS program.

213.2

2) Phase out avoided methane emissions crediting for new projects within three years and align deliverability requirements for biomethane and bio-hydrogen pathways with the existing deliverability requirements for new electricity pathways.

213.3

3) Obligate jet fuel consumed within the California airspace starting in 2025, with a cap on lipid-based fuels crediting.

213.4

4) For pathways that utilize hydrogen as a feedstock such as e-fuels, subject the low-CI electricity used to produce the hydrogen to additionality and deliverability requirements consistent with the use of low-CI electricity for hydrogen, rather than low-CI electricity used as a process fuel.

213.5

5) Increase the scope of credit generation for transport electrification from charging infrastructure and fixed guideway public transit to simultaneously help the LCFS achieve equity goals and more ambitious target levels.

In the subsequent sections, we provide additional analysis and data from our review used to develop these recommendations.

The Proposed Approach Overestimates GHG Savings from Biomass-Based Diesel

Our analysis finds that the ISOR overstates the environmental benefits of the "Proposed Alternative." This is largely because the methodology attributes the GHG savings of existing federal biofuels policies to the LCFS program. Over the past decade, the federal Renewable Fuel Standard (RFS) program has been the primary driver for BBD production in the country.[6] Under the RFS, the EPA sets annual volume mandates for biofuels, based on an assessment of national production capacity, economics, and existing federal and state subsidies. External policies like the LCFS also influence EPA's volume projections. EPA has assessed what the 2023-2025 national biofuels market could look like in the absence of the RFS program in its supporting analysis to last year's volume rulemaking.[7] By comparing fuel volumes from scenario tables with and without an RFS in place, it found that BBD volumes would be reduced by half in a "no RFS" scenario - reflecting market conditions that operate independently of the RFS (e.g., ethanol as an oxygenate). Given that California makes up nearly half of the national BBD market,[8] we can infer that a substantial portion of this growth in volumes is driven by the federal RFS. We present the estimated share of biofuel volumes for each major feedstock category that are attributable to the RFS program in Table 1.

Table 1. Biofuel volumes projected to be consumed in the U.S. that are attributable to federal RFS program. Calculated from Tables 2.1.5-2 and 3.1-4 of 2023 RIA

Volumes attributed to federal RFS	**2023**	**2024**	**2025**
Cellulosic biofuel	59%	63%	68%
BBD	54%	50%	50%
Other advanced biofuels	21%	21%	21%
Conventional renewable fuel	5%	5%	6%

213.6 The Draft Environmental Impact Analysis[9] is also a departure from CARB's previous methodology. Previously, CARB only attributed emissions impacts beyond a 50% GHG reduction threshold to LCFS policy in updates to the 2018 LCFS rulemaking,[10]; i.e., emission reductions beyond the RFS' minimum emissions reduction threshold for BBD that could plausibly have been incentivized by the LCFS program. In the 2024 Draft Environmental Impact Analysis, CARB counted the full GHG reductions of BBD as fully attributable to the LCFS and has thus overstated them. For these reasons, it is likely

[6] https://theicct.org/wp-content/uploads/2022/01/impact-renewable-diesel-us-jan22.pdf
[7] https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1017OW2.pdf
[8] https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1017OW2.pdf
[9] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/appd.pdf
[10] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2018/lcfs18/15dayattf2.pdf

213.6 that CARB has also overstated the benefits that the LCFS has on regional air quality and health outcomes. Developing a more accurate estimate would require additional modeling to disentangle the effects of the LCFS from other climate and federal biofuels policies.

Using the CATS model default inputs shared at the July 2023 workshop and assuming a 30% carbon intensity reduction target for 2030, ICCT modeled the compliance trajectory of the LCFS and estimated the GHG reductions by fuel pathway.[11] Based on this default data, we estimate that the LCFS would generate approximately 35 million cumulative tonnes of GHG reductions from virgin vegetable oils from 2024-2034, after which virgin vegetable oil begins to generate deficits. Using CARB's previous methodology of only counting the GHG reductions above 50% (which no soy oil-derived BBD pathway exceeds), approximately 6% of the cumulative 558 Mtonne CO_2e reduction calculated by CARB in its Draft analysis from 2024 through 2045 would thus not have been attributed to the LCFS, significantly narrowing the GHG savings gap between the Proposed Alternative and Alternative 1. While higher BBD growth could provide some GHG reductions in the near-term, these reductions are offset by its uncertain and significant upstream emissions impacts and inability to guide California on a path towards net-zero decarbonization. We discuss these impacts in detail below.

The LCFS is Creating Market Distortions with the National Renewable Fuel Standard

We note that the LCFS's continued reliance on BBD feedstocks will necessarily impact other states' ability to meet their own climate goals. Based on a modeling run of the CATS model based on CARB's default inputs published in summer 2023, the modeling suggests that BBD consumption could peak at 2.1 billion gallons in 2025, or more than 70% of the federally mandated BBD volume that year. Current trends in California suggest that California could be at risk of overtaking the volume of BBD mandated under the RFS, which could depress RIN credit prices or trigger the AAM. If the
213.7 renewable diesel boom in California pushes national BBD consumption beyond annual RFS mandates, this could have significant implications on RIN markets. Gerveni and Irwin have modeled the possibility of a "RIN cliff", where RIN prices fall to $0 per gallon if the BBD mandate becomes non-binding.[12] Because BBD is the marginal unit of compliance under the RFS, these price implications extend beyond the BBD RIN category. Without an increase in federal BBD mandates or a contraction in BBD supply,
213.7 the value of BBD in the U.S. could steeply drop. This risk is even more likely if the AAM is activated given that current CATS modeling projections may understate the level of BBD required for LCFS compliance.

[11] https://ww2.arb.ca.gov/our-work/programs/low-carbon-fuel-standard/lcfs-meetings-and-workshops#:~:text=v0.2%20Technical%20Documentation-,CATS%20Example%C2%A0Inputs,-.
[12] https://farmdocdaily.illinois.edu/2023/05/is-the-us-renewable-fuel-standard-in-danger-of-going-over-a-rin-cliff.html

Furthermore, it is likely that the modeling used by CARB results in an under-estimate of LCFS-induced demand for virgin vegetable oils. The model baseline is tuned to 2022 consumption data and does not include the impact of the automatic-acceleration mechanism (AAM). We find that the model takes until 2025 to increase demand for BBD
213.8 to present-day 2023 consumption, and the model's inability to assess the AAM prevents us from evaluating how high near-term credit prices could further accelerate demand for BBD in the near-term.

Consumption of BBD in California far exceeds its share of the national distillate fuel market. While California made up approximately 7% of national diesel consumption in the transportation sector in 2021,[13] it consumed approximately 44% of all BBD. Its share of renewable diesel consumption is far higher. Based on data from the 2023-2025 RFS impact analysis and California quarterly reports, we calculate that 87% of renewable diesel volumes credited under the RFS were consumed in California in 2022. Even more staggering, the EIA reports that California comprised 99% of national renewable diesel consumption in 2021.[14] If CARB does not curtail unchecked BBD growth in these
213.9 current amendments, the LCFS will continue to draw BBD from other geographic regions into California. This trend will hamper the ability of other states to meet their own clean fuel standard (CFS) goals including Washington, Oregon, and the CFS newly announced in New Mexico.[15] Other state-level CFS programs in Minnesota and New York are currently under development.[16]

Supply Chain Certification of Crop-Derived Biofuels Fails to Address Indirect Land-Use Change Emissions

Over the past decade, BBD has exhibited the highest growth rate of all fuel pathways. BBD is on track to make up 46% of total credits in 2023, up from 8% in 2011.[17] Rapid growth in BBD consumption has also been followed by changes in the composition of the BBD feedstock market. Until 2021, nearly all BBD consumed in California was sourced from waste oil feedstocks such as used cooking oil (UCO), corn oil, and tallow that do not compete for land area across multiple economic markets. Although the California market was previously dominated by lower-CI BBD feedstocks, BBD derived from vegetable oils has made up a rapidly growing share of LCFS credits in recent years. Vegetable oil (primarily soybean oil) is projected to account for 17% of BBD

volumes in 2023. Further, soy-BBD consumption more than doubled between 2021 and 2023 alone. We display the change in annual BBD volumes by feedstock category in Figure 1

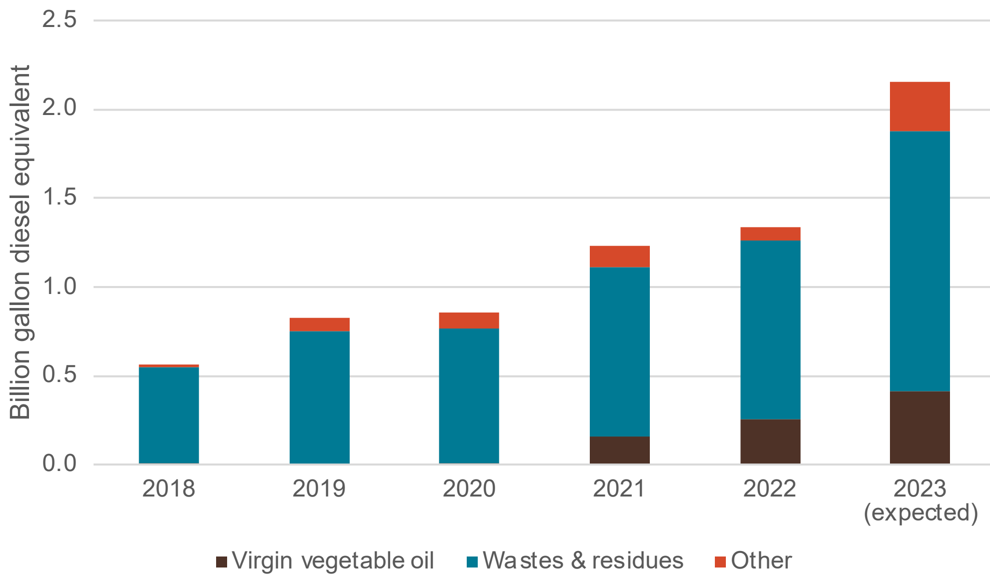

Figure 1. BBD volumes by feedstock category. Q1-Q3 2023 data is extrapolated through the end of the year.

There is no indication of this trend reversing or leveling off. EPA predicts that soybean crushing capacity could increase by more than 500 million bushels between 2022 and 2025,[18] equivalent to 770 million gallons in increased soybean oil BBD production. Industry associations including the American Soybean Association, National Farmers Union and Clean Fuels Alliance America are even more optimistic on soybean crush expansion. In comments submitted on the proposed 2023-2025 RFS volumes, these associations predicted that capacity commitments from soybean crushing facilities could result in 700-800 million gallons of additional BBD by the end of 2025.[19]

Gerveni and Irwin (2023) estimate that renewable diesel nameplate capacity could reach 7.4 billion gallons over the next decade, up from 4.1 billion gallons in 2023, and 0.8 billion gallons in 2020.[20] Similarly, the Energy Information Administration (EIA) estimates that RD capacity could more than double between 2023 and 2025 as a result of favorable state and federal biofuels policy and tax credits allocated under the Inflation

Reduction Act (IRA).[21] The majority of this growth will come from retrofits of existing refineries distributed along the U.S. West Coast, Gulf, and mountain regions.

The LCFS program's accelerating reliance on biomass-based diesel to meet the program's greenhouse gas targets is at odds with the emerging evidence on the market-mediated GHG emissions from growing biofuel demand using purpose-grown crops. The Draft Environmental Impact Analysis overlooks the magnitude of emissions uncertainty associated with crop-based biofuels production and overcounts emissions
213.10 reductions attributable to the LCFS program. This problem is particularly relevant to BBD fuels due to their significant upstream market and environmental impacts that are not well accounted for in supply chain (attributional) life-cycle assessment (LCA). Though CARB has evaluated the indirect land-use change (ILUC) emissions attributable to vegetable oil-derived fuels, recent studies suggest that these emissions may be understated, and the existing ILUC emission factor used in the LCFS may not be a sufficient safeguard.

We find that CARB's ILUC assessment may underestimate soy-BBD emissions significantly. When soybean oil is diverted from food, feed, and oleochemicals markets it
213.11 is often substituted with palm oil; [22] this greatly increases its upstream emissions impacts because palm oil is often grown on high-carbon stock land. In its recent RFS triennial review, EPA notes that there remains "potential for low-cost palm oil from ecologically sensitive areas in Southeast Asia to "backfill" diverted soybean oil from international vegetable oil markets." This risk is "especially [likely] if RFS program total biofuel mandates increase in the future".[23] Due to soy-palm substitution and pressure that soy expansion places on other markets, soy BBD's ILUC emissions may even exceed that of fossil fuel.

Despite years of dedicated research, ILUC modelers are no closer to reaching consensus around the upstream land-use impacts of biofuels production since the field emerged in the mid-2000s. Persistent scientific uncertainty and risk of deforestation has lead jurisdictions such as the European Union and United Kingdom to cap or limit the contributions of crop-based fuels within major fuels regulations.[24] In a 2022 report, the National Academies of Sciences, Engineering, and Medicine concluded that "substantial uncertainties remain on many key components of economic models used to assess [LUC] impacts" in their comprehensive review of LCA methodology.[25] The Carbon Offsetting and Reduction Scheme for International Aviation (CORSIA) incorporates LCA results from two different models in an attempt to account for the range of results across

[25] https://nap.nationalacademies.org/catalog/26402/current-methods-for-life-cycle-analyses-of-low-carbon-transportation-fuels-in-the-united-states

different inputs and methodologies.[26] Although modeling of starch and sugar-based pathways have reached relative alignment for the purposes of CORSIA, ILUC modelers assessing oilseed based pathways found substantial differences across models ranging from 7 to 90 gCO_2e/MJ for various oilseed-derived biofuel pathways.[27] Depending on which model is used to assess ILUC emissions, some pathways were found to have higher emissions than the fossil fuel baseline.

The Environmental Protection Agency (EPA) released a technical modeling comparison document last year that highlights the persistent scientific uncertainty of ILUC modeling.[28] As part of the exercise, EPA compared five models including their modeling structure, spatial and temporal resolution, representation of land types, and trade dynamics. Despite harmonized inputs, the models varied greatly in their representation of global economic activity and, notably, their ILUC emissions estimates. The analysis concluded that “the variability of LUC estimates significantly influences variability in overall biofuel GHG estimates.” Further, EPA found that level of uncertainty is particularly high for soybean oil due to its fungibility with other vegetable oils including palm oil in other markets. We display EPA’s results from its corn ethanol and soybean biodiesel scenario runs across the five models in Figure 2. ILUC emissions for soybean biodiesel range between 9 and 280 gCO2e/MJ while ILUC emissions for corn range between -1 and 29 gCO2e/MJ. Removing the ADAGE model as an outlier, soybean biodiesel results range by 49 gCO2e/MJ, more than half the certified CI of fossil diesel in California.

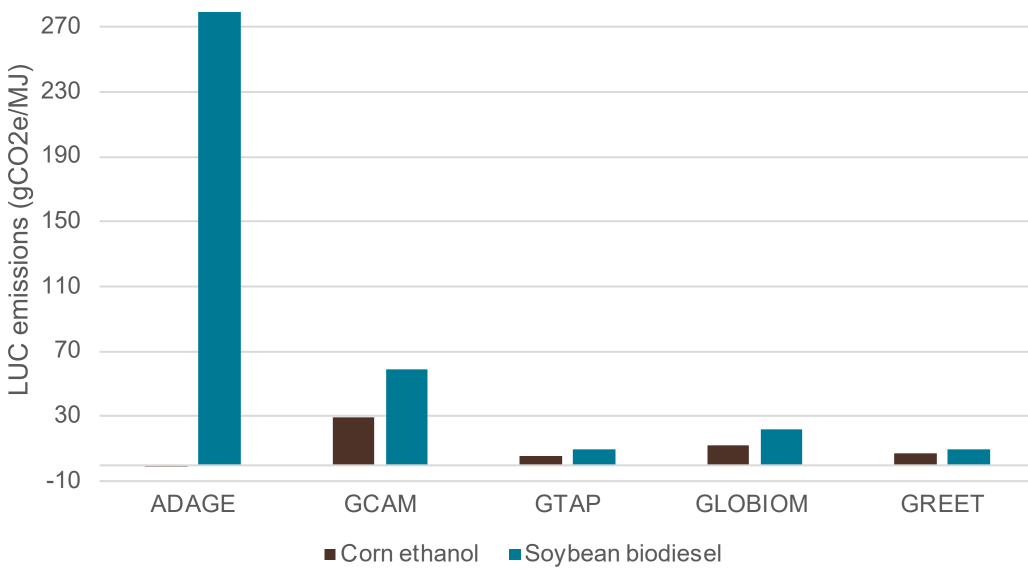

Figure 2. Land-use change emissions from EPA Modeling Comparison exercise

CARB uses a version of the Global Trade Analysis Project (GTAP-BIO) model in its 2015 ILUC assessment that modeled the impacts of demand shocks for crop-based biofuels on commodity prices and net global land conversion. Based on these modeling runs, CARB adopted an ILUC value of 29.1 gCO_2e/MJ for soy biodiesel. GTAP-BIO has been the subject of significant academic debate due to parametric assumptions such as its modeling of unmanaged forest land and high rates of yield intensification.[29] Most contentiously though, GTAP-BIO assumes that cropland expansion is likeliest to occur onto land parcels classified as "cropland pasture" and that this type of land conversion
213.12 sequesters rather than releases carbon.[30] This assumption conflicts with definitions used by the EPA that assume "cropland pasture" is land currently in a pasture state[31] and thus will result in soil organic carbon (SOC) loss when converted to cropland. As a result, the ILUC emissions adopted by CARB likely underestimate the upstream emission impacts associated with biofuel expansion.

CARB has acknowledged that "a rapid increase in oil crop demand for biofuel production could potentially add pressure to convert forested land or other land types into biofuel crop production." Rather than set a cap on high-risk feedstocks, CARB has proposed that biofuel producers adhere to a sustainability certification scheme (SCS) where independent auditors must track feedstocks to their point of origin and verify their environmental attributes to be certified. This proposal is aligned with other sustainability requirements set forth under the EU's Renewable Energy Directive (RED II) and

31 US EPA. "Renewable Fuel Standard Program (RFS2) Regulatory Impact Analysis," February 2010.

international CORSIA program. However, the SCS guardrail only applies to crop and forestry-based feedstocks; thus, excluding UCO supply chains with documented cases of fraud. Member States within the European Union have prosecuted several cases of UCO fraud, arising from UCO's high credit value under their implementation of the RED II.[32] In these examples, companies that were certified under SCSs forged the quantity of waste-based biofuel sold on the market or forged the makeup of these fuels entirely. An investigative report submitted to the European Commission found that the Dutch company Sunoil forged SCS certificates in 2020 of an unknown volume that credited crop-based biofuels as waste-based; the investigation is still underway.[33] Executives of the former company, Biodiesel Kampen, were arrested for fraud for falsely reporting the volumes of waste-oil fuel sold on the market. It is likely that employees may have also falsely labeled crop-based biofuel as waste-based to receive credit incentives.

The EU's experience has found that third-party verification schemes are an ineffective tool to address the environmental and social risks of biofuels. The European Anti-Fraud Office investigated a case involving numerous companies where 150,000 tonnes of virgin soy oil exported from the U.S. was fraudulently labeled as UCO to avoid anti-dumping fees and exploit national-level renewable energy incentives. A producer in the U.S., Greenworks Holdings LLC, also forged quality tests for UCO biodiesel and overstated production quantities to receive higher credit value under the federal Renewable Fuel Standard (RFS).[34]

While SCSs can help verify material and emission inputs across the fuel supply chain, supply chain certifications are fundamentally not suited to address the significant and uncertain environmental harm associated with market distortions from BBD demand.
213.13 Certification schemes, even if properly implemented, cannot measure or address ILUC. Thus, our analysis finds that it is critical that the volume of BBD feedstocks are capped at manageable levels. This exact threshold can be debated but should reflect a
213.14 feedstock's total availability accounting for competition from other sectors plus marginal growth in domestic production that is proportionate to California's share of the national distillate fuel market. Using this methodology, a previous ICCT analysis has suggested capping the contribution of lipid-based fuels, including vegetable and waste oils, at 1.2 billion gallons.[35] California has already far exceeded this supply threshold and is projected to produce 2.2 billion gallons of lipid-based BBD in 2023.

Although California has already exceeded its proportional share of domestic BBD supply, an energy or volume cap can help contain future unchecked growth in BBD markets. Given the substantial increase in BBD volumes since 2021 and difficulty associated with scaling down existing production, we recommend capping the

213.15 contribution at levels consistent with Alternative 1, which implements a roughly 2-billion-gallon cap on lipid-derived fuels starting in 2025. As explained above, the difference in emissions and implementation costs between this scenario and the Proposed Approach is substantially narrower than modeled by CARB, and this would reduce unintended climate impacts and market distortions. Further, we recommend that CARB extend the
213.15 SCS requirement to all feedstocks to mitigate fraud risk from UCO imports.

Implement livestock methane regulations and accelerate the phaseout of avoided methane emissions crediting

Avoided methane crediting has been used as a mechanism to comply with the state's Short-Lived Climate Pollutant (SLCP) strategy and precursor Senate Bill (SB) 1383 which requires that California reduce methane emissions 40% from 2013 levels by the year 2030. In place of developing binding regulations on in-state farms, previous CARB statements suggest that the LCFS is a sufficient incentive to meet the SLCP targets.[36] Notably, this methodological assumption is only applied to livestock and organic waste digester projects where methane capture is considered voluntary rather than legally required.[37] Livestock digester projects made up an estimated 90% of biomethane credit generation under the LCFS in 2023 while accounting for less than half of volumes (Figure 3).

Biomethane is consumed in a small number of natural gas vehicles (NGVs) that account for 5% of heavy-duty fuel consumption in the state.[38] NGV fuel consumption will decline in the coming decades due to the implementation of the Advanced Clean Trucks (ACT) and Advanced Clean Fleets (ACF) rulemakings that regulate a minimum share of zero-emission vehicles within California's medium and heavy-duty (MHDV) transportation fleet.[39] Despite its small role in the MHDV sector, biomethane crediting within the LCFS has accelerated in recent years. This has occurred while the delivered share of total volumes credited under the program have remained nearly constant. Biomethane is projected to make up 18% of LCFS credits and 5% of volumes in 2023, extrapolating from data from CARB's recently published Q3 report through the end of the year.[40]

The growing divergence between biomethane credits and volumes is due to the high LCFS incentive that biomethane receives when it is utilized as transportation fuel. When

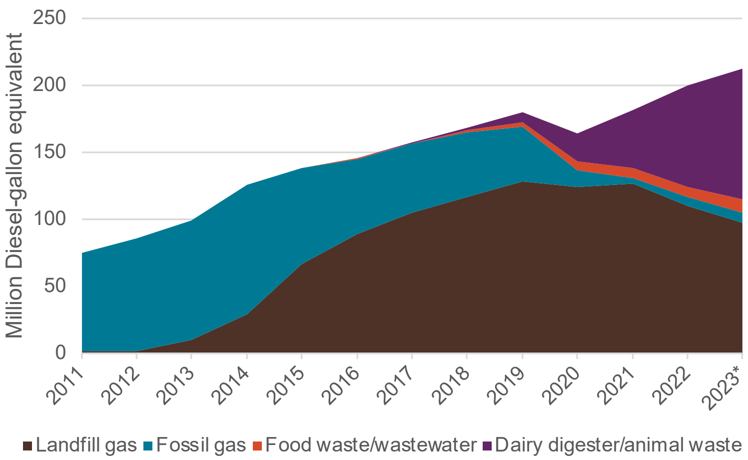
assessing the lifecycle impact of some biomethane pathways, CARB assumes that methane emissions would be vented to the atmosphere in the absence of an LCFS policy signal. We illustrate growth in biomethane volumes and credits by feedstock in Figure 3.



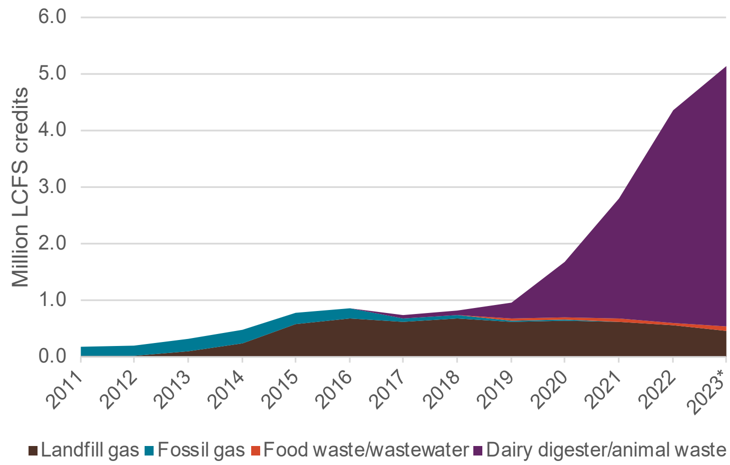


Figure 3. Share of CNG volumes by feedstock type (left); Share of CNG credits by feedstock type (right)

Rapid growth in livestock digester projects in California is motivated by its significant financial incentives. We find that active swine projects have an average CI of -406 gCO_2e/MJ while active dairy projects have an average CI of -285 gCO_2e/MJ based on data reported in the LCFS current pathways spreadsheet,[41]. This is equivalent to a $6.66/diesel-gallon equivalent(DGE) and $5.03/DGE credit value in 2023, respectively, assuming an $100/metric tonne credit price.[42] If biomethane is later converted to bio-hydrogen it receives an even higher credit incentive per volume of fuel due to hydrogen's 1.9x energy economy ratio (EER) in MHDV applications.[43] Using CARB's LCFS credit price calculator, we find that the value of bio-hydrogen could even exceed $5/kg assuming current credit prices, nearly double the tax incentive under the 2022 Inflation Reduction Act (IRA). We present common biomethane pathways, their average CI, and associated credit value in 2023 in Table 2. Pathways with negative emission CIs receive the highest LCFS credit value while pathways with higher average CIs such as landfills and wastewater plants receive a more moderate credit value.

Table 2. Average project CI value and credit values for certified biomethane pathways in 2023. Assumes $100/mt LCFS credit price

Feedstock pathway	Average CI (gCO_2e/MJ)	Credit value ($/MMBTU)	Credit value ($/DGE)
Landfill gas	62.6	$2.81	$0.36
Fossil NG	79.2	$1.05	$0.13
Wastewater	49.0	$4.24	$0.54
Food waste	-54.1	$15.11	$1.93
Organic waste	16.7	$7.64	$0.97
Swine manure	-406.2	$52.27	$6.66
Dairy manure	-285.2	$39.5	$5.03

Digester projects are also eligible for federal and state-level grant funding to reduce the cost of methane capture. The U.S. Department of Agriculture (USDA) offers loan financing under the Rural Energy for America Program (REAP) to cover up to 75% of eligible costs for energy projects.[44] Since 2015, the California Department of Food and Agriculture (CFDA) has awarded $227 million in funding for dairy digester projects concentrated in the Central Valley.[45] Dairy biomethane is also eligible for RIN credits, which have traded at a value of $2.50 per gallon ethanol equivalent ($4.1/DGE) over the last 5 years.[46] Between 2025 and 2027, the IRA 45Z tax credits will provide another funding stream of up to $1.00 per DGE for dairy biomethane consumed as a transportation fuel. In total, this amounts to a staggering incentive of ~$11-$12.50 per DGE for biomethane derived from dairy and swine digesters, assuming LCFS credit prices from Table 2 above.

The combination of high-value incentives from multiple overlapping policies and jurisdictions poses a particularly strong additionality risk for pathways certified with avoided methane emissions. Though CARB has generally avoided assessing the additionality of fuels delivered under the program, biomethane pathways pose a unique risk because of a combination of factors, namely 1) their very high negative emissions attributable to out-of-sector behavior, 2) the lack of meaningful deliverability requirements meaning that these fuels aren't necessarily consumed in California or in the transportation sector (as discussed in the subsequent section), and 3) the sheer size of the combined policy incentives for these fuels. While it can be argued that a biofuel consumed in California can benefit from a combination of policies to motivate its production and reduce its CI, that argument has less merit for crediting a unit of natural

[44] https://www.rd.usda.gov/programs-services/energy-programs/rural-energy-america-program-renewable-energy-systems-energy-efficiency-improvement-guaranteed-loans
[45] https://www.cdfa.ca.gov/oefi/DDRDP/docs/DDRDP_Program_Level_Data.pdf
[46] https://www.epa.gov/fuels-registration-reporting-and-compliance-help/rin-trades-and-price-information

gas paired with the attributes of an out-of-state dairy farm. Given the accelerating role of these pathways in the LCFS and their out-of-scale contribution to the program, implementing guardrails in this rulemaking would help to ensure that the LCFS is not diluted by GHG reductions whose attribution to the program is difficult to demonstrate.

We find that numerous digester projects that upgrade biogas to renewable natural gas (RNG) were already capturing methane independently of the LCFS program. These producers receive negative emissions credits for simply diverting biogas feedstock from existing applications to the transport sector rather than capturing methane that would have otherwise been vented to the atmosphere. For example, ICCT submitted comments on FirstElement Fuel's LCFS pathway application that highlights the lack of additionality for biomethane-based project crediting.[47] The candidate dairy farms were previously producing electricity on-site with excess transmitted to the local electric grid. Project data indicates that the digester was installed in 2010, far before the facility began upgrading biogas to transportation fuel.[48] Despite this pre-existing baseline, the facility operators assumed that methane would be vented to the atmosphere under a counterfactual scenario in their pathway application, later approved by CARB. This counterfactual scenario is simply not credible, and neither are the GHG emission reductions credited to the LCFS for this pathway.

213.16 Biomethane capture in anaerobic digesters will remain an effective method to reduce methane emissions but it is critical to recognize that the LCFS is often not the driver of this step and digesters are often installed or were installed years ago for other reasons. Thus, phasing out avoided methane crediting in the LCFS as soon as possible will help to "right-size" the value of RNG pathways compared to their genuine effect of reducing lifecycle GHG emissions and displacing fossil fuel consumption. We recommend that CARB phase out avoided methane credits at the end of existing pathways' current 10-year crediting cycle and within three years for new applications to help prevent crediting biomethane pathways that are not additional. It generally takes up to 2 years for developers to plan and construct new digester projects,[49] so this timeline would offer flexibility to developers that anticipated negative emissions crediting within their project economics. Following a similar timeline, the IRA 45V tax credit has set a vintaging requirement that renewable energy generation facilities must be built no earlier than 3 years before the tax credit takes effect to avoid crediting projects that are non-additional.[50]

213.17 Using the Argonne National Lab Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) Model, we estimate the emissions for dairy biogas to be approximately 19 gCO_2/MJ, assuming that the methane reductions and soil carbon

sequestration from digestate are not attributable to the LCFS (i.e. that a digester would still have been used in the counterfactual scenario).[51] This change still represents an approximately 80% GHG reduction relative to conventional, petroleum-derived fuels but more accurately reflects the emissions reductions from displacing fossil fuels.

213.18 Although capturing methane from dairy digesters is a laudable goal, there are other methods to meet the 40% reduction target of the SLCP. Changes to manure management practices and livestock diets can help reduce methane reduction at the source.[52] It may also be preferable to implement a regulation with a carbon border adjustment mechanism[53] to ensure that dairy products produced outside of California are treated consistently with those produced in-state. The EPA has detailed strategies that agricultural producers can pursue depending on the size of their operations and relative costs.

213.19 CARB's proposed phaseout dates of 2040 for biomethane and 2045 for bio-hydrogen are completely insufficient to prevent avoided methane credits from distorting the climate goals of the LCFS. Though the scenario modeling published by CARB indicates that these pathways will be phased out completely after 2040, this modeling does not take into account the opportunities for existing pathways to recertify for multiple, 10-year periods. For example, RNG pathways with avoided methane emissions credits that are certified before 2030 may qualify for up to three, 10-year credit periods. Furthermore, the Draft analysis does not evaluate the transition from dairy RNG pathways (which are separated in the results) to dairy biomethane electricity and dairy biomethane hydrogen pathways.

213.20 In summary we recommend that the phaseout of avoided methane emissions crediting takes effect by the end of the 10-year crediting period for certified projects and that avoided methane emissions credits are phased out for new projects within the next 3 years. These changes from the current ISOR proposal are critical to align the significant subsidies allocated to biomethane with its climate impact when consumed as a transport fuel.

Book-and-claim biomethane crediting sustains out-of-state and out-of-sector emissions crediting, diluting the LCFS's impact on California's transportation sector

By conflating methane reductions achieved under the SLCP strategy with the book-and-claim structure LCFS program, CARB has overstated the ability of biomethane to

---

[51] Argonne National Lab, 2021 "Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies Model",https://greet.es.anl.gov/; assuming 100% dairy cow-derived manure, California electricity grid mix, for renewable natural gas as an intermediate fuel.
[52] https://www.epa.gov/agstar/practices-reduce-methane-emissions-livestock-manure-management
[53] https://taxation-customs.ec.europa.eu/carbon-border-adjustment-mechanism_en

displace petroleum and achieve the state's broader decarbonization goals. Book-and-claim decouples fuel consumption from fuel production via the purchase and trade of environmental attributes; thus, it does not require any physical traceability of injected fuel. In many cases, RNG projects credited under the LCFS are located outside of California that have no direct impact on California's greenhouse gas (GHG) emissions or in-state agricultural practices. In other words, natural gas suppliers may gain revenue from LCFS credits for a unit of fossil gas produced and consumed in California (often in non-transportation uses) with an equivalent unit of renewable natural gas (RNG) produced across the country and injected into the national natural gas transmission grid.

Based on existing pathways certified under the LCFS, we find that **all** active landfill gas and swine digester projects credited under the LCFS are located outside of California while 48% of dairy digester projects and 83% of wastewater projects are located outside of the state based on CARB project data.[54] Similarly, CARB has found that, in 2022, the majority of RNG reported under the LCFS program came from "resources injected into the North American natural gas pipeline outside of California."[55]

We review the geographic makeup of biomethane derivative projects including bio-hydrogen and low-CI electricity in Figure 4. Out-of-state project crediting is particularly relevant for dairy manure projects that receive a highly negative CI under current LCFS methodology. We focus on dairy manure as a feedstock since dairy manure-derived biogas makes up the highest number of active biomethane, bio-hydrogen, and bio-electricity projects credited under the LCFS. We find that all dairy manure-derived bio-hydrogen projects are sourced from digesters located outside of California while roughly half of dairy biomethane projects are located outside of the state. We present the share of active dairy biomethane and derivative projects located within and outside California from CARB's pathways spreadsheet in Figure 4.

[55] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf

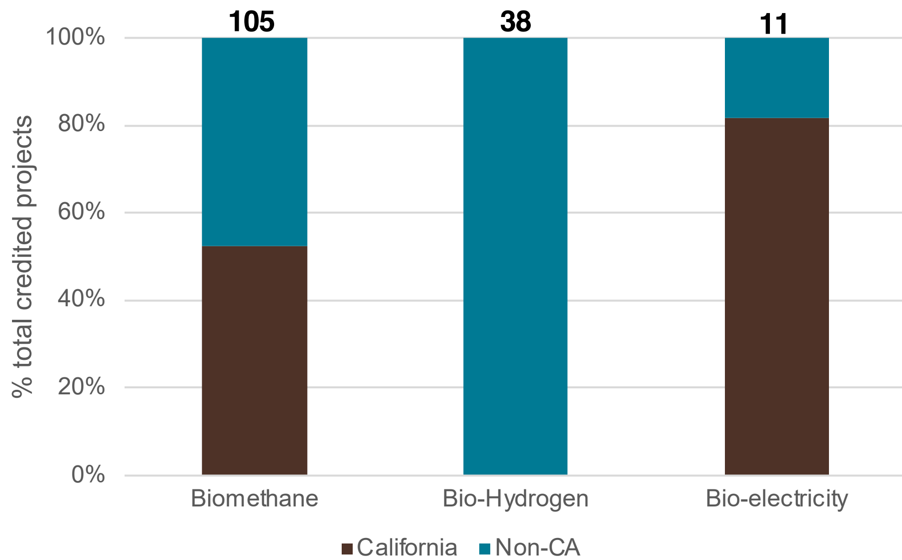

Figure 4. Share of dairy biomethane and derivative projects receiving LCFS credits located in and outside California. Total number of active projects are bolded at the top of each column.

