Pasture and Range Management: Stocking Density - ***(applies to grazing cattle only)***

The NRCS Reference Guide lists managing animal stocking density at grazing-based livestock operations as a mitigation method for ammonia emissions. However, the District does not have authority to regulate animals on pasture or rangeland, as they are not confined. This measure also does not recommend a specific stocking density; however, cattle that graze on pastureland and rangeland in California generally require low stocking densities to provide sufficient forage for cattle. The District has concluded that the measure discussed is not a viable mitigation option to include in Rule 4570.

Improved Genetics - ***(applies to all CAFs)***

A publication prepared for use in the United Kingdom includes genetic selection of useful traits to improve animal health and fertility as a potential mitigation measure to increase the efficiency of animals and reduce environmental impacts. Farmers select animal breeds that have improved genetics that increase efficiency as feasible to reduce overall costs and increase yield. The publication notes that use of animals with improved genetics "*is generally good in the poultry, dairy and pig industries*." Improvements in genetics and management practices to increase efficiency have already significantly reduced the environmental footprint of production from animal agriculture compared to previous years. As a result of genetic selection and improved diets, milk production per cow has increased and feed usage has decreased by 77 percent and water use has decreased by 65%.[196] GHG emissions from California dairy cattle per amount of milk produced have also decreased by over 45 percent in the 50 years from 1964 to 2014.[197] For poultry, it is estimated that genetic selection and the current feed practices have reduced nitrogen excretion by poultry by up to 55 percent, primarily due to the reduced time from egg to market age.[198]

Farmers are expected to continue to use animals with improved genetics that will increase efficiency and reduce production costs. However, there are several issues that cause this measure to be unsuitable as a requirement in a regulation. The study does not specify the genetic traits that need to be improved. The measure is largely theoretical and requires extensive research and funding to develop new breeds with the desired traits. It would take generations of each breed to evaluate the effectiveness of the breeds as it pertains to reducing ammonia emissions and any potential adverse impacts on the environment. There are also potential ethical concerns regarding if animals were to be genetically modified to accelerate selection of specific traits. Therefore, the District has concluded that the measure discussed is not a viable mitigation option to include in Rule 4570.

Planting a Tree Shelter Belt - ***(applies to all CAFs)***

This measure involves planting tree shelterbelts around livestock housing and manure slurry storage facilities to disrupt airflow around these sites. The effectiveness of tree shelterbelts as a measure to reduce particulate matter from facilities depends on the shelterbelt height, canopy density, and the prevailing environmental conditions. While some evidence demonstrates effectiveness for PM2.5 emissions reductions, there is little to no evidence for

ammonia emissions reductions. Effective tree shelterbelts are expensive and difficult to establish due to the large size of the facilities, severe water limitations, soil conditions, and the number of trees needed to protect these areas.

Irrespective of the lack of available data on the potential ammonia emissions reductions, implementation of this measure requires additional consideration with respect to animal health. Cattle facilities in the Valley depend on natural airflow to cool cattle and provide them with fresh air. Disrupting natural airflow can adversely affect cattle that depend on the natural flow of air, particularly during summer months where large numbers of heat-related animal mortalities occur in the San Joaquin Valley. Tree shelterbelts also require sufficient space to be effective, thus, dairies would need either to remove crops or acquire additional land for a shelterbelt. Furthermore, a shelterbelt of sufficient height to be effective would take a number of years to establish. In many cases in the Valley, where the soil has high salinity, conditions are unsuitable for planting tree shelterbelts.

In several cases, permitted CAFs proposed to grow shelterbelts to satisfy District BACT requirements, however, the shelterbelts were not sustainable. Agronomic land surveys of the facilities confirmed the poor soil quality would not sustain the tree shelterbelts. As a result, the District eliminated this option as a BACT requirement for these specific CAFs and allowed an alternative mitigation measure to be implemented.

For the reasons listed above, it is infeasible to require planting tree shelterbelts at animal facilities; however, the trees and plants in the agricultural fields and orchards that surround Valley animal facilities already capture a portion of emissions from these facilities and remove some of the ammonia by deposition. The District has concluded that the measure discussed is not a viable mitigation option to include in Rule 4570.

Using Plants with Improved Nitrogen Use Efficiency - ***(applies to all cattle)***

This measure involves developing new plant varieties with improved genetic traits for the capture of soil nitrogen, which would allow reduced fertilizer application. New plant varieties could also be developed with improved nutritional characteristics. This measure is theoretical and requires extensive research and funding to develop new plant varieties with the desired traits. Years of testing would be required to evaluate the effectiveness of new plant varieties for reducing ammonia emissions and any adverse impacts of the new plant varieties. Furthermore, capturing additional soil nitrogen would primarily benefit water quality rather than reducing ammonia emissions. The District has concluded that the measure discussed is not a viable mitigation option to include in Rule 4570.

Changing Land Use from Arable to Woodland - ***(applies to all CAFs)***

This measure involves changing land use from agricultural land to permanent woodland. However, many areas in the Valley are dry and often affected by droughts, and thus not suitable for the establishment of permanent woodlands. The District does not have authority to require that agricultural land be converted to forests. Moreover, conversion of agricultural land to farmland would result in total loss of income for the farmers and an associated loss in tax revenue. The District has concluded that the measure discussed is not a viable mitigation option to include in Rule 4570.

Reduced consumption of meat and eggs by humans by 63 percent - ***(applies to all CAFs)***

The District does not have authority to regulate what people eat and has concluded that the measure discussed is not a viable mitigation option to include in Rule 4570.

Evaluation of Potential Emissions Reductions from CAFs

As demonstrated in the evaluation above, the District has only identified a few measures that have the theoretical potential to reduce additional ammonia emissions beyond the practices currently enforced through Rule 4570. These measures are reducing CP content in feed for beef finishing cattle, incorporation of solid manure within 24 hours, and acidifying amendments for poultry litter and manure. Despite the technological and economic feasibility issues of these mitigation measures, the District evaluated the potential emission reductions and the impact they might have on the Valley's total ammonia emissions inventory if these measures were to be implemented. This was calculated as follows.

- Control efficiency of reducing CP content in feed for beef finishing cattle, applied to beef cattle emissions inventory:

  18.9% x 16.2 tpd = 3.1 tpd

- Control efficiency of incorporation of solid manure within 24 hours, applied to beef and dairy cattle emissions inventory:

  0.48% x 141.5 tpd = 0.7 tpd

- Control efficiency of acidifying amendments for poultry litter and manure, applied to broiler and layer emissions inventory:

  35% x 7.9 tpd = 2.8 tpd

The emissions reductions from the measures above total 6.6 tpd, which would be reduced from the total ammonia emissions inventory of 324.9 tpd:

6.6 tpd ÷ 324.9 tpd = 2.0%

Overall, ammonia emissions from CAFs in the Valley can only be reduced by 2 percent by implementing the mitigation measures above. This demonstrates that additional reductions in the EPA-recommended range of 30-70 percent are infeasible.

Fertilizers

Ammonia emissions from agricultural fertilizers are 111.2 tpd in 2023. Emissions growth from agricultural fertilizers are estimated by farmland acreage projection data developed by the Farmland Mapping & Monitoring Program (FMMP) of the California Department of Conservation.

The California Department of Food and Agriculture (CDFA) Feed, Fertilizer and Livestock Drugs Regulatory Services (FFLDRS) Branch primary focus is to ensure in every way possible a clean and wholesome supply of meat and milk, and to promote environmentally safe and agronomically sound use and handling of fertilizer materials. This is performed through regulating manufacturing, labeling, and use of fertilizing materials, feed and livestock drugs.

The CDFA Fertilizer Research and Education Program (FREP) funds and facilitates research to advance the environmentally safe and agronomically sound use and handling of fertilizing materials. FREP is voluntary and serves growers, agricultural supply and service professionals, extension personnel, public agencies, consultants, and other interested parties.

The Fertilizer Inspection Advisory Board (FIAB) is a statutory body that is advisory to the CDFA secretary on matters pertaining to fertilizer issues, including FREP activities. The Board consists of nine persons appointed by the secretary of agriculture, one of whom shall be a public member and eight of whom shall be licensed with CDFA to manufacture or distribute fertilizing materials, including organic inputs. The FIAB established the Technical Advisory Subcommittee (TASC) to advise the FIAB on matters related to the funding of FREP projects. The TASC serves as an expert scientific panel on matters concerning plant nutrition and on environmental effects related to fertilizing materials use. TASC assists in setting research priorities, reviews research proposals, and makes recommendations on projects for funding.

The composition of the TASC is determined by the FIAB. There should be at least nine members representing the major segments of the fertilizer industry, certified crop advisors, technical experts, farming community, public, and governmental agencies. Members have to demonstrate knowledge, technical and scientific expertise in the fields of fertilizing materials, agronomy, plant physiology, principles of experimental research, production agriculture, and environmental issues related to fertilizing materials use. One member can satisfy more than one of the criteria stated above. At minimum, one member shall be appointed from the membership of the FIAB, and one member on the TASC shall be from CDFA.

The TASC meets at least two times per year-once in spring to evaluate concept proposals and once in summer to evaluate full proposals. Additional meetings are necessary for special initiatives. Meetings typically last all day and alternate between Sacramento and other locations throughout the State. Serving on the TASC requires a time commitment in addition to participating in meetings. Members must read and critically evaluate all concept proposals (typically around 35 two-page proposals) and full proposals (typically at least ten 15-page proposals). In addition, TASC members are responsible for reviewing final research reports for FREP funded projects and may be asked to participate in conferences and special initiatives.

CARB has not found an ammonia emission reduction measure for fertilizers that meets EPA requirements for SIP submittal. CARB staff reached out to the National Association of Clean Air Agencies (NACAA) to ascertain whether other air pollution control agencies across the United States had any experience or regulations reducing ammonia emissions from fertilizers. NACAA reached out to all of their members and CARB staff did not receive any existing rules or regulations controlling ammonia emissions from fertilizers. CARB staff also reached out to

EPA Region 9 staff whether they were aware of any rules or regulations controlling ammonia emissions from fertilizers and they were not aware of any. EPA Region 9 staff did ask CARB to review some practices per Table 12.

Mitigation Measures

Table 13: Fertilizer Mitigation Measures Evaluated

Method	Measure	Reference
Fertilizer	Optimizing or minimizing use of fertilizer	Guthrie
	Adding a Urease Inhibitor	Guthrie
	Mixing and injecting fertilizer into the soil quickly	Guthrie and Eory
	Applying fertilizer during optimal weather conditions	Guthrie and Eory

Optimize or minimize use of fertilizer

The San Joaquin Valley is a part of Central Valley Water Board of the California Water Board, which is an expansive region extending south from the Oregon border to the northernmost portion of Los Angeles County. The California Legislature passed Senate Bill 390 in 1999, which required Water Boards to develop programs that regulate agricultural lands in accordance with the Porter-Cologne Water Quality Control Act (California Water Code Division 7). In 2003, the Central Valley Irrigated Lands Regulatory Program (ILRP) was established, regulating agricultural discharges to surface waters. The Central Valley Water Board extended the regulations in 2012 to include discharges to ground waters. With the exclusion of lands that are never-irrigated or are covered under a separate Central Valley Water Board program, all commercial irrigated lands are required to obtain regulatory coverage under the ILRP.[199] In accordance with the ILRP, growers are required to prepare farm management plans – which includes an Irrigation Nitrogen Management Plan Summary Report – that comply with the approved upon Waste Discharge Requirements (WDR). Using information from the Reports, inferences can be made about nitrogen management based on estimates that compare nitrogen applied (A) to the nitrogen removed (R) from a field: A/R ratio and A-R difference. Included in the nitrogen fraction is any nitrogen proactively added

[199] Central Valley Water Board. *Irrigated Lands Regulatory Program (ILRP) FAQs*. Available at: *https://www.waterboards.ca.gov/centralvalley/water_issues/irrigated_lands/ilrp_faq.pdf*

to a field such as organic amendments, synthetic fertilizers, manure, and irrigation water, whereas nitrogen removed refers to the nitrogen in the materials removed from the field.[200]

Though growers do not have an immediate requirement under ILRP to use nitrogen efficient strategies, growers that are deemed outliers in A/R ratio and A-R difference would be required to employ enhanced strategies to lower these estimates. CDFA FREP offers an Irrigation and Nitrogen Management training program[201] for this purpose among others. A subset of the Irrigation and Nitrogen Management training program is dedicated to nitrogen efficiency, including overviews of the "4 R's" of nitrogen management, and of efficient nitrogen practices.[202] The 4 R's principles are founded on applying the "Right source" of nitrogen at the "Right rate", "Right time", and "Right place". The right rate principle is with the identified measure, as it promotes strategies for providing nitrogen in rates that do not go beyond the crop demand for nitrogen. Examples of how this can be accomplished include adjusting the rate of application based on expected crop yield and adjusting season application rates based on soil and plant-tissue testing.

Guthrie et al. (2018) describe how minimizing the amount of fertilizer applied to an level that is optimal for crop can reduce ammonia emissions.[203] This measure and associated findings were not well described by both Guthrie et al. (2018) and the publications they referenced, nor were any specific regulations identified.[204,205,206,207] Additionally, the viewpoints of Guthrie et al. (2018) were prepared in the context of Europe and United Kingdom. There is therefore

a probability that the conditions and farming practices described by Guthrie et al. (2018) are consistent with those present and employed in California. This, combined with the lack in strong evidence demonstrating the emission reduction potentials, demonstrates the need for additional research be completed under conditions consistent with those of the San Joaquin valley before this measure can be considered.

Urease Inhibitor

When combined with urease enzyme present in plants, urea present in urea-based fertilizers can be converted into ammonia, which can then volatilize. Urease inhibitors are a class of nitrogen stabilizer designed to minimize volatilization from applied nitrogen sources by inhibiting the action of the urease, thereby reducing the formation of ammonia.

Nitrogen stabilizers are regulated by federal and State regulatory agencies. At the federal level, The Federal Insecticide, Fungicide, and Rodenticide Act requires that nitrogen stabilizers sold and distributed in the United States be registered with U.S. EPA.[208] At the state level, both the California Department of Pesticide Regulations (DPR) and CDFA maintain regulatory authorities over nitrogen stabilizers. While DPR requires all nitrogen stabilizers to be registered,[209] CDFA regulates licensing, registration, labeling, tonnage reporting, and inspection of only a subset of commercial nitrogen stabilizers.[210] In coordination with 4R Nutrient Stewardship and UC Davis Land and Water Resources, CDFA FREP also encourage growers to use enhanced-efficiency sources such as Urease Inhibitors, identifying these sources as possible "Right Source" through their 4 R's principles.[211]

Although urease inhibitors have shown tremendous promise in reducing ammonia emissions, some studies indicate potential occurrences of pollution swapping through increasing of NOx emissions which must be critically considered and explored prior to further considering the measure.[212,213] Additionally, although there are numerous identified benefits associated with the use urease inhibitors, there is little existing knowledge about their potential to enter the

food chain and impact food safety.[214] Further research is needed which demonstrates that there are no food safety-related issues prior to this measure being viable for consideration.

According to Guthrie et al. (2018), the addition of a urease inhibitor has the potential to reduce ammonia emissions by 40-70 percent.[215] Though this has the potential to hold remarkable mitigation potential, their estimates along with those of the original experiments, were prepared under European and United Kingdom conditions. As these findings were based outside of California where environmental and climatic conditions may differ, further research is needed that explores the reduction potentials of urease inhibitors in conditions consistent with those of the San Joaquin Valley. In addition to this, Guthrie et al. (2018) merely identified the measures but did not reference or identify any specific regulations.

Quick mixing and injecting into soil

The identified measure would involve rapid incorporation of fertilizers into soils after the fertilizers have been applied. As previously described, with the implementation of ILRP and WDRs by the Central Valley Water Board growers are required to prepare and management plans. The 4 R's of nitrogen management serve as guiding nitrogen efficiencies principles that growers are recommended to follow when developing their management plans. The identified measure is addressed through two of the four principles. The "Right time" principle refers to timed application of nitrogen to ensure availability to the plant during periods of greatest demand. The measure is also addressed through the "Right place" principle, which considers targeted application of fertilizer in the crop's effective rootzones to facilitate and enhance the uptake of nitrogen by the crop.

As described by Guthrie et al. (2018), ammonia emissions can be reduced by 50-90 percent through this measure, should the fertilizer be mixed in or injected into the soil within 4-6 hours of their application.[216] Though they do not touch on the speed of the process, Eory et al. (2016) likewise identified fertilizer injection as a candidate ammonia emission mitigation measure.[217] However, the publications referenced in Guthrie et al. (2018) and Eory et al. (2016) focus solely on manure application methods and do not provide estimates for

commercial fertilizers. [218,219] We cannot assume the mitigation potential of fertilizers to be consistent with that of manure sources. We therefore proceed with caution with the identified measure and will not be considering it at this moment. In addition to this, research from a California-context is profoundly limited,[220] resulting in uncertainty regarding the ammonia reduction potentials under California-specific conditions. Consistent with the previously mentioned fertilizer measures, Guthrie et al. (2018) and Eory et al. (2016) merely identify the measure, and do not reference any specific regulations.

Application during optimal weather conditions

Weather conditions (i.e., air temperature, precipitation, and wind speed) have a demonstrated effect on ammonia fluxes.[221] The identified measure would involve rapid incorporation of fertilizers into soils after the fertilizers have been applied. The 4 R's "Right time" principle covers the issue that this measure aims to address. The principle is based on timed nitrogen application in order to ensure the availability of nitrogen to the plant during the more nutrient demanding periods. This period is during vegetative growth in annual crops, and during early fruit and nut development in mature trees and vines.[222]

While describing the fertilizer injection measure, Eory et al. (2016) convey that additional work is needed to determine the emission benefits related to fertilizer application with respect to weather.[223] They however do not provide any additional or specific information regarding a measure or identify the reduction potential of its application. Guthrie et al. (2018) identified weather as affecting ammonia emissions by up to 5 percent and provided the recommendation that growers refrain from using urea-based fertilizers during warm, dry, and

windy conditions.[224] After reviewing the two publications referenced in Guthrie et al. (2018) for this measure, Zhang et al. (2017)[225] and Newell et al. (2011)[226], no information regarding concerning weather-related conditions was found. Other publications have demonstrated a link between weather conditions and ammonia emissions, though it is unclear which environmental factors are most appropriate for the various fertilizer types.[227,228] It is particularly important for further research to address the impact of weather and fertilizer application timing under conditions specific to the San Joaquin Valley. Lastly, as has been described previously, Guthrie et al. (2018) and Eory et al. (2016) do not refer to any specific regulations when identifying the measure.

Ammonia emissions from agricultural fertilizers are 111.2 tpd in 2023. Emissions growth from agricultural fertilizers are estimated by farmland acreage projection data developed by the

CARB has not identified effective mechanisms within its authority to regulate air emissions of ammonia from livestock, which overwhelmingly come from the decomposition of manure, or from fertilizers, the second largest category of emissions in the Valley. CARB's main source of authority is the California Health and Safety Code. CARB's authority is primarily over mobile sources, consumer products, and air toxics, as well as methane from livestock (see Cal. Health & Saf. Code §§ 43013, 39666, 39730.7, 41712).

Estimated feasible reductions in ammonia from this emissions source in the Valley are zero tons.

Composting and Other Sources

The District already regulates ammonia emissions from composting operations through District Rules 4565 and 4566. Based on the mitigation measures in practice at facilities

subject to Rule 4565 and 4566, ammonia emissions are already being reduced by 44 percent. With these controls in place, composting accounts for only 2 percent of the District's ammonia emissions; therefore, the District will not be further evaluating this source category at this time.

The other source category consists of ammonia emissions primarily from mobile sources and fuel combustion, which are heavily controlled. Therefore, the District will not be further evaluating this source at this time.

Estimated feasible reductions in ammonia from these emissions sources in the Valley are zero tons.

4. Research

CARB is working to fill knowledge gaps on feasible and effective ammonia controls. Development of effective air pollution mitigation strategies for ammonia requires additional spatiotemporal understanding of atmospheric ammonia emissions that are currently lacking as a result of limited data. CARB is conducting research, both in-house and with external partners, to characterize gaseous ammonia emissions from agricultural activities in the San Joaquin Valley. The results of these studies will help future development of CARB's ammonia emission inventory, SIP, Short-Lived Climate Pollutant Reduction Strategy, and community air protection program (AB 617). Findings from these research projects will help CARB better characterize ammonia emissions in the Valley, as a necessary prerequisite to identifying potential effective measures to achieve additional emissions reductions.

Ammonia emissions in general are not well quantified Statewide and further focused study is needed to facilitate quantification and potential further control strategies that are effective and cost-effective. As an example of the agency's work in this area, CARB's Research Division has developed a new mobile measurement platform equipped with a state-of-the-science ammonia analyzer and other advanced analytical instruments to improve the understanding of various ammonia sources in California. In September and October 2018, CARB staff collaborated with researchers from the University of California, Davis, to quantify emissions from several dairies in the Valley as part of the ongoing projects funded by the California Department of Food and Agriculture, CARB, and industry. Methane, oxides of nitrogen, and other air pollutants and meteorological parameters were measured at or near dairies in addition to ammonia. The major objective is to evaluate the effectiveness of various alternative manure management practices (AMMP) with respect to emission reductions as CARB staff will revisit these dairies after they implement the selected AMMP technologies. This effort is a direct response to Senate Bill 1383 requirements and goals. The AMMP is designed to identify air pollution sources and estimate their emission rates. Its mobility makes it ideal for field measurements that require large spatial coverage, such as mapping ammonia mixing ratios with an emphasis on determining the magnitude of emissions, characterizing spatial variability of emissions, and identifying dominant sources of emissions.

In addition, CARB is undertaking a suite of projects that address research needs. Many projects focus on emissions from dairies, while others, including those with a satellite or remote sensing component, can offer insight into ammonia emissions in the Valley from all source categories. CARB staff is also working with academic researchers and industry representatives to explore potential opportunities to reduce the emissions of ammonia and other air pollutants from dairy manure lagoons which are one of the largest contributors to ammonia in California. Preliminary experiments have been conducted, and further investigation is underway at some Valley dairies with the support from farmers. Additionally, CARB staff is planning to analyze existing satellite data to refine the spatial resolution and allocation of ammonia in California. This may also help evaluate the impact of major wildfires on surface ammonia levels in recent years, and can be used to compare with the estimation methodology in the current ammonia emission inventory associated with wildfires.

Due to research which indicates California is underestimating ammonia emissions in the air, CARB is reviewing and will reassess ammonia estimates in recognition of this research. This effort will help us update our understanding about modeled sensitivity of PM2.5 formation to changes in ammonia emissions.

5. Conclusion

While EPA guidance recommends modeling emissions reductions of PM2.5 precursors of between 30 and 70 percent to evaluate if precursor emissions reductions have a significant impact on PM2.5 levels, CARB and the District have determined that the 30 percent reduction in ammonia emissions is not achievable Moreover, CARB and the District have not identified methods within its authority to control air emissions of ammonia that achieve an overall 30 percent reduction in ammonia emissions. In practice, the District has implemented the best available control measures on livestock operations that have already achieved approximately 25 percent reduction from this source. CARB is not aware of controls that would achieve greater reductions on the order needed to achieve an overall 30 percent reduction of ammonia emissions in the Valley; nevertheless, CARB is pursuing further research specific to California and the Valley to improve our understanding of ammonia emissions from various sources as a necessary prerequisite to identifying potential effective measures to achieve additional emissions reductions.

The District and CARB analyzed potential control measures to reduce ammonia emissions from key source categories in order to evaluate whether a 30 percent reduction in emissions is feasible. Specific to the confined animal facility category, the District conducted a new, extensive evaluation of potential measures to control sources of ammonia emissions. EPA provided the list of measures to CARB and the District and requested that the measures and studies referenced be addressed specifically for the Valley. In this evaluation, the District has identified only a few measures that have the theoretical potential to reduce additional ammonia emissions beyond the practices currently enforced through District Rule 4570 (Confined Animal Facilities). These measures are reducing crude protein content in feed for beef finishing cattle, incorporation of solid manure within 24 hours, and acidifying amendments for poultry litter and manure. Despite the technological and economic feasibility issues of these mitigation measures, the District evaluated the potential emission reductions and the impact they might have on the Valley’s total ammonia emissions inventory if these measures were to be implemented. Overall, ammonia emissions in the Valley can only be reduced from the confined animal facilities source category by 2 percent by implementing these mitigation measures. For the fertilizer category, CARB has not identified effective mechanisms within its authority to regulate air emissions of ammonia from livestock, which overwhelmingly come from the decomposition of manure, or from fertilizers. Furthermore, CARB and the District are unaware of any other jurisdictions with rules for the source. In addition, CARB and the District did not identify feasible control measures for composting or other emissions sources.

Based on the extensive evaluation which identified feasible reductions of only approximately 2 percent, as summarized below in Table 14, CARB and the District conclude that a 30 percent reduction in ammonia emissions is not achievable.

Table 14. Estimated Feasible Emission Reductions

Emissions Category	Emissions (tpd, 2023)	Identified Controls	Feasible Ammonia Reductions
Confined Animal Feeding	186.5	• Reducing crude protein content in feed for beef finishing cattle • Incorporation of solid manure within 24 hours • Acidifying amendments for poultry litter and manure	6.6 tpd
Fertilizers	111.2	No authority or feasible controls identified	0
Composting	6.7	No feasible controls identified	0
Other sources	20.5	No feasible controls identified	0
Total Ammonia	324.9		6.6 tpd

A 2 percent reduction is consistent with the national trend identified in EPA guidance which stated that ammonia changes ranged nationally from an increase of six percent to a decrease of nine percent.[229] Moving forward, updated national guidance on ammonia emission reductions achievable in practice is needed, as well as guidance on available and feasible control measures.

CARB has followed EPA guidance to evaluate whether ammonia contributes significantly to PM2.5 levels that exceed the 15 µg/m3 annual standard NAAQS. Considering relevant contextualizing information including available controls, CARB determined that emissions of ammonia do not contribute significantly to PM2.5 levels that exceed the annual 15 µg/m3 standard in the San Joaquin Valley. Therefore, CARB has excluded ammonia from control requirements in the SIP.

I. INTRODUCTION AND BACKGROUND

A. INTRODUCTION

The California Environmental Quality Act (CEQA) and California Air Resources Board (ARB) policy require an analysis to determine any potentially significant adverse environmental impacts of ARB's regulations. The Renewable Electricity Standard (RES) is proposed to be adopted as a regulation. If adopted, it would advance the standard for the proportion of electricity generation by eligible renewable sources from 20 percent, as established in 2002 by the California Renewables Portfolio Standard (RPS), to 33 percent. The proposed 33 percent RES would modify other provisions contained in the existing RPS, as described in Chapter II.

RES is identified as one of the measures proposed in the Climate Change Scoping Plan (Scoping Plan), which was developed for the purpose of reducing emissions of greenhouse gases (GHG) in California, as directed by the California Global Warming Solutions Act of 2006 (AB 32, Chapter 488, Statutes of 2006). One of the key elements of the Scoping Plan recommendations is "Achieving a statewide renewables energy mix of 33 percent." As described in the Scoping Plan recommendations, "increasing the 20 percent RPS to 33 percent is designed to accelerate the transformation of the electricity sector, including investment in the transmission infrastructure and system changes to allow integration of large quantities of intermittent wind and solar generation," and other eligible renewable sources.

B. THE CALIFORNIA ENVIRONMENTAL QUALITY ACT AND FUNCTIONAL EQUIVALENCY

In PRC Section 21080(a) CEQA states, "Except as otherwise provided in this division, this division shall apply to discretionary projects proposed to be carried out or approved by public agencies, including but not limited to the enactment and amendment of zoning ordinances, the issuance of zoning variances, the issuance of conditional use permits, and the approval of tentative subdivision maps, unless the project is exempt from this division. " ARB determined that adoption and implementation of the proposed 33 percent RES constitutes a "project" as defined by Public Resources Code Section 21000 et seq. The CEQA Guidelines, Section 15378, define a project as:

(a) "Project" means the whole of an action, which has a potential for resulting in either a direct physical change in the environment, or a reasonably foreseeable indirect physical change in the environment, and that is any of the following:

(1) An activity directly undertaken by any public agency including but not limited to public works construction and related activities clearing or grading of land, improvements to existing public structures, enactment and amendment of zoning ordinances, and the adoption and amendment of

viewsheds of State Routes 14 and 58. For wind farms that would be sited along ridgelines and open plains, the wind turbines would be more prominent and would further increase the contrast between the natural and artificial visual environment, potentially damaging the visual character of the area. Views of construction and operation activities may be visible to some viewer groups in the area, including motorists along State Routes 14 and 58, residents in nearby communities, and recreationists using the Pacific Crest Trail. Residents and recreationists would be expected to experience a longer duration of views as opposed to motorists who would be passing through the Tehachapi area at higher speeds. However, the visual impact of wind turbines and associated facilities depends on several variables, including viewing distance, angle of view, and structure placement in the landscape. Because the Tehachapi Wind Resource Area already includes wind farms, it is possible that wind energy development in this area would not substantially exacerbate scenic impacts of State Routes 14 and 58. However, because specific locations are unknown, it is possible that wind turbines could be constructed in more pristine areas, resulting in significant scenic impacts.

Out of State – Low and High Load Conditions
Under the 20 percent low and high load conditions, implementation of the same degree of wind energy resource projects in Montana, the Pacific Northwest, Utah, Southern Idaho, and Wyoming may result in significant adverse effects on scenic vistas, scenic resources, and visual character in these areas. Some of these projects may occur on federal lands, which would subject such projects to environmental review of aesthetic impacts under NEPA. In some cases, renewable energy resource projects may also occur in states where such projects would be subject to the state's environmental review process. In any case, however, implementation of renewable energy resource projects in out-of-state locations may have significant effects primarily because such projects are typically located in areas of undeveloped, uninhabited land and would result in substantial alteration of the visual landscape. Implementation of Mitigation A-1 through A-10 would reduce scenic impacts, but it is uncertain whether mitigation would be sufficient to reduce the impact to a less than significant level.

Scenic impacts of wind energy development under the 20 percent RPS low and high load conditions would be potentially significant. This impact would be expected to occur even without adoption of the RES.

33 Percent Renewable Electricity Standard

Distributed Statewide – Low and High Load Conditions
No additional distributed wind energy is anticipated under the 33 percent RES over and above the 20 percent RPS, so no additional impact would occur from approval of the 33 percent RES.

Tehachapi – Low and High Load Conditions
Under the 33 percent RES, wind energy and transmission development in the Tehachapi area would be the same under both low and high load conditions, and the same as the high load condition under the 20 percent RPS. As such, scenic impacts of

some locations, the visible changes to these scenic resources may be potentially significant.

Out of State – Low and High Load Conditions
Out-of-state scenic impacts under the 33 percent RES, high and low load, for solar thermal would be identical to the 20 percent RPS, high and low load, described above.

Scenic impacts of solar thermal and transmission line development under the 33 percent RES low and high load conditions would be significant.

Solar Photovoltaic

20 Percent Renewable Portfolio Standard

Distributed Statewide – Low and High Load Conditions
Development of solar photovoltaic energy would occur in various locations throughout the State under the 20 percent RPS low and high conditions. Construction and operation of solar photovoltaic panels, access roads, and associated facilities would introduce new elements that have the potential to substantially degrade the existing quality of sites, particularly those in undeveloped areas. While specific locations of distributed solar photovoltaic energy development are unknown, such development may occur in areas with national, state, or county designated scenic vistas, other scenic resources, and State scenic highways. Solar photovoltaic development has the potential to substantially damage scenic resources.

Tehachapi – Low and High Load Conditions
Under the 20 percent RPS solar photovoltaic energy and transmission development is expected to occur in the Tehachapi area under both low and high load conditions. High load conditions under the RPS would require approximately three times the solar photovoltaic generation from this area. Although there are no officially designated State scenic highways in the Tehachapi area, portions of State Routes 14 and 58, which intersect near the Tehachapi Mountains, are eligible for designation. Depending on the locations of solar photovoltaic development, they may extend into the viewsheds of State Routes 14 and 58. Construction of solar photovoltaic facilities would create temporary, adverse changes in the visual character of the Tehachapi area and permanent facilities have the potential to create substantial changes in the visual quality and character of the flat desert areas south of the Tehachapi Mountains. Facility elements may be visible from public vantages, particularly State Routes 14, 58, and 138, which pass directly through the area where solar photovoltaic development would occur. Residents in the community of Rosamond may be affected by construction and operation activities near State Route 14. Some recreationists in the Sierra Pelona Mountains to the south of the Tehachapi area may be affected by the change in visual character, but this would largely depend on where the recreationist is located. Because specific locations of solar photovoltaic projects are unknown, it is possible that facilities could be constructed in pristine areas, resulting in significant scenic impacts.

Out of State – Low and High Load Conditions

Under the 20 percent low and high load conditions, implementation of the same degree of solar photovoltaic energy projects in Arizona/Southern Nevada—though modest—may result in significant adverse effects on scenic resources in these areas. Projects may occur on federal lands, in which case they would be subject to environmental review of aesthetic impacts under NEPA, and projects may also be subject to state environmental policies, rules, and regulations. In any case, however, implementation of solar photovoltaic projects in out-of-state locations may have significant effects primarily because such projects are typically located in areas of undeveloped, uninhabited land. Scenic impacts of solar photovoltaic development under the 20 percent RPS low and high load conditions would be significant. This impact would be expected to occur even without adoption of the RES.

33 Percent Renewable Electricity Standard

Distributed Statewide – Low and High Load Conditions

No additional distributed solar photovoltaic energy is anticipated under the 33 percent RES over and above the 20 percent RPS, so no additional impact would occur from approval of the 33 percent RES.

Tehachapi – Low and High Load Conditions

The amount of solar photovoltaic and transmission development in the Tehachapi area under 33 percent RES low and high load conditions is expected to be the same as under the 20 percent RPS high load scenario, discussed above.

Mountain Pass – Low and High Load Conditions

As with solar thermal, the level of solar photovoltaic energy and transmission development in the Mountain Pass area is anticipated to remain the same under both the 33 percent low and high scenarios. Construction activities and introduction of new solar photovoltaic energy facilities into the desert landscape may impair scenic vistas, resources, and aesthetic character. These visual elements would be visible primarily to motorists traveling on Interstate 15, which passes through the Mountain Pass project area and is a popular route for travelers to Las Vegas, and recreationists at the Primm Valley Golf Course. While not a State-designated scenic highway, San Bernardino County has designated portions of Interstate 15 that pass through the area as having scenic character of visual importance. Motorists are considered to have a low sensitivity to change of existing visual character because of their distance, angle, and duration of views in this area. Construction and operation activities may also be visible to residents in the nearby community of Primm, Nevada, although views may be minimal because of the community's distance from the area.

Although some transmission lines already pass through the Ivanpah Valley, the solar thermal energy facilities would introduce new artificial elements that would contrast photovoltaic with the existing natural environment as well as strong spatial and scale dominance. The proposed project would result in a significant visual change in the site and its surroundings.

Riverside East – Low and High Load Conditions

As with solar thermal, a similar amount of solar photovoltaic energy and transmission development is expected to occur in the Riverside East area under the 33 percent RES low and high load conditions. Construction activities would create a temporary, adverse change in the visual character of the area due to the introduction of heavy equipment in addition to site clearing and grading activities. Operation would introduce new solar photovoltaic energy facilities into the largely undeveloped desert landscape. These visual elements would be visible primarily to motorists traveling on Interstate 10, which passes through the project area, but which is not listed as a State scenic highway. The proposed project would introduce prominent solar photovoltaic structures into the foreground of motorists and into the background of residents in the nearby City of Blythe. Some recreationists at Joshua Tree National Forest to the west of the Riverside East area may also be affected by the substantial visual change in the desert landscape. Construction and operation of solar photovoltaic development would substantially degrade the Riverside East area and its existing natural surroundings by changing the environment to an industrial landscape. This would be a significant impact.

Fairmont –Low and High Load Conditions

Under the 33 percent RES low and high load conditions, development of solar photovoltaic energy and transmission is expected to occur in the Fairmont area. Construction activities would create a temporary, adverse change in the visual character of the Fairmont area due to the introduction of heavy equipment, access roads in addition to site clearing and grading. Construction activities may also alter naturally vegetated areas. Operation of the proposed project would introduce new solar photovoltaic facilities into areas that are largely undeveloped or used for agricultural purposes. These visual elements may be visible to motorists traveling on State Route 138, and to a much lesser extent, on State Route 14 although views from State Route 14 may be indiscernible. The proposed project would introduce prominent structures with an industrial character into the foreground of motorists and into the background of some residents in the nearby cities of Palmdale and Lancaster and the community of Little Rock, As a result, construction and operation of solar photovoltaic facilities would substantially degrade the Fairmont area and its existing natural surroundings.

Out of State – Low and High Load Conditions

Out-of-state scenic impacts under the 33 percent RES, high and low load, for solar photovoltaic would be identical to the 20 percent RPS, high and low load, described above.

Scenic impacts of solar photovoltaic and transmission line development under the 33 percent RES low and high load conditions would be significant.

III.B. AIR QUALITY

This section includes a general description of existing conditions (e.g., types of sensitive land uses and sources located out-of-state), a summary of applicable regulations, and evaluation of potential short-term and long-term air quality impacts associated with the out-of-state implementation of the proposed renewable energy development scenarios. Mitigation is recommended, as necessary, to reduce significant impacts.

As described in the Project Description, the RES Calculator was used to identify out-of-state electricity generation by resource type for: 2008 conditions; 20 percent RPS in 2020 under low and high load conditions; and 33 percent RES in 2020 under low and high load conditions. Tables II-1 and II-2 illustrate comparative data for 2008 (existing conditions for purposes of analysis), RPS and RES under low and high load conditions, respectively. Tables II-3 through II-6 illustrate electricity generation by resource type, by CREZ, for each scenario. Figure II-1 illustrates CREZ locations.

It is important to note that while the RES Calculator output represents the best available data to represent the results of the proposed regulation and a reasonable set of assumptions upon which to assess impacts, the manner in which renewable energy projects would actually come on line cannot be known with certainty. The number of potential future combinations of renewable resource mix, location, and timing, and degree that would satisfy RES requirements is nearly infinite and would depend upon myriad economic, political, and environmental factors. The plausible compliance scenarios identified by ARB and modeled using the RES Calculator represent a reasonable characterization of the way in which the future could unfold; analysis of additional potential future scenarios would not meaningfully add to the body of evidence necessary for ARB to make an informed decision with regard to the proposed regulation.

In addition, as with all of the environmental effects and issue areas, the precise nature and magnitude of impacts would depend on the types of projects authorized, their locations, their aerial extent, and a variety of site-specific factors that are not known at this time but that would be addressed by environmental reviews at the project-specific level.

1. ENVIRONMENTAL SETTING

Note to Reader: The evaluation of the in-State air quality impacts resulting from the renewable energy projects necessary for compliance with the RES is provided in Chapter IX of the RES Staff Report. Based on that analysis, implementation of new in-State renewable energy projects would not generate levels of emissions that conflict with applicable air quality plans, violate or contribute substantially to an existing or projected violation, result in a cumulatively considerable net increase in non-attainment areas, or expose sensitive receptors to substantial pollutant concentrations or odors with mitigation (e.g., compliance with applicable regulations). Thus, in-State air quality impacts from operation of renewable energy facilities is expected to result in beneficial effects. Generally, it is important to note that renewable electricity generation produces fewer pollutants per unit of electricity output than the fossil-fuel generation it would displace and less total electricity would be generated in-State in comparison to existing conditions.

Construction of any new facilities would be subject to site-specific mitigation imposed by local and potentially federal lead agencies and local air districts. Mitigation for construction related air quality impacts is expected to be the same or similar to those detailed below in Mitigation B-1. Please refer to the RES Staff report for additional information.

The following presents an evaluation of the potential out-of-state air quality impacts that could occur with implementation of the 33 percent RES.

(a). EXISTING OUT-OF-STATE SOURCES AND SENSITIVE LAND USES

Out-of-state renewable energy resources are projected by the RES Calculator to be developed in the following general areas: Alberta, Arizona/Southern Nevada, British Columbia, Montana, New Mexico, Northwest, Reno/Dixie Valley, Utah/Southern Idaho, and Wyoming.

The existing air quality environment in the proposed out-of-state areas is influenced by stationary, area, and mobile sources. According to EPA, there are areas within those mentioned above where out-of-state renewable energy resources are projected by the RES Calculator to be developed that are currently designated as nonattainment areas for ozone (8-hour), PM_{10}, $PM_{2.5}$, CO, SO_2, and lead) (EPA 2010). Sensitive land uses in such areas may include residences (e.g., single- and multi-family), schools, hospitals, nursing homes, and other uses that may include segments of the population that are sensitive to poor air quality.

2. REGULATORY SETTING

The following provides a brief description of the Federal and State regulations that could be applicable to an out-of-state renewable energy project. Local regulations may also apply; however, because the specific siting of the renewable energy facilities is not known at this time it would be speculative to present a discussion of applicable local regulations.

Table III.B-1. Applicable Laws and Regulations for Air Quality

Regulation	Description
Federal	
40 Code of Federal Regulations (CFR) (National Environmental Policy Act [NEPA])	NEPA requires all federal agencies to consider environmental factors through a systematic interdisciplinary approach before committing to a course of action. The NEPA process is an overall framework for the environmental evaluation of federal actions.

Table III.B-1. Applicable Laws and Regulations for Air Quality	
Regulation	**Description**
Clean Air Act and 40 CFR, Part 50	The Clean Air Act, which was last amended in 1990, requires EPA to set National Ambient Air Quality Standards (NAAQS) (40 CFR, Part 50) for pollutants considered harmful to public health and the environment. The Clean Air Act established two types of NAAQS. Primary standards set limits to protect public health, including the health of "sensitive" populations such as asthmatics, children, and the elderly. Secondary standards set limits to protect public welfare, including protection against decreased visibility, damage to animals, crops, vegetation, and buildings. EPA Office of Air Quality Planning and Standards (OAQPS) has set NAAQS for six principal pollutants, which are called "criteria" pollutants.
Other Applicable Federal-Level Regulations	This includes all other applicable regulations at the federal level for portions of the project area that are outside of the U.S. (e.g., Canada).
State	
Other Applicable State-Level Regulations	This includes all other applicable regulations at the state level for portions of the project area that are outside of California (e.g., Arizona, Nevada).

3. PROJECT IMPACTS

This section describes the project's out-of-state effects on air quality for the 20 percent RPS and 33 percent RES. The discussion includes the criteria for determining the level of significance of the effects and a description of the methods and assumptions used to conduct the analysis.

As with all of the impacts, the precise magnitude and extent of the impact would depend on the type of renewable energy project authorized, its specific location, its total length and size, and a variety of site-specific factors that are not known at this time. All of these issues would be addressed through project-specific environmental reviews that would be conducted by local land use agencies (e.g., cities, counties) or other regulatory bodies at such time the projects are proposed for implementation. ARB would not be the agency responsible for conducting the project-specific environmental review because it is not the agency with authority for making land use decisions.

(a). METHODOLOGY

Potential out-of-state impacts to air quality were assessed based on the potential for the 33 percent RES to exceed the thresholds of significance identified below. The analysis that is presented below evaluates the change from existing conditions to the 33 percent RES in 2020. However, an incremental portion of these impacts would occur regardless of whether the 33 percent RES is implemented. The CPUC approved the 20 percent RPS and this regulation would be implemented by 2020. The 33 percent RES would further the renewable energy objective and would be added to the 20 percent RPS. Therefore, the analysis below describes the impacts that would occur under the 20 percent RPS, the total impacts that would occur under the 33 percent RES (i.e., existing conditions to 33 percent RES), and the incremental impacts from 20 percent RPS to 33 percent RES. For each of these alternatives, a high and low load scenario is also evaluated (see Section II, Project Description, for additional details).

For some impacts below, the same type and magnitude would occur under each scenario and each alternative. Where this occurs, a combined analysis is presented to streamline the presentation of environmental impacts to avoid unnecessary repetition.

(b). THRESHOLDS OF SIGNIFICANCE

For purposes of this analysis, the following applicable thresholds of significance were used to determine whether implementing the 33 percent RES would result in a significant air quality impacts. The project would result in a significant impact if it would:

- conflict with or obstruct implementation of the applicable air quality plan;
- violate any air quality standard or contribute substantially to an existing or projected air quality violation;
- Result in a cumulatively considerable net increase of any criteria air pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard;
- Expose sensitive receptors to substantial pollutant concentrations; or
- Create objectionable odors affecting a substantial number of people.

IMPACT B-1	**Short-Term Construction Impacts to Air Quality from Out-of-State Project-Generated Emissions of Criteria Air Pollutants and Precursors. Because the specific air quality impacts of the 33 percent RES cannot be identified with any certainty, and construction activities associated with these projects could generate levels that conflict with applicable air quality plans, violate or contribute substantially to an existing or projected violation, or result in a cumulatively considerable net increase in non-attainment areas, this impact is considered *potentially significant* for all renewable energy types under the 33 percent RES (high and low load).**

All Renewable Energy Project Types

All renewable energy projects no matter their size, out-of-state location, or type would be required to seek local land use approvals prior to their implementation. Part of the land use entitlement process requires that each of these projects undergo environmental review consistent with Federal environmental review requirements (e.g., NEPA) or other applicable state requirements. The environmental review process for all renewable project types under either the 20 percent RPS or 33 percent RES would assess whether project implementation would result in short-term construction air quality impacts.

At this time, the specific location, type, and number of renewable energy projects constructed out-of-state is not known and would be dependent upon a variety of market factors that are not within the control of ARB including: economic costs, energy demands, environmental constraints, and other market constraints. Nonetheless, the analysis provided herein provides a reasonable accounting of the types of environmental impacts that would occur with implementation of the 33 percent RES plausible compliance scenarios (high or low load conditions) as discussed below for short-term construction emissions. Further, subsequent environmental review would be conducted at such time that a renewable energy project is proposed and land use entitlements are sought.

During construction of renewable energy projects out-of-state, criteria air pollutant and precursor emissions could be generated from a variety of construction activities and emission sources. These emissions would be temporary and occur intermittently depending on the intensity of construction on a given day. Site grading and excavation activities would generate fugitive PM dust emissions, which is the primary pollutant of concern during construction. Fugitive PM dust emissions (including PM_{10} and $PM_{2.5}$) vary as a function of parameters such as soil silt content and moisture, wind speed, acreage of disturbance area, and the intensity of activity performed with construction equipment. Exhaust emissions from off-road construction equipment, material delivery trips, and construction worker-commute trips could also contribute to short-term increases in PM emissions, but to a lesser extent. Exhaust emissions from construction-related mobile sources also include ROG and NO_x emissions. These emission types and associated levels fluctuate greatly depending on the particular type, number, and duration of usage for the varying equipment. Criteria air pollutants that are also associated with localized concerns (e.g., CO) are discussed under Impact B-3 below.

The site preparation phase typically generates the most substantial emission levels because of the on-site equipment and ground-disturbing activities associated with grading, compacting, and excavation. Site preparation equipment and activities typically include backhoes, bulldozers, loaders, and excavation equipment (e.g., graders and scrapers). Although detailed construction specific information is not available at this time, based on the types of renewable energy projects listed in the Section II, Project Description it would be expected that the primary sources of construction-related emissions include soil disturbance- and equipment-related activities (e.g., use of backhoes, bulldozers, excavators, and other related equipment). Based on typical emission rates and default parameters for above mentioned equipment and activities, construction of a out-of-state renewable energy project could result in hundreds of pounds of daily NO_x and PM_{10}, which may exceed general mass emissions limits depending on the exact location of generation. Thus, because the specific air quality impacts of renewable energy projects necessary to comply with the 33 percent RES cannot be identified with any certainty, and construction activities associated with these projects could generate levels that conflict with applicable air quality plans, violate or contribute substantially to an existing or projected violation, or result in a cumulatively considerable net increase in non-attainment areas, this impact is considered potentially significant for all renewable energy types under the 33 percent RES (high and low load). It is important to note that there is no difference in the impacts that would occur under the 20 percent RPS versus the 33 percent RES, as, based on the modeling, the magnitude of electricity generated from new out of-state renewable projects is relatively similar (e.g., approximately 9,500 GWh versus 10,900 GWh under both low and high load scenarios). Additionally, the magnitude of this impact is influenced more by the how (e.g., size of project footprint and types of construction activities required) and the where (e.g., whether located in a nonattainment area) of the new renewable projects, more so than the total amount of electricity generated.

IMPACT B-2

Long-Term Operational Impacts to Air Quality from Out-of-State Project-Generated Emissions of Criteria Air Pollutants and Precursors. Because renewable generation produces lower levels criteria air pollutants per unit of electricity output than fossil-fuel generation it would displace and less total electricity would be generated out-of-state in comparison to existing conditions, these projects would not be anticipated to result in significant environmental impacts (e.g., generate levels that conflict with applicable air quality plans, violate or contribute substantially to an existing or projected violation, or result in a cumulatively considerable net increase in non-attainment areas). This impact is considered *less than significant* for all renewable energy types under the 33 percent RES (high and low load).

All Renewable Energy Project Types

All renewable energy projects no matter their size, location out-of-state, or type would be required to seek local land use approvals prior to their implementation. Part of the land use entitlement process requires that each of these projects undergo environmental review consistent with Federal environmental review requirements (e.g., NEPA) or other applicable state requirements. The environmental review process for all renewable project types under either the 20 percent RPS or 33 percent RES would assess whether project implementation would result in long-term operational air quality impacts.

At this time, the specific location, type, and number of renewable energy projects constructed out-of-state is not known and would be dependent upon a variety of market factors that are not within the control of ARB including: economic costs, energy demands, environmental constraints, and other market constraints. Nonetheless, as discussed with regards to the in-state projects, renewable generation produces less criteria air pollutants per unit of electrical output than fossil-fuel generation it would displace with implementation of the 33 percent RES plausible compliance scenarios (high or low load conditions). Additionally, in comparison to existing conditions less total electricity would be generated out-of-state under the 33 percent RES (e.g., approximately 98,000 GWh versus 60,000 under the low load scenario and 86,000 under the high load scenario). Further, subsequent environmental review would be conducted at such time that a renewable energy project is proposed and land use entitlements are sought. Thus, project-generated long-term operational emissions of criteria air pollutants would not be anticipated to result in significant environmental impacts (e.g., generate levels that conflict with applicable air quality plans, violate or contribute substantially to an existing or projected violation, or result in a cumulatively considerable net increase in non-attainment areas). It is important to note that there is no difference in the impacts that would occur under the 20 percent RPS versus the 33 percent RES (e.g., in comparison to existing conditions less total electricity would be generated out-of-state under both the low and high load scenarios). This impact is considered less than significant for all renewable energy types under the 33 percent RES (high and low load).

IMPACT B-3	**Impacts to Sensitive Receptors in the Project Area from Exposure to Substantial Pollutant Emissions (e.g., localized criteria air pollutants, toxic air contaminates) and Odors. Because the specific out-of-state air quality impacts of the 33 percent RES cannot be identified with any certainty, and these projects could potentially expose sensitive receptors to substantial localized criteria air pollutants, toxic air contaminants , or odors, this impact is considered *potentially significant* for all renewable energy types under the 33 percent RES (high and low load).**

All Renewable Energy Project Types

As discussed above under Impact B-1, all renewable energy projects no matter their size, location out-of-state, or type would be required to seek local land use approvals prior to their implementation. Part of the land use entitlement process requires that each of these projects undergo environmental review consistent with Federal environmental review requirements (e.g., NEPA) or other applicable state requirements. The environmental review process for all renewable project types under either the 20 percent RPS or 33 percent RES would assess whether project implementation would result in the exposure of sensitive receptors to air quality impacts.

At this time, the specific location, type, and number of renewable energy projects constructed out-of-state is not known and would be dependent upon a variety of market factors that are not within the control of ARB including: economic costs, energy demands, environmental constraints, and other market constraints. Nonetheless, the analysis provided herein provides a reasonable accounting of the types of environmental impacts that would occur with implementation of the 33 percent RES plausible compliance scenarios (high or low load conditions) as discussed below for the exposure of sensitive receptors to substantial emissions. Further, subsequent environmental review would be conducted at such time that a renewable energy project is proposed and land use entitlements are sought.

The primary criteria air pollutant of localized concern is CO. Local mobile-source CO emissions near roadway intersections are a direct function of motor vehicle activity, particularly during peak commute hours, including traffic volume, speed, and delay. Transport of CO is extremely limited because it disperses rapidly with distance from the source under normal meteorological conditions. Under specific meteorological conditions, CO concentrations near roadways and/or intersections may reach unhealthy levels with respect to local sensitive land uses, such as residential areas, schools, playgrounds, childcare facilities, and hospitals. Consequently, CO emissions are typically analyzed at a local rather than a regional level. Additionally, because increased CO concentrations are usually associated with roadways that are congested and with heavy traffic volume, the criteria to determine if project-generated emissions would result in the exposure of sensitive receptors to substantial pollutant concentrations is tied the project’s effect on the delay times and LOS of local intersections.

As discussed in Section M, Transportation and Traffic, although detailed information is not currently available, renewable energy projects would be anticipated to result in short-term construction and long-term operational traffic from worker commute-, maintenance/operation-, and material delivery-related trips. The amount of construction activity would fluctuate depending on the particular type, number, and duration of usage for the varying equipment; and the phase of construction (e.g., demolition, construction, erection). These variations would affect the amount of project-generated traffic for both worker commute trips and material deliveries. The amount of operational traffic would also vary depending on the size and type of renewable energy project. Thus, depending on the amount of trip generation and the location of the renewable energy project, implementation could conflict with applicable programs, plans, ordinances, or policies, specifically the degradation of delay times and LOS of local intersections, which are tied as discussed above to localized CO impacts. Long-term operation of stationary sources could also result in localized CO emissions at sensitive receptors if located at close distance to new renewable energy projects.

During construction of renewable energy projects out-of-state, toxic air contaminants (TACs) could be generated from a variety of construction activities, but primarily composed of exhaust emissions from off-road construction equipment, material delivery trips, and construction worker-commute trips. Construction activities could be located in areas where naturally occurring substances are present in the soil, thatif These emission types and associated levels fluctuate greatly depending on the particular type, number, and duration of usage for the varying equipment. The amount of TAC’s and associated unit risk factors from operational activities would also vary depending on the size and type of renewable energy project. Even though project implementation would be anticipated to produce less TACs overall due to the fact renewable energy production produces less TAC’s per unit of electricity output than the fossil-fuel generation it would displace under the plausible compliance scenarios, the exposure of sensitive receptors is highly dependent on the their distance from the source.

With regards to both project-generated construction and operational TAC emissions, the dose to which receptors are exposed is the primary factor used to determine health risk. Dose is a function of the concentration of a substance or substances in the environment, which is positively correlated with distance from the source, and the duration of exposure to the substance. Thus, a new renewable energy project could be located in an area where sensitive receptors are currently located and no current sources exist, resulting in a net increase in exposure from project implementation.

Lastly, though the types of renewable energy projects listed in the Project Description would not be anticipated to result in any construction-related odor emissions, long-term operational activities could depending on the exact type of stationary sources on-site. Even diesel emissions at a close distance could be considered an objectionable odor source.

In summary, the specific location, type, and number of renewable energy projects constructed out-of-state is not known at this time. However, construction and operational activities could result in the generation of localized CO emissions, TACs, and odors. Thus, because the specific air quality impacts of new renewable projects needed to comply with the 33 percent RES cannot be identified with any certainty, and activities associated with these projects, depending on the exact location of the renewable energy projects in relation to existing sensitive receptors, could result in the exposure thereof to substantial pollutant concentrations or odors, this impact is considered potentially significant for all renewable energy types under the 33 percent RES (high and low load). It is important to note that there is no difference in the out-of-state impacts that would occur under the 20 percent RPS versus the 33 percent RES.

4. MITIGATION

Mitigation is required for the following significant or potentially significant impacts.

Mitigation Measure B-1

- **Proponents for the proposed renewable energy project shall coordinate with local land use agencies to seek entitlements for development of the project including completing all necessary environmental review requirements (e.g., NEPA). The local land use agency or governing body shall certify that the environmental document was prepared in compliance with applicable regulations and shall approve the project for development.**

- **Based on the results of the environmental review, proponents shall implement all mitigation identified in the environmental document to reduce or substantially lessen the environmental impacts of the project.**

- **Comply with local plans, policies, ordinances, rule, and regulations regarding air quality-related emissions and associated exposure.**

- **Apply for, secure, and comply with all appropriate air quality permits for project construction and operations from the local agencies with air** quality jurisdiction and from other applicable agencies (e.g., EPA), if appropriate, prior to construction mobilization.

- Prepare and comply with a dust abatement plan that addresses emissions of fugitive dust during construction and operation of the project.

The proponents and local land use agencies can and should be the parties responsible for the approval and implementation of the renewable energy project and its mitigation. ARB is not a land use agency and would not be responsible for ensuring that this mitigation is implemented. Implementation of the above mitigation would reduce this impact to a less-than-significant level

for all renewable energy types under the 33 percent RES plausible compliance scenarios (high and low load conditions).

Mitigation Measure B-2

- Implement Mitigation M-1 above.

The proponents and local land use agencies can and should be the parties responsible for the approval and implementation of the renewable energy project and its mitigation. ARB is not a land use agency and would not be responsible for ensuring that this mitigation is implemented.

Implementation of the above mitigation would reduce this impact to a less-than-significant level for all renewable energy types under the 33 percent RES (high and low load conditions).

BEFORE THE BOARD OF SUPERVISORS
COUNTY OF KINGS, STATE OF CALIFORNIA

* * * * * *

IN THE MATTER OF AMENDING THE LOCAL CEQA GUIDELINES FOR THE PREPARATION, EVALUATION AND PROCESSING OF ENVIRONMENTAL DOCUMENTS FOR THE COUNTY OF KINGS.	))))))	**RESOLUTION NO. 16-001** **RE: Local Guidelines for the Implementation of CEQA**

WHEREAS, pursuant to Section 21082 of the Public Resources Code of the State of California all public agencies are required to adopt by ordinance, resolution, rule or regulations, objectives, criteria, and procedures for the evaluation of projects, and the preparation of environmental impact reports and negative declarations under the provisions of the California Environmental Quality Act (hereinafter referred to as "CEQA", and found at Public Resources Code Section 21000 et seq; all generic "Section" references are to the Public Resources Code); and

WHEREAS, Section 21082 further requires that the objectives, criteria, and procedures adopted by a public agency shall be consistent with the provisions of CEQA and with the State CEQA Guidelines adopted by the Secretary of the Resources Agency pursuant to CEQA (as found in the California Code of Regulations, Title 14, Division 6, Chapter 3, and hereinafter referred to as the "CEQA Guidelines"); and

WHEREAS, the purpose of this Resolution is to further streamline the local CEQA process by rescinding in its entirety Resolution No. 09-001, adopted January 27, 2009, entitled "Amending the Local CEQA Guidelines for the Preparation, Evaluation and Processing of Environmental Documents for the County of Kings", and replacing it with the local guidelines for the implementation of CEQA set forth in Attachment A.

NOW, THEREFORE, BE IT RESOLVED AS FOLLOWS:

1. This action is exempt pursuant to Section 15061(b)(3) of the *Guidelines* for *California Environmental Quality Act* (*CEQA Guidelines*). This section states that a project is exempt from *CEQA* if the activity is covered by the general rule that *CEQA* applies only to projects, which have the potential for causing a significant effect on the environment. Where it can be seen with certainty that there is no possibility that the activity in question may have a significant effect on the environment, the activity is not subject to *CEQA*. The CEQA Implementation procedures are technical changes concerning general policy for the implementation of CEQA and there is no possibility that adopting these procedures will have a significant effect on the environment..

2. Except as otherwise expressly provided herein, the provisions of CEQA and the CEQA Guidelines are hereby referred to, adopted and made part of this Resolution and a part of the Local Guidelines as hereinafter defined, with the same effect as if fully set forth herein, and all the provisions thereof shall apply to projects proposed to be carried out or given discretionary review and approval by the County of Kings or any organizational subdivision thereof.

3. Resolution No. 09-001 entitled "Amending the Local CEQA Guidelines for the Preparation, Evaluation and Processing of Environmental Documents for the County of Kings" is hereby rescinded in its entirety.

4. The local guidelines in Attachment A of this Resolution are hereby enacted to implement the provisions of the California Environmental Quality Act in the County of Kings (such local guidelines are herein referred to as the "Local CEQA Guidelines").

The foregoing Resolution was passed and adopted on a motion by Supervisor Fagundes, seconded by Supervisor Neves, by said Board of Supervisors at a regular meeting held on the 5th day of January, 2016, by the following vote:

AYES:	**Supervisors Fagundes, Neves, Valle, Pedersen, Verboon**
NOES:	**None**
ABSENT:	**None**

Doug Verboon

Chairman of the Board of Supervisors
County of Kings, State of California

WITNESS my hand and seal of said Board of Supervisors this 5th day of January, 2016.

Melanie Curtis

Melanie Curtis
Deputy Clerk of said Board of Supervisors

ATTACHMENT A

LOCAL GUIDELINES FOR THE PREPARATION, EVALUATION AND PROCESSING OF ENVIRONMENTAL DOCUMENTS IN THE COUNTY OF KINGS, CALIFORNIA

Section 1. Purposes.

These Local Guidelines implement the provisions of the California Environmental Quality Act (CEQA) as contained in Division 13 (commencing at Section 21000) of the Public Resources Code of the State of California and the State CEQA Guidelines, as contained in Chapter 3 (commencing at Section 15000), Division 6, Title 14 of the California Code of Regulations, as adopted by the Secretary of the Resources Agency of the State of California. These Local Guidelines do not apply to ministerial projects, or to those projects which are statutorily exempt or excluded from CEQA review requirements, as set forth in Public Resources Code sections 21080 through 21080.35, or to those projects which are categorically exempt under the provisions of Article 19 (commencing at Section 15300) of the State CEQA Guidelines, or to those projects which are emergency projects under the provisions of Section 15269 of the State CEQA Guidelines.

Section 2. Definitions.

Whenever the following words or phrases are used in these Local Guidelines, unless otherwise defined, they shall have the meaning ascribed to them in this Section. These definitions are intended to clarify but not to replace or negate the definitions used in CEQA or in the State CEQA Guidelines, beginning at Section 15350, which are included herein by reference.

a. Consultant. An individual consultant or a consulting firm with expertise in environmental sciences and the preparation of environmental documents.

b. County or County Department. County or County Department means Kings County and any organizational subdivision thereof.

c. EAC - Environmental Advisory Committee - Committee. An informal committee appointed by the Board of Supervisors to advise County boards, commissions, committee, and departments on environmental matters, associated with their individual areas of expertise, concerning the implementation of CEQA, made up of the following members:

Kings County Health Officer,
Kings County Community Development Agency Director,
Kings County Director of Public Works,
Kings County Agricultural Commissioner and Sealer of Weights and Measures,
U.C. Cooperative Extension Services Farm Advisor, and
The Manager of the Kings Mosquito Abatement District.

d. Professional Services Agreement. An agreement between the County and a consultant which specifies the work that will be performed for the preparation of environmental documents and the cost of preparing such a document.

e. Reimbursement Agreement. An agreement between the County and the project proponent to reimburse the County for the actual cost to prepare the environmental documents for the project, including the cost of the "Agreement for Professional Services" and administrative costs incurred by County staff in processing the project.

f. Indemnification Agreement. An agreement between the County and the project proponent to reimburse the County's actual cost associated with challenges to the environmental documents prepared by, or under the direction of, the County for the project and to defend and indemnify the County against any and all challenges to the County's review, consideration, processing or approval of the project application.

g. Faithful Performance/Payment Bond. A performance bond, payment bond, cash deposit, letter of credit, or other suitable financial instrument approved by the County that is convertible to cash, or any combination of the above,, provided by the applicant to ensure the faithful performance of the project proponent's obligations, and/or the payment of amounts due, under a Reimbursement Agreement and/or an Indemnification Agreement entered into between the County and the Project Proponent under the terms and provisions of these Local Guidelines.

Section 3. Kings County Environmental Advisory Committee (EAC).

a. The Kings County Environmental Advisory Committee EAC shall consist of the following six members:

   Kings County Health Officer,
   Kings County Community Development Agency Director,
   Kings County Director of Public Works,
   Kings County Agricultural Commissioner and Sealer of Weights and Measures,
   U.C. Cooperative Extension Services Farm Advisor, and
   The Manager of the Kings Mosquito Abatement District.

b. The EAC shall be advisory only and will not hold public meetings. Each EAC member may provide written comments determined by the member to appropriately reflect that member's general and specific environmental concerns related to his or her area of expertise.

c. Duties of the Members of the EAC: The principal duty of the members of the EAC shall be to review initial studies which are submitted by County Departments during the 20-day public review period for proposed negative declarations and the 30-day or 45-day public review period for draft EIRs required by CEQA Section 21091. Committee members may make any of the following recommendations:

   1) Recommend approval of the initial study as a negative declaration, if, based upon the initial study, the Committee member determines that the project will not have a significant effect on the environment. Failure to notify the Planning Division of the Community Development Agency within the specified review period, indicates acceptance of the initial study as submitted; or

   2) In writing, request specific changes to the draft initial study, and with those specified changes recommend that the decision maker adopt a negative declaration; or

   3) In writing, recommend the preparation of an environmental impact report if, based upon the initial study, the Committee member believes that the project will have a significant adverse effect on the environment. The committee member shall specify, in writing, what effects on the environment he or she believes will be significant and why.

d. Each EAC member shall also be responsible for recommending to the Board of Supervisors' requests for additions to, or deletions from, the list of classes or projects that are exempt from environmental review pursuant to Sections 21084 through 21086, inclusive, of CEQA.

e. Limitations of Review by Environmental Advisory Committee: The review of negative declarations and environmental impact reports by the members of the EAC shall be advisory in nature and shall be limited to a determination of the objectivity and adequacy of the environmental documents submitted to its members, and shall ensure that the decision maker has sufficient information about the possible impacts to the environment, in the judgment of the committee member, that the project may cause. Committee members shall not consider the value of the project itself or whether the project should be approved or denied. Such determination is solely the responsibility of the decision maker for the project.

Section 4. Ministerial Projects and Actions in Kings County

Section 21080(b)(1) of CEQA provides that the Act does not apply to ministerial projects proposed to be carried out or approved by public agencies. Section 15268 of the State CEQA Guidelines states that the determination of what is "ministerial" can most appropriately be made by the public agency involved, and that each public agency should identify or itemize those projects and actions which are deemed ministerial.

The following is a non-exclusive list of types of projects that are ministerial and therefore exempt from CEQA review requirements:

a. Sheriff-Animal Control

1. Dog Licenses

b. Agricultural Commissioner-Sealer

1. Agricultural crop moving permits

c. Building Division of the Community Development Agency

1. Plan check reviews
2. Building Permits (including Electrical, Plumbing, and Mechanical Permits)
3. Demolition Permits
4. Mobile Home Installation Permits
5. Relocation Inspections and Permits
6. Utility Service Connections and Disconnections
7. Compliance Inspections and Reports
8. Water well permits

d. County Clerk

1. Marriage Licenses

e. Fire Department

1. Fireworks Sales Permits
2. Weed Abatement Program

f. Health Department

1. Food Vendor's Permits
2. Water Supply Permits (small public water systems and state small water systems)
3. Underground Storage Tank Permits, Authority to Construct, and Authority to Abandon
4. Hazardous Materials Business Plan and Inventory approvals
5. Risk Management and Prevention Program approvals
6. Medical Waste Management Registrations
7. Limited Quantity Medical Waste Hauler Exemptions
8. Registration of businesses engaged in the cleaning of septic tanks, chemical toilets, cesspools, and seepage pits
9. Reserved.
10. Plan approval for construction, modification, or remodeling of food facilities, public swimming pools and spas, on site sewage disposal systems, small public water systems, state small water system and/or underground storage tanks (including piping)
11. Occupational health and safety consultation services
12. Body art registrations

g. Planning Division of the Community Development Agency

1. Site Plan Reviews conducted by the Zoning Administrator under the provisions of Article 16 of the Kings County Development Code.
2. Land divisions exempted by Sections 2306 and 2308.I of Article 23 of the Kings County Development Code.
3. Certificates of Compliance
4. Lot Line Adjustments
5. Annual Fire Arms Dealers Reviews
6. Code enforcement investigations and orders for abatement of nuisances and violations
7. Abandoned Vehicle Abatement Program investigations and orders for abatement
8. Certificates of Voluntary Parcel Merger
9. Temporary Use Permits

h. Public Works Department

1. Encroachment Permits
2. Moving permits
3. Traffic control activities

i. Tax Collector
1. Dance, explosive, gun, and solicitors licenses
2. Rubbish disposal operator's license

A notice of exemption shall be filed for all projects determined to be statutorily, categorically or otherwise exempt from CEQA environmental review.

Section 5. Initial Study.

The initial study process shall be conducted according to the procedures outlined in the State CEQA Guidelines, Article 5, beginning with Section 15060.

The County department initiating a public project or receiving an application for discretionary approval of a private project may prepare its own initial study, or submit a description of the project to the Planning Division of the Community Development Agency for environmental review. If a project description is submitted to the Planning Division, the Planning Division shall conduct an initial study pursuant to Section 15063 of the State CEQA Guidelines and these Local Guidelines to determine if the project may have a significant effect on the environment. The County department or the applicant shall provide any additional information the Planning Division may require in preparing the initial study. Failure to provide the requested information in a timely manner may cause the application not to be certified as complete, and delay the development of the required environmental documents.

Section 6. Time Limits for the Certification of Environmental Documents.

Pursuant to Section 21151.5 of CEQA and Article 8 of the State CEQA Guidelines, the County of Kings hereby establishes one year as the time limit for the completion and certification of environmental impact reports, and 180 days for the completion and adoption of negative declarations, for projects which require environmental review. The commencement and running of these time periods shall be governed by CEQA and the CEQA Guidelines.

Extensions of Time for EIR's: Extensions of time for the processing of EIR's may be approved once, for an additional period not to exceed 90 days, by the Lead Agency provided that it finds that compelling circumstances justify the extension of time and that the project applicant consents to the specified extension, pursuant to Government Code Section 65957 and State CEQA Guidelines Section 15108. Extensions exceeding 90 days may be approved where the law expressly otherwise provides for such additional extensions.

Section 7. Deposit and Accounting on Private Project.

All applications for the discretionary review of private projects by the County shall include a fee, subject to Section 21089 of CEQA, in an amount set by Ordinance of the Kings County Board of Supervisors, at the time the project application is filed with the Planning Division of the Community Development Agency to cover the cost of preparation of the initial study.

If it is determined that an EIR should be prepared, the applicant shall be required to pay the cost of preparing the EIR (see Section 2 d, e, f, and g above). The Planning Division shall ensure the EIR is prepared according to the procedures described in Article 7 (Section 15084 through 15097) of the CEQA Guidelines.

The Planning Division may prepare the required documents, with Board of Supervisors approval, by engaging the services of a consultant with expertise in preparing environmental documents, based on a detailed work plan approved by the Planning Department staff, and made a part of the "Agreement for Professional Services", shall be submitted to the project applicant who shall enter into a *Reimbursement Agreement* with the County and deposit in an interest bearing account in the County Treasury the amount of the cost shown in the detailed work plan (agreement), plus an administrative fee determined by the Community Development Agency Director to be necessary to defray the cost of administering the agreement with the consultant and the staff time necessary to process the project to its completion.

As an alternative the applicant may submit detailed information in any form, including the form of a draft EIR. The Planning Division, with Board of Supervisors approval, may engage at the expense of the applicant the services of a consultant with expertise in preparing environmental documents, to advise the County on the adequacy of the information submitted, including, but not limited to, a draft EIR, if any is submitted. Reimbursement for the costs of the County's consultant shall be the same as described above.

An accurate accounting shall be kept by the Planning Division, with assistance from the County Department of Finance, of the actual cost of preparing and administering the EIR and shall be made available to the applicant at his request. Upon the completion of the project, after the decision maker's final action, the Planning Division shall refund to the applicant any money remaining in the account, including interest that was earned and not used.

Section 7.5. Indemnification and Bonding.

In its sole and absolute discretion, the County may determine that it has exposure to potential extraordinary costs and require an applicant to provide the county indemnification against extraordinary costs associated with the review and processing of a development application. The extraordinary costs the County may incur associated with the review and processing of a development application, may include, but are not limited to, applications for development entitlements requiring preparation of environmental impact reports, specific plans, and major general plan amendments, large urban development projects, project decisions that are appealed or challenged through law suits, etc. In addition, if it is determined that an Indemnification Agreement is required, the applicant will be required to provide a bond in an amount sufficient to ensure that the applicant's indemnification of the County is sufficient to protect the public interest in case of challenges to the process or action of the County related to the project, or failure of the applicant to provide the County with required reimbursements for the cost of the application review and processing under the terms of the Reimbursement Agreement. In its sole and absolute discretion, the County may determine that the Reimbursement Agreement and the Indemnification Agreement be combined as one document. The form, nature and amount of the bond and/or bonds or other suitable financial instrument, required under the terms of these Local Guidelines and in the light of any risks associated with a particular project shall be in the sole and absolute discretion of the County.

Section 8. Action by the Decision-Maker.

(a) When a proposed negative declaration has been forwarded to the decision-maker, the decision-maker shall, prior to making a decision on the project, either approve the negative declaration based upon a finding that the project will not have a significant effect on the environment, or shall refer the matter to the Planning Division of the Community Development Agency for preparation of an EIR, or mitigated negative declaration, based upon a finding that the project may have a significant effect on the environment. If the matter is referred for additional review, the decision maker shall take no further action on the project until a final EIR, or mitigated negative declaration, has been prepared as required by law.

(b) When a final EIR has been prepared and processed according to Article 7, beginning with Section 15080 of the State CEQA Guidelines, the decision-maker shall, prior to making a decision on the project, certify that the final EIR has been completed in compliance with CEQA and the State CEQA Guidelines, and shall review and consider the information contained in the final EIR. Based upon information contained in the final EIR, when the decision-maker finds that the project will have a significant effect on the environment, the decision-maker shall state in writing reasons to support its decision to approve or carry out the project based upon information contained in the final EIR or other information contained in the record.

Section 9. Mitigation Reporting and Monitoring Program.

When approving projects for which mitigation measures are required and adopted, the decision maker shall adopt as part of the approval action a "Mitigation Reporting and Monitoring Program", pursuant to Section 21081.6 of CEQA and Section 15097 of the State CEQA Guidelines, for the changes to the project. The "Mitigation Reporting and Monitoring Program", then becomes a condition of approval to mitigate or avoid significant effects on the environment. Failure of the project applicant to comply with the reporting requirements and mitigation measures are grounds for permit revocation or correcting the effects on the environment at the project applicant's cost.

The decision maker may require the applicant to deposit an amount of money estimated to offset the cost of monitoring the development and operation of the project into an interest bearing account in the Kings County

Treasury. Upon completion of the monitoring program any unused money in the account shall be returned to the applicant.

Section 10. Notice of Determination.

After making a decision on a project, the decision-maker shall cause to be filed a Notice of Determination, pursuant to Section 21080.4 of CEQA and 15094 of the State CEQA Guidelines. Such notice shall include a brief description of the project, the decision of the decision-maker to approve (carry out) or disapprove (not carry out) the project, the determination of the decision-maker whether the project will or will not have a significant effect on the environment, and a statement whether an environmental impact report has been prepared. The Planning Division of the Community Development Agency shall ensure that such notices are filed.

Section 11. Duties of the County Clerk.

All notices submitted to the County Clerk pursuant to CEQA shall posted by the County Clerk at the place designated by the County Clerk for the posting of all official notices. Members of the general public requesting copies of said notices shall be charged for the actual cost of reproducing that copy. The County Clerk shall prepare and maintain a list of the names and mailing addresses of all persons requesting review of a particular notice.

Section 12. Severability.

If any provision of these Local Guidelines or the application thereof to any person or circumstances is held invalid, such invalidity shall not affect other provisions or applications of these Local Guidelines which can be given effect without the invalid provision of application thereof, and to this end the provisions of these Local Guidelines are severable.

Site Plan Review No. 23-14 (Felicita Dairy)

PROJECT APPLICANT:
4-Creeks, Cole Martin, 324 S. Santa Fe St., Visalia, CA 93292
(559) 802-3052

PROJECT LOCATION - Specific:
22154 4th Ave.

PROJECT LOCATION - City
Hanford

PROJECT LOCATION - County:
Kings

DESCRIPTION OF PROJECT:
The applicant is proposing to construct a new anaerobic digester and ancillary equipment at the existing Felicita Dairy, located at 22154 4th Ave., Hanford, Assessor's Parcel Number 028-280-011. The proposed application includes the installation of a 360' L x 175' W x 25' D anaerobic digester and ancillary equipment. The biogas produced by the digester is proposed to be transported through a low-pressure pipeline to an onsite biogas conditioning pad for cooling and compression prior to entering the biogas collection line. It will then be transported to a centralized biogas upgrading facility, located on Assessor's Parcel Number 228-090-009 in Tulare County (Tulare County Special Use Permit No. PSP 18-015), for conditioning and electrical generation.

Document Description
CalBioGas South Tulare LLC proposes to construct 8.8 miles of a pressurized underground gas pipeline within portions of the County of Tulare rights-of-way of Roads 96, 128, 132 and 152; Avenues I84, 192 and 208; and Spacer Drive D 134), south of the City of Tulare. The intent of the project is to transport dairy biogas from participating dairies to a Southern California Gas Company mainline tie-in facility. The scope of the project consists of the installation of HDPE PE4710 SDR 11 gas pipeline and concomitant safety equipment along the 8.8-mile alignment. On August 18, 2020, the Tulare County Board of Supervisors approved an indemnification agreement to allow some segments of the underground pipeline to utilize County rights-of-way within easements along or across public roadways. All of Tulare County will benefit as the Project would recover manure methane at dairies and using the methane as a renewable source of natural gas thereby reducing greenhouse gas emissions.

Notice of Exemption

Exempt Status

Categorical Exemption

Type, Section or Code

Sec. 15301, Class 1, and Sec. 15303, Class 3

Reasons for Exemption

The Project will not involve any new developments or changes to existing land uses, nor are any proposed, there will be no additional vehicular trips generated as a result of the proposed Activity/Project. The Activity/Project will result in no adverse impact to the environment including aesthetics, air quality, agriculture, biology, cultural, greenhouse gases, hazards/hazardous materials, land use/planning, noise, public services, traffic, or utilities/service systems. Furthermore, the proposed Project site will be required to comply with applicable San Joaquin Valley Unified Air District rules and regulations, including but not limited to, Rule 2010 (Permits Required), Rule 2201 (New and Modified Stationary Source Review), and Rule

9510 (indirect Source Review). The Activity/Project will result in reduction of methane-related GHG by using methane gas emissions from the dairies as an alternative/renewable fuel source, is consistent with draft Tulare County Dairy Climate Action Plan (which incorporates strategies to promote the use of renewable energy sources, including digesters for energy-production), and is also consistent with and implements the California Environmental Protection Agency Air Resources Board's Short-Lived Climate Pollutant Reduction Strategy March 2017; Methane Emissions Reductions from Dairy Manure. As the equipment modification will occur at an existing site and pipelines for this Activity/Project will remain within County of Tulare Rights-of-Way, this action is consistent with 14 Cal. Code Regs. Section 15301 (b) Existing facilities or both investor and public owned utilities used to provide electric power, natural gas, sewerage, or other public utility services and; 14 Cal. Code Regs. Section 15303(d) Water main, sewage, electrical gas, and other utility extensions, including street improvements, or reasonable length to serve such construction. Therefore, the use of CEQA Guidelines Sections 1530l (b) and 15303 (d), as noted above, are applicable and appropriate for this Activity/Project.

SB 535 Disadvantaged Communities

California Climate Investments to Benefit Disadvantaged Communities

Disadvantaged communities in California are specifically targeted for investment of proceeds from the state's Cap-and-Trade Program. These investments are aimed at improving public health, quality of life and economic opportunity in California's most burdened communities, and at the same time, reducing pollution that causes climate change. The investments are authorized by the California Global Warming Solutions Act of 2006 (Assembly Bill 32, Nunez, 2016).

In 2012, Senate Bill (SB) 535 (De León, Chapter 830, Statutes of 2012) established initial requirements for minimum funding levels to "Disadvantaged Communities" (DACs). The legislation also gives CalEPA the responsibility for identifying those communities, stating that CalEPA's designation of disadvantaged communities must be based on "geographic, socioeconomic, public health, and environmental hazard criteria".

In 2016, Assembly Bill (AB) 1550 (Gomez, Chapter 369, Statutes of 2016) directed CalEPA to identify DACs and also established the currently applicable minimum funding levels:

- At least 25 percent of funds must be allocated toward DACs
- At least 5 percent must be allocated toward projects within low-income communities or benefiting low-income households
- At least 5 percent must be allocated toward projects within and benefiting low-income communities, or low-income households, that are outside of a CalEPA-defined DAC but within ½ mile of a disadvantaged community.

Final Designation of Disadvantaged Communities (May 2022)

English | En Español

After receiving public input at workshops and in written comments, in May 2022, CalEPA released its updated designation of disadvantages communities for the purpose of SB 535. In this designation, CalEPA formally designated four categories of geographic areas as disadvantaged:

1. Census tracts receiving the highest 25 percent of overall scores in CalEnviroScreen 4.0 (1,984 tracts).
2. Census tracts lacking overall scores in CalEnviroScreen 4.0 due to data gaps, but receiving the highest 5 percent of CalEnviroScreen 4.0 cumulative pollution burden scores (19 tracts).
3. Census tracts identified in the 2017 DAC designation as disadvantaged, regardless of their scores in CalEnviroScreen 4.0 (307 tracts).
4. Lands under the control of federally recognized Tribes. For purposes of this designation, a Tribe may establish that a particular area of land is under its control even if not represented as such on CalEPA's DAC map and therefore should be considered a DAC by requesting a

consultation with the CalEPA Deputy Secretary for Environmental Justice, Tribal Affairs and Border Relations at TribalAffairs@calepa.ca.gov.

The designation takes into account the latest and best available data and considers factors related to data unavailability. This designation will go into effect on July 1, 2022, at which point programs funded through California Climate Investments will use the designation in making funding decisions.

Disadvantaged Communities Map

[Click to open this map in a new window]

CalEPA California Environmental Protection Agency

SB 535 Disadva

State's Cap-and-Trade Program specifically targeted for investment in disadvantaged communities in California. These funds must be used for programs that further reduce emissions of greenhouse gases.

Senate Bill 535 (De León, Statutes of 2012) directed that at least a quarter of the proceeds go to projects that provide a benefit to disadvantaged communities and at least 10 percent of the funds go to projects located within those communities. The legislation gives CalEPA the responsibility for identifying those communities.

How to use this map

- Use your mouse or touchpad to pan around.
- Zoom in/out with a mouse wheel or the +/- icons.
- Search by location or census tract number with the **search icon**.
- Click on a census tract to view additional information in the pop-up window.
- Dock the pop-up window to the side of the screen by clicking the **dock** icon.
- Export a map view that includes the legend and popup using the **screenshot** widget.
- Click the links in the header to view additional resources related to SB 535 Disadvantaged Communities.

SB 535 Disadvantaged Communities 2022 (Census Tracts and Tribal Areas)

Download SB 535 CalEnviroScreen Data

In addition to the interactive map above, SB 535 disadvantaged communities data is available for download in other formats:

- [SB 535 Excel Spreadsheet and data dictionary (May 2022)]. There are two files in this zipped folder. 1) a spreadsheet showing the list of census tracts identified as disadvantaged communities, a list of the Federally recognized tribal areas identified as disadvantaged communities, and the raw data and calculated percentiles for individual indicators and combined CalEnviroScreen scores for census tracts identified as disadvantaged communities. 2) a pdf document including the data dictionary.
- [SB 535 ArcGIS Geodatabase (May 2022)]: A zipped file which can be unzipped, then opened using ArcGIS software to view the results. (ArcGIS is a paid subscription)

Service URL: ArcGIS feature service:
https://services1.arcgis.com/PCHfdHz4GlDNAhBb/arcgis/rest/services/SB_535_

Additional information as well as the previous identification of disadvantaged communities from 2017 using CalEnviroScreen 3.0 is available on the CalEPA page.

For questions, please contact CalEnviroScreen@oehha.ca.gov or (916) 324-7572.

Analysis of Progress toward Achieving the 2030 Dairy and Livestock Sector Methane Emissions Target

Final

March 2022

CALIFORNIA AIR RESOURCES BOARD

Table of Contents

List of Figures

List of Tables

Executive Summary

California took a major step toward reducing greenhouse gas (GHG) emissions and combatting climate change when the Legislature enacted Assembly Bill 32 (Núñez, Chapter 488, Statutes of 2006), which requires the State to reduce GHG emissions to 1990 levels by 2020. California achieved this target in 2016, four years earlier than mandated. To achieve deeper reductions, the Legislature enacted Senate Bill (SB) 32 (Pavley, Chapter 249, Statutes of 2016), which requires the State to further reduce GHG emissions to 40 percent below 1990 levels by 2030. In the same year, the Legislature enacted SB 1383 (Lara, Chapter 395, Statutes of 2016), which recognizes the immediate climate benefits of reducing short-lived climate pollutants (SLCP). In the 2017 Scoping Plan Update, the plan for achieving GHGs reductions in the State, the California Air Resources Board) CARB describes that short lived climate pollutant (SLCP) reductions account for about one-third of the cumulative GHG emissions reductions the State is relying on to achieve the statewide 2030 GHG emissions target established under SB 32.

Short-lived climate pollutants, including methane, are powerful climate forcers that have a relatively short atmospheric lifetime, but a high global warming potential compared to other GHGs such as carbon dioxide. SB 1383 establishes SLCP reduction targets and requires CARB to implement a Short-Lived Climate Pollutant Reduction Strategy (Strategy) to achieve these targets. The law sets a 2030 methane emissions reductions target for the dairy and livestock sector (2030 target), which produces more than half of the State's methane emissions. This target is a reduction of 40 percent below 2013 levels, or a reduction of 9 million metric tons carbon dioxide equivalent ($MMTCO_2e$)[1] by 2030. SB 1383 also requires CARB, in consultation with the California Department of Food and Agriculture (CDFA), to analyze the progress that the sector has made toward achieving the 2030 reduction target and achieving the goals identified in the SLCP Strategy, including progress made in overcoming technical and market barriers to implementing methane emissions reductions measures identified in the Strategy. This Analysis of Progress toward Achieving the 2030 Dairy and Livestock Sector Methane Emissions Target (Analysis) is responsive to that mandate.

Dairy and livestock methane emissions originate from two primary sources, manure management and enteric fermentation. Manure methane emissions can be reduced through two primary methods—installation of an anaerobic digester and alternative

[1] This emissions reduction estimate is calculated using the 100-year global warming potential (GWP) for methane (IPCC, 2007: Climate Change 2007: Synthesis Report; Contribution of Working Groups I, II and III to the Fourth Assessment Report of the Intergovernmental Panel on Climate Change [Core Writing Team, Pachauri, R.K and Reisinger, A. (eds.)]; IPCC, Geneva, Switzerland, 104 pp (AR4)). The Short-Lived Climate Pollutant Reduction Strategy estimated emissions using the 20-year GWP (AR4).

manure management practices. Anaerobic digesters capture methane-rich biogas for beneficial uses, including in electricity generation and fossil natural gas displacement. Alternative manure management practices reduce manure methane emissions in ways that do not involve an anaerobic digester. Examples include solid separation, conversion to dry scrape, and pasture-based management. Both digester and alternative manure management practices reduce GHG emissions and can improve water quality and nutrient management. Enteric methane emissions can be reduced through genetic selection, diet modification, and feed additives.

This Analysis shows that the dairy and livestock sector is projected to achieve just over half of the annual methane emissions reductions necessary to achieve the target by 2030 through modifications to manure management systems—primarily using anaerobic digesters—and additional reductions through decreases in animal populations. Figure ES-1 shows significant emissions reductions through 2030 absent additional funding after fiscal year 2019-20.[2]

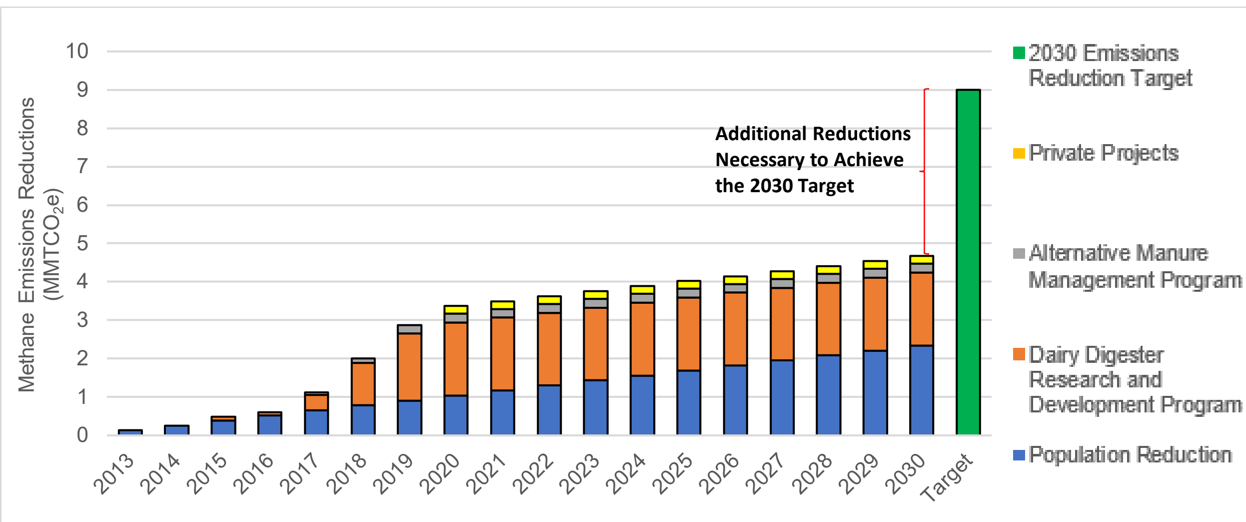

Figure ES-1. Projected Annual Methane Emissions Reductions through 2030 without Additional Funding beyond FY 2020-21

To meet the 2030 target, the dairy and livestock sector will need to achieve considerable emissions reductions from additional manure management projects, proven enteric mitigation strategies, or a combination of both over the next few years.

To understand what level of resources are needed to achieve the target, CARB staff looked at existing dairy methane emissions reduction efforts, including both grant

[2] This does not include $32 million in FY 2021-22 appropriations because it is uncertain how these appropriations will be allocated.

programs that fund the initial capital costs and market-based programs that incentivize GHG emissions reductions or low carbon fuel production.

Over the past six years, California Climate Investments (CCI)—the program that utilizes the State's Cap-and-Trade Program auction proceeds to facilitate GHG emissions reductions—has offset some capital costs through two CDFA grant programs to reduce manure methane emissions: the Dairy Digester Research and Development Program and the Alternative Manure Management Program. An approximate appropriation of $289 million in CCI funds has facilitated the construction of 233 dairy and livestock GHG emissions reduction projects. Many of these manure methane reduction projects are also generating environmental credits through CARB's Cap-and-Trade Program, Low Carbon Fuel Standard (LCFS) Program, and the federal Renewable Fuel Standard (RFS) Program. These projects, cumulatively funded through FY 2019-20, are expected to deliver the 2.0 $MMTCO_2e$ in annual methane emissions reductions noted above from manure management systems by 2030, or about 22 percent of the reductions necessary to achieve the 2030 target.

New or expanded local, State, or federal incentives or funding mechanisms could potentially accelerate the capture and beneficial use of California biomethane, provide additional revenue necessary to ensure that California's dairy manure methane emissions are captured, and direct the biogas to difficult-to-decarbonize sectors. Replacing fossil natural gas with upgraded dairy biogas (biomethane) or other alternatives is important for California's near and longer-term climate goals, but the cost to procure biomethane can be six to ten times more expensive than fossil natural gas. This cost disparity is almost entirely associated with the cost of bringing biomethane to market and will likely persist into the future. This is one of the primary reasons incentives are needed for California's dairy and livestock sector to adopt methane reduction strategies that also support the transition away from fossil natural gas supplies. Additional funding could also accelerate the adoption of alternative manure management projects. These projects provide climate benefits through avoided methane production and environmental co-benefits including water quality improvements and conservation, reduction of synthetic fertilizer usage and improvement of nutrient management, as well as groundwater protection.

Through coordinated State, industry, and utility efforts, the dairy and livestock sector has made meaningful progress in overcoming technical barriers to digester projects, interconnecting to utility electrical grids and pipeline networks, and meeting biomethane pipeline injection standards. Improved environmental credit certainty has also reduced the most considerable market barriers to digester projects by helping project developers obtain funding and financing. Challenging sector economics, insufficient availability of public funds, and underdeveloped markets for value-added manure products are persistent market barriers for both digester and alternative manure management projects. There has been limited progress in overcoming technical barriers to alternative manure management practices because emissions reductions vary based on site-specific factors. There has also been limited progress in overcoming both technical and market barriers to enteric reductions. Enteric methane-reducing feed additives may achieve considerable near-term emissions reductions. There are two commercially available products that were developed for enteric methane mitigation, with potential emissions reductions up to 10-20 percent. Additional feed additives are under development that may provide larger enteric methane emissions reductions.

Despite progress in overcoming barriers, there is more to do to ensure that the State meets the 2030 target. Remaining barriers may be overcome through multiple reasonable efforts, including allocation of additional local, State, or federal funding or incentives. If the remaining reductions needed to achieve the 2030 target are met through a mix of California dairy projects in which half are dairy digesters and half are alternative manure management projects, then at least 420 additional projects may be necessary. This approach would cost an amount between $0.8 and $3.7 billion, which could be supported by local, State, and federal funding, or other financial mechanisms, such as the pilot financial mechanism outlined in SB 1383.[3] If, going forward, only digester projects were developed to achieve the target, approximately 230 additional digesters may be needed, at a cost between $0.7 and $3.9 billion depending on the types of technologies selected. For example, prioritizing deploying digesters with internal combustion engines is the lowest-cost option ($0.7 billion) to achieve the 2030 target, but this would result in on-site criteria pollutant emissions. Alternatively, deployment of digesters that utilize fuel cell technology may avoid these emissions, but at a significantly higher cost ($3.9 billion). Finding 1-6 of this Analysis describes project types, technologies, and cost ranges. With respect to alternative manure management practices, based on currently funded projects and reduction trends observed to date, staff's analysis indicates that the State would be unable to achieve the 2030 dairy and livestock sector target through deployment of alternative manure management practices alone. A combination of dairy digesters, alternative manure management, enteric strategies, and dairy herd size population decreases will be needed to meet the 2030 target.

[3] On February 24, 2022, the California Public Utilities Commission approved Decision 22-02-025 adopting biomethane procurement standards pursuant to SB 1440 (Hueso, Chapter 739, Statutes of 2018), including procurement of biomethane from the California dairy and livestock sector.

Regardless of the project and technology mix used, the most important factors for achieving the 2030 target are ongoing capital funding for new methane emissions reduction projects, continued revenue streams that incentivize dairy biogas capture and beneficial use, and an available and accepted means of reducing enteric methane emissions. Even with considerable progress toward achieving the target since the enactment of SB 1383, the statute requires CARB to adopt a regulation to meet the target, provided that certain conditions are met. Further, CARB is only authorized to implement regulations to meet the 2030 target after January 1, 2024, provided that CARB, in consultation with CDFA, determine the regulations are technologically and economically feasible, cost-effective, include provisions to minimize and mitigate potential leakage, and include an evaluation of the achievements made by incentive-based programs. In designing a regulation for methane emission reductions, CARB staff will consider reasonable strategies to support the sector in meeting the 2030 target, which may include strategies that further support biogas capture and end-uses needed to advance the State's carbon neutrality efforts.

While the California dairy and livestock sector has made significant progress, it must still achieve considerable methane emissions reductions to meet the 2030 target. This will require implementation of additional methane emissions reductions strategies, and continued collaboration among agencies and other stakeholders. In addition, CDFA plans to convene a working group to address market development barriers for facilitate value-added manure products. CARB will continue to track progress of methane emission reductions project funding and outcomes, manure management and enteric methane reduction options, and will evaluate progress in the 2022 Scoping Plan Update.

Introduction

California has long championed environmental protection, and the State has made significant investments and efforts to decarbonize its economy. In 2006, the Legislature passed and the Governor signed the California Global Warming Solutions Act. Assembly Bill (AB) 32 (Núñez, Chapter 488, Statutes of 2006) requires the State to reduce greenhouse gas (GHG) emissions to 1990 levels by 2020. It also tasked the California Air Resources Board (CARB or Board) with developing a climate change scoping plan that details how the State will achieve its climate target and requires CARB to periodically update the plan. The Board adopted the first Climate Change Scoping Plan in December 2008 and updated this plan in 2013 and 2017.

Through aggressive pursuit of regulatory and voluntary GHG emissions reduction measures across economic sectors, California GHG emissions fell below 1990 levels in 2016, 2017, 2018, and 2019. Acknowledging the need to make deeper GHG emissions reductions to help slow climate change, the Legislature passed Senate Bill (SB) 32 (Pavley, Chapter 249, Statutes of 2016), which requires the State to reduce GHG emissions to 40 percent below 1990 levels by 2030. Figure 1 shows these GHG emissions reduction targets as well as the State's additional goal to reduce GHG emissions by 80 percent below 1990 levels by 2050.[4] Meeting these emissions reduction targets will be critical as California strives to achieve another goal – reaching carbon neutrality by 2045.[5] The Intergovernmental Panel on Climate Change (IPCC) has acknowledged carbon neutrality as necessary to limit global warming to 1.5 degree Celsius or less, the goal set by the international Paris Agreement on climate.

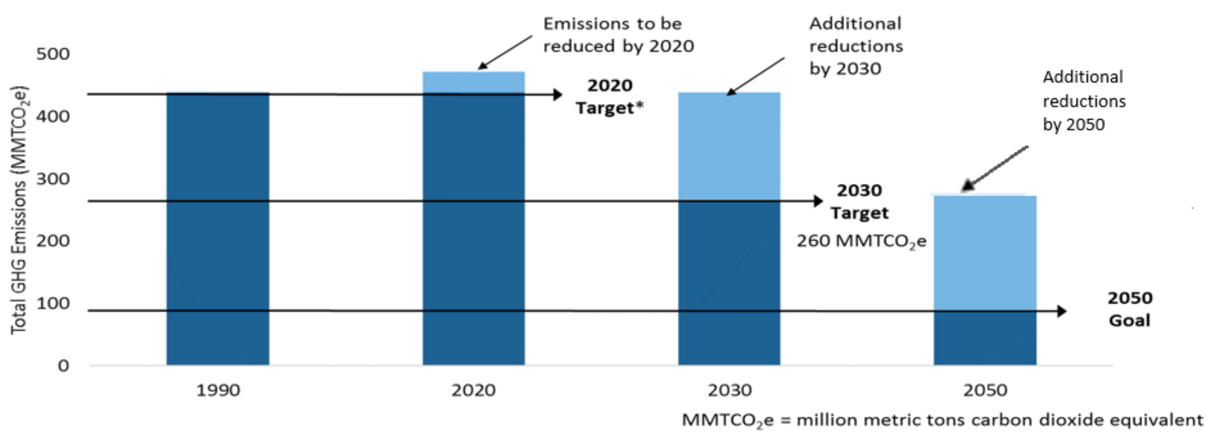

Figure 1. California GHG Emissions Reduction Targets and Goal through 2050

[4] Executive Order S-3-05.
[5] Executive Order B-55-18.

The Legislature also took action to limit emissions of short-lived climate pollutants (SLCP), which are powerful climate forcers that have relatively short atmospheric lifetimes but high global warming potentials (GWP). As a result, SLCP emissions reductions achieved now can have an immediate beneficial impact on climate change. Methane, a powerful SLCP, stays in the atmosphere for approximately a decade before being converted to carbon dioxide.[6] The effect of methane on climate change is 25 times stronger than that of carbon dioxide using the 100-year GWP (GWP 100), and 75 times stronger than carbon dioxide using the 20-year GWP (GWP 20).

CARB uses GWP 100 to quantify statewide methane emissions for inventory and regulatory purposes. GWP 100 is the standard for inventory development and aligns with IPCC and US Environmental Protection Agency (EPA) methods, allowing for comparison of the state inventory with other sub-national and international inventories through common methodologies and requirements for accuracy.

In 2014, the Legislature passed SB 605 (Lara, Chapter 523, Statutes of 2014), which requires CARB to develop a strategy to reduce SLCP emissions in the State. In response, staff developed and the Board approved a comprehensive Short-Lived Climate Pollutant Reduction Strategy (Strategy). In 2016, the Legislature passed SB 1383 (Lara, Chapter 395, Statutes of 2016), which requires CARB to approve and begin implementing the Strategy, and establishes a requirement, among others, for different SLCPs[7] to meet methane emissions reduction targets. More specifically, SB 1383 requires the California dairy and livestock sector to reduce methane emissions from enteric fermentation and manure management to 40 percent below 2013 levels by 2030. It also requires CARB, in consultation with the California Department of Food and Agriculture (CDFA), to adopt regulations to achieve this mandate if certain conditions are met. Specifically, SB 1383 intends to prioritize the use of voluntary and incentive-based measures to achieve those reductions before regulations are implemented. To achieve that end, the law calls for several specific efforts to incentivize reductions, including requiring CARB to work with stakeholders to identify and address technical, market, regulatory, and other challenges and barriers to development of dairy methane emissions reduction projects. Further, CARB is only

[6] While methane itself is not considered a toxic air contaminant, it is a large component of biogas, which may contain a mixture of gases including some toxic air contaminants like hydrogen sulfide. Removing these toxic air contaminants can reduce potential health impacts associated with the processing, transportation, and use of biogas streams.

[7] SB 1383 requires the reduction in the statewide emissions of methane by 40 percent, hydrofluorocarbon gases by 40 percent, and anthropogenic black carbon by 50 percent below 2013 levels by 2030. Additionally, the bill requires a 50 percent and 75 percent reduction in the level of the statewide disposal of organic waste from the 2014 level by 2020 and 2025, respectively. SB 1383 also sets a goal that not less than 20 percent of edible food that is currently disposed of is recovered for human consumption by 2025.

authorized to implement the regulations to meet the 2030 target after January 1, 2024, provided that CARB and CDFA determine the regulations are technologically and economically feasible, cost-effective, include provisions to minimize and mitigate potential leakage, and include an evaluation of the achievements made by incentive-based programs.

The Strategy put forward a path to achieve the SLCP emissions reduction goals established in SB 1383 in a way that provides both environmental and economic benefits to the State. Using the latest scientific and emissions information on SLCPs, it outlines the emissions reduction progress for specific SLCPs, potential options for additional reductions of these SLCPs, and strategies to achieve the respective emissions reduction targets. SLCP reductions are necessary to achieve the State's 2030 GHG emissions target, as described in the 2017 Scoping Plan Update, as well as the mid-century carbon neutrality goal. Notably, while some State programs incentivize dairy and livestock methane emissions reductions, no existing California programs directly require them or incentivize a sector-wide implementation of reduction measures. For example, CARB's Low Carbon Fuel Standard (LCFS) program provides some incentive for dairy operations to develop digesters and receive credits for biomethane production. However, on its own this program does not require operators to develop projects and through its credit system may not support statewide implementation of anaerobic digesters at dairies, and thus these emissions will not decrease without additional targeted programs or other interventions. In contrast, for the electricity and transportation sectors, the Cap-and-Trade Program acts as a backstop to ensure that GHG emissions reductions are achieved.

The Strategy describes a variety of manure management options that can provide the greatest methane emissions reduction potential, recognizing that not every option is feasible for each facility. The Strategy also recommends additional research to evaluate potential enteric methane emissions reduction options as well as the acceleration of early project development through incentives and market development. Prior to implementing regulations, incentives like California Climate Investments (CCI) allocations using Cap-and-Trade Program auction proceeds will encourage voluntary methane emissions reductions at dairies. The Strategy recognizes that implementing a variety of mitigation measures is necessary to achieve the 2030 target and will deliver significant reductions from the dairy and livestock sector while providing a variety of environmental and economic benefits.

Upon adoption of the Strategy and in compliance with SB 1383, CARB convened an interagency Dairy and Livestock Greenhouse Gas Emissions Working Group (Working Group) consisting of CARB, CDFA, California Energy Commission (CEC), and California

Public Utilities Commission (CPUC) principals. At the initial meeting in May of 2017, the Working Group convened three stakeholder subgroups composed of representatives and subject matter experts from State agencies, industry, academia, and the environmental justice community. The objective of these subgroups was to comply with SB 1383's requirement for CARB to work with stakeholders to identify and address barriers to dairy and livestock methane emissions reductions projects, and to develop actionable recommendations that State agencies could implement to help overcome these barriers.

Subgroup 1 provided recommendations to the Working Group to overcome barriers to non-digester manure management practices that focused on available and potential incentives, and developing value-added manure product markets. Subgroup 2 provided recommendations to the Working Group to overcome barriers to implementing livestock digester projects in California, along with a dairy digester emissions matrix that shows potential GHG and criteria pollutant emissions from dairy biogas use. Subgroup 3 focused on research needs related to dairy and livestock methane emissions reductions including enteric fermentation, and published a comprehensive Dairy Research Prospectus to Achieve California's SB 1383 Climate Goals, which outlines research concepts and needs to guide future funding of research projects in California. Over 18 months, the subgroups developed a set of Final Recommendations to the Dairy and Livestock Greenhouse Gas Reduction Working Group and presented them to the Working Group in December 2018. These recommendations outline potential solutions to overcome barriers to methane emissions reduction projects at California dairy and livestock operations and highlight innovative research on methane emissions reductions.

SB 1383 includes additional requirements on CARB to help provide market and environmental credit certainty to biogas-capturing anaerobic digester projects. These requirements, which CARB staff have fulfilled, include developing a white paper describing a potential pilot financial mechanism that, if implemented, could improve market stability for environmental credits from dairy digester projects. CARB, CDFA, and CPUC collaborated in selecting six dairy biomethane pipeline injection pilot projects to receive rate-recoverable infrastructure funding. Evaluating the factors that affect the cost and technical feasibility of these projects will help the State better understand and refine future incentives and regulatory measures. CARB staff also developed a frequently asked questions document discussing the potential impact that a dairy and livestock methane emissions reduction regulation would have on environmental credits generated under the LCFS Program and Cap-and-Trade Program.

Finally, SB 1383 requires CARB, in consultation CDFA, to analyze the progress that the sector has made toward achieving the 2030 target. This Analysis discusses the expected methane emissions reductions through 2022 and the estimated number of additional projects necessary to achieve the 2030 target. It also explores progress made in overcoming the technical and market barriers to implementing dairy and livestock methane emissions reductions projects.

Dairy and Livestock Sector Methane Emissions

In 2013, methane accounted for 40 million metric tons carbon dioxide equivalent ($MMTCO_2e$),[8] or approximately nine percent[9] of the State's GHG emissions (Figure 2). The dairy and livestock sector has been and continues to be the largest source of methane emissions in California, producing approximately 22 $MMTCO_2e$, or about 55 percent, of statewide methane emissions (Figure 3). Eighty percent of these emissions are from manure management and enteric fermentation at more than 1,300 dairies throughout the State. These dairies house more than 1.7 million milking cows and a similar number of replacement stock.[10]

Methane emissions at dairy and livestock operations come from two main sources—the animals themselves through enteric fermentation and manure management operations, especially at dairies. Enteric and manure emissions are both functions of cattle population, meaning that that more head of cattle there are, the higher the methane emissions. As a result, market dynamics such as changes in cost, revenue, or product demand can lead to fluctuations in methane emissions.

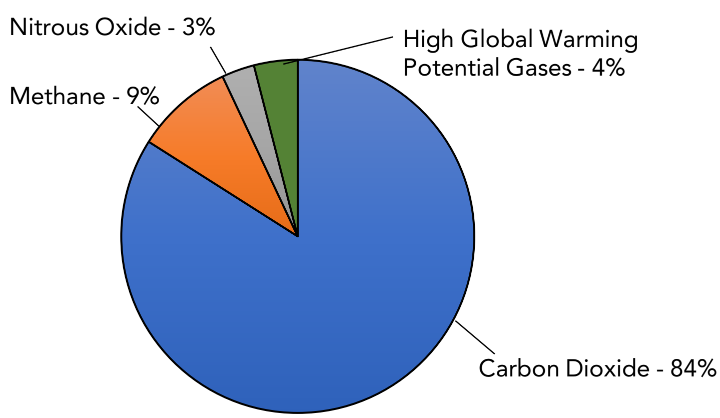

Figure 2. 2013 California GHG Emissions by Gas (Total 2013 Emissions~460 $MMTCO_2e$)

[8] 100-year GWP from IPCC AR4.
[9] California Greenhouse Gas Emissions for 2000 to 2017.
[10] California Agricultural Statistics Review 2018 to 2019.

The dairy and livestock sector has the potential to achieve significant methane emissions reduction from manure management operations at relatively low cost compared to other CCI-funded programs. Projects average $29 and $70 per $MMTCO_2e$ including both public and private funding for dairy digester and alternative manure management projects, respectively.[11,12] Enteric methane mitigation strategies also have important methane mitigation potential, but there is limited cost information available since only a few products are scientifically proven and commercially available.

Enteric fermentation is a natural digestive process that occurs within the digestive tract of ruminant animals such as cattle, sheep, and goats. In 2013, enteric fermentation emissions represented about 30 percent of California's total methane emissions (Figure 3), with two-thirds from dairy cows and the remaining one-third from other animal types. During the digestive process, microbes in the rumen decompose and ferment plant matter, which produces methane that ruminants subsequently emit, mostly through eructation (burping). A variety of factors influence enteric fermentation emissions including breed, diet, and the presence of feed additives, with the latter offering significant potential methane emissions reductions. In general, methane emissions from enteric fermentation can potentially be reduced through selective breeding, dietary modifications that improve milk production efficiency, and the introduction of methane-reducing feed additives.

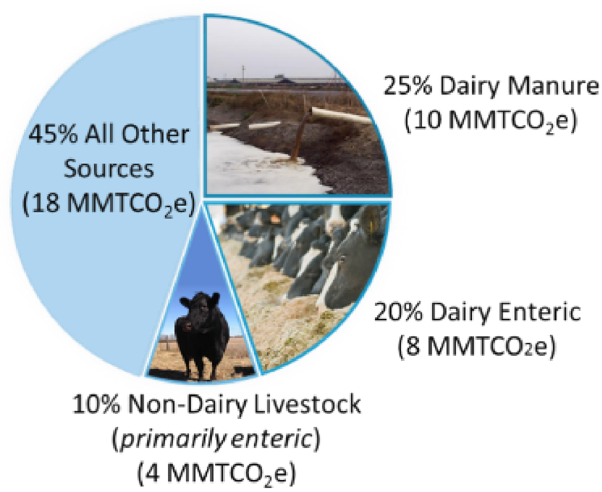

Figure 3. 2013 California Methane Emissions by Source

Anaerobic manure management and storage comprise the other main source of methane emissions at California dairy and livestock operations, accounting for about 25 percent of California's total methane emissions. Manure management systems that

[11] Dairy Digester Research and Development Report of Funded Project from 2015 to 2019.
[12] Alternative Manure Management Program Webpage.

treat or store manure under anaerobic conditions (i.e., those common to liquid manure management lagoons) are a large source of methane emissions. Anoxic manure treatment and storage conditions, common in manure settling basins and storage lagoons, are conducive to methanogenic bacteria producing methane from volatile solids. Methane emissions from anaerobic manure management can be mitigated through capture and destruction, or through avoidance of production.

Two types of projects—dairy digesters and alternative manure management projects—effectively reduce a significant amount of methane emissions from dairy and livestock operations. Dairy digesters involve installation of an anaerobic digester to capture biomethane produced from dairy waste for beneficial end-uses including but not limited to onsite electricity generation to offset facility needs, or delivery to the electrical grid. Upgraded biomethane that meets utility pipeline specifications set by the California Public Utilities Commission (CPUC) can also be injected into the natural gas pipeline network to offset use of fossil natural gas in multiple sectors. Use of upgraded biomethane in vehicles in place of diesel also provides the additional co-benefit of reducing nitrogen oxides (NOx) emissions. Dairy biomethane can also be used as a heat source in industrial application, or as a feedstock for low carbon fuels including renewable hydrogen and dimethyl ether. The biomethane produced is eligible for credits in CARB's LCFS program, the Federal Renewable Fuels Standard, or CARB's Cap-and-Trade offsets program, which act as an ongoing revenue stream for facilities to help offset the initial high capital costs of development as well as support the ongoing operational costs of the digester.

Alternative manure management practices reduce the amount of manure (and volatile manure solids) managed or stored under anaerobic conditions; the goal of these practices is to limit methane production and emissions. Examples of effective alternative manure management practices include conversion to "solid," "dry," or "scrape" manure management; installation of a compost-bedded pack barn; increase in the time animals spend on pasture; or implementation of solid-liquid separation technology into flush manure management systems (e.g., various types of mechanical separators and weeping walls). Other alternative manure management strategies that may result in methane emissions reductions include but are not limited to acidification, which involves the application of acid(s) to animal manure to reduce emissions; vermifiltration, which is an aerobic decomposition process that produces worm castings; and chemical flocculation, which involves using polymers to increase the solid separation rate from animal manure streams. A more detailed overview of these and other alternative manure management practices is available in the Newtrient technology catalog—a source of information on manure management practices that can reduce environmental impacts.[13]

These practices can also provide important environmental co-benefits including improved water quality and nutrient management, and more easily exportable manure solids. For example, dairies can contribute to groundwater pollution through nitrate and salt leaching when overapplying manure to cropland, however, these components may replace synthetic fertilizer or improve soil health in other regions. Exporting excess nutrients and solids may also help dairy and livestock operations comply with water quality requirements. In California, dairy manure is largely managed in liquid form, making it difficult and cost-prohibitive to export without solid-liquid separation. Certain alternative manure management practices can remove manure solids, nitrogen, and salt from the manure stream and concentrate them in the solids that can be more readily exported as organic fertilizer or converted them into environmentally benign end products such as nitrogen gas. Manure solids may be further processed into value-added manure products like compost or soil amendments that can provide additional revenue, though market development remains a barrier. Alternative manure management strategies also provide flexibility to operations seeking to reduce methane emissions where a digester may be infeasible.

Through the strategies described above, the dairy and livestock sector can make considerable progress toward achieving the target of reducing methane emissions to 40 percent below 2013 levels by 2030. This Analysis describes progress the sector has already made toward achieving the target through manure methane emissions reduction projects. It also assesses progress that may occur based on various funding scenarios, reductions in animal populations, or commercial availability of a methane-reducing feed additive. Additionally, it discusses technical and market barriers to methane emissions reductions strategies that must be overcome to achieve the 2030 target.

[13] Newtrient provides information about manure management strategies and associated environmental impacts to dairy producers through an online technology catalog. Newtrient participated in CARB's Dairy and Livestock GHG Emissions Workgroup but does not have a formal relationship to CARB. Reference to that material does not constitute an endorsement of that catalog, or any associated strategies, technologies, etc., included therein.

Analysis and Findings

Analysis Item 1: California's Dairy and Livestock Methane Emissions Reduction Progress and Projected Annual Emissions Reductions through 2030

Finding 1-1: The Sector Has Made Significant Progress, But Will Not Meet the 2030 Target without Almost a Doubling of Emissions Reductions Projects

The California dairy and livestock sector has predominantly relied on manure management strategies to achieve the methane emissions reductions directed by the Legislature. Even with limited enteric methane mitigation options, the sector is on course to achieve significant emissions reductions. Through private investments and public incentive funding programs, approximately 278 manure methane emissions reduction projects have been completed or are under construction at California's dairy farms. Of these, CCI funded 233 projects through CDFA's Dairy Digester Research and Development Program (DDRDP) and Alternative Manure Management Program (AMMP), which have been instrumental in driving manure methane emissions reduction projects at California dairy operations. DDRDP provides up to half of the capital cost of construction, and AMMP encourages private matching funds. Both programs are consistently over-subscribed, with requested funds usually about twice the amount available.

As of December 2020, 22 DDRDP and 61 AMMP projects were complete and operational. An additional 96 DDRDP and 54 AMMP projects are under construction, with expected completion by the end of 2022. The latest round of CCI funding in fiscal year (FY) 2019-20 funded 12 DDRDP and 13 AMMP projects; all are expected to be operational by the end of 2022. Aggregating the emissions reductions expected from all 233 CCI projects yields an estimated annual methane emissions reduction of 2.0 $MMTCO_2e$[14] by the end of 2022.[15] The emissions reductions counted toward the 2030 target represent over 20 percent of the 9 $MMTCO_2e$ required to achieve that target. Stated differently, CCI funded dairy and livestock projects are expected to

[14] Emissions reduction estimates are in 100-year GWP (AR4). Estimated emissions reductions using 20-year GWPs can be calculated by multiplying 100-year GWP figures in this Analysis by 2.88.

[15] These estimates do not include the anaerobic digestion projects receiving Aliso Canyon Mitigation Settlement funds, which will result in an estimated additional 0.3 $MMTCO_2e$ in annual methane emissions reductions. Since these projects count toward natural gas sector mitigation, they do not count toward the 2030 target.

reduce total methane emissions from the sector to about 9 percent below 2013 levels by the end of 2022.

CARB, in collaboration with air districts and dairy and livestock industry groups, identified as many as 45 additional manure management projects implemented or under development using only private funding throughout the State since January 1, 2013. Of these, 40 involve installation of a solid-liquid separation system, and the remaining five involve installation of an anaerobic digester. Solid separation systems reduce the amount of volatile solids that are managed anaerobically by diverting a fraction of these solids to a dry management system to produce compost, soil amendment, and bedding, preventing them from producing significant methane emissions. To estimate reductions from these projects, CARB staff used average methane emissions reductions for DDRDP and AMMP projects, respectively. The combined annual methane emissions reductions amount to 0.2 $MMTCO_2e$ from these projects, with 0.1 $MMTCO_2e$ each from digester and alternative manure management projects.

Changes in animal populations are an additional driver of methane emissions reductions, caused by factors including reduced product demand, increased costs, insufficient revenue, greater out-of-State competition, and land use changes. For example, consumer preferences may change, reducing the demand for animal-based products. Increased out-of-State competition and decreased national and international demand may also result in oversupply of products and animal population reductions. Increases in production costs for commodities like animal feed, electricity, and fuel can also have significant impacts on the financial viability of animal operations, especially when coupled with low commodity prices. In other cases, competing land uses like conversion to high-value crops or urban encroachment may lead to facility closures and animal population reductions.

Every five years, the U.S. Department of Agriculture (USDA) conducts a Census of Agriculture (Ag Census), which provides the most consistent and reliable population data available in absence of state-level activity data. As part of the Ag Census, USDA reports the number of animals by type on each farm in the U.S., allowing for state-specific population tracking, including for California's GHG Emission Inventory. USDA's two most recent Ag Census reports, from 2012 and 2017, cover dairy and livestock population changes between 2008 and 2017, and provide a basis for estimating methane emissions reductions from average annual population changes. The 2012 Ag Census also provides a reasonable 2013 baseline because it quantifies dairy and livestock populations in California by animal type as of December 31, 2012. Based on the 2012 and 2017 Ag Census reports, CARB staff calculated an average annual decline of 0.5 percent in animal populations from the sector between 2008 and 2017. Assuming that this population change trend will remain constant, methane emissions reduction attributable to sector population decreases will be ~0.13 $MMTCO_2e$ annually or 1.3 $MMTCO_2e$ total through 2022.

Adding methane emissions reductions expected from State- and privately funded manure management projects with those from expected animal population decreases yields a total methane emissions reduction in 2022 relative to 2013 of ~3.5 $MMTCO_2e$, as shown in

Table 1 below.[16] Assuming that the animal population will continue to decrease at approximately 0.13 $MMTCO_2e$ annually,[17] and not taking into account any additional funding that may be available for manure methane reduction projects beyond FY 2019-20, the total estimated 2030 methane emissions reductions would be approximately 4.6 $MMTCO_2e$. This would be just over half of the 9 $MMTCO_2e$ emissions reductions needed to meet the 2030 target – with about 4.4 $MMTCO_2e$ reductions remaining (Figure 4).

[16] Due to the time required to construct dairy methane emissions reductions projects—especially anaerobic digesters pipeline injecting biomethane (between 18 and 24 months)—a limited number of projects have been completed to date.

[17] Starting in March of 2020, California enacted shelter-in-place orders and temporary closures of public and private gathering spaces due to the global pandemic. Resulting closures of schools and restaurants likely exacerbated dairy sector economic challenges and may have lasting impacts, including accelerated facility closures and decreases in animal population. However, due to uncertainty about net long term impacts the pandemic may have on the dairy and livestock sector, this Analysis assumes that recent trends in animal population trends observed in USDA's 2012 and 2017 Ag Census change will remain consistent through 2030.

Table 1. Estimated California Dairy and Livestock Methane Emissions Reduction by the End of 2022

Reduction Type		**Number of Projects Funded through FY 2019-20**	**Expected Emissions Reductions Through 2022 ($MMTCO_2e$)**
Population Change		Not Applicable	1.3
Anaerobic Digester	State-funded (DDRDP)	118	1.8
	Privately funded	5	0.1
Alternative Manure Management Practices	State-funded (AMMP)	115	0.2
	Privately funded	40	0.1
Total		**278**	**3.5**

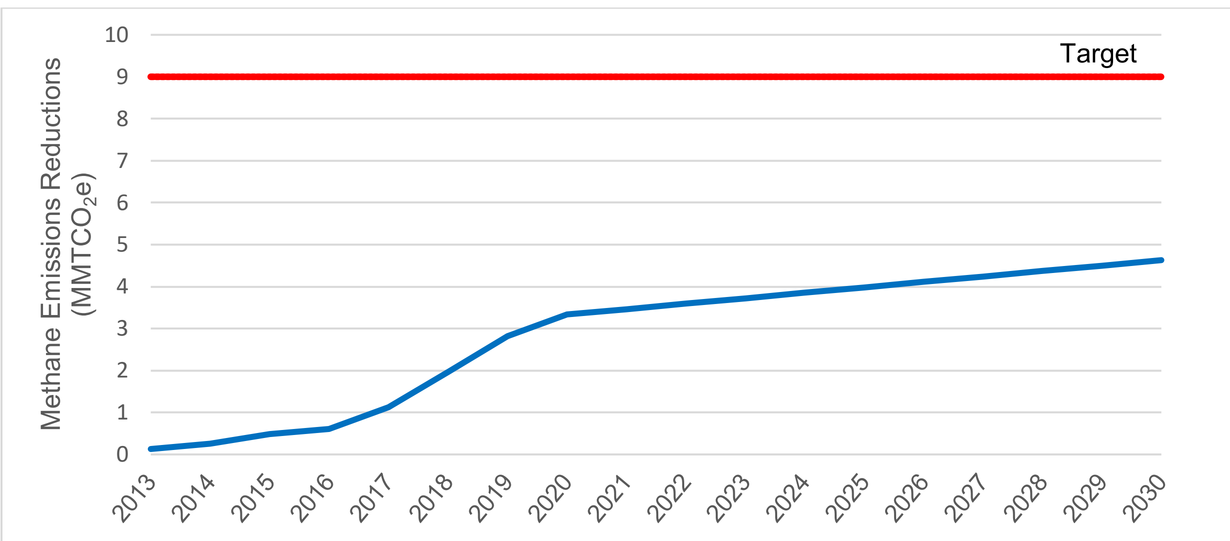

Figure 4. Projected Annual Methane Emissions Reductions through 2030 without Additional CCI Funding beyond FY 2020-21

The remaining 4.4 $MMTCO_2e$ in emissions reductions are expected to be achieved through manure management strategies but may be advanced by widespread adoption of effective enteric methane mitigation strategies. To estimate additional manure methane emissions reductions projects needed to reach the target, CARB staff used average reductions from DDRDP and AMMP projects. Staff calculated average project-level methane emissions reductions by program using figures reported by CDFA through DDRDP and AMMP. Based on the average emissions reductions, staff determined the number of additional projects necessary to achieve the 2030 target. This assumes that distribution of project types will remain roughly equal between digesters and alternative manure management projects, consistent with past practice. Based on this approach, at least 210 anaerobic digestion and 210 alternative manure management projects are necessary to achieve the remaining 4.4 $MMTCO_2e$ in methane emissions reductions. However, future project types may vary dependent upon available incentives and operator preference. If only dairy digester projects were implemented—which are about ten times as effective at reducing emissions than alternative manure management projects—over 230 projects would be necessary to achieve this level of emissions reductions. With respect to alternative manure management practices, based on currently funded projects and reduction trends observed to date, staff's analysis indicates that the State would be unable to achieve the 2030 dairy and livestock sector target through deployment of alternative manure management practices alone. A combination of dairy digesters, alternative manure management, enteric strategies, and dairy herd size population decreases will be needed to meet the 2030 target.

Finding 1-2: Public and Private Funding Support Methane Emissions Reduction Projects

Significant allocations of CCI funding have enabled the sector to make progress toward the 2030 target. From 2014 through 2020, the Legislature appropriated approximately $289 million in CCI funds for dairy methane emissions reduction projects. These funds, administered through CDFA's DDRDP and AMMP, have been effective in leveraging private capital investment and achieving cost-effective methane emissions reductions. With local, State, and federal funding, the dairy and livestock sector will be able to implement additional projects to help meet the 2030 target. Table 2 (below) shows that dairy methane projects constructed using CCI funds through the DDRDP and AMMP have successfully leveraged over $1.60 in match funding for each CCI dollar invested.[18]

[18] DDRDP eligibility requirements include a mandatory private match contribution of at least 50 percent of initial project cost estimates. AMMP does not require private match contributions.

Table 2. Private Funding Contributions per CCI Dollar Invested

Funding Sources	Programs		Total Funding
	AMMP	DDRDP	
CCI ($ million)	$67.8	$195.5	$263.3
Private Match ($ million)	$9.9	$413.1	$423.0
Private Match per CCI Dollar Invested ($)	$0.15	$2.11	-

In addition to DDRDP and AMMP, additional State programs, including the Cap-and-Trade Program, the LCFS Program, CPUC's Bioenergy Market Adjusting Tariff (BioMAT), CPUC's Renewable Gas Pipeline Interconnection Incentive Program and CPUC's SB 1383 Biomethane Pipeline Injection Pilot Project Program, have supported dairy and livestock methane emissions reduction projects through credit generation and grants, and other bioenergy and biofuel incentives. To date, more than $1 billion in combined public and private funding has supported approximately 280 anaerobic digester and alternative manure management projects. Additionally, public funds have supported rate-recoverable programs for biomethane pipeline interconnection infrastructure, which help deliver biomethane to end users.

The Strategy recommended a minimum funding amount[19] of at least $100 million per year for five years as necessary to accelerate significantly project development by offsetting capital costs and economic risks for manure management methane emissions reduction projects. CARB and CDFA, working with industry stakeholders and project developers during public development of the Strategy, estimated that $500 million would greatly increase the deployment rate of manure management projects within the State, though that amount was not estimated to be sufficient to achieve the 2030 target. To date, CDFA's DDRDP has awarded approximately $200 million in CCI funds for 118 dairy digesters, nearly an eightfold increase over the number of digesters operating prior to the availability of CCI funds. Similarly, CDFA's AMMP has awarded approximately $68 million for 115 alternative manure management projects and has greatly accelerated adoption of those practices. CARB staff estimates an additional $600 million in privately matched CCI funds, or similar public incentives, is necessary to achieve the emissions reductions still needed to meet the 2030 target through dairy digester projects. Despite considerable State investment and private match funding, incentives have not been sufficient to achieve

[19] In the Strategy, CDFA estimated that at least $100 million in the form of grants, loans, or other incentives would be needed for five years to support the development of necessary methane emissions reducing manure management projects including digesters and alternative manure management projects, as well as associated infrastructure.

the 2030 target. The FY 2019-20 CCI allocation of $34 million was considerably lower than the $99 million available in FY 2017-18 and FY 2018-19, falling $66 million short of annual funding needs. The proposed FY 2020-21 appropriation of $20 million did not materialize because of State budget cuts. The FY 2021-22 budget includes an appropriation of $32 million for CDFA's livestock methane reduction program, with priority given to AMMP.

CDFA's DDRDP projects have been the primary driver of GHG emissions reductions in the dairy and livestock sector since FY 2014-15. Prior to the availability of CCI funds, about 15 digesters were operating in California—far short of the 799 candidate dairies identified by the USDA AgSTAR program and 543 dairies identified in the Strategy[20] as necessary to achieve the 2030 target.[21] Most of the digesters installed prior to the start of CCI (2006-2013) relied heavily on public funding from CEC's Dairy Power Production Program. Emissions reductions resulting from these projects are not counted towards the target because they were online prior to the 2013 baseline year. Figure 5 below shows the number of digesters in place prior to the baseline year, the number of digesters resulting from CCI funding, and the number of additional digester projects necessary to achieve the 2030 target.

[20] The Strategy was adopted prior to the opening of the Alternative Manure Management Program and assumed that most of the necessary methane emissions reductions would result from digester installations.

[21] Noted in Table 17: Sector-wide implementation assumptions, and upfront capital costs of the Strategy.

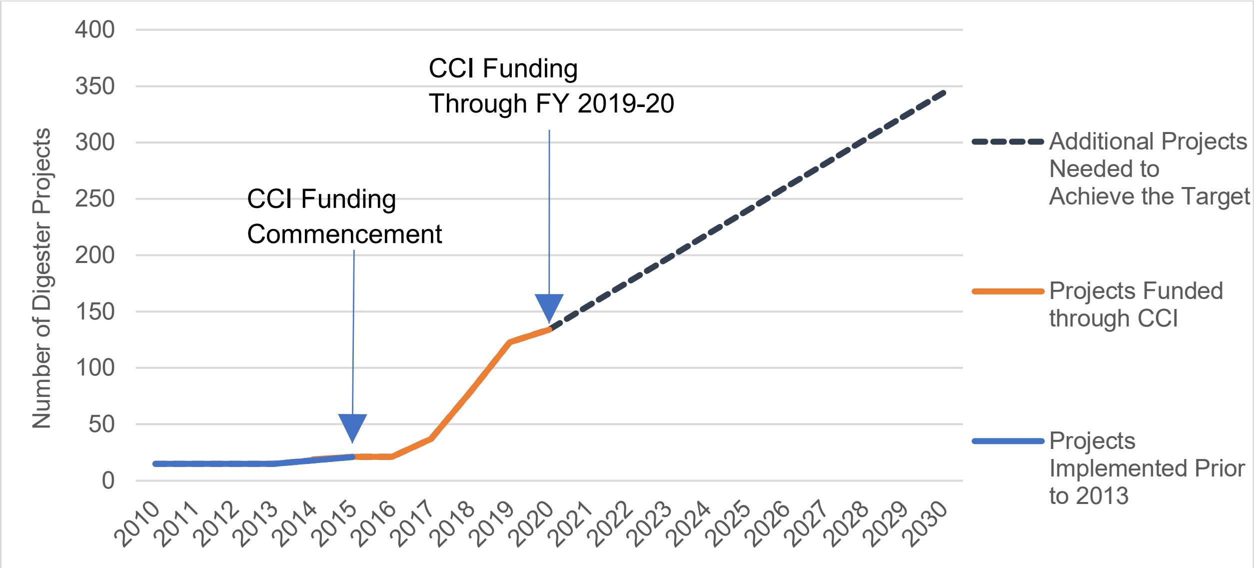

Figure 5. Number of Dairy Digesters in California[22]

Similarly, CDFA's AMMP is a primary source of funds for alternative manure management projects, which also rely heavily on public funds. Project developers are generally smaller dairies that are often not well suited to a digester because of limited financial resources, insufficient herd sizes, or other operational characteristics. While less expensive than a digester, alternative manure management projects on average cost about $600,000 per project. Unlike a digester project, alternative manure management projects do not produce bioenergy or biofuels and are not eligible to generate revenue from environmental credits. Some project developers realize cost savings from bedding purchases or sales of value-added manure products, while others—especially smaller pasture-based operations—are unable to capture any savings or revenue at all.

Infrastructure costs for digester systems producing onsite electricity from biogas including the cost to construct and install an anaerobic digester, construct conditioning facilities to upgrade biogas to necessary specifications, and either convert it to electricity using a reciprocating engine, a microturbine, or a fuel cell. These costs range from approximately $3 million to $17 million depending on the configuration and biomethane utilization option chosen, with average costs between $4 million and $7 million. Infrastructure costs to produce onsite electricity at the lower end assume that a project uses a reciprocating engine generator to produce onsite electricity, while upper end costs (~$17 million) assume the use of a solid oxide fuel cell. Infrastructure costs for digester systems that produce biomethane for pipeline

[22] Numbers shown in Figure 5 do not include the five privately funded dairy digester projects implemented since 2013.

injection (or trucking to injection point or fueling station) including the cost to install an anaerobic digester and a biogas upgrading facility. These costs range from $3 million to $16 million. Project variables include distance to the pipeline and whether the project is on a single dairy or part of a cluster of dairies.

According to CCI reports published to date, DDRDP and AMMP have delivered some of the most cost-effective GHG emissions reductions on a per-metric ton CO_2e basis compared to other CCI funded programs. Table 3 details State, private, and total investments into dairy manure methane emissions reduction projects.

Table 3. Estimated Cost Effectiveness of California Dairy and Livestock Methane Emissions Reductions through 2022

Program	State Investment ($/MTCO$_2$e)	Private Investment ($/MTCO$_2$e)	Total Investment ($/MTCO$_2$e)
DDRDP	$9	$20	$29
AMMP	$61	$9	$70

Alternative manure management projects can be further subdivided into three project types, including compost bedded pack barns, flush-to-scrape conversions, and solid-liquid separation systems. Methane emissions reduction potential and cost-effectiveness varies across these project types. Table 4 shows the average methane emissions reductions and cost-effectiveness of these alternative manure management project types. According to the table, solid-liquid separation projects have the highest per-project average methane emissions reductions and the lowest implementation costs among these alternative manure management practices. Importantly, site-specific conditions affect methane reductions potential and cost-effectiveness across all project types.

Table 4. Estimated Methane Emissions Reduction Potential and Cost-Effectiveness of Alternative Manure Management Projects through 2022

AMMP Practices	Reduction per Project (MTCO$_2$e)	Cost-effectiveness ($/MTCO$_2$e)	
		State Investment	Total Investment
Compost Bedded Pack Barn	1,880	$73	$91
Flush-to-Scrape Conversion	1,420	$78	$88
Solid-Liquid Separation	2,120	$54	$58

In addition to public funding of digester construction costs, incentive funds and other mechanisms are available to provide ongoing support to project developers. This includes the BioMAT, the Cap-and-Trade Program, and the LCFS Program. The Cap-and-Trade Program allows dairy digester developers to quantify the methane emissions reductions resulting from the installation of a digester using the CARB Compliance Offset Protocol for Livestock Projects. These methane emissions reductions can generate carbon offset credits that developers can sell to capped entities. The Cap-and-Trade Program is designed to encourage capped entities to reduce their GHG emissions while providing flexibility in how those reductions are achieved. The LCFS Program is designed to reduce the average carbon intensity of transportation fuels[23] in California by incentivizing the production and use of low carbon fuels. Alternative fuels like biomethane generate credits in the LCFS program that can be sold to entities generating deficits for supplying high carbon fuels for sale in California.

Dairy digester projects are increasingly participating in the LCFS credit market,[24] where credit prices averaged $192 in 2019.[25] A hypothetical 3,000 milking cow dairy supplying transportation fuel could generate approximately $3.5 million in annual LCFS credit value.[26] Equivalent emissions reductions from the same dairy project might generate $250,000 in annual compliance offset credit value through the Cap-and-Trade Program, using the weighted average price for livestock offset credit transfers.[27,28] However, these potential credit revenue values do not include project-specific variations in additional revenue streams or costs, which may be considerable, even among projects with similar sizes and designs. While dairy digesters offer significant and cost-effective methane emissions reductions, without large-scale public incentives, the rate of adoption would likely decrease greatly. Incentives such as the

---

[23] Information on current fuel pathways can be obtained through the CARB Current Fuel Pathways Spreadsheet, which is searchable and sortable, by feedstock, fuel, classification, and/or facility name. Accessed in December 2020.

[24] Anaerobic digester projects cannot simultaneously generate both LCFS and Cap-and-Trade credits.

[25] Monthly LCFS Credit Transfer Activity Reports. Accessed in August 2020.

[26] The LCFS credit value represents potential gross revenue from sale of LCFS credits in 2020; this does not include revenues from the sale of fuel, nor the potential revenue from sale of Renewable Identification Numbers (RIN) under the federal EPA Renewable Fuel Standard (RFS). Project development costs are not included in these estimates due to significant variability; costs may include but are not limited to project feasibility, design, and interconnection studies, digester and gas upgrading equipment and installation, and pipeline interconnection infrastructure construction.

[27] Cap-and-Trade Compliance Offset Credits from livestock projects were valued at $13.67 on average per metric ton for transactions occurring in 2019. Summary of Market Transfers Completed in 2019.

[28] Offset credit revenue from livestock projects may vary considerably, even across similarly sized and designed projects resulting from variations in project costs, location, and additional revenue streams. The gross revenue values provided in this Analysis are intended to illustrate potential offset credit revenue for programmatic comparison but may not accurately describe actual net project revenues.

Cap-and-Trade Program, LCFS Program, or RFS Program significantly improve the attractiveness of investment in digester projects.

Finding 1-3: The 'Social Cost of Methane' Metric Cannot be Used to Determine the Net Societal Benefits or Disbenefits of Methane Emissions Reduction Projects Comprehensively; Methane Reduction Benefits or Disbenefits Vary by Project Type

In addition to mandating SLCP emissions reductions, the Legislature passed AB 197 (Garcia, Chapter 250, Statutes of 2016), which directs CARB to consider the social costs associated with GHG emissions mitigation rules and regulations. The social cost of methane is a measure of the long-term damages caused by emitting one ton of methane in a given year. Using the methodology developed in 2009 by a federal interagency working group convened by the U.S. Council of Economic Advisors and the Office of Management and Budget, CARB staff estimated the potential range in the social cost of methane emissions from 2015 through 2030 in the 2017 Climate Change Scoping Plan.[29] The current analysis focuses on the social costs of methane emissions in 2030 using different discount rates[30] in 2020 dollars[31]—or the value today of preventing environmental damages in the future (Table 5).

The social cost of methane is a metric that can contribute to understanding the societal benefits or disbenefits that accrue from reducing methane emissions. The social cost of methane accounts for damages that occur from the release of methane, including damages due to changes in human health, changes in net agricultural productivity, property damages from increased flood risk, changes in energy system costs, non-market amenities (based on outdoor recreation), and changes to human settlements and ecosystems. Importantly, the models used to estimate the social cost of methane emissions cannot assess the monetary value of all physical, ecological, or economic impacts of climate change. As such, actual societal benefits or disbenefits could differ considerably from the calculated values used in this analysis.

Furthermore, when conducting a complete cost benefit analysis, net societal benefits from a specific project may accrue despite an estimated project disbenefit (negative values shown in Table 5) associated solely with the social value of reducing methane

[29] More information is available in Table 8 in the 2017 Climate Change Scoping Plan.

[30] Discount rate is the rate at which society is willing to trade present benefits for future benefits. Discount rate affects decision making parameters including net present value, cost-effectiveness ratio, internal rate of return, return on investment.

[31] All social cost values have been adjusted to 2020 dollars using the U.S. Bureau of Labor Statistics Historical Consumer Price Index for All Urban Consumers. Accessed in December 2020.

emissions. A methane emissions reduction project may yield a social disbenefit when only accounting for methane emission reductions but may result in substantial improvements to air quality and water quality that are not quantified or monetized by only looking at the social cost of methane. For example, for the dairy and livestock sector, manure management projects such as anaerobic digesters have been successful at reducing methane emissions. The captured methane from digesters can be converted to an energy product, such as renewable electricity produced through fuel cells and internal combustion engine generators, resulting in potential net societal benefits or disbenefits associated with methane emissions reductions before considering other environmental and socioeconomic co-benefits.

Staff used the social costs of methane in Table 5 to estimate the societal benefits and disbenefits of various methane mitigation projects, including fuel cells and internal combustion engine generators at discount rates of 2.5, 3.0, and 5.0 percent. Subtracting the project investment costs from the social cost of methane estimates the net societal benefits or disbenefits of reducing methane emissions by investing in specific manure methane emissions reduction projects, solely from a methane mitigation perspective.[32] Depending on project types, societal benefits or disbenefits from reducing one metric ton of methane vary, ranging from a societal disbenefit of $2,806 to a societal benefit of $1,878. However, as previously noted, this methodology does not fully assess the monetary value of all environmental and socioeconomic co-benefits that may result from establishing these projects, nor does it fully assess any additional societal disbenefits that may arise from non-methane emissions. For example, implementing such strategies may offer improved nutrient management to farms through more precise application of manure solids to crop lands at agronomic rates and potential reductions in synthetic fertilizer use. Conversely, adoption of other methane emissions reductions strategies such as converting biogas to electricity using internal combustion engine generators may increase NOx and other air pollutant emissions, resulting in societal disbenefits. Given that most California dairies are in or near disadvantaged communities that may be disproportionately exposed to air quality impacts, ensuring air quality and other environmental benefits in these communities to the extent feasible is important, independent of the limitations to current social cost of methane estimates.

[32] The overall societal value of a project maybe positive even if a methane emissions reduction project has a social cost of methane disbenefit. Without conducting a comprehensive cost analysis of all environmental and socioeconomic factors, actual net societal benefits of a project remain unknown.

Table 5. Social Cost and Societal Benefits or Disbenefits of Reducing One Metric Ton of Methane Emissions in 2030

Discount Rate	Social Cost of Methane ($/MT CH_4)	Methane Emissions Reduction Cost ($/MT CH_4)		Net Societal Disbenefits (-) or Benefits (+)‡ ($/MT CH_4 Reduced)
		Fuel Cell	IC Engine	
5.0%	$949	$3,755	$773	$-2,806 to $176
3.0%	$1,997	$3,145	$648	$-1,148 to $1,349
2.5%	$2,496	$3,002	$618	$-506 to $1,878

Methane emission reduction scenarios shown in Table 5 assume methane is captured using a dairy digester and destroyed using either fuel cell or an internal combustion engine. These examples provide upper and lower bound estimates for net social benefits and disbenefits. (While pipeline injection projects are the most frequently implemented project types, they are not shown here because costs are highly variable based on project site. However, they would fall within the range shown.)

‡Net societal benefits or disbenefits of reducing one metric ton of methane emissions do not account for all environmental and socioeconomic co-benefits resulting from that reduction.

Finding 1-4: Feed and Manure Additive Methane Mitigation Strategies Could be Scaled to Help Achieve the 2030 Target

In addition to the manure management practices described above, additional strategies are under development to achieve further reductions from the sector. For example, certain markets have begun using additives that reduce methane emissions from enteric fermentation in ruminants, though use in North America is limited due to pending regulatory approval. Additives to reduce methane emissions from manure management are also under development. Such additives may potentially achieve important, cost-effective methane emissions reductions from dairy and livestock operations while offering increased flexibility and avoiding the significant upfront capital investment associated with installing a digester or implementing an alternative manure management practice.

Animal Feed Additives

Methane emissions from enteric fermentation in dairy and livestock account for about 30 percent of statewide methane emissions, or approximately 12 $MMTCO_2e$ annually. This presents an opportunity to achieve significant methane emissions reductions, potentially at a cost of approximately $50 per metric ton on a carbon dioxide equivalent basis.[33] Potential strategies to reduce emissions from the digestion process

[33] Assumes use of a product with a ten percent enteric methane emissions reduction effectiveness at an annual cost of approximately $48 per ton ($0.05 per cow per day) on a carbon dioxide equivalent basis.

include diet modifications, feed additives, feed efficiency improvements, and selective breeding of low methane producing animals. Of these, feed additives offer the greatest potential for sector-wide methane emissions reductions because they potentially deliver considerable methane emissions reductions shortly after adoption. In comparison, strategies like diet modifications, feed efficiency improvements, and selective breeding require a relatively long time to achieve significant emissions reductions. Unlike the manure management strategies described above, these strategies can be implemented at existing operations with minimal need to modify facility design and without significant upfront capital requirements. This makes these strategies potentially attractive for dairy and livestock operations, especially rented or leased operations.

Research suggests that certain feed additives may have promising methane emissions reduction potential. For example, 3-Nitrooxypropanol (3-NOP under the commercial name of Bovaer®),[34] has shown an emissions reduction potential between 20 and 40 percent across multiple ruminant species under various testing conditions.[35,36,37] The additive 3-NOP has undergone both laboratory-scale and on-farm testing for effectiveness in reducing methane emissions safely, and for potential impacts on animal health, reproduction, and productivity. It is a chemical product that is currently undergoing US Food and Drug Administration (FDA) approval and may become available within the next few years.[38] Nitrate is another feed additive that has shown an

[34] Mention of trade names or commercial products does not constitute or imply CARB endorsement or recommendation.

emissions reduction potential between 10 and 20 percent.[39,40,41,42,43] However, existing research is insufficient to conclude that microbes in the rumen will acclimate to increased nitrate without causing adverse animal health impacts. Agolin® Ruminant,[44] an essential oil mix, has shown methane reduction potential between 10 and 20 percent for dairy cows without impacting milk yield and composition. Mootrol® Ruminant, a pelleted product made from garlic and orange extract, has also shown methane mitigation potential in both *in vitro* and *in vivo studies* [45,46] and researchers are currently investigating its long-term effectiveness in beef cattle. Both Agolin® Ruminant and Mootral® Ruminant are commercially available and are Generally Regarded As Safe (GRAS)[47] by the FDA. Novel additives, such as lemongrass and seaweed[48] have also shown emissions reduction potential but lack sufficient *in vivo* (animal) studies to demonstrate long-term effectiveness and potential impacts on

productivity and human or animal health.

To better understand the potential contribution of feed additives in achieving the 2030 target, staff evaluated six potential enteric methane emissions reduction scenarios that focused on the use of feed additives. These scenarios shown in Figure 6 (below) illustrate potential annual methane emissions reductions resulting from the use of feed additives with methane mitigation effectiveness of 10, 30, and 50 percent,[49] representing the low, medium, and high potential of different feed additives, at adoption rates of 50 and 75 percent. The 2030 target is shown as a red dotted line at the top of the graph. At the bottom of the graph, a solid red line shows the methane emissions reductions attributed to dairy and livestock population change and manure methane emissions reduction projects already completed or under construction. It assumes that no additional projects will be implemented.[50] As the figure shows, if solely enteric feed additives are utilized beyond 2022 and no additional manure methane projects are implemented, a feed additive with a methane emissions reduction effectiveness of at least 50 percent would need to be adopted by at least 75 percent of ruminants in the sector to achieve the 2030 target.

[49] These values represent the enteric methane mitigation effectiveness of various feed additives. Ten percent represents a conservative estimate of mitigation effectiveness for currently available products; thirty percent represents a median estimated effectiveness for 3-NOP, which shows mitigation potential between 20-40 percent, and is expected to become commercially available in the near future; fifty percent represents a conservative estimate for the most effective emerging approaches, such as seaweed.

[50] Additional manure methane emissions reduction projects are expected to be developed but have been omitted from Figure 6 to illustrate the potential of feed additive-based enteric methane emissions reductions.

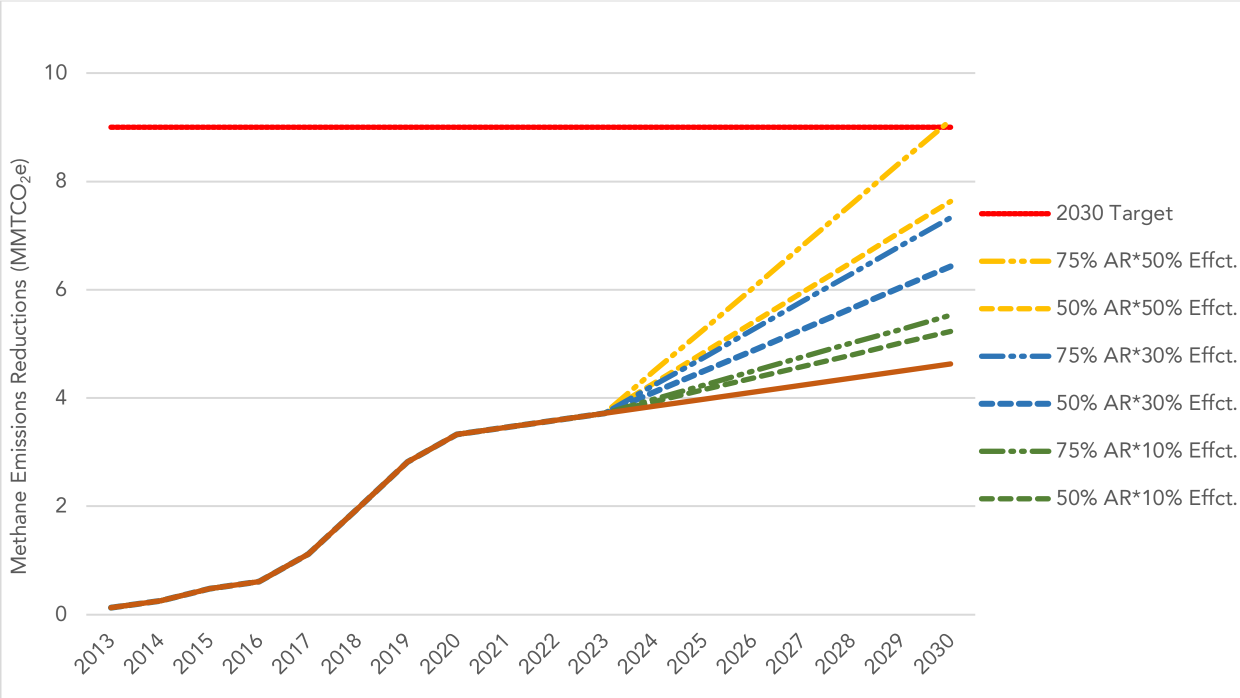

Figure 6. Projected Annual California Dairy and Livestock Sector Enteric Methane Emissions Reductions through 2030 Under Various Feed Additive Adoption Rates (AR) and Methane Mitigation Effectiveness (Effct.)

Manure Additives to Reduce Methane Emissions

Most of California's manure methane emissions originate from anaerobic manure treatment and storage lagoons. Manure additives can potentially modify environmental conditions in manure treatment and storage facilities, including but not limited to pH, redox potential, and microbial composition, to levels that are less conducive to methane production. Examples of potential manure additives include incorporation of biochar or proprietary lagoon additives, as well as the use of manure acidification. However, these strategies require additional investigation of their methane emissions mitigation effectiveness, applicability to California dairy and livestock manure management systems, and potential unintended impacts to air or water quality. For example, biochar has been shown to reduce methane emissions through incorporation into manure slurry; however, it may not be practical or effective in liquid manure management systems that are predominant on California dairy operations. Similarly, acidification of manure slurry may be effective at reducing methane emissions but may be impractical for California operations due to the need for large acid volumes that require special handling and safety equipment. CARB will continue tracking developments in manure additives as they become available, especially those with long-term studies that detail potential methane emissions mitigation effectiveness and environmental co-benefits.

Finding 1-5: Dairy and Livestock Sector May Fall Short of the 2030 Target absent an Enteric Strategy and Sufficient Public Funds[51]

To estimate potential emissions reductions from manure management projects under various public funding scenarios, CARB staff developed scenarios to extrapolate funding outcomes through 2030. These projections are based on project development costs and emission reductions described above, and do not account for environmental credit values on project costs. The impact of LCFS and RFS environmental credit prices on project economics is discussed in the following section. Figure 7 (below) illustrates potential methane emissions reductions achievable through the combination of an available enteric strategy, changes in animal populations, and from manure management projects at different levels of CCI funding assumptions.52 The 2030 target is shown as a red dotted line at the top of the graph. Potential methane emissions reductions from average animal population changes (discussed in Finding 1-1) are shown as a dark blue dashed line at the bottom of the graph.

[51] Trends discussed in this section are based on publicly available data wherever possible. In instances where available information was incomplete or insufficient, CARB staff used reasonable and conservative assumptions based on existing trends and available information.

[52] Funding projections assume that DDRDP and AMMP will fund an approximately equal number of projects, consistent with past practice.

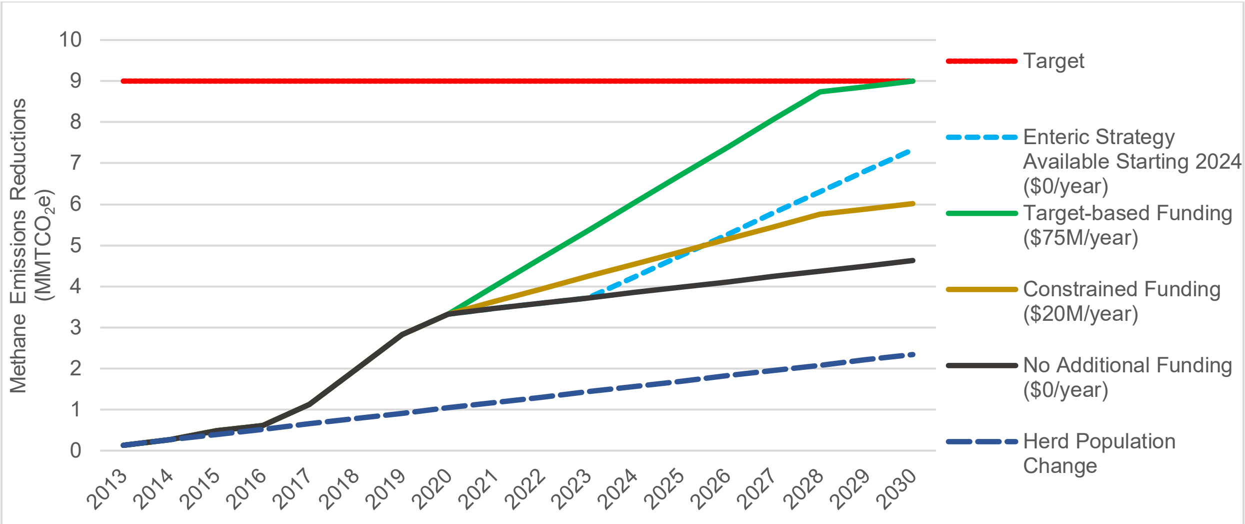

Figure 7. Projected Annual California Dairy and Livestock Sector Methane Emissions Reductions through 2030[53][54]

Additionally, Figure 7 shows methane emissions reductions expected under three different funding scenarios from FY 2020-21 through FY 2027-28 (green, brown, and dark gray solid lines).[55] It also shows potential emissions reductions from herd population changes and a potential enteric strategy (dark and light blue dashed lines, respectively). The funding scenarios assume that the observed decline in animal populations will continue at a constant rate through 2030. While emissions reductions attributable to a potential enteric strategy are shown in the figure, those emissions reductions are not accounted for in any of the funding scenarios above.

Each scenario includes emissions reductions expected from changes in population through 2030 as well as reductions expected from DDRDP and AMMP projects funded through FY 2019-20.

Incentive Funding Scenario 1: No Additional Funding

This scenario assumes that no additional appropriations of local, state, and federal funds are available for DDRDP and AMMP beyond FY 2019-20. Methane emissions reductions expected under Scenario 1 are shown in Figure 7 by the gray line labeled "No Additional Funding." This scenario assumes that funding is the limiting factor in new projects coming online. The y-axis difference between this line and the population

[53] Funding levels identified in Figure 7 do not reflect potential revenue from the generation of Cap-and-Trade, LCFS, or RFS RIN credits.
[54]Funding levels identified in Figure 7 do not reflect potential revenue from the generation of Cap-and-Trade, LCFS, or RFS RIN credits.
[55] Funding levels do not reflect private match funding that is required for DDRDP projects.

change line represents emissions reductions attributed mostly to State funds, emphasizing their importance in achieving the methane emissions reductions through 2022. Staff estimates this scenario will achieve 4.6 $MMTCO_2e$ of methane emissions reductions by 2030, falling 4.4 $MMTCO_2e$ short of the 2030 target.

Incentive Funding Scenario 2: Constrained Funding

This scenario assumes that consistent annual appropriations of $20 million for DDRDP and AMMP from FY 2020-21 through FY 2027-28. Methane emissions reductions expected under Scenario 2 are shown by the yellow line in Figure 7. This scenario assumes that allocations between DDRDP and AMMP will fund an approximately equal number of projects, consistent with past practice. With constrained funding through FY 2027-28, all funded projects will likely be operational by 2030. Staff estimates this scenario will achieve 6.0 $MMTCO_2e$ of methane emissions reductions by 2030, falling 3.0 $MMTCO_2e$ short of the 2030 target.

Incentive Funding Scenario 3: Target-Based Funding

This scenario assumes annual appropriations of $75 million for DDRDP and AMMP beyond FY 2019-20 through FY 2027-28—a level sufficient to achieve the 2030 target through manure emissions mitigation projects. This scenario accounts for a 20 percent project cost increase over current levels due to projects with smaller cattle populations and increased distances to the nearest natural gas pipeline with sufficient capacity. Methane emissions reductions expected under Scenario 3 are shown by the green line in Figure 7. Staff estimate that this scenario will achieve the 2030 target of 9.0 $MMTCO_2e$.

Enteric Strategy Scenario

Staff also estimated that a scientifically proven, cost-effective, safe, and consumer-accepted enteric methane mitigation strategy may be commercially available within the next three to five years to help achieve the 2030 target, shown by the light blue dashed line near the top of Figure 7. This assumes adoption of a feed additive with 30 percent enteric methane mitigation potential across ruminant species in California starting in 2024, and a linear annual adoption rate of approximately 11 percent through 2030, totaling 75 percent of the ruminant population.

For simplicity, the target-based funding scenario assumes that no enteric strategy will be available before 2030. Similarly, the enteric strategy scenario described below assumes that no public funding will be available beyond FY 2019-20. While both scenarios are based on reasonable estimates and are illustrative of potentially achievable methane emissions reductions, actual methane emissions reductions may vary.

While these scenarios focus on the outcomes of public investments and required private match funding to meet the 2030 target, revenue available through the California Cap-and-Trade Program and LCFS Program, as well as the federal RFS Program, can substantially reduce or eliminate the need for public funding of these projects. These revenue streams have become strong drivers of anaerobic digestion projects, helping ensure their long-term operation and financial stability.

Alternative Manure Management Practice Scenarios

Staff also evaluated the potential for different adoption rates of alternative manure management practices at California dairies to help achieve the 2030 target. As above, staff used average methane emissions reduction values to calculate potential reductions from various numbers of additional projects at California dairies. Staff also assumed that the approximately 280 dairy operations that had already implemented a manure methane strategy would not incorporate additional manure or implement enteric methane reduction strategies, leaving approximately one thousand dairies available for project implementation. Staff evaluated potential annual methane emission reductions resulting from alternative manure management project adoption under three different scenarios with 250, 500, and 750 additional dairies.