213.21 CARB has proposed setting deliverability requirements on biomethane to better align project crediting with the state's methane reduction targets and address the recent rise in book-and-claim crediting. Deliverability requirements stipulate that biomethane must flow through "common carrier pipelines that physically flow within [or toward] California…50% of the time on an annual basis" beginning in 2041 for biomethane and 2046 for bio-hydrogen. The proposed language is consistent with deliverability requirements that biomethane-based electricity must adhere to under the state's Renewable Portfolio Standard (RPS); however, the ISOR does not specify how these requirements would translate to the natural gas grid and CARB has not provided further information on how it would be implemented and to what extent it would constrain the existing system. A simple geographic deliverability requirement will be more transparent, easier to implement, and is precedented from the deliverability requirements for low-CI electricity. 213.22 Drawing from an analysis conducted by the U.S. Department of Energy (DOE) for 45V tax credit implementation, we recommend that CARB limit geographic eligibility for biomethane to the states of Washington, Oregon, and California, as this would be roughly consistent with the geographic deliverability for electricity proposed for 45V.[56] Alternatively, CARB can reference geographic zones from the U.S. natural gas transmission network to set its deliverability boundaries.[57]

We note that the deliverability requirements for biomethane for hydrogen specifically are far less stringent than those for low-CI electricity derived hydrogen. Despite achieving a higher theoretical credit price than green hydrogen, green hydrogen made from low-CI electricity must satisfy a more rigorous series of requirements to ensure geographic

[56] https://www.federalregister.gov/documents/2023/12/26/2023-28359/section-45v-credit-for-production-of-clean-hydrogen-section-48a15-election-to-treat-clean-hydrogen
[57] https://www.eia.gov/naturalgas/archive/analysis_publications/ngpipeline/index.html

deliverability, that low-CI electricity comes from new generation, and no double-
counting. In contrast, biomethane producers who sell their environmental attributes to
existing grey hydrogen producers must only demonstrate the retirement of
environmental attributes. Thus, a pathway that enables further use of existing natural
gas SMR technology generates higher credit values in the LCFS and has looser book-
213.23 and-claim requirements than a green hydrogen pathway that involves deploying new
electrolyzer technology. We recommend that CARB set deliverability requirements on
bio-hydrogen that are consistent with other biomethane pathways. That is, implemented
within the next three years and adherent to the same geographic boundaries.

The deliverability requirements proposed in the ISOR also fall short of initiating any
meaningful change to current operating conditions. This is due to significant
implementation delay and looser guidance granted to hydrogen producers. CARB has
noted that this delay is intentional to encourage a "rapid buildout of biomethane capture
projects" before the end of the decade to meet the state's methane reduction goals.
However, attributing biomethane capture to the LCFS program belies the reality that
majority of these emissions reductions occur out of state and outside the transportation
sector. Credited RNG volumes may also begin to exceed the quantity of natural gas
consumed in California's transportation sector, further stretching the plausibility of the
213.24 argument that RNG contributes to reducing California's transportation GHG emissions.
Previous ICCT analysis has found that RNG volumes credited under the LCFS
accounted for 98% of natural gas vehicle consumption in California in 2021.[58] As
demand for CNG declines even further, new RNG production will have no little to no
impact on displacing in-state petroleum consumption and meeting the goals of the 2022
Scoping Plan.

In summary, we recommend that CARB implement stronger deliverability requirements
213.25 for all pathways derived from biomethane within the next three years to prevent
subsidizing out of sector emission reductions within an in-state transportation policy. For
pathways that are already certified, we recommend that deliverability requirements take
effect at the end of the current 10-year crediting period.

Obligate fossil jet fuel as a deficit-generating fuel before 2028 and paired with a cap on lipid-based fuels

CARB has proposed obligating jet kerosene as a deficit-generating fuel beginning in
213.26 2028. This will increase crediting opportunities for sustainable aviation fuel (SAF) and
encourage economic growth in a budding California SAF market. Due to the small size
of the volume obligation, this growth will be limited. Without expanding the obligation
scope to cover all inter-state jet fuel, it will also require that other transport sectors

[58] https://theicct.org/wp-content/uploads/2023/05/california-rng-outlook-2030-may23.pdf

continue to shoulder the burden of decarbonizing the state's aviation emissions. If LCFS
213.27 amendments do not incentivize sufficient quantities of SAF, the aviation sector can source credits from sectors that over-comply with their annual CI reduction targets to meet annual compliance.[59]

California has signaled stronger support for SAF in earlier proposals that are notably less ambitious in the ISOR. In 2021, California legislature passed AB 1322 that set a 20% SAF blending target by 2030, approximately 1.5 billion gallons.[60] This bill was later vetoed by Governor Newsom on the grounds that the LCFS was already an effective policy lever to meet these goals.[61] Absent any proposed amendments, ICCT research has found that the LCFS alone is an insufficient tool to promote SAF uptake in California.[62] Study authors found that obligating intra-state aviation would only expand the LCFS program by 5% based on the quantity of deficits generated on intra-state flights. Pavlenko and Mukhopadhaya estimate that fuel consumed on intra-state flights accounts for roughly 6% of jet fuel uplifted in California.[63] At a maximum, that level of obligation would deliver a maximum of approximately 113 million gallons of SAF production by 2030 assuming that aviation obligations are met in-sector rather than through out-of-sector credits from renewable diesel or electric vehicle charger.

In comparison, CATS modeling suggests that jet fuel deficits will make up 1.8% of total deficits (0.76 million tonnes CO_2e) in 2030 under a 30% CI reduction target. Jet fuel makes up approximately 0.7% of deficits (0.23 Mt CO2e) under the baseline 20% CI reduction target. If jet fuel was obligated at an earlier date, this could generate an additional 2.6 million tonnes in CO_2e deficits between 2025 and 2027 under the proposed scenario. This corresponds to approximately 500 million gallons of cumulative SAF production, based on the average carbon intensity of SAF consumed in California in 2021.

If California were to obligate the entirety of jet fuel consumed over its airspace, this could motivate SAF production even further. We analyze what this obligation might look like based on routing data from California airports, using an updated version of the Global Aviation Carbon Assessment (GACA) model developed by Graver et al. (2020.)[64] Jet fuel consumed over the California airspace is approximately 3 times the magnitude of fuel consumed on intra-state flights (i.e., those that begin and end in California). We source jet fuel deficit quantities directly from the CATS model and calculate SAF production assuming a conversion ratio of 0.005 tonnes of offset CO_2e per gallon. Our estimates likely overstate SAF production by assuming that SAF credits fully offset the quantity of jet kerosene deficits. In practice, the quantity of SAF would be lower due to the relatively lower cost of using out-of-sector credits.

[60] https://leginfo.legislature.ca.gov/faces/billTextClient.xhtml?bill_id=202120220AB1322
[61] https://www.gov.ca.gov/wp-content/uploads/2022/09/AB-1322-VETO.pdf?emrc=7598b6
[62] https://theicct.org/wp-content/uploads/2023/01/ca-aviation-decarbonization-jan23.pdf
[63] Ibid.
[64] https://theicct.org/publication/co2-emissions-from-commercial-aviation-2013-2018-and-2019/

We review results from the August 2023 CATS model under a baseline (20% CI reduction, proposed (30% CI reduction), and proposed with expanded obligation the entire CA airspace scenario in Figure 5. These scenarios assume that jet fuel is obligated beginning in 2025, 3 years ahead of the published ISOR proposal. We find that near-term SAF production is significant under the proposed scenario (30% CI reduction) and increases to 198 million gallons in 2030 while SAF production gradually increases to 49 million gallons under the baseline scenario (20% CI reduction). Obligating the entirety of the CA airspace would result in far higher SAF production. We this obligation could result in 1.1 billion gallons of new SAF production in 2030.

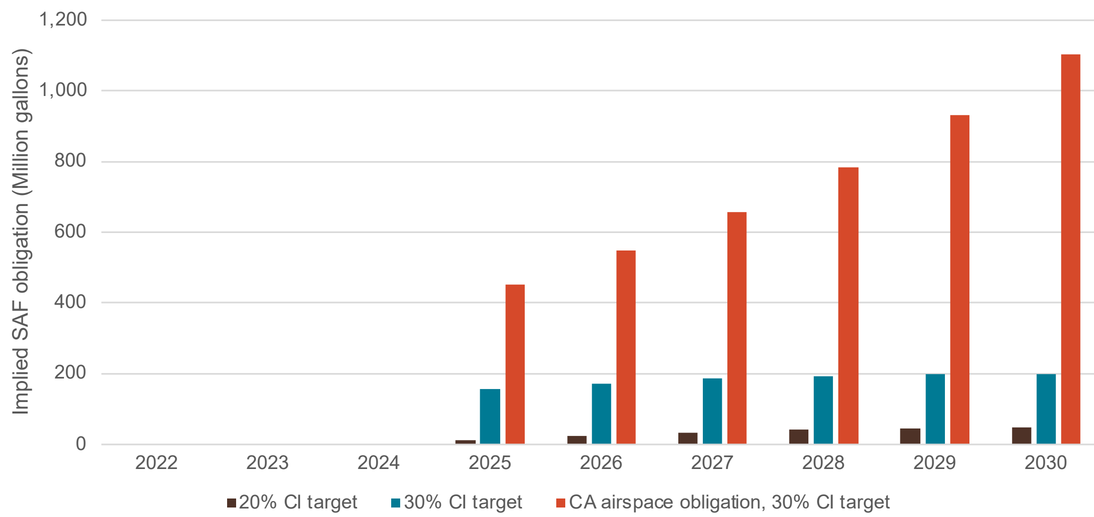

Figure 5. Estimated SAF production to offset jet kerosene deficit generation under three LCFS scenarios

Obligating jet fuel demand could help incentivize SAF production in California but would fall short of the legislative intent of AB 1322 across all scenarios. If CARB waits until 2028 to implement this obligation, this will reduce the cumulative production of SAF by 500 million gallons based on the proposed scenario and 1.66 billion gallons, assuming an obligation of the entire CA airspace.

213.28 While an increase in SAF can deliver public health and emissions reduction benefits, it is important that this growing fuel market does not exacerbate upstream emissions impacts from other transport sectors. SAF is often co-produced with renewable diesel at bio-refineries and thus is sourced from the same waste and virgin vegetable oil feedstocks. This increases demand for lipids that are already in limited supply and could exacerbate unintended emissions consequences associated with biofuel production. These risks include ILUC, plummeting RIN prices, and waste oil fraud as discussed above.

To summarize, though we support expanding the scope of the LCFS to include the aviation sector, we caution that it must be done without exacerbating the underlying problems in the LCFS. If aviation is obligated without a separate safeguard on lipid-
213.29 based fuels, this could undermine the GHG emission and public health benefits of regulating aviation emissions. Thus, we recommend that CARB obligate jet fuel consumed over the entire CA airspace to spur growth in nascent SAF markets and deliver public health benefits but only if this obligation is paired with a cap on the consumption of lipid-based fuels. We also recommend that this obligation take effect in 2025 to increase cumulative SAF output and signal earlier support for the production scale-up of advanced fuel pathways.

Establish criteria for low-CI electricity used to produce e-fuels consistent with criteria for green hydrogen production

In the proposed amendments to the LCFS, CARB staff propose new requirements for the attribution of low-CI electricity used as a transportation fuel, direct air capture, and for hydrogen used directly as a transport fuel. These requirements are a welcome change from the previous guidance for the crediting of low-CI electricity under the LCFS, and will help to ensure that low-CI electricity is not being diverted from existing uses by ensuring that it is new production, deliverable within the same grid region, and that renewable energy attributes are not double-claimed.

However, we note that as written, the current guidance will restrict the use of e-fuels made from low-CI electricity, as these are not included in the current language. Thus the proposal would effectively restrict low-CI electricity from being eligible for attribution unless it was supplied via a direct electricity connection. However, it is likely that as with most green hydrogen production, grid-connected projects will have greater economic
213.30 competitiveness due to a higher capacity factor.[65] Therefore, to provide more flexibility for e-fuel pathways based on converting green hydrogen into other fuels, we recommend that CARB treat these pathways' use of low-CI electricity consistent with green hydrogen and direct air capture. This will still maintain crucial safeguards on project vintage, deliverability and double-counting, while providing necessary flexibility for these projects to use renewable electricity supplied via the grid.

Expand Opportunities for ZEV crediting

The Proposed Alternative relies heavily on virgin vegetable oils and avoided emissions from biomethane to meet 2030 targets, despite these pathways' sustainability risks and the potential for over-attribution of GHG savings to the LCFS program. In CARB's Draft analysis, both Alternative 1 and the EJ scenario that scaled back reliance on these

[65] https://theicct.org/publication/fuels-us-eu-cost-ekerosene-mar22/

pathways were penalized for the lower GHG reductions attributable to these safeguards. However, we recommend that CARB instead pair these safeguards with expanded credit generation opportunities from ZEVs in order to complement CARB's existing strategies on ZEV deployment and equity while also maintaining its goals of more ambitious LCFS targets.

Currently, the LCFS greatly limits credit generation from fixed guideway public transit systems by limiting the energy-economy ratio multiplier of 4.6x to track lengths that were constructed after 2011. Despite these' systems high energy efficiency, potential to displace vehicle use and local air pollution, and contribution to local communities, their role in the LCFS to date has been minimal. For example, the BART system plays a crucial role in electric mobility in the Bay Area, but approximately 90% of its system predates 2011.[66] Extrapolating this under-crediting to the fixed guideway pathway as a whole, we find that there is substantial potential for credit generation to support public transit in California by applying the EER to all fixed guideway systems regardless of construction date. In July 2023 CATS modeling, we calculate approximately 6.2 Mtonnes of LCFS credits from fixed guideway systems would be generated from 2024-2045. Assuming a similar 90% relationship as in the BART system, applying the EER uniformly to all fixed guideway systems would increase the total credits over that time period to 26.3 Mtonnes—approximately 75% of the credits generated by virgin vegetable oils over that same time period. These credits could enable a virtuous cycle, enabling further capacity improvements for transit agencies and increasing ridership while displacing automobile use. Furthermore, these credits would allow CARB to set ambitious targets while implementing safeguards such as capping lipid-based fuels.

To help achieve California's long-term goals of electrification, using the LCFS to support the build-out of light and heavy-duty charging infrastructure is another opportunity to create a virtuous cycle. Lack of charging infrastructure remains a substantial barrier to EV adoption, particularly for low-income drivers or those living in multi-family housing.[67] There remain substantial further needs for charging infrastructure in California. For example, we estimate that Los Angeles will need more than 3,000 public fast charging stations by 2030 and San Francisco would require approximately 350. The proposed phasing down of light-duty fast charging infrastructure credits to 0.5% of the previous
213.31 year's deficits in the proposal occurs too soon.[68] Therefore, we propose maintaining the size of the LDV FCI infrastructure credits at 2.5% of previous year's deficits.

RE: Draft Low Carbon Fuel Standard (LCFS) 45-Day Comment Package

Dear Chair Randolph and fellow Board Members,

Air Products is pleased to provide comments in support of the California Air Resources Board (CARB) rulemaking for the Low Carbon Fuel Standard (LCFS). We support California's climate goals and Air Products stands ready to help the State facilitate the energy transition needed to meet these challenges. We are very appreciative that CARB has recognized the substantial role that hydrogen will play to decarbonize transportation by proposing many related improvements to the LCFS in the proposed 45-day package.

Air Products is the only U.S.-based global industrial gas company and the largest hydrogen producer globally, nationally, and in California. The company is a trusted hydrogen supplier for numerous markets, including transportation. Within California, Air Products safely operates 10 hydrogen production facilities, about 30 miles of hydrogen pipeline and currently supplies and operates a network of light-duty and heavy-duty hydrogen fueling stations, facilitating the transition to zero-emission transportation. Air Products has also been selected to be part of the California ARCHES LLC Hydrogen Hub Project.

We are committed to rapidly scaling and decarbonizing global hydrogen supplies to support decarbonization efforts internationally. Air Products has announced[1] that it will spend or at least $4 billion in additional new capital for the transition to clean energy over the next five years. Air Products had previously announced approximately $11 billion in clean energy investments, bringing its total recent commitment to clean energy investments targeting hard-to-abate economic sectors to $15 billion.

Summary: Key Areas of Support and Improvement

214.1 • We support the most ambitious carbon intensity (CI) reduction targets feasible and a robust stepdown of at least 7% prorated for 2024 to send a strong signal to the market once the rule is effective.

214.2 • We support the inclusion of the Auto-Acceleration Mechanism but believe the assessment should start in 2026 based on 2025 data.

[1] Air Products Announces Additional "Third by '30" CO2 Emissions Reduction Goal, Commitment to Net Zero by 2050, and Increase in New Capital for Energy Transition to $15 Billion

214.3 - We strongly support the inclusion of a technology-neutral CI-based book-and-claim approach for hydrogen but suggest that it be used for all transportation fuel regardless of where they are produced, if they are consumed in California consistent with standard LCFS treatment of fuels.
214.4 - We appreciate the extension of low-CI electricity book-and-claim to include process energy demand for the full hydrogen fuel value chain but believe the eligibility for all transportation in the current regulation should be maintained and the resource-shuffling and time-matching requirements should apply equally to both hydrogen and electricity.
214.5 - We support the additional time provided to hydrogen for the beneficial use of biomethane.
214.6 - We applaud the proposed extension of Hydrogen Refueling Infrastructure (HRI) crediting to medium and heavy-duty vehicles, along with additional time for light-duty vehicle stations and look forward to working on language with CARB to accommodate refueling stations that serve all vehicle types.
214.7 - We are very pleased with the inclusion of a Tier 1 Simplified Calculator for hydrogen and clarification that hydrogen plants that are not co-located with refineries are eligible under the project-based crediting provisions.

Program Stringency

We urge CARB to be as ambitious as possible in setting the new carbon intensity reduction targets between now and 2045 and align targets with levels no less than what is needed to achieve California's greenhouse gas targets and outcomes established in the 2022 Scoping Plan Update. Setting the target
214.8 at a 30% CI reduction by 2030 should be the minimum. If additional information becomes available from stakeholders or CARB analysis during the 45-day public comment period to support a larger CI reduction, then we urge CARB to make this change, provided it does not require restarting the rulemaking process and necessitate reissuing the 45-day package notice. CARB should be confident in setting ambitious standards, given the existing robust cost-containment provisions in the regulation, and provide regulated party protection, should low-carbon fuel supplies not develop as quickly as anticipated. As discussed in the 2022 Scoping Plan Update, a statewide carbon reduction target of 48% below 1990 levels by 2030 as well as carbon neutrality by 2045 creates decarbonization targets that need to be supported by the LCFS targets. The transportation sector and fuel production pathways are the largest component of statewide greenhouse gas emissions, accounting for about half of the state's climate footprint, so the LCFS needs to provide a proportional amount of the reductions toward the 48% reduction target.

214.9 We support including both the initial 2025 accelerated stepdown of at least 5% and automatic stringency 'ratcheting' mechanism conceptually as proposed in the 45-day package. Based on the most recently published banked credit balance of over 20 million metric tonnes (Q3 2023), a step down of at least 7% is more appropriate. In the ICF International comments submitted to CARB last year, a CI reduction level of between 20% and 25% may still have an associated credit bank build.[2] A stepdown in the range of 7% to 10% would result in a CI reduction target from 20.75% to 23.75% relative to the current target of 13.75% in 2025 – well within the range of ICF's predicted potential increase in banked

[2] See attachment at the following link: https://ww2.arb.ca.gov/form/public-comments/submissions/4306

credits. We also request that a prorated stepdown occur for the partial year of 2024, as soon as the rule is effective, to send the right signal to the market as early as possible.

The LCFS program is most effective when the credit pricing is consistently at a level that incentivizes the innovation and clean fuel supply needed to decarbonize the transportation sector. Enabling the program to make this adjustment automatically through the proposed Auto Acceleration Mechanism (AAM) would be very powerful for accelerating deployment of low carbon fuels. We believe that there will be a strong need for this mechanism in the future as many policies and funding streams outside of the LCFS will contribute to the decarbonization of transportation, which further depresses LCFS credit values. This will translate into reduced investments and less innovation in clean low-CI fuels. For example, there are substantial programs that support battery electric vehicles outside of the LCFS and provide significant incentives for the purchase and use of light duty battery electric vehicles[3]. Such programs will result in a substantial increase of credits in the LCFS program from the displacement of gasoline with electricity as a fuel. The stringency of the LCFS program will need to be tightened aggressively to sustain the important signal it provides to all clean fuels.

In terms of AAM design, we prefer that the trigger bring stability to the market without price volatility, and that the action taken be predictable and thereby more certainty as market participants project credit balance outlook and value. We support CARB's proposed AAM, but request that the implementation be set one year earlier than proposed to allow faster acceleration of the targets – providing increased stringency to the program if the 2025 stepdown fails to bring the program back in balance. The signal to the market has been diminished based on substantial overcompliance for many years and based on the current and growing bank balance, we foresee this trend continuing unless CARB sets an ambitious CI reduction target. To facilitate the most flexible and effective AAM, we request that
214.10 CARB change the reference year in 95484 (b) from 2027 to 2026 and reference years in 95484 (c), (d), (e), and (f) from 2028 to 2027.

Hydrogen Book-and-Claim Provisions

Air Products appreciates CARB's willingness to provide a 'book-and-claim' accounting approach for low-
214.11 CI hydrogen and we strongly support the provision's focus on a technology-neutral, CI-focused metric to establish eligibility for low-CI hydrogen. Focusing on CI is consistent with CARB's longstanding approach under the LCFS and the definition of clean hydrogen set in the Inflation Reduction Act (IRA). To advance the State's transportation decarbonization goals, meet greenhouse gas reduction targets and support the nascent low-carbon hydrogen market, it is essential to capture the CI attribute of hydrogen that is transported in multi-source/multi-use distribution systems, where lower-carbon hydrogen is comingled with conventionally produced hydrogen. A robust book-and-claim system for hydrogen will ensure that the low-carbon attributes of the hydrogen are retained and applied to end-uses where the most environmental benefit can be derived. This sends the necessary long-term signal for low-carbon hydrogen to play a meaningful role in decarbonizing transportation. CARB's design of such a system will serve as a model to other jurisdictions considering or implementing an LCFS program. It is important to get this right.

---

[3] Volkswagen Environmental Mitigation Trust Fund, California Energy Commission EnergIIZE Infrastructure Funding Program and Clean Transportation Programs, and the National Electric Vehicle Infrastructure Program

214.12 To that end, one key improvement needed is to eliminate the requirement that eligible hydrogen must be supplied to California in a dedicated pipeline as proposed in §95488.8(i)(3)(A). This requirement places an unnecessary constraint on a nascent market and will stifle investments at a time when massive capital outlays are needed to bring low-carbon hydrogen to scale. There are no dedicated interstate hydrogen pipelines to California. As such, this requirement favors only in-state hydrogen pipelines and fails to recognize the value of using hydrogen as a feedstock to renewable fuels produced out of state and imported for use in California. These fuels are actively contributing to decarbonizing California's transportation energy and will become more important as sustainable aviation fuel is further incented in the regulation. In fact, 95488.8(i)(3) specifically indicates the intention that the low-CI hydrogen book-and-claim approach should be applied to hydrogen used in "Alternative Fuel Production", but this proposed eligibility requirement precludes alternative fuel facilities out of state from realizing these benefits. These renewable fuel facilities are located in fuel producing regions across North America, are connected to regional hydrogen pipelines, and are planning to lower their CI by utilizing low-CI hydrogen. For example, we believe that CARB would welcome out-of-state projects whereby a renewable fuel facility that consumes low-zero-carbon intensity hydrogen from a direct connection, delivers those renewable fuels to California. However, a specific geographic limitation directing that the hydrogen be supplied to
214.13 California would make such a project ineligible, consequently lowering the incentive for producing low-CI hydrogen and forgoing related emission reductions. We urge CARB to adopt a wider worldview that acknowledges the need for a multi-jurisdictional supply chain for low-carbon hydrogen capable in order to displace the existing, equally global fossil fuel supply chain and demonstrate California's leadership in driving decarbonization nationally. Promoting hydrogen energy infrastructure nationally and globally will drive down costs, promote wider adoption and achieve decarbonization more quickly if CARB does not put artificial barriers in place.

We find no statement in Appendix E as to the rationale behind this requirement. In fact, the rationale for providing a book-and-claim approach for low-CI hydrogen is expressly to "facilitate and spur the use of low-CI hydrogen in support of California's decarbonization efforts." Renewable liquid fuels have played, and will continue to play, a key role in California's decarbonization efforts – and there should be no distinction between those produced in-state or those imported. CARB should encourage the development of all low-CI hydrogen supply that help lower the CI of liquid fuels, provided that the fuels are consumed in California. This is consistent with science, the design of the LCFS, and delivers real reductions of greenhouse gas emissions. <u>We request that CARB modify §95488.8(i)(3)(A) as follows:</u>

214.14 *"Low-CI hydrogen is injected into a dedicated hydrogen pipeline physically connected to ~~California~~ <u>a distribution system or a production facility that provides transportation fuel to California."</u>*

§95488.8 (i)(3) also limits the use of a low-CI hydrogen book-and-claim approach to hydrogen used directly as a transportation fuel and hydrogen that is used to produce alternative fuels. As long as hydrogen is still an eligible feedstock for project-based crediting in §95489, low-CI hydrogen book-and-claim should be available to all transportation fuels consumed in California, including conventional fuels. <u>We request CARB make this improvement to enable more emission reductions across a broader array of transportation fuels and further spur investment in low-CI hydrogen. We recommend modified language in §95488.8(i)(3) as follows:</u>

"Book-and-Claim Accounting for Pipeline-Injected low-CI Hydrogen Used in FCV and ~~Alternative~~ Transportation Fuel Production. Indirect accounting may be used for low-CI

214.14 *hydrogen used in FCVs or to produce ~~alternative~~ transportation fuel for transportation purposes provided the conditions set forth below are met:…"*

We note that the low-CI hydrogen book-and-claim requirements are appropriately applied to low-CI hydrogen in the gaseous phase that is commingled in pipelines – including hydrogen conveyed as a liquid before pipeline injection as a gas. CARB has indicated in discussions that liquid hydrogen (or hydrogen derivatives like ammonia) of varying CIs that are mixed in transport and distribution systems can be volumetrically balanced, similar to other liquid alternative fuels like ethanol, renewable diesel, and biodiesel, and that this can be accommodated via the fuel pathway and existing accounting systems without amendment to the regulation. We request CARB clarify, consistent with past discussions with
214.15 staff, that a book-and-claim approach for commingled liquid hydrogen or liquid hydrogen derivatives in these systems is not needed, and that the necessary provisions are included in the existing regulations to enable such an approach.

We appreciate the explicit clarification in §95488.8(i)(3)(B) that biomethane book-and-claim can be used to reduce hydrogen CI but request CARB to confirm that other renewable feedstocks or production technologies can be used to lower the carbon intensity and produce eligible hydrogen as long as the proposed CI thresholds are validated via approved fuel pathways. We do not see this precluded in any way in the proposed language. Such feedstocks could include bio-offgases or renewable ammonia.

We note that §95488.8(i)(3)(C) safeguards against resource shuffling and encourages new projects that provide eligible hydrogen. We support this requirement but want to clarify that the term "expand" used in the provision is not narrowly interpreted to mean that every project must increase the amount of
214.16 hydrogen produced. Instead, we encourage an interpretation, that it refers to an expansion in the production of lower carbon hydrogen that meets the CI thresholds established in §95488.8(i)(3)(B). It is quite possible that existing facilities not producing eligible hydrogen will be modified to produce low-CI eligible hydrogen without a net increase in total hydrogen produced. We request that such projects are eligible consistent with past discussions with CARB staff.

Lastly, we note that the new low-CI hydrogen book-and-claim provision includes a requirement to report the contracted price of hydrogen to CARB in unredacted invoices. We support the need for
214.17 robust tracking of hydrogen volumes to ensure the quantity and environmental attributes of the hydrogen tracked via book-and-claim is verifiable but find no rationale for including hydrogen pricing. In fact, sharing information on the contracted hydrogen price creates the possibility of irreparable harm to both Air Products and its customers. Even in situations where data is published in an aggregated fashion, the limited supply of this hydrogen from a handful of entities would likely lead to competitors deducing this proprietary information and leveraging that information to their advantage in bidding processes. We urge CARB to strike the requirement to report this information in 95488.8(i)(3)(E).

Low-CI Electricity Book-and-Claim Provisions

Air Products strongly supports CARB's proposal in §95488.8(i)(1) to extend the existing book and claim
214.18 accounting approach for low-CI electricity to include the process energy associated with other components used to process and distribute hydrogen, like liquefaction and compression. By looking beyond just the production of feedstock hydrogen, this proposal will enable greater carbon reduction ambition in California policies. Extending book-and-claim provisions to process energy will not only

incentivize bringing more renewable production on-line but will also enable hydrogen to further lower its CI and help California decarbonize cars, trucks, buses, and other combustion-dependent equipment. While Air Products supports the extension of low-CI electricity book-and-claim to process energy demand in the hydrogen value chain, we do not believe that the use case of low carbon hydrogen produced in this manner to produce transportation fuel should be eliminated. Because hydrogen is an important feedstock in the manufacture of either renewable biofuels or conventional transportation fuels (under the project-based crediting provisions), and the expectation that these fuels will be used for decades, CARB should encourage all emission reductions possible in all fuels used for transportation in California. Substantive emission reductions can be encouraged, along with renewable electricity growth, by continuing to enable hydrogen CI to be lowered via low-CI electricity book-and-claim for all fuels used in California. We request retention of the end-use flexibility provided in the current regulation by modifying the following provisions as indicated:

214.19

Modify proposed provision 95488.1 (i)(1*): as follows:*

> *"… for hydrogen production ~~through electrolysis~~ and processing for transportation purposes (including hydrogen that is used in the production of ~~as~~ a transportation fuel), or for direct air capture projects, provided the conditions set forth below are met:…."*

Modify proposed provision 95488.8 (i)(1)(C) as follows*:*

> *"For direct air capture projects or for hydrogen used as a transportation fuel (including hydrogen that is used in the production of a transportation fuel), low-CI electricity must meet the following criteria: …"*

While the California Public Utilities Code is referenced in the regionality requirement provision §95488.8(i)(1)(C)(1), we understand that the initial clause of this provision "*The low-CI electricity must be supplied to the grid within the local balancing authority where the electricity is consumed"* is intended to apply to hydrogen production and associated renewable power outside of the state of California. Please add the parenthetical *"(or local balancing authority for hydrogen produced outside of California)"* similar to what is provided in 94488.8(i)(1)(A).

Lastly, while we are supportive of the new resource shuffling and quarterly time-matching requirements applied to the low-CI electricity book-and-claim provisions for hydrogen in §95488.8 (i)(1)(C)(3) and (4), respectively, we note that these same new requirements are not imposed on electricity used as a transportation fuel in 95488.8(i)(1)(A). We propose that both electricity and hydrogen supplied as transportation fuels should be treated equally with regards to eligibility and recordkeeping provisions and suggest that both fuel requirements be aligned with the new restrictive standards. Alternatively, hydrogen could retain the current eligibility and recordkeeping requirements that are already aligned with electricity supplied as a transportation fuel.

Biomethane Book-and-Claim

214.20 Air Products appreciates CARB's proposal to provide additional time to allow biomethane use for hydrogen in a book-and-claim scenario and enabling avoided methane crediting in the calculation of the CI. We do also note and appreciate that these new restrictions do not apply for projects initiated during the balance of this decade which incentivizes early action on projects that will accelerate decarbonization. However, we still believe that none of these requirements should be imposed for hydrogen supporting zero-emission solutions – even in 2045 as proposed. Eliminating these proposed requirements will not only continue to incent beneficial use of biomethane wherever it can be cost-effectively developed, but also help lower the CI of hydrogen to enable broad use of low carbon hydrogen across many transportation sectors, especially large off-road equipment like locomotives, marine, and aircraft, consistent with the 2022 Scoping Plan through 2045. The use of low-CI hydrogen in fuel cell vehicles is fully aligned with California's goals of phasing out combustion in the transportation sector. In fact, placing constraints on biomethane that is used to produce low-CI hydrogen for fuel cell vehicles advantages electricity over hydrogen even though both support zero emission transportation. We request that CARB not impose any new requirements for biomethane book-and-claim used in the production of hydrogen.

214.20 In a parallel concept to what is proposed in the 45-day package for hydrogen produced and processed using low-CI electricity, we request that CARB clarify that biomethane book-and-claim provisions can be used to displace fossil methane used both as a reactant in the stoichiometric conversion to hydrogen and for the thermal energy needed to catalyze the reaction. We believe that the combined reactant and thermal energy demand for fossil methane should be considered "production" for the purposes of biomethane book-and-claim provisions. Please confirm.

Hydrogen Refueling Infrastructure (HRI) Credits

214.21 Air Products strongly supports the expansion of crediting to medium and heavy duty (MHD) vehicles and continued crediting for light duty (LD) vehicles. The current HRI program, in combination with other California incentives, has been very effective in promoting the build-out of zero-emission vehicle infrastructure. It is important that CARB build on this success by expanding the program to the truck and bus markets. This expansion will complement CARB's ambitious goals under the Advanced Clean Truck (ACT) and Advanced Clean Fleet (ACF) regulations and help advance the state's goals for zero-emission vehicles in line with Executive Order N-79-20.

214.22 We previously supported the requirement that LD hydrogen refueling stations (HRS) be located in designated disadvantaged communities, as it is important to continue incentivizing the build out of LD hydrogen refueling stations beyond core market areas in the state to bring hydrogen Fuel-Cell Electric Vehicle (FCEV) accessibility to a larger share of the state's population. We also support CARB's proposal to extend location eligibility to other low income and rural areas, as this additional coverage will further promote accessibility and connectivity throughout the state.

214.23 Air Products appreciates the flexibility in provisions in 95484.2(a)(1), (a)(7), and 95486.3(a)(1) to allow the dispenser owner or designee to apply for HRI credits. However, we recommend that CARB add a provision for executive officer review and discretion to negate such an arrangement if said arrangement is found to circumvent the 1% deficit cap for a single entity or any other relevant provision for HRI crediting. A company applying for credit should not be able to exceed the deficit cap simply by diversifying the credit claims via multiple commercial arrangements and registered entities.

214.24 We support the proposed location requirements for MHD fueling stations as written but seek clarity that the 1-mile distance requirement is based on a radius for the proposed location relative to the criteria and not a 1-mile driving distance.

We appreciate CARB providing an option for private MHD stations to receive HRI credits in support of the Advanced Clean Fleets regulation and we support the lower credit cap for these stations. Providing some crediting for private stations, but a higher level of crediting for public stations, strikes a good balance in the two use cases and will drive investments in the infrastructure necessary for meaningful fleet conversion.

214.25 Consistent with past crediting windows, we believe that for both LD and MHD vehicles going forward, a full 15-year crediting period should be allowed. This will help ensure continued station support through 2045 in support of CARB's carbon neutrality goals.

Air Products believes that multi-modal stations which include fueling for both LD and MHD vehicles, utilizing shared compression, storage and dispensing equipment will play an important role in California's hydrogen fueling network. Clarity is needed in the regulation or in guidance as to how the provisions in the separate LD and MHD sections apply. We have drafted language that we believe provides an approach for stations with combined fueling capabilities (in italics below) and propose that it be added to the regulation. Moreover, there is a misalignment in the Energy Economy Ratio (EER) value split and the new HRI provisions as MD vehicles are coupled with LD vehicles in Table 5 for EERs, but are coupled with HD vehicles for the purposes of HRI crediting which apply a credit calculation
214.26 formula employing an HD EER. Please clarify what tracking or recordkeeping is necessary to assign the correct EER value for HRI crediting.

Proposed combined LD and MHD HRI crediting language – add new § 95486.3 (a)(7) as follows:

(7) Requirements to Generate HRI Credits for Combined ZEV/LD and MHD Hydrogen Refueling Stations.

Application for ZEV/LD-HRI crediting capacity to MHD-HRI Refueling Capacity must submit an application to the Executive Officer to generate additional credits based on the increased dispensing capacity and number of light-duty dispensing units at a MHD hydrogen HRI station. A hydrogen station that fuels ZEV/LD and MHD vehicles will follow the requirements of the current MHD section 95486.3 (a)(1) through (6) with the exception of subsections 95486.2(a)(3)(A), 95486.2(a)(7)(I), 95486.3(a)(4)(G), and 95486.3(a)(4)(G)1, and 95486.3(a)(5).

(A) Whenever section 95486.3(a)(7) is the HRI crediting pathway, calculation of estimated potential HRI Credits will be calculated as the sum of subsections 95486.2(a)(2)(F) and 95486.3 (a)(2)(F) for HRI pathway applications received on or before December 31, 2025. Beginning January 1, 2026, the Calculation of Estimated potential HRI credits will be calculated as the sum of subsections 95486.2(a)(7)(D) and 95486.3(a)(5).

(B) Whenever section 95486.3(a)(7) is the HRI crediting pathway, the estimated cumulative value of HRI credits generated for the station in the prior quarter must be less than the difference between 1.5 times the initial capital expenditure reported pursuant to section 95486.3(a)(6)(C)(1) and the total grant revenue or other funding for capital, operational and maintenance expenses reported pursuant to section 95486.3(a)(6)(C)5 and (C)6 in the prior quarter. The capital and operational expenditure cap may be additive for shared station equipment supporting LD and MHD fuel dispensing.

1. *The estimated value of HRI credits, for the purpose of this determination, shall be calculated using the number of ZEV/LD and MHD credit generated for the station in the quarter and the average LCFS credit price for that quarter published on the LCFS website. Credits will be calculated as the sum of 95486.2(a)(5) and 95486.3(a)(5) for the HRI pathway application.*

(C) Whenever section 95486.3(a)(7) is the HRI crediting pathway, calculations of HRI Credits for Combined ZEV/LD and MHD Hydrogen Refueling Stations will be calculated using the equations found in Sections 95486.2(a)(5) for the light-duty portion of the refueling station and 95486.3(a)(5) for the medium/heavy-duty portion of the refueling station for the HRI application received before December 31, 2030. These two credit calculations will be additive.

Section 95486.3.a(4)(H) caps HD HRI credits to initial eligible capital expenditure reported and cumulative value of MHD-HRI credits earned. CARB should ensure sure that on-site hydrogen production costs are not included in the capital calculation, which would create an unlevel playing field.
214.27 §95486.3 (a)(6)(B)(1) would create a situation that favors on-site hydrogen generation vs. the more efficient centralized hydrogen production and distribution approach. Operations and maintenance costs should be included in the MHD HRI payback metric as these are differential to the costs associated with electric vehicle charging.

214.28 It is our understanding that the grant revenue being referenced in 95486.3.a(4)(H) is related to specific grants or funding revenue related to station construction and station operations and maintenance costs. Please confirm that any value for the production of hydrogen upstream of the station provided by the Inflation Reduction Act under sections 45V or 45Q is not considered "grant revenue or other external funding" for the purposes of this calculation for HRI credits.

214.29 References in proposed §95486.3 (a)(4)(G) (see below) – should be (a) and not (b). The HRI section in Appendix A-2 inadvertently references the FCI provisions.

"(G) The estimated cumulative value of MHD-HRI credits generated for the station in the prior quarter must be less than the difference between 1.5 times the initial capital expenditure reported pursuant to section 95486.3(a)(6)(B)1 and the initial grant revenue or other funding reported pursuant to section 95486.3(~~b~~a)(6)(B)5 and section 95486.3(~~b~~a)(6)(B)6 in the prior quarter"

Hydrogen Tier 1 Simplified Calculator and CalGREET4.0 Model

214.30 Consistent with the proposed change to extend low-CI electricity book-and-claim to both production and process energy under 95488.8(i)(1), please update the Tier 1 simplified calculator to provide the necessary inputs and CI calculations to accommodate this proposal.

The emissions factor for liquid hydrogen storage and dispensing (cell E19 on CA-GREET4.0 sheet) is higher than the gaseous hydrogen factor. Does this result come from the CA-GREET4.0 model? Please provide more information on how that factor was determined. It's significantly higher than what we would expect for power consumption at a liquid hydrogen fueling station, so it is important to understand the assumptions behind the factor.

Air Products suggests that it would benefit all users of the model to build into the CA-GREET4.0 sheet, or the instruction manual, information on how to use the CA-GREET4.0 full model to calculate the emission factors given in the Tier 1 calculator. There would be two benefits to this: (1) increased awareness/confidence the Tier 1 calculator is consistent with CA-GREET4.0; and (2) providing a starting point for pathway applications which need to propose modifications to CA-GREET4.0 for Tier 2 applications of complex pathways. We recommend including this additional information.

We note the substantial decrease in the California average grid electricity CI used as a transportation fuel from a value of 93.75 gCO2e/MJ to 81 gCO2e/MJ in Table 7-1. A similar value should be applied as a default in the Tier 1 Simplified Hydrogen Calculator to grid connected electrolysis units that are deployed in California as this is incremental grid demand similar to direct supply of electricity to charging. This would place hydrogen and electricity supply to zero-emission vehicles on a more level playing field.

Intrastate Jet Inclusion as Deficit-Generating Fuel

214.31 Air Products is supportive of actions to further the state's decarbonization goals and stimulate additional credit demand in the LCFS program. To this end, we are supportive of including intrastate jet fuel as an obligation-generating fuel. This will spur demand for cleaner jet fuel and possibly hydrogen for aviation in the future consistent with Governor Newsom's target of 20% sustainable aviation fuels by 2030 and the full transition to clean aviation fuels by 2045 as presented in the 2022 Scoping Plan Update scenario.

Project-Based Crediting

214.32 Air Products appreciates CARB's amendments throughout §95489 to clarify that hydrogen production facilities not co-located with a petroleum refinery can generate credits under the refinery investment credit and renewable hydrogen provisions. This is an important clarification and provides equitable treatment between third-party hydrogen production and production embedded in refinery operations.

214.33 We urge CARB to reconsider retaining the opportunity for renewable hydrogen to be eligible for project-based crediting beyond 2040. While CARB anticipates a substantial phase-down of petroleum refining, it will be important to preserve some emission reduction opportunities for the refining capacity that remains, as recognized in the 2022 Scoping Plan Update, and preserving the renewable hydrogen option recognizing the role that hydrogen can play to ensure that residual petroleum refining helps meet CARB's decarbonization goals for the transportation sector. We note the exemption from phase-out provided for Carbon Capture and Sequestration (CCS) and renewable hydrogen has a similarly important role to play. There is still refining capacity anticipated in 2045 so enabling crediting to at least 2045 will continue to promote emission reductions at these facilities.

Additional Language and Technical Suggestions and Clarifications

- We appreciate the improvements proposed for the renewable hydrogen definition but suggest
214.34 some additional changes to ensure that all conversion technologies and potential feedstocks are captured, including renewable ammonia used as a feedstock to produce hydrogen.

> *"§95481 (a) "Renewable Hydrogen" means hydrogen derived from (1) electrolysis of water or aqueous solutions using renewable electricity; (2) catalytic cracking, partial oxidation, autothermal reforming, ~~oxidation~~ or steam methane reforming of biomethane or other biogenic or renewable feedstocks ~~hydrocarbons~~; or (3) thermochemical conversion of biomass, including the organic portion of municipal solid waste (MSW). Renewable electricity, for the purpose of renewable hydrogen production by electrolysis, means electricity derived from sources that qualify as eligible renewable energy resources as defined in California Public Utilities Code sections 399.11-399.36."*

- 214.35 There is a reference to hydrogen in the Low CI electricity as a fuel section – §95488.8 (i)(1)(A) - which was not deleted like other similar references. We believe this reference is no longer needed given the new section related to hydrogen as a fuel.

- 214.36 We request that CARB consider including information on how many credits are generated via smart charging and smart electrolysis in the quarterly summary spreadsheet posted on-line – distinct from other charging and electrolysis credit-generation pathways. This information will help the market understand the opportunity for incremental credit generation associated with these pathways.

- 214.37 95488.10 (a)(4) should acknowledge that low-CI electricity can also be used for process energy for hydrogen used as a transportation fuel – and not just for the "hydrogen production via electrolysis" – consistent with 95488.8(i)(1).

- 214.38 Air Products supports phasing down electric forklift crediting based on existing fleets that effectively transitioned to electrification where credits under the LCFS are understood to have little to no impact on the rate or magnitude of the transition (i.e., electrification is the baseline for new purchases/replacements and no longer should be considered an opt-in source eligible to generate LCFS credits). This is a durable principle that can be applied to other sectors when the transition is sustainable. However, we do not believe that adjusting the Energy Economy Ratio (EER) is a valid way to do this and are concerned about the precedent this will set for other vehicle classes. The CI targets in the LCFS regulation are anchored in the CI of the base fuels – gasoline and diesel. The EERs that are used in the credit generation calculation should likewise always be calculated relative to the conventional fuel vehicles that are being replaced. This helps ensure proper crediting for the vehicle turnover that is needed to comply with various ZEV regulations and mandates.

Air Products appreciates the opportunity to provide this feedback on the 45-day package and we would be happy to meet with CARB to discuss any of these topics further. Please feel free to contact me at hellermt@airproducts.com.

Respectfully,

Miles Heller
Director, Greenhouse Gas, Hydrogen, and Utility Regulatory Policy

Re: Twelve Benefit Corporation Comments on the Proposed Low Carbon Fuel Standard Amendments

Dear Sir/Madam:

Twelve Benefit Corporation (Twelve), based in northern California, appreciates the opportunity to comment on the above-referenced Low Carbon Fuel Standard (LCFS) rulemaking package issued by the California Air Resources Board (CARB).[1]

As detailed below, our comments address the following points:

215.1
- CARB should consider broadening the proposed definition of "renewable naphtha;"

215.2
- Some of the proposed revisions to the book-and-claim accounting provisions for low-carbon intensity (low-CI) electricity used for hydrogen production are unexplained, unwarranted, and short-sighted;

215.3
- Most importantly, CARB through this rulemaking should put in place regulatory provisions to foster the production and uptake of ultra-low carbon Power-to-Liquid Sustainable Aviation Fuel (PtL SAF) and other PtL fuels;

215.4
- The "physically connected to California" requirement should be eliminated from proposed subsection 95488.8(i)(3)(A); and

215.6
- In view of the proposed revisions to section 95490, CARB should revisit the system boundary for carbon capture and sequestration (CCS) projects when the carbon dioxide (CO_2) is captured at an alternative fuel production facility.

215.7
Please note that Twelve is also a signatory of the comment letter submitted by Infinium on behalf of various PtL fuel producers and airlines.

614 Bancroft Way, Suite B, Berkeley, CA 94710

As we did in our July 3, 2023, submission to CARB on potential changes to the LCFS Program,[2] we first provide background information on our company and our groundbreaking carbon transformation™ technology, as well as a brief overview of PtL fuels, sometimes referred to as electrofuels or e-fuels, before setting out our detailed comments in Part II below.

I. Background

A. Twelve and Carbon Transformation

Founded in 2015 and headquartered in Berkeley, Twelve currently employs a staff of almost three hundred chemists, engineers, techno-economic experts, product developers, and other specialists, with the vast majority of our personnel working in one of our locations in the San Francisco Bay area. We are on a mission to eliminate global CO_2 emissions and build a fossil-free future.

Our proprietary carbon transformation technology takes captured CO_2 and, using only water and renewable energy, transforms it into synthesis gas (syngas), a combination of carbon monoxide and hydrogen. Once formed, the syngas is routed through an integrated Fischer-Tropsch reactor and then upgraded, ultimately resulting in our E-Jet® fuel – PtL SAF (or as CARB refers to it under the LCFS Program, alternative jet fuel) that meets the specifications in Annex A1 of ASTM International's D7566 Standard (*Standard Specification for Aviation Turbine Fuel Containing Synthesized Hydrocarbons*) – as well as our E-Naphtha™. We expect our E-Jet, which has been tested and validated under a grant from the U.S. Air Force,[3] to reduce lifecycle greenhouse gas (GHG) emissions by up to 90% in comparison to conventional, petroleum-based jet fuel.[4]

Last summer, we began constructing our first E-Jet plant in Moses Lake, Washington.[5] We selected Moses Lake in part because of the availability and abundance of low-carbon electricity in the state of Washington, including existing (especially hydropower) and new renewable energy sources. Over the next few years, we intend to develop commercial-scale fuel production plants in various locations around the country, and to supply our E-Jet and E-Naphtha to the global airline and chemical industries and other customers. As a California-based company, we hope to be able to arrange for uplift in the state of a sizable portion of the PtL SAF that we produce. Our ability to generate LCFS credits for our ultra-low carbon jet fuel

---

[4] For more on Twelve and carbon transformation, our revolutionary electrochemical technology, please visit our website at twelve.co.

[5] The Moses Lake AirPlant™, which will transform biogenic CO_2 captured from an industrial source, will have a water electrolyzer operating alongside our CO_2 electrolyzer, but in the future, we may produce the clean hydrogen that is needed for the syngas via an alternative hydrogen production pathway (e.g., one of the non-water electrolysis pathways included in the U.S. Department of Energy's 45VH2-GREET Model), or we may opt to obtain the clean hydrogen from a supplier.

will, of course, be a key factor in whether this happens.

B. PtL Fuels in General

While technological approaches to the production of PtL fuels can vary, the common thread among all such fuels is the utilization of the same feedstocks: CO_2 that is either captured from an industrial source (e.g., an ethanol facility) or obtained from direct air capture; and a renewable source of electricity (e.g., solar, wind, hydropower) that is used to create clean hydrogen through the electrolysis of water (or perhaps through some other hydrogen production pathway). The national blueprint for transportation decarbonization, a multi-agency effort released by the federal government early last year, points out that PtL fuels represent "a viable pathway" to sustainable, low-carbon transportation fuels.[6] According to the U.S. Department of Energy (DOE), one of the federal agencies involved in that effort, PtL fuels "have dramatically smaller land, water, and [GHG] footprints compared to fossil fuels."[7]

Specifically in the context of the hard-to-abate aviation sector,[8] PtL SAF poses fewer land-related issues than most biomass-based SAF, is also advantageous from a water demand standpoint, and has been cited as "the only SAF technology that has the potential for unbounded production,"[9] an apt description given the ever-increasing amount of CO_2 in the Earth's atmosphere. For its part, Airbus, the commercial aircraft manufacturer, has referred to PtL SAF as an "exciting option" for fueling airplanes, one that "will be necessary to meet [expected SAF] demand,"[10] while the International Energy Agency recently asserted that e-fuels "made from biogenic or air-captured CO2 can potentially provide full emissions reduction,

making them the primary production pathway that is consistent with achieving [the global aviation sector's goal of] net zero emissions by mid-century."[11]

II. Twelve's Comments on the CARB Proposal

With the above background in mind, our detailed comments on CARB's proposed LCFS amendments follow.

A. CARB Should Consider Broadening the Proposed Definition of Renewable Naphtha

As an initial matter, we note that among the new definitions that CARB is proposing to add to section 95481(a) of the LCFS regulation is a definition of the term "renewable naphtha." The definition would provide, in relevant part, that the term "means naphtha that is produced from hydrotreated lipids and biocrudes, or from gasified biomass that is converted to liquids using the Fischer-Tropsch process."[12]

215.8 As indicated above, Twelve's Moses Lake plant and our future commercial-scale facilities will produce not only E-Jet but also an electrochemical, E-Naphtha. For this reason, Twelve recommends that CARB consider broadening the proposed definition of "renewable naphtha" so that it also encompasses the E-Naphtha to be produced at Twelve's facilities. We suggest the following possible revision to the first sentence of the proposed definition (underline to indicate additions and ~~strikeout~~ to indicate deletions):

> "Renewable Naphtha" means naphtha that is produced from hydrotreated lipids and biocrudes, ~~or~~ from gasified biomass that is converted to liquids using the Fischer-Tropsch process, or from captured CO_2, water, and low-CI electricity that are converted to liquids using electrolysis and the Fischer-Tropsch process.

215.9 While we offer this recommendation, we also acknowledge the proposed revision to section 95488.1(d)(4) that would identify "synthetic hydrocarbons" as drop-in fuels subject to Tier 2 pathway classification.[13] If PtL-based naphtha like Twelve's E-Naphtha is meant to be covered by this particular revision, we would appreciate CARB providing clarification to that effect.

[12] Appendix A-1: Proposed Regulation Order (Appendix A-1) at 23.

[13] Appendix A-1 at 117.

B. Some of the Proposed Changes to the Indirect Accounting Provisions for Low-CI Electricity Used for Hydrogen Production Are Unexplained, Unwarranted, and Short-Sighted

Proposed section 95488.8(i)(1) would include a major revision to the language on book-and-claim accounting for low-CI electricity that is used in the production of hydrogen. Currently, this regulatory provision allows indirect accounting in two instances: (1) when the low-CI electricity is supplied as a transportation fuel (i.e., for use in an electric vehicle); and (2) when the low-CI electricity is used to make hydrogen via electrolysis, where that hydrogen is then used either as a transportation fuel (i.e., in a hydrogen fuel cell electric vehicle (FCV)) or in the production of another transportation fuel.[14]

CARB is proposing to restructure section 95488.8(i)(1) and the three subsections encompassed within it (i.e., existing subsections (A) and (B) and new subsection (C)), but most important to Twelve is the proposed deletion of the parenthetical in section 95488.8(1) that reads, "(including hydrogen that is used in the production of a transportation fuel)," along with the proposed insertion of the phrase "as a transportation fuel" in the italicized subheading for section 95488.8(i)(1). The deletion of the parenthetical (as well as the corresponding subheading insertion) is irksome and troubling because CARB offers absolutely no explanation or rationale for it – not in the ISOR, and not in Appendix E.[15]

To be sure, CARB has proposed to include in the introductory clause of what would be new section 95488.8(i)(3) language stating that indirect accounting may be used for low-CI hydrogen that is used "to produce alternative fuel for transportation purposes,"[16] but this new section would only apply to low-CI hydrogen injected into a dedicated hydrogen pipeline physically connected to California. We also observe that CARB has not proposed any changes to the introductory language of section 95488.8(i)(2), which allows indirect accounting for pipeline-injected biomethane that is used "to produce hydrogen for transportation purposes (including hydrogen that is used in the production of a transportation fuel)."[17] Yet under new subsection 95488.8(i)(1)(C), CARB is proposing to allow book-and-claim accounting for low-CI electricity only when it is used in direct air capture projects or in the production of hydrogen that is used as a transportation fuel. For unexplained reasons, CARB is seeking to eliminate book-and-claim
215.10 accounting for low-CI electricity when the electricity is used to make hydrogen that is then used in the manufacture of another transportation fuel (e.g., PtL SAF).

---

[15] *See* Staff Report: Initial Statement of Reasons (ISOR) at 34; Appendix E: Purpose and Rationale of Proposed Amendments for the Low Carbon Fuel Standard Requirements (Appendix E) at 68-69.

[16] Appendix A-1 at 156.

[17] 17 CCR § 95488.8(i)(2); *see also* CARB, "Low Carbon Fuel Standard (LCFS) Guidance 19-05: Reporting and Recordkeeping for Natural Gas and Book-and-Claim Accounting for Biomethane," at 6 (Feb. 2024), available at https://ww2.arb.ca.gov/sites/default/files/2024-02/lcfsguidance_19-05.pdf.

Twelve maintains that this deletion is wholly unwarranted, and we respectfully request that CARB reverse itself or at the very least provide a thorough explanation detailing the rationale for why it believes this change is needed, especially given that CARB knows full well that hydrogen is an integral input in the production of SAF.[18] From our perspective, depriving fuel producers like Twelve of the ability to use indirect accounting for low-CI electricity used to make the electrolytic hydrogen that is essential to the production of PtL SAF is short-sighted and would be a huge misstep in that it would make the scale-up of ultra-low carbon PtL SAF even more challenging than it already is.

215.10 con't

It seems fairly clear from both the ISOR and Appendix E that CARB wants to prioritize hydrogen for the on-road vehicle sector, i.e., direct use of hydrogen as fuel for cars and trucks.[19] Twelve has no quarrel with hydrogen's use as a motor vehicle fuel in FCVs. What we vigorously object to is CARB tipping the scale on book-and-claim accounting for low-CI electricity and disadvantaging the aviation sector and PtL SAF producers, as CARB is clearly doing in the proposed rulemaking by limiting book-and-claim only to low-CI electricity that is used to produce hydrogen for use as a transportation fuel.

C. CARB Should Put in Place Regulatory Provisions To Foster the Production and Uptake of Ultra-Low Carbon PtL SAF and Other PtL Fuels

215.11 In our July 3, 2023, comment letter on potential changes to the LCFS Program, we recommended that CARB expand the indirect accounting rules for low-CI electricity under section 95488.8(i) by enabling book-and-claim accounting for low-CI electricity when it is used as a feedstock for the production of PtL transportation fuels. CARB appears not to have considered Twelve's proposal, but as noted above, in the context of the proposed Tier 2 classification updates in section 95488.1(d), CARB openly acknowledges that "there is a growing interest in producing synthetic fuels by combining hydrogen with captured CO_2."[20] In the ISOR, CARB states that "the proposed amendments, and the LCFS more broadly, are structured to encourage ongoing innovation and improvement in reducing the carbon intensity of transportation fuels as well as investment in innovative . . . carbon capture, *utilization*, and sequestration approaches."[21] In view of these statements, and considering that the PtL process is a prime example of carbon capture and utilization,[22] Twelve is submitting its proposal anew.

---

[18] *See* ISOR at 34 (referring to "hydrogen used in the production of low-carbon transportation fuels such as renewable diesel and AJF").

[19] In this regard, it bears noting that earlier this month, Shell announced it was permanently closing all of its hydrogen light-duty vehicle fueling stations in California. *See* "Shell is Immediately Closing All of Its California Hydrogen Stations" (Feb. 9, 2024), available at https://insideevs.com/news/708156/shell-closes-california-hydrogen-stations/.

[20] Appendix E at 59.

[21] ISOR at 80 (emphasis added).

[22] *See, e.g.,* DOE, "Clean Fuels & Products Shot™: Alternative Sources for Carbon-based Products," available at https://www.energy.gov/eere/clean-fuels-products-shottm-alternative-sources-carbon-based-products; European Commission, "Questions and Answers on the EU Industrial Carbon Management Strategy" (Feb. 6, 2024), available at https://ec.europa.eu/commission/presscorner/detail/en/qanda_24_586.

In addition to our earlier submission, we are attaching to these comments a marked-up version of Appendix A-1.1 showing the textual regulatory revisions we are proposing today. These revisions are simple, straightforward, and narrowly tailored to "power-to-liquid fuel," a term that would be defined to mean transportation fuel that is produced from captured CO_2, water, and low-CI electricity. Allowing indirect accounting for low-CI electricity used in the production of PtL fuel would greatly incentivize the scale-up of these fuels, especially ultra-low carbon PtL SAF, which does not present the indirect land use change impacts or feedstock constraints that other types of SAF (e.g., crop-based SAF and waste oil- or animal fat-based SAF) do. Equally if not more important, extending book-and-claim to the low-CI electricity that is a feedstock (and not process energy) for PtL SAF production would ease the path to achieving the 90 percent jet fuel CI reduction in 2045 that CARB has proposed in Table 3,[23] a reduction level that Twelve fully supports and that CARB stresses "is necessary to accelerate decarbonization of the transportation fuels sector and support the State's broader climate goals."[24]

In Appendix E, CARB emphasizes that "the 2022 Scoping Plan Update includes consideration for *integrating other fuels into the LCFS program* and *highlights the importance of continuing to support low-carbon liquid fuels for sectors that are more difficult to transition to ZEV technology, such as aviation*,"[25] while in the ISOR, CARB explains that the 2022 update "anticipates a major shift away from fossil jet fuel by 2045, including 20% zero-emission aviation."[26] Twelve urges CARB to use the current rulemaking to enable book-and-claim accounting for the low-CI electricity that is essential to PtL SAF (and other PtL fuel) production and thereby facilitate the role ultra-low carbon PtL SAF can play in the decarbonization of California's aviation sector. Without indirect accounting for feedstock electricity, it will be very difficult for Twelve's E-Jet and the PtL SAF produced by other fuel producers to contribute to the state's goal, enshrined in section 38562.2(c) of the Health and Safety Code, of achieving an 85 percent reduction in anthropogenic GHG emissions (below 1990 levels) by 2045.

Please note that if CARB incorporates in the final rule the revisions we are seeking in this part of our comment letter, the feedback provided in Part II.B above becomes moot inasmuch as the recognition of book-and-claim accounting for low-CI electricity used to produce a PtL fuel would encompass both the electricity to make electrolytic hydrogen from water as well as, in Twelve's case, the electricity to electrolyze CO_2.[27]

---

[23] *See* Appendix A-1 at 67 (Table 3 specifying for fossil jet fuel substitutes an average CI in 2019 of 94.17 gCO_2e/MJ, dropping to 10.57 gCO_2e/MJ in 2045, for an 88.78 percent reduction).

[24] ISOR at 24.

[25] Appendix E at 86 (emphasis added).

[26] ISOR at 26. CARB, in fact, foresees SAF accounting for at least 80 percent of aviation fuel demand in 2045. *See* CARB, *2022 Scoping Plan for Achieving Carbon Neutrality*, at 73, 206 (Dec. 2022), available at https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf.

[27] As we indicated in footnote 17 of our July 3, 2023, comment letter, Twelve's electrochemical technology is unique in that we also use electricity to transform the CO_2 molecule.

D. The Physical Connection Requirement Should Be Eliminated From Proposed Subsection 95488.8(i)(3)(A)

As mentioned above, CARB has proposed in section 95488.8(i)(3), which would be a brand new provision in the LCFS regulation, "to expand [the] use of indirect accounting to include low-CI hydrogen injected into a dedicated hydrogen pipeline, which can be either used directly in transportation, or used in alternative fuel production."[28] To Twelve's knowledge, nowhere in the rulemaking documents does CARB speak to the extent to which dedicated hydrogen pipelines currently exist in, or to use the phrasing of proposed subsection 95488.8(i)(3)(A), are "physically connected to California." As best we can tell, the state had only 16 miles of hydrogen pipeline as of late 2020.[29]

215.12 Due to this apparent paucity of in-state hydrogen pipeline infrastructure, Twelve recommends that CARB eliminate the "physically connected to California" requirement that is included in proposed subsection 95488.8(i)(3)(A). We note in this regard that while the ISOR and Appendix E mention the physical connection prerequisite, both are silent on the underlying rationale for it.[30] So long as pipeline-injected low-CI hydrogen meets all of the other conditions laid out in proposed subsections 95488.8(i)(3)(B)-(F), an entity should be allowed to avail itself of indirect/book-and-claim accounting. In Twelve's view, this would better "incentivize and spur increased development and supply of low-CI hydrogen by providing flexibility to hydrogen production facility siting and supply logistics" and "facilitate and spur the use of low-CI hydrogen in support of California's decarbonization efforts."[31]

Thus, book-and-claim accounting would apply to low-CI hydrogen injected into a dedicated hydrogen pipeline network irrespective of whether the pipeline network is physically connected to California. This should have the ultimate effect of encouraging out-of-state fuel producers that use dedicated hydrogen pipeline-supplied low-CI hydrogen in their fuel production process to export their low-carbon fuel to California, and also enable California to benefit to an even greater extent from low-CI hydrogen that is produced outside the state.

E. CARB Should Revisit the System Boundary for Carbon Capture and Sequestration Projects When the CO_2 is Captured at an Alternative Fuel Production Facility

Finally, Twelve notes that CARB is proposing various modifications to the provisions in section 95490 governing CCS. Assuming these modifications are adopted, CARB may need to amend its CCS Protocol, which is referenced in the eligibility provision of section 95490 and "applies to CCS projects that capture [CO_2] and sequester it onshore, in either saline or depleted oil and gas reservoirs, or [in] oil and gas reservoirs used for CO_2-enhanced oil recovery (CO_2-

---

[28] Appendix E at 71.

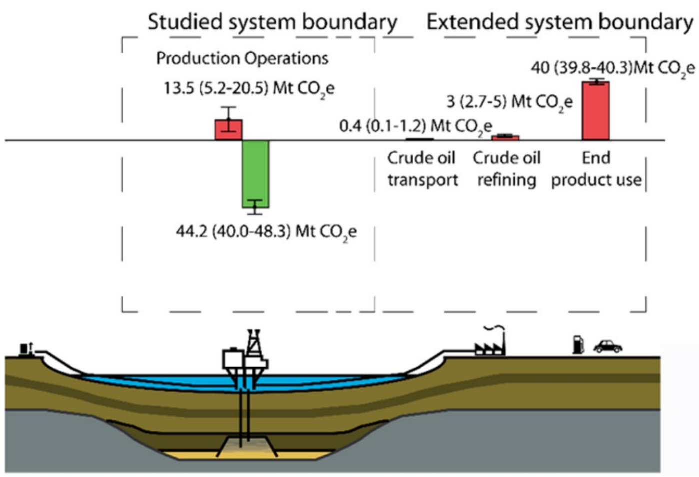
[29] *See* Congressional Research Service, *Pipeline Transportation of Hydrogen: Regulation, Research, and Policy*, at 5 (Mar. 2, 2021), available at https://www.everycrsreport.com/files/2021-03-02_R46700_294547743ff4516b1d562f7c4dae166186f1833e.pdf.

[30] *See* ISOR at 34; Appendix E at 71-73.

[31] Appendix E at 72.

EOR)."[32] Even if the Protocol would not need to be updated as a result of the approved LCFS amendments, Twelve maintains that CARB should review one specific aspect of it – CO_2
215.13 capture and sequestration in oil and gas reservoirs used for CO_2-EOR when the CO_2 was captured on-site at an alternative fuel production facility.

Currently, the CCS Protocol provides that irrespective of whether CO_2 is captured and sequestered in a depleted oil and gas reservoir or saline formation or captured and sequestered in an oil and gas reservoir used for CO_2-EOR, "the system boundary begins with carbon capture and ends with injection operations including CO_2 leakage. Any emissions downstream of the sequestration site (except entrained CO_2 in the case of CO_2-EOR) are excluded since they are associated with the downstream products rather than the CCS project."[33] Twelve urges CARB to revisit this system boundary for CO_2-EOR projects when the CO_2 is captured on-site at an alternative fuel production facility. More specifically, we believe the system boundary for such
215.14 CCS projects should be extended to include rather than exclude any GHG emissions associated with the downstream products, as depicted in the figure below. In other words, the emissions



associated with the transport, refining, and end-product use of the recovered oil should be reflected in the CI score of the Tier 2 fuel produced by the alternative fuel producer. In our view, only by including these emissions can there be a truly accurate CI score of the applicable alternative fuel.

* * *

Thank you for your consideration of our comments and proposed regulatory revisions. Please do not hesitate to contact me or my colleague, Ira Dassa (ira.dassa@twelve.co), if you have any questions.

Re: Twelve Benefit Corporation Feedback on Potential Changes to the Low Carbon Fuel Standard

Dear Dr. Laskowski:

Although there is no longer an open feedback period for any of the informal public meetings and workshops that the California Air Resources Board (CARB) has held over the last several months on potential changes to the Low Carbon Fuel Standard (LCFS) Program, Twelve Benefit Corporation (Twelve) is taking this opportunity to submit these comments inasmuch as the formal rulemaking stage for the "Proposed LCFS Amendments" has yet to be reached.[1] To the extent specificity is needed pursuant to the introductory paragraph on CARB's "LCFS Meetings and Workshops" webpage, please consider this comment letter and the accompanying proposed regulatory language as referring to the virtual community meetings held on June 1 and June 2, for which the timeframe for feedback ended on June 14, 2023.[2]

As detailed below, our comments pertain to section 95488.8(i) of the current LCFS regulation. In particular, this letter proposes and discusses the basis for the attached revisions to the regulatory text. The revisions would enable indirect accounting mechanisms for renewable or low-carbon intensity (low-CI) electricity when it is used as a feedstock for the production of power-to-liquid (PtL) transportation fuels, sometimes referred to as electrofuels or e-fuels. We believe these revisions are warranted, as they would significantly incentivize the scale-up of these ultra-low carbon fuels, which are regarded as one of the most promising pathways, if not the most promising pathway to decarbonization of the aviation (and broader heavy-duty transportation) sector. Twelve respectfully requests that CARB include these proposed revisions in its forthcoming LCFS rulemaking package.

Before setting out our comments in Part II below, we first provide background information on Twelve and our groundbreaking carbon transformation™ technology, as well as a brief general overview of PtL fuels.

[1] *See* https://ww2.arb.ca.gov/sites/default/files/2022-11/2022-11-1%20LCFS%20Amendments%20Admin%20Record%20Commencement%20Memo.pdf.

I. Background

A. Twelve and Carbon Transformation

Founded in 2015 and based in northern California, Twelve currently employs a staff of almost three hundred chemists, engineers, techno-economic experts, product developers, and other specialists, with the vast majority of our personnel working in one of our locations in Berkeley and Alameda. We are on a mission to eliminate global carbon dioxide (CO_2) emissions and build a fossil-free future.

Our patented carbon transformation technology takes captured CO_2 and, using only water and renewable electricity, transforms it into syngas, a combination of carbon monoxide and hydrogen. Once formed, the syngas is routed through an integrated Fischer-Tropsch reactor and then upgraded, ultimately resulting in our E-Jet® fuel – PtL sustainable aviation fuel (SAF, or as CARB refers to it under the LCFS Program, alternative jet fuel) that meets the specifications in Annex A1 of ASTM International's D7566 Standard (*Standard Specification for Aviation Turbine Fuel Containing Synthesized Hydrocarbons*). We expect our E-Jet, which has been tested and validated under a grant from the U.S. Air Force,[3] to reduce lifecycle greenhouse gas (GHG) emissions up to 90% in comparison to conventional, petroleum-based jet fuel.[4]

At the Paris Air Show last month, we publicly announced plans to begin construction of our first E-Jet plant in Moses Lake, Washington.[5] We selected Moses Lake in part because of the availability and abundance of low-carbon electricity in the state of Washington, including existing and new renewable sources. Over the next few years, we intend to develop additional fuel production plants in various other locations around the country. As a California-based company, we hope to be able to arrange for the uplift of a sizable portion of the PtL SAF we produce by aircraft in California.

B. PtL Fuels in General

While technological approaches to the production of PtL fuels vary, the common thread among all such fuels is the utilization of the same feedstocks: CO_2 that is either captured from an industrial source (e.g., an ethanol facility) or obtained through direct air capture; water, which is electrolyzed to produce hydrogen; and a renewable source of electricity (e.g., solar, wind, hydropower). The national blueprint for transportation decarbonization, a multi-agency effort released by the federal government earlier this year, points out that PtL fuels represent "a viable

---

[4] For more on Twelve and our revolutionary CO_2 electrolysis technology, please visit our website at twelve.co.

[5] *See* https://www.commerce.wa.gov/news/twelve-announces-plans-to-scale-production-of-sustainable-aviation-fuel-made-from-co2-in-washington-state/.The Moses Lake plant will use biogenic CO_2 captured from an industrial point source, but our carbon transformation technology also converts CO_2 extracted from the air via direct air capture.

pathway" to sustainable, low-carbon transportation fuels.[6] According to the U.S. Department of Energy (DOE), one of the federal agencies involved in that effort, PtL fuels "have dramatically lower land, water, and [GHG] footprints compared to fossil fuels."[7] Specifically in the context of the hard-to-abate aviation sector,[8] PtL SAF poses fewer land-related issues than most biomass-based SAF, is also advantageous from a water demand standpoint, and has been cited as "the only SAF technology that has the potential for unbounded production,"[9] an apt description given the ever-increasing concentration of CO_2 in the Earth's atmosphere. For its part, Airbus, the commercial aircraft manufacturer, has referred to PtL SAF as an "exciting option" for fueling airplanes.[10]

With the above background in mind, our LCFS comments follow.