The estimated annual emissions reductions for each scenario are shown in Figure 8 (below). The 2030 target is shown as a red dotted line at the top of the graph. At the bottom of the graph, a solid red line shows the methane emissions reductions attributed to dairy and livestock population change and manure methane emissions reduction projects already completed or under construction. It assumes that no additional digesters projects and no enteric methane reduction strategies are implemented, showing the potential impact of alternative manure management projects on progress towards the 2030 target. The blue, yellow, and gray lines show expected annual emissions reductions from implementing new alternative manure management practices on 250, 500, and 750 additional dairies, respectively. On their own, none of these scenarios are estimated to provide sufficient methane emissions reduction to achieve the 2030 target.

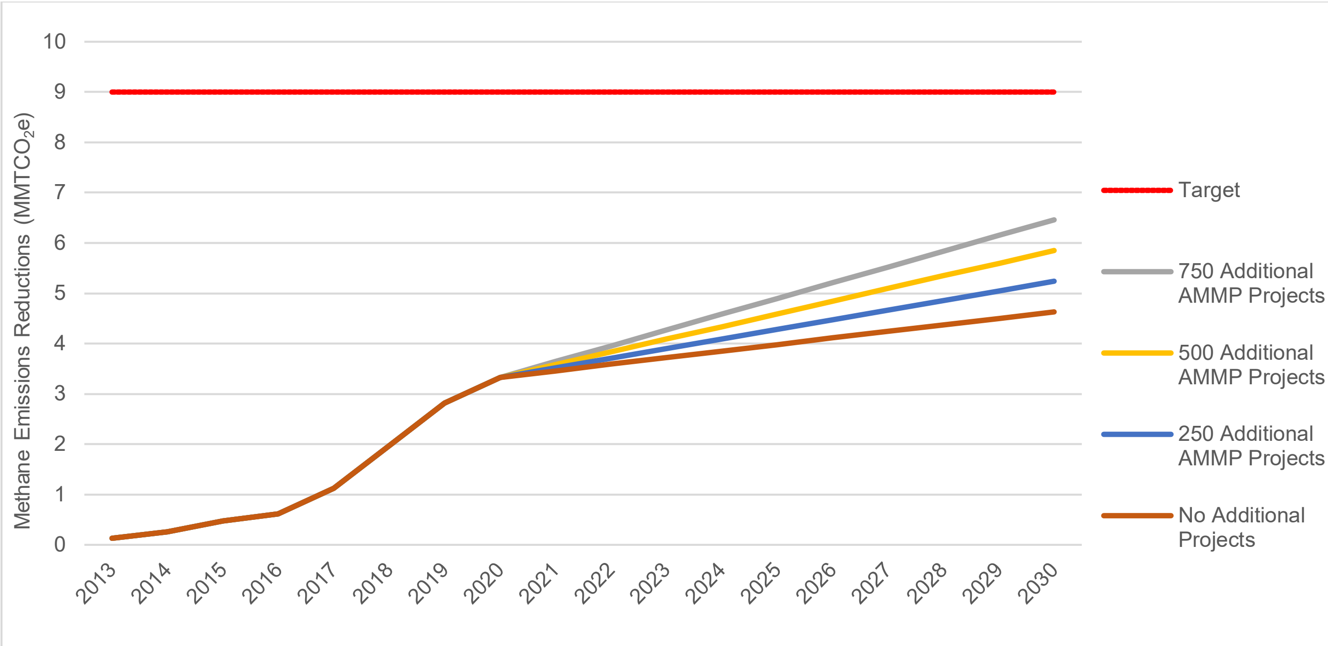

Figure 8. Projected Annual California Dairy and Livestock Sector Methane Emissions Reductions through 2030 Resulting from Implementing Additional Alternative Manure Management Projects

However, alternative manure management practices are important strategies that may provide significant additional environmental co-benefits. First, these practices may be more broadly implemented across the sector, including at small- and medium-sized dairies due to reduced upfront capital and maintenance costs compared to digesters. They may also provide flexibility to dairies with configurations that make digester implementation infeasible. Second, implementing certain alternative manure management practices alone or in combination with practices incentivized by other programs such as State Water Efficiency and Enhancement Program may provide additional water conservation and GHG benefits. These practices include conversion to scrape manure management, use of sub-surface drip irrigation, or pasture dairy conversion. Third, alternative manure management practices may improve solids and nutrient management, reduce nitrate leaching and improve water quality, reduce chemical fertilizer use, increase crop yield, and provide cost savings to dairy and livestock operations.

In addition to solid-liquid separation, compost bedded pack barns, conversion to scrape manure management, and pasture dairy conversion, stakeholders have proposed eligibility for other alternative manure management practices. These practices include but are not limited to manure acidification, vermifiltration, advanced chemical flocculation, and dissolved air flotation. Given the emergent nature of these strategies, additional research or observation at California dairy and livestock operations is necessary to evaluate methane reduction potential, long-term effectiveness, and potential unintended environmental impacts. Staff will continue monitoring deployment of these and other promising alternative manure management practices as they become available.

In some cases, alternative manure management practices can be combined with digesters to achieve greater emissions reductions than either strategy might on its own. Solid-liquid separators are commonly installed in conjunction with covered lagoon digesters to remove coarse solids, potentially reducing digester maintenance needs. These separated solids can be used for animal bedding, providing cost savings to the farmer. These same solids and nutrients can also be further processed into compost or soil amendment for onsite land application or export offsite, potentially generating additional revenue or cost savings while reducing chemical fertilizer needs. Stricter control of solids and nutrients can also help minimize water quality impacts by reducing nutrient leaching to groundwater.

Finding 1-6: Dairy Digester Development Will Need Significant Policy and Incentive Support, Providing Additional Methane Emissions Reduction Potential and Biomethane Supply

Generating environmental credits through the California Cap-and-Trade Program, LCFS Program, and federal RFS Programs can provide important revenue streams to dairy operators and project developers. As a result, these credit values are likely to drive additional dairy digester project development, methane emissions reductions, and increases in-State biomethane supply.

To estimate statewide dairy biomethane supply and production cost, staff reviewed existing literature and reports[56,57,58] as well as recent dairy population data from Regional Water Quality Control Board permits and annual reports. As part of that evaluation, and to refine supply estimates, staff adjusted underlying datasets to reflect facilities that had implemented an alternative manure management practice[59] or had closed. Staff assume that the remaining dairies can implement a digester project and

[59] Facilities with alternative manure management practices implementation are less likely to divert animal waste to anaerobic digesters for biomethane production.

estimate that at least an additional 210 digester projects are necessary to achieve the target (in addition to 210 alternative manure management projects).

The six project technology options below describe potential pathways to use methane captured in a digester. These options include onsite electricity production using a reciprocating engine, a microturbine, or a solid oxide fuel cell, as well as direct injection into a natural gas pipeline from a single dairy, cluster of dairies, or through trucking to an existing interconnection point where it can displace fossil natural gas. While these technology options may result in similar methane emissions reductions, criteria pollutant performance, potential carbon intensities, project costs, and project revenues may vary considerably. Staff assume that project developers will select the digester technology option that is most suitable for their facility.

Anaerobic Digestion Technology Option 1: Reciprocating Engine Generator for Electricity Generation

This technology option involves using a reciprocating engine generator to generate electricity on site using biogas and offset fossil fuel-derived electricity for a variety of end uses, including but not limited to electric vehicle charging.[60] However, reciprocating engine generators also result in new sources of air pollutant emissions that adversely impact regional air quality, attainment of ambient air quality standards, and public health outcomes. For example, the San Joaquin Valley is home to the majority of the State's dairy and livestock operations, it has among the worst air quality in the country and is home to many of the State's most disadvantaged and low-income communities. Given the potential for further impacts, utilizing even the cleanest reciprocating engine generator is the least desirable option.

Anaerobic Digestion Technology Option 2: Microturbine for Electricity Generation

This technology option involves using a microturbine certified under the CARB Distributed Generation (DG) Certification Program to generate electricity using biogas. The DG Certification Program requires manufacturers of electrical generation technologies that are exempt from air district permit requirements to certify their technologies to specific criteria pollutant emission standards before selling products in California. Common DG technologies certified under this program include fuel cells and microturbines. Microturbines have higher costs compared to reciprocating engine generators but produce fewer air pollutant emissions, and therefore have fewer associated impacts on regional air quality and public health. As with all onsite

[60] The LCFS Program includes three California dairies projects that use reciprocating engine generators, one of which received a -630.92 g/MJ carbon intensity score, the lowest LCFS carbon intensity score to date.

electricity generation projects, microturbines do not require pipeline interconnection, improving their locational flexibility compared to pipeline projects.

Anaerobic Digestion Technology Option 3: Fuel Cell for Electricity Generation

This technology option involves using a fuel cell to generate onsite electricity using biogas to support electric vehicle charging.[61] Fuel cells generate onsite electricity with very low air pollutant emissions, especially when compared to emissions associated with reciprocating engine generators. These projects provide electricity using biogas that avoids up to 90 percent of the NOx and up to 80 percent of the particulate matter emissions resulting from other combined heat and power technologies on a life-cycle basis.[62] Fuel cells installed at dairies have the potential to be certified for ultra-low carbon intensity scores, and the potential LCFS credit revenue may make them competitive in the long-term. As with all onsite electricity generation projects, fuel cells do not require pipeline interconnection, improving their locational flexibility compared to pipeline projects.

Anaerobic Digestion Technology Options 4a & 4b: Onsite Injection of Biomethane into a Natural Gas Pipeline

These technology options include either single dairy or cluster pipeline interconnection projects. These are the most common options and involve biogas capture, upgrading to pipeline biomethane specifications, and injection into a natural gas pipeline. These projects reduce GHG emissions further when they replace fossil natural gas. They also avoid onsite combustion for electricity generation and the associated onsite air pollutant emissions and public health impacts. As a result, these projects are preferable to onsite combustion projects but may not be feasible due to factors including distance to the nearest natural gas pipeline with enough capacity, and whether the facility is part of a cluster. Project cost between these two categories differ notably, with single dairy projects costing considerably more compared to cluster projects due to lack of ability to share upgrading facility and pipeline extension costs.

Anaerobic Digestion Technology Option 5: Trucking Biomethane to an Existing Interconnection Point for Injection into Natural Gas Pipeline

This technology option involves trucking biomethane to the closet injection point or natural gas vehicle refueling station. This option assumes that biomethane is

[61] Two DDRDP projects use Bloom Energy solid oxide fuel cells.
[62] An Assessment of Energy Technologies and Research Opportunities: Chapter 4: Advancing Clean Electric Power Technologies September 2015.

transported by a zero-emissions electric or natural gas heavy duty truck with few criteria pollutant (including oxides of nitrogen) and particulate matter emissions compared to a diesel heavy-duty truck. Using natural gas or electric heavy-duty trucks reduces criteria pollutant emissions and avoids emissions of harmful diesel particulate matter from biomethane transport, with negligible impact on project cost compared to using a diesel truck. Trucking biogas, referred to as a "virtual pipeline," may reduce project costs and provide flexibility compared to construction of dedicated pipelines. It also mitigates the risk of stranded infrastructure in the event of reduced demand from a site-specific large downstream consumer (e.g., milk processing operation). Trucking biomethane to existing injection points may be a cost-effective delivery option that results in fewer emissions than reciprocating engine generator and microturbine projects. However, it will also increase vehicle miles traveled, likely in disadvantaged communities, so incentives or regulatory approaches should encourage facilities to reduce reliance on trucking where feasible and use of zero emission vehicles or natural gas heavy-duty trucks when necessary.

Potential Biomethane Supply from Anaerobic Digestion

The preceding anaerobic digestion technology options describe potential pathways to deliver biomethane to market through electricity generation or pipeline injection. This section illustrates the potential biomethane supplied to market and associated costs under each of these options in a baseline scenario, and under various environmental credit price scenarios. Figure 9 below shows potential biomethane supply and market delivery cost under a baseline scenario, which is absent any State or federal financial incentives. The dashed red line shows expected biomethane supply by 2022, approximately 4.7 trillion British thermal units (Btu). The dashed black line indicates the estimated amount of biomethane supply (~13.5 trillion Btu) needed to achieve the 2030 target. Without State or federal financial incentives like the State's LCFS Program or the federal RFS Program, none of the technology options described above (Figure 9) are financially viable.

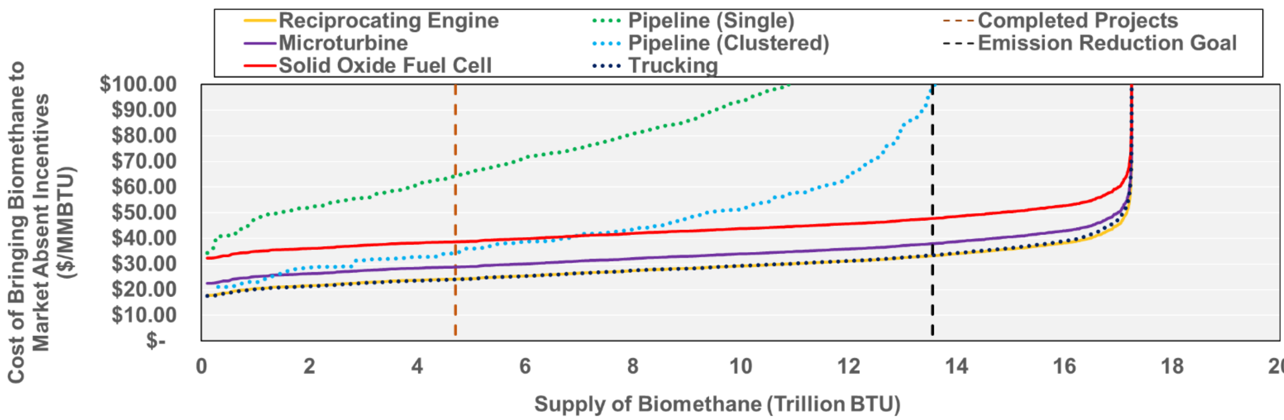

Figure 9. Biomethane Supply and Market Delivery Cost under Different Technology Options absent Federal and State Incentives

Figure 9 illustrates the cost of bringing biomethane to market under each technology option absent any public incentives (e.g., CCI funds, Cap-and Trade Program compliance offset credits, LCFS credits, RFS RIN credits). The costs portrayed for this curve and the subsequent supply curves in Figures 10 through 12 show levelized cost, and therefore includes financing assumptions for the digester projects as well as the additional capital and operating expenses associated with the technology that uses the dairy gas produced through anaerobic digestion. For instance, the levelized cost of pipeline projects is inclusive of the covered lagoon and anaerobic digestion system, upgrading the gas, building the pipeline, and injecting the gas into the pipeline. For the other technologies, the costs include any upgrading costs, as well as any additional equipment costs (e.g., solid oxide fuel cell) required to bring the gas to market.

In general, the supply curves for pipeline-based technologies have a substantially greater upward slope. Pipeline interconnection distances vary for each facility, and facilities that are further away from pipelines will have higher costs to build the network relative to facilities that are closer to pipeline interconnection points. Additionally, facilities that produce more biomethane (i.e., larger facilities) will be able to recoup fixed pipeline costs by distributing these costs over larger quantities of produced biomethane over time. As such, the lowest cost pipeline projects will generally be for large facilities that are closer to pipeline interconnections. The other technologies largely scale linearly with the size of the facility. As such, the slope for non-pipeline technologies is generally more gradual.

The cost to deliver biomethane to market may be as low as $30 per MMBtu if trucked to an existing pipeline interconnection or used to produce onsite electricity using a reciprocating engine generator. In contrast, delivering biomethane to market may cost as much as $100 per MMBtu for pipeline injection at a cluster of dairies—the costliest option with sufficient capacity to achieve the 2030 target. For comparison, in October 2020 wholesale fossil natural gas prices on Henry hub were approximately $3 per MMBtu, but has increased to approximately $5 per MMBtu in October 2021. Given that the price of fossil natural gas is approximately one tenth to one sixth that of biomethane, it is uneconomic to utilize biomethane without incentives beyond sale price.

Staff used biomethane delivery costs and volumes from Figure 9 to estimate potential costs for implementing at least 210 additional digester projects necessary to achieve the 2030 target. To be conservative, staff developed estimates using expected biomethane delivery costs from the 2030 target line to reduce potential underestimation of the total cost to achieve the target for feasible scenarios. Project costs on this line are expected to be the highest over time and assumes that more financially feasible projects have already been implemented.

To bound the potential total cost of achieving the 2030 target, staff used the solid oxide fuel cell scenario costs as an upper bound and costs associated with trucking biomethane to an existing interconnection point and producing onsite electricity using a reciprocating engine generator as the lower bound value. Though cluster pipeline projects may also potentially deliver sufficient biomethane to meet the 2030 target, this scenario is unlikely to be implemented at enough facilities to achieve the target. The costs associated with constructing additional pipelines to supply enough biomethane to achieve the target make it increasingly unlikely that the more costly projects would be implemented. Instead, it is more likely that these facilities will choose the lower cost options of generating onsite electricity or trucking biomethane to an existing interconnection point. As such, it is inappropriate to use direct pipeline injection as an upper cost bound.

Staff also assumed, as previously discussed in Finding 1-1, that at least 210 alternative manure management projects may be implemented at an assumed per project cost of $0.6 million, resulting in a total cost of $0.1 billion. Staff added this $0.1 billion to the total costs associated with the lower and upper bound cost of implementing the additional 210 digester projects. Based on these assumptions, the estimated total cost to achieve the 2030 target range from $0.8 to $3.7 billion absent any public incentives. The 2030 target may also be achieved solely through implementation of as few as 230 additional digester projects costing between $0.7 and $3.9 billion.

With public incentives like LCFS credits and RFS RINs, the need for upfront public investment in digester projects[63] may be reduced or even eliminated, assuming project developers will have access to debt financing for upfront project construction cost. These incentives can be sufficient to offset project development, operational, and financing costs in some cases depending on the level of incentive available, providing a positive project revenue stream and making the project financially viable.

Staff evaluated the same methane emissions reduction technology options used in the baseline scenario above to estimate biomethane supply and cost under various combinations of LCFS and RFS RIN credit prices.[64,65,66] These credit value scenarios range from $150-$200 per credit for LCFS and $0-$2 per RIN. Table 6 shows potential credit values from delivering one MMBtu of biomethane to market at these price ranges under different technology options. Potential credit values at such levels may make these projects competitive with fossil natural gas and with other sources of biomethane.

Table 6. Potential Environmental Credit Value ($) from Producing One MMBtu of Biomethane under Different Technology Options at Various LCFS and RIN Credit Prices[67]

Biomethane Delivery Option	LCFS $150			LCFS $200		
	RIN $0	RIN $1	RIN $2	RIN $0	RIN $1	RIN $2
Reciprocating Engine	$41	$41	$41	$55	$55	$55
Microturbine	$55	$55	$55	$74	$74	$74
Solid Oxide Fuel Cell	$64	$64	$64	$85	$85	$85
Pipeline (Single or Cluster)	$49	$62	$75	$66	$79	$92
Trucking	$44	$57	$70	$59	$72	$85

63 Alternative manure management projects are not eligible for State and federal biomethane incentive programs because, while they do reduce dairy methane emissions, they do not produce biomethane.

64 Assumes D3 cellulosic RIN

65 Electricity generation projects are not currently able to generate RFS RIN credits and have been assigned a $0.00 RIN price across all evaluated credit price scenarios.

66 Offset credits are not evaluated because the LCFS credits value is considerably more than the Cap-and-Trade program.

67 The assumed carbon intensities, energy efficiency rating (EER), and percent efficiency rating for the identified biomethane delivery options are as follows:

- Reciprocating Engine: -490 grams per mega Joule (g/MJ), 3.4 EER, 32% efficiency
- Microturbine: -490 g/MJ, 3.4 EER, 44% efficiency
- Solid Oxide Fuel Cell: -400 g/MJ, 3.4 EER, 57% efficiency
- Pipeline (Single or Cluster): -230 g/MJ, 0.9 EER, 100% efficiency
- Trucking: -230 g/MJ, 0.9 EER, 100% efficiency

Figure 10 through Figure 12 below illustrate the potential biomethane supply and market delivery cost under three different combinations of LCFS and RIN credit prices. These scenarios illustrate a potential lower bound, a potential upper bound, and a scenario with medium credit values. They are described in greater detail below. Values below $0.00 on the y-axis provide positive revenue to projects making them financially viable because revenues exceed project costs. Conversely, values above $0.00 indicate that revenues are insufficient to offset project costs, making the projects infeasible because supply costs are too high.

Environmental Credit Price Scenario 1: $150 LCFS and $0 RIN

This scenario estimates biomethane supply and production cost assuming values of $150 for LCFS credits and $0 for RIN credits (Figure 10). Under this scenario, single dairy pipeline projects can supply approximately 1 trillion Btu of biomethane to the market, falling far short of the required volume to meet the 2030 target. Previously funded projects exceeded this capacity, which suggests that future single pipeline injection projects are not viable at these prices.

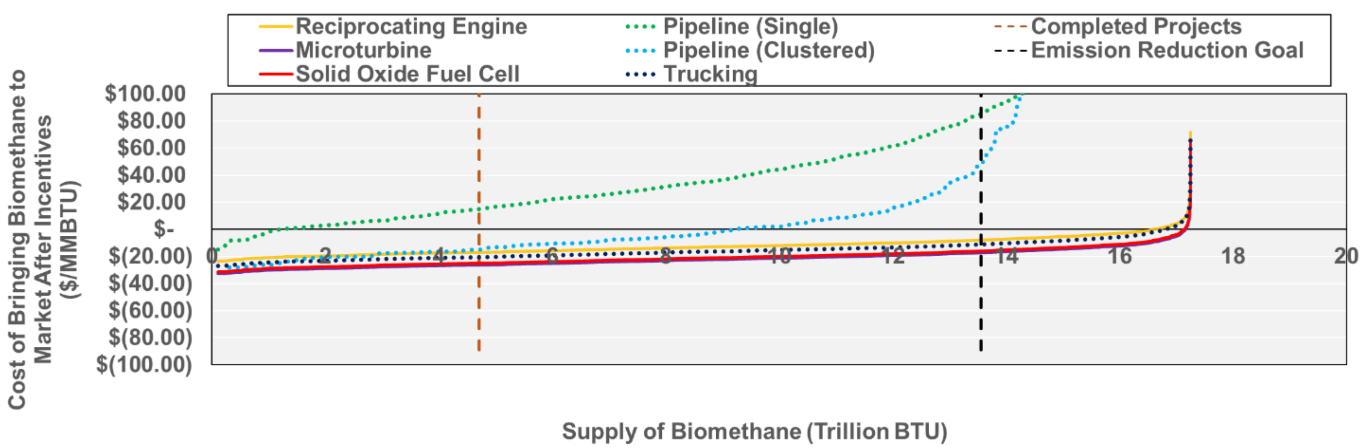

Figure 10. Biomethane Supply and Market Delivery Cost at LCFS and RIN Credit Prices of $150 and $0, Respectively

For comparison, clustered pipeline projects can supply approximately 9 trillion Btu. While a significant increase over the single pipeline projects, this still falls short of the volume required to meet the target. Under Scenario 1, both the single and cluster pipeline injection options are unable to bring sufficient dairy biomethane to market to meet the target without additional incentives.

However, biomethane-to-electricity projects and trucking biomethane to existing interconnection points may provide enough biomethane volume to the market to meet the 2030 target. In this scenario, the solid oxide fuel cell technology option generates the highest revenue with an LCFS environmental credit value of $64 per

MMBtu. Biogas-to-electricity projects that use reciprocating engines and microturbines result in less revenue but cost less than solid oxide fuel cell projects.

Environmental Credit Price Scenario 2: $200 LCFS and $1 RIN

This scenario estimates biomethane supply and production cost assuming values of $200 for LCFS and $1 for RIN (Figure 11). Under this scenario, single-dairy pipeline projects can cost-effectively supply approximately 8 trillion Btu of biomethane to the market, which is a considerable increase over Scenario 1, but still more than 5 trillion Btu short of the 2030 target. Cluster pipeline injection projects will not be able to cost-effectively supply sufficient biomethane to achieve the target either, falling short by approximately 1 trillion Btu. Consistent with Scenario 1, biogas-to-electricity, solid oxide fuel cell projects, and biomethane trucking projects can supply sufficient biomethane to achieve the 2030 target, with the latter two offering the considerably higher credit revenue. Under this scenario, only dairy pipeline injection projects would require additional incentives to achieve the target.

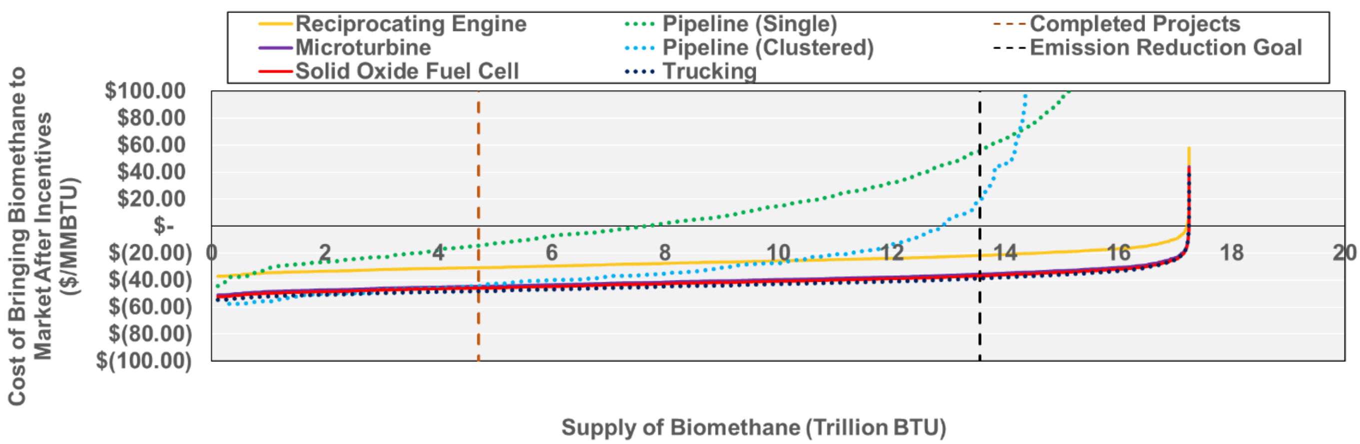

Figure 11. Biomethane Supply and Market Delivery Cost at LCFS and RIN Credit Prices of $200 and $1, Respectively

Environmental Credit Price Scenario 3: $200 LCFS and $2 RIN

This scenario estimates biomethane supply and production cost assuming values of $200 for LCFS and $2 for RIN (Figure 12). In this scenario, single-dairy pipeline injection projects can cost-effectively bring about 10 trillion Btu of biomethane to market, the highest volume across scenarios but still fall short of the target by 3 trillion Btu. Cluster pipeline injection projects can cost-effectively bring over 13 trillion Btu of biomethane to market, nearly achieving the target. Trucking projects are the most cost-effective overall resulting from credit revenue available and relatively low project development costs. Solid oxide fuel cell projects are another cost-effective option given the estimated credit value. Under this scenario, all but pipeline injection projects can cost effectively bring enough biomethane to market without the need for additional incentives.

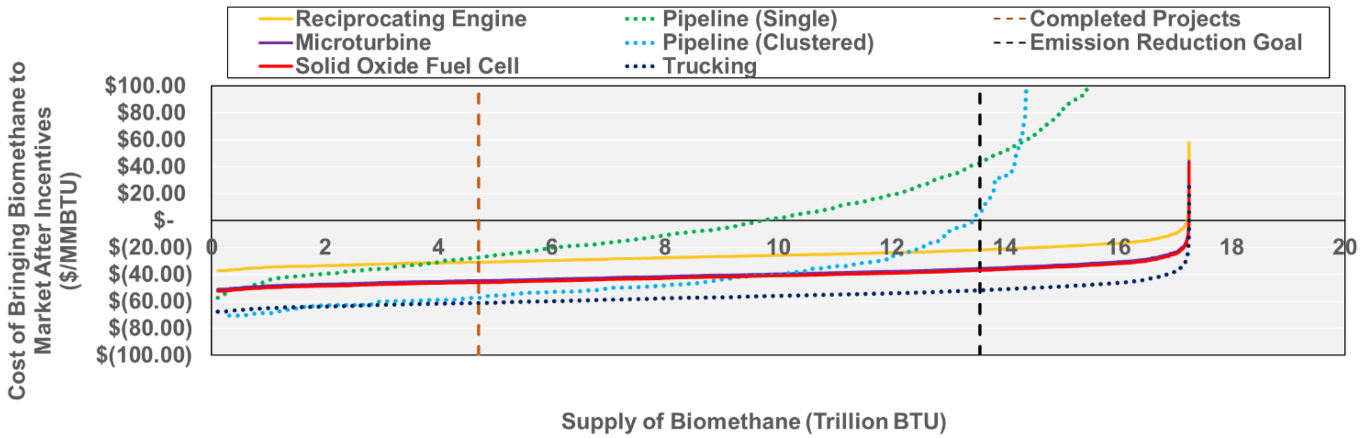

Figure 12. Biomethane Supply and Market Delivery Cost at LCFS and RIN Credits Prices of $200 and $2, Respectively

Current Federal and State Environmental Credits, Combined with Project Development Incentives, May Be Sufficient to Support Dairy Biomethane Projects

As the scenarios above illustrate, LCFS and RFS RIN credit prices are significant drivers of economic feasibility for anaerobic digestion projects at California dairy and livestock operations. This is especially true for projects that do not receive public funding. It is also clear that, given sufficient and sustained credit prices, most of these project types can cost-effectively supply sufficient biomethane to achieve the 2030 target with no additional public incentive funding, potentially reducing the need for those resources.

While each of these anaerobic digestion scenarios can potentially generate revenue or even profits to support construction and operation of digester projects, LCFS and RFS credit markets may be perceived as relatively uncertain as compared to conventional project financing options. Developers unable to obtain debt financing will need additional equity, assets, or public funding like that available through CCI to avoid delays in project implementation, or foregoing projects altogether. In these cases, local, state, and federal funding can ensure that projects will continue to move forward.

State law requires DDRDP expenditures funded by CCI to prioritize projects based on criteria pollutant emissions reduction benefits. While environmental credit prices may be sufficient to drive and sustain projects without additional public funds, the absence of these incentives may result in less desirable projects. For example, projects that use a reciprocating engine generator to produce electricity from biogas are often lower cost than other options but result in criteria pollutant impacts, potentially in some of California's most disadvantaged communities.

Similarly, trucking of biomethane to existing interconnection points may be a lower-cost option but may result in increased criteria pollutant emissions and vehicle miles traveled throughout the State. Reducing or eliminating CCI or other public funding for dairy and livestock methane emissions reduction projects may eliminate prioritization of projects that deliver important environmental and public health co-benefits.

Alternative Manure Management Projects Are Unlikely to be Implemented Without Incentives

Alternative manure management practice projects are not eligible to generate environmental credits because it is difficult to quantify methane emissions reductions relative to facility baseline emissions. This results from site-specific project variations that influence methane emissions mitigation. Variability in outcomes is a barrier to develop an offset quantification protocol for alternative manure management practices, so these projects are currently ineligible to generate carbon offset credits under CARB's Cap-and-Trade Program. As a result, financial viability is dependent on public funding, cost savings, and potential sales of value-added manure products like soil amendments and compost. In many cases, these combined savings and revenues are insufficient to offset project development costs, so public investments are critical. Without them, it is unlikely that a large number of projects will be implemented, which may impede the sector's ability to maximize its contribution to the target. These projects also provide important environmental and economic co-benefits through production of high-quality soil amendments, destruction of pathogens, reduction in nitrates and salts that threaten water quality, and production of a product that can be cost effectively transported to replace chemical fertilizer across the State.

Additional State Policies and Incentives Can Support Dairy Biomethane Projects

Long-term policies and incentives can play critical roles in supporting ongoing capture and use of biomethane from the dairy sector to achieve the 2030 target and the State's broader carbon neutrality goals. For example, a funding mechanism that incentivizes the capture of biomethane in California could expand to advance the production and use of biomethane and could provide market certainty to help project developers obtain project financing. While dairy biomethane is currently directed to the transportation fuel market through the LCFS Program, other market-based programs could play a role in directing the biomethane to alternative end uses, including towards industries that are difficult to electrify and otherwise decarbonize.

As described in the 2017 Scoping Plan Update, California must prioritize electrification wherever possible to in order to achieve its GHG emissions reduction goals. The State's electricity sector has already made considerable progress in moving toward zero- or low-GHG emissions generation, but other sectors including transportation, residential, and commercial still offer significant potential to decarbonize using electricity from sources like wind and solar. Some sectors, however, are difficult to electrify so directing dairy and livestock biomethane to these sectors can help decarbonize them, contributing to State carbon neutrality goals. The Scoping Plan Update will discuss additional policies to diversify dairy biomethane use and ensure long-term success of these projects to contribute to State's climate targets.

Analysis Item 2: Progress Made in Overcoming Technical and Market Barriers to Dairy and Livestock Methane Emissions Reductions Projects

The Strategy identifies barriers to methane emissions reductions measures that the dairy and livestock sector must overcome to achieve the 2030 target. These include technical barriers that impede project development based on various factors including technology limitations, incomplete development, or lack of standardized information. Market barriers impede project development based on factors including cost, availability of financing, environmental credit uncertainty, consumer acceptance, cost-effectiveness, and sector economics. This section will provide a short summary description of how to understand the technical and market barriers in this sector, followed by findings regarding the identified technical barriers and market barriers. Ultimately, the findings support that investment by the State and successful collaborations between agencies, developers, and stakeholders have largely overcome previously significant barriers.

Technical Barriers

Technical barriers impede both manure management methane emissions reduction projects and enteric mitigation strategy development. Specific to manure management, technical barriers impact both anaerobic digestion and alternative manure management projects. As described in the Strategy, technical barriers to anaerobic digestion include difficulties interconnecting with utility electrical grids and natural gas pipeline networks.

Technical barriers to alternative manure management projects result from inconsistent methane emissions reductions across project types and the resultant difficulty with accurately quantifying methane emissions reductions. In some cases, technical barriers may reinforce market barriers, making them even harder to overcome. For example, challenges in quantifying alternative manure management projects impedes the development of offset protocols or other market mechanisms that could improve their financial viability.

Market Barriers

Like the technical barriers discussed above, market barriers also impede both anaerobic digestion and alternative manure management projects. As detailed in the Final Recommendations to the Dairy and Livestock Greenhouse Gas Reduction Working Group, existing market barriers for manure methane reduction projects include project development costs, perceived lack of environmental credit certainty, out-of-State RNG competition, and underdeveloped markets for manure-based products. In addition to competition from out-of-State RNG, electricity and biofuels from California dairy waste faces competition from other sources of in-State renewable electricity such as solar and wind electricity, and competition from other sources of biomethane like landfills. As a result, dairy project developers rely on incentive funding or environmental credit revenues to make projects feasible. However, demand for incentives has consistently outpaced supply, especially for grant funding. Table 7 summarizes the status of progress for each technical and market barrier discussed in this section.

Table 7. Technical and Market Barriers to Implementing Manure Management and Enteric Fermentation Methane Emissions Reductions Projects

	Technical Barriers	**Market Barriers**
Manure Management	Alternative manure management projects ✗ Inconsistent reductions ✗ Difficulty quantifying reductions Anaerobic Digesters ✓ Grid and pipeline interconnection ✓ Biomethane quality standards	✓ Project development costs and financing ✓ Environmental credit certainty ✗ Sector economics ✗ Insufficient public funds ✗ Undeveloped markets for value-added manure products
Enteric Fermentation	✗ Transient effect/rumen adaptation ✗ Potential animal health impacts Limited availability ✓ Limited products with commercial availability ✗ Seasonal products	? Consumer acceptance ? Cost-effectiveness

✓ = Progress made ✗ = Persistent barrier? = Limited information available

Finding 2-1: Technical Barriers: Progress Has Been Made on Grid and Pipeline Interconnection and Biomethane Quality Standards, but Other Technical Barriers Remain

Technical Barriers to Anaerobic Digestion Projects

The dairy and livestock sector has made progress in overcoming certain technical barriers of manure methane emissions reductions projects, including access to pipeline networks and utility electrical grids. Project developers and utilities collaborated to understand technological and cost requirements for pipeline and electricity grid interconnection to reduce project development timelines.

Specific to pipeline injection projects, state agencies, utilities, project developers, and suppliers of biomethane upgrading equipment collaborated to identify technology immediately available for dairy operations to upgrade biomethane onsite.[68] Raw biogas from dairy and livestock facilities is mostly comprised of methane and carbon dioxide, with traces of many other constituents including oxygen, nitrogen, hydrogen sulfide, and water. To be injected into the utility pipeline, it must be upgraded, conditioned, and compressed to required pressures. Since the adoption of the Strategy, in Proceeding R.13-02-008, CPUC lowered the minimum heating value required for biomethane injected into natural gas pipelines. Prior to this change, achieving minimum heating value standards was a significant technical challenge and cost barrier for biomethane injection projects. This change resulted in decreased upgrading costs and removed the technical barrier without endangering public health or pipeline integrity.

In 2008, Pacific Gas and Electric Company (PG&E) interconnected the first dairy biomethane pipeline injection project, the first of its kind in California. PG&E continues to allow biomethane producers like dairy and livestock operations to interconnect to the natural gas pipeline system within their coverage area where sufficient capacity and downstream demand within the local pipeline exists. Interconnecting to the PG&E natural gas pipeline network consists of three steps. The first step involves an interconnection screening study which PG&E uses to determine the closest pipeline that can accept a producer's pipeline quality biomethane supply. Step two involves a preliminary engineering study where PG&E reviews the safest, most efficient interconnection route before developing a preliminary cost estimate for the

[68] Online Article. Xebec Enters California Dairy RNG Market with Maas Energy Works. Accessed on December 05, 2019.

interconnection. The final step consists of a detailed engineering study followed by construction of the interconnection.

In 2015, Southern California Gas Company (SoCalGas) began offering the Biogas Conditioning/Upgrading Services Tariff to allow the utility to plan, design, procure, construct, own, operate, and maintain biogas conditioning and upgrading equipment on customer premises. This optional fee service can further assist customers in their coverage area to overcome technical difficulties associated with interconnecting to the natural gas pipeline system. These potential biogas upgrading options help facilities achieve biomethane quality standards necessary for pipeline injection.

PG&E and SoCalGas are also working with dairy biomethane producers to engineer and construct pipeline infrastructure for six dairy biomethane pilot projects pursuant to SB 1383. These projects will help producers, utilities, and the State better understand the technical and economic factors affecting biomethane injection while ensuring and demonstrating successful biomethane delivery into the pipeline network. Additionally, three in-State projects that currently inject biomethane to the utility pipeline system have consistently met SoCalGas biomethane delivery specifications. In 2019, one of these projects completed construction of a digester cluster in Pixley, California and began delivering biomethane to the SoCalGas natural gas pipeline network. While costly, achieving pipeline quality specifications is technically feasible and no longer considered a technical barrier. In fact, in response to CARB's May 2020 webinar on this Analysis, SoCalGas submitted comments clarifying that the utility no longer views achieving pipeline quality specifications for biomethane injection a significant technical barrier.

Project developers and electric utilities have also overcome financial and technical barriers to accessing utility electrical grids. Interconnecting to utility electrical grids requires initial feasibility studies, which can cost several hundred thousand dollars, to outline site-specific technology requirements. Equipment and installation costs for system upgrades can be up to $1 million or more. While the costs and timelines associated with interconnections have not decreased considerably, experience from initial projects has helped to improve understanding of the processes and technical requirements and increased the deployment rate of electricity generation at dairy facilities. Three in-State dairy operations currently have certified LCFS pathways to deliver renewable electricity to the grid for electric vehicle charging with additional facilities—including two solid oxide fuel cell projects under development—that will pursue similar electric vehicle charging pathways to capitalize on potential LCFS credit revenue.

Technical Barriers to Alternative Manure Management Projects

Methane emissions reductions from alternative manure management practices vary substantially based not only on the technology chosen, but also on project-specific implementation variables. For example, a properly operated single stage slope screen solid-liquid separation system might reduce total and volatile solids sent to anaerobic storage by 17 percent. That same separation system operating in exceedance of its throughput capacity may process the same manure stream but with a reduced separation efficiency, allowing manure solids to bypass separation and proceed directly to anaerobic storage, eliminating the benefits intended by the system. Similarly, the composition of manure streams may affect the solid-liquid separation efficiency of the system with some manure streams being more readily separated than others. Such factors can cause considerable variability in solids removal and overall methane emissions reduction effectiveness, making it difficult to quantify reductions accurately and with certainty. In conclusion, alternative manure management practices have great methane emissions reduction potential, but many operational factors can affect their efficiencies, resulting in difficulties to quantify with appropriate certainty the methane emissions reductions benefits. CDFA and CARB have invested in the following research projects consistent with Dairy and Livestock Subgroup 1 Recommendations to better understand the methane emissions reduction potential of various alternative manure management practices:

- **Evaluation of Dairy Manure Management Practices for Greenhouse Gas Emissions Mitigation in California**
  In 2015, CDFA funded this University of California (UC), Davis study to measure the efficiency of various solid-liquid separation technologies. Results showed high variability across technologies resulting from factors including project design, operational capacity, and material throughput, and the associated report recommended additional research, particularly on weeping walls. This study also included an economic analysis to evaluate the cost-effectiveness of methane mitigation strategies on California dairy farms.

- **Characterize Physical and Chemical Properties of Manure in California Dairy Systems to Improve Greenhouse Gas Emission Estimates**
  In 2016, CARB funded this UC Davis research to characterize the physical and chemical properties of manure in California dairy systems.

- **Research and Technical Analysis to Support and Improve the Alternative Manure Management Program Quantification Methodology**
  In 2017, CARB funded this UC Davis literature review to assess methane emissions reduction potential of various alternative manure management practices, including solid-liquid separation and weeping walls. Results found all studied technologies had variable performance and the associated report recommended additional research on factors affecting performance of these systems.

- **Benchmarking of Pre- and Post-Alternative Manure Management Program Dairy Emissions and Prediction of Related Long-Term Airshed Effect**
  Between 2016 and 2018, CARB and CDFA collaborated to fund these complementary studies to monitor GHG and air pollutant emissions before and after implementation of various alternative manure management practices at six AMMP-funded dairies. In a separate but complementary effort, CARB installed flux towers to measure methane emissions on three of the six AMMP-funded dairies.

- **Development of the California Dairy Emissions Model**
  In 2019, CARB funded UC Davis to develop a California dairy emissions model to evaluate the effectiveness of potential mitigation strategies and to estimate GHG and other air pollutant emissions from California dairies.

Technical Barriers to Enteric Methane Mitigation Strategies

Enteric strategies, especially feed additives, hold considerable methane mitigation potential from all ruminant species. However, limited commercial availability and seasonal availability of effective feed additives, a lack of long-term effectiveness, and the potential for adverse impacts on animal health for certain products remain persistent technical barriers.

A few methane reducing feed additives with proven long-term effectiveness and no adverse impacts on animal or human health have become commercially available, indicating progress towards overcoming that barrier. However, limited availability of proven strategies remains a barrier for enteric mitigation strategies. For example, the most well-studied potential feed additive, 3-NOP, is expected to become commercially available in the United States in 2024.[69] There is a significant body of evidence to support the effectiveness of 3-NOP in reducing enteric methane emissions by approximately 30 percent. 3-NOP is currently undergoing long-term trials as part of

[69] Mitloehner, F., Kebreab, E., Tricarico, J., Wallace, J., Gooch, C., Gibbs, C. (2020). Dairy Feed Additives to Reduce Enteric Methane Emissions. Newtrient.

the FDA evaluation and approval process before final approval for commercial distribution.

Grape pomace is another additive that may reduce emissions and may not require FDA approval. However, it is only available in late summer and early fall during grape harvest, limiting its feasibility for year-round emissions reductions. Some novel additives such as seaweed also show methane emissions mitigation potential, but with limited *in vivo* (animal) studies to evaluate their long-term effectiveness and potential impacts on animal health, productivity, and product safety. For example, *Asparagopsis,* a special species of seaweed, shows mitigation potential of up to 90 percent during *in vitro* (non-animal studies using rumen simulation technologies) studies,[70] while *in vivo* studies show a mitigation potential of approximately 50 percent during enteric fermentation.[71] However, this additive is still under development, with many unaddressed technical barriers including the potential risk of elevated bromide residues in milk (a food safety concern), palatability concerns causing decreased feed intake and milk production, and low availability and high cost for the product.

Another persistent technical barrier for enteric methane mitigation strategies is limited long-term information about product effectiveness for most available or emerging options. There are a variety of products in various stages of commercial development that face barriers mentioned above. For example, some additives may impact animal health and productivity. Others may have limited long-term effectiveness due to rumen adaptation leading to rapid additive breakdown.[72] While some additives show great mitigation potential, their long-term impacts on animal health, availability, and cost-effectiveness are not well known. In short, feed additives offer promising potential as a mitigation strategy, but require further research and development before being required for use as part of any CARB regulation. SB 1383 requires that only incentive-based mechanisms are authorized for enteric emissions reductions until CARB, in consultation with CDFA, determines that another mechanism is cost-effective, considering the impact on animal productivity and must be scientifically proven to reduce enteric methane emissions, and that adoption of the enteric

emissions reduction method would not damage animal health, public health, or consumer acceptance.

Additional Research to Address Technical Barriers

The California legislature appropriated $5 million for research grants for FY 2021-22 to measure and verify emissions reductions associated with dairy livestock methane emissions reduction projects. Specifically, the Legislature requires additional research in the following areas:

- Assessment of the cost-effectiveness of various dairy and livestock methane mitigation strategies on a per ton basis including a comparison of projects funded under AMMP and DDRDP
- Assessment of the cost-effectiveness of enteric methane mitigation strategies
- Additional research on value-added manure-based products development
- Measurement of greenhouse gases and criteria pollutants before and after livestock methane reduction projects are implemented

These research projects will further the State's understanding of the effectiveness of anaerobic digestion and alternative manure management projects at achieving methane emissions reductions and environmental co-benefits. In addition, these studies will allow further investigation of the efficacy and cost-effectiveness of enteric strategies, should additional strategies become available.

Finding 2-2: Market Barriers: The State and Federal Incentive Programs Have Helped Achieve Progress with Project Funding and Incentives

Similar to the technical barriers detailed above, the State, along with others, have made considerable progress in overcoming market barriers to implementing methane emissions reductions projects. Improved understanding of project development costs and significant allocations of CCI funding for manure methane emissions reduction projects have contributed to progress in overcoming barriers related to project funding (Table 8).

Table 8. State Investment in Manure Methane Emissions Reduction Projects

State Investment Program	Investment ($ million)
DDRDP	$196
AMMP	$68
Pilot pipeline construction	$319
Renewable Gas Pipeline Incentive Program	$40
Total	**$623**

This Analysis has already discussed the critical role that market-based programs like Cap-and-Trade and LCFS, RFS, and grant programs like DDRDP and AMMP, have played in driving manure management project development. In addition to those programs, with year-over-year funding to support project development, the Legislature also enacted other initiatives to reduce market barriers for anaerobic digestion projects. Through SB 1383, the Legislature directed CPUC, along with CARB and CDFA, to select six pilot projects to demonstrate biomethane injection into the common carrier pipeline network. This pilot program committed $319 million in rate-recoverable funding to 45 dairies for pipeline infrastructure and operational expenses over 20 years with no private match funding requirement.[73] These projects will provide valuable information on pipeline interconnection processes and the associated costs.

CPUC also administers BioMAT, which provides long-term power purchase agreements with a guaranteed price to projects that generate onsite electricity from certain biogenic feedstock and deliver that electricity to the grid. This market program allows three utilities (Pacific Gas and Electric Co., San Diego Gas & Electric Co., and Southern California Edison) to offer favorable rates to onsite generation projects using a market adjusting mechanism that periodically increases the rate until there are enough market participants. BioMAT has funded two projects for a cumulative total of $8 million, with eight additional projects pending. To date, dairy electricity generation projects have filled nearly 19 megawatts (MW) of the 90 MW available. Another program administered by CPUC is the Renewable Gas Pipeline Interconnection Incentive Program, which provides cost share for dairy biomethane pipeline injection projects. The Legislature appropriated $40 million for pipeline interconnection projects, with up to $3 million in infrastructure cost share available for single-dairy projects, and up to $5 million for dairy cluster projects. Although these programs predate SB 1383, both have seen increased interest since it was enacted.

These incentive programs have been critical to funding the upfront costs of anaerobic digesters, and have also been consistently oversubscribed, which shows an unmet need for additional local, state, and federal investment. However, the availability of incentives coupled with environmental credit revenue has led to increased private investment. Private equity firms and companies have invested in anaerobic digesters, creating additional opportunities for project developers and financers. Increased private funding may result in projects that are financially solvent without upfront incentives, but these funding sources are limited. Sustained environmental credit

[73] California Public Utilities Commission. (December 3, 2018). CPUC, CARB, and Department of Food and Agriculture Select Dairy Biomethane Projects to Demonstrate Connection to Gas Pipelines.

revenue can further reduce risk to lenders and deliver quicker returns on investments, making these projects increasingly attractive to private capital.

One important consideration about the role of public funding is its ability to prioritize multiple benefits. For instance, private capital will pursue biomethane or electricity options that minimize costs and maximize revenue available through environmental credits. In contrast, the State can require funded projects to meet multiple goals. For example, CDFA prioritizes DDRDP projects that minimize environmental impacts including NOx and air pollutants and maximize the environmental co-benefits and community benefits as required by the Legislature when it passed SB 859 (Chapter 368, Statutes of 2016). Implementation of SB 859 has resulted in widespread implementation of pipeline injection projects due to their lower air quality impact compared to relatively lower-cost onsite combustion or trucking projects.

Alternative manure management practices and enteric methane mitigation strategies have not seen similar progress in project funding; without additional local, State, and federal funding, these project types are unlikely to move forward.

Finding 2-3: Market Barrier: Clarity from the State Has Improved Environmental Credit Certainty

California's Cap-and-Trade Program and LCFS Program, and the federal RFS Program, are the primary policy and programmatic mechanisms that provide environmental credit revenue for dairy digesters. To improve market certainty of the Cap-and-Trade Program and LCFS Program for dairy digesters, CARB developed the following two documents:

- Credit Generation for Reduction of Methane Emissions from Manure Management Operations helps project developers better understand potential impact to environmental credit generation that a methane emissions reduction regulation may have, to provide greater market certainty.

- The SB 1383 Pilot Financial Mechanism Paper describes a potential pilot financial mechanism that, if implemented, could improve stability and certainty around LCFS credits generated from anaerobic digestion at dairy operations. The white paper describes two potential approaches—put options and contracts for differences—to ensure that participating facilities can receive a set minimum LCFS credit price. Increasing revenue certainty helps project developers access private financing, potentially reducing or eliminating the need for long-term public support. For the mechanism to be implemented, however, it would need an administrator and initial funding. The white paper notes that CARB should not administer this program because of a conflict of interest as the LCFS Program administrator.

Finding 2-4: Market Barriers Remain for Value-Added Manure Products, Alternative Manure Management Projects, and Enteric Methane Mitigation Strategies

Despite progress, persistent market barriers for alternative manure management projects and enteric methane mitigation strategies create an enduring need for funding to support these methane emissions reduction strategies.

Market Barriers for Value-Added Manure Products

Underdeveloped markets for value-added manure products is a persistent market barrier that, if addressed, could improve the financial viability of manure management projects and provide a variety of environmental co-benefits. Most alternative manure management practices produce compost that could be further commodified to provide an additional revenue stream for dairy operators. Improved markets for such products may also drive additional upstream or downstream GHG emissions reductions. For example, manure compost typically contains fewer contaminants and has higher nutrient content than municipal green waste. Similarly, dairy-based organic fertilizers avoid the upstream GHG emissions resulting from manufacture and distribution of synthetic, fossil-based fertilizers. As a result, value-added manure products can potentially provide an important revenue stream to dairy and livestock operations that could reduce reliance on public funding.

Additionally, these products can provide important environmental co-benefits, including soil health, water retention, and potential displacement of petrochemical fertilizers. Market maturation would offer more opportunity to export nutrient-rich manure solids and reduce potential for water quality impacts from land application of manure. These benefits may be especially important in the San Joaquin Valley, where representative groundwater monitoring shows widespread water quality impacts.[74]

Despite considerable potential benefit to producers and consumers, there is limited information available about the demand for value-added manure products or the quantity that can be cost effectively delivered to the market. To help overcome market barriers and facilitate value-added manure products market development, CDFA is

[74] Shrestha, A. & Luo, W. (2017). An assessment of groundwater contamination in Central Valley aquifer, California using geodetector method. *Annals of GIS*, 23(3), 149-166.

planning to convene a focused working group to address these obstacles and improve financial viability of alternative manure management projects.

Market Barriers to Alternative Manure Management Projects

In many cases, adopting alternative manure management practices at dairies may not be cost-effective due to the lack of revenue streams to generate attractive rates of return to farmers and developers. Additionally, many of the dairies that implement these practices may not have the have the resources to diversify their operations to take advantage of new or expanded market opportunities. In the absence of public funding, these operations—often smaller and less able to capitalize on economies of scale—will need to rely on cost savings and revenue from the sale of value-added manure products (e.g., compost and soil amendment). However, the limited financial benefits of these projects are often insufficient to offset project costs. Additionally, ineligibility for environmental credits and underdeveloped markets for value-added manure products present additional market barriers. As a result, the availability of debt financing is limited.

Market Barriers to Enteric Methane Mitigation Strategies

Limited information is available for a comprehensive analysis of market barriers for enteric mitigation strategies, though market barriers may arise as options become available. However, to be viable, the market requires potential products to gain consumer acceptance and be cost-effective. SB 1383 requires cost-effectiveness of products, among other requirements, prior to requiring their use. Additives that fail to meet these requirements are unlikely to be adopted as effective enteric methane mitigation strategies.

Next Steps

Moving forward, the dairy and livestock sector must still achieve considerable methane emissions reductions to meet the 2030 target. Achieving the target will require careful consideration of potential methane emissions reductions strategies and coordination with other agencies, the dairy and livestock sector, and the public, including environmental justice and disadvantaged communities. Implemented strategies must not only reduce methane emissions from the sector sufficient to achieve the 2030 target but should also be consistent (to the extent feasible) with other State objectives. These objectives include reduced impacts to air and water quality, improved soil health, reduced impacts to environmental justice communities, and maximized GHG emissions reductions while minimizing emissions leakage. This will require coordinated action between the State and the dairy and livestock sector to overcome barriers to implementing proven methane emissions reduction projects and emerging mitigation options, especially for enteric fermentation. Improved accuracy in tracking and quantifying methane emissions reductions achieved by operational manure management projects or expected from future projects—especially alternative manure management projects and emerging enteric methane reducing feed additives—is also critical to evaluating progress toward the 2030 target. These improvements will help identify effective incentives and policies in the near-term and will aid in the design of potential regulations should that be necessary for achieving the 2030 target. The 2022 Scoping Plan Update will further assess and describe the role that the dairy and livestock sector can play to help achieve carbon neutrality.

CARB staff will continue to monitor the dairy and livestock sector's methane emissions reductions progress and refine its understanding of emissions sources, emissions reduction potential, and the achievements of incentives. CARB will continue to research additional technology options and management practices that can achieve methane emissions reductions, as well as research the effectiveness of practices used today. CARB will consider potential options to improve quantification of methane emissions reductions from manure management projects as well as ways to refine GHG emissions accounting for the sector. In order to comply with the statutory direction, CARB will consider regulation development to ensure that the 2030 target is achieved, assuming the conditions outlined in the statute are met. These next steps are described in greater detail below.

Continue Tracking Progress of Methane Emissions Reduction Projects and Funding

The State's appropriation of $289 million in CCI funds for manure methane emissions reductions to date has resulted in 233 dairy manure management projects that will achieve an estimated 2.0 $MMTCO_2e$ in annual reductions by 2022. This funding delivers some of the most cost-effective SLCP emissions reductions to date. CARB staff will continue to track the availability of local, State, and federal incentive funding, the progress of existing projects, and future projects implemented using both public and private funds. Additionally, CARB staff will continue to monitor market developments for value added manure products, and CDFA will convene a working group to reduce market barriers and improve the financial viability of alternative manure management projects.

Continue Tracking Manure Management Methane Emissions Reduction Options

CARB staff will track advancements in manure methane emissions reductions. Specifically, staff will continue to monitor the results of ongoing research including the monitoring emissions at AMMP project sites pre- and post-implementation, CPUC pilot pipeline infrastructure projects, methane emissions flux monitoring, literature reviews, and the development of a dairy emissions model to better understand changes from manure management methane emissions reduction projects. CARB, in collaboration with CDFA, will also continue to evaluate the potential for additional alternative manure management practices.

Continue Tracking Enteric Methane Emissions Reduction Options

There are limited commercially available animal feed for mitigating enteric methane emissions reductions additives in the United States. Some regions, including Brazil, Chile, and Europe have recently approved the use of 3-NOP.[75,76] CARB staff will continue to track the progress of these enteric methane emissions mitigation strategies, analyze their cost-effectiveness, and assess consumer acceptance.

Address GHG Emission Inventory Challenges

In addition to tracking enteric and manure methane emissions reductions options, CARB staff is evaluating options to improve the accuracy of the annual GHG Emission Inventory. Gathering operational or "activity data"[77] from facilities within the sector is an important first step to refining inventory models and associated assumptions to be more California-specific. These refinements would improve GHG Emission Inventory accuracy and inform incentive planning and regulatory development efforts.

Detailed facility activity data on the parameters that affect methane emissions should be collected annually. Specific data may include animal breed, population, production stage, diet composition, animal housing type, and the manure collection rate, storage conditions and length, treatment methods, and land application rates of manure. A more accurate accounting of these parameters can help assess methane mitigation strategies and calibrate emission models.

---

[75] https://www.bloomberg.com/news/articles/2021-09-09/world-s-top-beef-supplier-approves-methane-busting-cow-feed

[76] https://www.dsm.com/corporate/news/news-archive/2022/dsm-receives-eu-approval-Bovaer.html

[77] Activity data refers to important factors that can impact emissions from dairy and livestock operations. Some example factors include animal population size, breed, age, lactation status, diet, and type of manure management.

CARB recommends a collaborative effort including public agencies and industry to gather activity data from dairy and livestock operations. Specifically, it may evaluate leveraging or modifying existing reporting structures like annual water quality reports to gather additional activity data from the sector. This approach may increase the likelihood of a high response rate, reduce resources needed to develop a new reporting structure, and reduce the reporting burdens to dairy and livestock operations. A voluntary survey of the sector could also provide useful activity data if a new or modified reporting structure is infeasible.

If these efforts are infeasible or are unsuccessful, a recordkeeping and reporting regulation developed pursuant to SB 1383[78] could provide a mechanism to obtain the necessary activity data. Reported information would be used to improve inventory accuracy, evaluate methane emissions reduction progress, and inform design of potential emissions reduction regulations, should that be necessary.

Executive Summary

This Scoping Plan lays out the sector-by-sector roadmap for California, the world's fifth[1] largest economy, to achieve carbon neutrality by 2045 or earlier, outlining a technologically feasible, cost-effective, and equity-focused path to achieve the state's climate target. This is a challenging but necessary goal to minimize the impacts of climate change. There have been three previous Scoping Plans. Previous plans have focused on specific greenhouse gas (GHG) reduction targets for our industrial, energy, and transportation sectors—first to meet 1990 levels by 2020, then to meet the more aggressive target of 40 percent below 1990 levels by 2030. This plan, addressing recent legislation and direction from Governor Newsom, extends and expands upon these earlier plans with a target of reducing anthropogenic emissions to 85 percent below 1990 levels by 2045. This plan also takes the unprecedented step of adding carbon neutrality as a science-based guide and touchstone for California's climate work. The plan outlines how carbon neutrality can be achieved by taking bold steps to reduce GHGs to meet the anthropogenic emissions target and by expanding actions to capture and store carbon through the state's natural and working lands and using a variety of mechanical approaches.

Greenhouse gases ↓85% | Air pollution ↓71% | Petroleum demand ↓94%

What this means for California is an ambitious and aggressive approach to decarbonize every sector of the economy, setting us on course for a more equitable and sustainable future in the face of humanity's greatest existential threat, and ensuring that those who benefit from this transformation include communities hardest hit by climate impacts and the ongoing pollution from the use of fossil fuels. The combustion of fossil fuels has polluted our air—particularly in low-income communities and communities of color—for far too long and is the root cause of climate change. This Scoping Plan helps us chart the path to a future where race and class are no longer predictors of disproportionate burdens from harmful air pollution and climate impacts.

The major element of this unprecedented transformation is the aggressive reduction of fossil fuels wherever they are currently used in California, building on and accelerating carbon reduction programs that have been in place for a decade and a half. That means rapidly moving to zero-emission transportation; electrifying the cars, buses, trains, and trucks that now constitute California's single largest source of planet-warming pollution. It also means phasing out the use of fossil gas used for heating our homes and buildings. It means clamping down on chemicals and refrigerants that are thousands of times more powerful at trapping heat than carbon dioxide (CO_2). It means providing our communities with sustainable options for walking, biking, and public transit to reduce reliance on cars and their associated expenses. It means continuing to build out the solar arrays, wind turbine capacity, and other resources that provide clean, renewable energy to displace fossil-fuel fired electrical generation. It also means scaling up new options such as renewable hydrogen for hard-to-electrify end uses and biomethane where needed. Successfully achieving the outcomes called for in this Scoping Plan would reduce demand for liquid petroleum by 94 percent

1 In October 2022, California was poised to become the world's fourth largest economy.

and total fossil fuel by 86 percent in 2045 relative to 2022.[2] Despite these world-leading efforts, some amount of residual emissions will remain from hard-to-abate industries such as cement, internal combustion vehicles still on the road, and other sources of GHGs, including high global warming chemicals used as refrigerants.

The plan addresses these remaining emissions by re-envisioning our natural and working lands—forests, shrublands/chaparral, croplands, wetlands, and other lands—to ensure they play as robust a role as possible in incorporating and storing more carbon in the trees, plants, soil, and wetlands that cover 90 percent of the state's 105 million acres while also thriving as a healthy ecosystem. Modeling indicates that natural and working lands will not, on their own, provide enough sequestration and storage to address the residual emissions. For that reason, it is necessary to research, develop, and deploy additional methods of capturing CO_2 that include pulling it from the smokestacks of facilities, or drawing it out of the atmosphere itself and then safely and permanently utilizing and storing it, as called for in recent legislation. Carbon removal also will be necessary to achieve net negative emissions to address historical GHGs already in the atmosphere.

This is a plan that aims to shatter the carbon status quo and take action to achieve a vision of California with a cleaner, more sustainable environment and thriving economy for our children. This ambitious plan will serve as a model for other partners around the world as they consider how to make their transition. As we have so often in the past, California can continue to serve as a leader in innovation that has produced not only the fifth largest economy on the planet, but ultimately one of the most energy-efficient economies, with a track record of demonstrating the ability to decouple economic growth from carbon pollution. This plan also builds upon current and previous environmental justice efforts to integrate environmental justice directly into the plan, to ensure that all communities can reap the benefits of this transformational plan. Specifically, this plan identifies a path to keep California on track to meet its SB 32 GHG reduction target of at least 40 percent below 1990 emissions by 2030.

2 See *CARB's energy demand reductions*.

- Identifies a technologically feasible, cost-effective path to achieve carbon neutrality by 2045 and a reduction in anthropogenic emissions by 85 percent below 1990 levels.
- Focuses on strategies for reducing California's dependency on petroleum to provide consumers with clean energy options that address climate change, improve air quality, and support economic growth and clean sector jobs.
- Integrates equity and protecting California's most impacted communities as driving principles throughout the document.
- Incorporates the contribution of natural and working lands (NWL) to the state's GHG emissions, as well as their role in achieving carbon neutrality.
- Relies on the most up-to-date science, including the need to deploy all viable tools to address the existential threat that climate change presents, including carbon capture and sequestration, as well as direct air capture.
- Evaluates the substantial health and economic benefits of taking action.
- Identifies key implementation actions to ensure success.

The path forward is informed by robust science. The recent Sixth Assessment Report (AR6) of the Intergovernmental Panel on Climate Change (IPCC) summarizes the latest scientific consensus on climate change. It finds that atmospheric concentrations of CO_2 have increased by 50 percent since the industrial revolution and continue to increase at a rate of two parts per million each year.[3] By the 2030s, and no later than 2040, the world will exceed 1.5°C warming unless there is drastic action. While every tenth of a degree matters — every incremental increase in warming brings additional negative impacts — climate-related risks to human health, livelihoods, and biodiversity are projected to increase further under 2°C warming, compared to 1.5°C.[4] For example, at 1.5°C of global warming, we would experience increasing heat waves, longer warm seasons, and shorter cold seasons, but at 2°C of global warming, heat extremes would more often reach critical tolerance thresholds for human health and agriculture.[5] We are already seeing unprecedented climate change impacts, such as continued sea level rise, that are "irreversible" for centuries to millennia, and we are dangerously close to hitting 1.5°C in the near term.[6] To avoid climate catastrophe and remain below 1.5°C with limited or no overshoot of that threshold, global net anthropogenic CO_2 emissions need to reach net zero by 2050.

6 *United Nations. 2021. IPCC report: 'Code red' for human driven global heating, warns UN chief. August 9.*

It has been 16 years since the Global Warming Solutions Act of 2006 was passed and signed into law. In 2017, the second update to the Assembly Bill (AB) 32 Climate Change Scoping Plan[7] (2017 Scoping Plan) laid out a cost-effective and technologically feasible path to achieve the 2030 GHG reduction target. At the time, many characterized the plan and the AB 32 target as unachievable, citing that it would lead to massive business and job loss, and excessive costs. Those predictions proved to be incorrect as California achieved its AB 32 target years ahead of schedule, all the while growing our economy, with the state distinguishing itself as a hub for green technology investment. This Scoping Plan draws on a decade and a half of proven successes and additional new approaches to provide a balanced and aggressive course of effective actions to achieve carbon neutrality in 2045, if not before, in addition to the 2030 goal.

California's economy is projected to grow vigorously in the coming years and decades. In 2045, under a Reference Scenario, the gross state product would be $5.1 trillion, nearly $2 trillion more than in 2021, and allow growth that would add hundreds of thousands of jobs. Under the Scoping Plan scenario, impacts to economic and job growth would be negligible in both 2035 and 2045, while delivering $199 billion of benefits in the form of reduced hospitalizations, asthma cases, and lost work and school days due to the cleaner air supported by this plan. This should come as no surprise given the tremendous growth of California's economy since the Great Recession of 2007–2009, even as the state has taken drastic measures to lower emissions. As noted, the savings associated with ambitious climate action are extensive, both in terms of avoided climate impacts and health costs. As described in Chapter 1, the health costs of climate and air pollution in the U.S. are well over $800 billion today and will continue to grow in the coming years[8] without robust action. Similarly, the costs of delayed or insufficient climate action could cost the U.S. upwards of $14.5 trillion over the next 50 years.[9] We can either take action now or pay the cost of inaction, both now and later.

Grows CA's economy to $5.1 trillion by 2045

New jobs ↑ 4 million

Health costs ↓ $200 billion

We cannot take on this unprecedented challenge alone. Collaboration with the federal government, other U.S. states, and other jurisdictions around the world will continue to be fundamental for California to succeed in achieving its climate targets, especially as the pace of our efforts increases in the coming years. We believe this collaboration and coordination also creates a race to the top, encouraging and enabling other jurisdictions to achieve climate and air quality goals as well, and often providing lessons for national action.

One example of fruitful collaboration is California's longstanding vehicle emissions standards programs, which have repeatedly been freely adopted by other states, consistent with the federal Clean Air Act. California's programs frequently pioneer more rigorous standards or new technologies—such as the now-standard catalytic converter and the rules that led directly to the nation-leading numbers of zero-emission vehicles on our roads today. From initial standards for cars

and trucks decades ago to the world-leading Advanced Clean Trucks program currently helping to electrify heavy-duty vehicles, this partnership continues to offer regulatory options and spread innovative technologies. A major example of future work is the Advanced Clean Cars II program, which lays out California's legally binding path to achieving 100 percent zero emission vehicle (ZEV) sales in 2035.[10] The California Air Resources Board (CARB) continues to work closely with many other states that also see zero-emission vehicles as critical to their climate and public health goals and expects many states to choose to adopt this regulation as well. This partnership with other states also creates market certainty for automakers, which in turn helps to ensure that California consumers have access to a variety of ZEVs at multiple price points.

The Scoping Plan Process

Four scenarios were extensively modeled to develop this Scoping Plan, with the objective of informing the most viable path to remain on track to achieve our 2030 GHG reduction target: a reduction in anthropogenic emissions by 85% below 1990 levels and carbon neutrality by 2045. All four have their merits and are informed by stakeholder input. The scenario ultimately chosen as the basis of this Scoping Plan is the alternative that most closely aligns with existing statute and Executive Orders. It was selected because it best achieves the balance of cost-effectiveness, health benefits, and technological feasibility.

For the first time, this Scoping Plan includes modeling and quantification of GHG emissions and carbon sequestration in natural and working lands (NWL). To date, the focus has been only on reducing the emissions of GHGs from our transportation, energy, and industrial sectors. The state's 2020 and 2030 GHG reductions targets only include these sources, as they are the primary drivers of climate change and disproportionate harmful air pollution in our vulnerable communities. This Scoping Plan, through the lens of carbon neutrality, expands the scope to more meaningfully consider how our NWL contribute to our long-term climate goals. For the first time, new and cutting-edge modeling tools allow us to estimate the quantitative ability of our forests and other landscapes to remove and store carbon under different scenarios. These cutting-edge tools were developed through a stakeholder process and in coordination with other agencies for the purpose of this update and will continue to be refined over time and made available to others seeking to do similar work.

10 *Executive Department. State of California. Executive Order N-79-20.*

As recent data and Scoping Plan modeling shows, our NWL also can act as a source of emissions, principally in the form of wildfires. California's forests are experiencing a deadly combination of drought and heat combined with a century of misguided fire suppression management. Scoping Plan modeling shows that, at this time and until our forests reach a balance through appropriate treatments, California's NWL will act as a net source of emissions, not a sink. As such, the Scoping Plan includes policy direction and actions intended to quickly move the sector toward being a net sink and a more natural state, where wildfires will continue to be an important part of the healthy forest cycle but not at the intensity and frequency observed in recent years.

Development of this Scoping Plan also includes careful consideration of, and coordination with, other state agencies, consistent with Governor Gavin Newsom's whole-of-government approach to tackling climate change. State agency plans and regulations, including the SB 100 Joint Agency Report,[11] State Implementation Plan, Climate Action Plan for Transportation Infrastructure,[12] AB 74 Studies on Vehicle Emissions and Fuel Demand and Supply,[13,14,15] Short-Lived Climate Pollutant Strategy (SLCP Strategy),[16] CARB's Achieving Carbon Neutrality Report,[17] Climate Smart Lands Strategy,[18] Natural Working Land Implementation Plan,[19] and the California Climate Insurance Report: Protecting Communities, Preserving Nature, and Building Resiliency,[20] among others, provided critical inputs and data points for this plan. This Scoping Plan is the product of work by multiple agencies across the Administration, including dozens of public workshops and years of rigorous analysis and economic modeling by California's leading institutions. This cooperation on planning lays the foundation for even closer coordination among and between state agencies to put the plan into effect.

The plan is also the product of tireless efforts of, and recommendations from, the AB 32 Environmental Justice Advisory Committee (EJ Advisory Committee). The EJ Advisory Committee, created by statute, plays a critical role to inform the development of each Scoping Plan and helps to ensure environmental justice is integrated throughout the plan. CARB reconvened the EJ Advisory Committee in early 2021 to advise on the development of this Scoping Plan. In their advisory role, the EJ Advisory Committee has worked together to provide inputs to CARB to inform the development of scenarios and the associated modeling. And in April 2022, the EJ Advisory Committee provided draft preliminary recommendations in advance of the Draft 2022 Scoping Plan to help ensure the draft plan meaningfully addresses environmental justice. The CARB Board and EJ Advisory Committee held a joint board hearing on September 1, 2022, where the EJ Advisory Committee presented their final recommendations on the Scoping Plan. Over five dozen of the recommendations are reflected in the Scoping Plan. Going forward, as this plan is ultimately acted on by the Board, ongoing input from the EJ Advisory Committee will be essential to address environmental justice and achieve the ambitious vision outlined in the plan throughout its implementation in the coming years.

Importantly, per legislative direction, the Scoping Plan development includes modeling and analyses of emissions, economics, air quality, health, jobs, and public health. This work is important to inform the discussion around trade-offs and how to balance the various legislative direction in identifying a path to achieve the state's climate goals. The technical work serves as a backdrop to what this means to Californian's daily lives—to how they will work, play, and live as we act to eliminate fossil fuel combustion and achieve the many public health and environmental benefits that will result from that action.

Ensuring Equity and Affordability

The state has a long history of public health and environmental protection. However racist and discriminatory practices such as redlining have resulted in low-income communities and communities of color being disproportionately exposed to health hazards and pollution burdens.[21] These communities are often located adjacent to major roadways and large stationary sources that not only emit GHGs, but also harmful localized air pollution. The plan delivers on the promise to transform the way we move, live, and work by nearly eliminating our dependence on fossil fuels. It includes effective actions to move with all possible speed to clean energy, zero-emission cars and trucks, energy-efficient homes, sustainable agriculture, and resilient NWL. And it prioritizes working with the communities most impacted to ensure that these strategies address their needs.

An important part of our equity consideration is ensuring the transition to a zero-emission economy is affordable and accessible, and that it uplifts disadvantaged, low-income communities and communities of color. Some aspects of the transition will have associated costs (e.g., escalating efforts to retrofit existing homes and businesses to support electric appliances and vehicles and increased costs of insurance). The state must ensure that these costs do not disproportionately burden consumers. In addition, the state has an important role to play in providing financial incentives, especially to low-income consumers, to allow for uptake of clean technologies. The Department of Community Services and Development's Low Income Weatherization Program is a prime example of this approach, enabling low-income Californians to be part of the zero-emission transition, all while lowering energy bills. The program provides low-income households with solar

21 *CalEPA. 2021. Pollution and Prejudice: Redlining and Environmental Injustice in California. August 16.*

photovoltaic systems and energy efficiency upgrades at no cost to residents, helping cushion the impact of climate change on vulnerable communities.

With this Scoping Plan, the state also adds another tool to help identify and close climate change impact gaps that will emerge over time. As California invests in climate mitigation and adaptation, it is essential to understand the relative impact of climate change across the state's diverse communities. We know not all communities are equally resilient in the face of climate impacts due to persisting health and opportunity gaps. We also know that a global metric such as the Social Cost of Carbon cannot adequately capture the incremental additional impact faced by overly burdened communities. The Climate Vulnerability Metric (CVM) is specifically focused on quantifying the community-level impacts of a warming climate on human welfare.

Energy and Technology Transitions

To support the transformation needed, we must build the clean energy production and distribution infrastructure for a carbon-neutral future. The solution will have to include transitioning existing energy production and transmission infrastructure to produce zero-carbon electricity and hydrogen, and utilizing biogas resulting from wildfire management or landfill and dairy operations, among other substitutes. In almost all sectors, electrification will play an important role. That means that the grid will need to grow at unprecedented rates and ensure reliability, affordability, and resiliency through the next two decades and beyond. It also means we need to keep all options on the table, as it will take time to fully grow the electricity grid to be the backbone for a decarbonized economy. We also know that electrification is not possible in all situations. As such, this plan systematically evaluates and identifies feasible clean energy and technology options that will bring both near-term air quality benefits and deliver on longer-term climate goals.

4x
solar & wind generation

1,700x
renewable hydrogen

100%
ZEV sales by 2035

This transition will not happen overnight. It will take time and planning to ensure a smooth transition of existing energy infrastructure and deployment of new clean technology. And while this Scoping Plan has the longest planning horizon of any Scoping Plan to date, this 25-year horizon is still relatively short in terms of transforming California's economy. We must avoid making choices that will lead to stranded assets and incorporate new technologies that emerge over time. Importantly, given the pace at which we must transition away from fossil fuels, we absolutely must identify and address market and implementation barriers to be successful. The scale of transition includes adding four times the solar and wind capacity by 2045 and about 1,700 times the amount of current hydrogen supply.

As we transition our energy systems, we must also rapidly deploy the clean technologies that rely on a decarbonized grid. As called for in Executive Order N-79-20, all new passenger vehicles sold in California will be zero-emission by 2035, and all other fleets will have transitioned to zero-emission as fully possible by 2045. This means the percentage of fossil fuel combustion vehicles will continue to rapidly decrease, becoming a fading vision of the past. Successful implementation of this Executive

Order (EO) and other zero-emission priorities will have to be attractive to consumers. As an example, electric and hydrogen transportation refueling must be readily accessible, and active transportation and clean transit options must be cheaper and more convenient than driving.

Cost-Effective Solutions Available Today

Ultimately, to achieve our climate goals, urgent efforts are needed to slash GHG emissions. Fortunately, cost-effective solutions are available to do so in many cases. In short, this plan relies on existing technologies—it does not require major technological breakthroughs that are highly uncertain.

For example, targeted action to reduce methane emissions can be achieved at low or negative cost, and with significant near-term climate and public health benefits. In many cases, renewable energy and energy storage are cheaper than polluting alternatives, and are already firmly part of our business-as-usual approach; modeling related to the most recent integrated resource planning process at the California Public Utilities Commission (CPUC) has shown that scenarios associated with the best emissions outcomes had the lowest average rates. As another example, research from Energy Innovation shows that the U.S. can achieve 100 percent zero-carbon power by 2035 without increasing customer costs.[22]

The same is either already true, or soon to be true, for zero-emission vehicles as well. Myriad studies show cost parity for light-duty and heavy-duty ZEVs being achieved by mid-decade or shortly thereafter. A carbon neutrality study conducted by the University of California (UC) Institute of Transportation Studies and funded by the California Environmental Protection Agency (CalEPA) shows that achieving carbon neutrality in the transportation sector will save Californians $167 billion through 2045.[23] Similar research from the Goldman School of Public Policy at UC Berkeley finds that achieving 100 percent light-duty ZEV sales nationwide would save consumers $2.7 trillion through 2050; equivalent to $1,000 per household, per year, for 30 years.[24]

22 *Phadke, A. et al. 2020. "Illustrative Pathways to 100 Percent Zero Carbon Power by 2035 Without Increasing Customer Costs, Energy Innovation." September.*

23 *Brown, A. L., et al. 2021. Driving California's Transportation Emissions.*

24 *Goldman School of Public Policy. 2021. 2035: The Report: Transportation. UC Berkeley. April.*

Many of these outcomes are a direct result of California's vision and policy development to advance clean energy and climate solutions, including through the Renewables Portfolio Standard, Advanced Clean Cars II regulations, SLCP Reduction Strategy, and others. While the world collectively has not yet fully deployed clean energy and climate solutions at the scale needed to adequately address climate change, California has made tremendous progress—even since the last Scoping Plan update in 2017. Continued ambition, leadership, and climate policy development from California will help the state achieve the scale of emissions reductions needed from technologies and strategies that are already cost-effective or close to it today, and will move additional technologies and strategies to that point in the near future. Achieving those outcomes and reducing costs for the entire array of climate solutions needed to achieve carbon neutrality and then maintain net-negative emissions will prove the true measure of California's success. This will enable California to not just meet our own climate targets, but to ultimately develop the replicable solutions that can scale globally to address global warming.