II. Indirect Accounting for Renewable or Low-CI Electricity is Warranted for PtL Fuels

Section 95488.8(i), which was added to the LCFS regulation as part of the 2018 rulemaking, makes clear that indirect accounting mechanisms for renewable or low-CI electricity can only be used under the Program in two instances: (1) when the electricity is used as a transportation fuel (i.e., in an electric vehicle); and (2) when the electricity is used to make hydrogen via electrolysis, where that hydrogen is then used either as a transportation fuel (i.e., in a fuel cell electric vehicle) or in the production of another transportation fuel.[11]

[11] 17 CCR § 95488.8(i)(1); *see also* CARB, "Low Carbon Fuel Standard (LCFS) Guidance 19-01: Book-and-Claim Accounting for Low-CI Electricity," at 1-2 (Dec. 2022), available at https://ww2.arb.ca.gov/sites/default/files/2022-12/19-01_updated%20for%20WREGIS%20changes_ADA.pdf; CARB, "LCFS Electricity and Hydrogen Provisions," available at https://ww2.arb.ca.gov/resources/documents/lcfs-electricity-and-hydrogen-provisions.

In its November 2018 Final Statement of Reasons (2018 FSOR), CARB reiterated what it had indicated at the outset of the 2018 rulemaking, that "[t]he CI of pathways for electricity supplied to vehicles, and hydrogen produced by electrolysis rely almost entirely on the source of the electricity, but no options exist under the current regulation for matching low-CI electricity to an EV or electrolysis load."[12] CARB then explained in the 2018 FSOR as follows:

> Pathways . . . for hydrogen produced by electrolysis use electricity as a feedstock. Staff views the flexibility for indirect accounting of low-CI electricity for these pathways as analogous to the flexibility that the LCFS has always offered to other biofuels in using a mass balance approach to allocation of finished fuel to various feedstocks. In this regard, electricity has historically been disadvantaged in the program by being limited to the regional grid CI. Additionally, these changes create consistency between the treatment of biomethane that is indirectly supplied through the common carrier pipeline, and renewable electricity that is supplied through the electrical grid.[13]

CARB went on to emphasize that it was not recognizing indirect accounting under the LCFS Program in any other instances (i.e., in instances other than the two specified in section 95488.8(i)(1)) in part because "[t]he GHG benefits of allowing indirect accounting for renewable or low-CI process energy are expected to be relatively small as most alternative fuel production does not rely extensively on electricity consumption."[14]

As indicated in the attached document, which shows the textual regulatory revisions we are proposing, Twelve maintains that indirect accounting for renewable or low-CI electricity should likewise be allowed in a third, specific and limited instance: when the electricity is used in the production of a PtL transportation fuel like Twelve's E-Jet. The language changes laid out in the attachment are simple, straightforward, and narrowly tailored. In addition to minor add-ons in section 95488.8(i), all of which are shown in redline, we are putting forward a proposed definition of the term "power-to-liquid fuel" to ensure the intended scope of the proposal is not exceeded.[15] Importantly, the conditions in subparagraphs (1)(A) and (B) would have to be met for indirect accounting to be allowed.

As with the existing authorized uses now contained in section 95488.8(i)(1), the CI value of any fuel producer's PtL fuel depends, as CARB put it in the 2018 FSOR, "almost entirely on the

---

[12] 2018 FSOR at 172, quoting from the Initial Statement of Reasons (2018 ISOR) at III-95. In the 2018 ISOR, CARB proffered as the rationale for indirect accounting that "[s]upport for electricity decarbonization for electric vehicles allows for ultra-low carbon fuel pathways, which will help California better meet GHG emission reduction goals." 2018 ISOR at III-96.

[13] 2018 FSOR at 172. Elsewhere in the document, CARB stated that "[i]ndirect, or book-and-claim, accounting for renewable or low-CI energy is recognized under the LCFS only for feedstocks or when the input is used directly as a fuel, not process energy." *Id.* at 483.

[14] *Id.* at 173.

[15] We acknowledge that the term "low-CI electricity" is a defined term in the LCFS regulation (17 CCR 95481(a)(94)) and expressly includes "'an eligible renewable resource" as defined under the California Renewables Portfolio Standard Program. Nevertheless, insofar as the subtitles of subsection (i) and paragraph (1) each include the term "renewable," we recommend from a pure drafting standpoint that this term also be inserted elsewhere in section 95488.8(i)(1), as shown in the attachment.

source of the electricity." In a presentation at a recent Commercial Aviation Alternative Fuels Initiative event, Dr. Ian Rowe, who co-leads the DOE CO_2 Reduction and Upgrading for e-Fuels Consortium, confirmed this, pointing out that PtL fuels "can have a very low carbon intensity IF they are made with renewable electricity."[16] Moreover, as with electrolytic hydrogen production, electricity serves as a feedstock for PtL fuel production, not as process energy. Finally, indirect accounting in this additional instance is further justified by the fact that, separate and apart from the electricity being a feedstock rather than process energy, the GHG emission reductions that would result from the allowance of indirect accounting would be quite significant inasmuch as the fuel production process, once again as CARB put it in the 2018 FSOR, "rel[ies] extensively on electricity consumption." That, of course, is the whole premise behind the burgeoning PtL fuel industry – using electricity (from a renewable source) to ultimately transform CO_2 into an ultra-low carbon liquid fuel.[17]

From a public policy perspective, allowing indirect accounting for renewable or low-CI electricity used in the production of a PtL transportation fuel makes good sense in that it would significantly incentivize not only the scale-up of these promising liquid fuels, but also the much-needed development and utilization of renewable energy resources like solar, wind, and hydroelectric. It is undeniable that the LCFS Program is designed to reduce GHG emissions from the transportation sector, and Twelve's proposal would squarely further that purpose. That the proposal would also yield ancillary benefits for the electricity grid by supporting lower-CI stationary electricity generation should not be ignored or disregarded, particularly given that for a host of reasons, PtL fuel producers cannot always co-locate their facilities at a renewable electricity source or build a solar or wind farm as part of their fuel production facility.

* * *

Thank you for your consideration of our comments and proposed regulatory revisions. Please do not hesitate to contact me or my colleague, Ira Dassa (ira.dassa@twelve.co), if you have any questions. As a California-based company, and with the manufacture of the all-important CO_2 electrolyzer stacks that will be deployed at our first fuel production plant now taking place at our facility in Alameda, I want to stress in closing that we would be pleased to meet or otherwise engage with you or your staff on any aspect of our proposal.

[16] *See* Ian Rowe (DOE Bioenergy Technologies Office), "Emerging Technologies to Support the SAF Grand Challenge 2050 Goal: Routes to Achieving Net-Zero Fuels and E-Fuels," at slide 11 (June 16, 2023) (emphasis in original), available at https://caafi.org/resources/pdf/SAF_Virtual_Conf_June2023_Session_13_Ian_Rowe.pdf.

[17] Twelve's proprietary process is unique in that we use electricity not only to create electrolytic hydrogen for the syngas but, equally important, to electrolyze CO_2 via our revolutionary CO_2 electrolyzer technology. Under the current LCFS regulation, our understanding is that indirect accounting can be used for the water electrolysis step. (Note that in the future, we may opt to obtain green hydrogen from a supplier.) However, we are submitting this proposal because the novel CO_2 electrolysis step in our process does not appear to be encompassed within section 95488.8(i)(1), which we assume triggers the applicability of the section 95488.8(h) preclusion against indirect accounting mechanisms "[u]nless expressly provided elsewhere in [the LCFS regulation]." This, in turn, would affect the CI score of our E-Jet fuel.

Sincerely yours,

Andrew Stevenson

Anil Prabhu, Manager, Fuels Evaluation Section

§ 95481. Definitions and Acronyms.

(New (a)(120))

(120) "Power to Liquid Fuel" means a synthetic fuel that is produced from captured carbon dioxide, water, and renewable or low-CI electricity.

* * *

§ 95488.8. Fuel Pathway Application Requirements Applying to All Classifications.

* * *

(i) *Indirect Accounting for Renewable or Low-CI Electricity and Biomethane.*

(1) *Book-and-Claim Accounting for Renewable or Low-CI Electricity Supplied as a Transportation Fuel ~~or~~, Used to Produce Hydrogen, or Used to Produce a Power-to-Liquid Fuel.* Reporting entities may use indirect accounting mechanisms for renewable or low-CI electricity supplied as a transportation fuel ~~or~~, for hydrogen production through electrolysis for transportation purposes (including hydrogen that is used in the production of a transportation fuel), or for the production of a power-to-liquid fuel for transportation purposes, provided the conditions set forth below are met:

(A) Reporting entities may report renewable or low-CI electricity used as a transportation fuel or as an input to hydrogen or power-to-liquid fuel production delivered through the grid without regard to physical traceability if it meets all requirements of this subarticle.
The renewable or low-CI electricity must be supplied to the grid within a California Balancing Authority (or local balancing authority for hydrogen or power-to-liquid fuel produced outside of California) or alternatively, meet the requirements of California Public Utilities Code section 399.16, subdivision (b)(1). Such book-and-claim accounting for renewable or low-CI electricity may span only three quarters. If a renewable or low-CI electricity quantity (and all associated environmental attributes, including a beneficial CI) is supplied to the grid in the first calendar quarter, the quantity claimed for LCFS reporting must be matched to grid electricity used as a transportation fuel or for hydrogen or power-to-liquid fuel production no later than the end of the third calendar quarter.
After that period is over, any unmatched renewable or low-CI electricity quantities expire for the purpose of LCFS reporting.

(B) Renewable or ~~L~~low-CI electricity can be indirectly supplied through a green tariff program (including the Green Tariff Shared Renewables program described in California Public Utilities Code Section 2831-2833) or other contractual electricity supply relationship that meets the following requirements:

1. Electricity is generated by, or supplied under contract to, the pathway applicant for all environmental attributes of the claimed electricity. In order to substantiate renewable or low-CI electricity claims, the applicant must make contracts available to the Executive Officer, upon request, to demonstrate that the electricity meets the requirements of this subarticle. Generation invoices or metering records are required to substantiate the quantity of renewable or low-CI electricity produced from the renewable assets. Monthly invoices must be unredacted copies of originals showing electricity sourced (in kWh) and contracted price;

2. All electricity procured by any LSE for the purpose of claiming a lower CI must be in addition to that required for compliance with the California Renewables Portfolio Standard (described in California Public Utilities Code sections 399.11-399.32) or, for hydrogen or power-to-liquid fuel produced outside of California, in addition to local renewable portfolio requirements;

3. Renewable energy certificates or other environmental attributes associated with the electricity, if any, are retired and not claimed under any other program with the exception

of the federal RFS, and the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800). Retirement of renewable energy credits for the purpose of demonstrating Green Tariff Shared Renewables procurement to the California Public Utilities Commission does not constitute a double claim.

APPENDIX A-1.1

Proposed Regulation Order

Proposed Amendments to the Low Carbon Fuel Standard Regulation

[Showing Twelve Benefit Corporation's Proposed Insertions on pp. 21 and 149-50]

[Note: This alternative version of the proposed amendments is provided to improve the accessibility and readability of the regulatory text. This version is not the authoritative version for this proposed rulemaking. **For the authoritative version that complies with Government Code section 11346.2, subdivision (a)(3), please see Appendix A-1**. The existing, original regulatory language currently adopted into the CCR is shown as plain, clean text, while the proposed amendments subject to comment in this rulemaking are shown in tracked changes (underline to indicate additions and ~~strikeout~~ to indicate deletions from the existing regulatory text). [Bracketed underline text] is placeholder text for these amendments' approval date. Vertical lines in the left margins and text balloons in the right margins are to flag where changes are proposed (both substantive and nonsubstantive) for ease of reference and are not part of the proposed amendments. Blank cells in Table 9 (section 95489) are a result of formatting in "No Markup" or "Clean" reviewing options and are not part of the proposed amendments. To review this document in a clean format (no underline or strikeout to show changes), please select "Simple Markup" or "No Markup" in Microsoft Word's Review menu, or accept all changes. You can also change the view to the original (originally proposed regulatory text prior to proposed modifications) by selecting "Original" or rejecting all tracked changes. Additionally, "Advanced Track Changes Options" will allow for further options regarding color and other markings. Instructions on using/viewing Track Changes can be found here]

Proposed Regulation Order

Title 17, California Code of Regulations

Amend Sections 95481, 95482, 95483, 95483.2, 95483.3, 95484, 95485, 95486, 95487, 95486.1, 95486.2, 95488, 95488.1, 95488.2, 95488.3, 95488.5, 95488.6, 95488.7, 95488.8, 95488.9, 95488.10, 95489, 95490, 95491, 95491.1, 95495, 95500, 95501, 95502, 95503 of title 17, California Code of Regulations, to read as follows:

§ 95480. Purpose.

The purpose of this regulation is to implement a low carbon fuel standard, which will reduce the full fuel-cycle, carbon intensity of the transportation fuel pool used in California, pursuant to the California Global Warming Solutions Act of 2006 (Health & Safety Code [H&S], section 38500 et seq.).

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95481. Definitions and Acronyms.

(a) *Definitions.* For the purposes of sections 95480 through 95503, the definitions in Health and Safety Code sections 39010 through 39060 shall apply, except as otherwise specified in this section or sections 95482 through 95503:

~~(1)~~"Account Administrator" means the person who can establish and activate user accounts for the reporting party organization as well as upload data (but not necessarily "submit" reports) into the LRT-CBTS. Account administrators with "signatory authority" may submit Quarterly and Annual Reports; initiate and view all credit transfers and credit transfer activity; access the Credit Balance ledger for the organization; and select/authorize broker(s) to represent them.

~~(2)~~"Advanced Credits" means LCFS base electricity credits that are issued prior to the quarter in which credit-generating transactions have occurred. Advanced credits can only be sold via the Credit Clearance Market, and only retired for the purpose of meeting compliance obligation.

~~(3)~~"Advanced Credit Window" is the six-year period during which advanced credits can be issued and after which base credit issuances will be adjusted to account for advanced credits.

~~(4)~~"Adverse Validation Statement" and "Adverse Verification Statement" means a statement rendered by a verification body attesting that: (1) the verification body cannot say, with reasonable assurance, that the reported value is free of a material misstatement, or (2) the data submitted contain one or more correctable errors, or (3) both, and thus is not in conformance with the requirement to fix such errors pursuant to section 95501(b)(6). This definition applies to Adverse Validation Statements for fuel pathway applications and Adverse Verification Statements for Annual Fuel Pathway Reports, Quarterly Fuel Transactions Reports, Crude Oil Quarterly and Annual Volumes Reports, Low-Complexity/Low-Energy-Use Refinery Reports, and Project Reports. "Material misstatement" for each type of report is assessed pursuant to sections 95501(b)(9) through (11).

~~(5)~~"AEZ-EF Model" means the Agro-Ecological Zone Emissions Factor model (December 31, 2014),~~ posted at http://www.arb.ca.gov/fuels/lcfs/lcfs_meetings/lcfs_meetings.htm and~~ available for download at http://www.arb.ca.gov/fuels/lcfs/lcfs_meetings/aez-ef_model_v52.xlsm, which is incorporated herein by reference.

~~(6)~~"Aggregated Transaction Indicator" means an identifier for reported transactions that are a result of an aggregation or summing of more than one transaction in the LRT-CBTS. An entry of 'True' indicates that multiple transactions have been aggregated and are reported with a single Transaction Number. An entry of 'False' means that the transaction record results from one fuel transaction reported as a single Transaction Number.

~~(7)~~"Alternative Fuel" means any transportation fuel that is not CaRFG~~ or a~~, diesel fuel, or fossil jet fuel including those fuels specified in section 95482(a)(3) through (a)(13).

~~(8)~~"Alternative Jet Fuel" means a drop-in fuel, made from ~~petroleum or~~ non-petroleum sources, which can be blended ~~and used with~~into conventional ~~petroleum~~ jet fuel~~s~~ without the need to modify aircraft engines and existing fuel distribution infrastructure.

"Alternate Method" means the collection of data to support or replace a measurement required by this subarticle. An alternate method may include a calculated value based on accurate measurements of system inputs and outputs or based on a conservative calculation using previously collected quality assured data.

~~(9)~~"Animal Fat" means the inedible fat that originates from a rendering facility as a product of rendering the by-products from meat processing facilities including animal parts, fat and bone. "Yellow grease" must be reported under an applicable animal fat pathway if evidence is not provided to the verifier or CARB to confirm the quantity that is animal fat and the quantity that is used cooking oil.

~~(10)~~“Application” means the type of vehicle where the fuel is consumed in terms of LDV/MDV for light-duty vehicle/medium-duty vehicle or HDV for heavy-duty vehicle.

“Automatic Acceleration Mechanism” is a mechanism implemented pursuant to section 95484 which advances all annual carbon intensity benchmarks by one year when specified conditions are met.

~~(11)~~“Aviation Gasoline” means a complex mixture of volatile hydrocarbons, with or without additives, suitably blended to be used in aviation engines.

~~(12)~~“Avoided Cost Calculator” means the Excel-based spreadsheet model (May 22, 2018) produced by Energy and Environmental Economics, Inc. (E3) for use in demand-side cost-effectiveness proceedings at the California Public Utilities Commission (CPUC), which is incorporated herein by reference~~, and is available for download at http://www.cpuc.ca.gov/General.aspx?id=5267.~~..

~~(13)~~“Battery Electric Vehicle (BEV)” means any vehicle that operates solely by use of a battery or battery pack, or that is powered primarily through the use of an electric battery or battery pack but uses a flywheel or capacitor that stores energy produced by the electric motor or through regenerative braking to assist in vehicle operation.

~~(14)~~“Biodiesel” means a fuel as defined in California Code of Regulations, title 4, section 4140(a).

~~(15)~~“Biodiesel Blend” means biodiesel blended with CARB diesel.

~~(16)~~“Biogas” means the raw gaseous mixture comprised primarily of methane and carbon dioxide and derived from sources, including but not limited to, the anaerobic decomposition of organic matter in a landfill, lagoon, or constructed reactor (digester). Biogas often contains a number of other impurities, such as hydrogen sulfide, and it cannot be directly injected into natural gas pipelines or combusted in most natural-gas-fueled vehicles. It can be used as a fuel in boilers and engines to produce electrical power. The biogas can be refined to produce near-pure methane, which is sold as biomethane.

~~(17)~~“Bio-CNG” means biomethane which has been compressed to CNG. Bio-CNG has equivalent performance characteristics when compared to fossil CNG.

~~(18)~~“Bio-LNG” means biomethane which has been compressed and liquefied into LNG. Bio-LNG has equivalent performance characteristics when compared to fossil LNG.

~~(19)~~“Bio-L-CNG” means biomethane which has been compressed, liquefied, re-gasified, and re-compressed into L-CNG, and has performance characteristics at least equivalent to fossil L-CNG.

~~(20)~~"Biomass" means non-fossilized and biodegradable organic material originating from plants, animals, or micro-organisms, including: products, by-products, residues and waste from agriculture, forestry, and related industries; the non-fossilized and biodegradable organic fractions of industrial and municipal wastes; and gases and liquids recovered from the decomposition of non-fossilized and biodegradable organic material.

~~(21)~~"Biomass-based Diesel" means a biodiesel or a renewable diesel.

~~(22)~~"Biomethane" means methane derived from biogas, or synthetic natural gas derived from renewable resources, including the organic portion of municipal solid waste, which has been upgraded to meet standards for injection to a natural gas common carrier pipeline, or for use in natural gas vehicles, natural gas equipment, or production of renewable hydrogen. Biomethane contains all of the environmental attributes associated with biogas and can also be referred to as renewable natural gas.

~~(23)~~"Blendstock" means a component that is either used alone or is blended with another component(s) to produce a finished fuel used in a motor vehicle. Each blendstock corresponds to a fuel pathway in the ~~California-modified Greenhouse Gases, Regulated Emissions, and Energy use in Transportation version 3.0 (~~CA-GREET ~~3~~4.0~~)~~ model, ~~(August 13, 2018), which is incorporated herein by reference.~~[Date of adoption]. A blendstock that is used directly as a transportation fuel in a vehicle is considered a finished fuel.

"Book-and-Claim Accounting" is an indirect accounting system where a physical product and its environmental attributes can be separately traded. In the LCFS, the separated environmental attributes of low-CI electricity, biomethane or low-CI hydrogen may be matched under certain conditions to the use of grid electricity, fossil natural gas or hydrogen respectively.

"Break ground" means earthmoving and site preparations necessary for construction of the digestor system and supporting infrastructure that starts following approval of all necessary entitlements/permits for the project.

~~(24)~~"Brown Grease" means an emulsion of fat, oil, grease, solids, and water separated from wastewater in a grease interceptor (grease trap) and collected for use as a fuel feedstock. Brown grease must be reported under an applicable used cooking oil (UCO) pathway, i.e., reported as "unprocessed UCO" only if evidence is provided to the verifier or CARB to confirm that it has not been processed prior to receipt by the fuel production facility.

~~(25)~~"Business Partner" refers to the counterparty in a specific transaction involving the fuel reporting entity. This can be either the buyer or the seller of fuel.

"Byproduct" means a secondary product with marginal economic value outside its use in a biofuel pathway.

"California-modified Greenhouse Gases, Regulated Emissions, and Energy use in Transportation model (CA-GREET)" is a modified version of Argonne National Lab's Greenhouse Gases, Regulated Emissions, and Energy use in Transportation (GREET) model used to evaluate well-to-wheel GHG emissions in the LCFS. The CA-GREET model is periodically updated, and includes a version number suffix, e.g., CA-GREET4.0.

"California Reformulated Gasoline Blendstock for Oxygenate Blending (CARBOB)" is gasoline blendstock that, when blended with ethanol, results in a finished gasoline which meets the requirements of California Reformulated Gasoline (RFG) Regulations

"Carbon capture and sequestration (CCS) project" means a project that captures CO_2 by an eligible entity specified in section 95490(a) of this subarticle, transports the captured CO_2 to an injection site, and injects and permanently sequesters the captured CO_2 pursuant to the Carbon Capture and Sequestration Protocol and as specified by section 95490 of this subarticle.

~~(26)~~"Carbon Intensity (CI)" means the quantity of life cycle greenhouse gas emissions, per unit of fuel energy, expressed in grams of carbon dioxide equivalent per megajoule (gCO_2e/MJ).

~~(27)~~"Cargo Handling Equipment" means any off-road, self-propelled vehicle or equipment, other than yard trucks, used at a port or intermodal rail yard to lift or move container, bulk, or liquid cargo carried by ship, train, or another vehicle, or used to perform maintenance and repair activities that are routinely scheduled or that are due to predictable process upsets. Equipment includes, but is not limited to, rubber-tired gantry cranes, top handlers, side handlers, reach stackers, loaders, aerial lifts, excavators, tractors, and dozers.

~~(28)~~"CHAdeMO Connector" means a connector and communication protocol for vehicle DC charging initially developed in Japan during 2005-2009. It was first adopted into international standards IEC 61851-23/24 and IEC 62196-3 in 2014 and then into USA standard IEEE 2030.1.1 in 2015. Further updates to the protocol are managed by the CHAdeMO Association.

~~(29)~~"Clean Fuel Reward" is a statewide program established by EDUs to provide a reduction in price ~~on new light duty EV~~ purchases or leases for new medium- or heavy-duty electric vehicles that are not subject to the High Priority and Federal Fleets requirements as specified in, title 13, California Code of Regulations, section 2015(a)(1) in California. The Clean Fuel Reward is funded exclusively through LCFS proceeds generated by EDUs from electricity fuel.

~~(30)~~"Compressed Natural Gas (CNG)" means natural gas that has been compressed to a pressure greater than ambient pressure.

~~(31)~~"Conflict of Interest" means a situation in which, because of financial or other activities or relationships with other persons or organizations, a person or body is unable, or potentially unable, to render an impartial validation or verification statement on a potential client's LCFS data report, or the person or body's objectivity in performing validation or verification services is, or might be, otherwise compromised.

"Conservative" means reducing the estimated GHG reduction benefits of an operation or utilizing methods and factors that over-estimate energy usage or carbon intensity (90th percentile or highest value) or under-estimate produced fuel volumes (10th percentile or lowest value).

~~(32)~~"Contract Description Code" means the alphanumeric code assigned by an exchange to a particular exchange product that differentiates the product from others traded on the exchange.

~~(33)"Conventional~~ "Jet Fuel" means aviation turbine fuel including Commercial and Military Jet Fuel. Commercial Jet Fuel includes products known as Jet A, Jet A-1, and Jet B. Military Jet Fuel includes products known as JP-5 and JP-8.

"Co-product" means a product with significant market value that is produced alongside a main primary product.

~~(34)~~"Correctable Errors" means one or more errors that result from a nonconformance with this subarticle and are identified by the verification team as errors that affect data subject to validation or verification as specified in section 95500. Differences that, in the professional judgment of the verification team, are the result of differing but reasonable methods of truncation or rounding or averaging, where a specific procedure is not prescribed by this subarticle, are not considered errors.

"Credit Bank" is the total credits retained from previous crediting periods that have not been retired to demonstrate compliance.

~~(35)~~"Credit Generator" means a fuel reporting entity or a project operator that generates LCFS credit in the LCFS program.

~~(36)~~"Credits" and "Deficits" mean the units of measure used for determining a regulated entity's compliance with the average carbon intensity requirements in section 95484. Credits and deficits are denominated in units of metric tons of carbon dioxide equivalent (CO_2e), and are calculated pursuant to sections 95486.1(a), (c), 95486.2(a)(5) and (b)(5), 95489 and 95490.

~~(37)~~"Day" means a calendar day unless otherwise specified as a business day.

~~(38)~~"Deficit Generator" means a fuel reporting entity who generates deficits in the LCFS program.

~~(39)~~"Diesel Fuel" (also called conventional diesel fuel) has the same meaning as specified in California Code of Regulations, title 13, section 2281(b).

~~(40)~~"Direct Current Fast Charging" means charging an electric vehicle at 50 kW and higher using direct current.

~~(41)~~"Disadvantaged Communities" means communities that are defined by California Health and Safety Code section 39711(a) that are identified based on geographic, socioeconomic, public health, and environmental hazard criteria, and may include, but are not limited to, either of the following: (1) areas disproportionately affected by environmental pollution and other hazards that can lead to negative public health effects, exposure, or environmental degradation or (2) areas with concentrations of people that are of low-income, high unemployment, low levels of homeownership, high rent burden, sensitive populations, or low levels of educational attainment.

~~(42)~~"Distiller's Corn Oil" has the same meaning as "Technical Corn Oil."

"Distiller's Grains and Solubles" is a coproduct of ethanol production rich in protein and fiber, typically used for animal feed. DGS is subcategorized as Dry (DDGS), Modified (MDGS), or Wet (WDGS) based on the extent of moisture removal at an ethanol production facility.

~~(43)~~"Distiller's Sorghum Oil" has the same meaning as "Technical Sorghum Oil."

~~(44)~~"Drayage Trucks" means vehicles as defined in California Code of Regulations, title 13, section 2027(c).

~~(45)~~"E100," also known as "Denatured Fuel Ethanol," means nominally anhydrous ethyl alcohol.

~~(46)~~"Electrical Distribution Utility" means an entity that owns or operates an electrical distribution system, including:

~~(A)~~(1) a public utility as defined in the Public Utilities Code section 216 (referred to as an Investor Owned Utility, or IOU); or

~~1.~~(A) "Large Investor-owned Utility" means an IOU with annual load served equal to or more than 10,000 Gigawatt-hours (GWh) in 2017;

~~2.~~(B) "Medium Investor-owned Utility" means an IOU with annual load served of less than 10,000 GWh and equal to or more than 700 GWh in 2017;

~~3.~~(C) "Small Investor-owned Utility" means an IOU with annual load served equal to or less than 700 GWh in 2017.

or

~~(B)~~(2) a local publicly-owned electric utility (POU) as defined in Public Utilities Code section 224.3;

~~1.~~(A) "Large Publicly-owned Utility" means a California POU with annual load served equal to or more than 10,000 Gigawatt-hours (GWh) in 2017;

~~2.~~(B) "Medium Publicly-owned Utility" means a California POU with annual load served of less than 10,000 GWh and equal to or more than 700 GWh in 2017;

~~3.~~(C) "Small Publicly-owned Utility" means a California POU with annual load served of less than 700 GWh in 2017.

or

~~(C)~~(3) an Electrical Cooperative (COOP) as defined in Public Utilities Code section 2776.

~~(47)~~"Electric Cargo Handling Equipment (eCHE)" means cargo handling equipment using electricity as the fuel.

~~(48)~~"Electric Power for Ocean-going Vessel (eOGV)" means shore power provided to an ocean going vessel at-berth.

~~(49)~~"Electric Transport Refrigeration Units (eTRU)" means refrigeration systems powered by electricity designed to refrigerate or heat perishable products that are transported in various containers, including semi-trailers, truck vans, shipping containers, and rail cars.

~~(50)~~"Electric Vehicle (EV)," for purposes of this regulation, refers to Battery Electric Vehicles (BEVs) and Plug-In Hybrid Electric Vehicles (PHEVs).

"Emission Factor" is a measure of greenhouse gas emissions per unit of a specific product or activity (i.e., gCO2e/mile transported). Emission factors are used extensively in Tier 1 calculators to provide simplified results of more complex lifecycle analysis equations derived from the CA-GREET model.

"Emissions & Generation Resource Integrated Database (eGRID)" is the database maintained and published by the U.S. Environmental Protection Agency (EPA) that provides resource mix and emission data for electrical power generated in the United States.

~~(51)~~"Energy Economy Ratio (EER)" means the dimensionless value that represents the efficiency of a fuel as used in a powertrain as compared to a reference fuel used in the same powertrain. EERs are often a comparison of miles per gasoline gallon equivalent (mpge) between two fuels. EERs for fixed guideway systems are based on MJ/number of passenger-miles.

~~(52)~~“Environmental Attribute” means greenhouse gas emission reduction recognition in any form, including verified emission reductions, voluntary emission reductions, offsets, allowances, credits, avoided compliance costs, emission rights and authorizations under any law or regulation, or any emission reduction registry, trading system, or reporting or reduction program for greenhouse gas emissions that is established, certified, maintained, or recognized by any international, governmental, or non-governmental agency.

~~(53)~~“Executive Officer” means the Executive Officer of the California Air Resources Board, or his or her delegate.

~~(54)~~“Exchange” means a central marketplace with established rules and regulations where buyers and sellers meet to conduct trades.

~~(55)~~“Export” means transportation fuel reported in the LRT-CBTS program that is subsequently delivered outside of California and not used for transportation in California.

~~(56)~~“Feedstock First Collection Point” means the facility that aggregates and stores or treats feedstock materials collected from a point of origin. The first collection point may be upstream of the fuel production facility, or, if feedstocks are transported to the fuel production facility directly from the point of origin, the first collection point is the fuel production facility.

~~(57)~~“Feedstock Transport Mode” means the applicable combination of actual delivery methods and the distance through which the feedstock was transported to any intermediate entities and ending at a fuel production facility. The fuel pathway holder and any entity reporting the fuel must demonstrate that the actual feedstock transport mode and distance conforms to the stated mode and distance in the certified pathway.

~~(58)~~“Final Distribution Facility” means the stationary finished fuel transfer point from which the finished fuel is transferred into the cargo tank truck, pipeline, or other delivery vessel for delivery to the facility at which the finished fuel will be dispensed into motor vehicles.

~~(59)~~“Finished Fuel” means a fuel that is used directly in a vehicle for transportation purposes without requiring additional chemical or physical processing.

~~(60)~~“First Fuel Reporting Entity” means the first entity responsible for reporting in the LRT-CBTS for a given amount of fuel. This entity initially holds the status as the fuel reporting entity and the credit or deficit generator for this fuel amount, but may transfer either status pursuant to sections 95483 or 95483.1.

~~(61)~~“Fish Oil” means the fat that originates from fish processing operations as a product of rendering fat from residual fish parts.

~~(62)~~"Fixed Guideway System" means a system of public transit electric vehicles that can operate only on its own guideway (directly operated, or DO), or through overhead or underground electricity supply constructed specifically for that purpose, such as light rail, heavy rail, cable car, street car, and trolley bus.

"Food Scraps" is the organic portion of municipal solid waste (MSW) that consists of wastes derived from plants or animals for the explicit preparation for consumption by humans or other animals that is predominantly disposed by landfilling. This includes inedible waste from foods processed or consumed at residences, hospitality facilities (hotels, restaurants, amusement parks, stadiums, special events, etc.), institutions (hospitals, schools, prisons, etc.), and grocery stores. Food scraps do not include liquid wastes, fat/oil/grease (FOG) materials, or other by-products of industrial food processing, manufacturing, and distribution facilities.

"Forest" means land spanning more than 0.5 hectares with trees higher than 5 meters and a canopy cover of more than 10 percent, or trees able to reach these thresholds in situ. It does not include land that is predominantly under agricultural or urban land use.

"Fossil CNG" means CNG that is derived solely from petroleum or fossil sources, such as oil fields and coal beds.

~~(63)~~"Fossil Jet Fuel" means Jet Fuel that is derived solely from petroleum or fossil sources, such as oil fields and coal beds.

~~(64)~~"Fossil LNG" means LNG that is derived solely from petroleum or fossil sources, such as oil fields and coal beds.

~~(65)~~"Fossil L-CNG" means L-CNG that is derived solely from petroleum or fossil sources, such as oil fields and coal beds.

~~(66)~~"Fuel Pathway" means, for a particular finished fuel, the collective set of processes, operations, parameters, conditions, locations, and technologies throughout all stages that CARB considers appropriate to account for in the system boundary of a complete well-to-wheel analysis of that fuel's life cycle greenhouse gas emissions.

~~(67)~~"Fuel Pathway Applicant" refers to an entity that has registered in the Alternative Fuel Portal pursuant to section 95483.2 and has submitted an application including all required documents and attestations in support of the application requesting a certified fuel pathway.

~~(68)~~"Fuel Pathway Code" means the identifier in the LRT-CBTS that applies to a specific fuel pathway certified pursuant to sections 95488 through 95488.10.

~~(69)~~"Fuel Pathway Holder" means a fuel pathway applicant that has received a certified fuel pathway carbon intensity based on site-specific data, including a Provisional fuel pathway.

~~(70)~~"Fuel Production Facility" means the facility at which the fuel is produced. "Fuel Production facility" means, with respect to biomethane to vehicle fuel pathways, a facility at which fuel is upgraded, purified, or processed to meet standards for injection to a natural gas common carrier pipeline or for use in natural gas vehicles.

~~(71)~~"Fuel Reporting Entity" means an entity that is required to report fuel transactions in the LRT-CBTS pursuant to section 95483 or 95483.1. Fuel reporting entity refers to the first fuel reporting entity and to any entity to whom the reporting entity status is passed for a given quantity of fuel.

~~(72)~~"Fuel Transport Mode" means the applicable combination of actual fuel delivery methods, such as truck routes, rail lines, pipelines, and any other fuel distribution methods, and the distance through which the fuel was transported under contract from the entity that generated or produced the fuel, to any intermediate entities, and ending at the fuel blender, producer, importer, or provider in California. The fuel pathway holder and any entity reporting the fuel must demonstrate that the actual fuel transport mode and distance conforms to the stated mode and distance in the certified pathway.

"Fugitive Methane" is methane emitted atmospherically from leaks, venting or incomplete combustion. Fugitive methane sources may be quantified either using standard values or a site-specific energy balance of methane inside the fuel pathway system boundary.

"Full verification" means all verification services as provided in section 95501.

~~(73)~~"Green Tariff" means a program in which a retail seller of electricity offers its customers an opportunity to purchase electricity sourced from low-carbon intensity energy resources. This includes the Green Tariff Shared Renewables program established pursuant to California Senate Bill 43 (2013) and defined under the California Public Utilities Code sections 2831-2833.

~~(74)~~"GTAP" or "GTAP Model" means the Global Trade Analysis Project Model (December 2014), which is incorporated herein by reference, and is a software available for download at https://www.gtap.agecon.purdue.edu/resources/res_display.asp?RecordID=4577.

~~(75)~~"Heavy-Duty Vehicle" means a vehicle that is rated at or greater than 14,001 pounds gross vehicle weight rating (GVWR).

"Higher Heating Value (HHV)" is the quantity of heat energy produced by complete combustion of a fuel, including the heat of condensation for water vapor produced during combustion.

~~(76)~~“Holdback Credits” means the portion of base residential EV charging credits issued to an EDU that are not contributed by the EDU to the Clean Fuel Reward program.

~~(77)~~“Home Fueling” means the dispensing of fuel by use of a fueling appliance that is located on or within a residential property with access limited to a single household.