Continue with a Portfolio Approach

Over the past decade and a half, the state has undertaken a successful three-pronged approach to reducing GHGs: incentives, regulations, and carbon pricing. The 2017 Scoping Plan leveraged existing programs such as the Renewables Portfolio Standard, Advanced Clean Cars, Low Carbon Fuel Standard, Short-lived Climate Pollutant Strategy, mobile source measures to achieve federal air quality targets, and a Cap-and-Trade Program, among others, to lay out a technologically feasible and cost-effective path to achieve the 2030 GHG reduction target. When looking toward the 2045 climate goals and the deeper GHG reductions needed across the AB 32 GHG Inventory sectors, all of the existing programs must be evaluated and, as necessary, strengthened to support the rapid production and deployment of clean technology and energy, as well as the increased pace and scale of actions on our natural and working lands.

The challenge before us requires us to keep all tools on the table. Given the climate mitigation co-benefits, critical actions to deliver near-term air quality benefits, such as those included in the State Implementation Plan to achieve the federal air quality standards, are incorporated into this Scoping Plan, as are new legislative mandates to decarbonize the electricity and cement sectors. And, if additional gaps are identified, new programs and policies must be developed and implemented to ensure all sectors are on track to reduce emissions. Opportunities to leverage these programs to address ongoing air quality disparities must also be considered, along with targeted environmental justice policies such as the AB 617 Community Air Protection Program and the investments made possible through the California Climate Investments Program.

Conclusion

California has never undertaken such a comprehensive, far-reaching, and transformative approach to fighting climate change as that called for in this plan. Once implemented, it will place every aspect of how we live, work, play, and travel in California on a more sustainable footing, with a focus on directly benefitting those communities already most burdened by pollution. This comprehensive approach reflects how climate change is already changing life in California. We have all experienced the impacts of devastating wildfires, extreme heat, and drought. Despite much progress, California still has some of the worst air pollution in the nation, especially in the San Joaquin Valley and the Los Angeles Basin, which is driven by the continued use of fossil fuel-powered trucks and cars.

This Scoping Plan provides a solution; a way forward and a vision of a California where we can and will address those impacts. This plan is fundamentally based on hope. It is a hope grounded in experience and science that we can fundamentally improve the California we leave to future generations. The plan is built on the legacy of effective actions and on the conviction that we can effectively marshal the combined capabilities of California—from state, regional, tribal, and local governments to industry to our research institutions, and most importantly, to the nearly 40 million Californians who will benefit from the actions laid out in the plan. It addresses the challenge of our generation by laying out a pathway and guideposts for action across three decades. But the Scoping Plan is only that: a plan. The hard work—and hopeful work—is putting its recommendations into action. And there is no time to waste.

Post-adoption of the Scoping Plan

As with previous Scoping Plans, CARB Board approval is the beginning of the next phase of climate action. Specifically, approval of this plan catalyzes a number of efforts, including the development of new regulations as well as amendments to strengthen regulations and programs already in place, not just at CARB but across state agencies. The unprecedented rate of transition will also require the identification and removal of market and implementation barriers to the production and deployment of clean technology and energy. All of these actions and more will be needed if we are to achieve our climate goals.

This page intentionally left blank

Chapter 1: Introduction

"The debate is over around climate change. Just come to the state of California. Observe it with your own eyes."

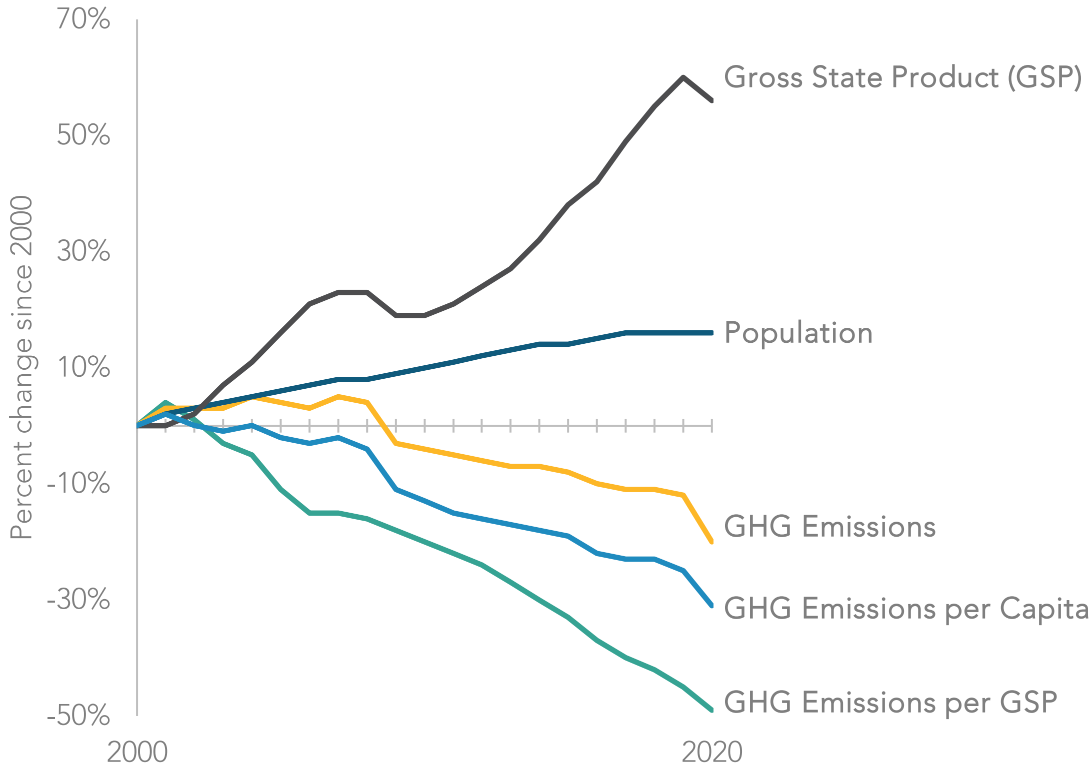
- California Governor Gavin Newsom in September 2020 after surveying the devastation caused by catastrophic wildfires

The impacts of climate change are no longer a distant threat on the horizon—they are right here, right now, with a growing intensity that is adversely affecting our communities and our environment, here in California and across the globe. The science that, decades ago, predicted the impacts we are currently experiencing is even stronger today and unambiguously tells us what we must do to limit irreversible damage: we must act with renewed commitment and focus to do more and do it sooner. That science is indisputable. Unless we increase ambition, we will be faced with more fire, more drought, more temperature extremes, and deadly, choking air pollution. The future of our state—our communities, economy, and ecosystems—is inextricably tied to the way we respond in this decade and the partnerships we forge along the way.

The impacts of climate change fall most heavily on frontline communities that bear the brunt of extreme heat, drought, wildfires, and other effects. Low-income communities and communities of color are also disproportionately impacted by fossil fuel combustion-related air pollution and related health problems. The continued phaseout of fossil fuel combustion will advance both climate and air quality goals and will deliver the greatest health benefits to the most impacted communities.

As it has responded to this climate crisis, California has established itself as a global leader in science-based, public health-focused climate change mitigation and air quality control. The California Legislature has worked with both Republican and Democratic governors to advance action on public health and environmental protections—and California has made progress on addressing climate change during periods of both Republican and Democratic federal administrations. Since the passage of Assembly Bill 32 (AB 32) (Núñez and Pavley, Chapter 488, Statutes of 2006), California has developed bold, creative, and durable policy solutions to protect our environment and public health, all while growing our economy. In fact, California met the target established in AB 32—a return of greenhouse gas (GHG) emissions to 1990 levels by 2020—years ahead of schedule, even as the state established itself as the one of the largest economies in the world. As Figure 1-1 below shows, California's emissions and economic growth have continued to decouple, and California is now the fifth largest economy in the world.

Figure 1-1: California total and per capita GHG emissions[25]



Recognizing both California's early successes in achieving GHG emissions reductions while growing the economy, as well as the worsening impacts of climate change, our governors and legislators have continued to enact ambitious goals. California's unwavering commitment to address climate change is based on indisputable science and data. This commitment is also informed by our collective efforts to address environmental justice and advance racial equity, such that race will no longer be a predictor for disproportionate environmental burdens faced by low-income communities and communities of color. As the Office of Environmental Health Hazard Assessment's

[25] Due to the global pandemic, 2020 is an outlier year and should not be considered indicative of a trend; emissions are likely to increase as economies recover from the impacts of the pandemic.

(OEHHA's) recent analysis of race/ethnicity and air pollution vulnerability and CalEnviroScreen 4.0 scores demonstrate, much work remains to be done.[26]

Many of California's environmental policies have served as models for similar policies in other U.S. states, and at national and international levels. Moving forward, California will continue its pursuit of collaborations and advocacy for action to address climate change at all levels of government. While California is responsible for just one percent of global GHG emissions, and we must do our part, we also play an important role in exporting both political will and technical solutions to address the climate crisis globally.

Today, we have a chance to re-envision California's future and set the state on a path to be carbon neutral no later than 2045 while advancing equity, addressing environmental justice, and continuing to grow our economy. This Scoping Plan provides a roadmap outlining key policies we can implement to achieve our climate goals while improving the health and welfare of Californians and addressing disparities in health outcomes to create a more equitable future. It will enable us to turn the corner in our efforts to protect and preserve our critical natural and public resources, all while providing unparalleled opportunities for clean, pollution-free economic growth.

Severity of Climate Change Impacts

With the increasing severity and frequency of drought, wildfire, extreme heat, and other impacts, Californians just have to look out their windows to know that climate change is real and rapidly getting worse. The impacts we thought we would see in the decades to come are happening now. We must act decisively to both reduce our GHG emissions and build resilience to these impacts for ourselves, future generations, and our iconic landscapes.

Wildfires

Of the twenty largest wildfires ever recorded in California, nine occurred in 2020 and 2021. The worst wildfire season in California's recorded history was in 2018, with over 24,226 structures damaged or destroyed and over 100 lives lost. The largest wildfire season ever recorded in state history was in 2020, where more than 4.3 million acres burned, albeit at different intensity and with varying ecological impacts, and over 112 million metric tons of

[26] OEHHA and CalEPA. 2021. Analysis of Race/Ethnicity and CalEnviroScreen 4.0 Scores. https://oehha.ca.gov/media/downloads/calenviroscreen/document/calenviroscreen40raceanalysisf2021.pdf.

carbon dioxide (CO_2) emitted into the atmosphere.[27] The economic damage of these fires was estimated to be over $10 billion in property damage and over $2 billion in fire suppression costs.[28] The Camp Fire, which destroyed much of Paradise, California, was the world's costliest natural disaster in 2018, with overall damages of $16.5 billion.[29] It was also the deadliest fire in California history, with 85 civilian fatalities. Wildfires have always been part of California's natural ecology and will continue to be. However, changes to the state's climate and precipitation expands the footprint of wildfire threat, severity, and intensity, with one quarter of California—more than 25 million acres—now classified as being under very high or extreme fire threat.[30]

The impacts of wildfire smoke have been linked to respiratory infections, cardiac arrests, low birth weight, mental health conditions, and exacerbated asthma and chronic obstructive pulmonary disease.[31] In 2020, with all of California covered by wildfire smoke for over 45 days—and 36 counties for at least 90 days—maximum fine particulate ($PM_{2.5}$) levels persisted in the "hazardous" range of the Air Quality Index for weeks in several areas of the state.[32,33]

Catastrophic wildfire damages extend beyond human health and the economy. The Castle Fire in 2020 and the KNP Complex and Windy Fires in 2021 led to the loss of an unprecedented number of giant sequoias: an estimated 13 to 19 percent of the giant

sequoia population in the Sierra Nevada. An iconic species, giant sequoias are the largest trees on earth, with exceptional longevity outside of climate extremes.[34,35]

It is clear that we must take drastic measures to prepare for future wildfires, which is why California invested $2.7 billion in wildfire resilience from fiscal years 2020 to 2023. The exponential increase in funding launched more than 552 wildfire resilience projects in less than a year, and CAL FIRE met its 2025 goal of treating 100,000 acres a full three years ahead of schedule. Since Fiscal Year 2019–20, treatment work has significantly increased, and CAL FIRE has averaged 100,000 acres treated each fiscal year.

Although we are making progress, we have a lot more work to do in order to achieve our goal of treating one million acres annually by 2025. The Governor's Wildfire and Forest Resilience Strategy details 99 actions needed to address the key drivers of catastrophic wildfires, ramp up the pace and scale of forest management, and make threatened communities more resilient to catastrophic fires. It is also important to note that natural wildfire cycles are a part of a sustainable forest ecosystem and will continue to play a role in a healthy forests' future. We should not expect wildfires to cease, but we must manage our lands to address catastrophic wildfires that result from buildup of carbon stocks due to our interventions to suppress wildfires and from climate change resulting from fossil fuel combustion.

Drought

Drought is a recurring feature of the California climate that has been intensified by increasingly warmer average temperatures. Anthropogenic climate trends have exacerbated drought conditions; human-caused climate change accounts for 19 percent of drought severity and 42 percent of the soil moisture deficit in this region since 2000. The governor declared a drought state of emergency in October 2021, and as of September 2022, 94 percent of California was in severe drought, and 99.8 percent[36] of the state was in at least moderate drought. The first three months of 2022 were the driest January, February, and March on record in California.[37] The harsh drought conditions affecting California are part of a larger megadrought—a drought lasting more than two

decades—that has been ongoing in the Southwestern region of North America since 2000. The past 22 years have been the region's driest period since at least 800 CE.[38]

While large urban water districts with diversified sources of water supply have maintained water deliveries to customers through the drought, hundreds of individual well owners and some small water systems have suffered disruption. The state is providing funding for water system consolidation and modernization projects in small communities, emergency repairs and replacements for dry wells, and bottled and hauled water deliveries. A 2021 law requires small suppliers to create drought contingency plans. During the drought of the last three years the state has delivered emergency drinking water assistance to nearly 10,000 households and 150 water systems.

California agriculture is responsible for more than half of all U.S. domestic fruit and vegetable production, and in 2021 drought resulted in the fallowing of nearly 400,000 acres of fields.[39] Direct crop revenue losses were approximately $962 million, and total economic impacts were more than $1.7 billion, with over 14,000 full- and part-time job losses.[40] During the 2011–2017 drought, California's agricultural industry suffered at least $5 billion in losses.[41] The 2022–23 budget includes $100 million to support agricultural water conservation practices, provide on-farm technical assistance, and provide direct relief to small farm operators.

Though native California species are adapted to drought, human engineering has altered most streams and wetlands in the state, making drought increasingly stressful to fish and wildlife. The state has conducted hundreds of fish and amphibian rescues in this drought to move creatures from diminished habitat, upgraded hatcheries, and boosted hatchery production, and has hauled millions of young hatchery salmon to San Francisco Bay to avoid adverse river conditions. State biologists monitor dozens of streams statewide and have negotiated voluntary agreements with landowners and water users to improve stream flows and temperatures.

California has started to implement major policies to build resilience to combat drought—such as the Sustainable Groundwater Management Act of 2014, the governor's Water Resilience Portfolio (2020), the governor's Water and Supply Strategy (August 2022), and

new standards for indoor, outdoor, and industrial water use. However, it is crucial that we take further actions to minimize the impacts of drought in the years to come.

Extreme Heat

California's hottest summer on record was 2021.[42] Death Valley recorded the world's highest reliably measured temperature (130°F) in July 2021, breaking its own record (129°F) from summer 2020.[43] Meanwhile, Fresno also broke one of its own records, with 64 days over 100°F in 2021.[44] This is part of a trend: the daily maximum average temperature, an indicator of extreme temperature shifts, is expected to rise 4.4°F–5.8°F by 2050 and 5.6°F–8.8°F by 2100.[45] Heat waves that result in public health impacts are also projected to worsen throughout the state. By 2050, these heat-related health events are projected to last two weeks longer in the Central Valley and occur four to ten times more often in the Northern Sierra region.[46]

Heat ranks among the deadliest of all climate hazards in California, and heat waves in cities are projected to cause two to three times more heat-related deaths by mid-century.[47] Climate vulnerable communities[48] will experience the worst of these effects, as heat risk is associated and correlated with physical, social, political, and economic factors. Aging populations, infants and children, pregnant people, and people with chronic illness are especially sensitive to heat exposure.[49,50] Combining these characteristics and existing health inequities with additional factors such as poverty, linguistic isolation,

housing insecurity, and the legacy of racist redlining practices, can put individuals at a disproportionately high risk of heat-related illness and death.[51,52] Rising temperatures will also speed up smog-forming chemical reactions, leading to worse asthma, reduced lung function, cardiac arrest, and cognitive decline. African American, American Indian/Alaskan Native, and Puerto Rican Californians are particularly sensitive to smog, as they are between 28.6 and 132.5 percent more likely to be diagnosed with asthma than white Californians.[53]

In addition to the dangers to public health, California's September 2022 heat wave is particularly illustrative of how more frequent extreme heat strains the state's infrastructure we depend on to adapt to a changing climate. For example, as all-time high temperature records were broken in Sacramento, San Jose, Santa Rosa and Fairfield, electricity demand for air conditioning threatened to overwhelm the state power supply.[54]

California has taken major steps to protect communities from the impacts of extreme heat. Our recent budgets invest $800 million to cool our schools and neighborhoods, including projects to reduce urban overheating. The Extreme Heat Action Plan, released in April 2022, outlines the all-of-government approach California is taking to reduce urgent risks and build long-term resilience to the impacts of extreme heat. In September 2022, Governor Newsom signed multiple bills addressing extreme heat, including AB 2238 (Rivas, Chapter 264, Statutes of 2022), which will create the nation's first extreme heat advance warning and ranking system to better prepare communities ahead of heat waves. The Administration is committed to addressing extreme heat, but we still have a lot of work to do.

Wildfires, drought, and extreme heat are some of the most pronounced climate impacts California is experiencing, but they are not the only ones. Sea level rise, rising ocean temperatures, ocean acidification, and inland flooding are also already having devastating impacts on our communities, ecosystems, and economy, and will continue to do so in the years and decades to come. The decisions and actions that we take today will determine how strongly we will feel the impacts of climate change in the future.

Imperative To Act

Consequences of Further Warming

The Intergovernmental Panel on Climate Change (IPCC) Sixth Assessment Report (AR6) found that it will not be possible to keep global warming within the threshold of 1.5ºC to avoid the most severe impacts of climate change unless we make immediate and large-scale reductions in GHG emissions. It finds that atmospheric concentrations of CO_2 have increased by 50 percent since the industrial revolution, and that they continue to increase at a rate of two parts per million each year.[55] Without immediate action, the world will exceed 1.5ºC (or 2.7ºF) warming by the 2030s, and no later than 2040.

While every tenth of a degree matters—every incremental increase in warming brings additional negative impacts—climate-related risks to human health, livelihoods, and biodiversity are projected to increase further under 2ºC (or 3.6ºF) warming, compared to 1.5ºC.[56] To remain below 1.5ºC with limited or no overshoot of that threshold, global net anthropogenic CO_2 emissions need to be cut by about half by 2030 and reach net-zero by 2050.

If we fail to make rapid changes, we may not be able to limit global warming to 2ºC,[57] and the consequences of inaction would be catastrophic. Our planet is already 1.2ºC warmer than pre-industrial times due to human-induced warming, and many impacts we are already experiencing, such as sea level rise, are "irreversible" for centuries to millennia.[58] Californians with the fewest resources, who are disproportionately low-income communities and communities of color, are the most vulnerable to the impacts of climate change. While the human costs associated with health impacts can never be fully monetized, a recent report finds that the health costs of climate and air pollution in the U.S. are well over $800 billion today and will continue to grow in the coming years.[59]

[59] Alwis, D. D., and V. S. Limaye. No date. *The Costs of Inaction*. https://www.nrdc.org/sites/default/files/costs-inaction-burden-health-report.pdf.

Any delays in action or insufficient action are a threat to public health and the environment. The impacts to our economy would be devastating as well. While not specific to California, a 2022 report from Deloitte Economics Institute finds that failing to take sufficient action to reduce emissions could result in economic losses to the U.S. of more than $14.5 trillion over the next 50 years.[60] On a hopeful note, however, the report finds that if the country invests now and in the coming years in a net-zero economy, $3 trillion could be added to the economy over the next 50 years. The U.S. annual gross domestic product (GDP) would be 2.5 percent higher in 2070 in this fast-action scenario than in the delayed action scenario. The lessons for California from these analyses are clear: invest now or pay the price later. As shown in Figure 1-2, inaction can lead to negative consequences for individuals, communities, the economy, and society as a whole. As discussed later, Governor Newsom and the Legislature have accepted this imperative and made significant investments in climate action. This Scoping Plan combined with the historic investments and policy direction from the governor and Legislature, will result in unprecedented action to address the climate crisis.

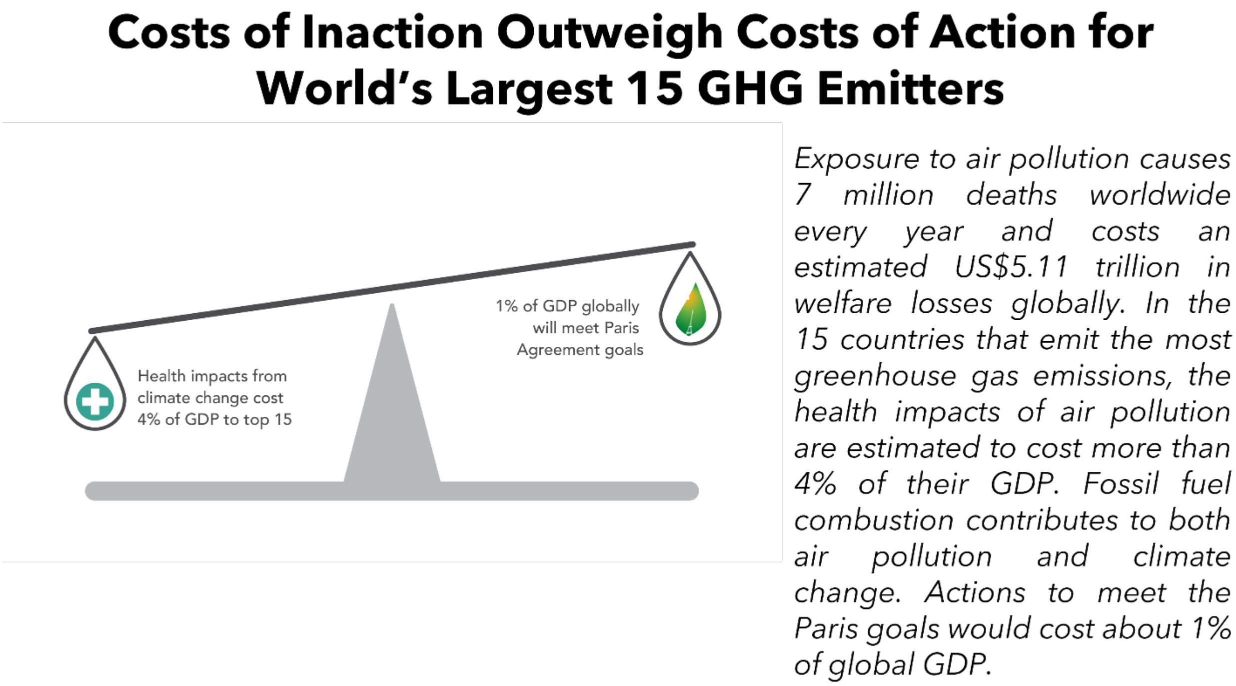
Figure 1-2: The real costs of inaction[61]



Scoping Plan Overview

Previous Scoping Plans

The Scoping Plan is a strategy the California Air Resources Board (CARB) develops and updates at least one every five years, as required by AB 32. It lays out the transformations needed across our society and economy to reduce emissions and reach our climate targets. This Scoping Plan is the third update to the original plan that was adopted in 2008. The initial Scoping Plan laid out a path to achieve the AB 32 2020 limit of returning to 1990 levels of GHG emissions, a reduction of approximately 15 percent below business as usual.[62] The 2008 Scoping Plan included a mix of incentives, regulations, and carbon pricing, laying out the portfolio approach to addressing climate change and clearly making the case for using multiple tools to meet California's GHG targets. The 2013 Scoping Plan assessed progress toward achieving the 2020 limit and made the case for addressing

[61] Katowice, P. 2018. *Health benefits far outweigh the costs of meeting climate change goals.* WHO. https://www.who.int/news/item/05-12-2018-health-benefits-far-outweigh-the-costs-of-meeting-climate-change-goals.

[62] CARB. 2008. *Climate Change Scoping Plan.* https://ww2.arb.ca.gov/sites/default/files/classic/cc/scopingplan/document/adopted_scoping_plan.pdf.

short-lived climate pollutants (SLCPs).[63] The most recent update, the 2017 Scoping Plan,[64] also assessed the progress toward achieving the 2020 limit and provided a technologically feasible and cost-effective path to achieving the Senate Bill 32 (SB 32, Pavley, Chapter 249, Statutes of 2016) target of reducing GHGs by at least 40 percent below 1990 levels by 2030.

Overview of this Scoping Plan

It is paramount that we continue to build on California's success by taking effective actions and doubling down on implementation of the strategies outlined here. As such, this Scoping Plan builds on and integrates efforts already underway to reduce the state's GHG, criteria pollutant, and toxic air contaminant emissions by identifying the clean technologies and fuels that should be phased in as the state transitions away from combustion of fossil fuels. By selecting and pursuing a sustainable and clean economic path, the state will continue to successfully execute existing programs, work to eliminate air pollution inequities, demonstrate the coupling of economic growth and environmental progress, and enhance new opportunities for engagement within the state to address and prepare for climate change.

The 2022 Scoping Plan for Achieving Carbon Neutrality (Scoping Plan) is the most comprehensive and far-reaching Scoping Plan developed to date. It identifies a technologically feasible and cost-effective path to achieve carbon neutrality by 2045 while also assessing the progress California is making toward reducing its GHG emissions by at least 40 percent below 1990 levels by 2030, as called for in SB 32 and laid out in the 2017 Scoping Plan.[65] The 2030 target is an interim but important stepping stone along the critical path to the broader goal of deep decarbonization by 2045. Modeling for this Scoping Plan shows that this decade must be one of transformation on a scale never seen before to set us up for success in 2045.

The relatively longer path assessed in this Scoping Plan incorporates, coordinates, and leverages many existing and ongoing efforts to reduce GHGs and air pollution, while identifying new clean technologies and energy. Given the focus on carbon neutrality, this Scoping Plan also includes discussion for the first time of the Natural and Working Lands (NWL) sectors as both sources of emissions and carbon sinks. Chapter 2 of this document

[65] CARB. 2017. *California's 2017 Climate Change Scoping Plan.* https://ww2.arb.ca.gov/sites/default/files/classic/cc/scopingplan/scoping_plan_2017.pdf.

includes a description of a suite of specific actions to drastically reduce GHGs across all sectors. Chapter 3 provides the air quality and economic evaluations of the actions. Chapter 4 provides a broader description of the many actions needed across all sectors to achieve carbon neutrality. Chapter 5 provides an overview of the next steps and partnerships needed to implement this Scoping Plan. Guided by legislative direction, the actions identified in this Scoping Plan reduce overall GHG emissions in California and deliver policy signals that will continue to drive investment and certainty in a low carbon economy. This Scoping Plan builds upon the successful framework established by the Initial Scoping Plan and subsequent updates while identifying new, technologically feasible, and cost-effective strategies.

Principles That Inform Our Approach to Addressing the Climate Challenge

California has decades of experience addressing the climate challenge. Through this experience, and based on extensive engagement with stakeholders through our regulatory and program development processes, we have developed a set of principles to inform our approach.

Unprecedented Investments in a Sustainable Future

The scale of transformation needed over this decade to avoid the worst impacts of climate change and meet our ambitious climate goals is extraordinary. This is why Governor Newsom and the Legislature invested over $15 billion in climate action through the 2021–2022 California Comeback Plan, and why the 2022–2023 budget marks the beginning of the California Climate Commitment—the governor’s multi-year plan to invest $54 billion in climate action. The enacted budgets (Figure 1-3) and the California Climate Commitment represent investments of a historic scale and will advance precisely the type of all-of-government approaches necessary to create the whole-of-society changes described in this Scoping Plan that will enable us to avert the worst impacts of climate change.

Figure 1-3: Comprehensive California climate change investments

The *California Climate Commitment* includes the following game-changing elements:

- $10 billion for zero-emission vehicles (ZEVs), including $1.5 billion for electric school buses to protect students' health and $3 billion to build an accessible charging network. ZEV investments will particularly focus on programs such as heavy-duty vehicle and port electrification that will reduce emissions and protect public health in low-income communities.
- $2.1 billion for clean energy investments, such as long duration storage, offshore wind, green hydrogen,[66] and industrial decarbonization.
- $13.8 billion for programs that reduce emissions from the transportation sector, such as improving public transportation while also funding walking, biking, and adaptation projects.
- Over $720 million for California's higher education institutions and research that will support the next generation of climate innovations.

[66] For the purposes of this Scoping Plan, "renewable hydrogen" and "green hydrogen" are interchangeable and are not limited to only electrolytic hydrogen produced from renewables.

- Nearly $1 billion to build sustainable, affordable housing and over $1 billion to help low-income Californians realize energy cost savings through building decarbonization.
- Nearly $9 billion for wildfire risk reduction, drought mitigation, extreme heat resilience, and nature-based solutions.

These investments are incredibly important in the context of this Scoping Plan in that they accompany and help support implementation of the many policies and regulations that will continue to be necessary to achieve our 2030 and carbon neutrality targets. In addition, these incentive programs jump-start emission reduction strategies for priority sectors, sources, and technologies, leveraging private-sector investment and building sustainable, growing markets for clean and efficient technologies. Many of California's incentive programs work in concert with federal and other state programs to drive emission reductions. As an example, as California pushes to move to 100% sales of new zero emission-vehicles, including plug-in hybrid vehicles, the Newsom Administration continues to invest heavily in incentive programs that allow families, communities, and businesses to choose zero-emission vehicles. This is done while simultaneously working with the federal government, other states, and jurisdictions around the world to align policies, regulations, and incentives, creating market certainty for the automakers that serve our markets.

Centering Equity

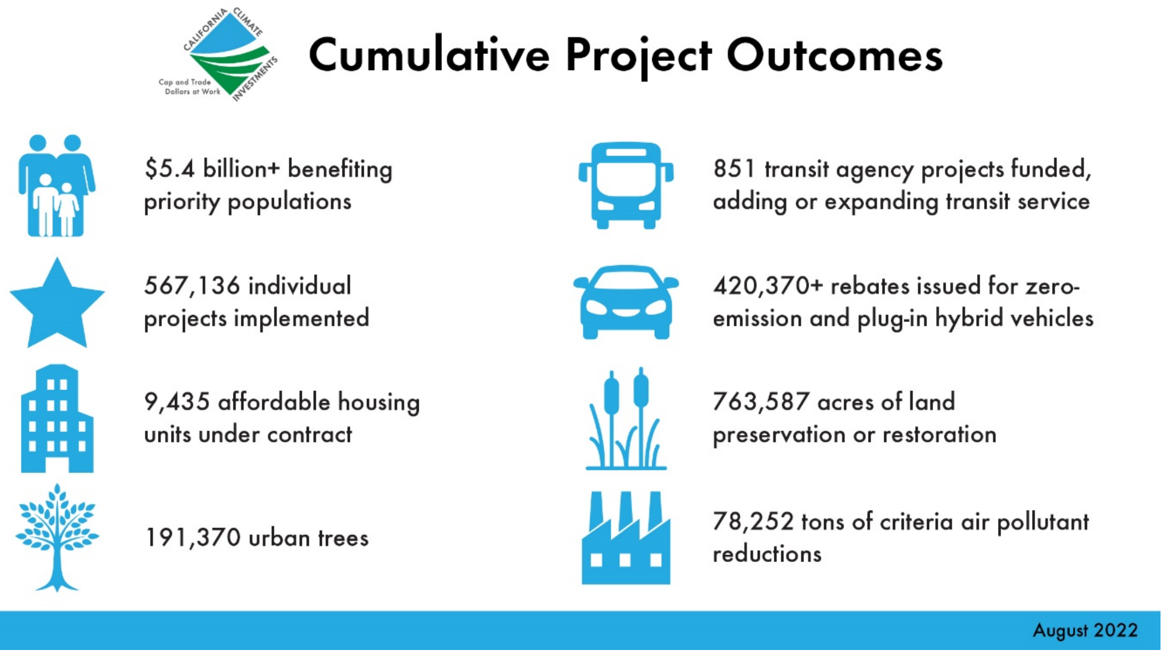
Prioritizing equity is just as important as the magnitude of the climate investments California is making. Addressing climate change and advancing our equity and economic opportunity goals cannot be decoupled. In line with the governor's Executive Order[67] to take additional actions to embed equity analysis and considerations, this plan works to center equity by addressing disparities for historically underserved and marginalized communities. California strives to ensure that our climate and air research, regulations, investments, and plans include provisions that specifically address and advance equity. This includes reducing and eliminating air pollution disparities, removing barriers that can prevent frontline communities from accessing benefits, lowering costs for low-income Californians, and promoting high-quality jobs. CARB's incentive programs regularly surpass their mandated equity targets, and CARB has incorporated equity-focused provisions in our research, planning, and regulatory efforts. For instance, statute requires that a minimum of 35 percent of California Climate Investments benefit low-income households along with disadvantaged and low-income communities (referred to as *priority*

---

[67] Executive Department. State of California. 2022. Executive Order N-16-22. GSS_9320_2-20220912152941 (ca.gov).

populations). However, 48 percent—over $5.4 billion—of implemented California Climate Investments project funding is benefiting priority populations, greatly exceeding the statutory minimums (see Figure 1-4). Senate Bill 535 (De León, Chapter 830, Statutes of 2012) and AB 1550 (Gomez, Chapter 369, Statutes of 2016) direct state and local agencies to make significant investments using auction proceeds to assist California's most vulnerable communities. Under these laws, a minimum of 25 percent of the total investments are required to be located within and provide benefits to disadvantaged communities, and at least 10 percent of the total investments must benefit low-income communities and households. Moving forward, the state will continue to devote a greater share of incentive funding to priority populations, with the light-duty vehicle incentive program as just one example. We can simultaneously confront the climate crisis and build a more resilient, just, and equitable future for all communities.

Figure 1-4: California climate investments cumulative outcomes[68,69]



Role of the Environmental Justice Advisory Committee

To inform the development of the Scoping Plan, AB 32 calls for the convening of an Environmental Justice Advisory Committee (EJ Advisory Committee) to advise CARB in developing the Scoping Plan, and any other pertinent matter in implementing AB 32. It requires that the Committee be comprised of representatives from communities with the most significant exposure to air pollution, including communities with minority populations and/or low-income populations. On January 25, 2007, CARB appointed the first

---

[68] CARB. 2022. California Climate Investments program implements $10.5 billion in greenhouse gas-reducing programs, expected to reduce 76 million metric tons of emissions. April 11. https://ww2.arb.ca.gov/news/california-climate-investments-program-implements-105-billion-greenhouse-gas-reducing-projects.

[69] SB 535 and AB 1550 require investments located in and benefiting low-income communities and households, which are termed *priority populations. Disadvantaged communities* are currently defined by CalEPA as the top 25 percent of communities experiencing disproportionate amounts of pollution, environmental degradation, and socioeconomic and public health conditions according to the Office of Environmental Health Hazard Assessment's *CalEnviroScreen tool,* plus certain additional communities including federally recognized Tribal Lands. Low-income communities and households are defined by statute as those with incomes either at or below 80 percent of the statewide median or below a threshold designated as low-income by the Department of Housing and Community Development.

Environmental Justice Advisory Committee to advise it on the Initial Scoping Plan and other climate change programs.

For this Scoping Plan, CARB reconvened the EJ Advisory Committee in May 2021. The committee is currently comprised of 14 environmental justice and disadvantaged community representatives, including the EJ Advisory Committee's first tribal representative, who was appointed in February 2022. In October 2021, the EJ Advisory Committee formally created eight workgroups. These workgroups are a space for EJ Advisory Committee members to better understand specific sectors of the Scoping Plan and to assist the EJ Advisory Committee in the development of recommendations on this Scoping Plan. In December 2021, the EJ Advisory Committee provided scenario input responses to help shape the modeling for this Scoping Plan. In February 2022, San Joaquin Valley EJ Advisory Committee members hosted their first community workshop, with over 100 attendees. In March 2022, the CARB Board held a joint public meeting with the EJ Advisory Committee to discuss their draft preliminary recommendations for this Scoping Plan. In June 2022, over 165 attendees participated in a statewide community workshop held by EJ Advisory Committee members. The full schedule of EJ Advisory Committee Meetings and meeting materials are available on CARB's website.[70] This Scoping Plan includes references where EJ Advisory Committee Final Recommendations[71] are included in the document. The final recommendations were discussed at a joint CARB and EJ Advisory Committee Hearing on September 1, 2022.

The integration of environmental justice is critical to ensure that certain communities are not left behind. The AB 32 EJ Advisory Committee provided recommendations on September 30 in advance of the final Scoping Plan. There are footnotes to indicate where there is alignment between the AB 32 EJ Advisory Committee's recommendations and this Scoping Plan. While the language in the text may not fully incorporate the specific EJ Advisory Committee's recommendation, the footnotes do acknowledge the places in the text where there is general alignment with the spirit of the EJ Advisory Committee's recommendation.

Partnering with Tribes

---

[70] CARB. Environmental Justice Advisory Committee Meetings and Events. https://ww2.arb.ca.gov/environmental-justice-advisory-committee-meetings-and-events.

[71] Environmental Justice Advisory Committee. September 30, 2022. 2022 Scoping Plan Recommendations. https://ww2.arb.ca.gov/sites/default/files/barcu/board/books/2022/090122/finalejacrecs.pdf.

There are 109 federally recognized tribes and over 60 non-federally recognized tribes in California. [72] In 2011, Governor Brown issued Executive Order B-10-11, recognizing and reaffirming the inherent right of tribes to exercise sovereign authority over their members and territory and directing state agencies to engage in government-to-government consultation with tribe and to work to develop partnerships and consensus.[73] In 2019, Governor Newsom issued Executive Order N-15-19, which acknowledges and apologizes on behalf of the state for the historical "violence, exploitation, dispossession and the attempted destruction of tribal communities."[74] Establishing partnerships with tribal leaders to incorporate their priorities, traditional expertise, and knowledge will be important to achieving California's climate goals. The Scoping Plan includes actions that tribal partners can voluntarily implement for sources under their jurisdiction (e.g., transitioning to zero emission fleets, installing infrastructure and control technologies, conducting climate smart land management). The Scoping Plan also uplifts the importance of having our tribal partners help guide actions that may impact tribal cultural resources and of benefitting from tribal input.

We also need alignment between state and local partners and tribes on actions related to land-use decisions. This means respecting and reinforcing tribal sovereignty and self-determination. As tribes do not always draw clear lines between the "natural" and "cultural" resources of a place, taking a holistic perspective will result in positive impacts in ability to address the complex issues of land management and regulatory undertakings.

Tribes have an intimate and historical knowledge of places and should be engaged early on to inform planning and future management related to activities that may impact tribal resources and areas including potential funding opportunities, technical assistance, and capacity building, where appropriate. Additionally, tribes should be involved in the identification of their own significant resources and areas of use. As decisions are made related to Scoping Plan undertakings, agencies should recognize and appropriately consider cultural resources and management from the beginning, not as an afterthought; and consider how the project could impact tribes.

---

[72] These numbers are subject to change depending on determinations made by the Bureau of Indian Affairs (BIA) and the Native American Heritage Commission (NAHC). Please consult the most current Federal Register for a list of federally recognized tribes and the NAHC for a list of non-federally recognized tribes in California. As of the date of the Scoping Plan, the current list for federally recognized tribes is located at 87 Fed. Reg. 4636 (Jan. 28, 2022).

[73] Executive Order B-10-11. https://www.ca.gov/archive/gov39/2011/09/19/news17223/index.html#:~:text=EXECUTIVE%20ORDER%20B-10-11%20Published%3A%20Sep%2019%2C%202011%20WHEREAS,and%20affirmed%20in%20state%20and%20federal%20law%3B%20and.

[74] Executive Order N-15-19. https://tribalaffairs.ca.gov/wp-content/uploads/sites/10/2020/02/Executive-Order-N-15-19.pdf.

Finally, to the extent allowed by law, traditional ecological knowledge and culturally sensitive information should be protected, as this is information that may not be common knowledge and may not be known outside the tribe, as each tribe is unique and influenced by its local environment and cultural practices. Protection of this information will help foster productive relationships with tribes and should be included as part of the process. CARB and other agencies should continue to foster relationships with tribal partners.

Maximizing Air Quality and Health Benefits

The state has over 50 years of experience successfully cleaning the air in California by addressing criteria pollutants and toxic air contaminants from mobile and stationary sources. CARB has been a leader in measuring, evaluating, and reducing sources of air pollution that impact public health. Its air pollution programs have been adapted for national programs and emulated in other countries. Significant progress has been made in reducing diesel particulate matter (PM), which is a designated toxic air contaminant, and many other hazardous air pollutants. CARB partners with local air districts to address stationary source emissions and adopts and implements state-level regulations to address sources of criteria and toxic air pollution, including mobile sources. CARB also collaborates with federal agencies to address air pollution from sources primarily under federal jurisdiction. In many instances, actions to reduce fossil fuel combustion and achieve federal air quality standards also help to reduce GHG emissions.

However, air pollution disparities still exist, and more must be done to ensure the most vulnerable populations have safe air to breathe. California must continue to evaluate opportunities to harmonize our climate and air quality programs through innovative policymaking and by building on existing programs like the Low Carbon Fuel Standard (LCFS) and Community Air Protection Program. The LCFS includes a provision that allows electric utilities to opt-in and generate residential electric vehicle (EV) charging credits, where some of the revenues are invested back into rebate programs that address air quality and climate pollution.[75] The Community Air Protection Program[76] is the first of its kind in the country and brings together diverse stakeholders, including CARB, local air districts, and residents of environmental justice communities to increase local air monitoring and develop community-led plans to improve air quality in the communities most impacted by air pollution.

This Scoping Plan identifies actions that will deliver near-term air quality benefits to communities with the highest exposures and provide long-term GHG benefits. Many of the actions in this Scoping Plan are key elements of the 2022 State Strategy for the State

[75] CARB. LCFS Utility Rebate Programs. https://ww2.arb.ca.gov/resources/documents/lcfs-utility-rebate-programs.
[76] CARB. Community Air Protection Program. https://ww2.arb.ca.gov/capp.

Implementation Plan to meet federal air quality standards,[77] which has a primary focus of reducing harmful air pollution and achieving federal air quality targets. California's approach of leveraging air quality and GHG policies together has yielded results. A 2022 report by the Office of Environmental Health and Hazard Assessment (OEHHA)[78] that evaluated GHG and harmful air pollution emissions from the heavy-duty vehicle (HDV) and large stationary source sectors found declines in emissions in both sectors, with the greatest declines in disadvantaged communities. Both sectors are subject to state GHG and air quality policies, in addition to federal and local rules on harmful air pollution. Because of historically racist and discriminatory practices such as redlining, both types of sources are disproportionately located adjacent to vulnerable communities, which are predominantly communities of color.[79] The key findings from the OEHHA report are as follows:

- Both HDVs and facilities subject to the Cap-and-Trade Program have reduced emissions of co-pollutants, with HDVs showing a clearer downward trend when compared to stationary sources. These emission reductions have major health benefits, including a reduction in premature pollution-related deaths.
- The greatest beneficiaries of reduced emissions from both HDVs and facilities subject to the Cap-and-Trade Program have been in communities of color and in disadvantaged communities in California, as identified by CalEnviroScreen (CES). This has reduced the emission gap between disadvantaged and non-disadvantaged communities, but a wide gap still remains.
- The transition to zero-emission HDVs will expedite further emissions reductions.
- While the progress observed is encouraging, inequities persist, and federal, state, and local climate and air quality programs must do more to reduce emissions of GHGs and co-pollutants to reduce the burden of emissions on disadvantaged communities and communities of color.

It will take all tools at all levels of government, with robust enforcement, to ensure that vulnerable communities continue to see improvements in air quality until no disparities exist in air pollution across the state.

Economic Resilience

The state's efforts to tackle the climate crisis will create economic and workforce development opportunities in the clean energy economy in communities across the state. Transitioning existing skills and expanding workforce training opportunities in climate-related fields are critical for reducing harmful emissions and supporting workers in transitioning to new, high-quality jobs. The Administration's recent budgets acknowledge the challenges facing workers in industries most affected by the state's response to climate change—especially those in the fossil fuel industry. It will invest $1 billion in regional partnerships and economic diversification to create new jobs and support a local tax base and workforce transition and development once opportunities are identified. It also will invest in safety nets to protect, and support impacted communities as part of the transition to a carbon neutral economy. Specifically, the Community Economic Resilience Fund Program[80] (CERF) supports communities and regional groups in producing regional roadmaps for economic recovery and transition that prioritize the creation of accessible, high-quality jobs in sustainable industries. The budget investments create the opportunity to future-proof and increase economic resilience in the face of more frequent climate impacts and shifting economic conditions. For these investments and implementation of the Scoping Plan to be successful in supporting the transition to a carbon neutral economy, workers and affected communities must be included in ongoing dialogue to ensure a high-road transition for regional economies.

That state also recognizes it can play a more direct role in supporting a sustainable work force through its incentive programs. In 2021, Assembly Bill 680 (AB 680) (Burke, Chapter 746, Statutes of 2021) was signed into law, requiring CARB to work with the California Labor and Workforce Development Agency to update the Funding Guidelines to include new workforce standards. CARB's Funding Guidelines currently include requirements for administering agencies to, wherever possible, foster job creation within California, provide employment opportunities or job training tied to employment, and target these opportunities to priority populations. The Funding Guidelines also recommend administering agencies prioritize investments in projects that directly support jobs or a job training and placement program, and that they report the estimated employment benefits and employment outcomes for projects that meet specified criteria. These new requirements apply to agencies administering certain California Climate Investments

[80] Office of Planning and Research. Community Economic Resilience Fund. https://opr.ca.gov/economic-development/cerf/.

programs that receive continuous appropriations from the Greenhouse Gas Reduction Fund and fall into the following six categories of standards:

- fair and responsible employer standards,
- inclusive procurement policies,
- prevailing wage for construction work,
- community workforce agreements for construction projects over one million dollars,
- preference for projects with educational institutions or training programs, and
- creation of high-quality jobs. CARB will be updating the Funding Guidelines through a public process over the next year to operationalize these new requirements.

Partnering Across Government

The Scoping Plan is an actionable plan to identify and align programs and policies to achieve California's climate targets. To realize the outcomes and deliver results in any Scoping Plan, action is critical. For this Scoping Plan, there are also actions that rely on our federal partners to take on sources primarily under their jurisdiction (such as aviation, and federally owned/managed lands) while they also continue to develop national programs for GHG reductions. The federal government is already taking major steps to advance these types of programs. The Inflation Reduction Act of 2022[81] includes $369 billion for domestic energy production and manufacturing and is expected to lead to U.S. GHG emission reductions of roughly 40 percent by 2030. Direct incentives will include those for clean vehicles and ENERGY STAR appliances, as well as improving transportation and clean energy in underserved communities.

We also need our local partners to align on actions related to land-use decisions that support sustainable, resilient, low-carbon communities and permitting for clean energy production facilities and infrastructure; diversion of organics from landfills; and other climate-related projects. State agencies also should use the Scoping Plan to review and update their own programs and policies to support the actions identified in this Scoping Plan. Importantly, the Scoping Plan also can serve as a resource as the Legislature considers new legislative direction and funding to support the state's path to carbon neutrality and continue action to address near-term air pollution disparities.

Partnering with the Private Sector

Government cannot achieve our climate targets alone. The scale of investment needed requires both private-sector investment and partnerships with philanthropies. Public

[81] Pub.L. No. 117-169 (August 16, 2022).

sector dollars, accompanied by strong and steady policy signals, must be a catalyst for deeper and broader investments by the private sector in both reducing emissions and building the resilience of our communities. Governor Newsom is committed to working collaboratively with businesses, including small businesses, to deploy the technologies, capital, and ingenuity that are hallmarks of the private sector.

California structures our climate policies and regulations to create market signals and certainty that spur private sector investment. For example, the Governor's Executive Order on Zero-Emission Vehicles[82] set 2035 as the target year for 100 percent zero-emission vehicle sales, creating a time horizon that allows automakers to scale up zero-emission fleets and sending a clear signal to the companies and utilities that would deploy charging infrastructure. The Executive Order has been followed by development and adoption of the Advanced Clean Cars II regulation. CARB convened auto manufacturers, environmental justice groups, labor organizations, and many other stakeholders to provide input into development of the regulation in a robust and transparent manner; again, with the aim of providing certainty for producers and consumers.

California also pursues public-private partnerships (PPP) as a mechanism to advance our collective climate goals. We know these vehicles can be effective at increasing the impact of public sector dollars and helpful in moving markets in a direction aligned with state policy. A new PPP the Administration is advancing is the Climate Catalyst Revolving Loan Fund, housed at the state's Infrastructure and Economic Development Bank (IBank). The fund offers a range of financial instruments—including flexible credit and credit support—to help bridge financing gaps currently preventing advanced climate solutions from scaling in the marketplace. The Catalyst Fund's initial areas of investment include forest biomass management and utilization (unlocking innovation to reduce wildfire threats), climate-smart agriculture, and clean energy transmission. The fund leverages public sector investments by mobilizing private finance for shovel-ready projects that are stuck in the deployment phase. As such, IBank is ideally positioned as the state's all-purpose "Green Bank," with increasing connection to federal financing programs such as US DOE's Loan Programs Office and the United States Environmental Protection Agency's (U.S. EPA) Greenhouse Gas Reduction Fund.

The Catalyst Fund builds from existing IBank financing programs that are themselves increasingly focused on the climate imperative. The IBank's Infrastructure State Revolving Fund provides supportive capital to climate-aligned projects promoted by local governments and certain nonprofit entities, and will be refining its criteria and market outreach strategies to increase its level of service. IBank's bonds program has supported

---

[82] Executive Department. State of California. Executive Order N-79-20. *https://www.gov.ca.gov/wp-content/uploads/2020/09/9.23.20-EO-N-79-20-Climate.pdf*.

multiple large environmental projects, including more than $2 billion in “green bonds,” and is poised to help expand access to the state’s deep and liquid bond capital market. Within IBank’s Small Business Finance Center, the new Climate Tech Loan Guarantee program encourages commercial banks to back climate-focused small businesses, leveraging federal capital to insure a portion of the private bank’s loan. And through IBank’s Expanding Venture Capital Access Fund program, the state is promoting greater diversity in the venture capital community, including climate equity and climate justice.

All of these financing programs exist to leverage private capital in support of the state’s climate goals, and to partner with state policy agencies driving the transition. IBank will also continue to collaborate closely with the State Treasurer’s Office in its provision of capital support to climate solutions, ensuring that funding flows to programs best positioned to deliver success. This partnership of public and private capital, responsive to and in communication with the climate policy community, will ensure that California gets the maximum possible benefit from its allocation of scarce resources.

Supporting Innovation

Reaching our ambitious, deep decarbonization goals will require continued technological innovation. Investment in research, development, and deployment of clean technologies has never been more critical. Sending clear and sustained market and policy signals will encourage large and small companies alike to pursue innovation that can be scaled up and deployed here and beyond our borders. The full suite of AB 32 policies[83] has touched nearly every sector of California’s economy and spurred technology innovation in the state, including the growth of technology developers, manufacturers, processors, and assemblers in many areas. Specifically, AB 32 policies and programs support both the supply side and the demand side to build new markets in California. On the supply side, AB 32 policies support businesses to demonstrate and refine technologies, and to help establish critical supply chains. On the demand side, AB 32 policies and programs provide outreach, education, and incentives—as well as disincentives—to motivate everyone from consumers to institutional purchasers to utility planners to adopt new, climate smart technologies. Innovations resulting directly from the state’s climate policies include the following:

- In the past 10 years, a growing market for heavy-duty zero-emission vehicles (HD ZEVs) was established in California, and this market now represents the largest single share of North American supply and demand for HD ZEVs. Vehicle

[83] CARB. Climate Change Programs. *https://ww2.arb.ca.gov/our-work/topics/climate-change*.

and component manufacturers are making long-term investments to develop and produce HD ZEVs within California.

- Total consumption of renewable diesel in the California LCFS market has skyrocketed from approximately 1.8 million gallons in 2011 to nearly 589 million gallons in 2020. The LCFS is a key driver of market development for renewable diesel and its coproducts. While the federal renewable fuel standard (RFS) and blenders tax credit also benefit producers, an analysis of their respective contributions to market development, and interviews with industry representatives and independent experts, point to LCFS as a more important factor in market development, at least in recent years.
- In the past five years, a market for small-scale energy storage in California was created where none previously existed. As of 2020, 185 megawatts (MW) of small-scale energy storage projects have been interconnected to the grid. The significant increase in deployment in the last five years is a result of the Self-Generation Incentive Program (SGIP), which significantly reduces the upfront costs to purchase and install small-scale energy storage devices, and of growing customer interest in disaster resiliency in the face of increasing risk from wildfire and related utility outages. These systems have already provided disaster resiliency benefits for residential and non-residential customers.

We have seen how quickly market barriers can be overcome in response to strong policy signals, as occurred in the solar panel and electric vehicle battery space. Government-stated priorities have a significant role in guiding private and public research, development, and deployment. This Scoping Plan unequivocally puts the marker down on the need for innovation to continue in non-combustion technologies, clean energy, CO_2 removal options, and alternatives for SLCPs. The five-year update to the Scoping Plan allows for a periodic evaluation of new tools to add to the state's toolkit.

Engagement with Partners to Develop, Coordinate, and Export Policies

California works closely with other states, tribal governments, the federal government, and international jurisdictions to identify the most effective strategies and methods to reduce GHGs, manage GHG control programs, and facilitate the development of integrated and cost-effective regional, national, and international GHG reduction programs. For example, the state's Cap-and-Trade Program has been linked with Québec's since 2014, and CARB staff regularly engage with jurisdictions throughout the world on the design features of our Cap-and-Trade Program through memoranda of understanding (MOUs) and venues such as the International Climate Action

Partnership.[84] Low carbon fuel mandates similar to California's LCFS have been adopted by the U.S. EPA and by other jurisdictions, including Oregon, Washington, British Columbia, the European Union, and the United Kingdom. Many other jurisdictions from Japan to New Zealand, Australia, and the European Commission also continue to seek information and technical experience on our LCFS. California has and will continue to share information and encourage ambitious emissions reductions with interested jurisdictions, with a focus on China, India, Mexico, Canada, and the European Union. California's early action to reduce super-pollutants such as methane and other SLCPs was reaffirmed by the 2021 Global Methane Pledge signed by the U.S. and over 100 other countries at the 26th Conference of the Parties to the United Nations Framework Convention on Climate Change (UNFCCC).[85]

In addition, under the Clean Air Act, the federal government is authorized to allow California to set more stringent vehicle emissions regulations than federal standards. California's goals and regulations to transition to 100 percent sales of new zero-emission passenger vehicles by 2035 (including plug-in hybrid vehicles), to drayage trucks by 2035, and other trucks and buses where feasible by 2045 are being emulated by partner states across the U.S. and in jurisdictions around the world. CARB's Advanced Clean Cars II regulation, [86] which codifies these targets, was approved in August 2022, and already at least four other states have announced their plans to adopt this regulation. Earlier in June 2020 CARB adopted the Advanced Clean Truck regulation, which requires truck manufacturers to meet increasing sale targets of zero-emission trucks in California through 2035. Since adoption, at least five other states—20 percent of the U.S. truck market—have adopted this regulation. These kinds of coordinated policies help signal to vehicle manufacturers a widespread and growing demand for zero-emissions technology, which in turn helps scale production and lower costs for consumers.

With the Mexican Secretariat for Environment and Natural Resources (SEMARNAT), California has engaged in a technical exchange on clean vehicle policies and helped to establish Mexico's Emissions Trading System (being piloted in 2022). A 2019 MOU signed between California and Environment and Climate Change Canada enables in-depth collaboration on policies and programs to decarbonize vehicles, engines, and fuels. This partnership has led to tangible emissions reductions, from aligning vehicle emissions targets and policies to collaborating on emissions testing and research critical to enforcing

[85] Global Methane Pledge. Homepage. https://www.globalmethanepledge.org/.

[86] Cal. Code Regs., tit. 13, §§ 1900,1961.2, 1961.3, 1962.2, 1962.3, 1962.4, 1962.5, 1962.6, 1962.7, 1962.8, 1965, 1968.2, 1969, 1976, 1978, 2037, 2038, 2112, 2139, 2140, 2147, and 2903; and Test Procedures located here: https://ww2.arb.ca.gov/rulemaking/2022/advanced-clean-cars-ii.

emissions limits for vehicle manufactures. At the national level, China has looked to California for cutting-edge requirements for car diagnostics and policies that promote zero-emissions vehicles. At a local level, Beijing has adopted California's vehicle emissions standards and several other progressive environmental regulations. California will continue and renew such efforts across China, including through a 2022 MOU signed with China's Ministry of Ecology and Environment.

Between 2021 and 2023, California also will serve as president of the Transport Decarbonisation Alliance, a global network of countries, regions, cities, and companies that come together to share experiences and technical expertise, and to increase the ambition and accelerate the deployment of targeted transportation decarbonization policies across freight, electric vehicle infrastructure, and active mobility. Throughout its presidency, California will focus its leadership on decarbonizing the cross-jurisdiction network of medium- and heavy-duty vehicles, both to ensure cleaner air in freight-adjacent communities and to stem the effects of climate change.

Over the years, California has also asserted the importance of and supported the ongoing efforts of state and local clean air and climate leadership. Through our participation in the Pacific Coast Collaborative alongside British Columbia, Washington, and Oregon,[87] the Under2 Coalition,[88] the U.S. Climate Alliance,[89] the International ZEV Alliance,[90] the Transportation Decarbonisation Alliance, and many more organizations, California has and will continue to build climate partnerships with state and local governments.

California also recognized the need to address the substantial emissions caused by the deforestation and degradation of tropical and other forests, and continues its work alongside other subnational governments as part of the Governors' Climate and Forests Task Force (GCF).[91] Founded in 2008, there are currently 39 GCF members, including states and provinces in Brazil, Colombia, Ecuador, Indonesia, Ivory Coast, Mexico, Nigeria, Peru, Spain, and the United States—all of whom are considering or operating programs to reduce emissions from deforestation, land-use, and rural development, and to benefit local and indigenous communities. CARB's California Tropical Forest Standard provides a rigorous methodology to assess jurisdiction-scale programs that reduce deforestation and to incentivize responsible action and investment.[92] The standard

provides a strong signal to value the preservation of tropical forests over continued destructive activities such as oil exploration and extraction and ensures rigorous social and environmental safeguards for indigenous peoples and local communities.

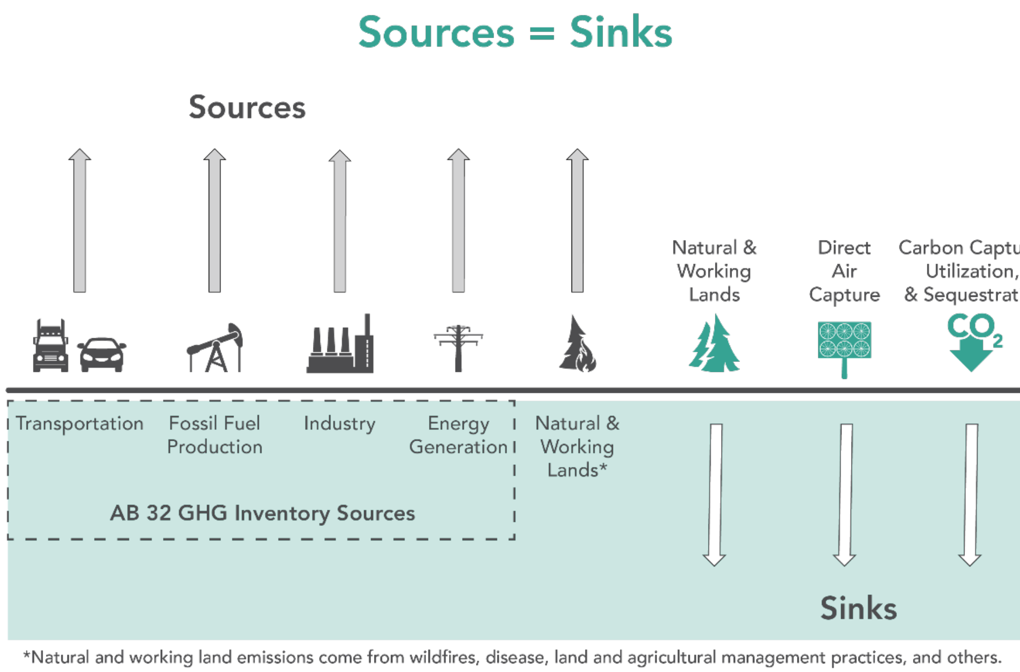
Working Toward Carbon Neutrality

To date, California and many other regions have focused on reducing GHG emissions from the industrial, energy, and transportation sectors. As defined in statute, the state's 2020 and 2030 targets include all in-state sources of GHG emissions—and those emissions associated with imported power that is consumed in the state. By moving to a framework of carbon neutrality, the scope for accounting is expanded to include all sources and sinks. As such, carbon neutrality is achieved when the GHG fluxes are at equilibrium—when sources equal sinks. Figure 1-5 depicts the sources included in the AB 32 GHG Inventory and the new sources and sinks added in this Scoping Plan under the framework of carbon neutrality. Natural and working lands are able to sequester carbon and therefore play an increasingly important role in this framework. However, modeling for this plan shows that carbon sequestration in our natural and working lands alone will be insufficient to achieve carbon neutrality no later than 2045. Therefore, this plan also considers the role of carbon capture and sequestration, as well as biological and mechanical carbon sequestration processes that are included in the IPCC Sixth Assessment Report,[93] as necessary tools for climate change mitigation.

---

[93] IPCC. 2021. *Climate Change 2021: The Physical Science Basis.* https://www.ipcc.ch/report/ar6/wg1/.

Figure 1-5: Carbon neutrality: Balancing the net flux of GHG emissions from all sources and sinks



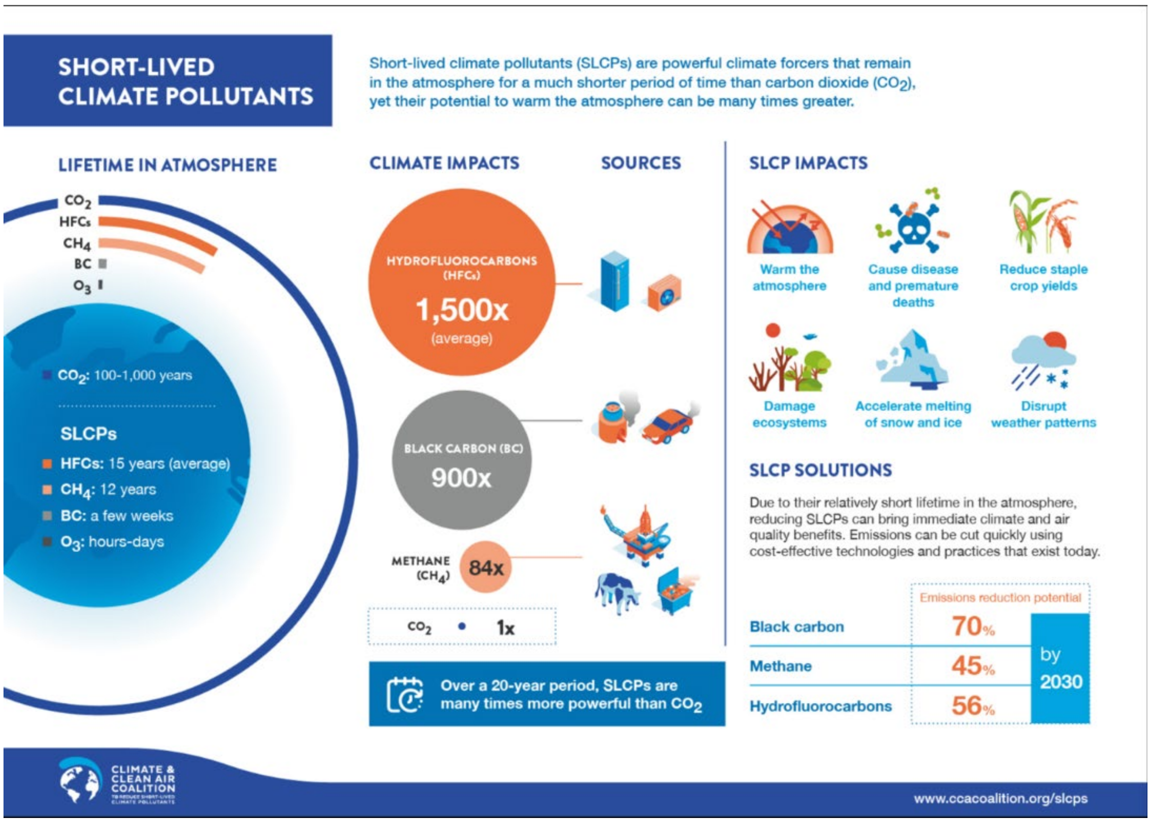
Supporting Healthy and Resilient Lands

Our natural and working lands are an important piece in California's fight to achieve carbon neutrality and build resilience to the impacts of climate change. Healthy land can sequester and store atmospheric carbon dioxide in forests, grasslands, soils, and wetlands. Healthy lands can also reduce emissions of powerful short-lived climate pollutants, limit the release of future GHG emissions, protect people and nature from the impacts of climate change, and build our resilience to future climate risks. Unhealthy lands have the opposite effect—they release more GHGs than they store and are more vulnerable to future climate change impacts. Through climate smart land management that focuses on supporting healthy living systems, we can support our carbon neutrality goals, reduce emissions, advance sequestration, and support healthy and more climate-resilient lands.

Maintaining the Focus on Methane and Short-Lived Climate Pollutants

Given the urgency of climate change, the often-disproportional impacts already being felt by underserved populations across California and the world, and the need to rapidly decarbonize and avoid climate tipping points as identified in the most recent IPCC assessment, efforts to reduce short-lived climate pollutants are especially important. SLCPs include methane (CH_4), black carbon (soot), and fluorinated gases (F-gases, including hydrofluorocarbons, or HFCs), and they are among the most harmful pollutants to both human health and the global climate. SLCPs are more potent than CO_2 in terms of their impact on climate change (and subsequently, global warming) and have a much shorter lifetime in the atmosphere than CO_2 does. That means they have an outsized impact on climate change in the near term—they are responsible for up to 45 percent of current climate forcing. It also means that targeted efforts to reduce short-lived climate pollutant emissions can provide outsized climate and health benefits, within weeks to about a decade (see Figure 1-6).

Figure 1-6: Short-lived climate pollutant impacts[94]



California has been a leader in addressing SLCP emissions. As part of the 2014 Scoping Plan,[95] CARB committed to developing a dedicated strategy to reduce SLCP emissions.

---

[94] Climate and Clean Air Coalition. Short-Lived Climate Pollutants (SLCPs). https://www.ccacoalition.org/en/content/short-lived-climate-pollutants-slcps.

[95] CARB. 2014. *First Update.* https://ww2.arb.ca.gov/sites/default/files/classic/cc/scopingplan/2013_update/first_update_climate_change_scoping_plan.pdf.

The resulting SLCP Reduction Strategy,[96] adopted by CARB in 2017, implements targets codified in SB 1383 (Lara, Chapter 395, Statutes of 2016) to reduce methane and HFC emissions by 40 percent by 2030 and anthropogenic black carbon emissions by 50 percent. California worked with several other states through the U.S. Climate Alliance to establish a similar goal to reduce SLCP emissions in line with the requirements of the Paris Agreement,[97] identifying the potential to reduce SCLPs by 40 to 50 percent by 2030 across the U.S. Climate Alliance.[98]

Process for Developing the Scoping Plan

This Scoping Plan was developed in coordination with the Governor's Office and state agencies, in accordance with direction from the Chair and Members of CARB, through engagement with the Legislature, with advice from the EJ Advisory Committee, in consultation with tribes, and with open and transparent opportunities for stakeholders and the public to engage in workshops and other meetings. Appendix A (Public Process) includes details of the public workshops, and Chapter 5 includes details of the EJ Advisory Committee's role in the Scoping Plan update process.

Guidance from the Administration and Legislature

This Scoping Plan reflects existing and recent direction in the Governor's Executive Orders and Statutes. Table 1-1 provides a summary of major climate legislation and executive orders issued since the adoption of the 2017 Scoping Plan.

Table 1-1: Major climate legislation and executive orders enacted since the 2017 Scoping Plan

Bill/Executive Order	Summary
Assembly Bill 1279 (AB 1279) (Muratsuchi, Chapter 337, Statutes of 2022) *The California Climate Crisis Act*	AB 1279 establishes the policy of the state to achieve carbon neutrality as soon as possible, but no later than 2045; to maintain net negative GHG emissions thereafter; and to ensure that by 2045 statewide anthropogenic GHG emissions are reduced at least 85 percent below 1990 levels. The bill requires CARB to ensure that Scoping Plan updates identify and recommend measures to achieve carbon neutrality, and to identify and implement policies and strategies that enable CO_2 removal solutions and carbon capture, utilization, and storage (CCUS) technologies. This bill is reflected directly in this Scoping Plan.
Senate Bill 905 (SB 905) (Caballero, Chapter 359, Statutes of 2022) *Carbon Capture, Removal, Utilization, and Storage Program*	SB 905 requires CARB to create the Carbon Capture, Removal, Utilization, and Storage Program to evaluate, demonstrate, and regulate CCUS and carbon dioxide removal (CDR) projects and technology. The bill requires CARB, on or before January 1, 2025, to adopt regulations creating a unified state permitting application for approval of CCUS and CDR projects. The bill also requires the Secretary of the Natural Resources Agency to publish a framework for governing agreements for two or more tracts of land overlying the same geologic storage reservoir for the purposes of a carbon sequestration project. The Scoping Plan modeling reflects both CCUS and CDR contributions to achieve carbon neutrality.
Senate Bill 846 (SB 846) (Dodd, Chapter 239, Statutes of 2022) *Diablo Canyon Powerplant: Extension of Operations*	SB 846 extends the Diablo Canyon Power Plant's sunset date by up to five additional years for each of its two units and seeks to make the nuclear power plant eligible for federal loans. The bill requires that the California Public Utilities Commission (CPUC) not include and disallow a load-serving entity from including in their adopted resource plan, the energy, capacity, or any attribute from the Diablo Canyon power plant. The Scoping Plan explains the emissions impact of this legislation.
Senate Bill 1020 (SB 1020) (Laird,	SB 1020 adds interim renewable energy and zero carbon energy retail sales of electricity targets to California end-use customers set at 90 percent in 2035 and 95 percent in 2040.

Chapter 361, Statutes of 2022) *Clean Energy, Jobs, and Affordability Act of 2022*	It accelerates the timeline required to have 100 percent renewable energy and zero carbon energy procured to serve state agencies from the original target year of 2045 to 2035. This bill requires each state agency to individually achieve the 100 percent goal by 2035 with specified requirements. This bill requires the CPUC, California Energy Commission (CEC), and CARB, on or before December 1, 2023, and annually thereafter, to issue a joint reliability progress report that reviews system and local reliability. The bill also modifies the requirement for CARB to hold a portion of its Scoping Plan workshops in regions of the state with the most significant exposure to air pollutants by further specifying that this includes communities with minority populations or low-income communities in areas designated as being in extreme federal non-attainment. The Scoping Plan describes the implications of this legislation on emissions.
Senate Bill 1137 (SB 1137) (Gonzales, Chapter 365, Statutes of 2022) *Oil & Gas Operations: Location Restrictions: Notice of Intention: Health protection zone: Sensitive receptors*	SB 1137 prohibits the development of new oil and gas wells or infrastructure in health protection zones, as defined, except for purposes of public health and safety or other limited exceptions. The bill requires operators of existing oil and gas wells or infrastructure within health protection zones to undertake specified monitoring, public notice, and nuisance requirements. The bill requires CARB to consult and concur with the California Geologic Energy Management Division (CalGEM) on leak detection and repair plans for these facilities, adopt regulations as necessary to implement emission detection system standards, and collaborate with CalGEM on public access to emissions detection data.
Senate Bill 1075 (SB 1075) (Skinner, Chapter 363, Statutes of 2022) *Hydrogen: Green Hydrogen: Emissions of Greenhouse Gases*	SB 1075 requires CARB, by June 1, 2024, to prepare an evaluation that includes: policy recommendations regarding the use of hydrogen, and specifically the use of green hydrogen, in California; a description of strategies supporting hydrogen infrastructure, including identifying policies that promote the reduction of GHGs and short-lived climate pollutants; a description of other forms of hydrogen to achieve emission reductions; an analysis of curtailed electricity; an estimate of GHG and emission reductions that could be achieved through deployment of green hydrogen through a variety of scenarios; an analysis of the potential for opportunities to integrate hydrogen production and applications with drinking water supply treatment needs; policy recommendations for regulatory and permitting processes

	associated with transmitting and distributing hydrogen from production sites to end uses; an analysis of the life-cycle GHG emissions from various forms of hydrogen production; and an analysis of air pollution and other environmental impacts from hydrogen distribution and end uses. This bill would inform the production of hydrogen at the scale called for in this Scoping Plan.
Assembly Bill 1757 (AB 1757) (Garcia, Chapter 341, Statutes of 2022) *California Global Warming Solutions Act of 2006: Climate Goal: Natural and Working Lands*	AB 1757 requires the California Natural Resources Agency (CNRA), in collaboration with CARB, other state agencies, and an expert advisory committee, to determine a range of targets for natural carbon sequestration, and for nature-based climate solutions, that reduce GHG emissions in 2030, 2038, and 2045 by January 1, 2024. These targets must support state goals to achieve carbon neutrality and foster climate adaptation and resilience. This bill also requires CARB to develop standard methods for state agencies to consistently track GHG emissions and reductions, carbon sequestration, and additional benefits from natural and working lands over time. These methods will account for GHG emissions reductions of CO_2, methane, and nitrous oxide related to natural and working lands and the potential impacts of climate change on the ability to reduce GHG emissions and sequester carbon from natural and working lands, where feasible. This Scoping Plan describes the next steps and implications of this legislation for the natural and working lands sector.
Senate Bill 1206 (SB 1206) (Skinner, Chapter 884, Statutes of 2022) *Hydrofluorocarbon gases: sale or distribution*	SB 1206 mandates a stepped sales prohibition on newly produced high- global warming potential (GWP) HFCs to transition California's economy toward recycled and reclaimed HFCs for servicing existing HFC-based equipment. Additionally, SB 1206 also requires CARB to develop regulations to increase the adoption of very low-, i.e., GWP < 10, and no-GWP technologies in sectors that currently rely on higher-GWP HFCs.
Senate Bill 27 (SB 27) (Skinner, Chapter 237, Statutes of 2021)	SB 27 requires CNRA, in coordination with other state agencies, to establish the Natural and Working Lands Climate Smart Strategy by July 1, 2023. This bill also requires CARB to establish specified CO_2 removal targets for 2030 and beyond as part of its Scoping Plan. Under SB 27, CNRA is to establish and maintain a registry to identify projects in the state

Carbon Sequestration: State Goals: Natural and Working Lands: Registry of Projects	that drive climate action on natural and working lands and are seeking funding. CNRA also must track carbon removal and GHG emission reduction benefits derived from projects funded through the registry. This bill is reflected directly in this Scoping Plan as CO_2 removal targets for 2030 and 2045 in support of carbon neutrality.
Senate Bill 596 (SB 596) (Becker, Chapter 246, Statutes of 2021) *Greenhouse Gases: Cement Sector: Net-zero Emissions Strategy*	SB 596 requires CARB, by July 1, 2023, to develop a comprehensive strategy for the state's cement sector to achieve net-zero-emissions of GHGs associated with cement used within the state as soon as possible, but no later than December 31, 2045. The bill establishes an interim target of 40 percent below the 2019 average GHG intensity of cement by December 31, 2035. Under SB 596, CARB must: • Define a metric for GHG intensity and establish a baseline from which to measure GHG intensity reductions. • Evaluate the feasibility of the 2035 interim target (40 percent reduction in GHG intensity) by July 1, 2028. • Coordinate and consult with other state agencies. • Prioritize actions that leverage state and federal incentives. • Evaluate measures to support market demand and financial incentives to encourage the production and use of cement with low GHG intensity. The Scoping Plan modeling is designed to achieve these outcomes.
Executive Order N-82-20	Governor Newsom signed Executive Order N-82-20 in October 2020 to combat the climate and biodiversity crises by setting a statewide goal to conserve at least 30 percent of California's land and coastal waters by 2030. The Executive Order also instructed the CNRA, in consultation with other state agencies, to develop a Natural and Working Lands Climate Smart Strategy that serves as a framework to advance the state's carbon neutrality goal and build climate resilience. In addition to setting a statewide conservation goal, the Executive Order directed CARB to update the target for natural and working lands in support of carbon neutrality as part of this Scoping Plan, and to take into consideration the NWL Climate Smart Strategy.

<table>
<tr><td></td><td>
Executive Order N-82-20 also calls on the CNRA, in consultation with other state agencies, to establish the California Biodiversity Collaborative (Collaborative). The Collaborative shall be made up of governmental partners, California Native American tribes, experts, business and community leaders, and other stakeholders from across the state. State agencies will consult the Collaborative on efforts to:

Establish a baseline assessment of California’s biodiversity that builds upon existing data and can be updated over time.
Analyze and project the impact of climate change and other stressors in California’s biodiversity.
Inventory current biodiversity efforts across all sectors and highlight opportunities for additional action to preserve and enhance biodiversity.

CNRA also is tasked with advancing efforts to conserve biodiversity through various actions, such as streamlining the state’s process to approve and facilitate projects related to environmental restoration and land management. The California Department of Food and Agriculture (CDFA) is directed to advance efforts to conserve biodiversity through measures such as reinvigorating populations of pollinator insects, which restore biodiversity and improve agricultural production.
The Natural and Working Lands Climate Smart Strategy informs this Scoping Plan.
</td></tr>
<tr><td>Executive Order N-79-20</td><td>
Governor Newsom signed Executive Order N-79-20 in September 2020 to establish targets for the transportation sector to support the state in its goal to achieve carbon neutrality by 2045. The targets established in this Executive Order are:

100 percent of in-state sales of new passenger cars and trucks will be zero-emission by 2035.
100 percent of medium- and heavy-duty vehicles will be zero-emission by 2045 for all operations where feasible, and by 2035 for drayage trucks.
100 percent of off-road vehicles and equipment will be zero-emission by 2035 where feasible.

The Executive Order also tasked CARB to develop and propose regulations that require increasing volumes of zero-electric passenger vehicles, medium- and heavy-duty
</td></tr>
</table>

	vehicles, drayage trucks, and off-road vehicles toward their corresponding targets of 100 percent zero-emission by 2035 or 2045, as listed above. The Scoping Plan modeling reflects achieving these targets.
Executive Order N-19-19	Governor Newsom signed Executive Order N-19-19 in September 2019 to direct state government to redouble its efforts to reduce GHG emissions and mitigate the impacts of climate change while building a sustainable, inclusive economy. This Executive Order instructs the Department of Finance to create a Climate Investment Framework that: • Includes a proactive strategy for the state's pension funds that reflects the increased risks to the economy and physical environment due to climate change. • Provides a timeline and criteria to shift investments to companies and industry sectors with greater growth potential based on their focus of reducing carbon emissions and adapting to the impacts of climate change. • Aligns with the fiduciary responsibilities of the California Public Employees' Retirement System, California State Teachers' Retirement System, and the University of California Retirement Program. Executive Order N-19-19 directs the State Transportation Agency to leverage more than $5 billion in annual state transportation spending to help reverse the trend of increased fuel consumption and reduce GHG emissions associated with the transportation sector. It also calls on the Department of General Services to leverage its management and ownership of the state's 19 million square feet in managed buildings, 51,000 vehicles, and other physical assets and goods to minimize state government's carbon footprint. Finally, it tasks CARB with accelerating progress toward California's goal of five million ZEV sales by 2030 by: • Developing new criteria for clean vehicle incentive programs to encourage manufacturers to produce clean, affordable cars. • Proposing new strategies to increase demand in the primary and secondary markets for ZEVs. • Considering strengthening existing regulations or adopting new ones to achieve the necessary GHG reductions from within the transportation sector.