~~(78)~~“Hybrid Electric Vehicle (HEV)” means any vehicle that can draw propulsion energy from both of the following on-vehicle sources of stored energy: 1) a consumable fuel, and 2) an energy storage device, such as a battery, capacitor, or flywheel.

“Hydrogen Fueling Capacity Model” or “HyCap” means a tool developed by the National Renewable Energy Laboratory to determine the dispensing capacity of hydrogen stations with different configurations and size parameters to accommodate heavy-duty fueling demands.

~~(79)~~“Hydrogen Station Capacity Evaluator” or “HySCapE” means a tool developed by the National Renewable Energy Laboratory to determine the dispensing capacity of a hydrogen station, HySCapE Version 1.0 (August 13, 2018), which is incorporated herein by reference and available at http://www.arb.ca.gov/fuels/lcfs/lcfs.htm~~http://www.arb.ca.gov/fuels/lcfs/lcfs.htm.~~.

“Hydroprocessed Ester and Fatty Acid (HEFA) Fuel” is any lipid feedstock converted to transportation fuel with addition of hydrogen in the presence of a catalyst. HEFA fuels can include renewable diesel, renewable naphtha, renewable propane and alternative jet fuel.

“Gasification” means the non-combustion thermal decomposition of biomass or organic matter in the presence of limited oxygen, air, or steam to produce heat and a mixture of gases, including but not limited to carbon monoxide and hydrogen (syngas) and solid hydrocarbon products.

~~(80)~~“Import” means to bring a product from outside California into California.

~~(81)~~“Importer” means the person who owns the transportation fuel or blendstock, in the transportation equipment that held or carried the product, at the point the fuel entered California. For purposes of this definition, “transportation equipment” includes, but is not limited to, rail cars, cargo tanker trucks, and pipelines.

~~(82)~~“Independent Reviewer” means an accredited lead verifier, within a verification body, who (A) has not participated in conducting the LCFS validation or verification services for the client for the current application period or reporting period, and (B) provides an independent review of findings and services rendered to the client as required in section 95501. The independent reviewer is not required to meet the additional specified competency requirements in sections 95502(c)(4) and 95502(c)(5) that the verification team leader must meet.

~~(83)~~“Ineligible Specified Source Feedstock” means a feedstock specified in section 95488.8(g)(1)(A) that does not meet the chain-of-custody documentation requirements specified in section 95488.8(g)(1)(B).

~~(84)~~“Intermediate Calculated Value” means a value that is used in the calculation of a reported value but does not by itself meet the reporting requirement under section 95491.

~~(85)~~“Intermediate Facility” means a facility in a fuel supply chain, which is not the fuel production facility, that contributes site-specific data for determination of a fuel pathway carbon intensity. Intermediate facilities produce components of a fuel or intermediate chemical that may be further processed into a fuel. This term includes feedstock-processing facilities.

~~(86)~~“LCFS Credit Broker” is a person registered in the LRT-CBTS specifically to facilitate the transfer of LCFS credits between LRT-CBTS accounts.

~~(87)~~“Lead Verifier” means a person who has met all the requirements in section 95502 and who may act as either (A) the lead verifier of a verification team providing validation or verification services, or (B) as a lead verifier providing an independent review of validation or verification services rendered.

“Less intensive verification” means the verification services provided in interim years between full verifications; less intensive verification does not require a site visit, and only requires data checks and document reviews of a submitted report based on the analysis and risk assessment in the most current sampling plan developed as part of the most current full verification services. This level of verification may only be used if the verifier can provide findings with a reasonable level of assurance.

~~(88)~~“Life Cycle Greenhouse Gas Emissions” means the aggregate quantity of greenhouse gas emissions (including direct emissions and significant indirect emissions, such as significant emissions from land use changes), as determined by the Executive Officer, related to the full fuel life cycle, including all stages of fuel and feedstock production and distribution, from feedstock generation or extraction through the distribution and delivery and use of the finished fuel to the ultimate consumer, where the mass values for all greenhouse gases are adjusted to account for their relative global warming potential.

~~(89)~~“Light-Duty Vehicle” and “Medium-Duty Vehicle” mean a vehicle category that includes both light-duty (LDV) and medium-duty vehicles (MDV).

~~(A)~~(1) “LDV” means a vehicle that is rated at 8,500 pounds or less GVWR.

~~(B)~~(2) “MDV” means a vehicle that is rated between 8,501 and 14,000 pounds GVWR.

~~(90)~~"Liquefied Compressed Natural Gas (L-CNG)" means LNG that has been liquefied and transported to a dispensing station where it was then re-gasified and compressed to a pressure greater than ambient pressure.

~~(91)~~"Liquefied Natural Gas (LNG)" means natural gas that has been liquefied.

~~(92)~~"Liquefied petroleum gas (LPG or propane)" has the same meaning as defined in Vehicle Code section 380.

~~(93)~~"Load-Serving Entity" means any entity that (A) sells or provides electricity to end users located in California, or (B) generates electricity at one site and consumes electricity at another site that is in California and that is owned or controlled by the company. A load-serving entity does not include the owner or operator of a co-generator.

~~(94)~~"Low-Carbon Intensity (Low-CI) Electricity" means any electricity that is determined to have a carbon intensity that is less than the average grid electricity for the region, including but not limited to an "eligible renewable energy resource" as defined in Public Utilities Code sections 399.11-399.36 under the California Renewables Portfolio Standard Program.

~~(95)~~"Low-Complexity/Low-Energy-Use Refinery" means a refinery that meets both of the following criteria:

~~(A)~~(1) A Modified Nelson Complexity Score equal to or less than 5 as calculated in section 95489(d)(1)(A~~).~~), and

~~(B)~~(2) Total annual energy use equal to or less than 5 million MMBtu as calculated in section 95489(d)(1)(B).

"Lower Heating Value (LHV)" is the quantity of heat energy produced by complete combustion of a fuel, excluding the heat of condensation for water vapor produced during combustion.

~~(96)~~"Low-Income Communities" means census tracts with median household incomes at or below 80 percent of the statewide median income or with median household incomes at or below the threshold designated as low income by the Department of Housing and Community Development's list of state income limits adopted pursuant to Health and Safety Code section 50093.

~~(97)~~"Mandatory Reporting Regulation" or "MRR" means CARB's Regulation for the Mandatory Reporting of Greenhouse Gas Emissions as set forth in title 17, California Code of Regulations, chapter 1, subchapter 10, article 2 (commencing with section 95100).

~~(98)~~"Material Misstatement of Operational Carbon Intensity" means any discrepancy, omission, or misreporting, or aggregation of the three, identified in the course of verification services that leads a verification team to believe that the reported operational CI (gCO_2e/MJ) contains one or more errors that, individually or collectively, result in an overstatement or understatement more than 5.00 percent of the reported operational CI, or 2.00 gCO_2e/MJ, whichever absolute value expressed in gCO_2e/MJ is greater. Material misstatement is calculated separately for each operational CI. All correctable errors identified must be fixed prior to the completion of the verification services to receive a positive or qualified positive verification statement.

~~(99)~~"Material Misstatement of Low-Complexity/Low-Energy-Use (LC/LEU) Refinery Data" means any discrepancy, omission, or misreporting, or aggregation of the three, identified in the course of LC/LEU refinery report verification services that leads a verification team to believe that a LC/LEU Refinery Report contains one or more errors that, individually or collectively, result in an overstatement greater than 5.00 percent of the regulated entity's annual sum of quarterly reported volumes of CARBOB or diesel produced from crude oil. Discrepancies, omissions, or misreporting, or an aggregation of the three, that result in an understatement of the annual sum of quarterly reported volumes of CARBOB or diesel produced from crude oil submitted in the LC/LEU Refinery Report is not a LC/LEU refinery data material misstatement. Material misstatement is calculated separately, pursuant to section 95501(b)(11), for the annual volume of CARBOB production from crude oil and for the annual volume of diesel production from crude oil. All correctable errors identified must be fixed prior to the completion of the verification services to receive a positive or qualified positive verification statement.

~~(100)~~"Material Misstatement of Project Data" means a discrepancy, omission, misreporting, or aggregation of the three, identified in the course of project verification services that leads a verification team to believe that a Project Report contains one or more errors that, individually or collectively, result in an overstatement greater than 5.00 percent of the regulated entity's reported total greenhouse gas emission reductions. Discrepancies, omissions, or misreporting, or an aggregation of the three, which result in an understatement of total reported greenhouse gas emission reductions in the Project Report, is not a project material misstatement. Material misstatement is calculated separately, pursuant to section 95501(b)(10), for each Project Report. All correctable errors identified must be fixed prior to the completion of the verification services to receive a positive or qualified positive verification statement.

~~(101)~~"Material Misstatement of Quarterly Fuel Quantity" means any discrepancy, omission, or misreporting, or aggregation of the three, identified in the course of validation or verification services that leads a verification team to believe that the regulated entity's reported fuel quantity per fuel pathway code per quarter contains one or more errors that, individually or collectively, result in an overstatement or understatement greater than 5.00 percent. Material misstatement is calculated separately, pursuant to section 95501(b)(9), for each quarterly fuel quantity per fuel pathway code. All correctable errors identified must be fixed prior to the completion of the verification services to receive a positive or qualified positive verification statement.

“Missing Data” means a loss of reliable data for a period of time during which a piece of data is not collected, is invalid, or is collected while the measurement device is not in compliance with the applicable quality-assurance requirements, including calibration requirements.

~~(102)~~“Modified Nelson Complexity Score” means a Nelson Complexity Score that is calculated without including lube oil and asphalt capacity, as set forth in section 95489(d)(1)(A).

~~(103)~~“Motor Vehicle” has the same meaning as defined in section 415 of the Vehicle Code.

~~(104)~~“Multi-fuel Vehicle” means a vehicle that uses two or more distinct fuels for its operation. A multi-fuel vehicle (also called a vehicle operating in blended-mode) includes a bi-fuel vehicle and can have two or more fueling ports onboard the vehicle. A fueling port can be an electrical plug or a receptacle for liquid or gaseous fuel. For example, most plug-in hybrid electric vehicles use both electricity and gasoline as the fuel source and can be “refueled” using two separately distinct fueling ports.

~~(105)~~“Multi-family Residence” means a dwelling unit in a building that consists of at least four condominium dwelling units or at least three apartment dwelling units in which each unit shares a floor or ceiling on at least one side.

~~(106)~~“Natural Gas” means a mixture of gaseous hydrocarbons and other compounds, with at least 80 percent methane (by volume), and typically sold or distributed by utilities, such as any utility company regulated by the California Public Utilities Commission.

~~(107)~~“Nelson Complexity Score” means the commonly used industry measure of a refinery's ability to convert crude oils to finished fuels, taking into consideration the complexity of the technologies incorporated within the process and related capacities as compared to crude distillation.

~~(108)~~“Nonconformance” means the failure to use any method or meet any other requirement specified in this subarticle.

~~(109)~~“Ocean-Going Vessel” means a commercial, government, or military vessel meeting any one of the following criteria:

~~(A)~~(1) A vessel greater than or equal to 400 feet in length overall (LOA) as defined in 50 Code of Federal Regulations (CFR) § 679.2, as adopted June 19, 1996;

~~(B)~~(2) A vessel greater than or equal to 10,000 gross tons (GT ITC) pursuant to the convention measurement (international system) as defined in 46 CFR § 69.51-.61, as adopted September 12, 1989; or

~~(C)~~(3) A vessel propelled by a marine compression ignition engine with a per-cylinder displacement of greater than or equal to 30 liters.

~~(110)~~"On-road" means a vehicle that is designed to be driven on public highways and roadways and that is registered or is capable of being registered by the California Department of Motor Vehicles (DMV) under Vehicle Code sections 4000 et seq. - or DMV's equivalent in another state, province, or country; or the International Registration Plan. A vehicle covered under CARB's In-Use Off-Road Regulation, Code of Regulations, title 13, section 2449, is not covered under this definition.

~~(111)~~"OPGEE" or "OPGEE Model" means the Oil Production Greenhouse gas Emissions Estimator Version ~~2.0 (June 20, 2018~~3.0b (May 14, 2022) posted at ~~http://www~~https://ww2.arb.ca.gov/~~fuels~~resources/documents/lcfs/~~lcfs.htm~~-life-cycle-analysis-models-and-documentation, which is incorporated herein by reference.

"Operating Condition" is a specific requirement developed by CARB that dictates operational changes and conditions, and how operational data/other information must be gathered, kept, reported, or calculated for a fuel pathway or set of pathways.

"Operational Data Period" is the date range for site-specific data in a given fuel pathway application or annual report.

~~(112)~~"Opt-in Fuel Reporting Entity" means an entity that meets the requirements of section 95483.1 and voluntarily opts in to be a fuel reporting entity and is therefore subject to the requirements set forth in this subarticle.

~~(113)~~"Opt-in Project" means a project approved for generating LCFS credits by the Executive Officer pursuant to sections 95489 or 95490.

"Organic Waste" is material that meets both the LCFS definitions of "biomass" and "waste."

~~(114)~~"Over-the-Counter" means the trading of LCFS credits or contracts not executed or entered for clearing on any exchange.

~~(115)~~"Performance Review" means an assessment conducted by CARB of an applicant seeking to become accredited or reaccredited as a verification body or lead verifier pursuant to section 95502 of this subarticle. Such an assessment may include a review of applicable past sampling plans, validation and verification reports, validation and verification statements, conflict of interest submittals, and additional information or documentation regarding the applicant's fitness for qualification.

~~(116)~~"Petroleum Intermediate" means a petroleum product that can be further processed to produce CARBOB, diesel, or other petroleum blendstocks.

~~(117)~~"Petroleum Product" means all refined and semi-refined products that are produced at a refinery by processing crude oil and other petroleum-based feedstocks, including petroleum products derived from co-processing biomass and petroleum feedstock together. "Petroleum product" does not include plastics or plastic products.

~~(118)~~"Plug-In Hybrid Electric Vehicle (PHEV)" means a hybrid electric vehicle with the capability to charge a battery from an off-vehicle electric energy source that cannot be connected or coupled to the vehicle in any manner while the vehicle is being driven.

~~(119)~~"Positive Validation Statement" and "Positive Verification Statement" means a statement rendered by a verification body attesting that the verification body can say, with reasonable assurance, that the reported value is free of material misstatement, when applicable, and conforms to the requirements of this subarticle. This definition applies to Positive Validation Statements for fuel pathway applications and Positive Verification Statements for Annual Fuel Pathway Reports, Quarterly Fuel Transactions Reports, Crude Oil Quarterly and Annual Volumes Reports, Low-Complexity/Low-Energy-Use Refinery Reports, and Project Reports.

"Power-to-Liquid Fuel" means transportation fuel that is produced from captured CO_2, water, and low-CI electricity.

"Primary Product" is a product that a system is optimized to produce, and typically represents the highest economic value of all system product outputs.

~~(120)~~"Private Access Fueling Facility" means a fueling facility with access restricted to privately-distributed electronic cards ("cardlock") or is located in a secure area not accessible to the public.

"Private MHD-FCI charging site" means an EV fast charging site that can be limited to be available only to MHD EVs under single ownership.

"Private MHD-HRI station" means a hydrogen refueling station that can be limited to be available only to MHD FCEVs under single ownership.

~~(121)~~"Producer" means, with respect to any fuel, the entity that made or prepared the fuel.

~~(122)~~"Product Transfer Document (PTD)" means a document that authenticates the transfer of ownership of fuel from a fuel reporting entity to the recipient of the fuel. A PTD is created by a fuel reporting entity to contain information collectively supplied by other fuel transaction documents, including bills of lading, invoices, contracts, meter tickets, rail inventory sheets, Renewable Fuels Standard (RFS) product transfer documents, etc.

~~(123)~~"Project Operator" means an entity that registers an opt-in project in the Alternative Fuel Portal and has it approved for generating LCFS credits. A project operator must meet the requirements of sections 95483.1 and 95489 or 95490.

~~(124)~~"Public Access Fueling Facility" means a fueling facility that is not a private-access fueling dispenser.

"Pyrolysis" means the non-combustion thermal decomposition of biomass or organic matter by the addition of heat with little to no added oxygen, air, or steam, to produce a mixture of liquids, solid hydrocarbon products, and combustible gases, including but not limited to carbon monoxide, hydrogen, bio-oil, and biochar.

~~(125)~~"Qualified Positive Validation Statement" and "Qualified Positive Verification Statement" means a statement rendered by a verification body attesting that the verification body can say, with reasonable assurance, that the reported value is free of material misstatement, when applicable, and is in conformance with the requirement to fix correctable errors pursuant to section 95501(b)(6), but the data may include one or more other nonconformance(s) with the requirements of this subarticle, which do not result in a material misstatement. This definition applies to Qualified Positive Validation Statements for fuel pathway applications and Qualified Positive Verification Statements for Annual Fuel Pathway Reports, Quarterly Fuel Transactions Reports, Crude Oil Quarterly and Annual Volumes Reports, Low-Complexity/Low-Energy-Use Refinery Reports, and Project Reports.

~~(126)~~"Rack" means a mechanism for delivering motor vehicle fuel or diesel from a refinery or terminal into a truck, trailer, railroad car, or other means of non-bulk transfer.

~~(127)~~"Reasonable Assurance" means a high degree of confidence that submitted data and statements are valid.

~~(128)~~"Regulated Entity" means an entity subject to any requirement pursuant to this subarticle.

~~(129)~~"Renewable Fuel Standard" means the program administered by the United States Environmental Protection Agency, under 40 CFR Part 80: Regulation of Fuels and Fuel Additives, Subparts K and M.

~~(130)~~"Renewable ~~Hydrocarbon~~ Diesel" means a diesel fuel that is produced from ~~non-petroleum renewable resources but is not a mono-alkyl ester~~hydrotreated lipids and ~~which is registered as a motor vehicle fuel~~biocrudes, or ~~fuel additive~~

~~under 40 Code of Federal Regulations part 79~~from gasified biomass that is converted to liquids using the Fischer-Tropsch process. This includes the renewable portion of a diesel fuel derived from co-processing biomass with a petroleum feedstock.

~~(131)~~"Renewable Hydrogen" means hydrogen derived from (1) electrolysis of water or aqueous solutions using renewable electricity; (2) catalytic cracking, oxidation or steam methane reforming of biomethane or other renewable hydrocarbons; or (3) thermochemical conversion of biomass, including the organic portion of municipal solid waste (MSW). Renewable electricity, for the purpose of renewable hydrogen production by electrolysis, means electricity derived from sources that qualify as eligible renewable energy resources as defined in California Public Utilities Code sections 399.11-399.36.

"Renewable Naphtha" means naphtha that is produced from hydrotreated lipids and biocrudes, or from gasified biomass that is converted to liquids using the Fischer-Tropsch process. This includes the renewable portion of a naphtha fuel derived from co-processing biomass with a petroleum feedstock.

"Renewable Natural Gas (RNG)" is an alternate term for "biomethane."

~~(132)~~"Renewable Propane" means liquefied petroleum gas (LPG or propane) that is produced from non-petroleum renewable resources.

"Residue" is a secondary product with no significant economic value outside of its use as in a biofuel pathway that does not incur significant disposal or management costs.

~~(133)~~"Rural Area" means a census tract with at least 75 percent of its population identified as rural by the latest US Census data.

~~(134)~~"SAE CCS Connector" means a connector that supports both AC J1772 and DC Charging and created by the Society of Automobile Engineers, which is a standards development organization for vehicle technology.

"Shared MHD-FCI charging site" means an EV fast charging site that is available to at least two MHD EV fleets under different ownership, or to the public for at least 12 hours each day. The site must not have obstructions or obstacles precluding the fleet vehicles from entering site premises, and no registered equipment training shall be required for individuals to use the site.

"Shared MHD-HRI station" means a hydrogen refueling station that is available to at least two MHD FCEV fleets under different ownership, or to the public for at least 12 hours per day. The station must not have any obstructions or obstacles precluding the fleet vehicles from entering station premises and no registered equipment training shall be required for individuals to use the station.

~~(135)~~"Shore Power" means electrical power being provided either by the local utility or by distributed generation to ocean-going vessels at-berth.

~~(136)~~"Single-family Residence" means a building designed to house a family in a single residential unit. A single-family residence is either detached or attached including duplex or townhouse units.

~~(137)~~"Site-specific Data" and "Site-specific Input" means an input value used in determination of fuel pathway carbon intensity value, or the raw operational data used to calculate an input value, which is required to be unique to the facility, pathway, and feedstock. All site-specific inputs must be measured, metered or otherwise documented, and verifiable, e.g., consumption of natural gas or grid electricity at a fuel production facility must be documented by invoices from the utility.

~~(138)~~"Specified Source Feedstocks" means feedstocks that require the chain of custody evidence specified in 95488.8(g)(1)(B) to be eligible for a reduced CI associated with the use of a waste, residue, by-product or similar material. Specified source feedstocks are identified in section 95488.8(g)(1)(A).

~~(139)~~"Staff" means CARB personnel unless otherwise specified or dictated by context.

"Standard Value" is an input value established or developed by CARB, which may be used under specified conditions and is typically not subject to validation or verification.

~~(140)~~"Station Operational Status System (SOSS)" means a software database tool developed and maintained by California Fuel Cell Partnership to publicly monitor the operational status of hydrogen stations.

~~(141)~~"Steam Quality" means the ratio of the mass of vapor to the total mass of a vapor-liquid mixture of water at its saturation temperature.

~~(142)~~"Technical Corn Oil" means inedible oil recovered from thin stillage or the distiller's grains and solubles produced by a dry mill corn ethanol plant, termed distiller's corn oil (DCO), or other non-food grade corn oil from food processing operations.

~~(143)~~"Technical Sorghum Oil" means inedible oil recovered from thin stillage or the distiller's grains and solubles produced by a dry mill sorghum ethanol plant, termed distiller's sorghum oil (DSO), or other non-food grade sorghum oil from food processing operations.

"Temporary Method" means a method used when necessary for the avoidance of missing data or to comply with the missing data provisions of this subarticle. As described in section 95491.2(b)(2)(A) for reports other than fuel pathways, a temporary method may not be used for a time period longer than six months during a calendar year for a source that was affected by a loss of data. A measurement device used as part of a temporary method is not subject to the calibration requirements in section 95488.8(j)(1); however, the entity must be able to demonstrate to the reasonable assurance of the verification body that the temporary method provides data accuracy within ±5.00 percent or is conservative.

~~(144)~~"Total Obligated Amount (TOA)" means the quantity of fuel for which the fuel reporting entity is the eligible credit or deficit generator. The LRT-CBTS calculates the TOA for each fuel pathway code. TOA is calculated as the difference between the fuel reported using transaction types that increase the net quantity of fuel that generates credits or deficits in the LRT-CBTS and the fuel reported using transaction types that decrease the net quantity of fuel that generates credits or deficits in the LRT-CBTS. Transaction types that increase the TOA include: Production in California, Production for Import, Import, Purchased with Obligation, Gain of Inventory. Transaction types that decrease the TOA include: Sold with Obligation, Loss of Inventory, Export, Not Used for Transportation.

~~(145)~~"Total Amount (TA)" means the total quantity of fuel reported by a fuel reporting entity irrespective of whether the entity retained status as the credit or deficit generator for that specific fuel volume. TA is calculated as the difference between the fuel reported using transaction types that increase the net fuel quantity reported in the LRT-CBTS and fuel reported using transaction type that decrease the net fuel quantity reported in the LRT-CBTS. Transaction types that increase the TA include: Production in California, Production for Import, Import, Purchased with Obligation, Purchased without Obligation, Gain of Inventory. Transaction types that decrease the TA include: Sold with Obligation, Sold without Obligation, Loss of Inventory, Export, Not Used for Transportation.

~~(146)~~"Transaction Date" means the title transfer date as shown on the Product Transfer Document.

~~(147)~~"Transaction Quantity" means the amount of fuel reported in a transaction. A Transaction Quantity must be reported in units, provided in Table 4 and in the LRT-CBTS.

~~(148)~~"Transaction Type" means the nature of a fuel-based transaction as defined below:

~~(A)~~(1) "Production in California" means the transportation fuel was produced at a facility in California for use in California;

~~(B)~~(2) "Production for Import" means the transportation fuel was produced outside of California and imported into California for use in transportation.

~~(C)~~(3) “Import” means the transportation fuel was produced outside of California and later brought by any party other than its producer into California for use in transportation.

~~(D)~~(4) “Purchased with Obligation” means the transportation fuel was purchased with the obligation to claim credits or deficits in the LRT-CBTS from a separate fuel reporting entity;

~~(E)~~(5) “Purchased without Obligation” means the transportation fuel was purchased without obligation to claim credits or deficits in the LRT-CBTS from a separate fuel reporting entity;

~~(F)~~(6) “Sold with Obligation” means the transportation fuel was sold with the obligation to claim credits or deficits in the LRT-CBTS by a fuel reporting entity;

~~(G)~~(7) “Sold without Obligation” means the transportation fuel was sold without obligation to claim credits or deficits in the LRT-CBTS by a fuel reporting entity;

~~(H)~~(8) “Export” means any fuel reported in the LRT-CBTS that is subsequently delivered outside of California and is not used for transportation in California;

~~(I)~~(9) “Loss of Inventory” means the fuel entered the California fuel pool but was not used due to volume loss;

~~(J)~~(10)“Gain of Inventory” means the fuel entered the California fuel pool due to a volume gain;

~~(K)~~(11) “Not Used for Transportation” means a transportation fuel was reported with compliance obligation under the LCFS but was later not used for transportation purposes in California or otherwise determined to be exempt under section 95482(d);

~~(L)~~(12) “eTRU Fueling” means providing fuel to electric transport refrigeration units.

~~(M)~~(13) “eCHE Fueling” means providing fuel to electric cargo handling equipment.

~~(N)~~(14) “eOGV Fueling” means providing shore power to an ocean-going vessel at-berth.

~~(O)~~(15) “EV Charging--Grid” means providing electricity to recharge EVs using the California Average Grid Electricity Lookup Table pathway for a given year as specified in section 95488.5;

~~(P)~~(16) "EV Charging--Non-Grid" means providing electricity that has a carbon intensity lower than the average grid electricity and is obtained through an approved arrangement as specified in section 95488.8(h) or section 95488.8(i) to recharge EVs;

~~(Q)~~(17) "EV Charging--Smart Charging" means providing electricity that is eligible to generate credits under the smart charging provisions in section 95488.5 to recharge EVs;

~~(R)~~(18) "Fixed Guideway Electricity Fueling" means fueling light rail, heavy rail, cable car, street car, and trolley bus, or exclusive right-of-way bus operations with electricity;

~~(S)~~(19) "Forklift Electricity Fueling" means providing fuel to electric forklifts;

~~(T)~~(20) "Forklift Hydrogen Fueling" means providing fuel to hydrogen forklifts;

(21) "Fossil Jet Fuel used for Intrastate Flight" means jet fuel consumed during a flight that takes off and lands in California.

~~(U)~~(22) "Fuel Cell Vehicle (FCV) Fueling" means the dispensing of hydrogen at a fueling station designed for fueling hydrogen fuel cell electric vehicles;

~~(V)~~(23) "Fuel Cell Vehicle (FCV) Fueling--Smart Electrolysis" means the dispensing of hydrogen that is eligible to generate credits under the smart charging or electrolysis provisions in section 95488.5;

~~(W)~~(24) "NGV Fueling" means the dispensing of natural gas at a fueling station designed for fueling natural gas vehicles;

~~(X)~~(25) "Propane Fueling" means the dispensing of propane at a fueling station designed for fueling propane vehicles.

~~(149)~~"Transmix" means a mixture of refined products that forms when these products are transported through a pipeline. This mixture is typically a combination of two of the following: gasoline, diesel, or jet fuel.

~~(150)~~"Transportation Fuel" means any fuel used or intended for use as a motor vehicle fuel or for transportation purposes in a non-vehicular source.

~~(151)~~"Uncertainty" means the degree to which data or a data system is deemed to be indefinite or unreliable.

"Urban Landscaping Waste" is organic MSW material collected from landscaping activities, including leaves, grass, branches, and stumps.

~~(152)~~"Used Cooking Oil" (or UCO) means fats and oils originating from commercial or industrial food processing operations, including restaurants, that have been used for cooking or frying. Feedstock characterized as UCO must contain only fats, oils, or greases that were previously used for cooking or frying operations. UCO must be characterized as "processed UCO" if it is known that processing has occurred prior to receipt by the fuel production facility or if evidence is not provided to the verifier or CARB to confirm that it is "unprocessed UCO."

~~(153)~~"Validation" means verification of a fuel pathway application.

~~(154)~~"Validation Statement" means the final statement rendered by a verification body attesting whether the fuel pathway application is free of material misstatement, and whether it conforms to the requirements of this subarticle.

~~(155)~~"Verification" means a systematic, independent and documented process for evaluation of reported data against the requirements specified in this subarticle.

~~(156)~~"Verification Body" means an entity accredited by the Executive Officer that is able to render a validation or verification statement and provide validation or verification services to entities required to contract for validation or verification.

~~(157)~~"Verification Services" means services provided during validation or verification as specified in section 95501 beginning with the development of the validation or verification plan to submitting a validation or verification statement to CARB.

~~(158)~~"Verification Statement" means the final statement rendered by a verification body attesting whether the responsible entity's report is free of material misstatement, when applicable, and whether the report conforms to the requirements of this subarticle.

~~(159)~~"Verification Team" means all persons working for a verification body, including all subcontractors, to provide validation or verification services to an entity required to contract for validation or verification.

~~(160)~~"Verifier Review" means all reviews and services specified in section 95501 that a verifier conducts, except the material misstatement assessment under section 95501(b)(9) through (11). If some data sources are selected for data checks based on the sampling plan, the verifier will check for conformance with the requirements of this subarticle.

"Wastewater Sludge" is a residual, semi-solid byproduct generated from wastewater treatment processes that can serve as a feedstock for biogas production.

~~(161)~~"Yard Truck" An off-road mobile utility vehicle used to carry cargo containers with or without chassis; also known as utility tractor rig (UTR), yard tractor, yard goat, yard hostler, yard hustler, or prime mover. For the purpose of LCFS crediting an electric yard truck is considered a heavy-duty truck.

~~(162)~~"Yellow Grease" means a commodity produced from a mixture of: (A) used cooking oil, and (B) rendered animal fats that were not used for cooking. This mixture often is combined from multiple points of origin. Yellow grease must be characterized as "animal fat" if evidence is not provided to the verifier or CARB to confirm the quantity that is animal fat and the quantity that is used cooking oil.

(b) *Acronyms.* For the purposes of sections 95480 through 95503, the following acronyms apply.

"AEZ-EF" means Agro-Ecological Zone Emissions Factor model.

"AJF" means Alternative Jet Fuel.

"ASTM" means ASTM International (formerly American Society for Testing and Materials).

"AFP" means Alternative Fuel Portal.

"BEV" means battery electric vehicles.

"CA-GREET" means California-modified Greenhouse Gases, Regulated Emissions, and Energy use in Transportation model.

"CARB" means the California Air Resources Board ("Board").

"CARBOB" means California reformulated gasoline blendstock for oxygenate blending.

"CaRFG" means California reformulated gasoline.

"CCM" means Credit Clearance Market.

"CEC" means California Energy Commission.

"CFR" means Code of Federal Regulations.

"CHAdeMO" means Charge de Move, a DC fast charging protocol.

"CI" means carbon intensity.

"CNG" means compressed natural gas.

"DC" means Direct Current.

"DCO" means Distiller's Corn Oil or Technical Corn Oil.

"DSO" means Distiller's Sorghum Oil or Technical Sorghum Oil.

"eCHE" means Electric Cargo Handling Equipment.

“EDU” means Electrical Distribution Utility.

“EER” means energy economy ratio.

“eTRU” means electric transport refrigeration unit.

“eOGV” means Electric Power for Ocean-going Vessel.

“EV” means electric vehicle.

“FCV” means fuel cell vehicle.

“FPC” means fuel pathway code.

“FSE” means fueling supply equipment.

“gCO_2e/MJ” means grams of carbon dioxide equivalent per megajoule.

“GTAP” means the Global Trade Analysis Project model.

“GTSR” means the Green Tariff Shared Renewables program.

“GVWR” means gross vehicle weight rating.

“HySCapE” means Hydrogen Station Capacity Evaluator.

“H_2” means hydrogen.

“HDV” means heavy-duty vehicles.

“HDV-CIE” means a heavy-duty vehicle compression-ignition engine.

“HDV-SIE” means a heavy-duty vehicle spark-ignition engine.

“HEV” means hybrid electric vehicle.

“ICEV” means internal combustion engine vehicle.

“LUC” means land use change.

“LCA” means life cycle analysis.

“LCFS” means Low Carbon Fuel Standard.

“LDV” means light-duty vehicles.

“L-CNG” means liquefied compressed natural gas.

“LNG” means liquefied natural gas.

“LPG” means liquefied petroleum gas.

“LRT-CBTS” means LCFS Reporting Tool and Credit Bank & Transfer System.

“LSE” means Load-Serving Entity.

~~“LVP” means LCFS Verification Portal.~~

"MCON" means marketable crude oil name.

"MDV" means medium-duty vehicles.

"MMBtu" means million British Thermal Units.

"MRR" means Mandatory Greenhouse Gas Reporting Regulation.

"MT" means metric tons of carbon dioxide equivalent.

"NG" means natural gas.

"NGV" means a natural gas vehicle.

"OPGEE" means Oil Production Greenhouse gas Emissions Estimator Model.

"PHEV" means plug-in hybrid vehicles.

"RFS" means the Renewable Fuel Standard.

"RNG" means renewable natural gas or biomethane.

"SAE CCS" means Society of Automotive Engineers Combined Charging System, a DC fast charging protocol.

"SMR" means steam methane reformation.

"SOSS" means Station Operational Status System.

"UCO" means used cooking oil.

"TEOR" means thermally enhanced oil recovery.

"ULSD" means California ultra-low sulfur diesel.

"U.S. EPA" means the United States Environmental Protection Agency.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95482. Fuels Subject to Regulation.

(a) *Applicability of the Low Carbon Fuel Standard.* Except as provided in this section, the California Low Carbon Fuel Standard regulation, California Code of Regulations (CCR), title 17, sections 95480 through 95503 (collectively referred to as the "LCFS") applies to any transportation fuel, as defined in section 95481, that is sold, supplied, or offered for sale in California, and to any person who, as a fuel reporting entity defined in section 95481 and specified in section 95483, is responsible for reporting a transportation fuel in a calendar year. The types of transportation fuels to which the LCFS applies include:

(1) California reformulated gasoline ("gasoline" or "CaRFG");

(2) California diesel fuel ("diesel fuel" or "ULSD");

(3) Fossil compressed natural gas ("Fossil CNG"), fossil liquefied natural gas ("Fossil LNG"), or fossil liquefied compressed natural gas ("Fossil L-CNG);

(4) Bio-CNG, bio-LNG, or bio-L-CNG;

(5) Electricity;

(6) Compressed or liquefied hydrogen ("hydrogen");

(7) A fuel blend containing greater than 10 percent ethanol by volume;

(8) A fuel blend containing biomass-based diesel;

(9) Denatured fuel ethanol ("E100");

(10) Neat biomass-based diesel ("B100" or "R100");

(11) Fossil Jet Fuel;

~~(11)~~(12) Alternative Jet Fuel;

~~(12)~~(13) Propane; and

~~(13)~~(14) Any other liquid or non-liquid fuel.

(b) *Opt-In Fuels.* Each of the following alternative fuels ("opt-in fuels") is presumed to have a full fuel cycle, carbon intensity that meets the compliance schedules set forth in sections 95484(b) through (d) through December 31, 2030. A fuel provider for an alternative fuel listed below may generate LCFS credits for that fuel only by electing to opt into the LCFS as an opt-in fuel reporting entity pursuant to section 95483.1 and meeting the requirements of this regulation:

(1) Electricity;

(2) Bio-CNG;

(3) Bio-LNG;

(4) Bio-L-CNG;

(5) Alternative Jet Fuel; and

(6) Renewable Propane.

(c) *Exemption for Specific Fuels.* The LCFS regulation does not apply to:

(1) An alternative fuel that:

(A) is not a biomass-based fuel; and

(B) is supplied in California by all providers of that particular fuel for transportation use at an aggregated quantity of less than 420-million MJ (3.6 million gasoline gallon equivalent) per year;

A fuel reporting entity that believes it is subject to this exemption has the sole burden of proving to the Executive Officer's satisfaction that the exemption applies to the entity.

(2) ~~Conventional jet fuel~~Fossil jet fuel produced or imported before 2028 or used for interstate or international flights, or aviation gasoline.

(3) Any deficit-generating fuel used in military tactical vehicles and tactical support equipment as defined in title 13, CCR, section 1905(a) and CCR, title 17, section 93116.2(a)(38), respectively.

(4) Any credit-generating fossil CNG or fossil propane dispensed at a fueling station with total throughput of 150,000 gasoline-gallons equivalent or less per year. The exemption for fossil propane dispensing stations expires January 1, 2021, when the use of that fuel in heavy-duty or off-road applications becomes deficit generating. The exemption for fossil CNG dispensing stations expires January 1, 2024, when the use of that fuel in heavy-duty or off-road applications becomes deficit generating.

(d) *Exemption for Specific Applications.* The LCFS regulation does not apply to any transportation fuel used in the following applications:

(1) Locomotives not subject to the requirements specified in CCR, title 17, section 93117; and

(2) Ocean-going vessels, as defined in CCR, title 17, section 93118.5(d). This exemption does not apply to shore power provided to ocean-going vessels at-berth, nor to recreational and commercial harbor craft, as defined in CCR, title 17, section 93118.5(d); and

(3) Any deficit-generating fossil propane and CNG used in school buses purchased prior to January 1, 2020.

(e) Nothing in this LCFS regulation (Cal. Code Regs., tit. 17, §§ 95480 et seq.) may be construed to amend, repeal, modify, or change in any way the California reformulated gasoline regulations (CaRFG, Cal.Code Regs., tit. 13, §§ 2260 et seq.), the California diesel fuel regulations (Cal.Code Regs., tit. 13, §§ 2281-2285 and Cal. Code Regs., tit. 17, § 93114), or any other applicable State or federal requirements. A person, including the regulated entity as that term is defined in the LCFS regulation, who is subject to the LCFS regulation or other State and federal regulations, shall be solely responsible for ensuring compliance with all applicable LCFS requirements and other State and federal requirements, including the CaRFG requirements and obtaining any necessary approvals, exemptions, or orders from either the State or federal government.

(f) Transportation fuel derived from palm oil or palm derivatives is ineligible for LCFS credit generation. Any volumes of transportation fuel derived from palm oil or palm derivatives reported through the LCFS program must be assigned the ULSD carbon intensity found in Table 7-1 of the LCFS regulation.

(g) For projects that break ground after December 31, 2029, pathways for bio-CNG, bio-LNG, and bio-L-CNG used in CNG vehicles are ineligible for LCFS credit generation after December 31, 2040. Any volumes of bio-CNG, bio-LNG, and bio-L-CNG used in CNG vehicles reported through the LCFS program after December 31, 2040 must be assigned the ULSD carbon intensity found in Table 7-1 of the LCFS regulation.

NOTE: Authority cited: Sections 38510, 38560, 38560.5, 38571, 38580, 39600, 39601 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95483. Fuel Reporting Entities.

The purpose of this section is to identify the first fuel reporting entities, subsequent fuel reporting entities, and the credit or deficit generator for each type of transportation fuel. The first fuel reporting entity is responsible for initiating reporting within the LRT-CBTS for a given amount of fuel and, by default, also holds the status as initial credit or deficit generator for the reported fuel quantity. The fuel reporting entities identified in this section are subject to the reporting requirements pursuant to section 95491 and to any other requirement applicable to a fuel reporting entity and credit or deficit generator under this subarticle.

(a) *For Liquid Fuels.* Liquid fuels in this subsection refer to fossil fuels (including CARBOB, gasoline, diesel, and ~~conventional~~fossil jet fuel), liquid alternative fuels (including ethanol as an oxygenate, biomass-based diesel, and alternative jet fuels), and blend of liquid alternative and fossil fuels.

(1) *Designation of First Fuel Reporting Entities for Liquid Fuels.* The first fuel reporting entity for liquid fuels is the producer or importer of the liquid fuel. For liquid fuels that are a blend of liquid alternative fuel components (including ethanol as an oxygenate, biomass-based diesel, or alternative jet fuels) and a fossil fuel component (including CARBOB, gasoline, diesel, ~~conventional~~fossil jet, or other fossil fuels), the first fuel reporting entity is the following:

(A) With respect to the alternative fuel component, the producer or importer of the alternative fuel component.

(B) With respect to the fossil fuel component, the producer or importer of the fossil fuel component.

(C) *Specifics for Alternative Jet Fuel.* For an alternative jet fuel or the alternative fuel portion of a blend with ~~conventional~~fossil jet fuel, the first fuel reporting entity is the producer or importer of the alternative jet fuel, which is delivered to a storage facility where fuel is stored before it is uploaded to an aircraft in California. ~~Conventional~~Fossil jet fuel produced or imported before 2028, including the ~~conventional~~fossil jet fuel portion of a blend, is not subject to the LCFS and must not be reported.

(2) *In the Case of Transfer of Fuel Ownership.* An entity transferring ownership of fuel is the “transferor” and an entity acquiring ownership of fuel is the “recipient.”

(A) *Transferring Status as Credit or Deficit Generator.* An entity can voluntarily transfer its status as a credit or deficit generator for a given amount of liquid fuel, with the ownership of the fuel, if the conditions set forth in subsections 1. through 4. below are met by the time ownership of fuel is transferred. If such a transfer occurs, the recipient also becomes the fuel reporting entity for the fuel while the transferor is still subject to reporting requirements pursuant to section 95491 and to any other requirement applicable to a fuel reporting entity under this subarticle.

1. The two entities agree by written contract that the recipient accepts all LCFS responsibilities of a fuel reporting entity and credit or deficit generator.

2. The transferor must provide the recipient a product transfer document that prominently states the information specified in section 95491.1(b)(1).

3. In the case of a deficit generating fuel, the transferor and recipient must meet the requirements specified in the subsection below:

a. By default, the ~~transferor's~~recipient's annual credit and deficit balance, as set forth in section 95485(b)(2), will be updated to include the $Deficits^{XD}_{Incremental20XX}$ as defined and set forth in section 95489(b).

b. By default, the recipient's annual credit and deficit balance, as set forth in section 95485(b)(2), will be updated to include $Deficits_{Base}^{XD}$, as defined and set forth in section 95489(b).

c. Paragraphs a. and b. above notwithstanding, the transferor and recipient of deficit generating fuels may, by the time the ownership is transferred, specify by written contract which party is responsible for accounting for the base deficit and incremental deficit in the annual credits and deficits balance calculation set forth in section 95485(b)(2).

4. The credit or deficit generator status cannot be passed to a downstream entity acquiring ownership of liquid fuel below the rack.

5. An entity acquiring ownership of fuel below the rack is not required to report the fuel transaction in the LRT-CBTS unless it is a fuel exporter pursuant to section 95483(a)(4)(C).

(B) *Retaining Status as Credit or Deficit Generator.* An entity can retain its status as a credit or deficit generator for a given amount of liquid fuel, while transferring the ownership of the fuel, if the conditions set forth in subsections 1. through 2. below are met by the time ownership of fuel is transferred. If such a transfer occurs, the recipient also becomes a fuel reporting entity for the fuel while the transferor is still subject to reporting requirements pursuant to section 95491 and to any other requirement applicable to a fuel reporting entity under this subarticle.

1. The two entities agree by written contract that the recipient accepts all LCFS responsibilities of a fuel reporting entity and the transferor retains the responsibilities as a fuel reporting entity and credit or deficit generator.

2. The transferor must provide the recipient a product transfer document that prominently states the information specified in section 95491.1(b)(2).

3. An entity acquiring ownership of fuel below the rack is not required to report the fuel transaction in the LRT-CBTS unless it is a fuel exporter pursuant to section 95483(a)(4)(C).

(3) *Transfer Period.* For all liquid fuels, the period in which credit or deficit generator status can be transferred to another entity, for a given amount of fuel, is limited to three calendar quarters. This means that, for example, if an entity receives title to a fuel along with credit or deficit generator status in the first calendar quarter, the status as credit or deficit generator for that amount of fuel can be transferred to another entity no later than the end of the third calendar quarter. After this period is over, the credit and deficit generator status for that amount of fuel cannot be transferred.

(4) *Designation of Fuel Exporter.* Entities responsible for reporting exports of fuel that has been previously reported in the LRT-CBTS are identified below:

(A) When the fuel is sold or delivered above the rack for export, the entity holding title to the fuel as it crosses the California border on its way toward the first point of sale/delivery is responsible for reporting the export in the LRT-CBTS.

(B) When the fuel is sold across the rack for export, the entity holding title to the fuel as the fuel crosses the rack is responsible for reporting the export in the LRT-CBTS.

(C) When the fuel is diverted out-of-state below the rack, the entity holding title to the fuel, as it crosses the California border, is responsible for reporting the export in the LRT-CBTS.

(b) *For Gaseous Fuels.* Gaseous fuels refer to natural gas fuels (including CNG, LNG and L-CNG), propane and hydrogen.

(1) *Designation of First Fuel Reporting Entities For Gaseous Fuels.* The first fuel reporting entity for different gaseous fuels is identified in subsections (A) through (E) below. For gaseous fuels, subsection (2) below provides entities the ability to contractually designate another entity as the first fuel reporting entity for a given amount of gaseous fuel.

(A) *Bio-CNG.* For bio-CNG, including the bio-CNG portion of a blend with fossil CNG, the first fuel reporting entity is the producer or importer of the biomethane.

(B) *Bio-LNG and Bio-L-CNG.* For bio-LNG and bio-L-CNG, including the biomethane portion of any blend with fossil LNG and L-CNG, the first fuel reporting entity is the producer or importer of the biomethane.

(C) *Renewable Propane.* For renewable propane, including the renewable propane portion of a blend with fossil propane, the first fuel reporting entity is the producer or importer of the renewable propane.

(D) *Fossil CNG, LNG, and L-CNG and Propane.* For fossil CNG, LNG, L-CNG, and propane, including the fossil portion of any blend with a renewable fuel component, the first fuel reporting entity is the entity that owns the fueling equipment through which the fossil fuel is dispensed to motor vehicles for transportation use.

(E) *Hydrogen.* The first fuel reporting entity for hydrogen is the entity that owns the fueling supply equipment ("hydrogen station owner") through which hydrogen fuel is dispensed to motor vehicles for transportation use. Notwithstanding the above, the first fuel reporting entity for hydrogen used in fuel cell forklifts is the forklift fleet owner.

(2) Subsections (1)(A) through (1)(E) above notwithstanding, an entity may elect not to be the first fuel reporting entity for a given gaseous fuel, provided another entity has contractually agreed to be the first fuel reporting entity for the fuel on its behalf. In such cases the two entities must agree by written contract that:

(A) The original first fuel reporting entity per subsections (1)(A) through (1)(E) above will not generate credits or deficits in the LCFS and will instead provide the amount of fuel dispensed, and other required information pursuant to sections 95483.2(b)(8), 95491 and 95491.1, to the contractually designated entity for the purpose of LCFS reporting and credit or deficit generation.

(B) The contractually designated entity accepts all LCFS responsibilities as the first fuel reporting entity and as a credit or deficit generator, as applicable.

(c) *For Electricity Used as a Transportation Fuel.*

(1) *Residential EV Charging.* For on-road transportation fuel supplied for electric vehicle (EV) charging in a single-family residence, or at dedicated or reserved parking at a multi-family residence, the following entities are the credit generators:

(A) *Base Credits.* The EDU or its designee is the credit generator for base credits for the portion of residential EV charging assigned to that EDU by the Executive Officer. The EDU may authorize a third party to sell the EDU's credits. The EDU or its designee must meet the requirements set forth in paragraphs 1. through ~~6. below~~5. Below, and ~~paragraphs 1. through 5. in section~~ 95491(~~d)(3)(A~~e)(5).

Within 30 days of the effective date of this subarticle for large and medium IOUs and POUs, or ~~by December 31, 2022 for small IOUs and POUs, or~~ within 30 days of opting into the LCFS program, whichever is later, each large or medium EDU seeking eligibility to generate base credits must demonstrate, by attestation or entrance into any applicable Clean Fuel Reward program (as defined in section 95481(a~~)(29~~)) governance agreement, its ability to contribute allocated credits to the Clean Fuel Reward program consistent with CPUC approval of Pacific Gas and Electric's, Southern California Edison's, and San Diego Gas and Electric's filing(s). The Executive Officer may revoke the eligibility of an EDU to generate base credits if it fails to make this required demonstration or if the EDU withdraws or has been removed as a party to the governance agreement. All base credits for any EDU that is not eligible to receive base credits pursuant to this provision will be allocated to the Clean Fuel Reward program pursuant to section 95486.1(c)(1)(A) paragraph 2. An EDU must submit any request to change their base credit generation eligibility status for the Clean Fuel Reward program to the Executive Officer by the September 30~~th~~ prior to the start of the effective credit generation year.

1. EDUs seeking eligibility to generate base credits must provide rate options that encourage off-peak charging and minimize adverse impacts to the electrical grid;

~~1.~~2. Upon California Public Utilities Commission (CPUC) approval of Pacific Gas and Electric's, Southern California Edison's, and San Diego Gas and Electric's filing(s) to initiate a Clean Fuel Reward program, all opt-in EDUs must contribute a minimum percent of base credits for residential EV charging (or net base credit proceeds) to provide a Clean Fuel Reward funded exclusively by LCFS credit proceeds, as per the contribution tabulated below:

EDU category	***~~% Contribution in years 2019 through 2022~~***	***% contribution~~ in years 2023 and subsequent years~~***
Large Investor-owned Utilities	~~67~~50%	~~67%~~
Large Publicly-owned and Medium Investor-owned Utilities	~~35~~25%	~~45%~~
Medium Publicly-owned Utilities~~ and Medium Investor-owned Utilities~~	~~20~~10%	~~25%~~
Small Publicly-owned Utilities and Small Investor-owned Utilities	0%	~~2%~~

Deleted Cells

Deleted Cells

The Executive Officer will review the implementation of any Clean Fuel Reward program, including the actual credit value contribution of each utility to the program, and present a report to the Board by January 1, 202~~5~~7 with recommendations for further increasing utility contributions to the Clean Fuel Reward program.

~~2. The reward amounts for any Clean Fuel Reward program must be calculated based on the vehicle's battery capacity as tabulated below:~~

~~***Battery Capacity (kWh)***~~	~~***Reward %***~~
~~$C < 5$~~	~~0%~~
~~$C = 5$~~	~~38.9%~~
~~$5 < C < 16$~~	~~$\left(38.9 + \frac{(C-5)}{11} \times 61.1\right)\%$~~
~~$C \geq 16$~~	~~100%~~

~~where:~~

~~$Reward\ \%$ means the percentage of maximum reward a vehicle would receive under the Clean Fuel Reward program funded by LCFS credit proceeds. The maximum reward is the amount a vehicle with a battery capacity of 16 kWh or greater can receive; and~~

~~C means the rated battery capacity of the electric vehicle in kWh.~~

3. All proceeds from base credits issued pursuant to section 95486.1(c)(1)(A) paragraph 2. As well as any previously allocated funds for the Clean Fuel Reward by all large and medium EDUs must be contributed to ~~any~~the Clean Fuel Reward program.

4. Administrative costs, excluding start-up costs (those costs associated with setting up the program and incurred prior to issuing rewards), to support any Clean Fuel Reward program funded by LCFS credit proceeds may not exceed ~~10~~5 percent of LCFS credit proceeds contributed to the Clean Fuel Reward program annually, unless approved in advance by the Executive Officer.

   a. A request to exceed ~~10~~5 percent administrative costs must be submitted by the administrator of the Clean

Fuel Reward program to the Executive Officer ~~on~~by September 30 of the ~~following schedule:~~prior year.

~~i. For the first six calendar months of the program including the month in which the first issuance of reward takes place, a request must be submitted at least 30 days prior to the first reward issuance.~~

~~ii. For the period starting with the seventh calendar month of the program through December 31, 2021, the request must be submitted at least 30 days prior to the beginning of month seven.~~

~~iii. For calendar year 2022 and subsequent calendar years, the request must be submitted by September 30th of the prior year.~~

b. Request submitted to the Executive Officer must include, and will be evaluated for approval based on, a complete description for why higher administrative costs are necessary, a detailed list of expected administrative costs including a description of all efforts made to obtain competitive rates and minimize costs, and a detailed estimate of expected program proceeds. Within 30 days of receiving a request for higher administrative costs, the Executive Officer will inform the administrator of its decision in writing. If the request is rejected, the Executive Officer will provide a rationale for the decision. If the rejection is due to insufficient information, the administrator may resubmit the request after addressing the deficiencies identified in the Executive Officer decision.

~~5. *Reporting on Clean Fuel Reward Program Implementation.* By April 30th the administrator of the Clean Fuel Reward program funded by LCFS credit proceeds shall submit a report to the Executive Officer describing the disposition of LCFS Clean Fuel Reward program funds from the previous calendar year. The first such report covering a period from the start of the program until the end of 2020 must be submitted by April 30, 2021. This report must include:~~

~~a. The monetary value of LCFS credit proceeds received by the Clean Fuel Reward program; and~~

b. ~~A summary, detailed list, and explanation of administrative costs, including start-up costs, utility overhead costs, and costs for program-related marketing, education, and outreach activities.~~

~~6.~~5. *Restrictions on Use of Holdback Credits.* Documentation of adherence to the following restrictions must be included in the annual report submitted pursuant to section 95491(~~d)(3~~e)(5)(A~~)5.~~).

a. *Holdback Credit Equity Projects.* Effective January 1, 202~~2~~5, at least ~~30~~75 percent ~~in year one, 40 percent in year two, and 50 percent in subsequent years~~ of holdback credit proceeds must be used to support transportation electrification for the primary benefit of or primarily serving disadvantaged communities and/or low-income communities and/or rural areas or low-income individuals eligible under California Alternative Rates for Energy (CARE) or Family Electric Rate Assistance Program (FERA) or the definition of low-income in Health and Safety code section 50093 or the definition of low-income established by a ~~POU's governing body.~~ POU's governing body or a community in which at least 75 percent of public school students in the project area are eligible to receive free or reduced-price meals under the National School Lunch Program, or a community located on lands belonging to a state and federally recognizes California Indian tribe. These projects may include:

~~i. Electrification and battery swap programs for school or transit buses.~~

~~ii.~~i. Electrification of drayage trucks as well as other medium-, heavy-duty, or off-road vehicles including school and transit buses.

~~iii.~~ii. Investment in public EV charging infrastructure and EV charging infrastructure in multi-family residences.

~~iv.~~iii. Investment in electric mobility solutions, such as EV sharing and ride hailing programs.

~~v. Multilingual marketing, education, and outreach designed to increase awareness and adoption~~

~~of EVs and clean mobility options and including information about: the environmental, economic, and health benefits of EV transportation; basic maintenance and charging of EVs; electric rates designed to encourage EV use; and local, state, and federal incentives available for purchase of EVs.~~

~~vi.~~iv. Additional rebates and incentives for low-income individuals beyond existing local, federal and State rebates and incentives ~~including the Clean Fuel Reward~~ for: purchasing or leasing new or previously owned EVs; installing EV charging infrastructure in residences; ~~promoting use of public transit and other clean mobility solutions;~~ and offsetting costs for residential or nonresidential EV charging.

v. Promoting use and additional incentives for use of public transit and other clean mobility solutions, via charging equipment or infrastructure for the following categories:

I. EV sharing and ride hailing programs,

II. Electrification of public transit and school buses, including battery swap programs, and

III. Use or ownership of neighborhood electric vehicles, eBikes, eScooters, eMotorcycles, and other micromobility solutions.

vi. Re-skilling and workforce development for transportation electrification and electric vehicle infrastructure applications, developed in coordination with the California Workforce Development Board or local workforce development agencies.

vii. Investments in grid-side distribution infrastructure necessary for medium- and heavy-duty EV charging.

viii. Transportation Electrification projects that are identified in, or consistent with, a Community Emission Reduction Plan created in response to AB 617.

~~vii.~~ix. Alternatively, EDUs, in coordination with local environmental justice advocates, local community-based organizations, and local municipalities, may develop and implement other projects that promote transportation electrification in disadvantaged and/or low-income communities and/or rural areas or for low-income individuals. These alternative projects are subject to approval by the Executive Officer. Applications submitted to the Executive Officer must include, and will be evaluated for approval based on, a complete description of the project, demonstration that the project promotes transportation electrification in disadvantaged and/or low-income communities and/or rural areas or provides increased access to electric transportation for low-income individuals, and evidence that the project was developed in coordination with local environmental justice advocates, local community-based organizations, and local municipalities.

~~b. *Additional Reporting Requirements for Holdback Credit Equity Projects.* As part of annual reporting required pursuant to section 95491(d)(3)(A)5., EDUs must include a discussion on how their portfolio of holdback credit equity projects is consistent with the findings and recommendations of the SB 350 Low-Income Barriers Study, Part B report prepared by CARB (rev. Feb. 2018), incorporated herein. This discussion must include, as applicable, a description of how the projects: support increased access to clean transportation and mobility options; consider, and to the extent feasible, either complement or build upon existing CARB, other State, or local incentive projects to diversify and maximize benefits from statewide investments; demonstrate partnership and support from local community-based organizations;~~

~~and meet community-identified clean transportation needs.~~

b. *Other Holdback Projects.* Holdback projects that are not specified in subsection 95483(c)(1)(A)6.a. must follow the requirements specified in 95491(e)(5). Below are examples of pre-approved uses for these other holdback credit proceeds:

i. Investments in grid-side distribution infrastructure necessary for EV charging.

ii. Support for vehicle-grid integration with projects such as:

I. Encouraging the optimization of EV charging through education in the following areas: peak demand, rate pricing, grid emergencies, potential power shutoffs, infrastructure deferral, renewable integration, and/or other signals and grid needs to provide grid and customer benefits.

II. Providing program incentives to encourage driver participation in monitored/managed charging, demand response, or vehicle-to-load / vehicle-to-grid applications.

III. Supporting the deployment and installation of bidirectional charging equipment.

IV. Other innovative approaches to promoting and managing EV charging and discharging that provides benefits to customers and the grid.

iii. Hardware and software that decrease the cost of or avoid updates to infrastructure, including load management software or outlet splitting.

c. *Administrative Costs of Holdback Credit Equity Projects.* Administrative costs to support the development and implementation of holdback credit equity projects must not exceed ~~10~~5 percent of total spending on holdback credit equity projects annually unless the EDU contracts with a community-based organization, and the exceedance is approved in advance by the Executive Officer. The request for administrative cost exceedance for a calendar year must be submitted by September 30~~th~~ of the prior year. The request must include, and will be evaluated for approval based on, a complete description of the equity projects planned by the EDU, an estimate of total administrative costs relative to total spending on the projects, and evidence that the community-based organization is a non-profit organization focused on serving disadvantaged and/or low-income groups. Within 30 days of receiving a request for higher administrative costs, the Executive Officer will inform the EDU of its decision in writing. If the request is rejected the Executive Officer will provide a rationale for the decision. If the rejection is due to insufficient information, the EDU may resubmit the request after addressing the deficiencies identified in the Executive Officer decision.

d. Holdback credit proceeds must not be used for the following activities:

i. To meet compliance obligations under the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800), including the purchase of allowances, for electricity sold into the California Independent System Operator markets.

ii. To pay for the costs of MRR, the AB 32 Cost of Implementation Fee Regulation (California Code of Regulations, sections 95200-95207), or the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800), including the purchase of allowances.

iii. To pay for lobbying costs, employee bonuses, shareholder dividends, or costs, penalties, or activities mandated by any legal settlement, administrative enforcement action, or court order. This provision does not prohibit the use of holdback credits to pay costs, penalties, or liabilities associated with the Clean Fuel Reward program in the event that Clean Fuel Reward program funds are insufficient.

(B) *Incremental Credits.* Any entity, including an EDU, is eligible to generate incremental credits for improvements in carbon intensity of electricity used for residential EV charging. An entity that generates incremental credits must meet the requirements set forth in ~~paragraphs 2. through 7. in section 95491(d)(3)(A~~95491(e)(5), as applicable.

1. For metered residential EV charging, incremental credits for each FSE may be generated for one of the following:

   a. Low-CI electricity; or

   b. Smart charging. In the case of an entity claiming smart charging incremental credits, the credit generator must demonstrate the residence is enrolled in a Time-of-Use rate plan, if offered by the LSE serving the residence.

2. Multiple claims for incremental credits for metered residential EV charging associated with a single FSE ID will be resolved pursuant to the following order of preference:

   a. The Load Serving Entity (LSE) supplying electricity to the EV associated with the FSE ID and metered data has first priority to claim credits;

   b. The manufacturer of the EV associated with the FSE ID has second priority; and

   c. Any other entity has third priority.

3. For non-metered residential EV charging, the EDU is eligible to generate incremental credits for supplying low-CI electricity to the EVs in its service territory.

(C) *Advanced Credits.* Large POUs and Large IOUs that opt-in to the LCFS and are eligible to receive base credits per section 95483(c)(1)(A) are the credit generators for advanced credits.

(2) *Non-Residential EV Charging.*

(A) For electricity supplied for non-residential EV charging, including chargers at multi-family residences that are not limited to serving dedicated or reserved parking spaces, the owner of the FSE is eligible to generate the credits.

(B) Subsection (A) above notwithstanding, the owner of FSE may elect not to be the credit generator and instead designate another entity to be the credit generator if the two entities agree by written contract that:

1. The owner of FSE will not generate credits and will instead provide the electricity data to the designated entity for LCFS reporting pursuant to sections 95483.2(b)(8), 95491 and 95491.1.

2. The designated entity accepts all LCFS responsibilities as the fuel reporting entity and credit generator.

(C) An entity that generates credits for non-residential EV charging must meet the requirements set forth ~~in paragraphs 2. through 7. in~~ section 95491(~~d)(3)(A), as applicable.~~e)(5).

(3) *Fixed Guideway Systems.* For electricity supplied as transportation fuel to a fixed guideway system, the transit agency operating the system is the fuel reporting entity and the credit generator for electricity used to propel the system. Upon submittal to the Executive Officer of the transit agency's written acknowledgment that it will not opt in and generate credits under this provision, the EDU becomes eligible to generate the credits for the electricity, and must meet the requirements set forth in sections 95491(d)(3)(A), paragraphs 3. through 5.

~~(4) *Electric Forklifts.*~~

~~(A) For transportation fuel supplied to electric forklifts, the fleet owner is the fuel reporting entity and the credit generator for electricity supplied to a specified fleet.~~

~~(B) Subsection (A) above notwithstanding, the electric forklift fleet owner may elect not to be the credit generator and instead designate another entity to be the credit generator, if the two entities agree by written contract that:~~

~~1. The electric forklift fleet owner will not generate credits and will instead provide the electricity data to the designated entity for LCFS reporting pursuant to sections 95483.2(b)(8), 95491 and 95491.1.~~

2. ~~The designated entity accepts all LCFS responsibilities as the fuel reporting entity and credit generator.~~

3. ~~The EDU can generate credits for electricity supplied to electric forklift fleet in its service territory during a reporting period if not claimed by any other entity under paragraphs 1. and 2., above. The EDU must meet the requirements in section 95491(d)(3)(A), paragraphs 3. through 5.~~

~~(5)~~(4) *Electric Forklifts, Electric Transport Refrigeration Units (eTRU), Electric Cargo Handling Equipment (eCHE), Electric Power for Ocean-going Vessel (eOGV).*

(A) For electricity supplied to Electric Forklifts, eTRU, eCHE, or eOGV, the owner of the FSE is the fuel reporting entity and the credit generator.

(B) Subsection (A) above notwithstanding, the owner of the FSE may elect not to be the credit generator and instead designate another entity to be the credit generator if the two entities agree by written contract that:

1. The owner of the FSE will not generate credits and will instead provide the electricity data to the designated entity for LCFS reporting pursuant to sections 95483.2(b)(8), 95491 and 95491.1.

2. The designated entity accepts all LCFS responsibilities as the fuel reporting entity and credit generator.

(C) An entity that generates credits for Electric Forklifts, eTRU, eCHE, or eOGV must meet the requirements set forth in ~~paragraphs 2. through 7. in~~ section 95491(~~d)(3)(A), as applicable.~~e)(5).

~~(6)~~(5) *Other Electric Transportation Applications.* For electricity supplied to a transportation application not covered in subsection (1) through (5) above, any entity can apply to the Executive Officer to be the fuel reporting entity and the credit generator for electricity supplied as long as it meets the requirements of section 95488.7(a)(3) and 95491.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95483.1. Opt-In Entities.

(a) *Eligibility.* An entity that meets one or more of the following criteria may opt into the LCFS program, thereby becoming a credit generator.

(1) *Opt-in Fuel Reporting Entity.* An entity meeting any of the following criteria can opt into the LCFS program in a capacity of fuel reporting entity.

(A) A qualified fuel reporting entity who provides a fuel specified in section 95482(b) that meets the requirements of section 95483, wherever applicable;

(B) An out-of-state producer of oxygenate for blending with CARBOB or gasoline, or biomass-based diesel for blending with CARB diesel, who is not otherwise already subject to the LCFS regulation as an importer. An out-of-sate producer under this subsection may retain the ability to generate credits or deficits, for a specific quantity of fuel or blendstock, only if it opts in as a first fuel reporting entity and meets the requirements of section 95483, wherever applicable.

(C) An entity that is in the distribution/marketing chain of imported fuel and is positioned on that chain between the producer in subsection (B) above and the importer ("intermediate entity"). The intermediate entity is subject to the following requirements.

The intermediate entity must provide written documentation demonstrating all the following requirements to the Executive Officer's written satisfaction before opting into the LCFS:

1. The entity received ownership of the fuel for which the entity is claiming to generate LCFS credits;

2. Either:

a. The entity received the fuel reporting entity status from a producer that opted in under section 95483.1; or

b. The producer did not opt in under section 95483.1(a)(1).

3. The entity actually delivered the fuel or caused the fuel to be delivered to California for use in California;

The fuel delivered under subsection 3. is shown to have been sold for use in California or was otherwise actually used in California; and

4. The entity is not otherwise already subject to the LCFS regulation as a fuel reporting entity.

5. The demonstrations in paragraphs 1. through 4. above must be made for the specific quantity of fuel upon which the entity first elects to opt into the LCFS. For subsequent quantities of fuel for which the entity is claiming to be the fuel reporting entity pursuant to this subsection, the entity must retain documentation to support the demonstrations required in paragraphs 1. through 4., above, and must submit such documentation to the Executive Officer within 30 ~~calendar~~ days upon request.

(2) *Project Operators.* An entity that has a project approved for crediting or is applying for approval by the Executive Officer under section 95489 must apply to opt into the LCFS program as a credit generator.

(3) *Clearing Service Provider.*

(A) An entity providing clearing services in which it takes only a temporary possession of LCFS credits for the purpose of clearing transactions between two entities with registered accounts in LRT-CBTS, may apply to opt in as a clearing service provider if the following conditions are met:

1. The eligible entity must be a derivatives clearing organization as defined in the Commodities Exchange Act (7 U.S.C § 1a (9)) that is registered with the U.S. Commodity Futures Trading Commission pursuant to the Commodities Exchange Act (7 U.S.C. § 7a-1(a)).

2. The entity must register in the LRT-CBTS pursuant to section 95483.2(b).

3. The entity must be located in the United States, according to the registration information reported pursuant to section 95483.2(b).

(B) A clearing service provider cannot own credits but can hold LCFS credits up to five days for clearing purposes only.

(b) *Opting in Procedure.* The procedure for opting into and opting out of the LCFS for such a person is set forth as follows.

(1) Opting into the LCFS program becomes effective when the opt-in entity establishes an account in the LRT-CBTS, pursuant to section 95483.2. The opt-in entity may not report and generate credits and deficits based on transactions that precede the quarter in which the entity opted in.

(2) Establishing an account in the LRT-CBTS under subsection (b)(1) above means that the entity understands the requirements of the LCFS regulation and has agreed to be subject to all the requirements and provisions of the LCFS regulation.

(c) *Opting Out Procedure.* An opt-in entity may decide later to opt out of the LCFS program by following the following procedure:

(1) For opt-out to be effective, the opt-in entity must complete all actions specified below:

(A) Provide to the Executive Officer a 90-day notice of intent to opt out and a proposed effective opt-out date;

(B) Submit in the LRT-CBTS any outstanding quarterly fuel transactions or project reports up to the quarter in which the effective opt-out date falls and a final annual compliance report (covering the year through the opt-out date); and

(C) Identify in the 90-day notice any actions to be taken to eliminate any remaining deficits by the effective opt-out date.

(2) *Opt-Out Approval.* The Executive Officer shall notify the opt-in entity of the final "approval" status of the opt-out request. Any credits that remain in the opt-in entity's account at the time of the effective opt-out date shall be forfeited and the opt-in entity's account in the LRT-CBTS shall be closed.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601, 41510, 41511 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516, 41510, 41511 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95483.2. LCFS Data Management System.

The LCFS Data Management System refers to all the online systems responsible for LCFS data management and program implementation.

The LCFS Data Management System comprises ~~three~~two interactive and secured web-based systems: Alternative Fuel Portal~~,~~ and LCFS Reporting Tool and Credit Bank and Transfer System~~, and LCFS Verification Portal~~.

(a) *Alternative Fuel Portal (AFP).* The AFP supports fuel pathway applications, certifications, and verifications. It also handles the registration of fuel production facilities and opt-in projects~~.~~, except for the projects described in section 95489(c)-(f).

(1) *Eligibility.* Any person who intends to be a fuel pathway applicant or an opt-in project operator can request to establish an account in the AFP.

(2) *Requirements to Establish an Account in AFP.* To establish an account in the AFP, an entity must complete and submit the online AFP account registration form and provide the following:

(A) Organization name, address, state and country, Organization Federal Employer Identification Number (FEIN), company EPA ID, if available, facility location(s).

(B) A letter on company letterhead stating the basis for qualifying for an account pursuant to subsection (1) above. This letter must be signed by the company owner, a president, a managing partner, or a corporate officer. An electronic copy of the signed letter must be uploaded in the AFP.

(C) The registrant must designate a primary account representative and at least one alternate account representative. The primary account representative and the alternate account representative(s) must attest, as follows:

"I certify under penalty of perjury under the laws of the State of California as follows: I was selected as the primary account representative or the secondary account representative, as applicable, by an agreement that is binding on all persons who have the legal right to access the AFP account. I have all the necessary authority to carry out the duties and responsibilities contained in California Code of Regulations, title 17, sections 95480 et seq. on behalf of such persons and that each such person shall be fully bound by my representations, actions, inactions, or submissions and by any order or decision issued to me by the Executive Officer or a court regarding the account."

(D) For each representative, name, title, relationship to the organization, business phone, e-mail address, username, and password.

(E) The account representatives can be changed by following steps set forth in subsection (B), (C), and (D) above. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous account representatives prior to the time and date when the Executive Officer receives the superseding information shall be binding on the entity.

(3) *Account Approval.*

(A) The account is established when the Executive Officer approves the application.

(B) Account registration application may be denied based on false, misleading, or missing information.

(4) *Account Management Roles and Duties*.

(A) The account representative is responsible for making any changes to the company profile within AFP.

(B) The account representative may designate users within the company who can access and manage the account.

(C) If any information required by section 95483.2(a)(2) changes, the entity holding the account must update the account to reflect the changes within 30 ~~calendar~~ days.

(b) *LCFS Reporting Tool and Credit Bank & Transfer System (LRT-CBTS).* The LRT-CBTS is designed to support fuel transaction reporting, compliance demonstration, credit generation, banking, ~~and transfers.~~ transfers, and additional verification processes described in section 95483.2(c).

(1) *Eligibility*. The following entities can request to establish an account in the LRT-CBTS:

(A) A fuel reporting entity;

(B) An entity opting into LCFS, pursuant to section 95483 or 95483.1; or

(C) An LCFS credit broker.

(2) *Deadline to Establish LRT-CBTS Account*.

(A) An entity responsible for reporting any transportation fuels pursuant to section 95483 must complete registration at least 30 days prior to the date for filing any required report.

(B) An opt-in entity can register anytime during a calendar year. All quarterly and annual reporting is then required, beginning with the quarter in which registration was approved, and continuing until any opt-out is completed.