	The Scoping Plan modeling reflects efforts to accelerate ZEV deployment.
Senate Bill 576 (SB 576) (Umberg, Chapter 374, Statutes of 2019) *Coastal Resources: Climate Ready Program and Coastal Climate Change Adaptation, Infrastructure and Readiness Program*	Sea level rise, combined with storm-driven waves, poses a direct risk to the state's coastal resources, including public and private real property and infrastructure. Rising marine waters threaten sensitive coastal areas, habitats, the survival of threatened and endangered species, beaches, other recreation areas, and urban waterfronts. SB 576 mandates that the Ocean Protection Council develop and implement a coastal climate adaptation, infrastructure, and readiness program to improve the climate change resiliency of California's coastal communities, infrastructure, and habitat. This bill also instructs the State Coastal Conservancy to administer the Climate Ready Program, which addresses the impacts and potential impacts of climate change on resources within the conservancy's jurisdiction.
Assembly Bill 65 (AB 65) (Petrie-Norris, Chapter 347, Statutes of 2019) *Coastal Protection: Climate Adaption: Project Prioritization: Natural Infrastructure: Local General Plans*	This bill requires the State Coastal Conservancy, when it allocates any funding appropriated pursuant to the California Drought, Water, Parks, Climate, Coastal Protection, and Outdoor Access For All Act of 2018, to prioritize projects that use natural infrastructure in coastal communities to help adapt to climate change. The bill requires the conservancy to provide information to the Office of Planning and Research on any projects funded pursuant to the above provision to be considered for inclusion into the clearinghouse for climate adaption information. The bill authorizes the conservancy to provide technical assistance to coastal communities to better assist them with their projects that use natural infrastructure.
Executive Order B-55-18	Governor Brown signed Executive Order B-55-18 in September 2018 to establish a statewide goal to achieve carbon neutrality as soon as possible, and no later than 2045, and to achieve and maintain net negative emissions thereafter. Policies and programs undertaken to achieve this goal shall: • Seek to improve air quality and support the health and economic resiliency of urban and rural communities, particularly low-income and disadvantaged communities. • Be implemented in a manner that supports climate adaptation and biodiversity, including protection of the state's water supply, water quality, and native plants and animals.

	This Executive Order also calls for CARB to: • Develop a framework for implementation and accounting that tracks progress toward this goal. • Ensure future Scoping Plans identify and recommend measures to achieve the carbon neutrality goal. This Scoping Plan is designed to achieve carbon neutrality no later than 2045 and the modeling includes technology and fuel transitions to achieve that outcome.
Senate Bill 100 (SB 100) (De León, Chapter 312, Statutes of 2018) *California Renewables Portfolio Standard Program: emissions of greenhouse gases*	SB 100 mandates that the CPUC, CEC, and CARB plan for 100 percent of total retail sales of electricity in California to come from eligible renewable energy resources and zero-carbon resources by December 31, 2045. This bill also updates the state's Renewables Portfolio Standard (RPS) to include the following interim targets: • 44% of retail sales procured from eligible renewable sources by December 31, 2024. • 52% of retail sales procured from eligible renewable sources by December 31, 2027. • 60% of retail sales procured from eligible renewable sources by December 31, 2030. Under SB 100, the CPUC, CEC, and CARB shall use programs under existing laws to achieve 100 percent clean electricity. The statute requires these agencies to issue a joint policy report on SB 100 every four years. The first of these reports was issued in 2021. This Scoping Plan reflects the SB 100 Core Scenario resource mix with a few minor updates.
Assembly Bill 2127 (AB 2127) (Ting, Chapter 365, Statutes of 2018) *Electric Vehicle Charging Infrastructure: Assessment*	This bill requires the CEC, working with CARB and the CPUC, to prepare and biennially update a statewide assessment of the electric vehicle charging infrastructure needed to support the levels of electric vehicle adoption required for the state to meet its goals of putting at least 5 million zero-emission vehicles on California roads by 2030 and of reducing emissions of GHGs to 40% below 1990 levels by 2030. The bill requires the CEC to regularly seek data and input from stakeholders relating to electric vehicle charging infrastructure. This bill supports the deployment of ZEVs as modeled in this Scoping Plan.

Senate Bill 30 (SB 30) (Lara, Chapter 614, Statutes of 2018) *Insurance: Climate Change*	This bill requires the Insurance Commissioner to convene a working group to identify, assess, and recommend risk transfer market mechanisms that, among other things, promote investment in natural infrastructure to reduce the risks of climate change related to catastrophic events, create incentives for investment in natural infrastructure to reduce risks to communities, and provide mitigation incentives for private investment in natural lands to lessen exposure and reduce climate risks to public safety, property, utilities, and infrastructure. The bill requires the policies recommended to address specified questions.
Assembly Bill 2061 (AB 2061) (Frazier, Chapter 580, Statutes of 2018) *Near-zero-emission and Zero-emission Vehicles*	Existing state and federal law sets specified limits on the total gross weight imposed on the highway by a vehicle with any group of two or more consecutive axles. Under existing federal law, the maximum gross vehicle weight of that vehicle may not exceed 82,000 pounds. AB 2061 authorizes a near-zero-emission vehicle or a zero-emission vehicle to exceed the weight limits on the power unit by up to 2,000 pounds. This bill supports the deployment of cleaner trucks as modeled in this Scoping Plan.

Consideration of Relevant State Plans and Regulations

Development of this Scoping Plan also included careful consideration of, and coordination with, other state agency plans and regulations, including the SB 100 Joint Agency Report,[99] the 2022 State Strategy for the State Implementation Plan,[100] Climate Action Plan for Transportation Infrastructure,[101] AB 74 Studies on Vehicle Emissions and Fuel Demand and Supply,[102,103,104] Short-Lived Climate Pollutant Strategy (SLCP Strategy),[105]

Input from Partners and Stakeholders

CARB also collaborated with other state agencies, held consultations with tribes, and solicited comments and feedback from affected stakeholders, including labor organizations and the public. The process to update the Scoping Plan began with kickoff workshops in early June 2021,[109] followed by over a dozen public workshops, including engagement with tribes,[110] and featured a series of EJ Advisory Committee and environmental justice community meetings.[111] The June 2021 workshop and several others were a joint agency effort, as there are many agencies with direct authority or jurisdiction over different sectors of the economy. Consultation with agencies also included bi-weekly, monthly, and weekly meetings.

During the summer of 2022 CARB held three community listening sessions, hosted by the CARB Chair and Board, in communities around the state, along with one virtual community listening session and one tribal listening session specifically for tribes. Many tribes provided written feedback, which was incorporated into this Scoping Plan. In addition, CARB respects tribal sovereignty and also engaged in a consultation campaign with tribes, which resulted in government-to-government consultations, and this Scoping Plan is reflective of this process.[112]

Emissions Data That Inform the Scoping Plan

Greenhouse Gas Emissions

AB 32 includes which GHGs are to be regulated, reduced, and included in the state's targets and goals. That list includes seven GHGs: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), sulfur hexafluoride (SF_6), hydrofluorocarbons (HFCs),

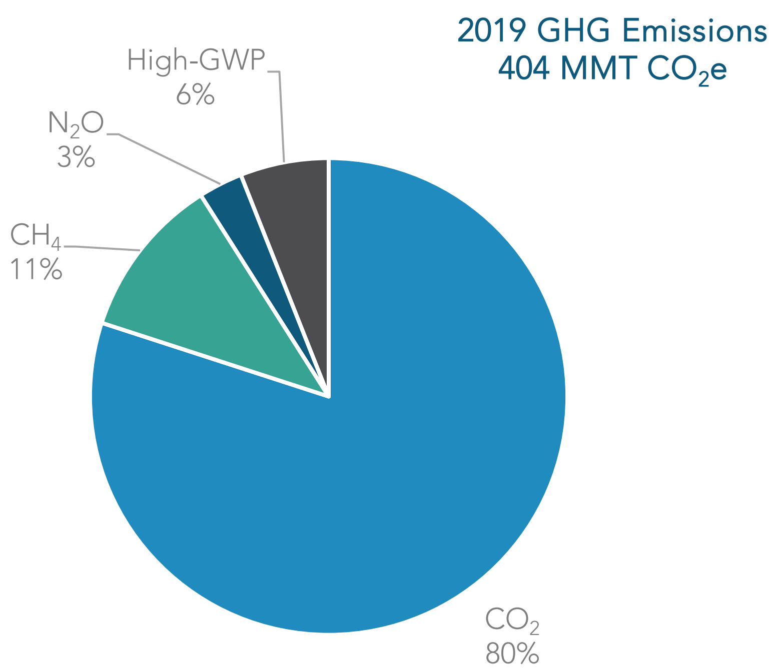
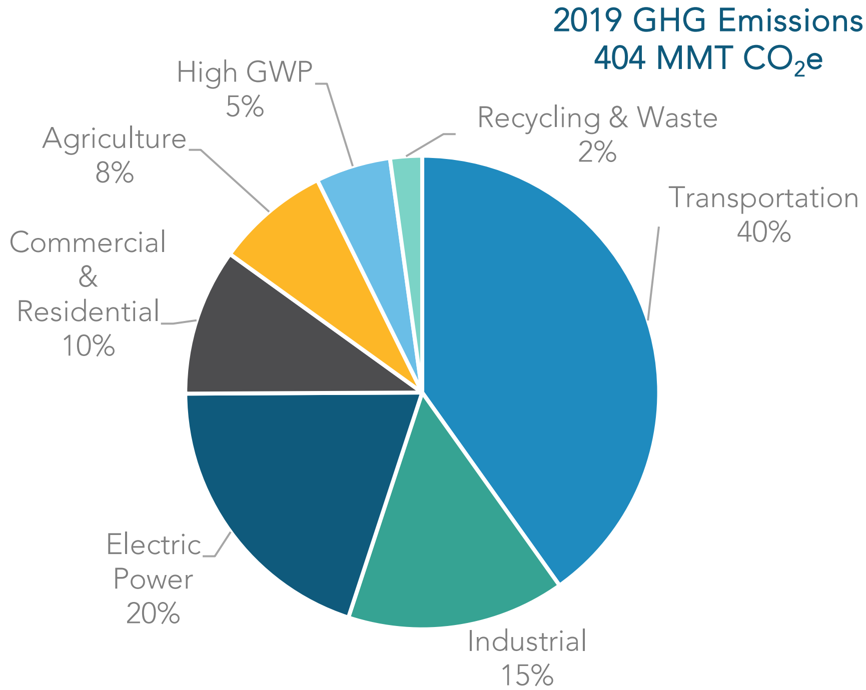
perfluorocarbons (PFCs), and nitrogen trifluoride (NF_3). Carbon dioxide is the primary GHG emitted in California, accounting for 83 percent of the total GHG emissions in 2019, as shown in Figure 1-7 below. Figure 1-8 illustrates that transportation (primarily on-road travel) is the single largest source of CO_2 emissions in the state. Upstream transportation emissions from the refinery and oil and gas sectors are categorized as CO_2 emissions from industrial sources and constitute about 50 percent of the industrial source emissions. When including these emissions, the transportation sector accounts for approximately half of statewide GHG emissions. Other significant sources of CO_2 include electricity production, industrial sources like refineries and cement plants, and residential sources like fossil gas. Figures 1-7 and 1-8 show state GHG emission contributions by GHG and sector based on the 2020 Greenhouse Gas Emission Inventory; GHG emissions for 2019 are shown because 2020 was an outlier due to the global pandemic. Emissions in Figure 1-8 are depicted by Scoping Plan sector, which includes separate categories for high-global warming potential (GWP) and recycling/waste emissions that are otherwise typically included within other economic sectors.

Figure 1-7: 2019 State GHG emission contributions by GHG[113]



[113] CARB. 2022. *California Greenhouse Gas Emissions for 2000 to 2020: Trends of Emissions and Other Indicators.* https://ww2.arb.ca.gov/sites/default/files/classic/cc/inventory/2000-2020_ghg_inventory_trends.pdf.

Figure 1-8: 2019 State GHG emission contributions by Scoping Plan sector[114]



The scope of the AB 32 GHG Inventory encompasses emission sources within the state's borders, as well as imported electricity consumed in the state. This construct for the inventory is consistent with IPCC practices to allow for comparison of statewide GHG emissions with those at the national level and with other international GHG inventories. Statewide GHG emissions calculations use many data sources, including data from other state and federal agencies. However, a significant source of data comes from reports submitted to CARB through the Regulation for the Mandatory Reporting of GHG Emissions (MRR). The MRR requires facilities and entities with more than 10,000 metric tons of carbon dioxide equivalent ($MTCO_2e$) of combustion and process emissions, all facilities belonging to certain industries, and all electric power entities to submit an annual GHG emissions data report directly to CARB. Furthermore, this regulation requires that reports from entities that emit more than 25,000 $MTCO_2e$ be verified by a CARB-

[114] The High GWP sector includes high global warming potential gas emissions from releases of ozone depleting substance (ODS) substitutes, SF_6 emissions from the electricity transmission and distribution system, and gases that are emitted in the semiconductor manufacturing process. ODS substitutes, which are primarily HFCs, are used in refrigeration and air conditioning equipment, solvent cleaning, foam production, fire retardants, and aerosols.

accredited third-party verification body. More information on MRR emissions reports can be found at CARB's Mandatory Greenhouse Gas Emissions Reporting website.[115]

All data sources used to develop the GHG Emission Inventory are listed in CARB's inventory supporting documentation.[116]

Natural and Working Lands

For natural and working lands, the 2018 ecosystem carbon inventory (NWL Inventory)[117] shows there are approximately 5,340 million metric tons (MMT) of carbon in the carbon pools[118] (reservoirs of carbon that have the ability to both take in and release carbon) that CARB has quantified (see Figure 1-9). For purposes of comparison, 5,340 MMT of ecosystem carbon stock is equivalent to 19,600 MMT of atmospheric CO_2. Forests and shrublands contain the majority of California's carbon stock because they cover the majority of California's landscape and have the highest carbon density of any land cover type. All other land categories combined comprise over 35 percent of California's total acreage, but only 15 percent of carbon stocks. Roughly half of the 5,340 MMT of carbon resides in soils and half in plant biomass.

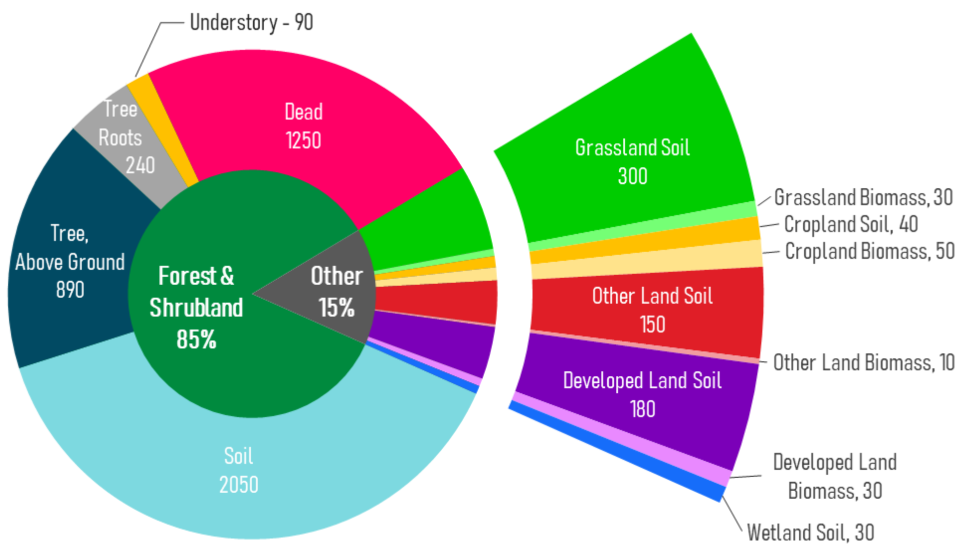
115 CARB. Mandatory Greenhouse Gas Emissions Reporting. https://ww2.arb.ca.gov/our-work/programs/mandatory-greenhouse-gas-emissions-reporting.

116 CARB. Current California GHG Emission Inventory Data. www.arb.ca.gov/cc/inventory/data/data.htm.

117 CARB. 2018. *An Inventory of Ecosystem Carbon in California's Natural and Working Lands.* https://ww3.arb.ca.gov/cc/inventory/pubs/nwl_inventory.pdf.

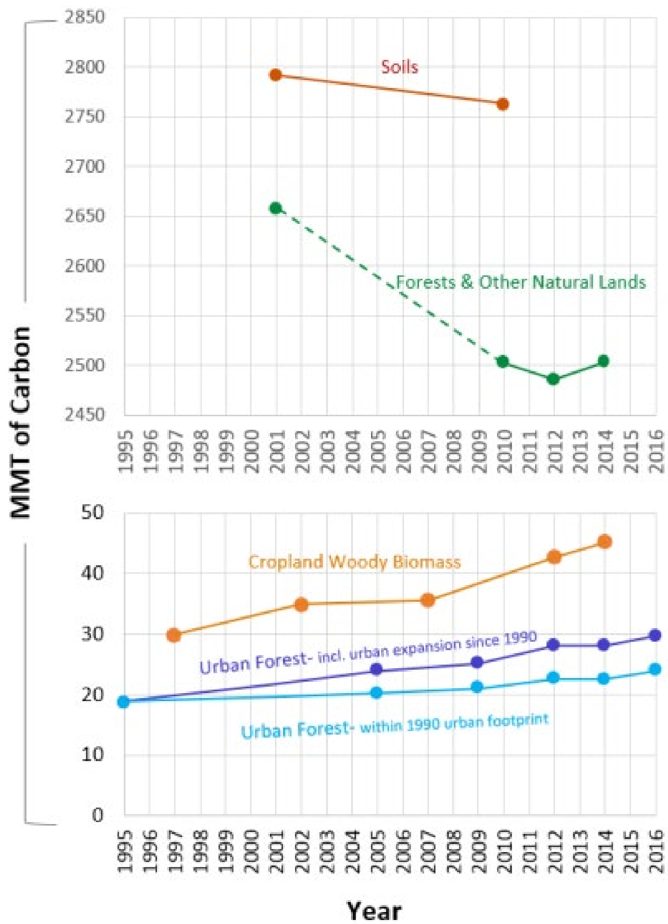
118 "Carbon pools" are Above-Ground Live Biomass (boles, stems, and foliage in shrubs, trees, grasses, and herbaceous vegetation), Below-Ground Live Biomass (roots in shrubs, trees, grasses, and herbaceous vegetation), Dead Organic Matter (standing or downed dead wood and litter), Harvested Wood Products (all wood and bark material that leaves harvest sites regardless of whether it is eventually incorporated into merchandisable products), and Soil Organic Matter (organic carbon in the top 30 centimeters of soil).

Figure 1-9: Carbon stocks in natural and working lands (MMT carbon)



In addition to providing an estimate of the ecosystem carbon that exists on California's landscape, the NWL Inventory also shows how those carbon stocks are changing (see Figure 1-10). The inventory attributes stock change to human activity, such as land use change, or to disturbances, such as wildfire. CARB's inventory shows these lands were a source of GHG emissions from 2001 to 2011, releasing more carbon than they stored, and then they returned to be a slight carbon sink from 2012 to 2014. These trends highlight the interannual and interdecadal variability of lands and their ability to be both a source and a sink of carbon.

Figure 1-10: Changes in carbon stock by landscape type



For natural and working lands, California's inventory is also based on IPCC methods for tracking ecosystem carbon over time, providing for comparability with other national and subnational inventories and carbon accounting. As such, the NWL Inventory is an important tool for tracking both carbon stock changes in California over time and the impacts that interventions such as those identified in this Scoping Plan, actions identified in the Climate Smart Land Strategy, and others have on NWL carbon stocks.

All data sources used to develop the NWL Inventory are listed in the technical support documentation at CARB's California Natural & Working Lands Inventory website.[119]

---

[119] CARB. California Natural & Working Lands Inventory. https://ww2.arb.ca.gov/nwl-inventory.

Black Carbon

In addition, CARB has developed a statewide emission inventory for black carbon in support of the SLCP Strategy. The inventory is reported in two categories: non-forestry (anthropogenic) sources and forestry sources.[120] The black carbon inventory is calculated using existing $PM_{2.5}$ emission inventories combined with speciation profiles that define the fraction of $PM_{2.5}$ that is black carbon. The black carbon inventory helps support implementation of the SLCP Strategy, but it is not part of California's GHG Inventory that tracks progress toward the state's climate targets under AB 32 or SB 32. The state's major anthropogenic sources of black carbon include off-road transportation, on-road transportation, residential wood burning, fuel combustion, and industrial processes. CARB estimated 2017 black carbon emissions to be approximately 8 $MTCO_2e$.[121] The majority of anthropogenic sources come from transportation—specifically, heavy-duty vehicles. The share of black carbon emissions from transportation is dropping rapidly and is expected to continue to do so between now and 2030 as a result of California's air quality programs. The remaining black carbon emissions will come largely from woodstoves/fireplaces, off-road applications, and industrial/commercial combustion. The forestry category includes non-agricultural prescribed burning and wildfire emissions.

Tracking Life-Cycle and Out-of-State Emissions

In recent years there has been increased interest in the embedded carbon in products, also known as *life-cycle emissions.* A life-cycle accounting framework refers to all of the GHG emissions generated from the sourcing, production, and transportation of products to an endpoint. In doing such assessments for a product, emissions may be associated with sourced materials and production activity outside a jurisdiction's borders. While life-cycle emissions can provide a more comprehensive picture of the emissions associated with the goods we consume and ongoing demand, life-cycle inventories are inconsistent with IPCC standards, as they would result in double counting of emissions across jurisdictions. Other countries and regions do produce their own inventory reports consistent with IPCC methods and are taking action to reduce emissions within their jurisdictions. In addition, jurisdictions often lack legal authority to regulate sources outside of their borders. Finally, it is difficult to obtain accurate data for sources and production activities outside of a region's border that would impact the accuracy of such an inventory. For these reasons, the inventory used in the Scoping Plan does not use a life-cycle

---

[120] SB 1383. https://leginfo.legislature.ca.gov/faces/billTextClient.xhtml?bill_id=201520160SB1383.

[121] This is a preliminary estimate developed for this Scoping Plan. Official Black Carbon emissions estimates are provided in the SLCP inventory here: https://ww2.arb.ca.gov/ghg-slcp-inventory.

approach and remains consistent with international accounting standards and consistent with how other countries and regions track emissions within their jurisdictions.

However, GHG mitigation action may cross geographic borders as part of subnational and international collaboration, or as a natural result of implementation of regional policies. In addition to the state's existing GHG inventory, CARB will develop an accounting framework that reflects the benefits of our policies accruing outside of the state. This accounting framework will be important to better understand the true impact of the state's policies on what is emitted into the atmosphere. For example, the LCFS incentivizes GHG reductions along the entire supply chain for the production and delivery of transportation fuel imported for use in the state. However, our inventory only captures the change in emissions from the tailpipe of when that fuel is used in California and does not capture any GHG reductions that occur in the production process if the fuel is produced out of state.

Natural and working lands forestry actions are another example, where California's policies are inspiring forest management actions in other states that result in increased permanent carbon sequestration. California's NWL inventory does not capture the increased carbon stocks resulting from forestry projects happening outside of California, and the CO_2 removals resulting from these projects are not applied in either CARB's NWL inventory or CARB's AB 32 GHG Emissions Inventory. For GHG reductions outside of the state to be attributed to our programs, those reductions must be real, quantifiable, verifiable, and permanent.

It also will be important to avoid any double counting (including claims to those reductions by other jurisdictions) and to transparently indicate whether any extra-jurisdictional emissions reductions might be included in another region's inventory. CARB is collaborating with other jurisdictions to ensure GHG accounting rules are consistent with international best practices, as robust accounting rules instill confidence in the reductions claimed and maintain support for joint action across jurisdictions. The policy goals of consistency and transparency are critical as we work together with other jurisdictions on our parallel paths to achieve our GHG targets with real benefits to the atmosphere.

Tracking Progress

Historically, the AB 32 GHG Inventory has been the primary metric to track progress toward achieving climate targets.[122] However, we must now deploy clean technology at unprecedented rates. The emissions modeling underpinning this Scoping Plan and

---

[122] Starting with the 2022 Edition of the AB 32 GHG inventory, the inventory development now relies more directly on the annually reported and third-party verified emissions from the Regulation for the Mandatory Reporting of Greenhouse Gas Emissions.

targets for clean technology in statute can serve as leading indicators across the economy on how our actions compare to the pace of action needed to be on track to achieve carbon neutrality. The California Climate Dashboard[123] was launched in 2022 and provides high-level metrics for clean energy production and technology deployment. Statistics such as the deployment of zero emission vehicles and clean electricity generation are just some of the examples of metrics across the economy that can be tracked, in addition to GHG emissions, to understand if the state is on track to meet its climate goals. A key indicator to track will be building of new energy infrastructure and deployment of clean technology as evaluated in the uncertainty analysis in Chapter 2. CARB will coordinate with state agencies to establish and make public similar metrics across all economic sectors to help provide transparency on the state's progress in deploying clean technology at the pace and scale needed to achieve carbon neutrality no later than 2045.

Chapter 2: The Scoping Plan Scenario

This chapter describes the Scoping Plan Scenario, which for the first time includes sources in both the AB 32 GHG Inventory and Natural and Working Lands (NWL). It begins with a short description of the alternatives evaluated. Four scenarios for the AB 32 GHG Inventory and NWL were considered separately and helped to inform the Scoping Plan Scenario. Each of the alternatives were considered in terms of the important criteria and priorities that the state's comprehensive climate action must deliver, including the need for GHG reductions that are not only technologically feasible and cost-effective, but also can deliver health and economic benefits for the state. All the scenarios were set against what is called the *Reference Scenario*—that is, what the GHG emissions would look like if we did nothing at all beyond the existing policies that are required and already in place to achieve the 2030 target of at least 40 percent below 1990 levels, or those expected with no new actions in the NWL sector. For this Scoping Plan, two sets of modeling tools were used to evaluate the AB 32 GHG Inventory and NWL sectors because no single model can assess both AB 32 sectors and NWL together. As a result, two different sets of scenarios were developed for each sector type. While this chapter breaks out discussion separately for the two sector types, the Scoping Plan Scenario reflects the combined actions across both sectors by choosing an alternative from each sector type. The modeling provides point estimates; however, that does not imply precision. As discussed in the uncertainty section, several types of uncertainties are associated with any outcomes projected by the modeling results. There will be ranges of estimates associated with each point that are not shown in the graphs or results.

Scenarios for the AB 32 GHG Inventory Sectors

The Reference Scenario for the AB 32 GHG Inventory sectors shows continuing but modest GHG reductions beyond 2030 that level off toward mid-century. The comprehensive analysis of all four alternatives indicates that the Scoping Plan Scenario is the best choice to achieve California's climate and clean air goals while balancing the legislative direction on prioritizing direct emissions reductions, reducing anthropogenic emissions by at least 85 percent by 2045, being technologically feasible, and being cost-effective. It also protects public health, provides a solid foundation for continued economic growth, and drastically reduces the state's dependence on fossil fuel combustion and does not disproportionately impact disadvantaged communities. Each of the alternative scenarios was the product of a process of development informed by public input, the governor,[124] CARB, legislative direction, and input by the EJ Advisory Committee.[125,126] Future updates to the Scoping Plan may consider new clean technologies and fuels beyond those included in this Scoping Plan.

The four scenarios evaluated shared many similarities. They each embodied the following characteristics:

- Drastic reduction in fossil fuel dependence, with some remaining in-state demand for fossil fuels for aviation, marine, and locomotion applications, and for fossil gas for buildings and industry
- Ambitious deployment of efficient non-combustion technologies such as zero emission vehicles and heat pumps
- Rapid growth in the production and distribution of clean energy such as zero carbon electricity and hydrogen
- Progressive phasedown of fossil fuel production and distribution activities as part of the transition to clean energy
- Remaining emissions of fugitive SLCPs such as refrigerants and fugitive methane
- Strong consumer adoption of clean technology and fuel options
- Removal of remaining CO_2 emissions to achieve carbon neutrality
- Some reliance on carbon capture and sequestration (CCS)

While the four scenarios had a lot in common, they also had some differences:

- Year in which carbon neutrality is achieved (2035 or 2045)
- Rate of deployment of clean technology and production and distribution of zero carbon energy
- Remaining amount of demand for fossil energy in the year carbon neutrality is achieved
- Constraints on technology and fuels deployed in certain sectors
- Consumer adoption rates of clean technologies and fuels
- Degree of reliance on CO_2 removal
- Degree of reliance on CCS

[126] CARB. January 25, 2022. Update on PATHWAYS Scenario Modeling Assumptions. *https://ww2.arb.ca.gov/sites/default/files/2022-01/Scenario%20Slides%20for%20Jan25%20EJAC%20Mtg_01242022.pdf*.

The summary below provides an overview of the alternatives designed and considered for the energy and industrial sectors in this update. Full details of each scenario considered can be found in the *Draft 2022 Scoping Plan Update*

Scoping Plan Scenario (modeling scenario Alternative 3 from the Draft): carbon neutrality by 2045, deploy a broad portfolio of existing and emerging fossil fuel alternatives and clean technologies, and align with statutes, Executive Orders, Board direction, and direction from the governor

Alternative 1: carbon neutrality by 2035, nearly complete phaseout of all combustion, limited reliance on carbon capture and sequestration and engineered carbon removal, and restricted applications for biomass-derived fuels

Alternative 2: carbon neutrality by 2035 and aggressive deployment of a full suite of technology and energy options, including engineered carbon removal

Alternative 4: carbon neutrality by 2045, deployment of a broad portfolio of existing and emerging fossil fuel alternatives, slower deployment and adoption rates than the Scoping Plan Scenario, and a higher reliance on CO_2 removal

Other considerations for the AB 32 GHG Inventory sectors include the following:

- To what extent does an alternative meet the statewide targets and any sector targets, and also deliver clean air benefits (especially in the near term) to address ongoing healthy air disparities, prioritize reductions for mobile and large stationary sources, and emphasize continued investment in disadvantaged communities?
- Does an alternative support California in building on efforts to collaborate with other jurisdictions and include exportable policies based on robust science?
- Does an alternative provide for compliance options and a cost-effective approach to reduce GHG emissions?
- Does the alternative present a realistic and ambitious path forward consistent with statute and science, and support economic opportunities, particularly in anticipated growth sectors?

Scenarios for Natural and Working Lands

For the natural and working lands sector, the Reference Scenario shows that NWL will continue to emit GHGs and lose carbon stocks into the future as the combined effects of past unhealthy management practices and climate change impact our lands. Relative to the Reference Scenario, the four NWL scenarios represent different scales of land management on seven landscapes (forests, shrublands/chaparral, grasslands, croplands, developed lands, wetlands, and sparsely vegetated lands) to support carbon neutrality.

The analysis of the four NWL scenarios shows that the Scoping Plan Scenario is the preferred choice because it prioritizes sustainable land management to sequester carbon over the long term, GHG and air pollution reductions, ecosystem health and resilience, and implementation and technological feasibility and cost-effectiveness. The Scoping Plan Scenario reduces catastrophic wildfire risk to the state; increases the health and resilience of California's forests, shrublands, and grasslands; increases soil health; and protects, restores, and enhances California's natural and working lands for future generations. The Scoping Plan Scenario takes into consideration the priority landscapes and nature-based strategies identified in California's Climate Smart Strategy[127] and reflects the state's priorities to manage lands in ways that support the multiple benefits they provide. The Scoping Plan Scenario, as well as each of the alternative NWL scenarios, were informed by input from other agencies, the public, and the EJ Advisory Committee. Additional landscapes and land management activities will be added and evaluated in future Scoping Plan updates and in response to AB 1757.

Each of the NWL scenarios have several similarities, including the following:

- Prioritizing NWL management actions on forests, shrublands, grasslands, croplands, developed lands, wetlands, and sparsely vegetated lands. These actions can reduce GHG emissions from these lands, protect ecosystems against future climate change, protect communities, and enhance the ecosystem benefits they provide to nature and society.
- Exploring the potential impacts of different levels of NWL management actions that are designed to achieve the objective associated with each scenario.
- Analyzing the carbon impacts of land management actions, climate change, wildfire, and water use on California's diverse natural and working lands through 2045.

There are also differences across the four NWL scenarios. These include:

- The level of NWL management actions taken on each landscape, such as varying the acres of healthy soils practices for croplands.
- The types of NWL management actions taken on each landscape, such as prescribed burning or thinning for forests, grasslands, and shrublands.

[127] CNRA. 2022. Natural and Working Lands Climate Smart Strategy. https://resources.ca.gov/-/media/CNRA-Website/Files/Initiatives/Expanding-Nature-Based-Solutions/CNRA-Report-2022---Final_Accessible_Compressed.pdf.

The summary below provides an overview of the alternatives designed and considered for the NWL sectors in this Scoping Plan. Full details of each scenario considered can be found in the *Draft 2022 Scoping Plan Update*.

Scoping Plan Scenario (NWL Alternative 3 from the Draft): land management activities that prioritize restoration and enhancement of ecosystem functions to improve resilience to climate change impacts, including more stable carbon stocks

NWL Alternative 1: land management activities that prioritize short term carbon stocks in our forests and through increased climate smart agricultural practices on croplands

NWL Alternative 2: land management activities representative of California's current commitments and plans

NWL Alternative 4: land management activities that prioritize reducing catastrophic wildfires in forests, shrublands, and grasslands

Evaluation of Scoping Plan Alternatives

CARB staff solicited feedback from topical experts, affected stakeholders, and the EJ Advisory Committee, including a tribal representative, at public meetings to assemble input assumptions for four carbon neutrality scenarios to model using PATHWAYS. Revisions to the Draft Scoping Plan were informed by direction in statute, the Governor's Executive Orders, public comments, and the recommendations of the EJ Advisory Committee. The three alternative scenarios were designed to explore the potential speed, magnitude, and impacts of transitioning California's energy demand away from fossil fuels. The modeling assumptions listed below identify the primary fossil fuel alternative that is commercially available and technically feasible for widespread use by 2045 for each sector. CARB assumes that any energy demand that remains after the alternative technology or fuel is applied—such as on-road internal combustion engines, industrial processes, and gas use in existing buildings that have not yet decarbonized—will continue to be met by fossil fuels, resulting in residual GHG emissions.

NWL Scoping Plan Alternatives

For the NWL sectors, staff significantly expanded the scale of the scientific analysis for NWL from previous Scoping Plan efforts. CARB staff utilized modeling tools for this expanded analysis to assess both the carbon and other ecological, public health, and economic outcomes of management actions on forests, shrublands, grasslands, croplands, developed lands, wetlands, and sparsely vegetated lands. CARB staff aligned the scenarios with both the landscape types and actions identified in other efforts called for in Governor Newsom's Executive Order N-82-20 (e.g., California's Climate Smart Strategy and Pathways to 30x30). As part of this Scoping Plan, CARB staff modeled as many of the management actions identified in the Natural and Working Lands Climate

Smart Strategy as were feasible. The management actions that were included in the model were selected because of the State of California's previous work to quantify these actions' impacts. It was not feasible to model every land management strategy for NWL, and so it is possible that larger volumes of sequestration (e.g., in soils or in oceans) could result from additional non-modeled activities. California's Natural and Working Lands Climate Smart Strategy includes a more comprehensive listing of priority nature-based solutions and management actions. It is important to note that the absence of a particular management action or its climate benefit in the modeling is not an indication of its importance or potential contributions toward meeting the target or toward supporting the carbon neutrality target for California.

Forests: Management strategies were modeled for forests: biological/chemical/herbaceous treatments (e.g., herbicide application), clearcut, various timber harvests (e.g., variable retention, seed tree / shelterwood, selection harvesting), mastication, other mechanical treatments (e.g., piling of dead material, understory thinning), prescribed burning, and thinning. Avoided land conversion to another land use was also included in the modeling. Wildfire was modeled and is responsive to management strategies and climate conditions.

Shrublands and chaparral: Management strategies were modeled for shrublands and chaparral: biological/chemical/herbaceous treatments, prescribed burning, mechanical treatment (e.g., mastication, crushing, mowing, piling), and avoided conversion from shrubland to another land use. Wildfire was modeled and is responsive to management strategies and climate conditions.

Grasslands: Management strategies were modeled for grasslands: biological/chemical/herbaceous treatments, prescribed burning, and avoided land conversion from grasslands to another land use. Wildfire was modeled and is responsive to management strategies and climate conditions.

Croplands: Management strategies were modeled for row crops: cover cropping, no till, reduced till, compost amendment, transition to organic[128] farming, avoided conversion of annual crop agricultural land through easements, establishing riparian forest buffers, alley cropping, establishing windbreaks/shelterbelts, establishing tree and shrubs in croplands, and establishing hedgerows. For perennial crops, windbreaks/shelterbelts, hedgerows, conversion from annual crops to perennial crops, and avoided conversion to other land uses were modeled.

[128] Note: N_2O reductions from decreases in synthetic fertilizer application in organic farming were not modeled.

Developed lands: Management strategies were modeled for developed lands: Increasing tree canopy cover through planting trees and improved management of existing trees, and removing vegetation surrounding structures in accordance with the CAL FIRE Defensible Space PRC 4291.

Wetlands: Management strategies were modeled for wetlands: Restoring wetlands through submerging cultivated land in the Sacramento-San Joaquin Delta and avoided land conversion in the Sacramento-San Joaquin Delta.

Sparsely vegetated lands: Management strategies were modeled for sparsely vegetated lands: Avoided conversion of sparsely vegetated lands to another land use.

Scoping Plan Scenario

The Scoping Plan Scenario achieves GHG emission reductions that exceed the levels expected based on existing policies represented in the Reference Scenario, keeping California on track to achieve the SB 32 GHG reduction target for 2030 and become carbon neutral no later than 2045. Actions that reduce GHG emissions and transition AB 32 GHG Inventory sources away from fossil fuel combustion affect each economic sector. Actions that lead to improved carbon stocks affect each landscape.

AB 32 GHG Inventory Sectors

The AB 32 GHG Inventory Sector Reference scenario is the forecasted statewide GHG emissions through mid-century, with existing policies and programs but without any further action to reduce GHGs beyond those needed to achieve the 2030 limit. The Reference Scenario was developed based on other projections of business-as-usual conditions. Sources of data and policies included are:

- California Energy Demand Forecast[129]
- The two transportation carbon neutrality studies required by AB 74[130]
- The Mobile Source Strategy[131]
- SB 100 60 percent Renewables Portfolio Standard
- A Low Carbon Fuel Standard carbon intensity reduction target of 20 percent

Policies that are under study or design, such the Advanced Clean Fleets regulation, are not included. The Reference Scenario reflects current trends and expected performance of policies identified in the 2017 Scoping Plan—some of which are performing better (such as the RPS and LCFS) and others that may not meet expectations (such as vehicle miles traveled [VMT] reductions and methane capture). Figure 2-1 provides the modeling results for a Reference Scenario for the AB 32 GHG Inventory sectors compared to the Scoping Plan Scenario.

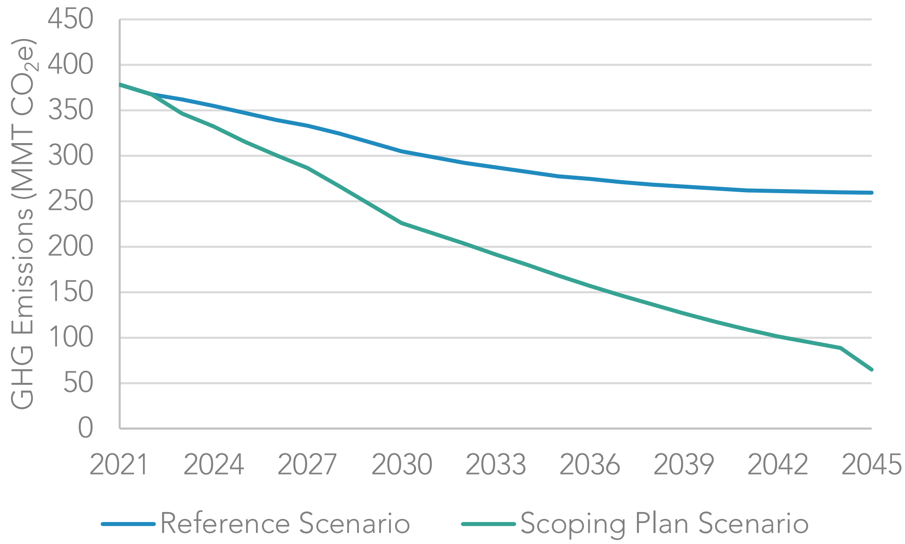
Figure 2-1: Reference and Scoping Plan Scenario GHG emissions[132]



The Scoping Plan Scenario is summarized in Table 2-1. The table shows the types of technologies and energy needed to drastically reduce GHG emissions from the AB 32 Inventory sectors. It also includes references to relevant statutes and Executive Orders, although it is not comprehensive of all existing new authorities for directing or supporting the actions described. Each action is expected to both reduce GHGs and help improve air quality, primarily by transitioning away from combustion of fossil fuels. The Scoping Plan Scenario achieves the AB 1279 target of 85 percent below 1990 levels by 2045 and identifies a need to accelerate the 2030 target to 48 percent below 1990 levels.

[132] The drop in emissions in 2045 reflects both the need to achieve an 85% reduction below 1990 levels in anthropogenic emissions per AB 1279 and Governor Newsom's request for a 100 MMT CO2e carbon removal and capture target in 2045. This was modeled by extending CCS to electric sector emissions.

Table 2-1: Actions for the Scoping Plan Scenario: AB 32 GHG Inventory sectors

Sector	Action	Statutes, Executive Orders, Other Direction, Outcome
GHG Emissions Reductions Relative to the SB 32 Target[133]	40% below 1990 levels by 2030	SB 32: Reduce statewide GHG emissions. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory
Smart Growth / Vehicle Miles Traveled (VMT)	VMT per capita reduced 25% below 2019 levels by 2030, and 30% below 2019 levels by 2045	SB 375: Reduce demand for fossil transportation fuels and GHGs, and improve air quality. In response to Board direction and EJ Advisory Committee recommendations
Light-duty Vehicle (LDV) Zero Emission Vehicles (ZEVs)	100% of LDV sales are ZEV by 2035	EO N-79-20: Reduce demand for fossil transportation fuels and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory 2035 target aligns with the EJ Advisory Committee recommendation.

[133] While the SB 32 GHG emissions reduction target is not an Action that is analyzed independently, it is included in this table for reference.

Sector	Action	Statutes, Executive Orders, Other Direction, Outcome
Truck ZEVs	100% of medium-duty (MDV)/HDV sales are ZEV by 2040 (AB 74 University of California Institute of Transportation Studies [ITS] report)	EO N-79-20: Reduce demand for fossil transportation fuels and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory
Aviation	20% of aviation fuel demand is met by electricity (batteries) or hydrogen (fuel cells) in 2045. Sustainable aviation fuel meets most or the rest of the aviation fuel demand that has not already transitioned to hydrogen or batteries.	Reduce demand for petroleum aviation fuel and reduce GHGs. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory In response to Governor Newsom's July 2022 letter to CARB Chair Liane Randolph
Ocean-going Vessels (OGV)	2020 OGV At-Berth regulation fully implemented, with most OGVs utilizing shore power by 2027. 25% of OGVs utilize hydrogen fuel cell electric technology by 2045.	Reduce demand for petroleum fuels and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory
Port Operations	100% of cargo handling equipment is zero-emission by 2037. 100% of drayage trucks are zero emission by 2035.	Executive Order N-79-20: Reduce demand for petroleum fuels and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory

Sector	Action	Statutes, Executive Orders, Other Direction, Outcome
Freight and Passenger Rail	100% of passenger and other locomotive sales are ZEV by 2030. 100% of line haul locomotive sales are ZEV by 2035. Line haul and passenger rail rely primarily on hydrogen fuel cell technology, and others primarily utilize electricity.	Reduce demand for petroleum fuels and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory
Oil and Gas Extraction	Reduce oil and gas extraction operations in line with petroleum demand by 2045.	Reduce GHGs and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory
Petroleum Refining	CCS on majority of operations by 2030, beginning in 2028 Production reduced in line with petroleum demand.	Reduce GHGs and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory

Sector	Action	Statutes, Executive Orders, Other Direction, Outcome
Electricity Generation	Sector GHG target of 38 million metric tons of carbon dioxide equivalent ($MMTCO_2e$) in 2030 and 30 $MMTCO_2e$ in 2035 Retail sales load coverage[134] 20 gigawatts (GW) of offshore wind by 2045 Meet increased demand for electrification without new fossil gas-fired resources.	SB 350 and SB 100: Reduce GHGs and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory In response to Governor Newsom's July 2022 letter, Board direction, and EJ Advisory Committee recommendation
New Residential and Commercial Buildings	All electric appliances beginning 2026 (residential) and 2029 (commercial), contributing to 6 million heat pumps installed statewide by 2030	Reduce demand for fossil gas and GHGs, and improve ambient and indoor air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory In response to Governor Newsom's July 2022 letter

[134] SB 100 speaks only to retail sales and state agency procurement of electricity. The *2021 SB 100 Joint Agency Report* reflects the agency authors' understanding that other loads—wholesale or non-retail sales and losses from storage and transmission and distribution lines—are not subject to the law.

Sector	Action	Statutes, Executive Orders, Other Direction, Outcome
Existing Residential Buildings	80% of appliance sales are electric by 2030 and 100% of appliance sales are electric by 2035. Appliances are replaced at end of life such that by 2030 there are 3 million all-electric and electric-ready homes—and by 2035, 7 million homes—as well as contributing to 6 million heat pumps installed statewide by 2030.	Reduce demand for fossil gas and GHGs, and improve ambient and indoor air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory In response to Governor Newsom's July 2022 letter
Existing Commercial Buildings	80% of appliance sales are electric by 2030, and 100% of appliance sales are electric by 2045. Appliances are replaced at end of life, contributing to 6 million heat pumps installed statewide by 2030.	Reduce demand for fossil gas and GHGs, and improve ambient and indoor air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory In response to Governor Newsom's July 2022 letter
Food Products	7.5% of energy demand electrified directly and/or indirectly by 2030; 75% by 2045	Reduce demand for fossil gas and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory

Sector	Action	Statutes, Executive Orders, Other Direction, Outcome
Construction Equipment	25% of energy demand electrified by 2030 and 75% electrified by 2045	Reduce demand for fossil energy and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory
Chemicals and Allied Products; Pulp and Paper	Electrify 0% of boilers by 2030 and 100% of boilers by 2045. Hydrogen for 25% of process heat by 2035 and 100% by 2045 Electrify 100% of other energy demand by 2045.	Reduce demand for fossil energy and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory
Stone, Clay, Glass, and Cement	CCS on 40% of operations by 2035 and on all facilities by 2045 Process emissions reduced through alternative materials and CCS	SB 596: Reduce demand for fossil energy, process emissions, and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory
Other Industrial Manufacturing	0% energy demand electrified by 2030 and 50% by 2045	Reduce demand for fossil energy and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory

Sector	Action	Statutes, Executive Orders, Other Direction, Outcome
Combined Heat and Power	Facilities retire by 2040.	Reduce demand for fossil energy and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory
Agriculture Energy Use	25% energy demand electrified by 2030 and 75% by 2045	Reduce demand for fossil energy and GHGs, and improve air quality. AB 197: direct emissions reductions
Low Carbon Fuels for Transportation	Biomass supply is used to produce conventional and advanced biofuels, as well as hydrogen.	Reduce demand for petroleum fuel and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory
Low Carbon Fuels for Buildings and Industry	In 2030s biomethane[135] blended in pipeline Renewable hydrogen blended in fossil gas pipeline at 7% energy (~20% by volume), ramping up between 2030 and 2040 In 2030s, dedicated hydrogen pipelines constructed to serve certain industrial clusters	Reduce demand for fossil energy and GHGs, and improve air quality. AB 197: direct emissions reductions for sources covered by the AB 32 Inventory

[135] *Biomethane* is also known as renewable natural gas (RNG).

Sector	Action	Statutes, Executive Orders, Other Direction, Outcome
Non-combustion Methane Emissions	Increase landfill and dairy digester methane capture. Some alternative manure management deployed for smaller dairies Moderate adoption of enteric strategies by 2030 Divert 75% of organic waste from landfills by 2025. Oil and gas fugitive methane emissions reduced 50% by 2030 and further reductions as infrastructure components retire in line with reduced fossil gas demand	SB 1383: Reduce short-lived climate pollutants.
High GWP Potential Emissions	Low GWP refrigerants introduced as building electrification increases, mitigating HFC emissions	SB 1383: Reduce short-lived climate pollutants.

Natural and Working Lands

The Reference Scenario for NWL represents the amount of land management that occurred between 2001 and 2014, and projects the outcomes from maintaining the 2001–2014 levels of land management until 2045. The management and land use practices that occur within the Reference Scenario were derived from empirical data used by staff. For forests, shrublands/chaparral, and grasslands, the Reference Scenario constitutes approximately 250,000 acres of annual statewide treatments. For croplands, the Reference Scenario represents no healthy soil practices because during this period the healthy soil program did not yet exist. For land use change within all land types that consider land use change, historical rates of land conversion from 2001–2014 also were taken from empirical data and modeled into the future for the Reference Scenario.

Table 2-2 summarizes the Scoping Plan Scenario. The table also includes references to relevant statutes and Executive Orders where available.

Table 2-2: Actions for the Scoping Plan Scenario: NWL sectors

Sector	Action	Statutes, Executive Orders, Outcome
Natural and Working Lands	Conserve 30% of the state's NWL and coastal waters by 2030. Implement near- and long-term actions to accelerate natural removal of carbon and build climate resilience in our forests, wetlands, urban greenspaces, agricultural soils, and land conservation activities in ways that serve all communities—and in particular low-income, disadvantaged, and vulnerable communities.	EO N-82-20 and SB 27: CARB to include an NWL target in the Scoping Plan. AB 1757: Establish targets for carbon sequestration and nature-based climate solutions. SB 1386: NWL are an important strategy in meeting GHG reduction goals.

Sector	Action	Statutes, Executive Orders, Outcome
Forests and Shrublands	At least 2.3 million acres[136] treated statewide annually in forests, shrublands/chaparral, and grasslands, comprised of regionally specific management strategies that include prescribed fire, thinning, harvesting, and other management actions. No land conversion of forests, shrublands/chaparral, or grasslands.	Restore health and resilience to overstocked forests and prevent carbon losses from severe wildfire, disease, and pests. Improve air quality and reduce health costs related to wildfire emissions. Improve water quantity and quality and improve rural economies. Provide forest biomass for resource utilization. EO B-52-18: CARB to increase the opportunity for using prescribed fire. AB 1504 (Skinner, Chapter 534, Statutes of 2010): CARB to recognize the role forests play in carbon sequestration and climate mitigation.

[136] The 2.3 million acre target is what the Scoping Plan modeling shows would be needed to realize the carbon stock target called for in this Scoping Plan by 2045.

Sector	Action	Statutes, Executive Orders, Outcome
Grasslands	At least 2.3 million acres[137] treated includes increased management of grasslands interspersed in forests to reduce fuels surrounding communities using management strategies appropriate for grasslands. No land conversion of forests, shrublands/chaparral, or grasslands.	Help to achieve climate targets, improve air quality, and reduce health costs.
Croplands	Implement climate smart practices for annual and perennial crops on ~80,000 acres annually. Land easements/ conservation on annual crops at ~5,500 acres annually. Increase organic agriculture to 20% of all cultivated acres by 2045 (~65,000 acres annually).	Reduce short-lived climate pollutants. Increase soil water holding capacity. Increase organic farming and reduce pesticide use. SB 859: Recognizes the ability of healthy soils practices to reduce GHG emissions from agricultural lands. Target increased in response to Governor Newsom's direction to prioritize sustainable land management.

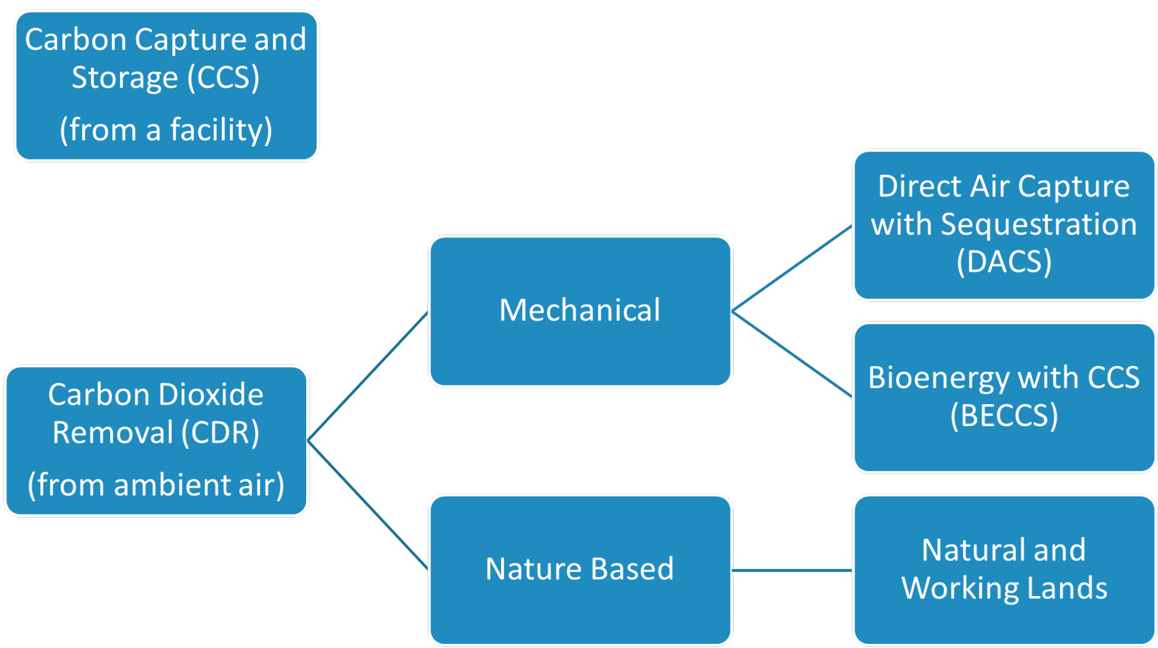
[137] The 2.3 million acre target is what the Scoping Plan modeling shows would be needed to realize the carbon stock target called for in this Scoping Plan by 2045.

Sector	Action	Statutes, Executive Orders, Outcome
Developed Lands	Increase urban forestry investment by 200% above current levels and utilize tree watering that is 30% less sensitive to drought. Establish defensible space that accounts for property boundaries.	Increase urban tree canopy and shade cover. Reduce heat island effects and support water infrastructure. Reduce fire risk via defensible space. AB 2251 (Calderon, Chapter 186, Statutes of 2022): Increase urban tree canopy 10% by 2035. Target increased in response to AB 2251 and Governor Newsom's direction on CO_2 removal targets in his July 2022 letter.
Wetlands	Restore 60,000 acres of Delta wetlands.	Increase carbon sequestration and reduce short-lived climate pollutants. Helps to reverse land subsidence while improving flood protection and providing critical habitat.
Sparsely Vegetated Lands	Land conversion at 50% of the Reference Scenario land conversion rate.	Reduce the rate of land conversion to more GHG-intensive land uses.

Strategies for Carbon Removal and Sequestration

To achieve carbon neutrality, any remaining emissions must be compensated for using carbon removal and sequestration tools. The following discussion presents more detail on the options available to capture and sequester carbon. Carbon removal and sequestration will be an essential tool to achieve carbon neutrality, and the modeling clearly shows there is no path to carbon neutrality without carbon removal and sequestration. Governor Newsom also recognized the importance of CO_2 removal strategies and directed CARB to establish CO_2 removal and carbon capture targets of 20 $MMTCO_2$ and 100 $MMTCO_2$ by 2030 and 2045, respectively, as well as signing 2022 legislation on carbon removal and sequestration, including: AB 1279, SB 905, SB 1137, and AB 1757. Carbon removal and sequestration can take different forms. Figure 2-2 illustrates the types of carbon removal and sequestration included in this Scoping Plan. There are numerous other carbon removal options undergoing research, development, and pilot deployment. As these options mature and new approaches emerge, they can be considered in future Scoping Plan updates.

Figure 2-2: Forms of carbon removal and sequestration considered in this Scoping Plan



The Role of Carbon Capture and Sequestration

Carbon capture and sequestration (CCS) will be a necessary tool to reduce GHG emissions and mitigate climate change while minimizing leakage and minimizing emissions where no technological alternatives may exist. CCS is a process by which large amounts of CO_2 are captured, compressed, transported, and sequestered. CCS projects are paired with a source of emissions, as the CCS project captures CO_2 as it leaves a facility's smokestack. CCS projects are often paired with large GHG-emitting facilities such as energy, manufacturing, or fuel production facilities. The sequestration component of CCS includes CO_2 injection into geologic formations (such as depleted oil and gas reservoirs and saline formations), as well as use in industrial materials (e.g., concrete). CCS is distinct from biological sequestration, which is typically accomplished through NWL management and conservation practices that enhance the storage of carbon or reduce CO_2 emissions with nature-based approaches. CCS is also distinct from mechanical CO_2 removal technologies, where CO_2 is removed directly from the atmosphere using mechanical and/or chemical processes.

CARB adopted a CCS Protocol in 2018 as part of amendments to the Low Carbon Fuel Standard.[138] At this time, no CCS projects have been implemented or have generated any credits under that protocol. However, CCS projects have been implemented elsewhere since the 1970s, largely on coal-fired power plants, with over two dozen projects operational around the world. Over 100 are at the stages of advanced or early development and are expanding beyond coal-fired plants to fossil gas, fuel production, and electricity generation facilities.[139] CCS projects are in development for addressing emissions from fuel, gas, energy production, and chemical production. As of November 2019, more than half of global large-scale CCS facilities (representing approximately 22 $MMTCO_2$/yr in capacity[140]) were in the U.S., mostly as a result of sustained governmental support for these technologies.[141] This support includes the federal 45Q tax credit for CCS[142,143] and research and deployment grants from federal agencies.[144,145] California's deep sedimentary rock formations in the Central Valley represent world-class

CO_2 storage sites that would meet the highest standards, with storage capacities of at least 17 billion tons of CO_2.[146,147]

In this Scoping Plan, CCS is included to address emissions from limited sectors, including electricity generation, cement production facilities, and refineries, to ensure anthropogenic emissions are reduced by at least 85 percent below 1990 levels in 2045, as directed in AB 1279. While the modeling outputs show CCS not being applied to the electricity sector until 2045, CCS could be implemented earlier on the electricity sector with a similar ramp up over time as that for refineries and cement plants. An earlier application of CCS in the electricity sector would yield additional reductions in years prior to 2045. In addition, CCS can support hydrogen production until such time as there is sufficient renewable power for electrolysis and an abundant water source.

Cement plants have emissions associated with combustion and process-related activities. Combustion emissions account for approximately 40 percent of the total emissions at cement plants. The remaining emissions are related to process-related activities. Due to the high heat content needed to produce cement, there is currently no technically feasible alternative to combustion. SB 596 calls for a 40 percent reduction in GHG intensity in cement emissions from 2019 levels by 2035, and then net zero emissions by 2045. To meet in-state demand, the state relies on cement both produced in state and imported. There are seven cement plants operating in California.[148] To minimize emissions leakage and address emissions from cement plants, the Scoping Plan Scenario includes CCS for cement plants. Additional reductions will need to be pursued and considered as part of implementation of SB 596, which calls for CARB to develop a comprehensive strategy by July 1, 2023, for the state's cement sector to achieve net-zero emissions of GHGs associated with cement used within the state as soon as possible, but no later than December 31, 2045. This effort began in the summer of 2022 and included sector specific workshops.

Even with implementation of EO N-79-20, and despite all of the ambitious efforts in the Scoping Plan Scenario, there will remain some demand for petroleum fuels for legacy vehicles on road applications, and in aviation, rail, and marine applications. Petroleum refineries will need to implement technology to decarbonize their operations and reduce their emissions. This Scoping Plan also assumes CCS at petroleum refineries as one of those potential strategies. Currently, there are seventeen petroleum refineries operating

[146] For comparison purposes, California's emitted 418.2 million metric tons of CO_2e in 2019.
[147] Lawrence Livermore National Laboratory. 2020. *Getting to Neutral: Options for Negative Carbon Emissions in California.* Revision 1. https://www-gs.llnl.gov/content/assets/docs/energy/Getting_to_Neutral.pdf.
[148] CARB. Mandatory GHG Reporting – Reported Emissions. https://ww2.arb.ca.gov/mrr-data

in the state.[149] On the supply side, the modeling assumes all in-state demand is met through some very limited refining activities in California. Figure 2-3 shows the emissions from the refining sector with and without CCS. If CCS is not deployed, the emissions would be directly emitted into the atmosphere, and CO_2 removal by NWL or direct air capture would need to increase to compensate for the sector's emissions.

Refineries can have a variety of point sources that emit CO_2—such as steam methane reformers for producing hydrogen, combined heat and power units, and catalytic crackers—that are best suited for CCS. Each configuration of a refinery can be unique to its footprint, onsite operations, and the types of crude oils processed. There are newer technologies with smaller footprints[150] that can be deployed in modular configurations to capture CO_2 in space-constrained and multiple-point-source facilities such as refineries. CCS can provide a path to reducing GHG emissions from these facilities to meet petroleum demand while avoiding leakage and until such time as some refineries can be transitioned to produce clean energy to support the transition away from fossil fuels.

While the Scoping Plan modeled deployment of CCS on refineries and identifies significant emissions reductions that can be achieved, the refineries in California are large and complex. The actual deployment of CCS at these facilities as modeled in the Scoping Plan is uncertain. It will be important to closely monitor the evolution of CCS deployment in the refinery sector and, in the next Scoping Plan update, to evaluate the progress toward use in this sector to determine whether the projected reductions will be achieved.

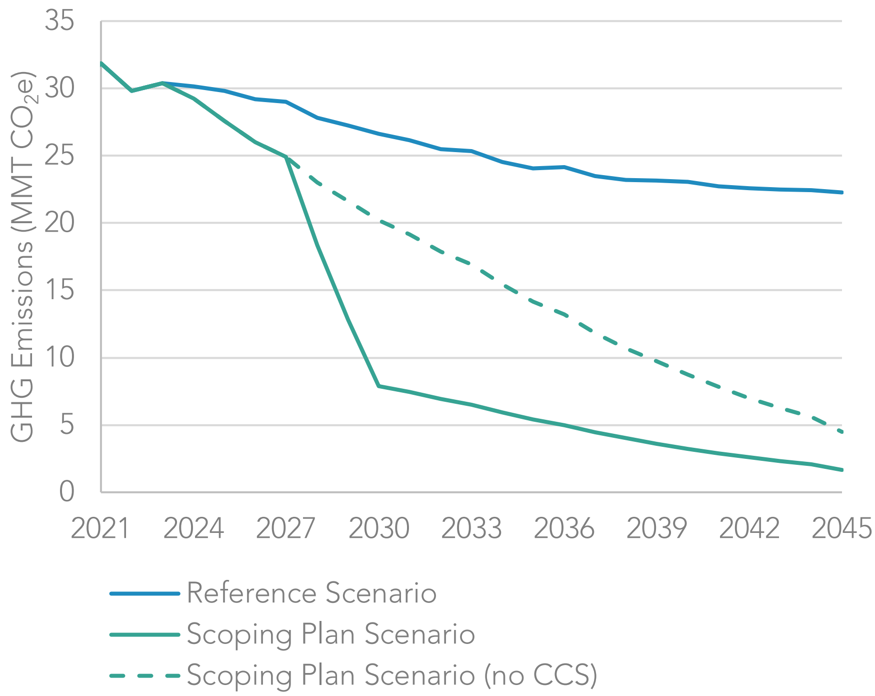
Figure 2-3: Petroleum refining emissions with and without carbon capture and sequestration



This Scoping Plan also calls for accelerating the transition from combustion of fossil fuels to hydrogen. Hydrogen can be produced through electrolysis with renewable electricity or through steam methane reformation of biomethane. There is a high degree of uncertainty around the availability of solar to support both electrification of existing sectors and the production of hydrogen through electrolysis. Producing hydrogen required under the Scoping Plan Scenario with electrolysis would require about 10 gigawatts (GW)[151] of additional solar capacity. If steam methane reformation is paired with CCS, the hydrogen produced could potentially be low carbon. Additionally, the biomethane used to generate hydrogen could be sourced from gasification of forest or agricultural waste resulting from forest management and other NWL management practices, which could also lead to net negative carbon outcomes. Steam methane reformation paired with CCS can thus ensure a rapid transition to hydrogen and increase hydrogen availability until such time as

[151] The Draft Scoping Plan included an estimate for solar capacity (40 GW) to support only electrolysis to produce all hydrogen in the Proposed Scenario. The Scoping Plan now includes steam methane reformation of biomethane and biomass gasification with CCS to produce hydrogen, along with electrolysis from off-grid solar. See Appendix H (AB 32 GHG Inventory Sector Modeling) for additional details.

electrolysis with renewables can meet the ongoing need, assuming there is also sufficient water supply. Additional background and next steps for CCS can be found in Chapter 4.

The EJ Advisory Committee has raised multiple concerns related to the inclusion of CCS and mechanical CDR in the Scoping Plan. Concerns range from potential negative health and air quality impacts in communities from operation of facilities utilizing CCS that continue to emit other emissions, to safety concerns related to potential leaks, to the viability of the current technology. Additionally, the EJ Advisory Committee has policy concerns about the strategy and wants to ensure that engineered carbon removal is not used as a substitute for strategies to achieve emissions reductions onsite and that it does not result in delays in phasing out fossil fuel use. Given these and other concerns and the importance of building public awareness, CARB recognizes the need for a multi-stakeholder process including other state, federal, and local agencies; tribes; independent experts; and community residents to further understand and address community concerns related to CCS. CARB hosted a CCS Symposium with U.S. EPA Region 9 and the Stanford Doerr School of Sustainability to discuss some of these critical issues with community members and other participants. As CARB begins the process of implementing SB 905 in 2023, that will provide an opportunity for further engagement.

In the context of CCS deployment, the Council of Environmental Quality (CEQ) also highlighted the need to further assess and quantify potential impacts on local criteria air pollutants and other emissions resulting from carbon capture retrofits at industrial facilities in response to concerns regarding potential cumulative emissions from single and/or multiple sources.[152] An October 2020 Stanford report[153] discussed how the potential post-combustion capture for CO_2 could also reduce emissions of criteria air pollutant emissions from certain facilities. Exploring these potential outcomes will be important to ensure deployment of CCS does not exacerbate air pollution impacts in communities and maximizes any air pollution benefits. The need for these types of evaluations is also included in SB 905.

The Role of Natural and Working Lands Emissions and Sequestration

California's NWL assessments highlight the importance of increasing the pace and scale of NWL actions to ensure that our ecosystems are better equipped to withstand future climate change so they continue to provide the benefits that nature and society depend

[152] Carbon Capture, Utilization, and Sequestration Guidance. 87 Fed. Reg. 8808 (Feb. 16, 2022), [2022-03205.pdf (govinfo.gov)].

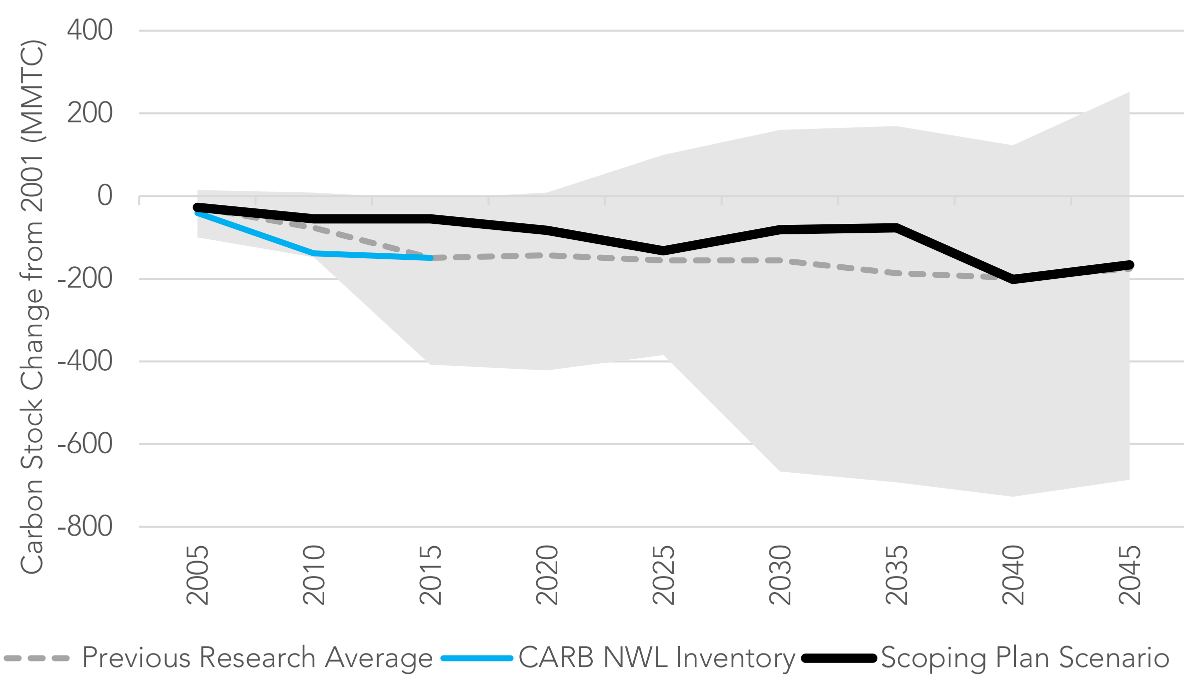
upon for survival. As climate change increases the likelihood of extreme wildfires, drought, heat, and other impacts, carbon stocks in California's NWL will face increased risks and impacts. We know from previous climate change and Scoping Plan work[154] that lands can be a net source of GHG emissions or a net sink, and that the magnitude of carbon stock changes and GHG emissions and sequestration from NWL are dependent on the effects of climate change and land management. The expanded modeling conducted for this Scoping Plan shows that NWL are projected to be a net source of emissions through 2045 and indicates a probable decrease of carbon stocks into the future. This projection is further corroborated by previous, independent research that has reached the same conclusion, showing a range of varying levels of carbon stock loss. Figure 2-4 shows the modeling results of the Scoping Plan Scenario overlaid with the NWL inventory and findings from independent research.

Figure 2-4: Comparison of the Scoping Plan Scenario (NWL) with existing research



The modeling indicates that immediate and aggressive climate action can reduce the environmental impacts that would occur in the absence of this action. The results of the modeling demonstrate that regular NWL management over the next two decades can

[154] CARB. 2019. January 2019. *Draft California 2030 Natural and Working Lands Climate Change Implementation Plan*. https://ww2.arb.ca.gov/sites/default/files/2020-10/draft-nwl-ip-040419.pdf.

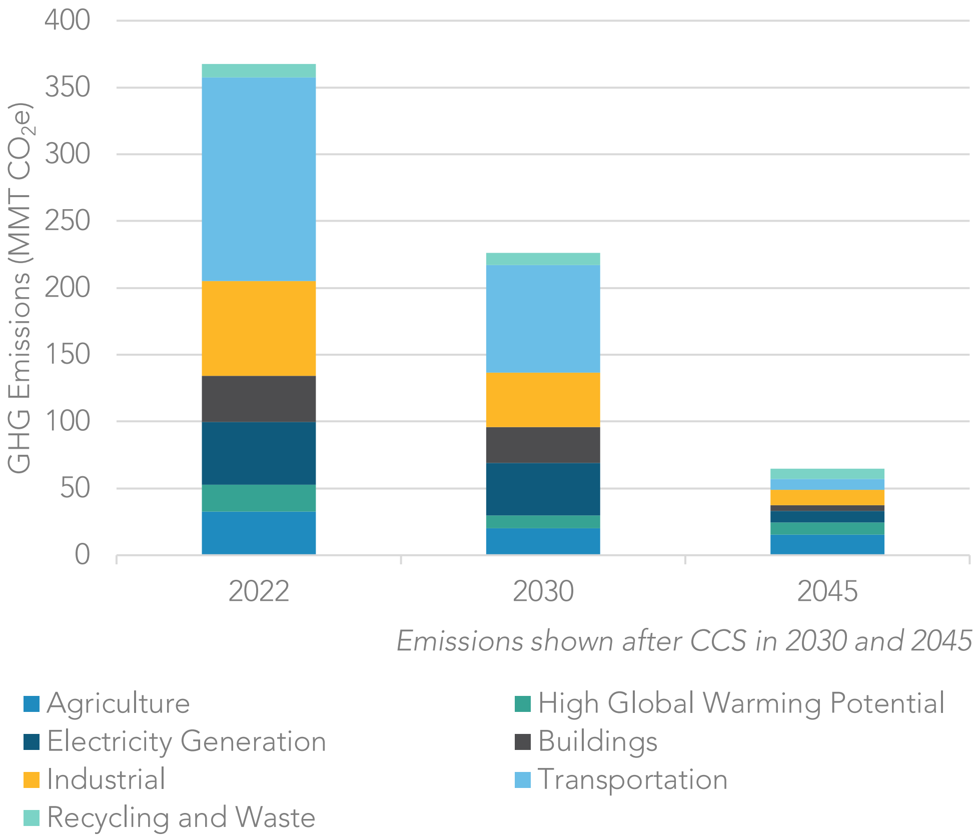
increase carbon stocks from the Reference Scenario trajectory, reduce GHG emissions from lands, and improve ecosystem and public health. This effort is the most comprehensive scientific effort taken by any government to include NWL within its overall climate strategy. Even so, we know that uncertainty exists about future climate and economic forces and the impacts they may have on our ecosystems, so it is important that the state take decisive and aggressive action to improve and diversify ecosystem structures and management.

The effects of climate change, including increased drought, wildfire, and extreme heat, play a significant role in determining the future of California's carbon stocks. And while management actions will help to reduce the impact that climate change will have on California, it is clear from the analysis that NWL sinks and sources are highly variable from year to year, and short time frames do not adequately demonstrate the impact that climate and management are having on ecosystems. For the purposes of climate planning, therefore, it is best to focus on carbon stock changes over longer periods rather than focusing on sequestration or emissions on shorter time frames. The Scoping Plan Scenario is estimated to result in additional NWL emissions of 7 million metric tons of carbon dioxide equivalent ($MMTCO_2e$) annually from 2025–2045. The Reference Scenario is estimated to result in annual emissions of 9 $MMTCO_2e$ over the same time period, and so the Scoping Plan Scenario slows the rate of emissions and provides an approximate 2 $MMTCO_2e$ in additional annual sequestration relative to the Reference Scenario. Because NWL are projected to be a net emissions source, the annual NWL emissions of approximately 7 $MMTCO_2e$ from the Scoping Plan Scenario will need to be compensated by additional CO_2 removal approaches to ensure California can achieve carbon neutrality by 2045.

The Role for Carbon Dioxide Removal (Direct Air Capture)

Even if anthropogenic emissions are reduced to at least 85 percent below 1990 levels by 2045 as called for by AB 1279, there will still be residual emissions in the AB 32 GHG Inventory sectors in 2045 that must be addressed in order to achieve the California's carbon neutrality target. Figure 2-5 includes the emissions by sector for the AB 32 GHG Inventory Sectors in 2022, 2030, and 2045 for the Scoping Plan Scenario.

Figure 2-5: Residual emissions in 2022, 2030, and 2045 for the Scoping Plan Scenario[155]



To achieve carbon neutrality, mechanical CDR will therefore need to be deployed. Because NWL management is not estimated to be a significant carbon removal path in the near term, additional CDR options will be needed. *Mechanical CDR* refers to a range of technologies that capture and concentrate ambient CO_2. Direct air capture (DAC) is one available option that is under development today and could be widely deployed. Note that, unlike CCS, DAC technologies are not designed to be attached to a specific source or smokestack. These technologies include chemical scrubbing processes that capture CO_2 through absorption or adsorption separation processes. Another carbon removal

[155] The High GWP sector includes high global warming potential gas emissions from releases of ozone depleting substance (ODS) substitutes, SF_6 emissions from the electricity transmission and distribution system, and gases that are emitted in the semiconductor manufacturing process. ODS substitutes, which are primarily hydrofluorocarbons (HFCs), are used in refrigeration and air conditioning equipment, solvent cleaning, foam production, fire retardants, and aerosols.

option that involves rapid mineralization of CO_2 at the Earth's surface is called *mineral carbonation.*[156] As is the case with CCS, mechanical CDR technologies will need governmental or other incentive support to overcome technology and market barriers. In the United States, the U.S. Department of Energy announced financing specifically for DAC in March 2020[157] and March 2021.[158] Additionally, almost $9 billion in CCS support was included in the $ 1 trillion Infrastructure Investment and Jobs Act of 2021.[159] This includes funding to establish four DAC hubs. The Inflation Reduction Act of 2022[160] increases the value of the 45Q tax credit to USD 85 per metric ton of CO_2 captured and stored in geologic formations from some industrial applications and USD 180 per metric ton for DAC with storage in geologic formations. In 2021, there were approximately 19 DAC facilities globally.[161]

Ultimately, the role for mechanical CDR will depend on the success of reducing emissions directly at the source in the AB 32 GHG Inventory sectors and the ability of the NWL to sequester carbon. However, mechanical CDR also provides an opportunity to not just achieve carbon neutrality, but also remove legacy GHG emissions from the atmosphere. As such, increased deployment of DAC can help achieve net negative emissions. This would further help avoid the most damaging impacts of climate change. While the federal incentives for DAC provide some support for this technology, the only California program that recognizes this technology is the LCFS program. Permitting must also happen across different levels of government and across multiple state agencies. Energy availability must also be addressed if DAC is to be implemented in remote areas. Additional information and next steps on DAC can be found in Chapter 4.

Carbon Dioxide Removal and Capture Targets for 2030 and 2045

Recognizing the importance of CO_2 removal, Governor Newsom and the Legislature identified the need for targets to send policy and regulatory signals to pilot, deploy, and scale action for those efforts. Governor Newsom requested that CARB set a CO_2 removal and capture target of 20 MMT for 2030 and 100 MMT for 2045, first prioritizing sequestration in NWL. And while this Scoping Plan prioritizes and recommends significant increased climate-smart action on all NWL to support carbon neutrality and healthy and resilient lands, the modeling indicates that, across all NWL, lands will be a net source of emissions when accounting for both carbon sequestration and GHG (CO_2, CH_4, and N_2O) emissions from lands.

Some landscapes, however, are projected to have a net increase in carbon stocks under the Scoping Plan Scenario between 2025 and 2045 relative to the reference case, indicating that NWL actions can help California achieve Governor Newsom's CO_2 removal targets. Carbon stocks in urban forests and grasslands are projected to increase relative to historical levels from implementation of the 2022 Scoping Plan. To support the governor's CO_2 removal targets, CARB estimates that lands would contribute an average of 1.5 MMT of CO_2 removals each year between 2025 and 2045. Any carbon sequestration contributions from lands need to reflect both long-term storage and an overall net increase in carbon stocks over time to ensure these NWL actions are contributing toward California's achievement and maintenance of carbon neutrality over time.