(C) Any broker must register in LRT-CBTS prior to facilitating any LCFS credit trades.

(3) *Requirements to Establish an Account in LRT-CBTS.* A company owner, a president, a managing partner, or a corporate officer with legal binding authority must complete and submit the online LRT-CBTS account registration form and provide the following:

(A) Organization name, address, state and country, Organization Federal Employer Identification Number (FEIN), date and place of incorporation.

(B) A letter on company letterhead stating the basis for qualifying for an account pursuant to subsection (1) above. This letter must be signed by the company owner, a president, a managing partner, or a corporate officer. A signed pdf copy must be uploaded in the LRT-CBTS to complete the application process.

(C) The online LRT-CBTS registration form must designate a primary account representative and at least one alternate account representative. The primary account representative and the alternate account representative(s) must attest in writing, as follows:

"I certify under penalty of perjury under the laws of the State of California as follows: I was selected as the primary account representative or the secondary account representative, as applicable, by an agreement that is binding on all persons who have the legal right to control LCFS credits held in the account. I have all the necessary authority to carry out the duties and responsibilities contained in California Code of Regulations, title 17, sections 95480 et seq. on behalf of such persons and that each such person shall be fully bound by my representations, actions, inactions, or submissions and by any order or decision issued to me by the Executive Officer or a court regarding the account."

(D) For each representative, name, title, relationship to the organization, business and mobile phone, e-mail address, username, and password.

(E) The account representatives can be changed by following steps set forth in subsections (B) through (D) above. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous account representatives prior to the time and date when the Executive Officer receives the superseding information shall be binding on the entity.

(F) A designated fuel reporting entity pursuant to section 95483(b) and (c) must also provide a written contractual agreement demonstrating it acquired the first fuel reporting entity status from another entity for each such entity.

(G) *Clearing Service Providers.* In addition to requirements specified in 95483.2(b)(3)(A) through (E), a clearing service provider requesting to establish an LRT-CBTS account must provide documents demonstrating their eligibility pursuant to section 95483.1(a)(3).

(4) *LCFS Credit Broker.* A broker may represent other LRT-CBTS account holders in LCFS credit transfers. To register a broker account, the broker must provide the following:

(A) Broker's organization name, address, state and country, Organization Federal Employer Identification Number (FEIN), date, and place of incorporation, if applicable.

(B) Broker's name, business and mobile phone, e-mail address, username, and password.

(C) Broker's statement attesting: “By submitting this broker registration application to the LCFS program for a broker account in the LRT-CBTS, I am submitting to the jurisdiction of the California courts. I certify under penalty of perjury that I have not been convicted of a felony in the last five years.”

(5) *Account Approval*.

(A) The account is established when the Executive Officer approves the application.

(B) Account registration application may be denied based on false, misleading or missing information.

(6) *Account Management Roles and Duties*.

(A) The account representative is responsible for making any changes to the company profile within LRT-CBTS.

(B) The account representative may designate users within the company who can access and manage the account.

(C) The account representative is responsible for meeting the reporting requirements as set forth in section 95491.

(D) If any information required by section 95483.2(b)(3) changes, the entity holding the account must update the account to reflect the changes within 30 ~~calendar~~ days.

(7) *Account Closure*.

(A) An LRT-CBTS account is subject to suspension or closure based on any of the following:

1. The account holder is no longer eligible to establish an LRT-CBTS account pursuant to section 95483.2(b)(1);

2. The account holder fails to comply with requirements of section 95483.2(b); and

3. The account holder intends to opt out pursuant to section 95483.1(c).

(B) The account holder must provide a notice of intent to the LRT-CBTS Administrator to close the account within 90 days after any condition in subsection (A) above. The entity must submit a final quarterly report for the quarter in which the notice was provided, submit a final annual report, and submit verification that any remaining deficits have been eliminated. The Executive Officer shall notify the entity of the final account closure. Any credits that remain in the entity's account at the time of the closure will be placed in the Buffer Account.

(C) Failure to provide notice pursuant to subsection (B) above will result in account closure and forfeit of any credits that remain in the entities account at the time of the closure.

(D) When an entity requests to reopen the LRT-CBTS account that was previously closed, the entity must follow the requirements as set forth in section 95483.2(b) to reopen the account.

(8) *Registration of Fueling Supply Equipment (FSE).* After establishing the LRT-CBTS account, fuel reporting entities for natural gas, electricity, propane, and hydrogen must register all fueling supply equipment in the LRT-CBTS using the FSE registration template available on the LRT-CBTS home page. The completed FSE registration template with supporting documents must be uploaded into the LRT-CBTS. Upon FSE registration, the applicant will receive a unique LCFS FSE ID that must be used for reporting fuel transactions in the LRT-CBTS pursuant to 95491. The following must be provided:

(A) *General Requirements.* All FSE registrations must include:

1. Federal Employer Identification Number (FEIN) for the entity registering, name of the facility at which FSE is situated, street address, latitude, and longitude of the FSE location.

2. Name and address of the entity that owns the FSE, if different from the entity registering the FSE.

(B) *Specific Requirements by Fuel Type.*

1. For CNG, FSE refers to a fueling station associated with a utility meter. A CNG station with multiple dispensers is considered a single FSE. Fuel reporting entities for CNG must provide the natural gas utility meter number at the FSE location, name of the utility company, and a copy of the most recent utility bill.

2. For LNG and propane, FSE refers to a fueling station. An LNG or propane station with multiple dispensers is considered a single FSE. Fuel reporting entities for LNG and propane must provide a unique identifier associated with the FSE used for their own fuel accounting or financial accounting or other purposes and copy of invoice or bill of lading for the most recent fuel delivery.

3. For non-residential EV charging, FSE refers to each piece of equipment capable of measuring the electricity dispensed for EV charging. Fuel reporting entities for non-residential EV charging for on-road applications must provide the serial number assigned to the FSE by the original equipment manufacturer (OEM) and the name of OEM. If there are multiple FSEs at the same location, each unique piece of equipment must be registered separately.

4. For residential metered EV charging, FSE refers to a piece of equipment or on-vehicle telematics capable of measuring the electricity dispensed for EV charging.

   a. Fuel reporting entities for metered residential EV charging using off-vehicle meters must provide the serial number assigned to the FSE by the OEM, the name of the equipment OEM, and the Vehicle Identification Number (VIN) for the vehicle expected to be charged at the location.

   b. Fuel reporting entities using vehicle telematics must provide the VIN.

   c. FSE registration is optional when reporting metered electricity to generate base credits.

d. Notwithstanding subsection (8)(A) above, location information and address is not required for residential charging.

5. Fuel reporting entities for fixed guideway systems are exempt from subsection (A)1. above. The LRT-CBTS will assign FSE IDs for reporting purposes based on the information provided in the LRT-CBTS account registration form.

6. For electric forklifts, eCHE, ~~or~~ eOGV, or eTRU, FSE refers to the facility or location where electricity is dispensed for fueling. If there are multiple FSEs capable of measuring the electricity dispensed at the facility or location, then it is optional to provide serial number assigned to each equipment by the OEM and the name of OEM.

~~7. For eTRU, FSE refers to each eTRU. Fuel reporting entities for eTRU fueling must provide the serial number assigned to the unit by the OEM and the name of the OEM.~~

~~8.~~7. For hydrogen, FSE refers to a fueling station. A hydrogen station with multiple dispensers is considered a single FSE. Fuel reporting entities for hydrogen must provide the station ID assigned by SOSS.

~~9.~~8. For transportation applications not covered in paragraphs 1. through 8. above, FSE refers to a fuel dispenser or a transportation equipment with the capability to measure the dispensed fuel in that equipment.

(c) ~~*LCFS Verification Portal (LVP).*~~*LRT-CBTS for verification.* The ~~LVP~~LRT-CBTS is ~~designed to support~~capable of supporting LCFS verification processes.

(1) *Eligibility.* Any entity providing verification services pursuant to section 95500 (Executive Officer accredited verification body) can request an account in ~~LVP~~LRT-CBTS.

(2) *Requirements to Establish an Account in ~~LVP~~LRT-CBTS.* A company owner, a president, a managing partner, a corporate officer, or any other person with binding legal authority must complete and submit the online ~~LVP~~LRT-CBTS account registration form and provide the following:

(A) Organization name, address, state and country, Organization Federal Employer Identification Number (FEIN), date and place of incorporation.

(B) The online ~~LVP~~LRT-CBTS registration form must designate a primary account representative and at least one alternate account representative.

The primary account representative and the alternate account representative(s) must attest in writing, as follows:

"I certify under penalty of perjury under the laws of the State of California as follows: I was selected as the primary account representative or the secondary account representative, as applicable, by an agreement that is binding on all persons who have the legal right to submit information on behalf of the verification body. I have all the necessary authority to carry out the duties and responsibilities contained in California Code of Regulations, title 17, sections 95480 et seq. on behalf of such persons and that each such person shall be fully bound by my representations, actions, inactions, or submissions and by any order or decision issued to me by the Executive Officer or a court regarding the account."

(C) For each representative, name, title, relationship to the organization, business and mobile phone, e-mail address, username, and password.

(D) The account representatives can be changed by following steps set forth in subsection (B) and (C) above. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous account representatives prior to the time and date when the Executive Officer receives the superseding information shall be binding on the entity.

(3) *Account Approval*.

(A) The account is established when the Executive Officer approves the application.

(B) Account registration application may be denied based on false, misleading or missing information.

(4) *Account Management Roles and Duties*.

(A) The account representative is responsible for making any changes to the company profile within ~~LVP~~LRT-CBTS.

(B) The account representative may designate users within the company who can access and manage the account.

(C) The account representative is responsible for meeting the requirements as set forth in section 95500 through 95502.

(D) If any information required by section 95483.2(c)(2) changes, the entity holding the account must update the account to reflect the changes within 30 ~~calendar~~ days.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95483.3. Change of Ownership or Operational Control.

If an entity or a facility registered in the LRT-CBTS~~, the AFP,~~ or the ~~LVP~~AFP undergoes a change of ownership or operational control, the following requirements apply.

(a) *CARB Notifications.* Within 30 days of the change of ownership or operational control, the previous owner or operator of the regulated entity or facility and the new owner or operator of the entity or facility must provide the following information to CARB:

(1) The previous owner or operator must notify CARB in writing of the ownership or operational control change, including the name of the new owner or operator and the date of the ownership or operational control change.

(2) The new owner or operator must notify CARB in writing of the ownership or operational control change, including the following information:

(A) Previous owner or operator;

(B) New owner or operator;

(C) Date of ownership or operator change;

(D) Name of new account representatives pursuant to section 95483.2 for the affected entity's account in the LRT-CBTS~~, AFP~~ or ~~LVP~~AFP.

(3) The first owner must give the Executive Officer direction regarding the disposition of net credits in the first owner's LRT-CBTS account and the certified fuel pathways associated with the first owner's AFP account.

(b) *Reporting Responsibilities.* The owner or operator of record at the time of a reporting or verification deadline specified in this subarticle has the responsibility for complying with the requirements of this subarticle, including submitting quarterly and annual reports, certifying that the reports are accurate and complete, obtaining verification services, and completing verification.

(1) Reported data must not be split or subdivided for a reporting period, based on ownership. A single reporting period data report must be submitted for the entity by the current owner or operator. This report must represent required data for the entire reporting period.

(2) Previous owners or operators are required to provide data and records to new owners or operators that is necessary and required for preparing quarterly and annual reports required by this article.

(c) *New Owner Responsible for Net Deficits.* The new owner, when filing the annual report, is responsible for demonstrating compliance pursuant to section 95485.

(d) *Bankruptcy.* Deficits constitute regulatory obligations under California law.

(e) *Fate of Credits After an Entity Dissolves.* The Executive Officer will place into the Buffer Account any net credits in the account of a party that dissolves or otherwise ceases to exist without notifying the Executive Officer pursuant to paragraph (3) of subdivision (a) of this section.

(f) *Fate of Deficits After an Entity Dissolves.* Prior to dissolution, a fuel reporting entity is responsible for retiring credits equal to any net deficits in its LRT-CBTS account and fulfill account closure requirements as set forth in section 95483.2(b)(7).

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95484. Annual Carbon Intensity Benchmarks.

(a) The Executive Officer's credit and deficit calculations, as described in Sections 95486 and 95486.1, will use the appropriate annual carbon intensity benchmarks set forth in Tables 1, 2, and 3 of this section.

(b) *Automatic Acceleration Mechanism.* Starting 2027, on May 15 of each year, the Executive Officer will announce on the LCFS website whether the Automatic Acceleration Mechanism has been triggered and the cumulative number of times that the Automatic Acceleration Mechanism has been triggered.

(1) The Automatic Acceleration Mechanism cannot be triggered in the calendar year that immediately follows an announcement that the Auto Acceleration Mechanism has been triggered.

(2) The Automatic Acceleration Mechanism is triggered when the conditions in both subparagraphs (A) and (B) below are met, and if it was not triggered in the immediately prior calendar year.

(A) The Credit Bank to Average Quarterly Deficit Ratio exceeds 3:

$$\frac{Credit\ Bank_{20xx}}{{}^{1}/_{4} \times Deficits_{20xx}} > 3$$

where:

$Credit\ Bank_{20xx}$ is the final credit bank for the program as calculated at the end of compliance year 20xx, the compliance year preceding the year for the current May 15 Automatic Acceleration Mechanism announcement; and

$Deficits_{20xx}$ is the total number of deficits generated under the program as calculated at the end of compliance year 20xx, the compliance year preceding the year for the current May 15 Automatic Acceleration Mechanism announcement.

(B) Credit Generation exceeds Deficit Generation:

$$\frac{Credits_{20xx}}{Deficits_{20xx}} > 1$$

where:

$Credits_{20xx}$ is the total number of credits generated under the program as calculated at the end of compliance year 20xx, the compliance year preceding the year for the current May 15 Automatic Acceleration Mechanism announcement; and
$Deficits_{20xx}$ is the total number of deficits generated under the program as calculated at the end of compliance year 20xx, the compliance year preceding the year for the current May 15 Automatic Acceleration Mechanism announcement.

(c) Updating the Benchmark Schedules. Starting January 1, 2028, the compliance year for which an average carbon intensity benchmark applies will also take into account the number of times the Automatic Acceleration Mechanism has been triggered pursuant to section 95484(b).

(1) An updated benchmark schedule will be posted to the LCFS website on May 15 for any year that the Executive Officer announces that the Automatic Acceleration Mechanism has been triggered.

(2) An updated benchmark schedule posted pursuant to 95484(c)(1) will override any prior benchmark schedules and will take effect January 1 of the calendar year after the Automatic Acceleration Mechanism was triggered.

~~(b)~~(d) *Benchmarks for Gasoline and Fuels used as a Substitute for Gasoline*. Starting in 2028 the defined average carbon intensity benchmarks for each future year will be advanced by one year each time the Automatic Acceleration Mechanism has been triggered pursuant to section 95484(b).

Table 1. LCFS Carbon Intensity Benchmarks for 2011 to 20~~30~~45 for Gasoline and Fuels Used as a Substitute for Gasoline.

20~~30~~45 and subsequent years	~~80.36~~10.57[δ]

[δ] These CI targets may be accelerated by the Automatic Acceleration Mechanism pursuant to section 95484(b).

* The benchmarks reflect reductions from base year (2010) CI values for ~~conventional~~fossil jet fuel (89.37).

** The benchmark for years 2025 through 2045 reflect reductions from revised base year (2010) CI Values for fossil jet fuel (89.43).

[a] The benchmark schedule in 2025 has been updated to include a 5% increase in stringency, achieving an 18.75% CI reduction compared to the 13.75% CI reduction specified in the 2018 adopted regulation.

~~(e)~~(g) *Carbon Intensity Benchmarks for an Alternative Fuel Other Than a Biomass-Based Diesel Fuel Intended for Use in a Vehicle.*

(1) The Executive Officer will use the benchmarks for gasoline set forth in section 95484(~~b~~d) for credit and deficit calculations for any alternative fuel, other than biomass-based diesel fuel, if the alternative fuel is used or intended to be used in any single-fuel light- or medium-duty vehicle.

(2) The Executive Officer will use the benchmarks for diesel fuel set forth in section 95484(~~c~~e) for credit and deficit calculations for any alternative fuel, other than biomass-based diesel fuel, that is used or intended to be used in any single-fuel application not identified in section 95484(e)(1).

~~(f)~~(h) *Carbon Intensity Benchmarks for Biomass-Based Diesel Fuel.* The benchmark for diesel fuel, set forth in section 95484(~~c~~e), applies to biomass-based diesel fuel is used or intended to be used in any:

(1) light-, medium-, or heavy-duty vehicle;

(2) off-road transportation application;

(3) off-road equipment application;

(4) locomotive or commercial harbor craft application; or

(5) non-stationary source application not otherwise specified in subsections (1) through (4) above.

~~(g)~~(i) *Carbon Intensity Benchmarks for Transportation Fuels Intended for Use in Multi-Fuel Vehicles*.

(1) The Executive Officer's credit and deficit calculations involving alternative fuel provided for use in a multi-fueled vehicle use:

(A) the benchmarks for gasoline set forth in section 95484(~~b~~d) if one of the fuels used in the multi-fuel vehicle is gasoline; or

(B) the benchmarks for diesel fuel set forth in section 95484(~~c~~e) if one of the fuels used in the multi-fuel vehicle is diesel fuel.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95485. Demonstrating Compliance.

(a) *Compliance Demonstration*.

(1) A fuel reporting entity must demonstrate that it met its annual compliance obligation by submitting an annual compliance report, showing that it possessed and has retired a number of credits from its credit account that is equal to its compliance obligation.

(2) *Mandatory Retirement of Credits for the Purpose of Compliance.* At the time of annual compliance report submission, for a fuel reporting entity that possesses credits and has also incurred deficits, the LRT-CBTS will retire a sufficient number of credits so that:

(A) Enough credits are retired to completely meet the fuel reporting entity's compliance obligation for that compliance period, or

(B) If the total number of credits available in entity's account is less than the total number of deficits incurred, all the credits within entity's possession will be retired.

(b) *Calculation of Credit Balance and Annual Compliance Obligation*.

(1) *Compliance Period.* Beginning in 2011 and every year thereafter, the annual compliance period is January ~~1st~~1 through December 31~~st~~ of each year.

(2) *Calculation of Compliance Obligation and Credit Balance at the End of a Compliance Period.* The Executive Officer will calculate each LRT-CBTS account holder's compliance obligation and credit balance at the end of a compliance period as follows:

$$ComplianceObligation = Deficits^{Generated} + Deficits^{CarriedOver}$$

$$\begin{aligned} CreditBalance \\ &= \left(Credits^{Generated}\right. \\ &+ Credits^{Acquired} + Credits^{Released} + \left.Credits^{CarriedOver}\right) \\ &- \left(Credits^{Retired} + Credits^{Sold} + Credits^{OnHold}\right. \\ &+ Credits^{CCMPledge} + \left.Credits^{Adjustments}\right) \end{aligned}$$

where:

$Deficits^{Generated}$ are the deficits generated pursuant to sections 95486 and 95489 in the current compliance period;

$Deficits^{CarriedOver}$ are the deficits carried over from the previous compliance period and not deferred pursuant to section 95485(c);

$Credits^{Generated}$ are the credits generated pursuant to sections 95486 and 95489 in the current compliance period;

$Credits^{Aquired}$ are the credits purchased or otherwise acquired in the current compliance period, including carryback credits acquired pursuant to section 95486;

$Credits^{Released}$ are the credits released from the hold due to enforcement or administrative action;

$Credits^{CarriedOver}$ are the credits carried over from the previous compliance period;

$Credits^{Retired}$ are the credits retired within the LCFS in the current compliance period;

$Credits^{Sold}$ are the credits sold or otherwise transferred in the current compliance period;

$Credits^{OnHold}$ are the credits placed on hold due to enforcement or administrative action. While on hold these credits cannot be used for meeting an annual compliance obligation;

$Credits^{CCMPledge}$ are the credits pledged for the Credit Clearance Market and withheld from the ongoing LCFS market; and

$Credits^{Adjustments}$ are the credits adjusted or invalidated due to administrative or enforcement action.

(c) *Credit Clearance Market*.

(1) If a fuel reporting entity does not retire sufficient credits to meet its year-end compliance obligation under section 95485(a), that party must purchase its pro-rata share of credits in the Credit Clearance Market, if one occurs.

(A) *If the Credit Clearance Market occurs*, a fuel reporting entity that fails to comply with section 95485(a) is nevertheless in compliance if the party:

1. Retires all credits in its LRT-CBTS account;

2. Acquires its Pro-Rata Obligation in the Credit Clearance Market and retires that number of credits by August 31~~st~~ of the year subsequent to the compliance year in question; and

3. Retires the remaining balance of its annual obligation, with interest, within five years.

(B) *If no Credit Clearance Market occurs*, the Executive Officer will record any entity's unmet compliance obligation, and the fuel reporting entity will be deemed in compliance for that year, provided that it has retired all credits in its account, and retires credits equivalent to the Accumulated Deficits, with interest as explained in section 95485(c)(5) below, within five years.

(2) *Acquisition of "Clearance Market" Credits to Meet an Annual Compliance Obligation*.

(A) *Clearance Market Period.* The Clearance Market, if one occurs, will operate from June ~~1st~~1 to August 30~~th~~. A fuel reporting entity subject to section 95485(c)(1) must acquire credits pledged into the Credit Clearance Market to be retired toward compliance in the previous compliance year. Credits acquired for this purpose are defined as "Clearance Market" credits.

(B) *Use of Clearance Market Credits.* A Clearance Market credit can only be used for the purpose of meeting the fuel reporting entity's compliance obligation from an immediate prior year.

(C) A regulated entity that participates in the Credit Clearance Market for two consecutive years must submit a Compliance Plan to CARB, by August 31~~st~~ of that second consecutive year, detailing its plan to obtain sufficient credits to meet future annual compliance obligations within a five-year period.

1. *Compliance Plan Requirements.* Submitted Compliance Plans must include the following:

a. A detailed list of specific business initiatives, strategies, and actions that, if implemented, will achieve a positive credit balance within a five-year timeframe;

b. Quantification of anticipated LCFS credit generation and acquisition, and discussion of uncertainties and contingencies associated with each listed initiative, strategy, or action;

c. Quantification of anticipated annual credit shortage and uncertainties over the following five compliance years;

d. A target timeline for implementing all outlined provisions in the plan;

e. Data and underlying calculations used to arrive at emission reduction quantification and timelines;

f. Reference to management policies or practices applicable to implementing listed plan initiatives, strategies, and actions;

g. List of key roles or positions within the company involved in executing and completing implementation of provisions of the plan;

h. Data records, including written contracts and associated verbal or electronic records, and invoices used to demonstrate actions underway consistent with the submitted plan;

i. Any other information related to or supporting demonstration of plan requirements necessary to allow CARB to develop a general understanding of the approaches being taken to implement the plan.

2. *Compliance Plan Approval.* The Executive Officer shall approve each submitted compliance plan if it meets the requirements of section 95485(c)(2)(C) paragraph 1. If the Executive Officer determines that the requirements for approval have not been met, the Executive Officer will notify the regulated entity of which specific requirements of section 95485(c)(2)(C) paragraph 1 have not been met. The regulated entity must then submit additional information to correct deficiencies identified by the Executive Officer. If the regulated entity is unable to correct any deficiencies found with their plan within 45 days of the Executive Officer's receipt of the original plan, the plan will be denied on that basis, and the regulated entity will be informed in writing. At any point during the evaluation process, the Executive Officer may request in writing additional information or clarification from the regulated entity.

3. *Compliance Plan Implementation Reporting.* In addition to other reports required to be submitted by this subarticle, entities required to submit compliance plans must submit annual compliance plan implementation reports that clearly demonstrate actions taken and progress made to comply with the approved plan. The regulated entity must disclose and explain any deviations from the submitted plan in their compliance plan implementation report and identify the actions that will be taken to correct these deviations.

a. Annual compliance plan implementation reports must be submitted by April 30~~th~~ each year for a five-year period starting the calendar year after the plan was approved.

b. If a regulated entity's annual credit shortage in any given year is greater than the annual credit shortage that was approved in the original compliance plan, implementation reports that identify deviations from the approved compliance plan will be made public on the CARB website.

(D) Entities required to acquire credits in the Credit Clearance Market must complete payment to the seller before the credit transfer is initiated, unless the buyer and seller agree on other payment terms. All credit transfers must be completed on or before the final date of the Clearance Market Period.

(3) *Procedure for Selling in the Clearance Market.*

(A) *Call for Credits.* On the first Monday in April, the Executive Officer shall issue to all fuel reporting entities and credit generators a call for credits to be pledged for sale in the Clearance Market. When calling for credits, the Executive Officer will inform fuel reporting entities of that year's Maximum Price for Credits as determined in section 95487(a)(2)(D).

(B) *Pledging Credits for Sale into the Clearance Market.* Fuel reporting entities and credit generators pledging credits for sale into the Clearance Market must report to the Executive Officer in the Annual Compliance Report (on or before April 30~~th~~) the number of credits they are pledging for sale.

(C) *Advanced Credits.* If, for any compliance year, insufficient credits are pledged for sale into the Credit Clearance Market to fully clear outstanding deficits, the Executive Officer shall issue credits equal to the difference between the number of outstanding deficits and the number of credits pledged for sale in the Credit Clearance Market subject to the following:

1. Advanced credits will be issued to eligible Large IOUs and Large POUs that opt into the LCFS and are eligible to receive base credits per section 95483(c)(1)(A). Advanced credits will be allocated to eligible utilities based on their prorata share of base credits received in the most recent issuance. Advanced credits must be pledged for sale in the current Credit Clearance Market and may only be sold at the

maximum LCFS price per section 95487(a)(2)(D). A minimum portion of proceeds generated from the sale of advanced credits must be allocated using the 2023 and onward contribution percentages found in section 95483(c)(1)(A) paragraph 1. to the Clean Fuel Reward program.

2. The first such issuance of advanced credits will mark the start of the six-year “advanced credit window,” during which advanced credits can be issued and after which base credit issuances will be adjusted to account for advanced credits.

3. *Cumulative Advanced Credits.* The cumulative number of advanced credits issued during the advanced credit window shall not exceed ~~10~~30 million.

4. *Adjusting Future Issuance of Base Credits.* After the six-year advanced credit window is closed, total base credits issued every year will be adjusted downwards to account for advanced credits as per the following schedule. Base credit adjustment for each EDU will be pro-rated based on their share of total advanced credits received. Annual adjustments will be spread equally across each quarter.

Year	***Percent of total advanced credits***
Year 7	5%
Year 8	10%
Year 9	20%
Year 10	30%
Year 11	35%

where:

Year *n* refers to the n^{th} year from the first year the advanced credits were issued. For example, if the first advanced credits are issued in 2021, marking year 1, then the first year that base credit issuance will be adjusted would be 2027.

(D) *Calculation of the Maximum Price for Credits in the Clearance Market.* The maximum price for credits acquired, purchased or transferred via the Credit Clearance Market shall be set pursuant to section 95487(a)(2)(D).

(E) *Eligibility to Sell.* Only fuel reporting entities that demonstrated compliance pursuant to section 95485(a) for the prior year can pledge credits for sale into the Clearance Market. Fuel reporting entities that have an Accumulated Deficit obligation cannot pledge credits for sale into the Clearance Market.

(F) *Selling in the Clearance Market.* By pledging credits for sale in the Clearance Market, parties agree to the following provisions:

1. Parties pledging credits agree to withhold those credits from sale in the ongoing LCFS credit market until the Executive Officer determines whether a Clearance Market will occur and, if a Clearance Market will occur, until August 31~~st~~.

2. The Executive Officer will announce whether a Clearance Market will occur by May 15~~th~~ of each year.

3. If the Executive Officer announces that a Clearance Market will not be held that year, parties who have pledged credits to the Clearance Market shall be released from their agreement to withhold those credits from sale in the ongoing LCFS credit market.

4. If a Clearance Market does occur, parties agree to sell or transfer credits at or below the Maximum Price for the pertinent year, until the Clearance Market closes on August 30~~th~~.

5. Parties that have voluntarily pledged credits to sell into the Clearance Market cannot reject, based on credit pricing terms, an offer to purchase those pledged credits at the Maximum Price, provided they have not sold or contractually agreed to sell those pledged credits.

(4) *Clearance Market Operation.* The Executive Officer will inform each fuel reporting entity that failed to meet the Annual Compliance obligation under section 95485(a) of its pro-rata share of credits available into the Clearance Market by June ~~1st~~1.

(A) *Calculation of Pro-Rata Shares.* Each fuel reporting entity's pro-rata share of credits available in the Clearance Market will be calculated by the following formula:

Fuel reporting entity A's pro-rata share =

$$\left[\frac{(A's\ deficit)}{(total\ deficits)}\right] \times [lesser\ of: (pledged\ credits)\ or\ (total\ deficits)]$$

where:

$deficit$ refers to one fuel reporting entity's obligation for the compliance year that has not been met pursuant to section 95485(a);

$total\ deficits$ refers to the sum of all fuel reporting entities' obligations for the compliance year that have not been met pursuant to section 95485(a); and

$pledged\ credits$ means the sum of all credits pledged pursuant to section 95485(c)(3).

(B) *Publishing a List of Entities Participating in the Clearance Market.* On or before June ~~1st~~1, the Executive Officer will post the following information on the LCFS ~~web site~~website:

1. The name of each entity that did not meet the requirement of section 95485(a);

2. The name of each entity that has pledged to provide credits for sale in the credit clearance market and the number of credits that each party has agreed to provide and

3. The name of each entity that received advanced credits and the total number of advanced credits pledged for sale in the credit clearance market.

(C) *Submission of Amended Annual Compliance Reports.* Fuel reporting entities that purchased credits in the Clearance Market must submit to the Executive Officer an Amended Annual Compliance Report by August 31~~st~~ that accounts for the acquisition and retirement of their pro-rata share of Clearance Market credits, and for all deficits carried over as Accumulated Deficits.

(D) *Accumulated Deficits.* If, after purchasing its pro-rata share of credits and retiring those credits, a fuel reporting entity retains an unmet compliance obligation, the Executive Officer shall record remaining deficits from that compliance year in the entity's account.

(5) *Rules Governing Accumulated Deficits*.

(A) *Compound Interest on Accumulated Deficits.* Fuel reporting entities with an Accumulated Deficit will be charged interest to be applied annually to all deficits in a fuel reporting entity's account. Interest will be applied on Accumulated Deficit from previous compliance years in terms of additional deficits that must be retired pursuant to section 95485(c)(1)(A) at a rate of 5 percent annually, applied on each September ~~1st~~1.

(B) *Repayment of Accumulated Deficits.* Fuel reporting entities that participate in the Clearance Market in order to meet their compliance obligations must repay all deficits, plus interest no later than five years from the end of the compliance period in which any such deficit was incurred.

(C) *Restrictions on the Repayment of Accumulated Deficits.* Fuel reporting entities may repay Accumulated Deficits as part of a subsequent annual report. However, no repayment of any Accumulated Deficits is allowed unless the fuel reporting entity meets 100 percent of its current compliance obligation.

(D) *Prohibitions on Credit Transfers.* Fuel reporting entities that have an Accumulated Deficit obligation cannot transfer or sell credits to another fuel reporting entity.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95486. Generating and Calculating Credits and Deficits.

(a) *Generation and Acquisition of Transferrable Credits*.

(1) *Credit and Deficit Issuance.* Upon submission and acceptance of timely reports as required by this subarticle, the total number of credits and deficits generated will be issued in the LRT-CBTS account of the applicable credit or deficit generator. Once issued, credits may be retained indefinitely, retired to meet a compliance obligation, or transferred to other entities through the LRT-CBTS. The Executive Officer will issue the credits and deficits in the LRT-CBTS if:

(A) The credit or deficit generator met all the reporting requirements pursuant to this subarticle;

(B) The credit or deficit generator successfully reconciled the fuel quantity reported per FPC using transaction types Sold with Obligation and Purchased with Obligation with business partners by the quarterly reporting deadline, if required;

(C) The activity is not prohibited pursuant to section 95486(a)(2) or any other provision of this subarticle.

(2) *No Retroactive Credit Claim.* Unless expressly provided elsewhere in this subarticle, no credit generator may generate or claim credits retroactively for a period for which the reporting deadline has passed. Similarly, no

deficit generator may eliminate deficits retroactively for a period for which the reporting deadline has passed.

(3) *Buffer Account.* The Executive Officer may create an LRT-CBTS account under the control of the Executive Officer. In this account, the Executive Officer may place:

(A) An equivalent number of credits for any LCFS credits that could have been claimed (or deficits that could have been eliminated) if reported timely, if not for the prohibition on retroactive credit claims in section 95486(a)(2).

(B) ~~An~~Unless otherwise specified in section 95488.10(b), an equivalent number of credits representing the difference between the reported CI and the verified operational CI from annual Fuel Pathway Reports for each fuel pathway code reported with the following liquid fuel transaction types “Production in California”, “Production for Import”, and “Import” and all non-liquid fuel transaction types during a compliance year~~. These credits~~ will be placed in the buffer account after August 31~~st~~ for the prior compliance year and will be calculated according to the following equation:

$$Credits^{FPC}_{CI\ difference}\ (MT) = \left(Credits^{FPC}_{verified\ opertaional\ CI}\ (MT) - Credits^{FPC}_{reported\ CI}\ (MT)\right)$$

If $Credits^{FPC}_{CI\ difference} > 0$

where:

$Credits^{FPC}_{CI\ difference}$ is the number of credits representing the difference between the reported CI and verified operational CI for each fuel pathway code.

$Credits^{FPC}_{verified\ opertaional\ CI}$ is the number of credits calculated using $CI^{XD}_{verified\ opertional}$ instead of $CI^{XD}_{reported}$ in the equation in section 95486.1(a)(1). $CI^{XD}_{verified\ opertional}$ is determined by the Executive Officer on the basis of the annual Fuel Pathway Reports pursuant to section 95488.10 for each fuel pathway code; and

$Credits^{FPC}_{reported\ CI}$ is the number of credits calculated using equation in section 95486.1(a)(1) for each fuel pathway code;

(C) Contribution from CCS projects pursuant to the CCS Protocol.

(D) All net credits remaining in any deactivated LRT-CBTS accounts.

(E) The Executive Officer may retire credits in the Buffer Account to address the invalidation of credits, pursuant to section 95495, if the person responsible for the invalidated credits no longer exists or is otherwise unavailable to reimburse the program.

(4) The Executive Officer may, at the time of credit generation or credit transfer, assign a unique identification number to each credit. Credits are subject to review and audit by the Executive Officer or his designee, and credits may be invalidated or adjusted as necessary pursuant to section 95495.

(5) *Acquisition of "Carryback" Credits to Meet Obligation*.

(A) *Carryback Credit Acquisition Period.* A fuel reporting entity may acquire, via purchase or transfer, additional credits between January ~~1st~~1 and April 30~~th~~ ("carryback period") to be used for meeting the compliance obligation of the year immediately prior to the carryback period. Credits acquired for this purpose are defined as "carryback" credits. All carryback credit transfers must be completed in the LRT-CBTS pursuant to section 95487(b) by April 30~~th~~. In order to be valid for meeting the compliance obligation of the year immediately prior.

(B) *Use of Carryback Credits.* A carryback credit may be used for the purpose of meeting the compliance of an immediate prior year if all of the conditions below are met:

1. The credit was acquired during the carryback period;

2. The credit was generated in a compliance year prior to the carryback period;

3. A fuel reporting entity electing to use carryback credits must identify the number of credits it desires to use as carryback credits in its annual compliance report submitted to the Executive Officer no later than April 30~~th~~ of the year in which the carryback credits were obtained; and

4. A fuel reporting entity electing to use carryback credits must:

a. Acquire and retire a sufficient amount of carryback and other credits to meet 100 percent of its compliance obligation in the prior compliance year, or

b. Minimize its compliance shortfall by retiring all credits in its possession at the end of the previous compliance year, as well as all credits purchased during the carryback period that are eligible to be used as carryback credits.

(b) *Calculation of Credits and Deficits Generated.* The Executive Officer will calculate the number of credits and deficits generated within the LRT-CBTS using the methods specified in section 95486.1 and section 95489. The total credits and deficits generated are used in determining the overall credit balance for a compliance period, pursuant to section 95485. All credits and deficits are denominated in units of metric tons (MT) of carbon dioxide equivalent.