CARB will work to update and revise these estimates as part of implementation of AB 1757, which was signed by the governor in September 2022 and requires that CARB and the California Natural Resources Agency (CNRA) work with an expert advisory committee to determine an ambitious range of carbon sequestration targets by January 1, 2024, for the years 2030, 2038, and 2045.

For the AB 32 GHG Inventory sectors, the Scoping Plan Scenario modeling indicates that the scenario would meet or exceed the 2030 SB 32 target through GHG reduction policies without the need for CDR. CDR will, however, be necessary to increase ambition for an accelerated 2030 target and in increasing amounts over the following decades to achieve carbon neutrality by 2045.[162] Given the likelihood of NWL to be a net source of emissions, and the need for CDR to compensate for residual emissions to achieve carbon neutrality

---

[162] The modeled scenarios assume that residual emissions will be compensated using DAC technologies by including the direct cost in terms of dollars per ton CO_2 removed. The energy source for DAC is not modeled, but renewable electricity and/or hydrogen produced from electrolysis are zero carbon options consistent with the carbon neutrality targets in this Scoping Plan.

by 2045, California will need increasing deployment of mechanical CDR over the coming decades. In the immediate future, scaling nature-based CDR approaches also can help to provide some CO_2 removal quickly while mechanical CDR is scaled up between now and 2045. Table 2-3 provides estimates of CO_2 removal and capture needed in 2030[163] and 2045.

[163] As identified in Chapter 1, SB 27 (Skinner, Chapter 237, Statues of 2021) directed CARB to "establish carbon dioxide removal targets for 2030 and beyond" as part of this Scoping Plan. CARB is establishing these targets to satisfy both the requirements of SB 27 and the directive from Governor Newsom to establish CO_2 removal targets for 2030 and 2045.

Table 2-3: GHG emissions and removals needed to achieve carbon neutrality and meet the 20 $MMTCO_2$ removal and capture target in 2030 and the 100 $MMTCO_2$ removal and capture target in 2045.[164]

	2030 ($MMTCO_2e$)	2045 ($MMTCO_2e$)
GHG Emissions	233	72
AB 32 GHG Inventory Sector Emissions	226	65
Net NWL GHG Emissions Across All Landscapes (annual average from 2025–2045)	7	7
Carbon Capture and Sequestration (CCS): Avoided GHG Emissions from Industry and Electric Sectors	(13)	(25)
Carbon Dioxide Removal (CDR) including natural and working lands carbon sequestration,[165] Direct Air Capture, and Bioenergy with CCS (BECCS).	(7)	(75)
Net Emissions (GHG Emissions + CDR)	226	(3)

In 2030, the CO_2 removal and capture target is 20 MMT, but because the SB 32 target only encompasses the AB 32 GHG Inventory sectors, only CCS that reduces GHG emissions on AB 32 sources count toward achieving more ambitious GHG emission reductions in 2030. In 2045, the CO_2 removal and capture must compensate for any residual emissions from the AB 32 Inventory sectors and NWL emissions to support achieving carbon neutrality while also totaling at least 100 MMT. It is important to note that NWL, particularly forests, need a natural wildfire cycle to remain healthy. While the modeling projected wildfires, and implementing the Scoping Plan will result in a reduction in future wildfire emissions, getting to zero wildfires in the sector is not the goal, nor the

[164] Modeled estimates from the Scoping Plan Scenario indicate the relative quantity of emissions and removals to achieve carbon neutrality and meet carbon removal and capture targets. These estimates are not intended to imply precision, as the required policies are yet to be implemented and all models have some uncertainty in their forecasts.

[165] For the purposes of quantifying how to achieve the governor's 20 MMT and 100 MMT CO_2 removal and capture target, CARB included 1.5 $MMTCO_2e$ sequestration from NWL, which is the sequestration from urban forests. This is included as CO_2 removal because it is this sequestration that CARB can consider as having some permanence. Permanence is necessary for incorporating NWL into carbon neutrality. The net NWL emissions of 7 $MMTCO_2e$, identified in the second row of Table 2-3, includes *all* emissions and sinks from all NWL landscapes, which is inclusive of the 1.5 $MMTCO_2e$ sequestration. CARB will develop an accounting framework to accommodate NWL carbon stocks.

right approach to a sustainable forestry sector. In contrast in 2045, the reductions from programs and policies are estimated to reduce emissions by 169 $MMTCO_2e$ from business as usual.

The 2030 target for engineered CDR also provides a near term milestone for California and can serve as an important marker for progress in deploying CDR to support California's carbon neutrality goal. Preliminary estimates indicate that, globally, capacity from already announced projects will range from about 2 million metric tons per year ($MMTCO_2$/y) to 8 $MMTCO_2$/y from bioenergy paired with CCS, and from about 2,000 metric tons per year ($MTCO_2$/y) to 1 $MMTCO_2$/y from DACs by 2027,[166] which indicates that California's 2030 target is an ambitious, but achievable, goal.

Scenario Uncertainty

Greenhouse Gas Emissions Modeling

Several types of uncertainty are important to understand in both forecasting future emissions and estimating the benefits of emission reduction actions. In developing this Scoping Plan we forecasted a reference scenario and estimated the GHG emissions outcome of the AB 32 GHG Inventory sectors using the PATHWAYS[167] model. Inherent in the reference scenario modeling is the expectation that many of the existing programs will continue in their current form, and that the expected drivers for GHG emissions, such as energy demand, population growth, and economic growth, will match our current projections.

However, there is also the expectation that each of the policies included and implemented to achieve the 2030 target in the 2017 Scoping Plan will deliver their exact outcomes. It is unlikely the future will precisely match our projections, and this will lead to uncertainty in the forecast. For example, we never could have foreseen and forecasted economic and emissions impacts related to the extended disruptions from the COVID-19 pandemic. Thus, the single "reference" or "forecast" line should be understood to represent one possible future in a range of possible predictions. For this Scoping Plan, PATHWAYS utilized inputs that reflect technically feasible levels of deployment or adoption of low- or zero-carbon fuels and technologies. Each of the input assumptions provided to PATHWAYS has some uncertainty, which also contributes to uncertainty in the resulting reference scenario.

---

[166] IHS Markit. August 2021. Carbon Removal Potential. https://ww2.arb.ca.gov/sites/default/files/2021-08/ihsmarkit_presentation_sp_engineeredcarbonremoval_august2021.pdf.
[167] See Appendix H (AB 32 GHG Inventory Sector Modeling).

Similarly, for the NWL modeling, CARB used a mix of individual modeling tools[168] to estimate the carbon and other ecological, public health, and economic outcomes. The Reference scenario assumes that the level of land management actions that occurred between 2001 and 2014 for forests, shrublands, grasslands, croplands, developed lands, wetlands, and sparsely vegetated lands continues into the future. Alternative scenarios assessed the effect of increasing levels of management actions from the reference scenario beginning in 2025. There is a great deal of uncertainty about exactly how lands are currently managed, and a larger uncertainty about how they may be managed in the future. For NWL, it is unlikely that the future will precisely match the carbon stock outcomes CARB has projected, particularly given the uncertainties around current and future land management and the effects climate change will have on our lands. For any modeling exercise these uncertainties exist; however, this modeling effort brings together the best available science, data, and models to quantify the impact our actions may have on the landscape under an unknown future.

Implementation

As this Scoping Plan is designed to chart a path to achieving carbon neutrality, additional work will be required to fully design and implement any policies and actions identified in this plan. During the subsequent development of policies, the Legislature, CARB, and other state agencies will learn more about the technologies and their costs, as well as how each industry works, as a more comprehensive evaluation is conducted in coordination with stakeholders, including community engagement. Significant areas of uncertainty include permitting wait times[169] and local ordinances that might limit or slow the build-out of utility scale renewables.[170,171] In another example, times to reach commercial operations for solar projects after securing an interconnection agreement also have increased in recent years, to 3.5 to 5.5 years.[172]

The level of natural and working lands climate action identified in this Scoping Plan is ambitious. Achieving the level of action needed to result in the quantified carbon,

emissions, health, and economic outcomes within this Scoping Plan requires coordination, investment, and partnerships across all levels of government and sectors of the economy. It is possible that not all of the actions at the identified level will begin in 2025. This uncertainty will result in diminished levels of beneficial outcomes quantified in the Scoping Plan Scenario. The levels of NWL action identified in this Scoping Plan represent CARB's assessment of the pace and scale of action needed to achieve the carbon stock targets and CO_2 removal targets identified in this Scoping Plan.

The Scoping Plan Scenario identifies that 2.3 million acres of forests, shrubland, and grassland management annually would achieve substantial levels of fire emissions reductions and the concomitant health and economics benefits. Currently, 1 million acres of forest treatment annually is the joint federal and state government goal (500,000 acres each). This target of one million acres annually by 2025 is for the purposes of increasing forest health and wildfire resilience in the near term, whereas the 2.3 million acre target is what the Scoping Plan modeling shows would be needed to realize the carbon stock target called for in this Scoping Plan by 2045. By identifying 2.3 million acres of climate action annually in forests, shrublands, and grasslands, this Scoping Plan emphasizes the importance of that 1 million acre annual goal as a milestone on the way to even more action and improved fire and air quality outcomes. The modeling indicates that substantial improvements to statewide fire emissions will occur at levels of action greater than 1 million acres per year. If these levels of action do not occur starting in 2025, the Scoping Plan has quantified climate benefits that will still occur, but to a lesser extent. In terms of fire emissions, compared to the Reference Scenario, 2.3 million acres of forest, shrubland and grassland management will result in a 10% reduction in wildfire emissions. At 1 million acres per year, this decreases to a 2.5% reduction. If 1 million acres per year is also not accomplished, then the emissions and health benefits are even lower.

Climate action in other NWL sectors also generates many co-benefits. Climate action identified in this Scoping Plan is aimed at not only fighting climate change but also improving air quality and public health. The climate action identified in the agricultural sector, for example, should result in decreased pesticide and synthetic fertilizer use. This decrease of synthetic chemical use in agriculture across California also should result in improved public health, especially for communities that work and live in and around agricultural lands. However, as with the forestry sector, the benefits of climate action in agricultural lands and in any other land are dependent on how much implementation takes place. Ramping up increased healthy soils practices and increasing organic agriculture in California will require continued and sustained implementation by private industry and public agencies. For example, achieving the carbon stock outcomes for the annual crops called for in this Scoping Plan would require deployment and maintenance of healthy soils practices on 80,000 additional acres of croplands in California every year between 2025 and 2045. For context, CDFA's Healthy Soils Program, which is an incentive program supporting healthy soils practices, took almost four years of sustained funding to achieve approximately 50,000 acres total under healthy soils practices.[173]

Given the uncertainty around the modeling assumptions, and performance uncertainty as specific policies are fully designed and implemented, estimates associated with the Scoping Plan Scenario are certain to be different than what is ultimately implemented. One way to mitigate for this is to develop policies that can adapt and increase certainty in GHG emissions reductions. Periodic reviews of progress toward achieving the 2030 target and longer term deeper decarbonization, as well as performance of specific policies, also provide opportunities for the state to consider any changes to ensure we remain on course to achieve the 2030 target and carbon neutrality. The need for this periodic review process was anticipated in AB 32, as it calls for updates to the Scoping Plan at least once every five years. For this Scoping Plan, the metrics provided on the rate of deployment of clean fuels and technologies, along with the annual AB 32 GHG Inventory, provide additional information that can be used to assess progress on sectors and aggregate emissions. This is also true of CARB's NWL carbon inventory. An uncertainty analysis for achieving an accelerated 2030 target is provided toward the end of this chapter.

Targeted Evaluations for the Scoping Plan: Oil and Gas Extraction and Refining

To achieve California's air quality and climate goals, we must end our dependence on petroleum. This will not happen overnight. There are about 28 million combustion engine heavy- and light-duty trucks and passenger vehicles in California, and these are almost always replaced at their end of life. The ZEV Executive Order (EO N-79-20) calls for 100 percent new ZEV car sales beginning in 2035 and a 100 percent ZEV medium- and heavy-duty fleet sales by 2045 where feasible. The result is an ongoing, albeit shrinking, pool of vehicles that will continue to require petroleum fuels. To avoid leakage, as called for in AB 32, and to meet that remaining demand for petroleum fuel, a complete phaseout of oil and gas extraction and refining is not possible by 2045. This Scoping Plan assumes a phasedown in both oil and gas extraction as well as petroleum refining in line with the reduction in demand for in-state on-road petroleum fuel demand. Since the transportation sector is the largest source of GHG emissions and harmful local air pollution, we must continue to research and invest in efforts to deploy zero emissions technologies and clean fuels, and to reduce VMT. An assessment of ongoing progress and efforts to reduce

[173] California Department of Food and Agriculture. 2021. *Incentives Program 2017–2020 Summary by the Numbers.* https://www.cdfa.ca.gov/oefi/healthysoils/docs/HSP_Incentives_program_level_data_funded_projects.pdf.

demand for petroleum fuels and of opportunities to phase down oil and gas extraction and refining will be included in the next Scoping Plan update.

In addition to supplying in-state demand, California is a net exporter of gasoline, diesel, and jet fuel. California pipelines supply the Nevada and Arizona regions[174] with approximately 87 million barrels gasoline equivalent of refined products annually.[175] California pipelines deliver approximately 85% of Nevada's and 40% of Arizona's refined product. Most finished fuels flowing from California to Nevada and Arizona are currently produced by California refineries. To manage the phasedown of oil and gas extraction and petroleum refining in California, exports of finished fuels must be considered and factored into that process, in addition to the declining in-state demand. The authorities and considerations related to supply and demand of petroleum fuels span federal, state, and local agencies. If supply of fossil fuels is to decline along with demand, a multi-agency discussion is needed to systematically evaluate and plan for the transition to ensure that it is equitable.

This inter-agency work should also consider related topics, such as the following:

- Direct and indirect job and economic impacts
- Demand for other liquid fuel types such as renewable fuels, and expected volumes
- Legal considerations
- Public health benefits
- Demand and supply strategies for petroleum fuels, including how to avoid short term supply constraints that may impact low-income consumers

Some of these topics were also discussed as part of two studies[176] supported by the California Environmental Protection Agency, which can serve as a starting point for a working group to analyze these questions and develop policy recommendations.

Oil and Gas Extraction

On April 23, 2021,[177] Governor Newsom directed CARB to evaluate the phaseout of oil and gas extraction no later than 2045 as part of this Scoping Plan. As noted above, this Scoping Plan still has some California demand for finished fossil fuels (gasoline, diesel,

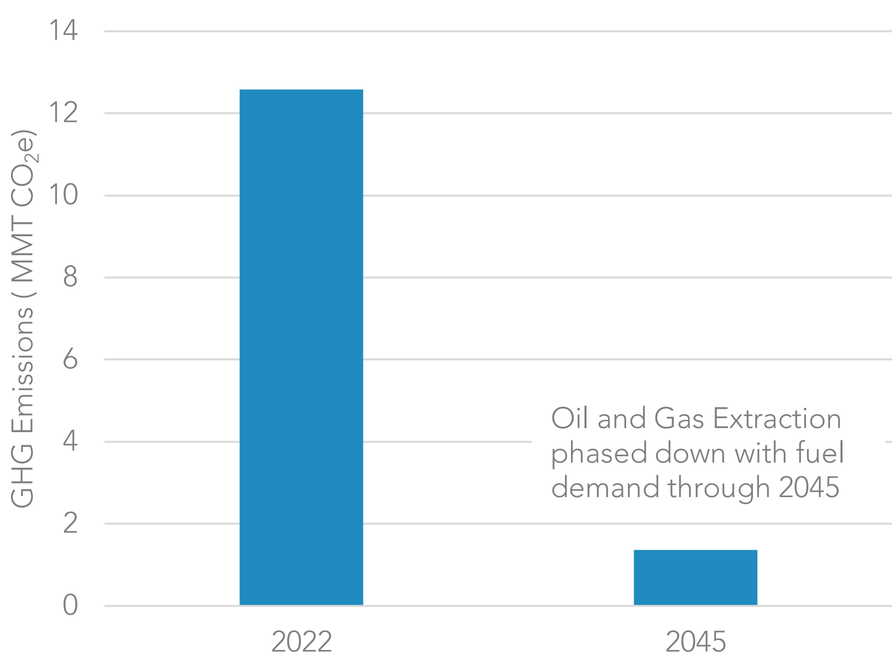
[177] Governor Newsom. April 23, 2021. Governor Newsom Takes Action to Phase Out Oil Extraction in California. Press Release. https://www.gov.ca.gov/2021/04/23/governor-newsom-takes-action-to-phase-out-oil-extraction-in-california/.

and jet fuel) in 2045. This demand is primarily for transportation, including for sectors that are directly regulated by the state and some that are subject to federal jurisdiction, such as interstate locomotives, marine, and aviation. As discussed more fully below, while significant GHG reductions from oil and gas extraction could be achieved as demand for fossil fuels is reduced due to strategies in this Scoping Plan, it is not feasible to phase out oil and gas production fully by 2045 given this remaining demand.

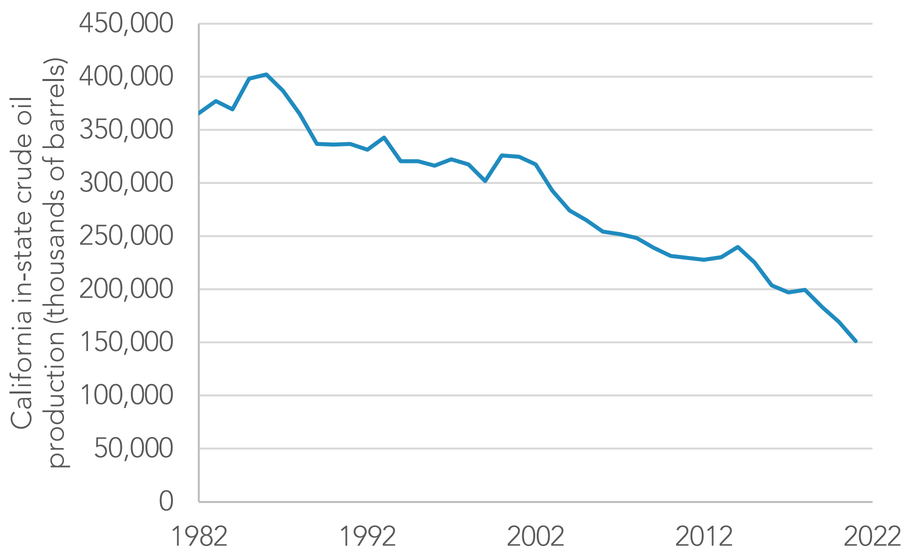
In the Scoping Plan Scenario, with successful deployment of zero carbon fuels and non-combustion technology to phase down petroleum demand, GHG emissions from oil and gas extraction could be reduced by approximately 89 percent in 2045 from 2022 levels if extraction decreases in line with in-state finished fuel demand. If in-state extraction were to be phased out fully, the future petroleum demand by in-state refineries would be met through increased crude imports to the state relative to the Scoping Plan Scenario. AB 32 defines leakage as, “a reduction in emissions in greenhouse gases within the state that is offset by an increase in emissions of greenhouse gases outside the state.” AB 32 also requires any actions undertaken to reduce GHGs to “minimize leakage.” Increases in imported crude could result in increased activity outside California to extract and transport crude into California. Therefore, our analysis indicates that a full phaseout of in-state extraction could result in GHG emissions leakage and in-state impacts to crude oil imported into the state. Figure 2-6 compares the 2022 emissions from this sector with the modeled results when the sector is phased down with in-state petroleum demand.

Figure 2-6: Oil and gas extraction sector GHG emissions in 2022 and 2045 when activity is phased down with in-state fuel demand



According to California Energy Commission (CEC) data used in Figure 2-7, the total oil extracted in California peaked at 402 million barrels in 1986. Since then, California crude oil production has decreased by an average of 6 million barrels per year, to about 200 million barrels in 2020. This steadily decreasing production of crude in California is expected to continue as the state's oil fields deplete.

Figure 2-7: California in-state crude oil production[178]



A UC Santa Barbara report estimated that, under business-as-usual conditions, California oil field production would decrease to 97 million barrels in 2045.[179] The business-as-usual model assumed no additional regulations limiting oil extraction in California.

Any crude oil demand by California refineries not met by California crude oil will be met by marine imports of Alaskan and foreign crude.[180] As shown in Figure 2-8, approximately 99 percent of crude imports into California are delivered by marine transportation. The

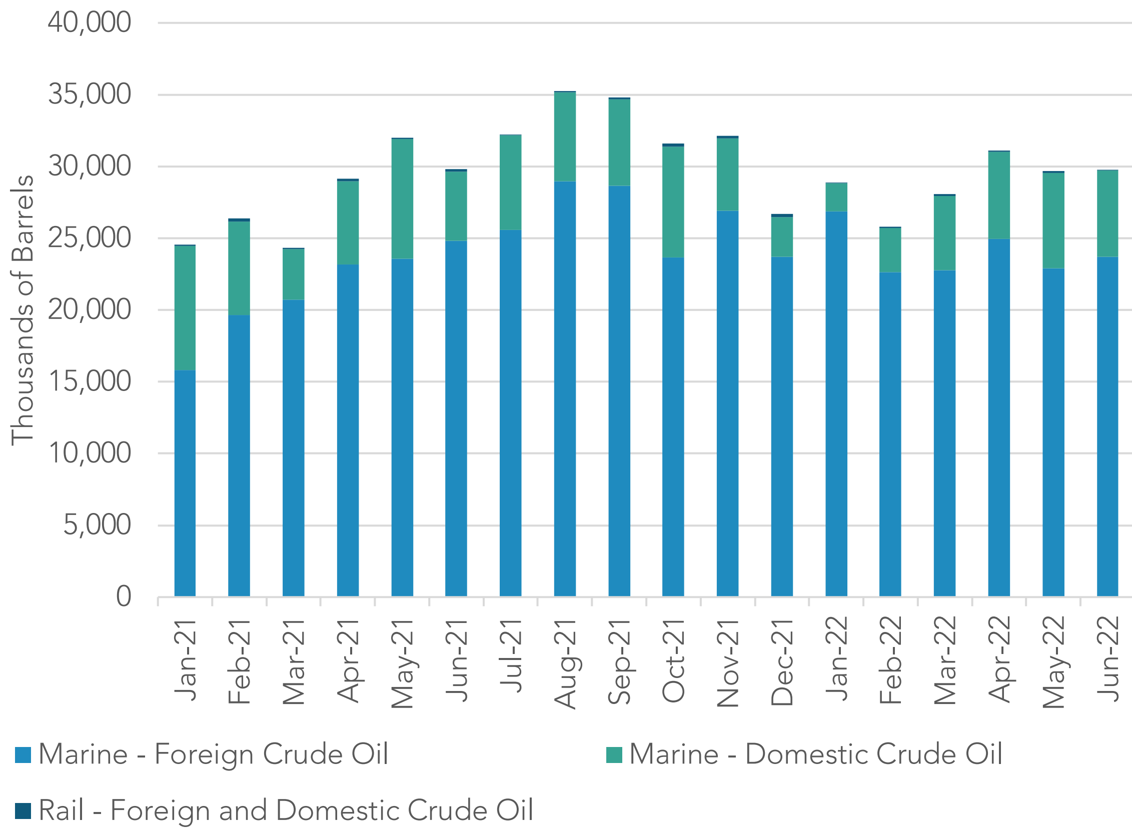
remaining imports occur by rail.[181] There are no pipelines that bring crude oil into California from out of state.[182]

Figure 2-8: Crude oil imports by transportation type[183]



Crude oil delivered by marine tankers is delivered to onshore storage tanks and subsequently to refineries via pipeline. Most crude oil produced in California is delivered to California refineries by pipeline. Using historical trends, any increases in imported crude above historic levels would result in increased deliveries through the marine ports. This increased activity could require more infrastructure to store and move larger volumes of crude to the refineries in state.

[182] CEC. 2020. *Petroleum Watch: How Petroleum Products Move.* March. https://www.energy.ca.gov/sites/default/files/2020-03/March_2020_Petroleum_Watch.pdf.

[183] CEC. June 2021. Crude Oil Imports. https://www.energy.ca.gov/data-reports/energy-almanac/californias-petroleum-market/crude-oil-imports-source.

California refineries import a variety of crude oils to meet refinery needs. California petroleum refineries are generally designed to process relatively heavy crude relative to other U.S. refineries. In 2018, crude inputs to California refineries had an average American Petroleum Institute (API) gravity of 26.18 and an average sulfur content of 1.64 percent. Processing significantly lighter or heavier crude blends would require significant changes to a refinery.[184] Most crude imported from Alaska and the Middle East is relatively light (API gravity > 30) compared to California crude (API gravity < 20).[185] If California crude production is insufficient to meet the demand at California refineries, then California refineries will need access to a similarly heavy source of crude so that the average API gravity of crude remains within their established operating window. South American crude oil imports into California are the heaviest relative to other regions, and therefore they may be the most likely to replace decreased California crude oil supply.[186]

In summary, the modeling indicates that demand for petroleum will persist due to legacy fleets that will not be replaced until end of life. The modeling also shows what the GHG emissions reductions would be if oil and gas extraction activities were phased down in line with the reduction of in-state petroleum demand. Trend data shows that oil and gas extraction already has been on the decline and will continue to decline. It is possible to anticipate the likely regions and types of crude that would be imported to meet in-state petroleum demand if in-state extraction was fully phased out by 2045. Importantly, activity at the ports would increase, and new infrastructure would be needed to store and deliver crude to in-state refineries. And while GHG emissions from this sector would go to zero in our AB 32 GHG Inventory with a full phaseout, emissions related to the production and transport of crude to California might increase elsewhere, resulting in emissions leakage.

As the state continues to reduce demand for petroleum, efforts to protect public health for communities located near oil and gas extraction sites must also continue. In October 2021, Governor Newsom directed action to prevent new oil drilling near communities and

---

[184] CEC. 2020. *Petroleum Watch: What Types of Crude?* February. https://www.energy.ca.gov/sites/default/files/2020-02/2020-02_Petroleum_Watch_ADA_0.pdf.
[185] CEC. 2020. *Petroleum Watch: What Types of Crude?* February. https://www.energy.ca.gov/sites/default/files/2020-02/2020-02_Petroleum_Watch_ADA_0.pdf.
[186] CEC. 2020. *Petroleum Watch: What Types of Crude?* February. https://www.energy.ca.gov/sites/default/files/2020-02/2020-02_Petroleum_Watch_ADA_0.pdf.

expand health protections.[187,188] In 2022, the Legislature passed, and the governor signed, SB 1137 to protect communities from existing and any new oil and gas extraction activities through 3,200 foot setbacks.

Petroleum Refining

In the Scoping Plan Scenario CARB modeled a phasedown of refining activity in line with petroleum demand. Meeting petroleum demand means sufficient availability of finished fuel (gasoline, diesel, and jet fuel). Crude is processed at in-state refineries to produce finished fuel. In response to stakeholder requests,[189] this evaluation focuses on the Scoping Plan Scenario, but with an evaluation of a complete phasedown of refinery operations in state.

The Scoping Plan Scenario results in California petroleum refining emissions of 4.5 $MMTCO_2e$ in 2045; a reduction of approximately 85 percent relative to 2022 levels, which is in line with the decline in in-state finished fuel demand.[190] Emissions from refining can be reduced further through the application of CCS technology, as shown in Figure 2-9. If in-state refining is phased down to zero and the demand for the finished fuels produced by that refining persists, imported finished fuels may be needed to meet the remaining in-state demand.[191] The current data shows unmet demand for liquid petroleum transportation fuels would most likely be met by marine imports. A CEC report notes, "The only way for California to receive large amounts of crude and refined products is by marine."[192]

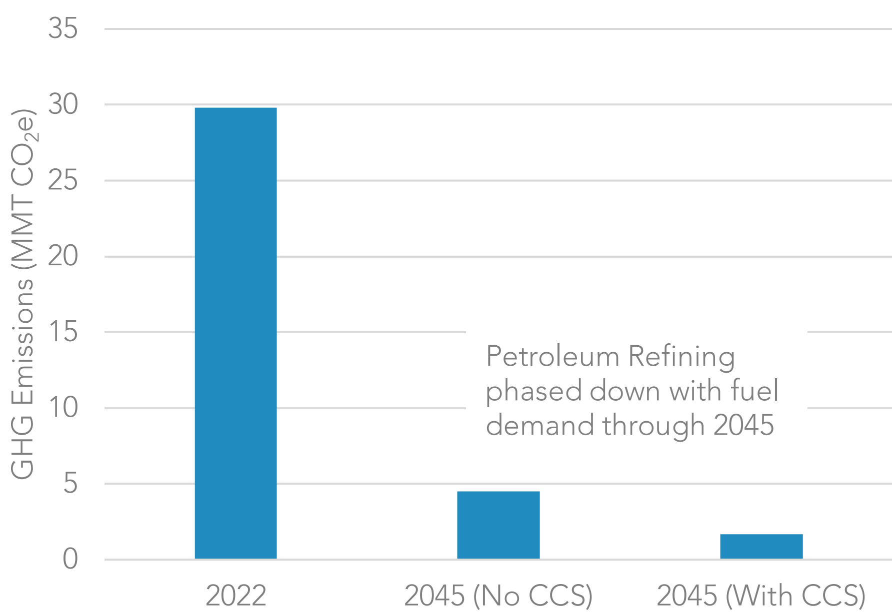
[190] This reduction in demand does not assume any need for ongoing operations to support exports to neighboring states.

[191] If demand assumes an ongoing need to support exports to neighboring states, the residual demand would require a five-fold increase in finished fuel imports.

[192] CEC. 2020. *Petroleum Watch: How Petroleum Products Move.* March. https://www.energy.ca.gov/sites/default/files/2020-03/March_2020_Petroleum_Watch.pdf.

There are currently no pipelines capable of bringing refined products to the state, and rail imports of refined products have historically made up less than 1 percent of all imports.[193] Significant increases in marine imports would likely require significant reconfiguring, retrofitting, or replacement of crude pipelines and storage tanks at current marine terminals, and possible reconfiguring of existing finished fuel infrastructure to account for changes in volumes and locations of supply points.

Figure 2-9: Petroleum refining sector GHG emissions in 2022 and 2045 (with and without CCS) when activity is phased down with fuel demand



If California's finished fuel demand is not met by continued refining activity in California, the state would need to import finished fuels to meet the ongoing demand. This would likely result in a two- to five-fold increase in the number of finished fuel ship deliveries to marine terminals. Marine tankers delivering refined products are often much smaller than crude oil tankers, so changes in fuel use and emissions cannot be easily estimated from the change in both the type and the number of ship deliveries.[194]

---

[193] CEC. 2020. *Petroleum Watch: How Petroleum Products Move.* March. https://www.energy.ca.gov/sites/default/files/2020-03/March_2020_Petroleum_Watch.pdf.

[194] Personal communication with CEC staff, March 2022; U.S EIA. 2017. *World Oil Transit Chokepoints*. 3. https://www.eia.gov/beta/international/regions-topics.php?RegionTopicID=WOTC.

If refining ceased in California, the rail and marine deliveries currently needed to support both refining processes and the export of waste products, such as petroleum coke, would cease.

In summary, the modeling indicates that demand for petroleum will persist through 2045. The modeling also shows what the GHG emissions reductions would be if refining activities were phased down in line with the reduction in in-state petroleum demand. CCS can further reduce emissions for this sector. Importantly, activity at the ports would increase, and new infrastructure would be needed to store and deliver finished fuel across the state, if in-state refining were fully phased down by 2045. And while GHG emissions from this sector would go to zero in our AB 32 GHG Inventory with a full phaseout, emissions related to the refining and transport of finished fuel to California might increase elsewhere, resulting in emissions leakage.

Progress Toward Achieving the Accelerated 2030 Target

The 2017 Scoping Plan laid out a path to achieving the SB 32 target of at least a 40 percent reduction of GHG emissions below 1990 levels by 2030 that focused on reducing emissions in the state and was technologically feasible and cost-effective, reflecting statutory direction. Many of the programs to achieve the 2030 target increased in stringency beginning January 1, 2021. However, the 2030 target must be increased to help achieve the deeper reductions needed to meet the state's statutory carbon neutrality target specified in AB 1279 and Executive Order B-55-18.

Starting in 2020 and extending into 2022, the COVID-19 pandemic impacts reverberated across the globe in a multitude of ways, including the devastating loss of millions of lives. The pandemic also had a significant impact on GHG emissions by virtue of its impact on global economies and lifestyle changes for Californians, with extended work and school disruptions. Thus, assessing our progress toward meeting our SB 32 target is confounded by the unprecedented nature of the pandemic. Nevertheless, an assessment of progress toward the 2030 target is critical, in particular the accelerated 2030 target called for in this Scoping Plan, since achieving the accelerated 2030 target would make the state well positioned to achieve its carbon neutrality goals and bring critical near-term air quality benefits to address historical and ongoing disparities in access to healthy air. Because there is only one year of data available for this decade, the analysis takes a prospective look using projected emissions over the remainder of this decade.

Estimating GHG emissions in 2030 requires projecting the effect of policies or measures that are currently deployed and undergoing implementation. Table 2-4 shows three distinct estimates of GHG emissions in 2030 that were created at different times and used different modeling approaches.

Table 2-4: Estimates of 2030 GHG emissions

Scenario Description	2030 GHG Emissions ($MMTCO_2e$)
2017 Scoping Plan: the projected outcome from implementing policies identified in the 2017 Scoping Plan that was approved by the CARB Board in December 2017.	320
Reference Scenario: the assessment of current trends and expected performance of policies identified in the 2017 Scoping Plan, as of February 2022, using the PATHWAYS model (E3).	305
Reference Scenario (Rhodium): the analysis of projected emissions from 2021 to 2030 from state and federal policies implemented as of July 2022, including the estimated impact of the Inflation Reduction Act and Advanced Clean Cars II using RHG-NEMS and other Rhodium Taking Stock 2022 methods (https://rhg.com/wp-content/uploads/2022/07/Taking-Stock-2022_US-Emissions-Outlook.pdf).	324

These three estimates of 2030 GHG emissions differ, which is expected. The estimates reflect different outcomes of the current and future impact of policies and measures. They also vary due to fundamental differences in the way these models work. For example, PATHWAYS is an economy-wide, scenario-based GHG accounting tool that tracks energy demands and supplies in line with scenario assumptions and is benchmarked to historical values. RHG-NEMS optimizes both the supply and demand sides of the energy system while factoring in consumer constraints and dynamic economic and energy systemwide feedback. Importantly, while these point estimates give the appearance of certainty and accuracy, there is significant uncertainty in future emissions projections that is documented thoroughly in each of the three emissions scenarios described above. No model can predict the future given unforeseen factors such as notable economic swings and implementation delays for programs. However, the range of emissions estimates provides a useful indication of possible outcomes from successful implementation of policies and measures.

An important source of uncertainty is the impact of delayed implementation of policy measures and market actions. The successful rate of deployment of clean technology and fuels—including consumer adoption patterns, economic recovery from the pandemic, and the permitting and build-out of necessary new assets and reuse of existing assets to produce and deliver clean energy—is essential to reach GHG emission reduction targets. Any delays will only increase GHG emissions in 2030.

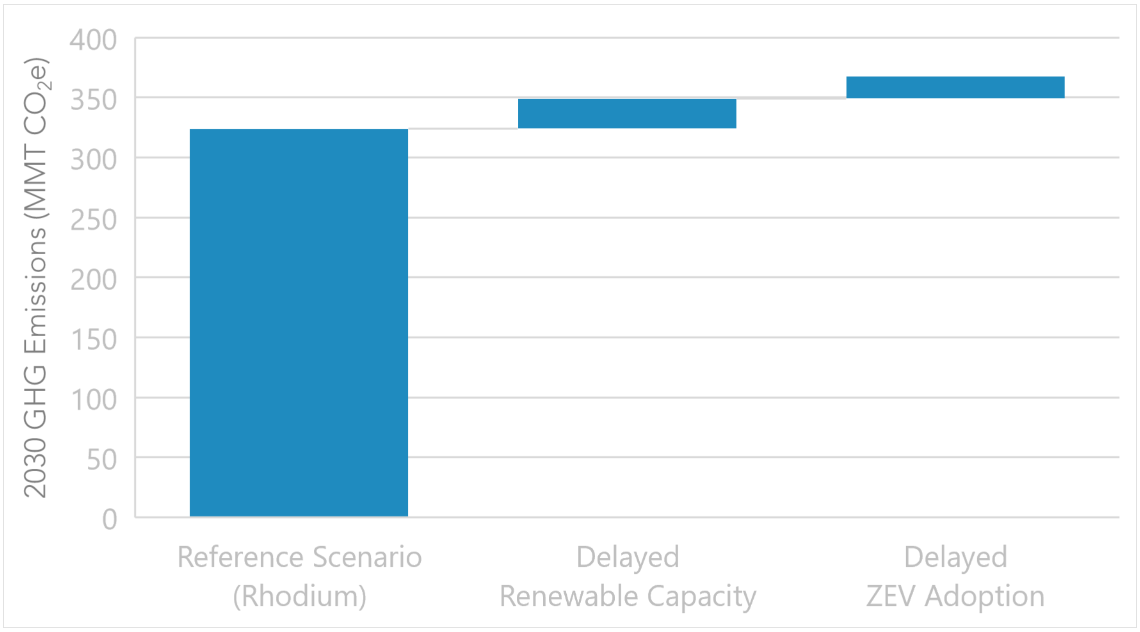
It is important to note that incentives, carbon pricing, and regulations all can result in similar types of responses including, but not limited to:

- Build-out of clean energy and infrastructure
- Deployment of clean technology
- Reduced demand for fossil energy
- Efficiency improvements

As such, the uncertainty analysis discussion focuses on implementation (technology and infrastructure deployment), and not any specific programs or policies. It is successful implementation that must ultimately happen for emissions reductions to be realized.

The uncertainty analysis described in Appendix J (Uncertainty Analysis) quantifies the impact of delayed permitting and building of renewable generation and transmission in the power sector and delayed adoption of ZEVs across all vehicle fleets in the transportation sector. The Reference Scenario (Rhodium) estimates emissions in 2030 to be 324 MMTCO2e. A five-year delay in renewable capacity would increase emissions by 8 percent in 2030 (25 MMTCO2e) relative to the Reference Scenario. If similar delays in clean energy production and deployment occur in other sectors, a larger increase in emissions relative to the reference scenario would be expected, jeopardizing the state's ability to achieve the 2030 target. Similarly, a delay in consumer adoption of zero emission vehicles (LDV, MDV, HDV) would increase emissions by 6 percent in 2030 (19 MMTCO2e) relative to the Reference Scenario. Delays in transitioning to electric equipment and appliances in homes and businesses would also lead to increased emissions in 2030. Figure 2-10 illustrates the impact on projected emissions in 2030 associated with delayed renewable capacity and delayed transportation vehicle electrification.

Figure 2-10: Impact of delayed implementation on 2030 GHG emissions[195]



Appendix J (Uncertainty Analysis) includes additional details on the assumptions and model used for the uncertainty analysis and the risks to achieve the emissions reductions from 2022 to 2030 that are anticipated in the Scoping Plan Reference Scenario. While the analysis focuses on renewable capacity and transportation, the analysis identifies a common set of themes that can impact emissions reductions across economic sectors, including permitting, technology availability, and consumer adoption. The impact of delayed emissions reductions will vary by sector and by the specific policy at risk of delay.

We give these quantitative examples of the impact implementation delays can have on GHG reductions, but almost every economic sector will have the need for permitting to enable at least a 40 percent reduction below 1990 levels. If we consider the increased ambition of the Scoping Plan Scenario, which identifies an accelerated 2030 target, the same types of uncertainty manifest themselves in successful implementation of the Scoping Plan Scenario, with the added need for CCS and CDR and a need to grow other energy sectors such as hydrogen.

[195] The implementation delay scenarios were modeled separately and do not necessarily reflect the combined impact of delayed renewable capacity and transportation vehicle electrification.

Cap-and-Trade Program Update

Since the adoption of the first Scoping Plan in 2008, carbon pricing in the form of a Cap-and-Trade Program has been part of the portfolio to achieve the state's GHG reduction targets, and it will remain critical as we work toward carbon neutrality. This section provides an update on the program and its role in achieving the 2030 target.

The Cap-and-Trade Program first came into effect in 2012, under AB 32, and included declining allowance caps through 2020. In 2017, AB 398[196] was passed by a supermajority in the Legislature and included prescriptive direction on the design of the program from 2021 through 2030. The AB 398 Cap-and-Trade Program came into effect on January 1, 2021, and it included the following changes:

- Doubling of stringency with an annual cap decline of 4 percent per year from 2021–2030
- AB 398 price ceiling
- AB 398 redesigned allowance price containment reserve with two tiers
- AB 398 100 percent leakage assistance factor for industry
- AB 398 lower offset limits: Usage limit cut from 8 percent to 4 percent, and half of offsets must provide direct benefits to California

The reduction in the role of offsets in the program was in recognition of ongoing concerns raised by environmental justice advocates regarding the ability of companies to use offsets for compliance instead of investing in actions on site to reduce GHG emissions that could also potentially reduce criteria or toxic emissions.[197,198] Note that data show the relationship between facility emissions of GHGs and co-pollutants is highly variable by sector and pollutant.[199] Changes to the allowance price containment reserve and the addition of the price ceiling were included to ensure protections against price spikes in the program, while the changes to the leakage assistance factors were to ensure the maximum protection against leakage in the program. The original design of the program included an auction floor price that increases by 5 percent plus inflation each year, and

[198] The OEHHA report also found that companies that use the most offsets often own the facilities that contribute to local $PM_{2.5}$ exposure. However, there was no causal relationship found to indicate that implementation of the Cap-and-Trade Program was contributing to increases in local air pollution. Also see: CARB. FAQ Cap-and-Trade Program. https://ww2.arb.ca.gov/resources/documents/faq-cap-and-trade-program.

[199] OEHHA. 2022. *Impacts of Greenhouse Gas Emission Limits Within Disadvantaged Communities*. https://oehha.ca.gov/media/downloads/environmental-justice/impactsofghgpoliciesreport020322.pdf.

that escalation factor is retained in the post-2020 program and is also applied to the allowance price containment reserve and price ceiling. These features, combined with the self-ratcheting mechanism for unsold allowances at auctions,[200] help to ensure the program is able to handle periods of high and low demand for allowances while continuing to ensure a steadily increasing price signal for regulated entities to invest in GHG reduction technologies.

As a result of achieving the 2020 target several years earlier than mandated by law, there are unused allowances in circulation. CARB estimated the amount to be approximately 310 million allowances after the conclusion of the third compliance period (2018–2020).[201] AB 398 had also called for a similar analysis, which was completed in 2018.[202] This bank represents approximately 5 percent of the total number of vintage 2013–2030 allowances issued within the joint market. This bank of allowances can only remain banked if year-over-year the covered emissions are declining by 14 MMT. If the annual decline in actual emissions is less than 14 MMT, regulated entities will need to use the banked allowances to cover their compliance obligations. It is likely that the existing bank of 310 million allowances will be needed over the early part of this decade and will be exhausted by the end of the decade. During the same period, prices for allowances will continue to increase at least 5 percent plus inflation year-over-year, sending a steadily increasing price signal to spur investment in onsite reductions for covered entities.

With the passage of AB 1279, the state has a statutory target to achieve carbon neutrality no later than 2045. This Scoping Plan demonstrates that planning on a longer time frame for the new carbon neutrality target means we must accelerate our near-term ambition for 2030 in order to be on track to achieve our longer-term target. CARB will use the modeling for this Scoping Plan to assess what changes may be warranted to the Cap-and-Trade or other programs to ensure we are on track to achieve an accelerated 2030 target. Since the original adoption of the Cap-and-Trade regulation, the program has been amended eight times through a robust public process. Moreover, then-California Environmental Protection Agency Secretary Jared Blumenfeld testified at a Senate hearing in 2022 that CARB will report back to the Legislature by the end of 2023 on the status of the allowance supply with any suggestions on legislative changes to ensure the number of allowances

---

[200] The self-ratcheting mechanism temporarily removes unsold allowances from the market until either sufficient demand manifests for two consecutive auctions and they are incrementally reintroduced at future auctions, or they are permanently removed from general circulation if demand remains low.
[201] CARB. 2022. BR 18-51 Cap-and-Trade Allowance Report. Attachment A. *https://ww2.arb.ca.gov/sites/default/files/cap-and-trade/Allowance%20Report_Reso18_51.pdf*.
[202] CARB. 2018. Staff Report: Initial Statement of Reasons: Proposed Amendments to the Cap on Greenhouse Gas Emissions and Market-Based Compliance Mechanisms Regulation. is appropriate to help the state achieve its 2030 target of at least 40% below 1990 levels. As part of that status update, CARB will also provide information on any potential program changes that may be needed to allowance supply to help achieve an accelerated target for 2030 identified in this Scoping Plan as necessary to achieve carbon neutrality no later than 2045. Engaging in this process in 2023 will allow for the consideration of this Scoping Plan, inclusion of additional data points for the second year of operation of the AB 398-designed program (which only came into force in January 2021), and an opportunity to hold public workshops.

It is also worth noting that the COVID-19 pandemic had significant impacts on economic activity in California and elsewhere.[203] Emissions were significantly lower in 2020 due to the impacts of the global pandemic. There is an expectation that emissions will increase as the economy recovers and behaviors continue to shift from the impacts of the ongoing pandemic. As a result, 2020 should be regarded as an outlier in the emissions trends. This scenario of increasing emissions is similar to what happened in the first compliance period for Cap-and-Trade, where the state economy was recovering from the Great Recession and does not correlate to a problem with the structure of this program or other programs that cover emissions related to the manufacturing or transportation sectors. In any assessment of this and other programs, it is essential to consider external factors such as economic activity and availability of zero carbon energy such as hydropower, among others.

To better understand the role of the Cap-and-Trade Program in achieving the 2030 target, Table 2-5 compares the 2030 GHG emissions estimates from the three reference scenarios described in Table 2-4. The 2017 Scoping Plan projection is from the PATHWAYS model for the Scoping Plan Scenario approved by the Board in late 2017. It excludes the contribution of the Cap-and-Trade Program, without any consideration of uncertainty factors (i.e., a characterization of the uncertainty that a given GHG reduction measure included in the 2017 Scoping Plan will actually achieve the GHG reductions it is projected to deliver). The Reference Scenario represents what GHG emissions would look like if we did nothing beyond the existing policies that are required and already in place to achieve the 2030 target; this scenario is based on the recent PATHWAYS modeling, excluding the contribution of the Cap-and-Trade Program, and without any consideration of uncertainty factors. It indicates that GHG emissions will be lower over this decade than originally projected when the 2017 Scoping Plan was approved. The

[203] CARB. November 4, 2021. Mandatory Greenhouse Gas Reporting - 2020 Emissions Year Frequently Asked Questions. https://www.arb.ca.gov/cc/reporting/ghg-rep/reported-data/2020mrrfaqs.pdf?_ga=2.264251343.1760432228.1650736660-1644197524.1577749754.

Reference Scenario (Rhodium) which also does not include uncertainty bounds, is the modeling used for the uncertainty analysis above.

Importantly, PATHWAYS is not able to explicitly model a carbon pricing policy, and therefore the Cap-and-Trade Program is not represented in the 2017 Scoping Plan or the Reference Scenario. Carbon pricing is included in RHG-NEMS, which reflects state and federal policies included in the U.S. Energy Information Administration (EIA) Annual Energy Outlook 2022 and the National Energy Systems Model (NEMS), which is the basis for RHG-NEMS.[204]

As detailed in EIA's documentation, California's Cap-and-Trade Program is represented through increased energy prices, which flow across economic sectors.[205] However, many of the emissions covered by the California Cap-and-Trade Program are not energy- and fuel-related emissions. Given that, the energy systems model RHG-NEMS was used to model the impact of California Cap-and-Trade on the energy system. However, RHG-NEMS does not explicitly model the entire program, which includes non-energy related emissions from the industrial, agricultural, waste, and transportation sectors.

---

[205] U.S. EIA. 2022. Electricity Market Module. https://www.eia.gov/outlooks/aeo/assumptions/pdf/electricity.pdf.

Table 2-5: Comparison of 2017 Scoping Plan and two Reference Scenarios

	2030 GHG Emissions ($MMTCO_2e$) (2017 Scoping Plan)	2030 GHG Emissions ($MMTCO_2e$) (Reference Scenario)	2030 GHG Emissions ($MMTCO_2e$) (Reference Scenario-Rhodium)
Reference Scenarios	320	305	324
Gap to Accelerated 2030 Target under the Scoping Plan Scenario (226)[206]	94	79	98

Under the Scoping Plan Scenario, in 2030 California emissions are anticipated to be 48% below 1990 levels. This represents an acceleration of the current SB 32 target of a 40% reduction below 1990 levels. Table 2-5 includes the gap between the different reference scenarios and the accelerated 2030 target achieved under the Scoping Plan Scenario. It also shows that depending on the modeling, there are a range of potential emissions levels in 2030 prior to accounting for the full impact of the Cap-and-Trade Program on emissions. That range is from 305 to 324 $MMTCO_2e$ in 2030. That represents a 19 $MMTCO_2e$ spread, or about 8.4 percent of the accelerated 2030 target of 226 $MMTCO_2e$. Importantly, none of these scenarios includes all of the actions identified in the Scoping Plan Scenario for this Scoping Plan; many of those actions, such as SB 596, CCS, and a more stringent LCFS program, will only begin to happen in this decade, and their contributions toward meeting the accelerated 2030 target are therefore not included in the reference scenarios. The actual emissions for the remainder of this decade will therefore likely be lower than in each of the scenarios in Table 2-5 once policies and regulations are in place to support an accelerated 2030 target. However, the degree of this difference between actual and projected emissions will differ across the modeled reference scenarios.

---

[206] Table 3 from the 2017 Scoping Plan included a range of 34 to 79 $MMTCO_2e$ for reductions needed from the Cap-and-Trade Program to achieve a 2030 target of 40 percent below 1990 levels.

Regardless of the uncertainty and differences in the models, it is clear additional GHG reductions must happen over this decade to achieve an accelerated 2030 target. This will require an evaluation of all major programs to assess the need to increase their stringency between now and 2030. As the actual reductions from non-Cap-and-Trade Program measures increase, California will be less reliant on the Cap-and-Trade Program to "fill the gap" to meet an accelerated 2030 reduction target. For example, CARB is developing a proposal to increase the stringency of the LCFS program for 2030, the recently adopted Advanced Clean Cars II regulation is more stringent than modeled for the 2030 40 percent target in the 2017 Scoping Plan, and SB 596 requires specific reductions in the cement sector over this decade and beyond. However, we also know we are not on track to achieve the VMT reduction called for in the 2017 Scoping Plan and will need to double down to achieve the even more ambitious target called for in the Scoping Plan Scenario. Also, we will need additional actions over the coming years to reduce short-lived climate pollutants to meet the emission reductions called for in SB 1383.

Collectively, any additional legislation or prescriptive policies for sectors, delays in successful implementation of non-Cap-and-Trade programs and policies, increases in incentive program funding, and delays in economic recovery from the pandemic will continue to affect the role the Cap-and-Trade Program will need to play over this decade to meet the state's GHG reduction obligations. In summary, the Cap-and-Trade Program must continue to be able to scale across a range of possibilities. With passage of AB 1279 and the need to accelerate the 2030 target, CARB will initiate a public process to utilize the modeling results from this Scoping Plan, specifically the Scoping Plan Scenario, to evaluate and potentially propose changes to the design of the Program, including the annual caps. This process will ensure that the Program supports an increased ambition for 2030 while retaining the ability to scale as other factors, such as changing economic conditions and implementation of non Cap-and-Trade programs, impact the actual emissions at the sources covered by the Program. Any changes to the Program must continue to support a well-designed system that continues to send a steadily increasing price signal, minimizes for leakage, reduces emissions in the covered sectors toward the state's targets, is cost-effective and technologically feasible, and avoids energy rate spikes. Importantly, the Program should support air quality benefits, especially in overly burdened communities, and not exacerbate existing air quality disparities.

Chapter 3: Economic and Health Evaluations

This chapter provides two approaches for quantifying the economic and health outcomes of the Scoping Plan Scenario. One approach is to consider the combined impact of all measures[207] in a scenario. The other approach is required by AB 197, where each measure within a scenario is evaluated independently. In addition to these two evaluation approaches, this chapter also includes a discussion of the Public Health implications for the Scoping Plan Scenario, an overview of the Climate Vulnerability Metric, and the Environmental Analysis conducted in accord with the California Environmental Quality Act (CEQA).

It is important to note that all of the analyses in this chapter use a variety of data sources, but because the modeling is economy-wide at the state level, none of them produce community specific detail outputs. The AB 32 GHG Inventory Sector analysis relies on PATHWAYS data at the state level that is proportionally applied across all regions of the state to translate changes in state level fuel combustion to local level changes. The NWL analysis similarly utilizes a variety of data sources and a suite of models that produce data that are scaled up to the statewide level. All of the models, except the Wildland Urban Interface (WUI) defensible space model, which is conducted at the county level, create aspatial projections that are not applicable at the community level.

Economic Analysis

As part of the process to develop this Scoping Plan, alternative scenarios that transition energy needs away from fossil fuels and achieve carbon neutrality no later than 2045 were developed. Alternative scenarios that assess the impact of different land management strategies on carbon stocks in NWL were also developed. These alternatives are described in Appendix C (AB 197 Measure Analysis). The following sections describe the Scoping Plan Scenario in terms of direct cost, the economy, employment, and health outcomes.[208]

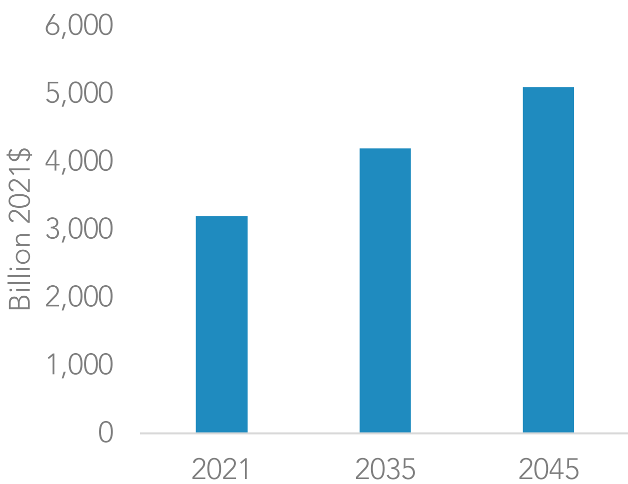
---

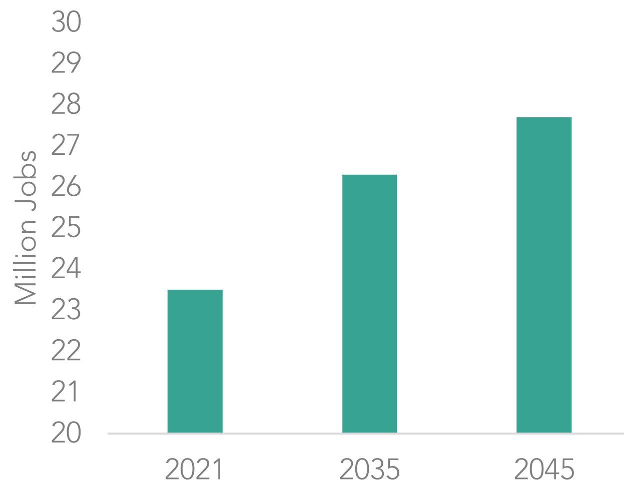
[207] AB 197 calls for the evaluation of "measures." This Scoping Plan treats each action and its variants on stringency as measures for the purposes of this chapter. Appendix C (AB 197 Measure Analysis) lists the measures and corresponding modeling assumptions for each alternative and the Scoping Plan Scenario. The modeling assumptions for the Scoping Plan Scenario are summarized in Table 2-1.

[208] For the Draft 2022 Scoping Plan Update, achieving carbon neutrality in 2035 and 2045 was evaluated. The AB 32 GHG Inventory sector direct cost, the economy, employment, and health outcomes were assessed in those years. Similarly, the Scoping Plan Scenario assessments that are presented in this chapter were made for years 2035 and 2045.

The California economy is growing, and it is projected to continue to grow about 2 percent each year, from $3.2 trillion in 2021 to $5.1 trillion in 2045, as shown in Figure 3-1. Similarly, employment in California is anticipated to grow 0.7 percent per year, from 23.5 million jobs in 2021 to 27.7 million jobs in 2045. It is in this context, termed the *Reference Scenario,* that CARB evaluates the Scoping Plan Scenario in terms of its impact on economic growth and employment. The projections shown in Figure 3-1 were produced by CARB to evaluate the incremental impact of regulations.

Figure 3-1: Projected California gross state product (left) and employment growth (right) from 2021 to 2035 and 2045





Source: California Air Resources Board

Transitioning away from fossil fuels to alternatives and increasing action on NWL will affect employment opportunities, household spending, businesses, and other economic aspects of our lives. Sectors expected to see growth include renewable electricity and hydrogen production, while other sectors may shrink. The deployment of clean technology may require higher upfront costs for things like heat pumps and induction stoves, but those could be offset by energy efficiency savings. Employment and economic development in NWL-related industries and sectors are expected to increase as land management actions increase, especially for the Forestry sector (in which a significant increase is called for under the Scoping Plan Scenario). The net impact of these actions on employment and jobs is presented in this chapter.

Estimated Direct Costs

One key metric is the direct cost, or net investment, reflecting any savings that result from actions. Similar approaches were used to estimate direct costs for the AB 32 GHG Inventory sectors and for the NWL, as described in this section.

AB 32 GHG Inventory Sectors

Transitioning away from fossil fuels requires investment in new equipment and infrastructure throughout the economy. It involves developing the capacity to produce fuels and electricity from renewable sources rather than producing fossil energy. This transition also takes time. One approach is to eliminate combustion of fossil fuels by replacing all equipment in a specified year. Another approach is to establish a future point at which all sales of new equipment rely on alternative energy sources and allow the transition to occur over time as equipment is replaced upon its end of life.

To evaluate the investment required through 2045, the PATHWAYS model was used to represent equipment stock and its turnover to non-fossil fuel alternatives over time. The annualized, incremental cost of infrastructure in excess of the annualized cost of the Reference Scenario[209] was computed for each year from 2022 through 2045. These costs were computed by first taking the absolute cost in each year—which includes both new equipment investment and also expenditures on energy, operations, and maintenance in each year—and then levelizing the costs (in the same way car or house payments are annualized or spread out over time) to arrive at an annualized cost. Fuel savings, and resulting cost savings, associated with changing energy demand—from gasoline to electricity for vehicles, for example—are included as a result of this methodology. Carbon dioxide removal includes DAC technology powered primarily by off-grid solar, BECCS to produce hydrogen or other fuels, and NWL sequestration, as discussed in Chapter 2.[210]

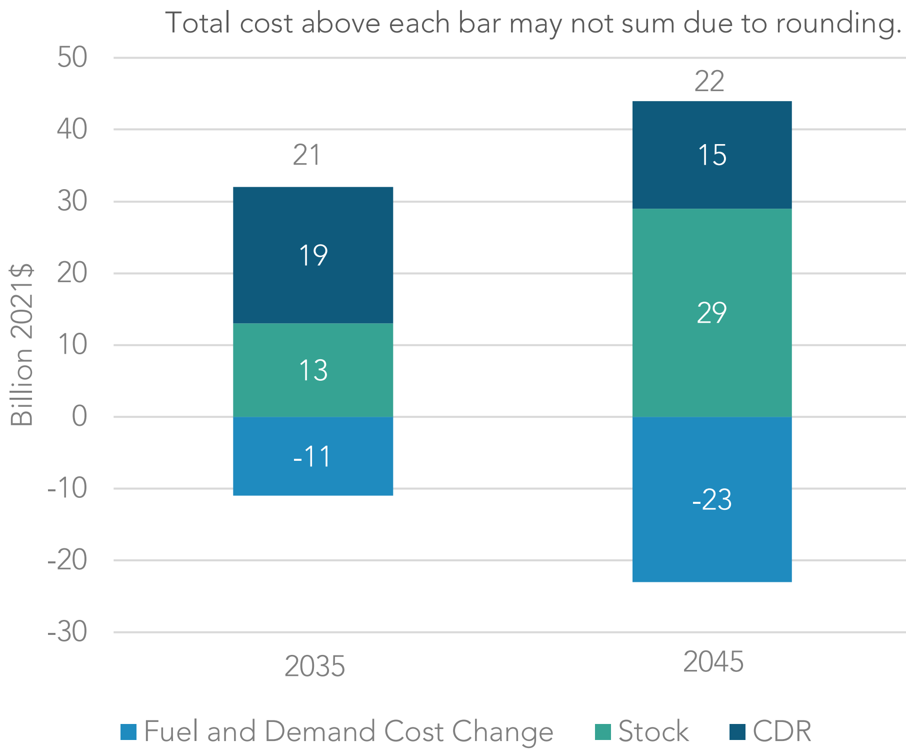
Figure 3-2 shows the stock investment cost, fuel/efficiency savings, and CDR cost. The Scoping Plan Scenario allows end-of-life transition of equipment. The cost of investing in new equipment is partially offset by savings associated with efficiency gains and reduced demand for fuels like gasoline. This is particularly relevant in the transportation sector, which leads to the majority of savings in 2045 in the Scoping Plan Scenario, which models near complete electrification of transport relying only on end-of-life replacement of vehicles. Appendix H (AB 32 GHG Inventory Sector Modeling) includes additional detail on direct costs in each sector and how costs change over time.

---

[209] The Reference Scenario described in Chapter 2 and in Appendix H (AB 32 GHG Inventory Sector Modeling) was the basis for the direct cost comparison.

[210] The energy source for DAC is not modeled, but renewable electricity and/or hydrogen produced from electrolysis are zero-carbon options consistent with the carbon neutrality targets in this Scoping Plan. The economic analysis associated the investment in DAC with the solar industry for consistency with the carbon neutrality targets.

Figure 3-2: Cost and savings relative to the growing California economy for the Scoping Plan Scenario in 2035 and 2045 (AB 32 GHG Inventory sectors)



Natural and Working Lands

For NWL, the direct costs of each management strategy were estimated using available academic literature, monitoring and reporting data, survey data, and cost data from existing subsidy programs on the per acre cost of implementing the management strategy. These cost data, in combination with the acreage of each management strategy under the scenarios, provided estimates of the overall direct cost to either the government or the private sector. The direct costs are independent of the policy lever used to implement the action and do not include many important benefits and externalities of the actions. They are assumed to be constant for each scenario and into the future. Avoided or secondary costs, such as those from reductions in wildfire suppression expenses, are not included. Appendix I (NWL Technical Support Document) includes additional direct cost details.

Table 3-1 includes the direct cost estimates for the Scoping Plan Scenario compared to the Reference Scenario.[211] Direct costs for the NWL sector are expected to be significant due to the ambitious level of action for each land type.

Table 3-1: Cost and savings relative to a growing California economy for the Scoping Plan Scenario (NWL)

Measure	Scoping Plan Scenario: Average Direct Annual Cost, 2025–2045 (millions $/year)
Forests / Shrublands / Grasslands	1,780
Annual Croplands	284
Perennial Croplands	4
Urban Forest	4,230
Wildland Urban Interface (WUI)	114
Wetlands	28
Sparsely Vegetated Lands	4
Totals	6,460
Note: Table values may not add to total due to rounding.	

CARB estimates that all jurisdictions, including private landowners, currently spend approximately $4 billion dollars annually on planting, maintenance, sidewalk repair, tree removal, and other expenses related to urban forests, and that reaching the theoretical maximum tree cover would require increasing that spending by a factor of 20. The cost of the Scoping Plan Scenario is predominantly a mix of urban forests and forests, shrubland, and grasslands spending.

[211] The Reference Scenario described in Chapter 2 and in Appendix I (NWL Technical Support Document) was the basis for the direct cost comparison.

Economy and Employment

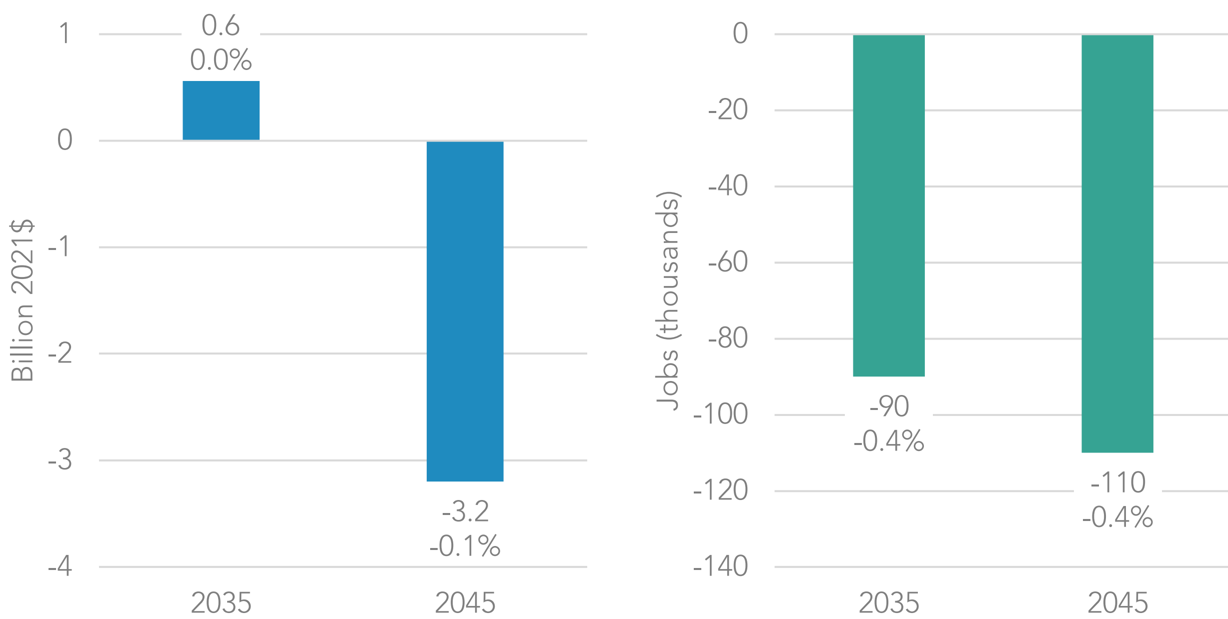
Two different models were used to estimate the overall impact that investing in a transition away from fossil fuels and in our NWL may have on the growing California economy. The transition away from fossil fuels was evaluated using the IMPLAN economic analysis model. The NWL investments were evaluated using the REMI PI+ economic model. These models provide similar outputs relative to the same economic and employment forecasts used to develop a Reference Scenario for use in each model.

AB 32 GHG Inventory Sectors

To estimate the overall impact that investing in a transition away from fossil fuels may have on the California economy, CARB used the IMPLAN model. Additional detail regarding the model, assumptions, and methodology are included in Appendix H (AB 32 GHG Inventory Sector Modeling). The IMPLAN model is a multisector representation of private industries in the U.S. economy that maps economic relationships across industries, households, and governments. This model translates direct costs and savings associated with transitioning away from fossil fuels with indirect effects such as wages, purchases of goods and services, business tax impacts, and supply chain effects. In addition, the induced effects of household purchases, local and import purchases, wages paid, and household tax impacts are estimated. This comprehensive assessment of the interactions between capital investment in fossil fuel alternatives and household purchases provides an indication of the response of the California economy to the Scoping Plan Scenario.

The Scoping Plan Scenario results in a small impact on the Gross State Product (GSP) and employment relative to the Reference Scenario, as shown in Figure 3-3. Economic growth is largely unaffected by the Scoping Plan Scenario in 2035 and slowed by 0.1 percent in 2045. Employment growth is also slowed a small amount, 0.4 percent in 2035 and in 2045, and employment still grows. Assuming annual growth rates of 0.7 percent means there would be more than 193,000 additional jobs in 2045.

Figure 3-3: Gross state product (left) and employment (right) relative to a growing California economy for the Scoping Plan Scenario in 2035 and 2045 (AB 32 GHG Inventory sectors)



California households will see increased costs from the purchase of new capital stock and savings from reduced spending on fuel, as shown in Figure 3-2. Households also will face increased costs associated with CDR, costs associated with energy efficiency measures, and commercial stock purchases—all of which are assumed to be passed directly to consumers. The impact to California households, however, is not limited to these direct costs, as changes in relative prices, employment, and wages can affect household well-being. Personal income, which captures the direct, indirect, and induced impacts, is a metric commonly used to evaluate the impact of policies on households.

Personal income in California is projected to grow from $2.7 trillion in 2021 to $3.6 trillion in 2035 and $4.4 trillion in 2045. Household projections are based on California Department of Finance population projections, which estimate the state's population to grow an average of 0.3 percent each year from 2021 to 2045.[212] California households are projected to increase from 13.3 million in 2020 to 14.6 million in 2035 and 15.0 million in 2045.

[212] California Department of Finance. Population Projections (Baseline 2019). https://dof.ca.gov/forecasting/demographics/projections/.

While the transition away from combustion of fossil fuels will improve air quality for all Californians (and even, more so in overly burdened communities), the economic impacts of the Scoping Plan Scenario are unlikely to be equal among Californians. Table 3-2 presents the change in income by household income group relative to the Reference Scenario in 2035 and 2045. While in 2035 there is a net decrease in personal income of $600 million, total income for households that make less than $100,000 per year is estimated to decline by $4.1 billion dollars, and the total income for households that make more than $100,000 per year will increase by $3.5 billion under the Scoping Plan Scenario. In 2045, although there is no net change in personal income across all California households, results vary by income level. Total income for households that make less than $100,000 per year are estimated to decline by $5.3 billion dollars, while the total income for households that make more than $100,000 per year will increase by $5.3 billion under the Scoping Plan Scenario.

Table 3-2: Income Impacts by California household income group in 2035 and 2045 for the Scoping Plan Scenario (AB 32 GHG Inventory Sectors)

Household Income Group ($2021)	Percentage of 2021 California Households[213]	Change in Income (Billion $2021)	
		2035	2045
Less than $50,000	30	-2.9	-3.9
$50,000 to $100,000	27	-1.2	-1.4
$100,000 to $200,000	28	2.5	4.0
More than $200,000	15	1.0	1.3
Total	100	-0.6	0.0

[213] U.S. Census Bureau. 2021. Household Income. California. https://data.census.gov/cedsci/table?q=california%20income.

In addition to income level, there is likely to be an impact to California personal income that varies based on race/ethnicity.[214] Table 3-3 shows the percentage of households within each income group based on eight race/ethnicity categories identified in the American Community Survey 2021. As shown in Table 3-2, households in lower income groups are anticipated to see negative impacts, while households in higher income groups are anticipated to see positive impacts from the Scoping Plan Scenario in both 2035 and 2045. Because more than 60% of households in the race/ethnicity categories of Hispanic, Black alone, Native Hawaiian (HI) or Pacific Islander, American Indian or Alaskan Native, Other, and Two or More make less than $100,000 per year, these populations generally are likely to experience reduced income. White and Asian households will generally experience both increased and decreased income because these households are distributed more evenly across all four income groups.

The state recognizes the need to ensure that accessibility to clean technology and energy do not further exacerbate health and opportunity gaps for low-income households and communities of color. The Climate Change Investments program exceeds the statutory minimums to invest in projects to benefit disadvantaged communities.[215] Utilities implement programs for reduced energy bills for qualifying low-income customers.[216] There are also resources for waste and water bills that leverage federal funds.[217] CARB also coordinated with the CPUC to ensure that the Climate Credit[218] funded from the sale of Cap-and-Trade allowances provided to utilities on behalf of ratepayers is credited equally to households and not based on how much energy is used. These are just a few examples of how the state is designing and implementing programs to avoid increasing existing disparities. The state must continue to find ways to relieve economic burdens on low-income households.

[214] The number of households in each bracket and the race/ethnicity categories are from American Community Survey 2021 results. Population changes through 2035 and 2045 are not forecast. Table 3-3: Percentage of households in each race/ethnicity category by household income group

Household Income Group ($2021)	Households in Income Group (%)							
	White Not Hispanic	Hispanic	Black Alone	Asian Alone	Native HI or Pacific Islander	American Indian or Alaskan Native	Other	Two or More
Less than $50,000	26	35	45	25	30	35	37	32
$50,000 to $100,000	25	32	27	21	31	33	33	30
$100,000 to $200,000	29	25	21	30	30	26	24	27
More than $200,000	19	7	7	24	9	7	5	11

Natural and Working Lands

The macroeconomic impact of the NWL scenario was evaluated separately in the REMI PI+ model. For the Scoping Plan Scenario, the macroeconomic impact was modeled by assuming that economic activity in the relevant industries grows in proportion to the proposed implementation spending in that industry. All funds for implementing the actions were assumed to be sourced from within the state. For urban forests, the funds were modeled as being sourced from a combination of state government and private property owners in proportion to the current estimated private/public spending ratio. For all other actions, funds were assumed to be sourced from the state government. In each modeled scenario, government spending and income to property owners were reduced relative to the Reference Scenario in proportion to the annual costs of implementation. None of the proposed spending was modeled as being sourced from increased taxes. Additional details on the methodology for evaluating macroeconomic impacts are in Appendix I (NWL Technical Support Document).

While the macroeconomic model does count the increased economic activity in the affected industries as part of GSP, it does not quantify many of the important economic, health, and environmental benefits that would occur if these actions were implemented. While these benefits—like the reduced use of pesticides, value of urban trees, and increased recreational opportunities—would be very significant, they are outside the scope of the macroeconomic model.

The macroeconomic model also makes projections about the total level of employment in the state. The model forecasts that the Scoping Plan Scenario, which greatly increases the level of NWL management actions, channels economic activity toward related industries and would lead to a slight increase in total employment. (Table 3-4). While the model does aim to accurately represent many labor market dynamics, including adjustments of wages and migration rates, it does not account for many costs that might be associated with dramatically scaling up employment in a particular industry, such as the cost of job training.

Table 3-4: Gross state product and employment relative to a growing California economy for the Scoping Plan Scenario in 2035 / 2045 (NWL)

	Scoping Plan Scenario (%)
Gross State Product	0.00 / 0.01
Employment	0.12 / 0.10
Personal Income	-0.04 / -0.04
Personal Income per Capita	-0.04 / -0.14

Health Analysis

Air quality is affected by pollutant emissions from various processes associated with energy systems, including the combustion of fossil fuels, as well as the combustion of vegetation biomass from NWL during wildfires. Pollutants that are important contributors to degraded air quality in California include nitrogen oxides (NO_x), particulate matter (PM), reactive organic gases (ROG), and others. Further, in the atmosphere these pollutants are transported away from the locations of the emissions by wind and other phenomena, and undergo chemical reactions that result in the formation of new pollutants such as ground-level ozone and fine particulate matter ($PM_{2.5}$). Both primary (emitted) and secondary (formed) pollutants are important from a public health standpoint and contribute to the incidence of air pollution-related mortality and disease within California populations. Measures focused on GHGs do not incorporate specific targets to reduce emissions of $PM_{2.5}$ or air toxics like benzene. These co-pollutants, which are emitted from many of the same pollution sources as GHGs, affect local air quality and pose known risks to public health, such as the risk of asthma and cardiovascular disease. Generally, for stationary sources, certain harmful pollutants are regulated via local rules and regulations that are reflected in permits for stationary sources and are enforced by local air districts, with CARB also regulating air toxics contaminants from stationary sources with the air districts.

AB 32 GHG Inventory Sectors

To assess health impacts for the AB 32 GHG Inventory sectors, an integrated modeling approach was used to quantify and value the air pollution-related public health benefits of the Scoping Plan Scenario relative to the Reference Scenario. Additional details about the models, assumptions, and methodology are included in Appendix H (AB 32 GHG Inventory Sector Modeling). Using output from the PATHWAYS model, projections of pollutant emissions to 2045 were developed for stationary, area, and mobile source emissions using a detailed base year CARB pollutant emissions inventory. Further, the emissions are processed, including for where and when they occur in California, using the Sparse Matrix Operator Kernels Emissions (SMOKE) model. For example, on-road vehicle emissions were allocated along existing roadways, and refining emissions were assigned to the locations of existing refineries. It should be noted that the emissions projections represent statewide average reductions associated with high-level assumptions about alternative fuels and technologies. For example, emissions occurring from refineries to produce liquid fuels are reduced in line with petroleum demand. This reduction is applied equally to all refineries in the Scoping Plan Scenario and does not specify individual facility responses to changing demand. Similarly, the Scoping Plan Scenario does not specify which refineries transition to biofuel production or where new electricity generation facilities are built.

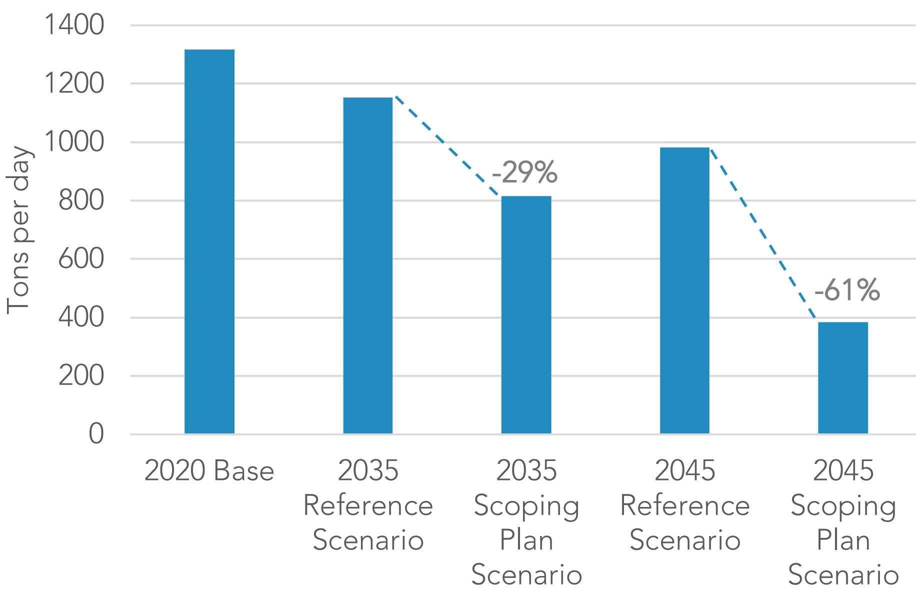
Next, emission changes were translated into impacts on atmospheric pollution levels, including ground-level ozone and $PM_{2.5}$, via an advanced photochemical air quality model called the Community Multiscale Air Quality (CMAQ) model, which accounts for atmospheric chemistry and transport. A comprehensive assessment of how pollutant concentrations are impacted throughout the year was achieved by simulating all months in 2035 and 2045 for the Scoping Plan Scenario.[219] Health benefits were estimated using the U.S. EPA's environmental Benefits Mapping and Analysis Program (BenMAP) model to translate pollutant changes into avoided incidence of mortality, hospital admissions, emergency room visits, and other outcomes as a result of reduced exposure to ozone and $PM_{2.5}$. These outcomes are associated with an economic value in order to aggregate health impacts.

The Scoping Plan Scenario shows a substantial reduction in pollutant emissions relative to the Reference Scenario, including NO_x, $PM_{2.5}$, and ROG. Reductions in NO_x are shown in Figure 3-4. Even under a business-as-usual trajectory, emissions are reduced from present levels by 26 percent in 2045 in the Reference Scenario, demonstrating the impact of current regulations and trends in energy sectors. The Scoping Plan Scenario further reduces NO_x

[219] This annual approach differs from the episodic modeling approach applied to the Proposed Scenario and Alternatives in the Draft 2022 Scoping Plan Update. Appendix H (AB 32 GHG Inventory Sector Modeling) describes both approaches.

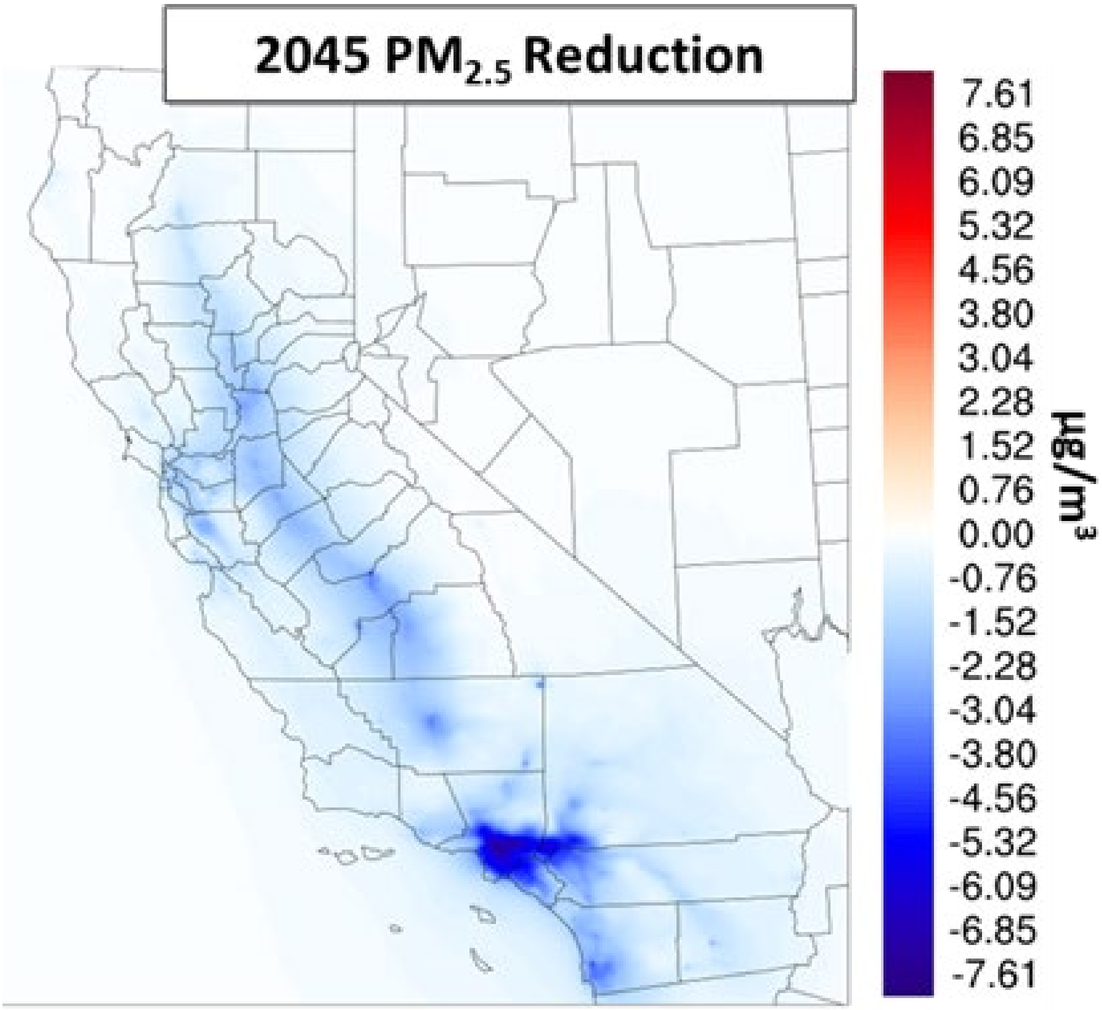
emissions from the Reference Scenario by 29% in 2035 and 61% in 2045. Emission reductions occur throughout the state with particular prominence in urban areas, including the South Coast Air Basin, due to the large presence and activity of emission sources. Appendix H (AB 32 GHG Inventory Sector Modeling) contains additional information about the pollutant emissions modeling and results.

Figure 3-4: Illustration of NOx emission reductions from current levels for the Reference Scenario and the Scoping Plan Scenario (AB 32 GHG Inventory sectors)



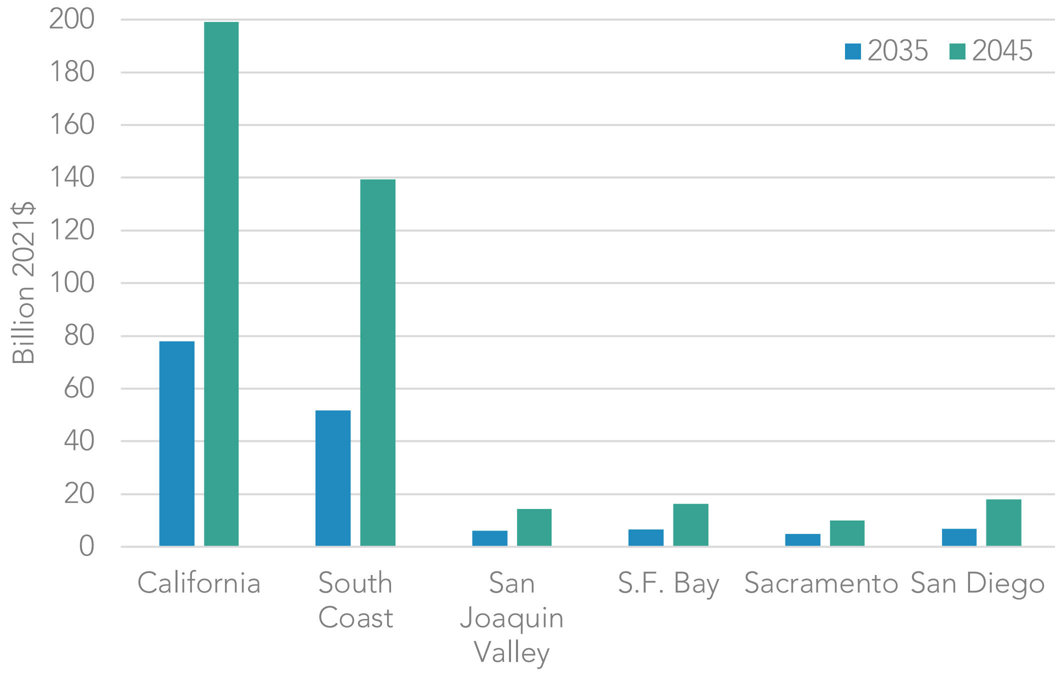
The emission reductions achieve important improvements in air quality throughout California, including reductions in the levels of ozone and $PM_{2.5}$. Reductions in annual $PM_{2.5}$ levels are shown in Figure 3-5. The greatest reductions are evident in Southern California, the San Joaquin Valley, the San Francisco Bay area, and the Greater Sacramento area due to the large presence and activity of emission sources, meteorology, topography, and others. To highlight the extent of the air quality improvements: reductions reach nearly 8 micrograms per cubic meter (μg/m^3) in 2045 and lead to 76% fewer exceedances of the health-based National Ambient Air Quality $PM_{2.5}$ standard of 12 μg/m^3. Similarly, ozone improvements reach 19 parts per billion (ppb) and yield 62% fewer exceedance events. Furthermore, the locations of improvements carry important implications for human health as these areas support large urban populations and generally experience the most degraded ozone and $PM_{2.5}$ pollution. Appendix H (AB 32 GHG Inventory Sector Modeling) provides details regarding the atmospheric modeling and results, including differences in ozone and $PM_{2.5}$.

Figure 3-5: Difference in annual average $PM_{2.5}$ ($\mu g/m^3$) in the Scoping Plan scenario relative to the Reference scenario in 2045 (AB 32 GHG Inventory sectors)



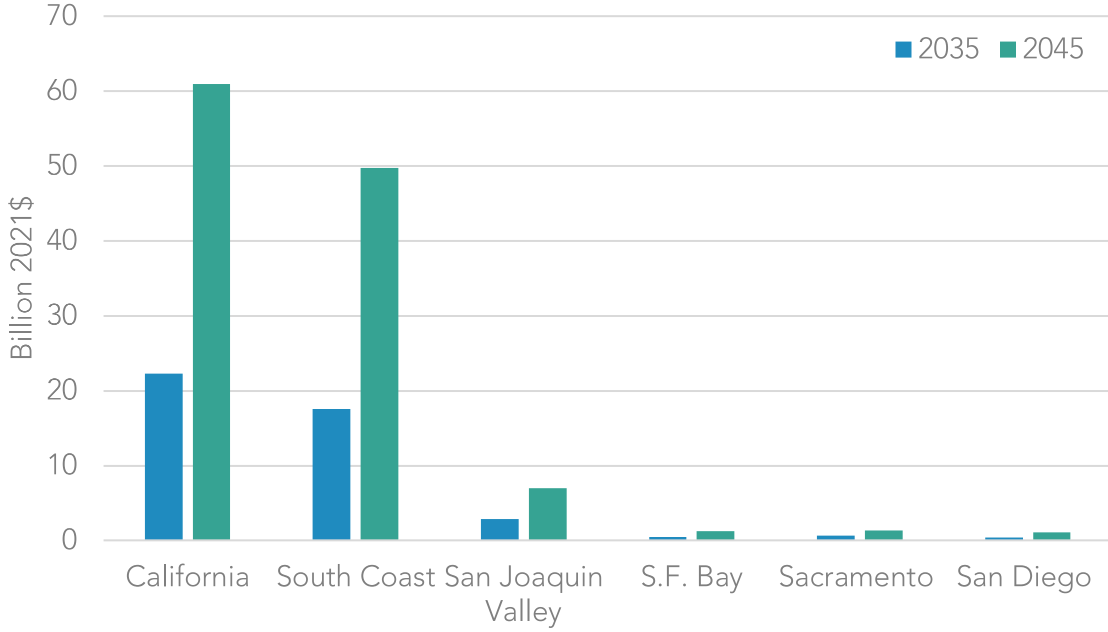
Notable health benefits representing the economic value of the avoided incidence of health effects are associated with the Scoping Plan Scenario. In total, the benefits reach $78 billion in 2035 and $199 billion in 2045, as shown in Figure 3-6. Populations in Southern California benefit the most due to preexisting air quality challenges, significant emission sources and activity, and the presence of a large, dense urban population. Additional details regarding the health impact assessment are provided in Appendix H (AB 32 GHG Inventory Sector Modeling).

Figure 3-6: Total health benefits estimated from air quality improvements in the Scoping Plan Scenario (AB 32 GHG Inventory sectors)



Furthermore, these benefits accrue within socially and economically disadvantaged communities identified by CalEnviroScreen, where they are most needed. Total health benefits within census tracts identified as disadvantaged communities using CalEnviroScreen 4.0 reach $22 billion in 2035 and $61 billion in 2045, as shown in Figure 3-7. Similarly to the statewide health benefits, the largest share of benefits occurs within disadvantaged communities in Southern California. Additional information on the health benefits within disadvantaged communities can be found in Appendix H (AB 32 GHG Inventory Sector Modeling).

Figure 3-7: Disadvantaged community health benefits relative to the Reference Scenario for the Scoping Plan Scenario (AB 32 GHG Inventory sectors)

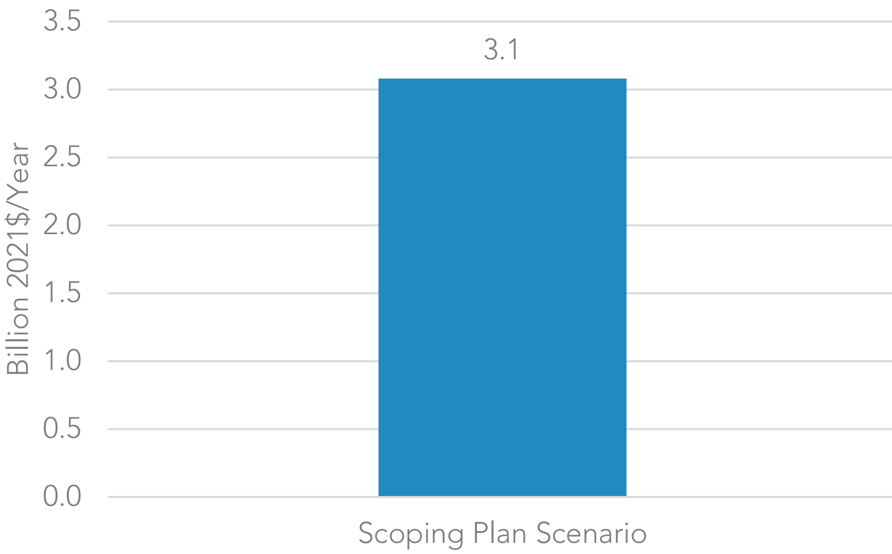


Natural and Working Lands

For NWL, health benefits were evaluated based on projected $PM_{2.5}$ wildfire emissions on forests, shrublands, and grasslands, discussed in the AB 197 Measure Analysis section of the chapter that follows.[220] The health endpoints for the Scoping Plan Scenario and in Appendix I (NWL Technical Support Document) for the alternative scenarios were the basis for the estimated health benefits shown in Figure 3-8. Health benefits were derived from the preliminary University of California, Los Angeles (UCLA) study that estimated annual health impacts and associated costs from California's wildfires from 2008–2018. Additional details are included in Appendix I (NWL Technical Support Document). These costs were applied to the health endpoints discussed in the AB 197 Measure Analysis section of the chapter.

[220] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N11, N14. *finalejacrecs.pdf (arb.ca.gov)*.

Figure 3-8: Total average annual health benefits relative to the Reference Scenario for the Scoping Plan Scenario (NWL)



As health impacts analyzed here are driven by wildfire emissions, the health benefits for the Scoping Plan Scenario are directly related to the amount of forest, shrubland, and grassland management action. These management actions reduce vegetation fuels and, as a result, wildfire activity. The Scoping Plan Scenario increases the amount of these management actions, reducing wildfire emissions and avoiding incidence of emission-related health effects. The health benefits, or economic value of the avoided incidence of health effects, correspondingly increase with an increasing management implementation rate. Additional details are included in Appendix I (NWL Technical Support Document).

Estimated health benefits do not include the direct impact of wildfires on injuries, deaths, or mental health, nor the indirect costs of lost ecosystem benefits to wildfire. Additional direct health costs may result from wildfire that would likely increase the health benefits from increased forest, shrubland, and grassland management to reduce wildfire activity. Nonetheless, the conservative health benefits under the Scoping Plan Scenario are estimated to be $3.1 billion per year relative to the Reference Scenario for all NWL actions identified in the Scoping Plan Scenario.

AB 197 Measure Analysis

This section provides estimates for information associated with GHG emissions reduction measures evaluated in this Scoping Plan.[221] These estimates, which were developed as part of the process for meeting the requirements of AB 197 (E. Garcia, Chapter 250, Statutes of 2016), provide information on the relative impacts of the evaluated measures when compared to each other. To support the design of a suite of policies that result in GHG reductions, air quality co-benefits, and cost-effective measures, it is important to understand if a measure will increase or reduce criteria pollutants or toxic air contaminant emissions, or if increasing stringency at additional costs yields few additional GHG reductions. To this end, AB 197 requires the following for each potential emissions reduction measure evaluated in any Scoping Plan update:

- The range of projected GHG emissions reductions that result from the measure;
- The range of projected criteria pollutant emission reductions that result from the measure; and
- The cost-effectiveness, including avoided social costs, of the measure.

The following sections describe the evaluation of measures for the AB 32 GHG Inventory sectors and NWL. For the purposes of this Scoping Plan, the identified emissions reduction measures for the analysis required by AB 197 are actions grouped by sectors where several policies and programs are expected to overlap. This approach reflects the most granular feasible analysis given the modeling tools available,[222] the overlap and interaction effects among policies and incentive programs, the longer planning horizon used for this Scoping Plan compared to previous efforts, and the scale of transition needed to achieve carbon neutrality. To implement this Scoping Plan, dozens of individual regulations, policies, and incentive programs are anticipated that work together to drive down emissions across all economic sectors and support actions. Every specific policy or incentive program that could contribute to the deployment of clean technology and energy called for in this plan may overlap in ways that make it infeasible to tease out those policies and programs' individual effects with any reasonable degree of certainty. For example, in the transportation sector, deploying ZEVs and reducing driving demand may be achieved through a combination of the implementation of new or existing regulations, fuels programs, incentive programs, and VMT reduction initiatives that can each contribute to reductions in emissions for the sector. It is not feasible to isolate each sub action from each other at this time in terms of the share of contribution to total reductions. The estimated emission

[221] AB 197 calls for the evaluation of "emission reduction measures." This Scoping Plan treats each action and its variants on stringency as emission reduction measures for the purposes of this chapter. Appendix C (AB 197 Measure Analysis) lists the measures and corresponding modeling assumptions for each alternative.
[222] See Appendix H (AB 32 GHG Inventory Sector Modeling and Appendix I (NWL Technical Support Document).

reductions, health endpoints, and costs by measure for the Scoping Plan Scenario are presented in this chapter, and the corresponding estimates for the Proposed Scenario and Alternatives 1, 2, and 4 are included in Appendix C (AB 197 Measure Analysis).

Because many of the measures and underlying assumptions interact with each other, isolating the GHG emission reductions, corresponding changes to fuel combustion, and associated cost of an individual measure is analytically challenging. Each measure is evaluated by examining the change in fuel combustion, cost, and emissions associated with just that measure using the PATHWAYS model. The difference between the Scoping Plan Scenario and the Reference Scenario is estimated for each measure. Starting from the Scoping Plan Scenario, the modeling assumptions for an individual measure are reverted to the Reference Scenario values, resulting in GHG reductions, changes to fuel combustion, and costs (or savings). This approach does not reflect interactions between sectors in PATHWAYS that influence the results for each complete alternative, presented earlier. As such, the values associated with each measure should not be added to obtain an overall scenario estimate.

To arrive at the 2045 target for NWL, CARB modeled the ecological impact that climate smart land-based management strategies (suites of on-the-ground actions, or *treatments,* that are used across the landscape to manipulate an ecosystem) will have on ecosystem carbon; and whenever possible, additional co-benefits from those actions. The Scoping Plan Scenario incorporates a set of land management actions at varying scales of implementation for each land type to achieve the GHG emission reductions. Each land type, and its associated management actions, was considered a measure for this analysis. For modeling individual landscapes and management actions, CARB used a suite of models. The complexity of these models varies by land type, depending on the existing science, data, and availability of existing models to use. Appendix I (NWL Technical Support Document) provides detailed modeling assumptions for each NWL type. The estimated emission reductions, health endpoints, and costs by measure under the Scoping Plan Scenario for each NWL type are presented in this chapter, and the corresponding estimates for the Proposed Scenario and NWL Alternatives 1, 2, and 4 are included in Appendix C (AB 197 Measure Analysis).

Estimated Emissions Reductions

Both GHG emissions reductions and emissions of criteria air pollutants were evaluated for the AB 32 GHG Inventory sectors and for NWL. The methods and results are described in this section.

AB 32 GHG Inventory Sectors

In the absence of having direct modeling results for criteria pollutant estimates from PATHWAYS, CARB estimated criteria pollutant emissions impacts by using changes in fuel combustion in units of exajoules from PATHWAYS and emission factors in units of tons per exajoule to estimate the change in emissions in tons per year. Emission factors from a variety of sources for each sector were utilized, including but not limited to CARB's mobile source emissions models,[223] U.S. EPA's AP 42 Emissions Factors,[224] and the South Coast Air Quality Management District's (AQMD's) District Rules.[225] These emission factors were applied to fuel burn change by fuel type, sector, equipment type, and process, where applicable. Statewide annual average emissions were estimated for three criteria pollutants: NO_x, $PM_{2.5}$, and ROG.

Table 3-5 provides the estimated GHG and criteria pollutant emission reductions for the measures in the Scoping Plan Scenario in 2035 and 2045. The other alternatives are presented in Appendix C (AB 197 Measure Analysis). Based on the estimates below, these measures are expected to provide air quality benefits. The estimates provided in this chapter and Appendix C (AB 197 Measure Analysis) are appropriate for comparing across alternatives considered for the development of this Scoping Plan, but they are not precise estimates.

Table 3-5: Estimated GHG and criteria pollutant emission reductions relative to the Reference Scenario for the Scoping Plan Scenario in 2035/2045 (AB 32 GHG Inventory sectors)

Measure	GHG Reductions ($MMTCO_2$)	NOx Reductions (Short Tons/Year)	$PM_{2.5}$ Reductions (Short Tons/ Year)	ROG Reductions (Short Tons/Year)
Deploy ZEVs and reduce driving demand	-46 / -84	-51,620 / -122,806	-2,008 / -6,506	-18,967 / -30,410
Coordinate supply of liquid fossil fuels with declining California fuel demand	-25 / -30	-1,601 / -2,707	-978 / -1,705	-747 / -1,323
Generate clean electricity	-8 / -31	-92 / -1,555	-177 / -1,382	-41 / -425
Measure	**GHG Reductions ($MMTCO_2$)**	**NOx Reductions (Short Tons/Year)**	**$PM_{2.5}$ Reductions (Short Tons/ Year)**	**ROG Reductions (Short Tons/Year)**
Decarbonize industrial energy supply	-9 / -22	-21,172 / -34,876	-1,188 / -2,527	-3,710 / -6,298
Decarbonize buildings	-14 / -35	-8,105 / -94,455	-826 / -6,877	-1,093 / -8,109
Reduce non-combustion emissions[a]	-0.41 / -0.52 ($MMTCH_4$)	N/A	N/A	N/A
Compensate for remaining emissions	-25 / -64	N/A	N/A	N/A

[a] Methane emissions reductions are reported for this measure.

The measures related to reducing non-combustion emissions and compensating for the remaining emissions do not include changes to fuel combustion, and therefore are not associated with changes to air pollutants. Biomethane combustion is captured in measures that reduce combustion of fossil gas, such as decarbonizing industrial energy supply and buildings.

Natural and Working Lands

NWL ecosystems naturally vary between being a source and a sink for carbon over time. The NWL ecosystem carbon stock changes projected through mid-century by the suite of models were used to estimate net emissions or emissions reductions relative to the Reference Scenario. These changes in carbon stocks were affected by projected climate change, the implementation of management actions under the various scenarios, land conversion, and (for forests, shrublands, grasslands) wildfire. Each NWL type was evaluated, and an overview of all NWL is presented in Table 3-6. More detailed results for each NWL type can be found in Appendix C (AB 197 Measure Analysis).

Table 3-6: Estimated average annual GHG and criteria pollutant emission reductions relative to the Reference Scenario for the Scoping Plan Scenario from 2025–2045 (NWL)

Measure	GHG Reductions ($MMTCO_2e$/year)	$PM_{2.5}$ Reductions (MT/Year)
Forests/Shrublands/Grasslands	-0.12	-17,500
Annual Croplands	-0.25	N/A
Perennial Croplands	-0.01	N/A
Urban Forest	-1.29	N/A
Wildland Urban Interface (WUI)	0.75	N/A
Wetlands	-0.43	N/A
Sparsely Vegetated Lands	<-0.01	N/A

Fine particulate wildfire emissions were evaluated for forests, shrublands, and grasslands only. Wildfire emissions decreased under the Scoping Plan Scenario compared to the Reference Scenario. The Scoping Plan Scenario's higher level of management actions that reduce tree or shrub densities, protect large trees, reintroduce fire to the landscape, and diversify species and structures result in greater reductions in wildfire emissions.

Estimated Health Endpoints

Climate change mitigation will result in both environmental and health benefits. This section provides information about the potential health benefits of the Scoping Plan Scenario. Health benefits are primarily the result of reduced $PM_{2.5}$ pollution, both from stationary and mobile sources, as well as wildfire in forests, shrublands, and chaparral.

AB 32 GHG Inventory Sectors

CARB used the criteria pollutant emissions in Table 3-5 to understand potential health impacts. Similar to the air quality estimates, this information should be used to understand the relative health benefits of the various measures and should not be taken as absolute estimates of health outcomes. CARB used the incidence-per-ton (IPT) methodology to quantify the health benefits of emission reductions. The IPT methodology is based on a methodology developed by the U.S.

EPA.[226,227,228,229] Under the IPT methodology, changes in emissions are approximately proportional to the resulting changes in health outcomes. IPT factors are derived by calculating the number of health outcomes associated with exposure to $PM_{2.5}$ for a baseline scenario using measured ambient concentrations and dividing that number by the emissions of $PM_{2.5}$ or a precursor. To estimate the reduction in health outcomes, the emission reductions are multiplied by the IPT factor. For future years, the number of outcomes is adjusted to account for population growth. IPT factors were computed for the two types of $PM_{2.5}$: primary $PM_{2.5}$ and secondary $PM_{2.5}$ of ammonium nitrate aerosol formed from precursors.

For this AB 197 analysis, CARB calculated the health benefits associated with the five key measures that are represented by changes to fuel combustion. The health benefits associated with emission reductions for the Scoping Plan Scenario were estimated for each air basin and then aggregated for the entire state of California. CARB assumed that the statewide emission reductions distribution among the air basins is proportional to the baseline emissions in that air basin.

Calculated health endpoints include premature mortality, cardiovascular emergency department (ED) visits, acute myocardial infarction, respiratory ED visits, lung cancer incidence, asthma onset, asthma symptoms, work loss days, hospitalizations due to cardiopulmonary illnesses, hospitalizations due to respiratory illnesses, hospital admissions for Alzheimer's disease, and hospital admissions for Parkinson's disease.[230,231,232] These health endpoints were calculated using the IPT method for estimated emission reductions. Table 3-7 compares the health benefits of emission reductions associated with each measure for the Scoping Plan Scenario in the year

[232] Cardio-pulmonary mortality, hospitalizations due to cardiopulmonary illnesses, and hospital admissions due to respiratory illnesses endpoints utilize studies documented in CARB's methodology document. For future assessments, CARB will use more recent studies to estimate cardiovascular hospital admissions and respiratory hospital admissions, as documented in CARB's updated health endpoints memo.

specified (2035 or 2045). The other alternatives are presented in Appendix C (AB 197 Measure Analysis).

Table 3-7: Estimated avoided incidence of mortality, cardiovascular and respiratory disease onset, work loss days and hospital admissions relative to the Reference Scenario for the Scoping Plan Scenario (AB 32 GHG Inventory sectors)

Measure	Mortality	Cardiovascular ED Visits	Acute Myocardial Infarction	Respiratory ED Visits	Lung Cancer Incidence	Asthma Onset	Asthma Symptoms	Work Loss Days	Hospital Admissions, Cardiovascular	Hospital Admissions, Respiratory	Hospital Admissions, Alzheimer's Disease	Hospital Admissions, Parkinson's Disease
Deploy ZEVs and reduce driving demand in 2035	635	170	70	400	45	1,475	128,930	92,510	95	115	245	40
Deploy ZEVs and reduce driving demand in 2045	1,820	475	200	1,115	135	3,995	343,095	255,800	295	350	745	125
Coordinate supply of liquid fossil fuels with declining CA fuel demand in 2035	115	30	15	70	10	275	23,530	16,880	20	20	50	10

Measure	Mortality	Cardiovascular ED Visits	Acute Myocardial Infarction	Respiratory ED Visits	Lung Cancer Incidence	Asthma Onset	Asthma Symptoms	Work Loss Days	Hospital Admissions, Cardiovascular	Hospital Admissions, Respiratory	Hospital Admissions, Alzheimer's Disease	Hospital Admissions, Parkinson's Disease
Coordinate supply of liquid fossil fuels with declining CA fuel demand in 2045	215	55	25	130	15	490	40,860	30,445	35	40	95	15
Generate clean electricity in 2035	20	5	0	10	0	45	3,930	2,820	5	5	10	0
Generate clean electricity in 2045	170	45	20	105	15	385	32,065	23,890	25	30	75	10
Decarbonize industrial energy supply in 2035	300	80	35	190	20	695	60,660	43,520	45	55	115	20
Decarbonize industrial energy supply in 2045	595	155	65	365	45	1,310	111,925	83,435	95	115	245	40

Measure	Mortality	Cardiovascular ED Visits	Acute Myocardial Infarction	Respiratory ED Visits	Lung Cancer Incidence	Asthma Onset	Asthma Symptoms	Work Loss Days	Hospital Admissions, Cardiovascular	Hospital Admissions, Respiratory	Hospital Admissions, Alzheimer's Disease	Hospital Admissions, Parkinson's Disease
Decarbonize buildings in 2035	155	40	15	95	10	360	31,130	22,335	25	30	60	10
Decarbonize buildings in 2045	1,610	420	175	985	120	3,550	303,830	226,500	260	310	665	115

Note: All values are rounded to the nearest 0 or 5.

The measures related to reducing non-combustion emissions and compensating for remaining emissions do not include changes to fuel combustion and therefore are not associated with changes to air pollutants or health endpoints. Biomethane combustion is captured in measures that reduce combustion of fossil gas, such as decarbonizing industrial energy supply and buildings.

Although the estimated health outcomes presented are based on a well-established methodology, they are subject to uncertainty. For instance, future population estimates are subject to increasing uncertainty as they are projected further into the future, and baseline incidence rates can experience year-to-year variation. Also, the relationship between changes in pollutant concentrations and changes in pollutant or precursor emissions is assumed to be approximately proportional.

In addition, emissions are reported at an air basin level and do not capture local variations. These estimates also do not account for impacts from global climate change, such as temperature rise, and are only based on the scenarios in this Scoping Plan.

The fuel changes for each AB 197 measure are estimated based on the impact of each measure compared to the Reference Scenario for the years 2035 and 2045. Therefore, aggregating the effect of each measure would overestimate the impacts of the Scoping Plan Scenario because the implementation of each measure would affect the level of benefits of the other measures. This measure-by-measure analysis uses a different methodology for calculating health endpoints than does the health analysis for the complete Scoping Plan Scenario provided earlier.

Natural and Working Lands

Implementation of NWL management strategies to mitigate and adapt to climate change will result in both environmental and health benefits. This section provides information about the potential health benefits of measures evaluated for the Scoping Plan Scenario. For this analysis, health benefit estimates were focused on increases or decreases to $PM_{2.5}$ resulting from wildfire emissions on forests, shrublands, and grasslands.[233] Other health benefits resulting from NWL management actions in the Scoping Plan Scenario are not quantified here but are important for all Californians. This includes, but is not limited to, reductions in exposure to synthetic pesticides when switching to organic agricultural systems, improvements in shade availability and mental health with increasing urban forest cover, improved mental health from opportunities for recreation in resilient and healthy environments, and protection from floods and rising sea levels.

---

[233] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N11, N14. finalejacrecs.pdf (arb.ca.gov).

These examples are by no means exhaustive, as our natural and working lands provide immense health benefits to everyone.

For this analysis, CARB used the $PM_{2.5}$ emissions in Table 3-6 to understand potential health impacts. This information should be used to understand the relative health endpoints of the various measures and should not be taken as absolute estimates of health outcomes of this Scoping Plan statewide or within a specific community. The IPT methodology was used to calculate health endpoints, similar to the AB 32 GHG Inventory Sector analysis. CARB calculated the annual health endpoints associated with the wildfire emissions changes resulting from the implementation of management strategies on forests, shrublands, and grasslands under each alternative. The annual health endpoints associated with emission reductions for the Scoping Plan Scenario were estimated for the entire state. Calculated health endpoints include emissions-caused mortality, hospital admittance, and emergency room visits from asthma; hospital admittance from chronic obstructive pulmonary disease; and emergency room visits from respiratory and cardiovascular outcomes. Table 3-8 compares the average annual health endpoints of wildfire emission reductions associated with the Scoping Plan Scenario over the period 2025–2045. The other alternatives are presented in Appendix C (AB 197 Measure Analysis).

Table 3-8: Estimated average annual avoided incidence of hospital admissions, emergency room visits, and mortality relative to the Reference Scenario for the Scoping Plan Scenario resulting from forest, shrubland, and grassland wildfire emissions (NWL)

Health Endpoints from Forest, Shrubland, and Grassland Wildfire Emissions	Average Annual Avoided Incidence
Hospital admissions from asthma	22
Hospital admissions from chronic obstructive pulmonary disease without asthma	19
Hospital admissions from all respiratory outcomes	63
Emergency room visits from asthma	155
Emergency room visits from all respiratory outcomes	419
Emergency room visits from all cardiovascular outcomes	156
All causes of mortality	394

Estimated Social Cost

Social costs are generally defined as the cost of an action on people, the environment, or society and are widely used to understand the impact of regulatory actions. One tool, the social cost of greenhouse gases (SC-GHG), is an estimate of the present value of the costs associated with the emission of GHGs in future years. It combines climate science and economics to help understand the benefits of reducing GHG emissions. The estimates of the social cost of carbon (SC-CO_2) and social cost of methane (SC-CH_4), two types of SC-GHGs presented here, estimate the value of the net harm to society associated with adding GHGs to the atmosphere in a given year; they do not represent the cost of actions taken to reduce GHG emissions (known as the *cost of abatement*) nor the cost of GHG emissions reductions. In principle, the SC-GHG includes the value of climate change impacts, including but not limited to, changes in net agricultural productivity, human health effects, property damage from increased flood risk and other natural disasters, disruption of energy systems, risk of conflict, environmental migration, and the value of ecosystem services. It reflects the societal value of reducing emissions of the gas in question by one metric ton.[234] Many of these damages from GHG emissions today will affect economic outcomes throughout the next several centuries.

In 2008, federal agencies began incorporating SC-CO_2 estimates into the analysis of their regulatory actions. U.S. EPA has used various models and discount rates to determine the value of future impacts. Generally, these models begin with assumptions to predict economic activity over time, along with projected GHG emissions. The modeled emissions are input into a model of the global climate system, which then translates into estimates of surface temperature, sea level rise, and other impacts. These outputs are used to estimate economic damages per ton of GHG emitted in a given year in the future. Since the models are calculating the present value of future damages, a discount rate is applied. For example, the SC-CO_2 for the year 2045 represents the value of climate change damages from a release of CO_2 in 2045 discounted back to today. The present value is significantly affected by the discount rate used; a higher discount rate results in a lower present value. For example, in 2021 dollars the SC-CO_2 in 2045 is $31 using a 5 percent discount rate, $88 using a 3 percent discount rate, and $122 using a 2.5 percent discount rate. Additional detail is included in Appendix C (AB 197 Measure Analysis).

The 2017 Scoping Plan utilized SC-CO_2 and SC-CH_4 Obama Administration-era values developed by the Council of Economic Advisors and the Office of Management and Budget-convened Interagency Working Group on the Social Cost of Greenhouse Gases (IWG)[235] to consider the social costs of actions to reduce GHG emissions. The Biden Administration reinstated these values in February 2021,[236] after they had been rescinded and significantly revised by the Trump Administration. The reinstatement was considered an interim step, and the Biden Administration also reconvened the IWG to continue its work to evaluate and incorporate the latest climate science and economic research and

A Return to Science: Evidence-Based Estimates of the Benefits of Reducing Climate Pollution. https://www.whitehouse.gov/cea/written-materials/2021/02/26/a-return-to-science-evidence-based-estimates-of-the-benefits-of-reducing-climate-pollution/.

respond to the National Academies' recommendations from 2017 as it develops a more complete revision of the estimates.

It is important to note that the models used to produce SC-GHG estimates do not include all of the important physical, ecological, and economic impacts of climate change recognized in the climate literature. There are additional costs to society, including the costs associated with changes in co-pollutants and costs that cannot be included due to modeling and data limitations. The IWG has stated that the range of the interim SC-GHG estimates likely underestimates societal damages from GHG emissions.[237] The revised estimates were originally slated to be released in early 2022 but were stalled.[238] CARB staff is applying the interim values presented in the IWG February 2021 Technical Support Document (TSD), which reflect the best available science in the estimation of the socioeconomic impacts of GHGs.[239] This Scoping Plan utilizes the TSD standardized range of discount rates, from 2.5 to 5 percent, to represent varying valuation of future damages.

AB 32 GHG Inventory Sectors

Table 3-9 presents the estimated social cost, in terms of avoided economic damages, for each measure of the Scoping Plan Scenario. For each measure, Table 3-9 includes the range of the SC-CO_2 and SC-CH_4 that results from the GHG emissions reductions in 2035 and 2045 at 2.5 and 5 percent discount rates. Additional background on the SC-GHG and methodology for calculating the SC-CO_2 and SC-CH_4 estimates in this Scoping Plan, as well as estimates for the alternatives, are provided in Appendix C (AB 197 Measure Analysis).

---

[237] Interagency Working Group on Social Cost of Greenhouse Gases. 2021. Technical Support Document. https://www.whitehouse.gov/wp-content/uploads/2021/02/TechnicalSupportDocument_SocialCostofCarbonMethaneNitrousOxide.pdf

[238] See *Louisiana v. Biden* (W.D. La. 2022) 585 F.Supp.3d 840, stayed pending review (5th Cir. Mar. 16, 2022) 2022 WL 866282. A federal district court ruling issued in early February 2022 had granted a preliminary injunction blocking the Biden Administration from using the interim IWG SC-GHG estimates. However, a federal appeals court overturned the lower court's preliminary injunction in March 2022, which allows the Biden Administration to continue using the policy as legal proceedings continue. CARB will continue to monitor the litigation. However, the federal action does not prohibit CARB from using social cost of carbon and CARB will use the best available science regardless of politics. A separate federal appeals court upheld the Biden administration's use of the IWG SC-GHG estimates in October 2022. *Missouri v. Biden* (8th Cir. 2022) ____ F.4th ____.

[239] Interagency Working Group on Social Cost of Greenhouse Gases. 2021. Technical Support Document. https://www.whitehouse.gov/wp-content/uploads/2021/02/TechnicalSupportDocument_SocialCostofCarbonMethaneNitrousOxide.pdf

Table 3-9: Estimated social cost (avoided economic damages) of measures considered in the Scoping Plan Scenario (AB 32 GHG Inventory sectors)

Measure	Social Cost of Carbon in 2035, 5%–2.5% Discount Rate Billion USD (2021 dollars)	Social Cost of Carbon in 2045, 5%–2.5% Discount Rate Billion USD (2021 dollars)
Deploy ZEVs and reduce driving demand	1.12–4.87	2.64–10.23
Coordinate supply of liquid fossil fuels with declining California fuel demand	0.61–2.63	0.95–3.67
Generate clean electricity	0.20-0.88	0.97–3.75
Decarbonize industrial energy supply	0.23–1.01	0.69–2.67
Decarbonize buildings	0.35–1.52	1.11–4.32
Reduce non-combustion emissions	0.51–1.29 (SC-CH_4)	0.86–2.01 (SC-CH_4)
Compensate for remaining emissions	0.61–2.66	2.03–7.84
Scoping Plan Scenario SC-CO_2 **Scoping Plan Scenario SC-CH_4** **Scoping Plan Scenario (Total)[a]**	2.4–10.4 0.51–1.3 2.9–11.7	5.6–21.9 0.86–2.0 6.5–23.9

[a] CARB staff could not precisely separate some CO_2 and CH_4 from other GHGs from PATHWAYS outputs, but the contribution is believed to be small for purposes of calculating the social cost of carbon. The approach used to estimate GHG emissions reductions for individual measures in PATHWAYS does not reflect cross-sector interactions. Therefore, the GHG values for each measure do not sum to the overall scenario total. The total GHG emissions reduction used in this calculation is 97 $MMTCO_2e$ in 2035 and 180 $MMTCO_2e$ in 2045.

Natural and Working Lands

The SC-CO_2 estimates for the NWL measures shown in Table 3-10, in terms of avoided economic damages, reflect 2021 IWG interim values, updated for inflation, similar to the AB 32 GHG Inventory Sector analysis. This analysis utilizes the 2.5 percent and 5 percent discount rate and the average annual emissions reductions from each NWL type from 2025–2045. Estimates for all alternatives are included in Appendix C (AB 197 Measure Analysis).

Table 3-10: Estimated social cost (avoided economic damages) of measures considered in the Scoping Plan Scenario (NWL)

Measure	Social Cost of Carbon in 2035, 5%–2.5% Discount Rate Billion USD (2021 dollars)	Social Cost of Carbon in 2045, 5%–2.5% Discount Rate Billion USD (2021 dollars)
Forests/Shrublands/Grasslands	0.003–0.012	0.004–0.014
Annual Croplands	0.006–0.027	0.008–0.031
Perennial Croplands	<0.001–0.001	0.000–0.001
Urban Forest	0.032–0.138	0.041–0.157
Wildland Urban Interface (WUI)	(0.018) – (0.080)[a]	(0.023) – (0.090)
Wetlands	0.011–0.046	0.014–0.053
Sparsely Vegetated Lands	<0.001	<0.001

[a] Parentheses indicate an increase in estimated social cost, i.e., an increase in economic damages. This is only the case for WUI measures where emissions are increased, shown in Table 3-6. The estimated social cost does not account for the decrease in wildfire risk or decrease in wildfire damages resulting from the WUI measures.

Social Costs of GHGs in Relation to Cost-Effectiveness

AB 32 includes a requirement that rules and regulations "achieve the maximum technologically feasible and cost-effective" greenhouse gas emissions reductions.[240] Under AB 32, *cost-effectiveness* means the relative cost per metric ton of various GHG reduction strategies,[241] which is the traditional cost metric associated with emission control. In contrast, the SC-CO_2, SC-CH_4, and social cost of nitrous oxide (SC-N_2O), because they are estimates of the cost to society of additional GHG emissions, can be used to estimate of the economic benefits of reducing emissions, but do not take into account the cost of the actions that must be taken to achieve those GHG emissions reductions.

There may be technologies or policies that do not appear to be cost-effective when compared to the SC-CO_2, SC-CH_4, and SC-N_2O associated with GHG reductions. However, these technologies or policies may result in other benefits that are not reflected in the IWG social costs. Examples include the evaluation of social diversification of the portfolio of transportation fuels (a goal outlined in the Low Carbon Fuel Standard) and reductions in criteria pollutant emissions from power plants (as in the Renewables Portfolio Standard). Additionally, costs for new technology may be higher early on in a technology's development cycle and may drop over time as use of the technology is scaled up.

Estimated Cost per Metric Ton

AB 197 requires an estimation of the cost-effectiveness of the measures evaluated for this Scoping Plan. The cost (or savings)[242] per metric ton of CO_2e reduced for each measure is one metric for comparing the performance of the measures. Additional factors beyond the cost per metric ton that could be considered include continuity with existing laws and policies, implementation feasibility, contribution to fuel diversity and technology transformation goals, and health and other benefits to California. These considerations are not reflected in the cost per metric ton estimates presented below. It is important to understand the relative cost-effectiveness of individual measures as presented in this section. However, the economic analysis presented earlier in this chapter, in Appendix H

[240] AB 32 Air pollution: greenhouse gases: California Global Warming Solutions Act of 2006. (AB 32, Nuñez, Chapter 488, Statutes of 2006). https://leginfo.legislature.ca.gov/faces/billNavClient.xhtml?bill_id=200520060AB32.

[241] Health & Saf. Code § 38505(d).

[242] Similarly, to the direct costs reported earlier, the cost per metric ton of a measure reflects the stock costs and any fuel or efficiency savings associated with a measure divided by the GHG emission reduction achieved by the measure. Costs are reported as positive values, and savings are reported as negative values.

(AB 32 GHG Inventory Sector Modeling), and in Appendix I (NWL Technical Support Document) provides a more comprehensive analysis of how the Scoping Plan Scenario and alternative scenarios affect the state's economy and jobs.

AB 32 GHG Inventory Sectors

The cost per metric ton for the AB 32 GHG Inventory sectors was computed for each measure independently relative to the Reference Scenario using the sensitivity calculations based on PATHWAYS and RESOLVE outputs. The difference in the annualized cost between the Scoping Plan Scenario and the Reference Scenario was computed for each measure in 2035 and in 2045. The incremental cost was divided by the incremental GHG emissions impact to calculate the cost per metric ton in each year. To capture the fuel and GHG impacts of investments made from 2022 through 2035, or from 2022 through 2045, CARB computed an average annual cost per metric ton. The incremental cost in each year was averaged over the period. This value is divided by the corresponding annual, incremental GHG impact averaged over the same period.

The cost metric includes the annualized incremental cost of energy infrastructure, such as zero-emission vehicles, electric appliances, and required revenue to support all electric assets. A residual value for equipment such as vehicles or appliances that are retired early is included. The annual fuel cost or avoided fuel cost that results from efficiency improvements or changes to demand for fuels associated with transitioning to alternative fuels is included. Not included in this cost metric are costs that represent transfers within the state, such as incentive payments for early retirement of equipment.

It is important to note that this cost per metric ton does not represent an expected market price value for carbon mitigation associated with these measures. In addition, the values do not capture fuel savings or GHG reductions associated with the full economic lifetime of measures that have been implemented by the target date of 2035 or 2045 but whose impacts extend beyond the target date.

Table 3-11 includes the cost per metric ton and annual average cost per metric ton estimates for the Scoping Plan Scenario. The other alternatives are presented in Appendix C (AB 197 Measure Analysis). Measures that are relatively less costly in 2035 or 2045 are also less costly over the extended period. As noted earlier, incremental costs of new vehicles are generally offset by gains in efficiency and avoided fuel consumption resulting in negative cost per metric ton.

Table 3-11: Estimated cost per metric ton of reduced CO_2e relative to the Reference Scenario for measures considered in the Scoping Plan Scenario (AB 32 GHG Inventory sectors)

Measure	Annual Cost, 2035 ($/ton)	Average Annual Cost, 2022–2035 ($/ton)	Annual Cost, 2045 ($/ton)	Average Annual Cost, 2022–2045 ($/ton)
Deploy ZEVs and reduce driving demand	-171	-99	-103	-122
Coordinate supply of liquid fossil fuels with declining CA fuel demand	60	109	-50	39
Generate clean electricity[a]	101	156	145	161
Decarbonize industrial energy supply	290	217	257	274
Decarbonize buildings	235	230	112	213
Reduce non-combustion emissions	93	94	106	99
Compensate for remaining emissions	745	823	236	485

[a] Note: The denominator of this calculation (2045) does not include GHG reductions occurring outside of California resulting from SB 100. If these reductions were included, this number would be lower.

Natural and Working Lands

The cost per metric ton for NWL measures were computed for the Scoping Plan Scenario relative to the Reference Scenario using the projected carbon stock/sequestration data from the NWL modeling and the direct cost estimates for each management action, described earlier. Direct costs represent the cost of implementing a certain management action. The projected emissions reductions take into account the loss of carbon that results from the management action, such as fuels reduction treatments in forests, as well as climate change effects on growth. The direct cost for each NWL measure was divided by the average annual emission reductions presented in Table 3-6 to produce the cost per metric ton. The increasing effect of climate change on diminished future growth reduces the ability of the land to sequester or store carbon, driving up the cost per ton.

It is important to note that this cost per metric ton does not represent an expected market price value for carbon mitigation associated with these measures. In addition, emissions benefits of NWL management actions often take longer time periods to accrue, and these values only capture GHG reductions up to 2045.

Table 3-12 includes the average cost per metric ton estimates for the average annual CO_2e reductions from 2025 through 2045 for the Scoping Plan Scenario. The other alternatives are presented in Appendix C (AB 197 Measure Analysis).

Table 3-12: Estimated average cost per metric ton of reduced CO_2e relative to the Reference Scenario for measures considered in the Scoping Plan Scenario (NWL)

Measure	Average Cost per Reduced Ton CO_2e ($/Ton)
Forests/Shrublands/Grasslands	15,500
Annual Croplands	1,100
Perennial Croplands	412
Urban Forest	3,270
Wildland Urban Interface (WUI)	N/A
Wetlands	64
Sparsely Vegetated Lands	451,000

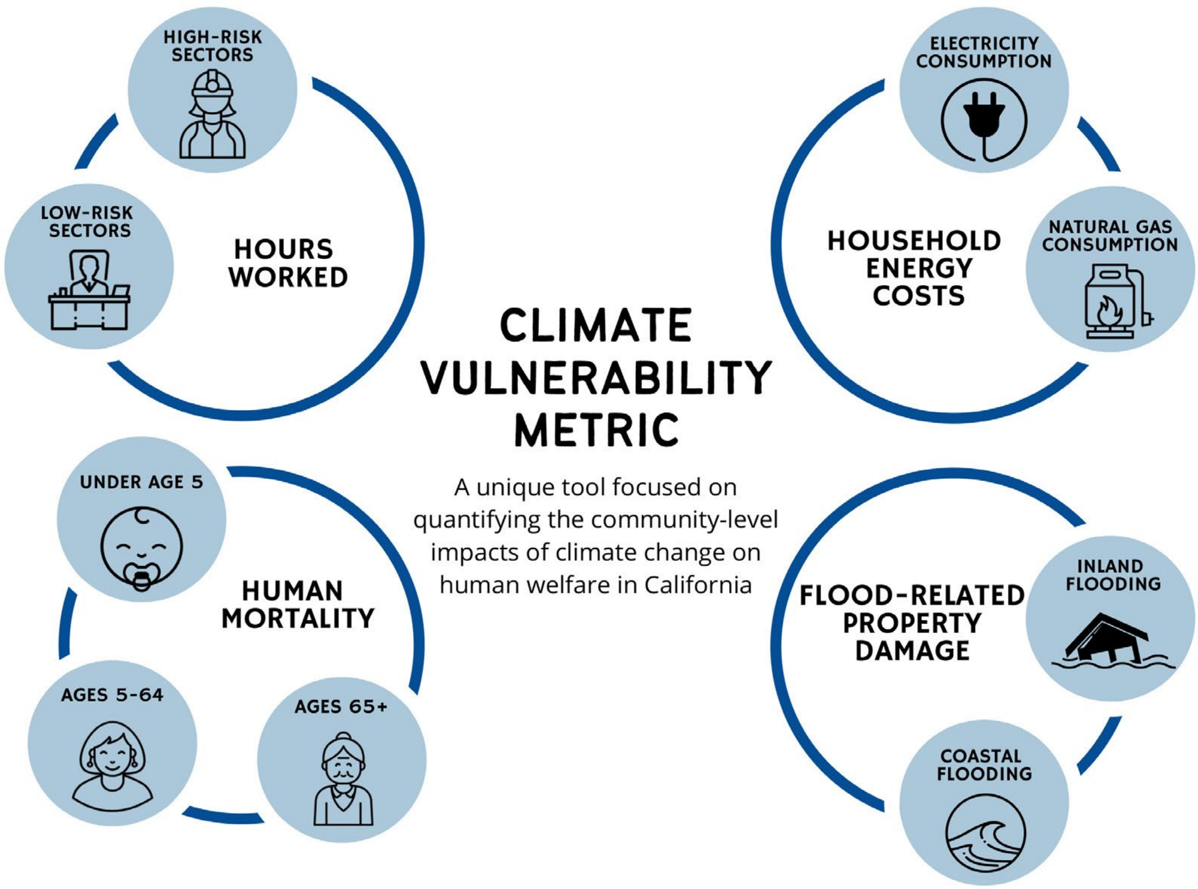
Climate Vulnerability Metric

As California invests in climate mitigation and adaptation, it is essential to understand that the relative impact of climate change will vary across the state's communities. Due to persisting health and opportunity gaps, not all communities are equally resilient in the face of climate impacts. A global metric such as the Social Cost of Carbon cannot adequately capture the incremental additional economic impact faced by overly burdened communities. The Climate Vulnerability Metric (CVM) is specifically focused on quantifying the community-level impacts of a warming climate on human welfare and the additional costs. Additional details and results are included in Appendix K (Climate Vulnerability Metric).

The CVM aggregates the impacts of climate change that can be quantified at the census tract level using robust and currently available research. The CVM includes the projected impacts of climate change on human welfare across four categories (hours worked, household energy costs, human mortality, and flood-related property damage) through midcentury. The CVM identifies nine components of the four climate impacts as shown in Figure 3-9 and aggregates the data to generate a total CVM result for each census tract. To ensure that the CVM represents the diversity of California communities, it is reported as the aggregate monetized impact of climate change as a percentage of census tract-specific incomes.[243] For example, a CVM value of 3 implies that by 2050, a census tract is projected to experience human welfare impacts of climate change that amount to 3% of annual income in that tract.

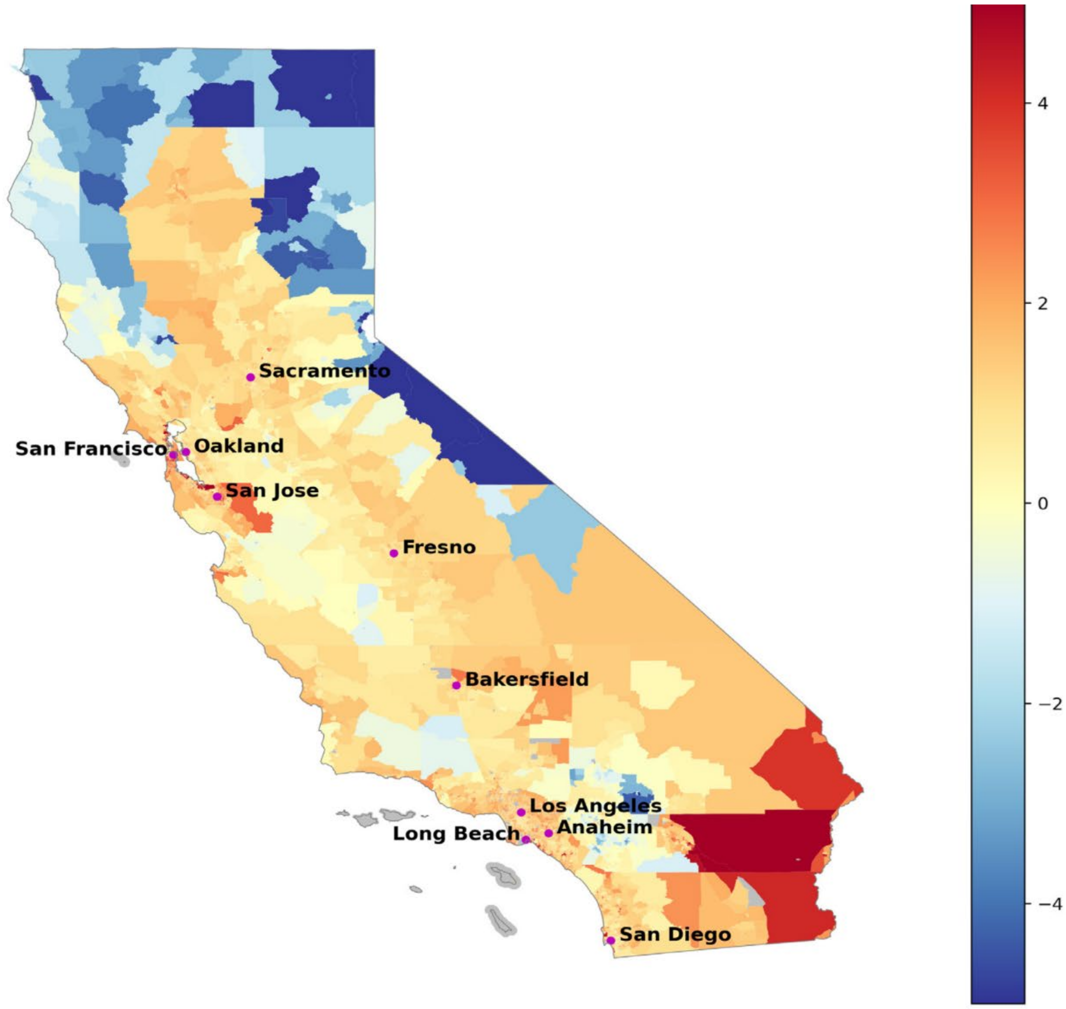
[243] Per capita income in 2019 for census tracts across California ranges from $633 to $176,388, with a median of $32,181 ($2019). Source: American Community Survey.

Figure 3-9: Categories of climate change impacts on human welfare included in the Climate Vulnerability Metric.



The CVM shows that climate change will have highly unequal impacts across California. While some southeastern regions of California are estimated to suffer damages that exceed 5% of annual income, other high-elevation northeastern regions of California are estimated to see benefits of up to 10%. Some low-lying urban areas, such as the San Francisco Bay Area, are estimated to be particularly vulnerable, while much of the Central Valley is estimated to suffer at least moderate economic damages relative to the rest of the state. It is important to note that the CVM does not set a threshold for vulnerability. Instead, it shows relative impacts across census tracts. The CVM is limited to the impacts that can currently be quantified at the census tract level.

Figure 3-10: Combined impacts of climate change in 2050 under a moderate emissions scenario; damages as share of 2019 tract income (%)



The map shows combined impacts of climate change in 2050 under a moderate emissions scenario (RCP 4.5), reported as a share of 2019 census tract income. For example, a CVM value of 3 implies that by 2050, a census tract is projected to experience human welfare impacts of climate change that amount to 3% of annual income. Impacts are combined across the categories shown in Figure 3-9. The higher the CVM for a given census tract, the more damaging the projected impacts of climate change on human welfare. Census tracts with high CVMs are represented by positive percentages in orange and red. A lower CVM is associated with lower projected impacts of climate change, shown in yellow, while a negative CVM value represents a projected beneficial impact of climate change (e.g., through reductions in deaths caused by extremely cold winter weather). Negative CVMs are represented by negative percentages in blue.

By providing information about how climate vulnerability varies across California (Figure 3-10), the CVM results can be used to direct resources to enhance resiliency in the state's most vulnerable communities based on the specific impacts, such as heat or flooding, they are experiencing. The CVM may be used in combination with existing screening tools, such as CalEnviroScreen 4.0, to identify communities that face environmental and health hazards that contribute to disproportionate economic impacts in addition to climate vulnerability. The CVM can become an essential source of information to implement this Scoping Plan and build a more resilient, just, and equitable future for all communities.

Public Health

Health Analysis Overview

This section focuses on a broader evaluation of public health and climate change. Science demonstrates that taking action to address climate change presents one of the most significant opportunities to improve public health outcomes.[244] Transitioning to clean energy and technology and improving land and ecosystem management will lead to a much healthier future. Many actions to reduce GHG emissions also have health co-benefits that can improve the health and well-being of populations across the state, as well as address climate change. This section and the accompanying Appendix G (Public Health) provide a qualitative analysis of health benefits to accompany the quantitative health analysis included in this chapter, in Appendix C (AB 197 Measure Analysis), and in Appendix H (AB 32 GHG Inventory Sector Modeling). Together the qualitative and quantitative analyses of benefits are demonstrating the many ways that climate action and health improvements go hand in hand.

Climate change can lead to a wide range of direct health impacts such as increased heat-related illnesses (i.e., heat exhaustion and heat stroke), and injuries and deaths from extreme weather events or disasters (e.g., severe storms, flooding, wildfires). Indirect impacts include:

- more air pollution-related exacerbations of cardiovascular and respiratory diseases (e.g., due to increased smog, wildfire smoke)
- increased vector-borne and fungal diseases due to changes in the distribution and geographic range of disease-carrying species (e.g., mosquitoes, ticks, fungi in dust)
- negative nutritional consequences related to decreases in agricultural food yields
- stress and mental trauma due to extreme weather-related catastrophes
- anxiety, depression, and other mental health impacts associated with gradual changes in the climate (e.g., prolonged drought or temperature shifts affecting jobs and industries) that result in unemployment and income loss

---

- residential displacement and home loss (e.g., sea level rise impacting coastal communities)

Wildfires and wildfire smoke are one area where we have already seen and expect to see even further drastic impacts on the health of Californians. According to CalFire, since 1932 the top eight largest wildfires in California have occurred in the past five years (2017–2022), with 151 deaths due directly to fires during that period.[245] Researchers estimate that wildfire smoke during fall 2020 may have led to as many as 3,000 excess deaths, with at least 95% of Californians suffering unhealthy levels of particle pollution due to wildfires in 2020.[246] Continued climate change is projected to further increase smoke exposure from wildfires through the end of the century.[247] Wildfires also create a high-risk environment for outdoor workers, including agricultural workers. While the direct medical and physical health impacts are often most noticeable, the psychological impacts can develop and persist well after the event. Estimates indicate that 20%–65% of survivors of extreme weather events have mental health issues following the event.[248]

Extreme heat, drought, and associated worsened air quality impacts are among the most serious climate-related exposures affecting the health of Californians. Numerous studies find a wide range of adverse health effects accompanying extreme heat, including heat stroke and adverse birth outcomes, and find that extreme heat can harm most body systems. Climate change exacerbates air pollution problems that cause difficulty breathing and can lead to serious illness and death in many parts of California. Increasing temperatures cause increases in ozone and other pollution concentrations, including for California's most polluted regions, and heighten health risks for the vulnerable and marginalized populations living in these areas.[249] In 2020, there were 157 ozone polluted days across Los Angeles, Orange, Riverside, and San Bernardino Counties—the most days since 1997. In addition, particulate matter exposure is a heightened problem during

droughts, which are expected to increase over this century.[250,251] Worse air quality leads to illnesses, emergency room visits, and hospitalizations for chronic health conditions, including chronic obstructive pulmonary disease (COPD), asthma, chronic bronchitis, and other respiratory and cardiovascular conditions, as well as increased risk for respiratory infections, which all result in greater health costs to the state.[252,253,254] These and other climate-related health impacts are discussed in more detail in Appendix G (Public Health).

Health Analysis Components

This Scoping Plan health analysis focuses on the contrast between a California that is still dependent on a fossil fuel-based economy and a California that is transitioned to a carbon-neutral, clean energy future. This qualitative analysis evaluates and demonstrates the broad range of benefits of a dramatic reduction in fossil fuels by 2045 combined with healthier ecosystem management, comparing health outcomes for a "no-action" scenario (Reference) to a "take-action" decarbonization scenario. As this is a qualitative analysis, it looks more broadly at the public health benefits of a drastic reduction in fossil fuel combustion. While this analysis provides scientific evidence for Scoping Plan benefits based on achieving carbon neutrality by 2045, it does not analyze a specific scenario.

The key areas of focus for the analysis are: heat impacts, children's health and development, economic security, food security, mobility and physical activity, urban greening, wildfires and smoke impacts, and housing affordability. For each area of focus, the analysis covers the scientific evidence and compares expected health effects between the Reference and decarbonization scenarios. This analysis looks at the major health outcomes, provides directional effects for each health outcome, and where possible provides information on the strength and scale of health impacts. Some areas include quantitative information where tools are available to measure health outcomes. While the analysis is focused on health outcomes statewide, it also includes discussion

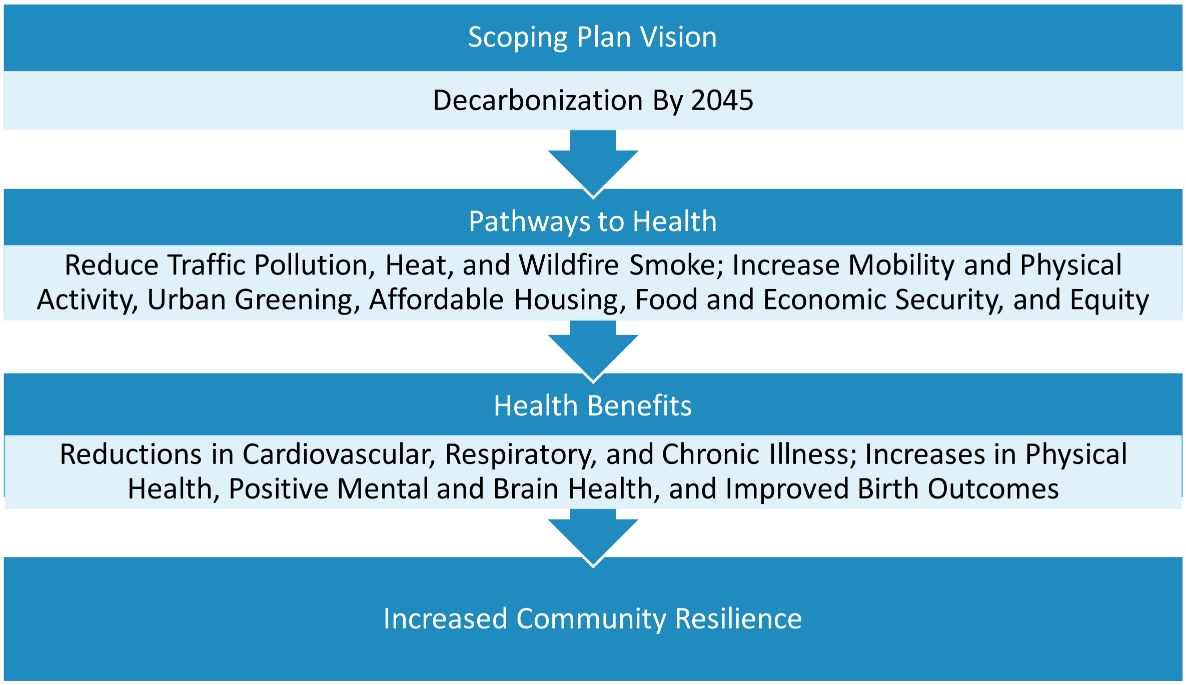
of benefits to community health and climate resilience, as well as potential inequities experienced at a community level. Figure 3-11 shows the co-benefit areas covered in this Scoping Plan and the path to health improvements and increased community resilience.

Figure 3-11: Scoping Plan outcome and the path to health improvements



Social and Environmental Determinants of Health Inequities

Communities across the state do not experience exposure to pollution sources and the resulting effects equally. Low-income communities and communities of color (including Black, Latino and Indigenous communities) consistently experience significantly higher rates of pollution and adverse health conditions than others due to factors including historic marginalization rooted in systemic racism. As shown in Figure 3-12, the most impacted neighborhoods according to CalEnviroScreen (CES) are home to very high percentages of people of color while the least impacted neighborhoods are predominantly white. Recent findings show that Black Californians have 19% higher $PM_{2.5}$ exposure from vehicle emissions than the state average, and the census tracts with the highest $PM_{2.5}$ pollution burden from vehicle emissions have a high proportion of people of color.[255] Air pollutant emissions from mobile sources have disproportionate impacts on low-income communities and communities of color due to their proximity.[256] Diesel-fueled vehicles traveling on California's freeways and major roads expose nearby residents to pollution that is linked to lung cancer, hospitalizations and emergency department visits for chronic heart and lung disease, and premature death.[257,258] A combination of historical and social inequities are evident in communities of color disproportionately living close to freeways and other major sources of vehicle pollution. Environmental exposures and contaminants are one component of a broader set of social, economic, and environmental factors that can amplify health conditions, and the combination of all these factors can compound the health effects of individual exposures. This broader set of community factors can be referred to as "cumulative impacts." In addition, specific populations are more sensitive to pollution and face greater susceptibility. This includes young children, older adults, and individuals with existing health conditions.

Social Determinants of Health Inequities

The physical and mental health of individuals and communities is shaped, to a great extent, by the social, economic, and environmental circumstances in which people live, work, play, and learn. According to the World Health Organization, these same circumstances—or social determinants of health—are "mostly responsible for health inequities: the unfair and avoidable differences in health status seen within and between countries." In fact, a strong body of research demonstrates that more than 50 percent of long-term health outcomes are the result of social determinants affecting an individual.[260] Race/ethnicity and socioeconomic status, for example, have been found to amplify impacts from long- and short-term environmental exposures for several health outcomes,

[259] The figure represents the top and bottom decile scoring of CalEnviroScreen census tracts for pollution burden. This chart is modified from Figure 2. Race in the Least and Most Impacted Census Tracts of CalEnviroScreen 4.0 in the Office of Environmental Health Hazard Assessment, California Environmental Protection Agency. such as mortality and birth outcomes.[261,262,263,264] Social factors combine in low-income communities and communities of color to create levels of toxic chronic stress and limit opportunities for healthy food and healthy lifestyles. Social factors also can cause health disparities through psychosocial pathways such as discrimination and social exclusion.[265] While the importance of social determinants is well known, measuring the specific and cumulative impacts of social determinants is challenging.

There are several important tools to evaluate and map cumulative impacts and factors contributing to the results of historical practices such as redlining, and these tools have been used for air quality and climate planning, community protection, and investments. CalEnviroScreen is a tool that maps cumulative pollution burdens and vulnerabilities on a statewide basis and ranks census tracts based on environmental, exposure, population, and socioeconomic indicators. An analysis using CES shows a direct, persistent relationship between exposure to environmental burdens and socioeconomic and health vulnerabilities affecting communities of color and historical redlining practices. OEHHA has evaluated health impacts of certain climate change policies on disadvantaged communities and communities of color utilizing CES rankings.[266] The Healthy Places Index (HPI) maps indicators that affect life expectancy on a statewide basis. In the future, these and other tools can be helpful to prioritizing investments and informing implementation efforts for GHG emission reductions policies.

Environmental Determinants of Health Inequities

Communities with large percentages of Black and other socially vulnerable and marginalized groups are disproportionately located near pollution sources, such as traffic

and freight facilities, industrial facilities, and hazardous waste sites.[267,268,269,270] Research shows large disparities in exposure to pollution between white and non-white populations in California, and between low-income and communities of color (Figure 3-13). The research also shows Black and Latino populations experience significantly greater air pollution impacts than white populations in California.[271] Additionally, Native Americans are disproportionately impacted by air pollution with high rates of exposure to industrial, diesel, and residential pollution sources and higher rates of diseases linked to air pollution.[272, 273]

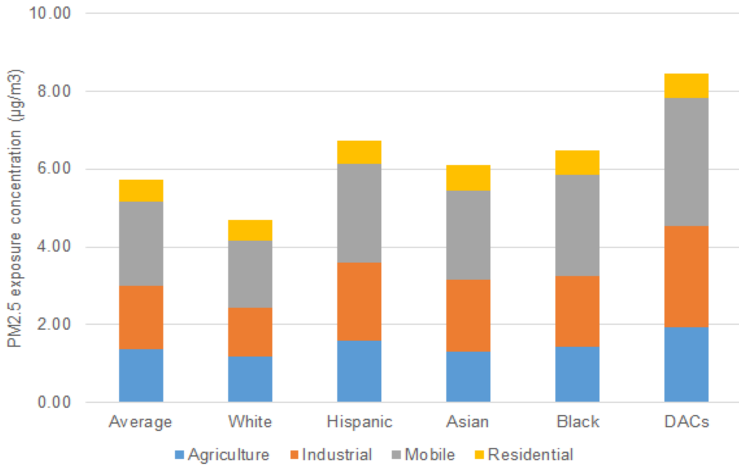
Figure 3-13: Top sources of $PM_{2.5}$ and their contribution to $PM_{2.5}$ exposures by race and in disadvantaged communities



These disparities in exposure to pollution sources generate health inequities. Communities located near major roadways are at increased risk of asthma attacks and other respiratory and cardiac effects. Studies consistently show that mobile source pollution exposure near major roadways or freight sources contributes to and exacerbates asthma, impairs lung function, and increases cardiovascular mortality.[274] The exposure to mixtures of gaseous and particulate pollutants in mobile sources (including PM, NO_x, and benzene) is associated with higher rates of heart attacks, strokes, lung cancer, autism, and dementia.[275]

Environmental hazards found in communities also can include exposures to toxic substances and emissions, as well as occupational exposures. Due to historical inequities, under-resourced communities and communities of color are often located close to sources of toxic pollution, including chrome platers; metal recycling facilities; oil and gas operations; agricultural burning; railyards; facilities transporting, managing, or disposing of hazardous waste; and areas impacted by pesticides, among others. Some populations may be at increased risk of exposure to pollutants, both at work and home.

Children are more susceptible to environmental pollutants for many reasons, including the ongoing development of their nervous, immune, digestive, and other bodily systems. Moreover, children eat more food, drink more fluids, and breathe more air relative to their

body weight, as compared to adults.[276] Exposure to high levels of air pollutants, including indoor air pollutants, increases the risk of respiratory infections, heart disease, and asthma.[277] Children living in low-income communities near industrial operations, rail yards, and heavily trafficked freeways and streets in urban areas are at especially high risk of chronic respiratory conditions. Black children are four times more likely to be hospitalized for asthma compared with white children, and urban Black and Latino children are two to six times more likely to die from asthma than white children.[278] Native American children also experience more impacts from asthma and Native American children, along with Black children, have the highest prevalence of asthma.[279]

For older adults, increased vulnerability is linked to respiratory, cardiovascular, and immune systems weakened by aging.[280] Preexisting health conditions interact with environmental pollutants to enhance risks of adverse health outcomes.[281,282] The recent COVID-19 pandemic has highlighted the heightened vulnerability of older adults as well as communities of color to respiratory disease, as hospital admissions and mortality data linked to COVID-19 cases for these groups have been higher than other groups. Research has also underscored the important link between COVID-19 mortality and morbidity and air pollution, demonstrating significantly higher mortality and morbidity for COVID-19 in areas of elevated $PM_{2.5}$ pollution.

Climate Vulnerabilities

Climate change is expected to exacerbate the existing disparities of health conditions and worsen climate vulnerability, which is the degree to which natural systems and people or

communities are at risk of experiencing the negative impacts of climate change.[283] A report from the California Climate Change Center warned that the impacts of climate change will likely create especially heavy burdens on low-income and other vulnerable populations: "*Without proactive policies to address these equity concerns, climate change will likely reinforce and amplify current as well as future socioeconomic disparities, leaving low-income, minority, and politically marginalized groups with fewer economic opportunities and more environmental and health burdens*."[284]

In the U.S. Environmental Protection Agency's "Climate Change and Social Vulnerability in the United States: A Focus on Six Impacts,"[285] investigators analyzed risks of six primary climate change impacts disproportionately affecting communities across income, educational attainment, race/ethnicity, and age groups. Four socially vulnerable populations—low income, communities of color, no high school diploma, and age 65 and older—were identified as having a higher likelihood of experiencing the greatest impacts of a changing climate (according to the projected 2°C of global warming or 50 centimeters of global sea level rise). Disproportionate impacts were projected for climate events, including air quality, extreme temperature, coastal flooding, and other impacts, leading to increased risk of health and other adverse outcomes. The study projected significant health impacts for low-income communities, certain racial and ethnic subgroups, and those with lower educational attainment.

Several climate vulnerability tools have been developed or are under development to better understand and map areas at higher risk of climate impacts. The Climate Change and Health Vulnerability Indicators (CCHVIs) for California helps state and local health officials prepare for and reduce adverse health impacts due to a changing climate.[286] For example, Los Angeles County shows higher than state average climate vulnerability overall, particularly for those who are linguistically isolated (more than twice the state average).

In summary, there are many environmental, social, individual, and economic factors affecting health and equity in California and contributing to worsening health outcomes from climate change impacts. This section and Appendix G (Public Health) reference a substantial and growing body of research documenting the different social and

environmental factors affecting health outcomes and the many groups that are vulnerable to increased effects or that experience health inequities in California (see Table 3-13).

Table 3-13: Examples of vulnerable groups due to socioeconomic, environmental, developmental, and climate change factors

Examples of Vulnerable Groups Due to Socioeconomic, Environmental, Developmental, and Climate Change Factors		
Older People	People with Existing Chronic Illness	People Impacted Due to Working Conditions
Tribal Groups	Infants and Children	Low-Income People
People with Disabilities	People Experiencing Homelessness	Pregnant People
Communities of Color	Marginalized People	Immigrants/Refugees
People with Less Educational Options	Linguistically Isolated Households	People Impacted Due to Poor Housing Conditions

Summary of the Qualitative Health Analysis

CARB has developed a detailed health analysis that covers eight social and environmental co-benefit areas that impact public health (listed below). These co-benefit areas were selected due to ongoing research in these areas as well as discussion in a public workshop on climate change and health impacts held in summer 2018. For each social and environmental area, the analysis includes:

- a discussion of health impacts and disparities,
- key health metrics or epidemiological research on this topic,
- a discussion of how these areas would be affected by "no-action" (i.e., Reference) scenario compared to a "take-action" (i.e., Scoping Plan) scenario
- a discussion of where there are actions to consider for further success, and
- the types of mitigation actions that can help reduce or eliminate disparities and promote greater health equity and resilience.

All co-benefit areas are interconnected, and pursuing benefits in all areas has the potential to multiply positive results and further support building community resilience. *Community resilience* is the ability of a community to reduce harm and maintain an acceptable quality of life in the face of climate-induced stresses, which vary depending on that community's circumstances and location. Below is a brief description of the areas evaluated for public health co-benefits. The specific health outcomes impacted by each area, as well as the directional health benefits, are included in the Summary of Health Benefits section of the chapter and covered in more detail in Appendix G (Public Health).

Heat Impacts

Globally, increased GHG concentrations in the atmosphere are causing a continuing increase of the planet's average temperature. California temperatures have risen since records began in 1895, and the rate of increase is accelerating. Recent heat waves have broken heat records and caused serious illness across the state, and these events are becoming more frequent. Heat waves have a particularly high impact in Southern California, where they have become more intense and longer lasting. In the past two years, Los Angeles recorded 121°F, and the Coachella Valley had its hottest year ever, with temperatures reaching 123°F. Heat island effects in urbanized areas can elevate heat effects and disproportionately affect low-income communities and communities of color. Heat events exacerbate respiratory and cardiac illness and cause emergency room visits to soar. Strategies that reduce the impacts of heat exposure promote improved health outcomes.

Wildfires and Smoke

California's NWL cover more than 90 percent of California and include rangeland, forests, woodlands, grasslands, and urban green space. They provide biodiversity and ecosystem benefits, including their ability to sequester carbon from the atmosphere. Protecting and managing California's forests and other natural lands and maintaining their ecosystem health are key practices for maximizing GHG benefits and minimizing negative climate change impacts. Vegetation plays an important role in storing carbon; however, it can also release CO_2 back into the atmosphere when it dies or is burned by fires. California's wildfires are getting worse with increased fire risks, higher frequency of occurrence, larger burn areas, more costly damage, and a longer fire season due to climate change. Strategies that promote healthy ecosystem management of natural and working lands and increased urban greening promote improved health outcomes. Healthy ecosystems provide many health and environmental benefits and can maximize carbon sequestration.

Children's Health and Development

There are a wide range of interconnected environmental, social, biological, and community factors associated with climate change that are adversely affecting children's health. This section focuses on air pollution and near-roadway or traffic pollution as environmental impacts that have a profound effect on children's health. Children's bodies and lungs are still developing, and they take in more air per body weight than adults do. Many low-income communities and communities of color in California experience disproportionately high levels of air pollution, as well as high levels of traffic and freight that impact children. This excess exposure harms children's development and predisposes them to increased risk of illness throughout their lives. Strategies that reduce air pollution and traffic emissions promote improved health outcomes for children.

Economic Security

Climate change is expected to result in serious adverse socioeconomic effects across many sectors. Economic factors, such as income inequality (among geographic regions), poverty, wealth, debt, unemployment rate, and job security are among the strongest determinants of health. Along the entire income spectrum, higher income is associated with increased life expectancy and improved health outcomes in the United States. Additionally, economic insecurity and negative health impacts are more pronounced in low-income communities and communities of color. Economic strategies, such as the promotion of clean energy and other green jobs and investments in low-income communities and communities of color, and promoting a transition to high road jobs in economic sectors tied to the current fossil fuel economy, can promote improved health outcomes.[287]

Food Security

The food system is under pressure from numerous factors, and climate change is a key concern. Climate change can affect food production and agricultural yield, impact culturally significant plants and animals for Native American tribes, and exacerbate factors that limit food availability, such as supply chain disruption. Food security is defined as stable access to affordable, sufficient food for an active, healthy life. Many Californians routinely experience food insecurity, and while that impacts Californians of all races and groups, low-income communities and communities of color and children are disproportionately affected by food insecurity. Many Native Americans depend on resources from the land, such as animals and plants for consumption and cultural practices. Strategies that promote sustainable agriculture, access to healthy foods, and reduced organic food waste promote improved health outcomes.