(1) All LCFS fuel quantities used for credit calculation using fuel pathways are in energy units of megajoules (MJ).

Fuel quantities denominated in other units, such as those shown in Table 4, are converted to MJ in the LRT-CBTS by multiplying by the corresponding energy density[1]:

Table 4. Energy Densities and Conversion Factors for LCFS Fuels and Blendstocks.

Fuel (units)	***Energy Density***
CARBOB (gal)	119.53 (MJ/gal)
CaRFG (gal)	115.83 (MJ/gal)
Diesel fuel (gal)	134.47 (MJ/gal)
LNG (gal)	78.83 (MJ/gal)
Fossil Jet Fuel (gal)	129.82 (MJ/gal)
CNG (Therms)	105.5 (MJ/Therm)
Electricity (KWh)	3.60 (MJ/KWh)
Hydrogen (kg)	120.00 (MJ/kg)
Dimethyl Ether (gal)	72.72 (MJ/gal)
Undenatured Anhydrous Ethanol	80.53 (MJ/gal)
Denatured Ethanol (gal)	81.51 (MJ/gal)
FAME Biodiesel (gal)	126.13 (MJ/gal)
Renewable Diesel (gal)	129.65 (MJ/gal)
Alternative Jet Fuel (gal)	126.37 (MJ/gal)

[1] Energy density factors are based on the lower heating values of fuels in CA-GREET~~3~~4.0 using BTU to MJ conversion of 1055.06 J/Btu.

Fuel (units)	Energy Density
Renewable Naphtha (gal)	123.36 (MJ/gal)
Renewable Gasoline (gal)	122.37 (MJ/gal)
Propane (LPG) (gal)	89.63 (MJ/gal)

(2) The total credits and deficits generated by a credit or deficit generator in a compliance period will be calculated as follows:

$$Credits^{Gen}(MT) = \sum_{i}^{n} Credits_i^{gasoline} + \sum_{i}^{n} Credits_i^{diesel} + \sum_{i}^{n} Credits_i^{jet} + \sum_{i}^{n} Credits_i^{projects}$$

$$Deficits^{Gen}(MT) = \sum_{i}^{n} Deficits_i^{gasoline} + \sum_{i}^{n} Deficits_i^{diesel}$$

where:

$Credits^{Gen}$ represents the total credits (a zero or positive value), in units of metric tons (MT), for all fuels and blendstocks determined from the credits generated under the gasoline, diesel, and fossil jet fuel annual carbon intensity benchmarks, and from opt-in projects, if applicable;

$Deficits^{Gen}$ represents the total deficits (a negative value), in MT, for all fuels and blendstocks determined from the deficits generated under either or both of the gasoline and diesel fuel annual carbon intensity benchmarks;

i is the finished fuel or blendstock index; and

n is the total number of finished fuels and blendstocks provided by a credit or deficit generator in a compliance period.

NOTE: Authority cited: Sections 38510, 38530, 38560, 38560.5, 38571, 38580, 39600, 39601 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95486.1. Generating and Calculating Credits and Deficits Using Fuel Pathways.

(a) *General Calculation of Credits and Deficits Using Fuel Pathways.* LCFS credits or deficits for each fuel or blendstock for which a fuel reporting entity is the credit or deficit generator will be calculated according to the following equations:

(1) $Credits_i^{XD}/Deficits_i^{XD}(MT) = \left(CI_{standard}^{XD} - CI_{reported}^{XD}\right) \times E_{displaced}^{XD} \times C$

where:

$Credits_i^{XD}/Deficits_i^{XD}(MT)$ is either the number of LCFS credits generated (a zero or positive value), or deficits incurred (a negative value), in metric tons, by a fuel or blendstock under the average carbon intensity requirement for gasoline (XD = "gasoline"), diesel (XD = "diesel"), or fossil jet fuel (XD = "jet");

$CI_{standard}^{XD}$ is the average carbon intensity requirement of either gasoline (XD = "gasoline"), diesel (XD = "diesel"), or fossil jet fuel (XD = "jet") for a given year as provided in sections 95484(b), (c) and (d), respectively;

$CI_{reported}^{XD}$ is the adjusted carbon intensity value of a fuel or blendstock, in gCO_2e/MJ, calculated pursuant to section 95486.1(a)(2);

$E_{displaced}^{XD}$ is the total quantity of gasoline (XD = "gasoline), diesel (XD = "diesel"), or fossil jet fuel (XD = "jet") fuel energy displaced, in MJ, by the use of an alternative fuel, calculated pursuant to section 95486.1(a)(3); and

C is a factor used to convert credits to units of metric tons from gCO_2e and has the value of:

$$C = 1.0x10^{-6}\frac{(MT)}{(gCO_2e)}$$

(2) $CI_{reported}^{XD} = \frac{CI_i}{EER^{XD}}$

where:

CI_i is the carbon intensity of the fuel or blendstock, measured in gCO_2e/MJ, determined by a CA-GREET pathway or a custom pathway and incorporates a land use modifier (if applicable); and

EER^{XD} is the dimensionless Energy Economy Ratio (EER) relative to gasoline (XD = "gasoline"), diesel (XD = "diesel"), or fossil jet fuel (XD = "jet") as listed in Table 5. For a vehicle-fuel combination not listed in Table 5, $EER^{XD} = 1$ must be used unless an applicant is granted certification of an EER-adjusted CI value pursuant to section 95488.7(a)(3).

(3) $E_{displaced}^{XD} = E_i \times EER^{XD}$

where:

E_i is the energy of the fuel or blendstock, in MJ, determined from the energy density conversion factors in Table 4, except as noted in subsection (4) below.

(4) For Fixed Guideway Systems ~~and Forklifts~~:

$$E_{displaced}^{XD} = E_i$$

where:

E_i is the energy of the fuel used to propel fixed guideway systems~~, electric forklifts, and hydrogen fuel cell forklifts.~~. For fixed guideway system expansion beyond 2010~~, and for electric and hydrogen fuel cell forklifts with model year 2011 or later~~, the formula for displaced energy in section 95486.1(a)(3) may be used with Executive Officer approval.

Table 5. EER Values for Fuels Used in Light- and Medium-Duty, and Heavy-Duty Applications.

Light/Medium-Duty Applications (Fuels used as gasoline replacement)		***Heavy-Duty/Off-Road Applications (Fuels used as diesel replacement)***		***Aviation Applications (Fuels used as fossil jet fuel replacement)***	
Fuel/Vehicle Combination	***EER Values Relative to Gasoline***	***Fuel/Vehicle Combination***	***EER Values Relative to Diesel***	***Fuel/Vehicle Combination***	***EER Values Relative to ~~Conven-tional~~Fossil Jet Fuel***
Gasoline (incl. E6 and E10) Or E85 (and other ethanol blends)	1	Diesel fuel Or Biomass-based diesel blends	1	Alternative Jet Fuel	1
CNG/ICEV	1	CNG or LNG (Spark-Ignition Engines)	0.9		
		CNG or LNG (Compression-Ignition Engines)	1		
Electricity/BEV, or PHEV	3.4	Electricity/BEV or PHEV* Truck or Bus	5.0		
		Electricity/Fixed Guideway, Heavy Rail	4.6		
		Electricity/Fixed Guideway, Light Rail	3.3		

On-Road Electric Motorcycle	4.4	Electricity/Trolley Bus, Cable Car, Street Car	3.1	
		Electricity Forklifts with lift capacity <12,000 lbs.	1.9	
		Electricity Forklifts with lift capacity ≥12,000 lbs.	3.8	
		eTRU	3.4	
		eCHE	2.7	
		eOGV	2.6	
H2/FCV	2.5	H2/FCV	1.9	
		H2 Fuel Cell Forlifts with life capacity < 12,000 lbs.	1.1	
		H2 Fuel Cell Forklifts with lift capacity ≥12,000 lbs.	2.1	
Propane	1.0	Propane	0.9	

*BEV = battery electric vehicle, PHEV= plug-in hybrid electric vehicle, FCV = fuel cell vehicle, ICEV = internal combustion engine vehicle.

(b) *Credit and Deficit Generation Frequency Using Fuel Pathways.* Unless expressly provided elsewhere in this subarticle, credits and deficits for fuel transactions reported each quarter will be generated in LRT-CBTS accounts upon completion of the reporting period for the given quarter, if all the conditions set forth in section 95486(a)(1) are met.

(c) *Calculation of Credits for EV Charging Using Fuel Pathways*.

(1) *Base Credits to EDUs.* “Base Credit” refers to the credit generated by an EDU for electricity using carbon intensity values provided in the Lookup Table pathway for California Average Grid Electricity and the credit calculation in 95486.1(a).

(A) *Determining Quantity of Electricity.* For calculating base credits to EDUs, the quantity of electricity must be determined as follows:

1. *For Non-Metered Residential EV Charging.* The Executive Officer will use the following method to calculate the quantity of electricity used for non-metered residential charging:

$$Electricity^{EV}_{Non\ metered} =$$

$$N^{EV}_{Non\ metered} \times Electricity^{EV}_{Daily\ Average} \times T^{days}_{reporting\ period}$$

where:

$Electricity^{EV}_{Non\ metered}$ is the total estimated electricity use in kWh of non-metered residential plug-in electric vehicles assigned to the EDU for the reporting period;

$N^{EV}_{Non\ metered}$ is the total number of non metered residential EVs within a given EDU service area for the reporting period;

$Electricity^{EV}_{Daily\ Average}$ is the quantity in kWh of electricity used daily for residential charging of EVs, based upon the best data available to the Executive Officer, during the reporting period;

$T^{days}_{reporting\ period}$ is the total number of days in the reporting period.

2. Using the equation in subsection 1. above, the Executive Officer may also calculate, based upon the best data available, the quantity of non-metered electricity used in residential EV charging within service areas for which the EDU has not opted in or is not eligible to receive base credit per section 95483(c)(1)(A). The Executive Officer may then calculate credits generated from this quantity of electricity and assign these credits to Large IOUs and Large POUs that are eligible to receive base credits.

3. *For Metered Residential EV Charging.* The EDU may demonstrate the quantity of electricity for the purposes of calculating the base credits for metered charging at residences through timely submission of Quarterly Fuel Transaction Reports based on meter records.

(B) *Calculation of Base Credits.* The Executive Officer will use the quantity of electricity as determined in subsection (A) above to calculate the base credit using the Lookup Table pathway CI value for California Average Grid Electricity and the credit generation equation provided in section 95486.1(a).

(C) Credits calculated and generated pursuant to subsection (B) above are exempt from the credit generation requirements pursuant to sections 95486(a)(2) and 95486.1(b).

(2) *Incremental Credits for Residential EV Charging.* "Incremental Credit" refers to any credits generated in addition to the base credits generated by

an EDU pursuant to subsection (1)(B) above, for the same electricity, using the calculation in subsection (2)(B), below.

(A) *Quantity of Electricity*.

1. *Non-Metered Residential EV Charging.* The Executive Officer shall use the formula in 95486.1(c)(1)(A) for calculating the quantity of electricity eligible to generate incremental credits for each residence that has an electric vehicle that is not separately metered and is shown to receive low-CI electricity, and is not claimed by another generator of incremental low-CI electricity credits using metered data.

2. *Metered Residential EV Charging for Incremental Credits.* Any entity generating incremental credit for metered residential EV charging must supply the quantity of electricity through timely submission of Quarterly Fuel Transaction Reports based on meter records.

(B) *Calculation of Incremental Credits.* Incremental credits for residential EV charging, including either low-CI electricity or smart charging, and incremental credits for smart electrolysis pathways, must be calculated according to the following equation:

$$Credits_i(MT) = \left(CI_{grid\ average} - CI_{reported}\right) \times Electricity \times C$$

where:

$Credits_i(MT)$ is the number of incremental LCFS credits generated (a zero or positive value), in metric tons, for improvements in carbon intensity of electricity supplied to residential EV charging or for hydrogen production using electrolysis compared to the grid-average carbon intensity;

$CI_{grid\ average}$ is the carbon intensity of California Average Grid Electricity pathway certified by the Executive Officer for a given year, or the applicable region's average grid electricity for hydrogen imported to California;

$CI_{reported}$ is the adjusted carbon intensity of electricity, in gCO_2e/MJ, as calculated for a certified Tier 2 pathway or a Lookup Table pathway, including smart charging or smart electrolysis pathways;

$Electricity$ is the total quantity of either low-CI electricity supplied for EV charging, or electricity supplied for smart charging or smart electrolysis and reported by hourly windows, in MJ, determined from the energy density conversion factors in Table 4; and

C is a factor used to convert credits to units of metric tons from gCO_2e and has the value of:

$$C = 1.0x10^{-6} \frac{(MT)}{(gCO_2e)}$$

(d) *Calculation of Credits for Non-Residential EV Charging Using Fuel Pathways.* The base and incremental framework does not apply to non-residential EV charging. Only one entity per FSE may claim credits for non-residential metered EV charging.

(1) An entity may generate credits for Non-Residential EV charging using a carbon intensity for California Average Grid Electricity, Zero-CI Electricity, or Smart Charging pathway from the Lookup Table in section 95488.5, or a carbon intensity value certified through the Tier 2 pathway application process, and the credit calculation in 95486.1(a).

(e) *Calculation of Credits for Other Electricity used as Transportation Fuel Using Fuel Pathways.* An entity may generate credits for the non-EV charging applications listed in sections 95483(c)(3) to (6), which use electricity to displace conventional transportation fuel, using a carbon intensity for California Average Grid Electricity or Zero-CI Electricity from the Lookup Table 7-1 in section 95488.5, or a carbon intensity value certified through the Tier 2 pathway application process, and the credit calculation in 95486.1(a).

(f) *Calculation of Credits for Hydrogen Using Fuel Pathways*.

(1) An entity may generate credits for hydrogen used as a transportation fuel using a carbon intensity for hydrogen found in the Lookup Table in section 95488.5, or a carbon intensity value certified through the Tier 2 pathway application process, and the credit calculation in 95486.1(a).

(2) *Smart Electrolysis Pathways for Hydrogen Production.* An entity can generate incremental credits, in addition to credits generated under a pathway for electrolytic hydrogen produced using average grid electricity, for hydrogen using smart electrolysis pursuant to section 95488.5 and the incremental credit calculation in section 95486.1(c)(2)(B).

(g) *Calculation of Deficit Obligation for Verified CI Exceedance.* Beginning with the 2025 fuel transactions reporting year, a fuel pathway holder for a non-provisional fuel pathway generates a deficit obligation following a verified CI exceedance. A verified CI exceedance occurs if the verified operational CI of a fuel pathway for a given compliance period, pursuant to section 95488.10, exceeds the certified CI used for reporting that fuel pathway, and is calculated as specified below.

(1) The quantity of deficits generated by CI exceedance is calculated as four times the difference between the verified operational fuel pathway CI and the reported CI, multiplied by the quantity of fuel reported using that fuel

pathway during the applicable year. Deficits will be calculated using the following equation:

$$Deficits(MT) = \left(CI_{operational} - CI_{reported}\right) \times E \times C \times 4$$

where:
$Deficits(MT)$ is the number of calculated deficits from CI exceedance;

$CI_{operational}$ is the verified operational fuel pathway CI for a given compliance period;

$CI_{reported}$ is the certified CI in LRT-CBTS under which the fuel was reported;

E is the reported fuel under a given certified fuel pathway in Megajoules;

C is a factor used to convert credits/deficits to unit of metric tons from gCO_2e and has the value of:

$$C = 1 \times 10^{-6} \frac{(MT)}{(gCO_2e)}$$

(2) Any pathway holder generating deficits following a verified CI exceedance must satisfy the compliance demonstration requirements of section 95485 of this subarticle.

(3) A pathway holder that meets the exemption criteria specified in subsection 95488.10(a)(7)(C) will not generate deficits under this subsection.

NOTE: Authority cited: Sections 38510, 38560, 38560.5, 38571, 38580, 39600, 39601 and 43018, Health and Safety Code; 42 U.S.C. section 7545; and *Western Oil and Gas Ass'n v. Orange County Air Pollution Control District*, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975). Reference: Sections 38501, 38510, 39515, 39516, 38571, 38580, 39000, 39001, 39002, 39003, 39515, 39516 and 43000, Health and Safety Code; Section 25000.5, Public Resources Code; and Western Oil and Gas Ass'n v. Orange County Air Pollution Control District, 14 Cal.3d 411, 121 Cal.Rptr. 249 (1975).

§ 95486.2. Generating and Calculating Credits for ZEV Fueling Infrastructure Pathways.

(a) *Hydrogen Refueling Infrastructure (HRI) Pathways*.

(1) *HRI Pathway Eligibility.* A hydrogen station owner or their designee identified in subsection 95483(b)(2) may submit an application to certify an HRI pathway subject to the following eligibility conditions:

(A) The proposed HRI must be located in California and open to the public.

(B) The HRI pathway application must be received on or before December 31, 2025.

(C) The following stations are not eligible for HRI crediting:

1. Any station receiving or spending funds pursuant to any settlement related to any California or Federal regulation enforcement; or

2. Any station built as a required mitigation measure pursuant to the California Environmental Quality Act.

(2) *HRI Application Requirements.* For each hydrogen refueling station, the station owner must submit an application in the LRT-CBTS containing the following information:

(A) Name and address of the owner of the proposed station.

(B) Contact person for the owner entity.

1. Name

2. Title or position

3. Phone number

4. Mobile phone number

5. Email address

(C) Name, street address, latitude, longitude and a location description for the proposed station.

(D) Expected daily permitted hours of operation for the station. If the daily permitted hours are less than 24 hours, the applicant must provide documentation from a permitting authority demonstrating that daily permitted hours for the station are limited.

(E) The station nameplate refueling capacity for the permitted hours of operation calculated using the HySCapE 1.0 model or an equivalent model or capacity estimation methodology approved by the Executive Officer. The applicant must submit a completed model with the application.

(F) The HRI refueling capacity for the station is the nameplate refueling capacity determined in subsection (E) above or 1,200 kg/day, whichever is less.

(G) The number of dispensing units at the station.

(H) Expected source(s) of hydrogen, CI value(s), and method(s) used for delivery.

(I) Expected date that the station will be operational.

(J) Justification for the station location and how the proposed location contributes in developing a hydrogen refueling station network to support ZEV adoption. The justification must include:

1. The role(s) the station location will play in the developing hydrogen station network;

2. The means by which the station contributes to robust growth of the statewide hydrogen fueling network;

3. Demonstration of potential for consistent and calculable hydrogen demand;

4. Demonstration that the proposed station capacity is an appropriate capacity based on documented, verifiable, and reproducible projections of daily hydrogen demand at the proposed location;

5. Calculation of the projected trajectory of annualized average station utilization (calculated as annual throughput divided by annual station capacity) at the proposed location; and

6. Demonstration that the proposed station location has been discussed with local authorities having jurisdiction and no early roadblocks have been identified.

(K) A signed attestation letter from the applicant attesting to the veracity of the information in the application packet. The attestation letter must be submitted as an electronic copy, be on company letterhead, be signed by an officer of the applicant with authority to attest to the veracity of the information in the application and to sign on behalf of the applicant, be from the applicant and not from an entity representing the applicant (such as a consultant or legal counsel), and include the following attestation:

I, an authorized representative of _______________ (applicant entity), attest to the veracity of the information submitted as part of the Hydrogen Refueling Infrastructure (HRI) application, attest that the proposed FSE is not receiving funds pursuant to any enforcement settlement related to any California or Federal regulation, and declare that the information submitted accurately represents the anticipated and intended design and operation of the hydrogen refueling station. Further, I understand and agree to each of the statements in the attached application. I am a duly authorized officer with authority to attest to the veracity of the information in the application and to sign on behalf of the respective applicant.

I understand that the following information in the HRI application will be made available on the LCFS ~~web site~~website: Name of the Applicant Entity, Station Name, Station Address, Number of Dispensing Units, HRI Refueling Capacity, and Effective Date Range for HRI Crediting.

By submitting this application, ____(applicant entity) accepts responsibility for the information herein provided to CARB. I certify under penalty of perjury under the laws of the State of California that I have personally examined, and am familiar with, the statements and information submitted in this document. I certify that the statements and information submitted to CARB are true, accurate, and complete.

______________________________ ______________________________ __________

Signature Print Name & Title Date

(L) CBI must be designated pursuant to the requirements described in section 95488.8(c).

(M) An application and supporting documents must be submitted electronically via the LRT-CBTS unless the Executive Officer has approved or requested in writing another format.

(3) *Application Approval Process*.

(A) The HRI application must be approved by the Executive Officer before the station owner may generate hydrogen refueling infrastructure credits. If estimated potential HRI credits from all approved stations exceed 2.5 percent of deficits in the prior quarter, the Executive Officer will not approve additional HRI pathways and will not accept additional applications until estimated potential HRI credits are less than 2.5 percent of deficits. HRI applications will be evaluated for approval on a first come, first served basis.

Estimated potential HRI credits will be calculated using the following equation:

$$Credits_{HRI}^{Potential} = Credits_{HRI}^{Prior\ qtr} \times \frac{Cap_{HRI}^{Approved}}{Cap_{HRI}^{Operational}}$$

where:

$Credits_{HRI}^{Potential}$ means the estimated potential HRI credits from all approved HRI stations;

$Credits_{HRI}^{Prior\ qtr}$ means the total HRI credits generated by operational stations in the prior quarter;

$Cap_{HRI}^{Operational}$ means the total HRI capacity of stations that were operational in the prior quarter; and

$Cap_{HRI}^{Approved}$ means the total HRI capacity of all approved stations, both operational and nonoperational.

(B) After receipt of an application designated by the applicant as ready for formal evaluation, the Executive Officer will advise the applicant in writing either that:

1. The application is complete, or

2. The application is incomplete, in which case the Executive Officer will identify which requirements of section 95486.2(a)(2) have not been met.

a. The applicant may submit additional information to correct deficiencies identified by the Executive Officer.

b. If the applicant is unable to achieve a complete application ~~within 180 days~~in the quarter of the Executive Officer's receipt of the original application, the application will be denied on that basis, and the applicant will be informed in writing. The applicant may submit a new application for the station.

3. At any point during the application evaluation process, the Executive Officer may request in writing additional information or clarification from the applicant.

(C) The Executive Officer will not approve an application if the Executive Officer determines, based upon the information submitted in the application and any other available information, that the application does not meet requirements in subsections 95486.2(a)(1) and (a)(2). The Executive Officer may reject an application if satisfactory justification is not provided for station location pursuant to subsection 95486.2(a)(2)(J). If the Executive Officer does not approve the application, the applicant will be notified in writing and the basis for the disapproval shall be identified.

(D) If the Executive Officer determines that the applicant and application have met all requirements for approval pursuant to subsections 95486.2(a)(1) and (a)(2), the Executive Officer will approve the application and provide an approval summary on the LCFS website including the station location and assigned identifier, number of dispensing units, HRI refueling capacity, and effective date range for HRI pathway crediting.

(E) *Crediting Period.* HRI crediting is limited to 15 years starting with the quarter following Executive Officer approval of the application.

(4) *Requirements to Generate HRI Credits.* To generate credits using HRI pathways the station must meet the following conditions. The station

owner must maintain, and submit to CARB upon request, records demonstrating adherence to these conditions.

(A) The station owner must update the HRI refueling capacity if different from the design HRI refueling capacity provided in the application. Any station design or operational information that deviates from the original application must be declared to the Executive Officer, and a new attestation must be submitted pursuant to 95486.2(a)(2).

(B) The station must be open to the public, meaning that no obstructions or obstacles exist to preclude vehicle operators from entering the station premises, no access cards or personal identification (PIN) codes are required for the station to dispense fuel, and no formal or registered station training shall be required for individuals to use the hydrogen refueling station.

(C) The station uses a public point of sale terminal that accepts major credit and debit cards.

(D) The station is connected to the Station Operational Status System (SOSS), is listed open for retail, and:

1. The station passed final inspection by the appropriate authority having jurisdiction and has a permit to operate.

2. The station owner has fully commissioned the station, and has declared it fit to service retail FCV drivers. This includes the station owner's declaration that the station meets an appropriate SAE fueling protocol.

3. At least three OEMs have confirmed that the station meets protocol expectations, and their customers can fuel at the station.

4. All dispensers installed in the hydrogen refueling station have undergone type evaluation according to the California Type Evaluation Program (CTEP) administered by the California Department of Food and Agriculture/Division of Measurement Standards (CDFA/DMS) and have either a Temporary Use Permit or a type approval Certificate of Approval issued by CDFA/DMS.

(E) The FSE registration must be completed pursuant to section 95483.2(b)(8) and the quantity of dispensed hydrogen must be reported as required in section 95491.

(F) Dispensed hydrogen meets the following CI and renewable content requirements on a company-wide, weighted average basis. The Executive Officer will consider all the stations registered by an entity with a unique FEIN in the LRT-CBTS for calculating the company-wide weighted average CI and renewable content.

1. CI of 150 gCO_2e/MJ or less before January 1, 2030, and 90 gCO_2e/MJ or less thereafter, and

2. Renewable content of 40 percent or greater before January 1, 2030, and 80 percent thereafter.

(G) The station must be operational within 24 months of application approval. If the applicant fails to demonstrate the operability within 24 months of approval then the application will be canceled. The applicant can reapply for the same station eligible only for 10 years of crediting.

(5) *Calculation of HRI Credits.* HRI credits will be calculated using the following equation:

$$Credits_{HRI}\ (MT) = (CI^{XD}_{standard} \times EER - CI_{HRI}) \times E_{H2} \times \left(Cap_{HRI} \times N \times UT - H2_{disp}\right) \times C$$

where:

$CI^{XD}_{standard}$ is the average carbon intensity requirement of gasoline (XD = “gasoline”) for a given year as provided in sections 95484(b);

EER is the dimensionless Energy Economy Ratio for H2/FCV relative to gasoline as listed in Table 5;

CI_{HRI} is the carbon intensity used for HRI crediting. Company-wide weighted average CI for dispensed hydrogen during the quarter or 0 g/MJ, whichever is greater;

E_{H2} is the energy density for hydrogen in MJ/kg as listed in Table 4;

Cap_{HRI} is the HRI refueling capacity for the station (kg/day);

UT is the the uptime multiplier which is the percentage of time that the station is available as reported to SOSS during the quarter;

$H2_{disp}$ is the quantity of hydrogen dispensed during the quarter (kg);

N is the number of days during the quarter;

C is a factor used to convert credits to units of metric tons from gCO_2e and has the value of:

$$C = 1.0x10^{-6} \frac{(MT)}{(gCO_2e)}$$

(6) *Reporting and Recordkeeping Requirements.* The following must be reported to the Executive Officer each quarter as set forth in section 95491 before credits will be issued to the LRT account associated with an approved HRI pathway.

(A) Station availability. This is the percentage of hours the station is available for fueling during the quarter relative to the permitted hours of operation for the station, as reported to the SOSS. Any period of time that SOSS reports that a portion of the station capacity is not available will count as a pro-rated amount of station availability, proportional to the percentage of the station capacity that remains available for fueling for this period of time.

(B) Company-wide, weighted average renewable content (percent) for dispensed hydrogen.

(C) Cost and revenue data. Provide a quarterly account of the following costs borne and revenues received by the station owner up through the most recent reporting quarter per station.

1. Total capital expenditures ($)

2. Total delivered cost ($) of hydrogen and average delivered cost ($/kg) for hydrogen

3. Total maintenance costs ($)

4. Total land rental cost ($)

5. Total grant revenue or other external funding received towards capital expenditures ($)

6. Total grant revenue or other external funding received towards operational and maintenance expenditures ($)

7. Total revenue ($) received from sale of hydrogen and average retail price ($/kg) for hydrogen sold

8. Other operational expenditures ($)

~~(7) *Applications for Expanded HRI Refueling Capacity.* Station owners who expand the capacity of a station and that is already generating HRI credits under the LCFS must submit an application to the Executive Officer to generate additional credits based on the updated capacity. Applications for expanded station capacity must be received before December 31,~~

~~2025 and do not extend the effective date range for the HRI crediting specified upon initial project approval in 95486.2(a)(3)(D). The application must include the following elements.~~

~~(A) In order to be eligible to generate HRI credits for expanded capacity, the station owner must demonstrate that station throughput in a reporting quarter is greater than or equal to 50 percent of the original approved HRI refueling capacity.~~

(7) ~~Updated~~ *Transition to Light-Duty Hydrogen Refueling Infrastructure (LD-HRI) Pathways.* Beginning January 1, 2026, a light-duty hydrogen station owner or designee may submit an application to certify an LD-HRI pathway. The LD-HRI pathway retains the requirements of the HRI pathway described in section 95486.2(a)(1-6), with the following amendments effective January 1, 2026:

(A) Subsection 95486.2(a)(1)(A) is amended. The proposed LD-HRI station must be located in California in a disadvantaged community, low-income community, or rural area and open to the public.

(B) Subsection 95486.2(a)(1)(B) is amended. The proposed LD-HRI pathway application must be received on or before December 31, 2030.

(C) Subsection 95486.2(a)(2)(E) is amended. The station nameplate refueling capacity ~~and updated HRI~~ for the permitted hours of operation calculated using the HyCap model or an equivalent model or capacity estimation methodology approved by the Executive Officer. The applicant must submit a completed model with the application.

~~(B)~~(D) Subsection 95486.2(a)(2)(F) is amended. The LD-HRI refueling capacity for the station is one-half the nameplate refueling capacity determined in subsection (C) above or 600 kg/day, whichever is less.

~~(C) If the sources of hydrogen and delivery methods stated in the original HRI application will change as a result of the added capacity, the station owner must disclose the new hydrogen sources and delivery methods.~~

~~(D) The station owner must maintain records demonstrating that any new equipment added as a result of the expansion in capacity, including storage and fueling dispensers, meet the requirements listed in 95486.2(a).~~

(E) Subsection 95486.2(a)(2)(J) is removed.

(F) Subsection 95486.2(a)(3)(A) is amended. If estimated potential LD-HRI credits from all approved stations exceed 0.5 percent of deficits in the most recent quarter data is available, the Executive Officer will not approve additional LD-HRI pathways and will not accept additional applications until estimated potential LD-HRI credits are less than 0.5 percent of deficits. LD-HRI potential credits are calculated separately from HRI potential credits described in this section.

(G) Subsection 95486.2(a)(3)(E) is amended. LD-HRI crediting is limited to 10 years starting with the quarter of Executive Officer approval of the application.

(H) Subsection 95486.2(a)(4)(G) is amended. If the applicant fails to demonstrate the operability within 24 months of approval and if the estimated potential LD-HRI credits exceed 0.5 percent of deficits in the most recent quarter for which deficit data is available, then the application will be canceled. The applicant may submit a new application for the same station the following quarter. The estimated value of LD-HRI credits, for the purpose of this determination, shall be calculated using the number of LD-HRI credits generated for the station in the quarter and the average LCFS credit price for that quarter published on the LCFS website.

(I) Subsection 95486.2(a)(4)(H) is added. The estimated cumulative value of LD-HRI credits generated for the station in the prior quarter must be less than the difference between 1.5 times the initial capital expenditure and the sum of total grant revenue or other external funding received towards capital, operational and maintenance expenditures in the prior quarter, reported pursuant to section 95486.2(a)(6)(C).

(J) Subsection 95486.2(a)(6)(C) is amended. Provide an annual account of the following costs borne and revenues received for the station. The cost and revenue account must be included in the annual report submitted pursuant to section 95491.

(K) Subsection 95486.2(a)(6)(C)1. is amended to include a breakdown of initial capital expenditure by equipment, labor, materials, fees and land ($). Costs for working capital and off-site facilities are not included.

(b) *DC Fast Charging Infrastructure (FCI) Pathways*.

(1) *FCI Pathway Eligibility.* An FSE owner or their designate identified in subsection 95483(c)(2)(B) may submit an application to receive an FCI pathway subject to the following eligibility conditions:

(A) The proposed FSE must be located in California and open to the public for charging.

~~(B) Upon an individual applicant's estimated potential FCI credits, calculated pursuant to section 95486.2(b)(3)(B), exceeding 0.5 percent of the deficits in the prior quarter, each additional site applied for by the applicant must meet the following requirements:~~

~~1. Charging equipment at the site must support at least two of the following three fast charging connectors: CHAdeMO, SAE CCS, and/or Tesla;~~

~~2. The site must have at least one FSE with a CHAdeMO connector protocol and at least one FSE with an SAE CCS connector protocol; and~~

~~3. No more than three-quarters of all FSE subject to this provision at the site can support only a single fast charging connector protocol.~~

~~(C)~~(B) The FCI pathway application must be received on or before December 31, 2025.

~~(D)~~(C) The following FSE are not eligible for FCI crediting:

1. Any FSE that is permitted to operate prior to January 1, 2019; or

2. Any FSE receiving or spending funds pursuant to any settlement related to any California or Federal regulation enforcement; or

3. Any FSE built as a required mitigation measure pursuant to the California Environmental Quality Act.

~~(E)~~(D) Each FSE must have a minimum nameplate power rating of 150 kW.

~~(F)~~(E) Each FSE must be networked and capable of monitoring and reporting its availability for charging.

(2) *FCI Application Requirements.* The applicant must submit an application in the LRT-CBTS containing the following information:

(A) Name and address of the owner of the proposed FSE.

(B) Contact person for the owner entity.

1. Name

2. Title or position

3. Phone number

4. Mobile phone number

5. Email address

(C) Name, street address, latitude, longitude and a location description for each proposed FSE site.

(D) The number of FSEs.

(E) The nameplate power rating (kW), connector type(s), and model for each FSE.

1. The total nameplate power rating for all FSE at a single site claiming FCI credit under this provision cannot exceed 2,500 kW.

~~2. Notwithstanding 95486.2(b)(2)(E)1 above, upon request the Executive Officer may approve an application with total nameplate power rating for all FSE at a single site up to 6,000 kW. The total number of FSE at sites with total nameplate power rating greater than 2,500 kW cannot exceed 10 percent of total FSE approved under FCI pathways. The applicant must provide justification for requesting a total power rating greater than 2,500 kW at the given site.~~

(F) The effective simultaneous power rating (kW) for each FSE calculated using the equation below. The effective simultaneous power rating must be at least 50 percent of the nameplate power rating for each FSE.

$$P_{Sim}^{i} = P_{NP}^{i} \times \frac{P_{Sim}^{Tot}}{\sum_{i=1}^{n} P_{NP}^{i}}$$

where:

P_{Sim}^{i} is the simultaneous power rating (kW) for FSE i;

P_{NP}^{i} is the nameplate power rating (kW) for FSE i;

P_{Sim}^{Tot} is the maximum total power (kW) that can be delivered to all FSEs at a single site when they are operated simultaneously; and

n is the number of FSEs at a single site.

(G) The FCI charging capacity for each FSE calculated using the following equation:

$$Cap_{FCI}^{i} = 43 \times (P_{FCI}^{i})^{0.45}$$

where:

Cap_{FCI}^{i} is the FCI charging capacity (kWh/day) for the FSE i; and

P_{FCI}^{i} is the nameplate power rating for the FSE or 350 kW, whichever is less.

(H) Expected date that the FSE will be operational.

(I) Expected daily permitted hours of operation for the site. If the daily permitted hours are less than 24 hours, the applicant must provide documentation from a permitting authority demonstrating that daily permitted hours for the FSE are limited.

(J) A signed attestation letter from the applicant attesting to the veracity of the information in the application packet. The attestation letter must be submitted as an electronic copy, be on company letterhead, be signed by an officer of the applicant with authority to attest to the veracity of the information in the application and to sign on behalf of the applicant, be from the applicant and not from an entity representing the applicant (such as a consultant or legal counsel), and include the following attestation:

I, an authorized representative of _______________ (proposed FSE owner entity), attest to the veracity of the information submitted as part of the DC Fast Charging Infrastructure (FCI) application, attest that the proposed FSE is not receiving funds pursuant to any enforcement settlement related to any California or Federal regulation, and declare that the information submitted accurately represents the anticipated and intended design and operation of the charging infrastructure. Further, I understand and agree to each of the statements in the attached application. I am a duly authorized officer with authority to attest to the veracity of the information in the application and to sign on behalf of the respective applicant.