Mobility and Physical Activity

Physical activity is one of the most important factors for a healthy lifestyle, and lack of activity increases the risk of chronic illness and premature death. Research shows that regular physical activity improves health in people of all ages by improving heart and lung

---

[287] According to the California Labor and Workforce Development Agency's High Road Training Partnership program, high road jobs are considered "Quality jobs [that] provide family-sustaining wages, health benefits, a pension, worker advancement opportunities, and collective worker input and are stable, predictable, safe and free of discrimination." https://cwdb.ca.gov/wp-content/uploads/sites/43/2020/08/OneSheet_Job-Quality_ACCESSIBLE.pdf.

function, muscle fitness, mental health and brain function, and sleep quality. A sedentary lifestyle contributes to chronic illnesses, including obesity, heart disease, and Type 2 diabetes among other chronic illnesses. Promoting community design that supports sustainable patterns of land use and transportation enables active transportation choices like walking, biking, and public transit over driving, and can significantly increase physical activity, leading to many valuable health benefits.

Affordable Housing

Housing is an important social determinant of health. The stability of housing, housing quality, conditions inside and outside the home, the cost of housing, and the environmental and social characteristics of the places people live all affect health (including energy efficiency and insulation, cooler building material, tree canopy, home size). Housing affordability is a key factor, and this section highlights how housing affordability supports not only improved health but also more sustainable land use and transportation patterns. A lack of affordable housing is increasing commute distances for low-income renters and creating health burdens. Strategies that support sustainable transportation and housing patterns, together with increased housing affordability, promote improved health outcomes.

Urban Greening

Urban Greening is well recognized as an important amenity, but the inherent health benefits are not always well understood. Under-resourced and vulnerable areas consistently show a lack of urban greening and higher percentages of concrete, asphalt, and impervious surfaces. Under-resourced communities have a greater proportion of concrete and heat-trapping surfaces and a lower amount of tree cover in the neighborhoods in which they live. Areas with reduced urban greening have the potential to create areas of higher temperatures as heat is reflected from pavements and buildings. By contrast, increasing urban greening can provide air pollution buffers and promote physical activity. Strategies that preserve and create urban parks, green space, natural infrastructure, and sustainable agricultural practices support improved physical and mental health outcomes.

No Action Scenario (Reference)

In a no-action scenario, California would remain dependent on fossil fuels and other GHG emitting technologies. Fossil-fuel powered mobile sources including cars, trucks, trains, tractors, and a myriad of other on-road and off-road vehicles and equipment are the largest source of criteria pollutants and toxic air contaminants that directly affect community health and contribute the largest portion of GHG emissions.[288] Other key GHG emission sources include buildings, natural and working lands, and power production and industry. The no-action scenario reflects a continued reliance on fossil fuels in mobile and stationary sectors, including buildings. The continued production and use of fossil fuels; ongoing dependence on gasoline and diesel cars, trucks, buses, and equipment; continued releases of short-lived climate pollutants; and decreased emphasis on forest and ecosystem health will impact communities by reducing climate resilience and health benefits. Green space will likely remain at the same levels or degrade, and urban heat islands will likely increase. With continued growth of vehicle miles traveled, physical activity and the accompanying health benefits will not increase.

Exposure to wildfire smoke will increase, and air quality is expected to worsen as rising temperatures will increase levels of harmful air pollution. Jobs and economic security will be affected by the continuing potential for price spikes in fossil fuels, impacts to the economy from climate change, and fewer job opportunities in green technologies such as solar and electric vehicles. Food security in California will decrease due to the effects of accelerating climate impacts to agriculture; and without increased recovery of organic waste, including food products, food security will continue to decline under a no action scenario. All these impacts can be linked to worse health outcomes. Adverse health impacts are often most felt by Black, Latino, Native American, and other people of color and in low-income communities. These groups are affected more intensely by the physical stress of environmental pollution, social inequities, and the psychological stress of extreme weather events and food and economic insecurity.

Take Action Scenario

In the Take Action scenario, California will drastically reduce reliance on fossil fuels for motor vehicles, freight, buildings, electricity, or other sectors. This scenario is not a specific scenario within this Scoping Plan but examines the broad outcomes of actions to achieve carbon neutrality in 2045. Implementation of this Scoping Plan would achieve a transition to ZEVs, with 100% sales of light-duty ZEVs by 2035 and 100% sales of zero emission trucks by 2040, along with 30% VMT reductions below 2019 levels by 2045. State and local action that supports sustainable land use and transportation patterns and enables more transit and active transportation will lead to substantial health benefits from physical activity, including reduced illness and deaths.

[288] CARB. 2022. *California Greenhouse Gas Emissions for 2000 to 2020.* https://ww2.arb.ca.gov/sites/default/files/classic/cc/inventory/2000-2020_ghg_inventory_trends.pdf.

The economic benefits of improved health through active transportation can be modeled using the Healthy Mobility Options Tool (HMOT).[289] In order to demonstrate the important health and economic benefits of VMT reduction, CARB and CDPH used the HMOT to analyze an illustrative trip reduction scenario for 2050 from the California Transportation Plan (CTP). The CTP has a goal of increasing active modes of travel and transit from the current level of 13 percent to a level of 23 percent of all travel trips. While the CTP goal of 23 percent for active modes of travel is not a VMT reduction target, the scenario increases active transportation through a mix of changes in land use planning for increased transportation options, including increases in biking, walking, and transit use, and it helps to show the health benefits of increased active transportation. By achieving the CTP 2050 goals, nearly 8,000 deaths would be avoided in 2050 alone (see Figure 3-14), along with significant reductions in chronic diseases. Achieving this would rank among the top public health accomplishments (see Appendix G [Public Health] for additional modeling results and detailed discussion).

The dramatic reduction in fossil fuel combustion, combined with reductions in VMT and freight and traffic emissions projected in this Scoping Plan will significantly reduce air pollution and its associated health impacts on a statewide basis and in communities near freight sources. Coordinated action strategies will emphasize natural and working lands management changes, including healthy forests, increased vegetative cover, and increased organic farming. Wildfire smoke exposure will reduce significantly with healthy ecosystem management strategies. Since many communities in California are disproportionately impacted by high levels of traffic pollution, the reduction in petroleum fueled vehicles will reduce the additional impacts of living or going to school near historically highly polluting sources. Indoor air quality is also likely to improve through a shift to non-fossil fuel appliances. Concerted state and local action to support sustainable land use and transportation patterns can enable more active transportation with health benefits from physical activity.

Figure 3-14: Quantified health benefits of active transportation from increased physical activity

*Calculated by the Healthy Mobility Options Tool, active transportation (including walking, rolling, cycling, and taking public transit) from the California Transportation Plan 2050 compared to business as usual for 2050.

Overall community resilience is expected to increase as physical activity and green space increases—potentially decreasing urban heat islands. Efforts to support VMT reduction will include coordination across state agencies on affordable housing measures. Reduced fossil fuel dependence will reduce economic pressure from wildfires, droughts, and price spikes in fossil fuels, especially as more jurisdictions implement plans with similar actions. Investment in sustainable agriculture, healthy forests, urban greening, and clean energy technologies will add sustainable jobs and further promote economic security. More sustainable agriculture and food recovery efforts will add to food security. All these impacts can be linked to wide ranging health benefits, including positive respiratory and cardiovascular effects, healthier birth and brain outcomes, improved mental health indicators, improved life expectancy, reductions in chronic illness and cancers, improved children's health and development, reduced depression, and other benefits. The magnitude of the possible co-benefits is extremely large, especially in areas that are currently the most affected.

Summary of Health Benefits

Below, Tables 3-14 and 3-15 show overall summaries of the directional benefits by co-benefit area estimated for this Scoping Plan. The supporting epidemiological studies used for qualitative or quantitative analysis of each co-benefit area are included in Appendix G (Public Health). Another section of Chapter 3, together with Appendix C (AB 197 Measure Analysis) and Appendix H (AB 32 GHG Inventory Sector Modeling), also includes the quantitative analysis of air pollution related health impacts, including recently added health endpoints for CARB's ongoing analysis.

Table 3-14: Scoping Plan directional benefits for health co-benefit areas (heat, affordable housing, food security, economic security, and urban greening)

	Health Co-benefit Areas*				
Quantitative vs. Qualitative	**Reduced Heat Impacts**	**Increased Affordable Housing**	**Increased Food Security**	**Increased Economic Security**	**Increased Urban Greening**
Research was used for Qualitative Analysis	↓ Mortality ↓ Emergency Room Visits for cardiovascular and respiratory causes and intestinal infections ↓Hospitalization for cardiovascular, respiratory causes ↓ Preterm Birth ↓ Mental Illness	↓ Infectious Disease ↓ Chronic Illness ↓ Asthma ↓ Injuries ↓ Mental Illness ↑ Children's Performance in Schools ↑ Children's Health ↓ Children's Behavioral Problems	↓ Mental Illness ↓ Iron Deficiency ↓ Chronic Diseases ↑ Life Expectancy ↓ Children's Mental Illness ↓ Children's Cognitive Problems ↓ Children's Behavioral Health Problems ↓ Children's Iron Deficiency ↓ Children's Oral Health Problems	↑ Life Expectancy ↑ Health Status ↑ Mental Health	↓ Mortality ↓ Asthma Prevalence ↓ Depression ↓ Adverse Birth Outcomes including low birth weight and small for gestational age ↑ Life Expectancy

*See Appendix G (Public Health) for a table with references to research for each health outcome listed.

In summary, the qualitative health analysis of the No-Action versus Take-Action scenarios for this Scoping Plan shows an overwhelming benefit for the state by taking action to move forward to carbon neutrality while continuing efforts to increase health equity and resilience in individual communities. Taking action can improve physical and mental health for adults and children, reduce a range of chronic illnesses, and promote improvements in life expectancy. Development and implementation of actions to achieve the outcomes called for in this Scoping Plan should consider how to engage affected communities in implementation, address the existing health and opportunity gaps, and pursue equitable implementation statewide and locally. This Scoping Plan deployment of clean technology and fuels, together with improved land management, will reduce GHGs and air pollution and create more resilient communities that are better able to prepare for and recover from extreme climate events.

Environmental Analysis

In May 2022, CARB, as the lead agency for the Scoping Plan, released for public review the Draft Environmental Analysis (Draft EA) for this Scoping Plan; it assessed the potential environmental impacts of implementing the Scoping Plan. CARB circulated the Draft EA for public review and comment for a period of 45 days that began on May 10, 2022, and ended on June 24, 2022. CARB held a public hearing on June 23, 2022 to provide the opportunity for public comment. During the review period, written and oral comments were received on the Draft EA. CARB reviewed the comments to identify environmental topics and began preparation of responses to those comments.

After the end of the Draft EA public review period, CARB identified potential revisions to certain aspects of this Scoping Plan that merit revisions to the project description. This new information results from, among other things, revisions to the project description regarding energy sector goals (including offshore wind), revised carbon removal targets, and additional strategies for natural and working lands. CARB released a Recirculated Draft EA for a written public comment period that started September 9, 2022, and ended on October 24, 2022. See Chapter 2 of the Recirculated Draft EA[290] for further information regarding the changes. The Recirculated Draft EA assesses the potential for significant adverse and beneficial environmental impacts associated with all proposed actions in this Scoping Plan, and provides a programmatic environmental analysis of the reasonably foreseeable compliance responses that could result from implementation of the Scoping

[290] CARB. 2022. Recirculated Draft EA. *https://ww2.arb.ca.gov/sites/default/files/2022-09/2022-draft-sp-appendix-b-draft-ea-recirc.pdf*.

Plan.[291] The Recirculated Draft EA concluded implementation of this Scoping Plan could result in the following:

- Beneficial impacts to: air quality (long-term operational-related) and GHG emissions (short-term construction-related and long-term operational-related)
- Less than significant impacts to: energy demand, mineral resources, population and housing, public services, recreation (short-term construction-related), and wildfire (short-term construction-related)
- Potentially significant and unavoidable adverse impacts to: aesthetics, agriculture and forest resources, air quality (construction-related and operational odors), biological resources, cultural resources, geology and soils, hazards and hazardous materials, hydrology and water quality, land use and planning, noise, recreation (long-term operational-related), transportation and traffic, tribal cultural resources, utilities and service systems, and wildfire (long-term operational-related

Before the public meeting at which the Board will consider this Scoping Plan Update, CARB will publish the Final EA as Appendix B (Final Environmental Analysis) to this Scoping Plan, along with written responses to timely submitted comments raising significant environmental issues received on the Draft EA and the Recirculated Draft EA, which will be presented to the Board for consideration.

[291] The Recirculated Draft EA is available at *https://ww2.arb.ca.gov/our-work/programs/ab-32-climate-change-scoping-plan/2022-scoping-plan-documents*.

Chapter 4: Key Sectors

Chapter 4 provides an overview of the major energy sources and technology in use today, and of alternative clean technology and fuels to support decarbonization based on the latest information available. Every sector of the economy will need to begin to transition in this decade to meet our GHG reduction goals and achieve carbon neutrality no later than 2045. AB 32 requires climate change mitigation policies to be considered in the context of the sector's contribution to the state's total GHG emissions. The transportation, electricity (in-state and imported), and industrial sectors are the largest contributors of GHGs in the state and present the largest opportunities for GHG reductions. Actions to reduce fossil fuel combustion in these sectors also can provide critical air pollution reductions in low-income communities and communities of color, which are often located adjacent to these sources. A carbon neutrality framework also elevates the role of CO_2 removal through natural and working lands and mechanical capture and storage. Actions that support energy efficiency, reduced VMT, alternative fuels, and renewable power also can provide benefits by reducing both criteria and toxic air pollutants.

What sets this plan apart from previous Scoping Plans is the focus on the accelerated rate of deployment of clean technology and energy within every sector. As a result, specific actions, including accelerated rates of deployment of clean technology and fuels identified within this Scoping Plan, will need to be translated into both new and amended regulations, policies, and incentive programs. State agencies will need to evaluate current authority to align existing policies or develop new ones to achieve outcomes called for in this Scoping Plan. Legislative support may be needed in some cases to ensure authority and funding is sufficient to ensure this Scoping Plan is translatable to action on the ground. Most regulations, or change to existing regulations, ultimately considered by the Board or other state agencies for adoption will be subject to administrative procedure requirements. Accordingly, they must rely on specific subsequent supporting analysis and extensive public processes and consultations with interested tribes to develop and identify appropriate proposals for effective implementation. For example, any proposal to strengthen the LCFS regulations through amendments increasing the stringency of the carbon intensity (CI) targets would be considered on the basis of a public process, including workshops, and focused environmental, economic, and public health analyses.

Policies that ensure economy-wide investment or program decisions that incorporate consideration of GHG emissions are particularly important. As we pursue GHG reduction targets, we must acknowledge the manner in which built and natural environments are connected, how changes in one may impact the other, and how policy choices in one sector can and do impact other sectors. For example, fostering more compact, transportation-efficient development in infill areas and increasing transportation choices with the goal of reducing VMT not only reduces demand for transportation fuel but also requires less energy for buildings and helps to conserve natural and working lands that sequester carbon. Therefore, the multiple and often interwoven actions that reduce VMT both reduce emissions from the transportation sector and support reductions needed in other sectors.

Legislation, such as SB 350[292] (De León and Leno, Chapter 457, Statutes of 2015), has recognized the need for CARB, the CEC, and the CPUC to work together to ensure the state's energy and climate goals are integrated in procurement decisions by load serving entities as part of Integrated Resource Plans. Moving forward, it is especially critical that similar approaches are adopted to break down silos across state agencies to ensure policies and programs are aligned with multiple state priorities outlined in this plan. Finally, supportive legislative direction, such as SB 905 that requires CARB to create the Carbon Capture, Removal, Utilization, and Storage Program, may also benefit emerging areas of policy to provide express agency authority and roles for these nascent efforts, including streamlining of permitting, while ensuring that protections for communities are in place.

Unlike previous Scoping Plans that separated out individual economic sectors, this Scoping Plan approaches decarbonization from two perspectives: (1) managing a phasedown of existing energy sources and technology and (2) ramping up, developing, and deploying alternative clean energy sources and technology over time. This approach supports a more comprehensive consideration of our energy infrastructure, the ability to repurpose existing assets, and the need to build new assets. It also provides multiple metrics beyond just the annual AB 32 GHG Inventory to better enable tracking progress. For example, it clearly demonstrates the production and distribution rates of specific types of clean energy, such as adding 4.3 GW of utility solar and 2.5 GW of storage year-over-year between now and 2035 to be on track to achieve carbon neutrality no later than 2045, and does the same for technology deployment, such as 11 million ZEVs in 2035.

The sections below include key actions to support success in the necessary transition away from fossil combustion, which is an overriding goal of this plan. The wide array of complementary and supporting actions being contemplated or to be undertaken across state government are detailed here. The broad view of actions described in this chapter thus provides context for the specific deployment of clean technology and fuels identified in the Scoping Plan Scenario described in Chapter 2. Actions identified in this Scoping Plan are based on currently known options and the latest science. As part of future Scoping Plan updates, additional clean technology and fuels may be identified and added to the mix of needed tools to continue to reduce the state's GHG emissions, support air quality co-benefits, and remove carbon from the atmosphere.

Transportation Sustainability

The transportation sector has long relied on liquid petroleum fuels as the primary energy source for internal combustion engine (ICE) vehicles, including cars, trucks, locomotives, marine equipment, and aircraft. Combustion of fossil fuels in vehicles emits significant amounts of GHGs, criteria pollutants, and toxic air contaminants. In 2019,[293] the transportation sector accounted for approximately 50 percent of statewide GHG emissions[294] and thus was by far the single largest source of carbon pollution in the state. In addition, the transportation sector accounted for over 80 percent of statewide NOx emissions and 30% of fine particulate matter emissions, including toxic diesel particulate matter.[295]

Communities adjacent to congested roadways, including ports and distribution centers, are exposed to the highest concentration of toxic pollutants from vehicles and equipment consuming fossil fuels, leading to a number of demonstrated health impacts such as respiratory illnesses, higher likelihood of cancer development, and premature death. In addition, communities located near oil extraction operations or crude oil refineries often experience higher exposure to poor air quality. While CARB's programs, along with local action, have made substantial progress over the past few decades, it is clear that California must transition away from fossil fuels to zero-emission technologies with all possible speed and pursue policies that result in less driving, in order to meet our GHG and air quality targets.

The transportation sector can be divided into three general categories: Technology, Fuels, and Vehicle Miles Traveled.

- *Technology* refers to the vehicles themselves, as well as the associated refueling infrastructure for those vehicles.
- *Fuels* refers to the energy source used to power vehicles and the facilities that produce them.
- Vehicle travel is measured as *vehicle miles traveled* (VMT), and is a product of development patterns and available transportation options.

---

[293] In 2020 the state experienced shelter-in-place orders in response to the COVID-19 pandemic. The orders, and the effects of the pandemic, led to a significant year-over-year decline in transportation emissions in 2020. This means 2019 is likely a more representative year for overall transportation emissions and 2020 a likely outlier in the historical transportation emissions trend data.

[294] CARB. 2022. *California Greenhouse Gas Emissions for 2000 to 2020.* https://ww2.arb.ca.gov/sites/default/files/classic/cc/inventory/2000-2020_ghg_inventory_trends.pdf. This includes upstream oil extraction and refining emissions.

Sector Transition

Technology

Vehicles must transition to zero emission technology to decarbonize the transportation sector. Executive Order N-79-20[296] reflects the urgency of transitioning to zero emission vehicles (ZEVs) by establishing target dates for reaching 100 percent ZEV sales or fleet transitions to ZEV technology. The primary ZEV technologies available today are battery-electric and hydrogen fuel cell electric vehicles (FCEVs), both of which emit zero tailpipe GHGs, criteria pollutants, and toxic air contaminants, as they do not burn fuel. These vehicles are rapidly growing in performance, affordability, and popularity.[297] Plug-in hybrid electric vehicles also offer a limited but increasing range of zero emission operation and will play a role in the transition to ZEVs.

Light-duty passenger vehicles consume the majority of gasoline in the state—12.9 billion gallons in 2019[298]—and are well-suited for transitioning to ZEVs. EO N-79-20 calls for 100 percent ZEV sales of new light-duty vehicles by 2035, and this target is reflected in this Scoping Plan.[299] The Advanced Clean Cars II regulation fulfills the goal in the Executive Order and serves as the primary mechanism to help deploy ZEVs. A number of existing incentive programs also support this transition, including the Clean Cars 4 All Program.[300] Heavy-duty trucks are the largest source of diesel particulate matter, a toxic air contaminant that is directly linked to a number of adverse health impacts, and EO N-79-20 also sets targets for transitioning the medium- and heavy-duty fleet to zero emissions: by 2035 for drayage trucks and by 2045 for buses and heavy-duty long-haul trucks where feasible. Replacing heavy-duty vehicles with ZEV technology will significantly reduce GHG emissions and diesel PM emissions in low-income communities and communities of color adjacent to ports, distribution centers, and highways. The existing Advanced Clean Trucks regulation, paired with the proposed Advanced Clean Fleets regulation, are designed to transition a significant amount of the

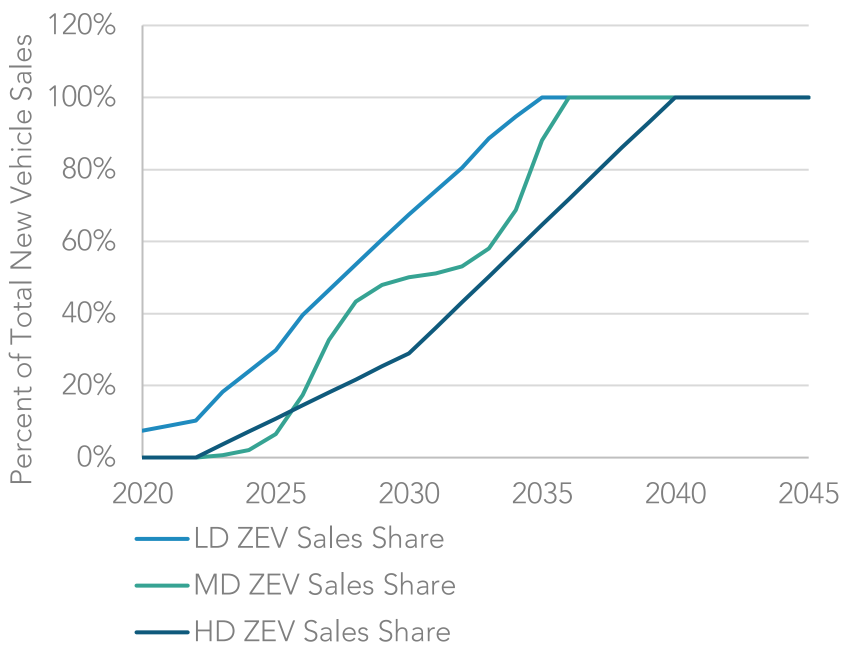
[300] CARB. Clean Cars 4 All. https://ww2.arb.ca.gov/our-work/programs/clean-cars-4-all. The Clean Vehicle Rebate Project (CVRP) also supports the transition to ZEVs. https://cleanvehiclerebate.org/en.

California truck fleet to ZEV technology. As with the LDV sector, a number of incentive programs support this transition, such as the Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project (HVIP).[301]

Figure 4-1 below illustrates the pace of transition in vehicle technology needed to drastically reduce GHG emissions from vehicles. All vehicle classes reach 100 percent ZEV sales before 2045, with some achieving this well before. The ZEV technology across the vehicle classes is assumed to be primarily battery electric and hydrogen fuel cell (reflecting the primary ZEV technologies available today).[302]

Figure 4-1: Transition of on-road vehicle sales to ZEV technology in the Scoping Plan Scenario



Today, off-road vehicles also rely heavily on ICE technology. Executive Order N-79-20 sets an off-road equipment target of transitioning the entire fleet to ZEV technology by 2035, where feasible. There is a great need for both investment and innovation in the off-road space in order to develop and commercialize zero emission equipment types that meet or exceed the performance of existing equipment. A number of funding sources currently support this transition, including programs such as FARMER, Carl Moyer, and

[301] California HVIP. Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project. https://californiahvip.org/?msclkid=efaf65f2c26f11eca6bdd08ecc323864.

[302] The light-duty fleet includes more than 11 million battery electric and hydrogen fuel cell vehicles in 2035 and over 23 million battery electric and hydrogen fuel cell vehicles in 2045.

the Community Air Protection Incentives—as well as Low Carbon Transportation Incentives, including the Clean Off-Road Equipment (CORE) program. In addition, the 2021–22 California budget provided record-high allocations for funding ZEVs, including off-road equipment, and the 2022–23 budget is similarly ambitious.[303] Several regulations focused on transitioning to zero emission off-road equipment have recently been adopted or are in the works, and apply to locomotives,[304] forklifts, ocean-going vessels at berth,[305] commercial harbor craft,[306] small off-road engines,[307] and more.

Intrastate aviation relies on ICE technology today, but battery-electric and hydrogen fuel cell aviation applications are in development, along with sustainable aviation fuel. The Scoping Plan Scenario includes a transition of 20% of aviation fuel demand to ZEV technologies by 2045 and sustainable aviation fuel for the rest.

Refueling infrastructure is a crucial component of transforming transportation technology. Electric vehicle chargers and hydrogen refueling stations must become easily accessible for all drivers to support a wholesale transition to ZEV technology. Deployment of ZEV refueling infrastructure is currently supported by a number of existing local and state public funding mechanisms, the new National Electric Vehicle Infrastructure (NEVI) federal funding mechanism, California's electric utilities, the Electrify America initiative that was established in response the Volkswagen ZEV commitment, and by numerous companies, such as EVgo, ChargePoint, Tesla, Ford, FirstElement Fuel, Chevron, Shell, and Iwatani, who are investing substantial private resources into developing these networks. Private investment in reliable, affordable and ubiquitous refueling infrastructure must drive the transition as the business case for ZEVs continues to strengthen.

Strategies for Achieving Success

- Achieve 100 percent ZEV sales of light-duty vehicles by 2035[308] and medium-heavy-duty vehicles by 2040.
- Achieve a 20% zero emission target for the aviation sector.

- Develop a rapid and robust network of ZEV refueling infrastructure to support the needed transition to ZEVs.
- Ensure that the transition to ZEV technology is affordable for low-income households and communities of color, and meets the needs of communities and small businesses.[309]
- Prioritize incentive funding for heavy-duty ZEV technology deployment in regions of the state with the highest concentrations of harmful criteria and toxic air contaminant emissions.[310]
- Promote private investment in the transition to ZEV technology, undergirded by regulatory certainty such as infrastructure credits in the Low Carbon Fuel Standard for hydrogen and electricity[311] and hydrogen station grants from the CEC's Clean Transportation Program[312] pursuant to Executive Order B-48-18.[313]
- Evaluate and continue to offer incentives similar to those through FARMER,[314] Carl Moyer,[315] the Clean Fuel Reward Program,[316] the Community Air Protection Program,[317] and Low Carbon Transportation,[318] including CORE.[319] Where feasible, prioritize and increase funding for clean transportation equity programs.[320]
- Continue and accelerate funding support for zero emission vehicles and refueling infrastructure through 2030 to ensure the rapid transformation of the transportation sector.

- Evaluate and align with this Scoping Plan relevant CARB policies such as Advanced Clean Cars II,[321] Innovative Clean Transit,[322] Zero Emission Airport Shuttle,[323] California Phase 2 GHG Standards,[324] Advanced Clean Trucks, Advanced Clean Fleets, Zero Emission Forklifts,[325] In-use Locomotives,[326] the Off-Road Zero-Emission Targeted Manufacturer rule, Clean Off-Road Fleet Recognition Program, In-use Off-Road Diesel-Fueled Fleets Regulation,[327] Commercial Harbor Craft,[328] Off-Road Zero-Emission Targeted Manufacturer rule, Clean Off-Road Fleet Recognition Program, Amendments to the In-use Off-Road Diesel-Fueled Fleets Regulation,[329] carbon pricing through the Cap-and-Trade Program,[330] and the Low Carbon Fuel Standard.[331]
- Identify and address permitting and market barriers to successful rapid ZEV technology deployment while protecting public health and the environment.

Fuels

Transitioning away from conventional ICE vehicles is part of the solution, but we must ensure that an adequate supply of zero-carbon alternative fuel and distribution is available to power these vehicles. Electricity and hydrogen are currently the primary fuels for ZEVs,

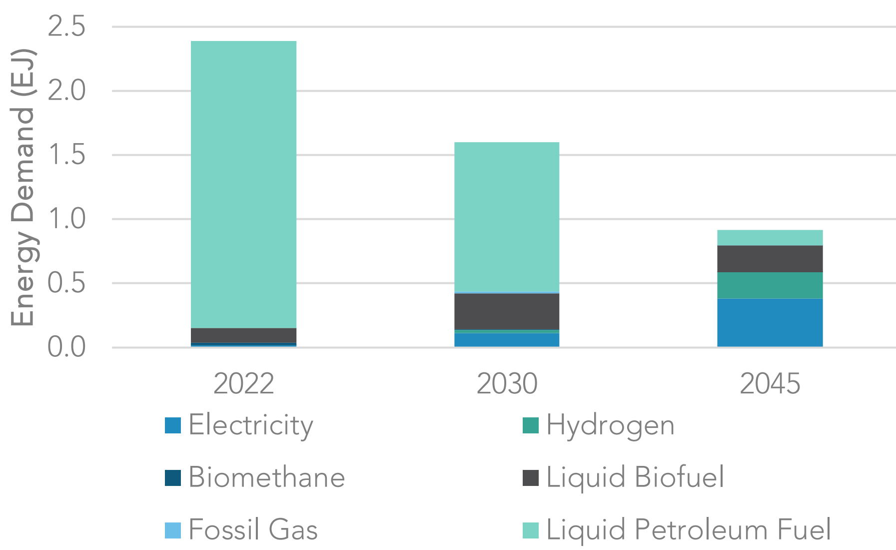
and both fuels must be produced using low-carbon technology and feedstocks to minimize upstream emissions.

The transition to complete ZEV technology will not happen overnight. Conventional ICE vehicles from legacy fleets will remain on the road for some time, even after all new vehicle sales have transitioned to ZEV technology. In addition, some equipment types are only now in the initial stages of development of ZEV technology for propulsion, such as commercial aircraft or ocean-going vessels. In addition to building the production and distribution infrastructure for zero-carbon fuels, the state must continue to support low-carbon liquid fuels during this period of transition and for much harder sectors for ZEV technology such as aviation, locomotives, and marine applications. Biomethane currently displaces fossil fuels in transportation and will largely be needed for hard-to-decarbonize sectors but will likely continue to play a targeted role in some fleets while the transportation sector transitions to ZEVs. Figure 4-2 provides the detail on fuels used in 2020 and the fuel mix under the Scoping Plan Scenario for 2035 and 2045.

Figure 4-2: Transportation fuel mix in 2022, 2030, and 2045 in the Scoping Plan Scenario[332]



Private investment in alternative fuels will play a key role in diversifying the transportation fuel supply away from fossil fuels. The Low Carbon Fuel Standard is the primary mechanism for transforming California's transportation fuel pool with low-carbon

---

[332] See https://ww2.arb.ca.gov/sites/default/files/2022-11/2022-sp-PATHWAYS-data-E3.xlsx for transportation fuels by year.

alternatives and has fostered a growing alternative fuel market. Partially as a result of the powerful market signals from the LCFS, fuels like renewable diesel, sustainable aviation fuel, biomethane, and electricity have all gained significant market shares and continue to displace gasoline and diesel in both on- and off-road vehicles. In addition, Executive Order N-79-20 calls on state agencies to support the transition of existing fuel production facilities away from fossil fuels and directs that this transition also protect and support workers, public health, safety, and the environment. In line with this direction, existing refineries could be repurposed to produce sustainable aviation fuel, renewable diesel, and hydrogen. This trend has already begun, and continuing to develop fuel production capacity in-state to support the energy transition while making the most efficient use of existing assets is critical to avoiding emissions leakage. If fuel demand persists after fuel production facilities have ceased operations, fuel demand will have to be met through imports.

As we transition or build new energy production facilities and infrastructure, it will be important to ensure low-income communities, tribes, and communities of color do not experience increases in existing air pollution disparities and continue to experience a reduction in the air pollution disparities that exist today. California must use the best available science to ensure that raw materials used to produce transportation fuels do not incentivize feedstocks with little to no GHG reductions from a life cycle perspective. A dramatic increase in alternative fuel production must not come at the expense of global deforestation, unsustainable land conversion, or adverse food supply impacts, to name a few examples. CARB will continue to monitor scientific findings on these topics to ensure that California policies, such as the LCFS, send the appropriate market signals and do not result in unintended consequences.[333]

Strategies for Achieving Success

- Accelerate the reduction and replacement of fossil fuel production and consumption in California.[334]
- Incentivize private investment in new zero-carbon fuel production in California.
- Incentivize the transition of existing fuel production and distribution assets to support deployment of low- and zero-carbon fuels while protecting public health and the environment.
- Invest in the infrastructure to support reliable refueling for transportation such as electricity and hydrogen refueling.

[333] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, F1E. finalejacrecs.pdf (arb.ca.gov).

[334] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, F3. finalejacrecs.pdf (arb.ca.gov).

- Evaluate and propose, as needed, changes to strengthen the Cap-and-Trade Program.
- Initiate a public process focused on options to increase the stringency and scope of the LCFS:
    - Evaluate and propose accelerated carbon intensity targets pre-2030 for LCFS.
    - Evaluate and propose further declines in LCFS post-2030 carbon intensity targets to align with this 2022 Scoping Plan.
    - Consider integrating opt-in sectors into the program.
    - Provide capacity credits for hydrogen and electricity for heavy-duty fueling.
- Monitor for and ensure that raw materials used to produce low-carbon fuels or technologies do not result in unintended consequences.[335]

Vehicle Miles Traveled

Transforming the transportation sector goes beyond phasing out combustion technology and producing cleaner fuels. Managing total demand for transportation energy by reducing the miles people need to drive on a daily basis is also critical as the state aims for a sustainable transportation sector in a carbon neutral economy. Though GHG emissions are declining due to cleaner vehicles and fuels, rising VMT can offset the effective benefits of adopted regulations.

Even under full implementation of Executive Order N-79-20 and CARB's Advanced Clean Cars II Regulations, with 100 percent ZEV sales in the light-duty vehicle sector by 2035, a significant portion of passenger vehicles will still rely on ICE technology, as demonstrated in Figure 4-2 above. Accordingly, VMT reductions will play an indispensable role in reducing overall transportation energy demand and achieving the state's climate, air quality, and equity goals. After a significant pandemic-induced reduction in VMT during 2020, passenger VMT has steadily climbed back up and is now closing in on pre-pandemic levels.[336] Driving alone with no passengers remains the primary mode of travel in California, amounting to 75 percent of the mode share for daily commute trips. Conversely, the transit industry, which was significantly impacted during

[336] U.S. Department of Transportation. 2021. December 2021 Traffic Volume Trends. Figure 3 - Seasonally Adjusted Vehicle Miles Traveled by Month. https://www.fhwa.dot.gov/policyinformation/travel_monitoring/21dectvt/figure3.cfm.

the lockdown months, and has struggled to recover; ridership only averages two-thirds of pre-pandemic levels,[337] [338] and service levels also lag behind.

Sustained VMT reductions have been difficult to achieve for much of the past decade, in large part due to entrenched transportation, land use, and housing policies and practices. Specifically, historic decision-making favoring single-occupancy vehicle travel has shaped development patterns and transportation policy, generating further growth in driving (and making transit, biking and walking less viable alternatives). These policies have also reinforced long-standing racial and economic injustices that leave people with little choice but to spend significant time and money commuting long distances, placing a disproportionate burden on low-income Californians, who pay the highest proportion of their wages on housing and transportation. While CARB has included VMT reduction targets and strategies in the Scoping Plan and appendices, these targets are not regulatory requirements, but would inform future planning processes. CARB is not setting regulatory limits on VMT in the 2022 Scoping Plan; the authority to reduce VMT largely lies with state, regional, and local transportation, land use, and housing agencies, along with the Legislature and its budgeting choices.

Appendix E (Sustainable and Equitable Communities) elaborates on reasons for reducing VMT and identifies a series of policies that, if implemented by various responsible authorities, could help to achieve the recommended VMT reduction trajectory included in this Scoping Plan (and related mode share increases for transit and active transportation). These policies aim to advance four strategic objectives:

1. Align current and future funding for transportation infrastructure with the state's climate goals, preventing new state-funded projects from inducing significant VMT growth and supporting an ambitious expansion of transit service and other multimodal alternatives.
2. Move funding for transportation beyond the gasoline and diesel taxes and implement fuel-agnostic pricing strategies that accomplish more productive uses of the roadway network and generate revenues to further improve transit and other multimodal alternatives.
3. Deploy autonomous vehicles, ride-hailing services, and other new mobility options toward high passenger-occupancy and low VMT-impact service models that complement transit and ensure equitable access for priority populations.
4. Encourage future housing production and multi-use development in infill locations and other areas in ways that make future trip origins and destinations

[337] U.S. Government Accountability Office. January 25, 2022. During COVID-19, Road Fatalities Increased and Transit Ridership Dipped. https://www.gao.gov/blog/during-covid-19-road-fatalities-increased-and-transit-ridership-dipped.
[338] American Public Transportation Association. APTA - Ridership Trends. https://transitapp.com/APTA.

closer together and create more viable environments for transit, walking, and biking.

The pace of change to reduce VMT must be accelerated. Certainly, structural reform will be challenging, but California has demonstrated time and again that it possesses the collective leadership and commitment to break away from ideas that no longer represent Californians' values and their aspirations for the many generations to come.

Strategies for Achieving Success

- Achieve a per capita VMT reduction of at least 25 percent below 2019 levels by 2030 and 30 percent below 2019 levels by 2045. [339]
- Reimagine new roadway projects that decrease VMT in a way that meets community needs and reduces the need to drive.
- Invest in making public transit a viable alternative to driving by increasing affordability, reliability, coverage, service frequency, and consumer experience.[340]
- Implement equitable roadway pricing strategies based on local context and need, reallocating revenues to improve transit, bicycling, and other sustainable transportation choices.[341]
- Expand and complete planned networks of high-quality active transportation infrastructure.[342]
- Channel the deployment of autonomous vehicles, ride-hailing services, and other new mobility options toward high passenger-occupancy and low VMT-impact service models that complement transit and ensure equitable access for priority populations.
- Streamline access to public transportation through programs such as the California Integrated Travel Project.
- Ensure alignment of land use, housing, transportation, and conservation planning in adopted regional plans, such as regional transportation plans (RTP)/ sustainable communities strategies (SCS), regional housing needs assessments (RHNA), and local plans (e.g., general plans, zoning, and local transportation plans), and develop tools to support implementation of these plans.

- Accelerate infill development and housing production at all affordability levels in transportation-efficient places, with a focus on housing for lower-income residents.

Clean Electricity Grid

Much of the state's success to date in reducing GHGs is due to decarbonization of the electricity sector as a result of the RPS, SB 100 implementation, and the Cap-and-Trade Program. Moving forward, a clean, affordable, and reliable electricity grid will serve as a backbone to support deep decarbonization across California's economy. Under this Scoping Plan, the role of electricity in powering the economy will grow in almost every sector.

In 2021, 70 percent of California electricity demand was served by in-state power plants totaling about 82 GW, with the rest coming from out-of-state imports.[343] Additionally, approximately 8 GW of customer solar photovoltaic capacity has been installed to date to help with in-state demand.[344] Figure 4-3 shows the breakdown of in-state and imported sources of electricity.

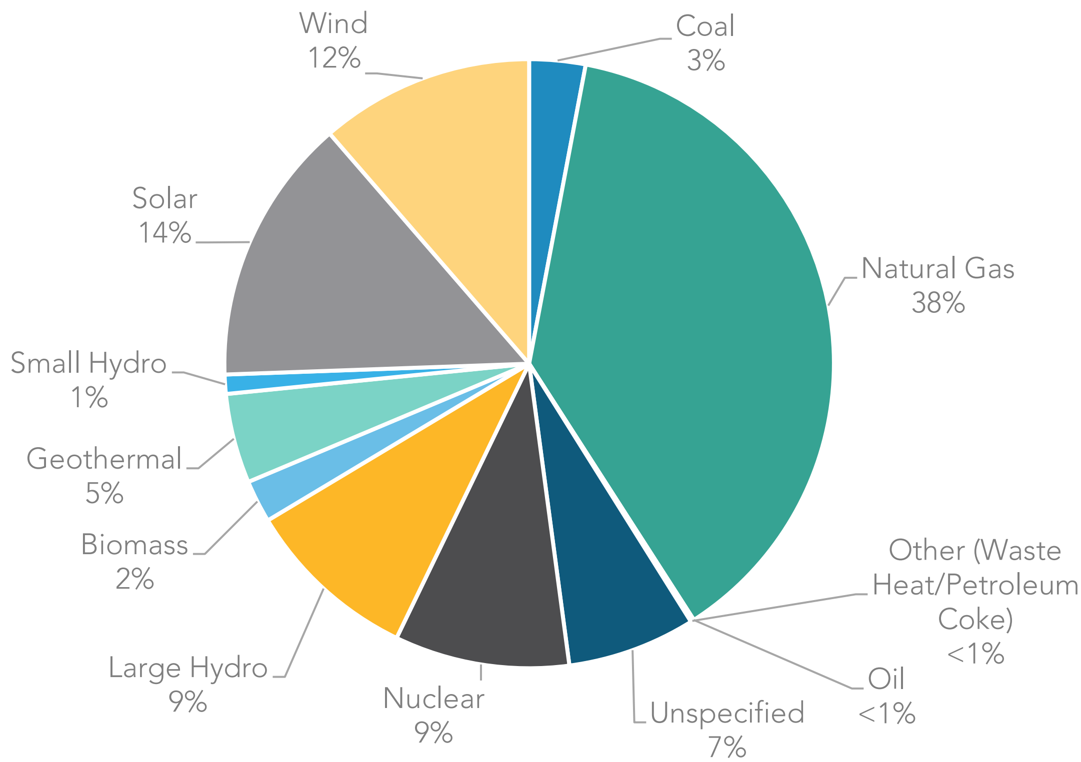
Data available at: https://www.energy.ca.gov/data-reports/energy-almanac/california-electricity-data/electric-generation-capacity-and-energy and CEC. 2021. Total System Electric Generation. Data available at: https://www.energy.ca.gov/data-reports/energy-almanac/california-electricity-data/2021-total-system-electric-generation. Capacity values are nameplate capacity from sources 1 MW and larger.
[344] CEC. 2021. *SB 100 Joint Agency Report Summary: Achieving 100% Clean Electricity in California, An Initial Assessment.* 10. https://www.energy.ca.gov/publications/2021/2021-sb-100-joint-agency-report-achieving-100-percent-clean-electricity.

Figure 4-3: 2021 total system electric generation (based on GWh)[345]



Note: Imports contributing to total system generation are comprised of 58% zero-carbon energy and 42% non-renewable and unspecified energy. Percentages do not add to exactly 100 due to rounding.

In 2021, about 48 percent of electricity generation serving California came from non-renewable and unspecified[346] resources, while 52 percent came from renewable and zero-carbon resources. The state's Strategic Reliability Reserve, established in AB 205 to provide additional reliability insurance during extreme events, may make three of the fossil gas-fired OTC plants planned for retirement available to support the grid on a limited basis after 2023. The state also adopted legislation to facilitate extension of the Diablo Canyon Nuclear Power Plant for five years beyond its 2025 planned closure.[347] At the

345 *Total system generation* is the sum of all utility-scale, in-state generation, plus net electricity imports. CEC. 2021 Total System Electricity Generation. https://www.energy.ca.gov/data-reports/energy-almanac/california-electricity-data/2021-total-system-electric-generation.
346 *Unspecified power* refers to electricity that is not traceable to a specific generating facility, such as electricity traded through open market transactions. It typically consists of a mix of resources and may include renewables.
347 In accordance with SB 846 (Dodd, Chapter 239, Statutes of 2022).

same time, the state continues to rapidly expand deployment of clean energy generation and storage resources and plan for increased electrification.[348] This is critical to reducing GHG emissions and addressing the long-term impacts of climate change.

Climate change is causing unprecedented stress on California's energy system—driving high demand and constraining supply. Heat, drought, and wildfires can both reduce electricity supply from reductions in hydropower generation and impacts on generation and transmission performance, and increase demand, especially in the evening hours when solar generation is declining.

California has experienced three straight years of energy reliability challenges, including a multi-day extreme heat event across the western United States with temperatures up to 20 degrees above normal in California, resulting in rotating outages in August 2020. In 2021, heat waves in June prompted a Grid Warning and the onset of emergency conditions, and the Bootleg Fire caused the loss of one transmission line, reducing import capability by 3,000 megawatts into the California Independent System Operator (CAISO) balancing authority area. And from August 31–September 9, 2022, a 10-day extreme heat event resulted in an unprecedented, sustained period of high peak loads in the CAISO system, averaging 47,000 MW and maxing at an all-time record of over 52,000 MW on September 6. The Western region also hit its record peak load on September 6, at 167.5 GW.

Reliable electricity service was maintained throughout the 10-day September 2022 heat wave in spite of the record breaking load levels. Factors that contributed to this outcome include the installation of over 3,500 MW of lithium-ion battery storage since summer 2020, enhanced coordination and communication within and outside of California, engagement with customer groups and other stakeholders, state actions to reduce load during critical times, and the additional capacity provided through the Strategic Reliability Reserve and other new state programs authorized in the 2022 Budget to provide load reduction and support the grid in extreme events. CEC, CPUC, CAISO, and the California Department of Water Resources will continue to build out strategies to enhance reliability in light of the increasing and compounding impacts of climate change on the electricity system.

[348] In June 2021, the CPUC adopted D.21-06-035 directing procurement of 11,500 MW of new capacity between 2023 and 2026 to ensure systemwide electric reliability as Diablo Canyon and several OTC facilities retire. It requires that, out of the 11,500 MW, 2,500 MW must be from zero-emission resources. Additionally, 2,000 MW must be long lead-time resources, with at least 1,000 MW of long-duration storage and 1,000 MW of firm capacity with zero on-site emissions or that qualifies under the RPS eligibility requirements.

While the electricity sector is using less fossil fuel due to increasing amounts of renewables,[349] existing fossil gas generation will continue to play a critical role in grid reliability until other clean, dispatchable alternatives can be deployed at scale. The integration of greater amounts of variable renewable generation resources[350] is changing power system planning and operations, and system operators need resources with flexible attributes to balance shifting supply and demand.

High levels of solar generation can lead to instances of oversupply during the middle of the day, when the sun is brightest.[351] In the evening hours, as the sun is setting, solar generation declines to zero and customers with solar generation shift back to the electric grid. In hot weather, customer demand remains high well into the summer evening period to power air conditioning, which can lead to reliability challenges.[352]

Figure 4-4 shows the energy sources used throughout one summer day in July. Renewable energy is consistent during the middle of the day, but it cannot meet all of the evening demand in the gray area. As illustrated in the figure, fossil gas generation is currently a resource that is typically ramped up to meet this evening demand as solar production begins to drop and electrical loads increase To help address this challenge, resource installations that pair solar with batteries, as well as a greater amount of battery build-out, are coming online currently and over the next five years. Nevertheless, the state's electricity grid is expected to be stressed further in the coming years by heat waves, drought, wildfires, and the growing intermittent power supply from renewables. California must accelerate deployment of diverse clean energy resources to maintain reliability and affordability in the face of climate change.

---

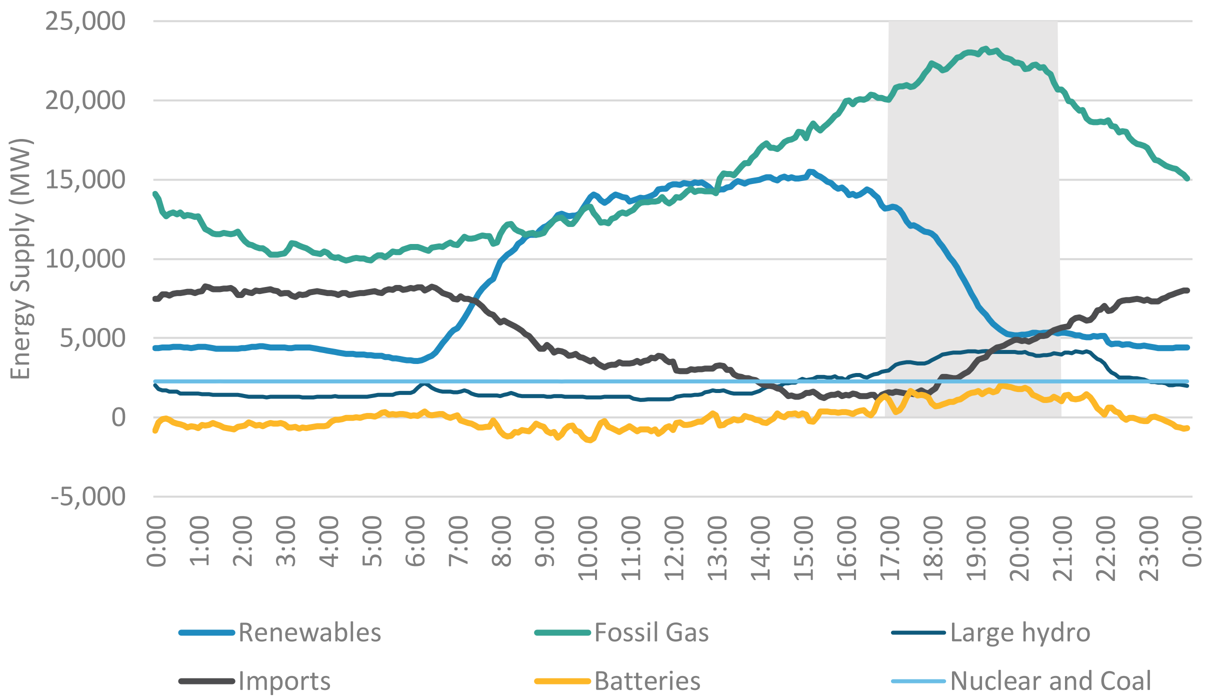
[349] CARB. 2022. *California Greenhouse Gas Emissions for 2000 to 2020.* https://ww2.arb.ca.gov/sites/default/files/classic/cc/inventory/2000-2020_ghg_inventory_trends.pdf.

[350] A *variable renewable generation resource* is a renewable source of electricity that is non-dispatchable due to its fluctuating nature and only produces electricity when weather conditions are right, such as when the sun is shining or the wind is blowing. Renewable resources that can be controlled and are dispatchable include geothermal, biomass, and dam-based hydroelectric power.

[351] *Brightness* is used colloquially here; solar energy depends on insolation (e.g., sun-hours), which is the measurement of cumulative solar energy that reaches an area over a period of time.

[352] CAISO, CPUC, and CEC. 2021. *Final Root Cause Analysis: Mid-August 2020 Extreme Heat Wave.* http://www.caiso.com/Documents/Final-Root-Cause-Analysis-Mid-August-2020-Extreme-Heat-Wave.pdf.

Figure 4-4: Electricity supply trend by resource for a California summer day, July 2022



Sector Transition

Decarbonizing the electricity sector is a crucial pillar of this Scoping Plan. It depends on both using energy more efficiently and replacing fossil-fueled generation with renewable and zero carbon resources, including solar, wind, energy storage,[353] geothermal, biomass, and hydroelectric power. The RPS Program[354] and the Cap-and-Trade Program continue to incentivize dispatch of renewables over fossil generation to serve state demand. SB 100 increased RPS stringency to require 60 percent renewables by 2030 and for California to provide 100 percent of its retail sales[355] of electricity from renewable and zero-carbon resources by 2045. Furthermore, SB 1020 has added interim targets to

---

[353] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, NF1, NF2. *finalejacrecs.pdf (arb.ca.gov)*.

[354] The CEC estimates that 36 percent of California's 2019 retail electricity sales was served by RPS-eligible renewable resources (see CPUC. 2021. CPUC Perspectives on Electric Sector Decarbonization. *https://ww2.arb.ca.gov/sites/default/files/2021-11/CPUC-sp22-electricity-ws-11-02-21.pdf*).

[355] SB 100 speaks only to retail sales and state agency procurement of electricity. The *2021 SB 100 Joint Agency Report* interprets this to mean that other loads—wholesale or non-retail sales and losses from storage and transmission and distribution lines—are not subject to the law.

SB 100's policy framework to require renewable and zero-carbon resources to supply 90 percent of all retail electricity sales by 2035 and 95 percent of all electricity retail sales by 2040; the governor has asked the CEC to establish a planning goal of at least 20 GW of offshore wind by 2045; and the governor directed that state agencies plan for an energy transition that avoids the need for new fossil gas capacity to meet California's long-term energy goals.[356] In addition to grid-level resources, state efforts have supported rapid growth of the distributed solar industry through key actions like the California Solar Initiative (SB 1, Murray, Chapter 132, Statues of 2006).[357] Steps to commercialize microgrids powered by clean resources[358] are also being examined as part of SB 1339 (Stern, Chapter 566, Statutes of 2018).[359]

California also continues to advance its appliance and building energy efficiency standards to reduce growth in electricity consumption and meet the SB 350 goal to double statewide energy efficiency savings in electricity and fossil gas end uses[360] by 2030. In 2018, the CEC adopted a building energy efficiency code requiring most new homes to have solar photovoltaic systems[361] (or be powered by a solar array nearby) starting January 1, 2020. In 2019, California reached the milestone of 1 million solar rooftop installations.

Increased transportation and building electrification and continued policy commitment to behind-the-meter solar and storage will continue to drive growth of microgrids and other distributed energy resources (DER).[362] The CPUC's High-DER proceeding is examining how to prepare the electric grid for a high DER future by determining how to integrate

---

[356] Newsom, Gavin. July 22, 2022. Letter from Governor Newsom to CARB Chair Liane Randolph. *https://www.gov.ca.gov/wp-content/uploads/2022/07/07.22.2022-Governors-Letter-to-CARB.pdf*.

[357] More information on the program, which closed in 2016, can be found on the CPUC website, including annual program assessment reports, at: *https://www.cpuc.ca.gov/industries-and-topics/electrical-energy/demand-side-management/california-solar-initiative*.

[358] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, In part (NF2, NF13). *finalejacrecs.pdf (arb.ca.gov)*.

[360] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, NF1, ES1. *finalejacrecs.pdf (arb.ca.gov)*.

[361] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, NF2. *finalejacrecs.pdf (arb.ca.gov)*.

[362] Distributed energy resources include rooftop solar and other distributed renewable generation resources, energy storage, electric vehicles, time variant and dynamic electric rates, flexible load management, demand response, and energy efficiency technologies.

millions of DERs within the distribution grid to maximize societal and ratepayer benefits from DERs while ensuring grid reliability and affordable rates.[363]

SB 350 also aims to connect long-term planning for electricity needs with the state's climate targets. This is primarily accomplished through CARB's establishment of 2030 GHG emissions targets for the electricity sector in general and for each electricity provider, which inform the CPUC and publicly owned utilities' integrated resource planning. A GHG planning target range of 30 to 53 MMTCO_2e—informed by the 2017 Scoping Plan—was originally developed and adopted by CARB in 2018. In its 2021 IRP planning cycle, the CPUC adopted a 38 MMT GHG target for the electricity sector in 2030, which drops to 35 MMT in 2032.[364]

The Scoping Plan Scenario incorporates SB 350's energy efficiency doubling goal, aligns with the CPUC's IRP 2030 GHG target and latest GHG emissions benchmarks through 2035,[365] the governor's 20 GW offshore wind and no new gas generation[366] goals, and SB 100's 2030 RPS and 2045 zero-carbon retail sales targets to reduce dependence on fossil fuels in the electricity sector by transitioning substantial energy demand to renewable and zero-carbon resources.[367] As described in Chapter 2, CCS is applied in limited sectors, including on 16.7 MMT of CO_2 from existing fossil gas electricity generation in 2045, to ensure the state achieves the 85 percent reduction in anthropogenic emissions required by AB 1279. Continued transition to renewable and

---

[363] The High-DER proceeding is one of four "anchor" proceedings in the CPUC's DER Action Plan 2.0 and is within the Action Plan's infrastructure track. Information on the High-DER proceeding is available at: https://www.cpuc.ca.gov/industries-and-topics/electrical-energy/infrastructure/distribution-planning. The Action Plan can be accessed at: https://www.cpuc.ca.gov/about-cpuc/divisions/energy-division/der-action-plan.

[364] The February 10, 2022, Decision 22-02-004 by the CPUC adopts the 2021 Preferred System Plan, completing the 2019–21 IRP cycle. https://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M451/K412/451412947.PDF. The Decision requires load serving entities to submit plans in the next IRP cycle detailing how they will meet their proportionate share of a 30 MMT electric sector target, as well as a 38 MMT GHG target.

[365] June 15, 2022, Administrative Law Judge's Ruling for 2022 integrated resource plan filings specifies the need for GHG targets to plan for in 2035 to continue progress toward the 2045 goal. The ruling proposes a straight-line projection from the GHG planning target for 2030. Corresponding to the adopted Preferred System Plan in D.22-02-004, 38 MMT in 2030 leads to a target of 30 MMT in 2035. https://docs.cpuc.ca.gov/PublishedDocs/Efile/G000/M485/K625/485625915.PDF.

[366] The governor's July 22, 2022, letter specifies no new gas generation but does not place any constraints on existing gas resources. Therefore, for purposes of RESOLVE electricity sector modeling, existing gas capacity is an available resource that is able to be reduced over time based on announced retirements or if selected for retirement by the model.

[367] CARB. 2021. PATHWAYS Scenario Modeling: 2022 Scoping Plan Update – Attachment B: Generation Technologies to be included in Modeling. https://ww2.arb.ca.gov/sites/default/files/2021-12/Revised_2022SP_ScenarioAssumptions_15Dec.pdf.

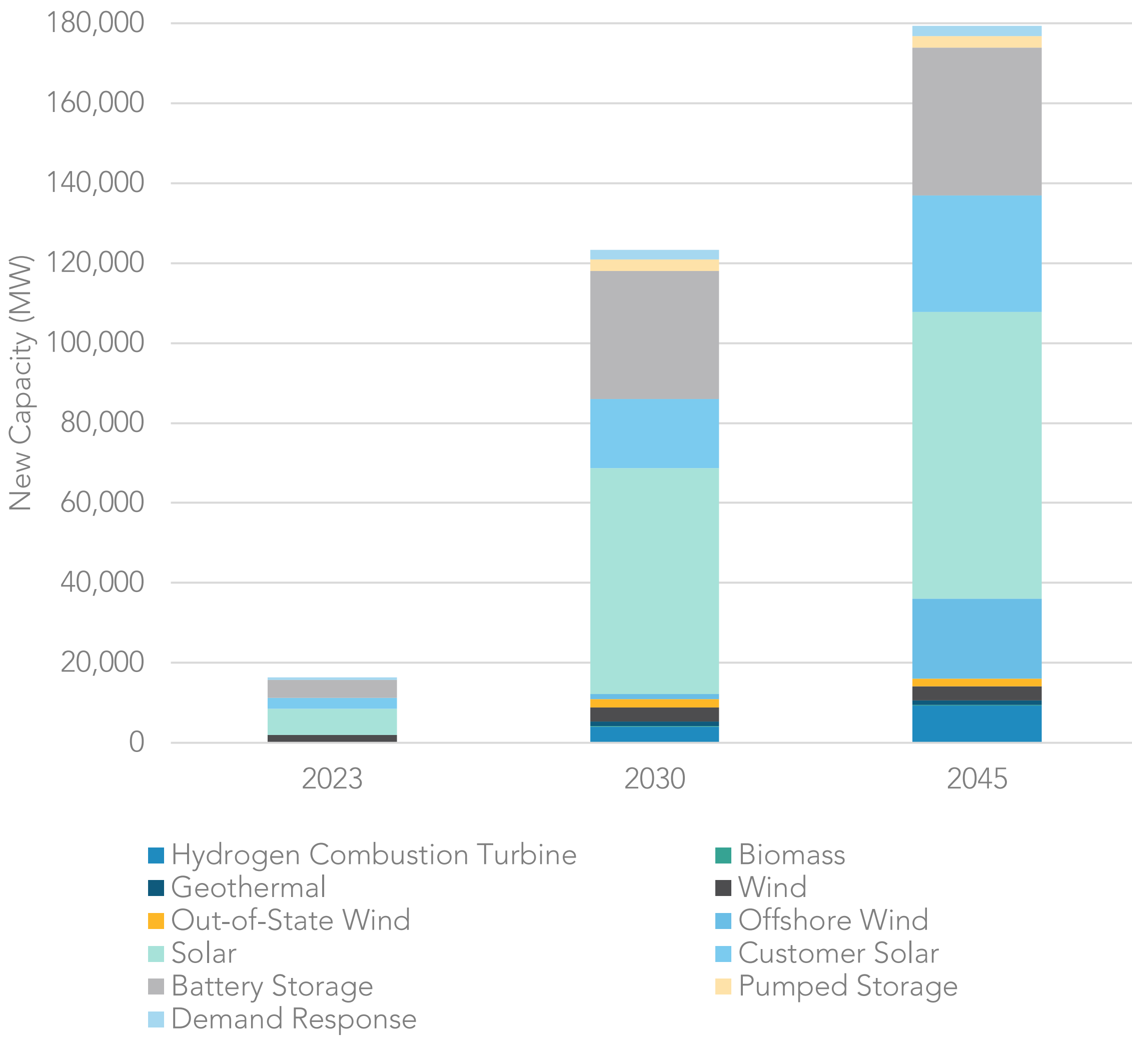
zero-carbon electricity resources will enable electricity to become a zero-carbon substitute for fossil fuels across the economy.

Figure 4-5 shows the modeled resource capacity to meet the SB 100 retail sales target.[368] Energy efficiency moderates some of the need for additional electricity generation. However, that is quickly surpassed by growing electricity demand of 26 percent by 2030 and 76 percent by 2045 compared to today (2022) from increased population and electrification of other sectors, as shown in Figure 4-6. The estimated resource build needed to meet this level of demand amounts to approximately 72 GW of utility solar[369] and 37 GW of battery storage by 2045. Annual build rates (over the 2022–2035 period) for the Scoping Plan Scenario will need to increase by about 60 percent and over 700 percent for utility solar and battery storage, respectively, compared to historic maximum rates.[370] To reach the 2045 target, the state will need to quadruple its current level of wind and solar capacity. This does not include capacity associated with hydrogen production nor mechanical CDR, which was modeled off-grid; assuming hydrogen production via electrolysis, this would roughly be equivalent to an additional 10 GW[371] of solar generation needed in 2045, and an additional 64 GW of solar generation for direct air capture in 2045. The scale of solar and battery build rates needed could be reduced through the commercialization of new zero-carbon technologies.

---

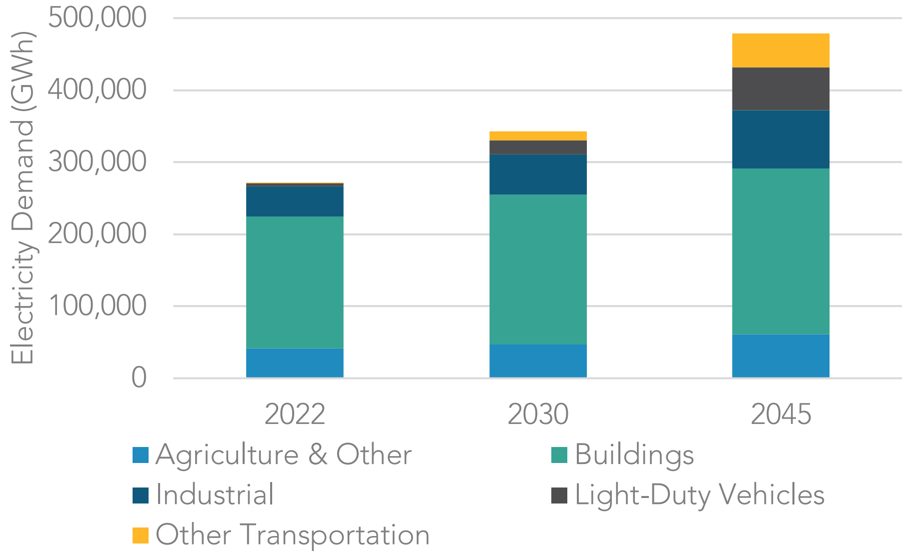
[368] SB 846 requires that load-serving entities exclude energy, capacity, or any attribute from the Diablo Canyon power plant in their resource plans. The Scoping Plan Scenario excludes energy, capacity, or any attribute from the Diablo Canyon power plant after the prior planned retirement date of 2025.
[369] The amount of additional customer solar included in the Scoping Plan Scenario is 29,208 MW by 2045.
[370] E3. 2022. CARB Scoping Plan: AB32 Source Emissions Final Modeling Results. PowerPoint. *https://ww2.arb.ca.gov/sites/default/files/2022-11/SP22-MODELING-RESULTS-E3-PPT.pdf*. Build rates are from EIA data historical builds in the 2011–2021 time frame.
[371] The estimate does not include hydrogen production assumed to be produced with bioenergy with carbon capture and storage (BECCS) and steam methane reforming (SMR).

Figure 4-5: Projected new electricity resources needed by 2045 in the Scoping Plan Scenario[372]



[372] See https://ww2.arb.ca.gov/sites/default/files/2022-11/2022-sp-PATHWAYS-data-E3.xlsx for the capacity build-out by resource type.

Figure 4-6: Electric loads in 2022, 2030 and 2045 for the Scoping Plan Scenario[373]



This transformation will drive investments in a large fleet of generation and storage resources but will also require significant transmission to accommodate these new capacity additions. Transmission needs include high-voltage lines to access out-of-state resources and major in-state generation pockets. In consideration of typical 8- to 10-year lead times for many projects, the CAISO published its first 20-Year Transmission Outlook to inform transmission planning focused on meeting the needs identified through the 2021 SB 100 Joint Agency Report process. The outlook calls for significant transmission development to access offshore wind and out-of-state wind and reinforce the existing CAISO footprint at an estimated cost of $30.5 billion.[374]

Presently, fossil gas power plants provide about 75 percent of the flexible capacity for grid reliability as more renewable power enters the system. Moving forward, other resources such as storage and demand-side management are essential to maintain reliability with high concentrations of renewables. Hydrogen produced from renewable resources and renewable feedstocks can serve a dual role as a low-carbon fuel for existing combustion turbines or fuel cells, and as energy storage for later use. Reliability

---

[373] *Other Transportation* includes all non-light-duty vehicles and reflects electrification of modes like passenger and freight rail, aviation, and ocean-going vessels.
[374] CAISO. 2022. *20 Year Transmission Outlook.* http://www.caiso.com/InitiativeDocuments/20-YearTransmissionOutlook-May2022.pdf.

also can be supported through increased coordination and markets in the interconnected western power grid; this is already helping to better integrate renewables.[375]

Strategies for Achieving Success

- Use long-term planning processes (Integrated Energy Policy Report, IRP, CAISO Transmission Planning Process, AB 32 Climate Change Scoping Plan) to support grid reliability and expansion of renewable and zero-carbon resource and infrastructure deployment.
- Complete systemwide and local reliability assessments across CAISO and other balancing authority areas, using realistic assumptions for land use, build rates, statewide and distribution system level constraints, and energy needs. Such assessments should be completed before state agencies update their electricity sector GHG targets.
- Prioritize actions to mitigate impacts to electricity reliability and affordability and provide sufficient flexibility in the state's decarbonization roadmap for adjustments as may be needed.
- Facilitate long lead-time resource development through the IRP and the SB 100 interagency process and through technology development and demonstration funding[376] that includes resources such as long-duration energy storage and hydrogen production.
- Continue coordination between energy agencies and energy proceedings to maximize opportunities for demand response.
- Continue to explore the benefits of regional markets to enhance decarbonization, reliability, and affordability.
- Address resource build-out challenges, including permitting, interconnection, and transmission network upgrades.
- Explore new financing mechanisms and rate designs to address affordability.[377]
- Per SB 350, double statewide energy efficiency savings in electricity and fossil gas end uses by 2030, through a combination of energy efficiency and fuel substitution actions.[378]
- Per SB 100 and SB 1020, achieve 90 percent, 95 percent, and 100 percent

renewable and zero-carbon retail sales by 2035, 2040, and 2045, respectively.

- Evaluate and propose, as needed, changes to strengthen the Cap-and-Trade Program.
- Target programs and incentives to support and improve access to renewable and zero-carbon energy projects (e.g., rooftop solar, community owned or controlled solar or wind, battery storage, and microgrids) for communities most at need, including frontline, low-income, rural, and indigenous communities.[379]
- Prioritize public investments in zero-carbon energy projects to first benefit the most overly burdened communities affected by pollution, climate impacts, and poverty.[380]

Sustainable Manufacturing and Buildings

Fossil gas is the primary gaseous fossil fuel used to produce heat at industrial facilities, as well as in residential and commercial buildings. In buildings, space and water heating, cooking, and clothes drying all rely on gaseous fuels today. Industrial processes that require heat for conventional boilers and other processes also rely on gaseous fuels. Refineries rely on fossil gas and other gaseous fossil fuels, like liquefied petroleum gas and refinery fuel gas, and fossil gas is also used to generate electricity, as discussed earlier.

Gaseous fossil fuel use can be displaced by four primary alternatives: zero-carbon electricity, solar thermal heat, hydrogen, and biogas/biomethane. Displacing gaseous fossil fuel use can yield indoor air quality benefits, protect public health and property from unexpected fossil gas leaks, and reduce short-lived climate pollutants, which are many times more potent in affecting climate change than CO_2. The Scoping Plan Scenario reduces dependence on fossil gas in the industrial and building sectors by transitioning substantial energy demand to alternative fuels. Reducing fossil gas combustion also will help toward achieving our air quality and equity goals by reducing pollution in neighboring areas and communities. In addition, reduced dependence on gasoline and diesel in the transportation sector diminishes the need for gaseous fossil fuels to support oil and gas production and petroleum refining operations as those are phased down relative to the demand.

Sector Transition

Industry

California's industrial sector contributes significantly to the state's economy, with a total output from manufacturing in 2019 of $324 billion (10.4 percent of the state total)[381] and employment of 1,222,000 manufacturing jobs (7.6 percent of the total state workforce).[382] California industry includes a diverse range of facilities, including cement plants, refineries, glass manufacturers, oil and gas producers, paper manufacturers, mining operations, metal processors, and food processors. Combustion of fossil gas, other gaseous fossil fuels, and solid fossil fuels provide energy to meet three broad industry needs: electricity, steam, and process heat. Non-combustion emissions result from fugitive emissions and from the chemical transformations inherent to some manufacturing processes. About 20 percent of the GHG emissions from the industrial sector are non-combustion emissions.

Decarbonizing industrial facilities depends upon displacing fossil fuel use with a mix of electrification, solar thermal heat, biomethane, low- or zero-carbon hydrogen, and other low-carbon fuels to provide energy for heat and reduce combustion emissions. Emissions also can be reduced by implementing energy efficiency measures and using substitute raw materials that can reduce energy demand and some process emissions. Some remaining combustion emissions and some non-combustion CO_2 emissions can be captured and sequestered. The strategy employed will depend on the industrial subsector and the specific processes utilized in production. The left side of Figure 4-7 illustrates the fuels used to meet industrial manufacturing energy demand in 2020. Industrial manufacturing energy demand needs to transition to the fuel mix shown for 2035 and 2045. The right side of Figure 4-7 illustrates the fuel mix needed to meet the energy demand of oil and gas extraction and petroleum refining operations for the same years. Energy demand in this portion of the industrial sector declines along with decreased demand for gasoline and diesel in the transportation sector. In both figures there is a continuing demand for fossil gas due to lack of non-combustion technologically feasible or cost-effective alternatives for certain industrial sectors. Policies that support decarbonization strategies like electrification, use of renewable energy, and transition to alternative fuels are needed.

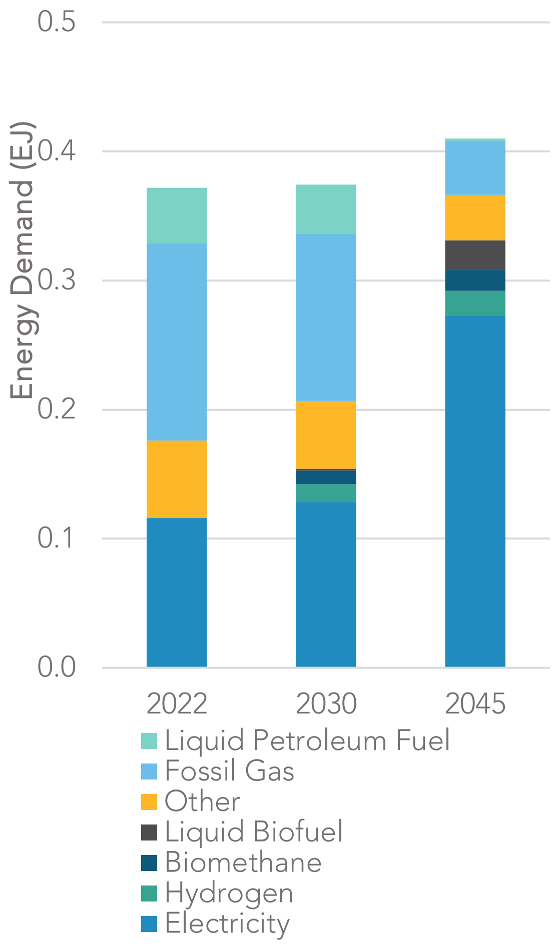
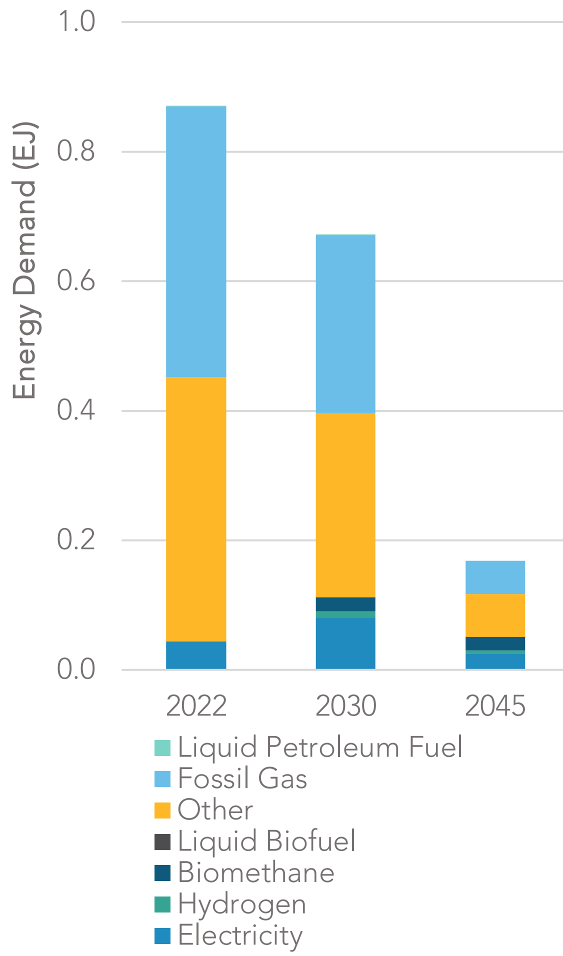
[382] NAM. 2021 California Manufacturing Facts. https://www.nam.org/state-manufacturing-data/2021-california-manufacturing-facts/.

Figure 4-7: Final energy demand in industrial manufacturing (left) and in oil and gas extraction and petroleum refining (right) in 2022, 2030, and 2045 in the Scoping Plan Scenario[383]





Electrification and solar thermal heat are best-suited to industrial processes that have relatively low heat requirements, such as food processors, paper mills, and industries that use low-pressure steam in their processes. Approaches could include replacing fossil gas boilers with electric boilers, process heaters with industrial electric heat pumps, steel forging furnaces with induction heaters, and implementing other sector-specific process electrification. Under current rate structures for industrial electricity and fossil gas in

[383] *Other* fuel in the industrial manufacturing sector is primarily coke and coal for cement production. *Other* fuel in the petroleum refining sector is primarily fossil gas associated with refining petroleum products.

California, most projects to electrify a fossil gas-powered industrial process will face operating cost barriers and potential reliability concerns. Microgrids powered by renewable resources and with battery storage are emerging as a key enabler of electrification and decarbonization at industrial facilities.

There are fewer commercially available and economically viable electrification options to replace industrial processes that require higher-temperature heat. For these processes, onsite combustion may continue to be needed, and decarbonization will require fuel substitution to hydrogen,[384] biomethane, or other low-carbon fuels. Fuel substitution and continued combustion will require monitoring and mitigation of any potential air quality impacts, especially in low-income and communities of color which already face disproportionate air pollution burdens. Industries in California with high heat needs include steel forging, glass manufacturing, and industries with calcination processes, such as manufacturing lime and cement.

Onsite emissions from cement manufacturing derive from two main sources: (1) fuel combustion to heat the kiln to a very high temperature and (2) process CO_2 emissions from the chemical transformation of limestone. Over 60 percent of emissions from the sector are process emissions unrelated to fuel use, and most emissions related to fuel use are from coal and petroleum coke combustion. Process emissions from cement manufacturing are significant and will continue even if the sector were to operate using only zero-carbon fuels; thus carbon capture and use/sequestration will be a likely component of any strategy to fully decarbonize cement manufacturing. There are additional opportunities to reduce GHG emissions from cement manufacturing via the combination of fuel-switching to low-carbon fuels (e.g., biomethane, municipal solid waste, biochar), increased blending of non-clinker materials, and efficiency improvements. High technological and economic barriers exist to electrifying kiln process heat at cement plants, as clinker production requires temperatures in excess of 1,500°C. There are potential decarbonization opportunities throughout the value chain of cement use, including in cement manufacturing, concrete mixing, and construction practices.[385] SB 596 (Becker, Chapter 246, Statutes of 2021), which was signed by Governor Newsom in September 2021, requires CARB to develop a comprehensive strategy for cement use in California to achieve a GHG intensity 40 percent below 2019 levels by 2035, and net-zero emissions by 2045.

Oil and gas extraction and refining make up over half of California's industrial GHG emissions. Reduced demand for transportation fossil fuels corresponds to reduced supply of fossil gas and other gaseous fossil fuels for refineries to produce these fuels. Some refining operations will continue to operate to produce fossil fuel for the remaining transportation energy demands, along with renewable diesel and sustainable aviation fuel, as discussed in the Transportation Sustainability section of this chapter.

Across industrial subsectors and processes, California facilities also could realize significant reductions in GHG emissions and energy-related costs by implementing advanced energy efficiency projects and tools.[386] While enhanced operation and maintenance practices are typical at industrial facilities, additional strategic energy management practices offer greater efficiency gains by focusing on setting goals, tracking progress, and reporting results.

Strategies for Achieving Success

- Maximize air quality benefits using the best available control technologies for stationary sources in communities most in need, including frontline, low-income, disadvantaged, rural, and tribal communities.[387]
- Prioritize alternative fuel transitions first in communities most in need, including frontline, low-income, disadvantaged, rural, and tribal communities.[388]
- Invest in research and development and pilot projects to identify options to reduce materials and process emissions along with energy emissions in California's industrial manufacturing facilities, leveraging programs like the CEC's Electric Program Investment Charge (EPIC).[389]
- Evaluate and propose, as needed, changes to strengthen the Cap-and-Trade Program.
- Support electrification with changes to industrial rate structures.
- Develop infrastructure for CCS and hydrogen production to reduce GHG emissions where cost-effective and technologically feasible non-combustion alternatives are not available.
- Implement SB 905.

- Establish markets for low-carbon products and recycled materials using Buy Clean California Act and other mechanisms relying on robust data
- Develop a net-zero cement strategy to meet SB 596 targets for the GHG intensity of cement use in California.
- Continue to leverage energy-efficiency programs, including the U.S. DOE's ENERGY STAR program,[390] U.S. DOE's Superior Energy Performance program,[391] and ISO 50001.[392]
- Evaluate and continue to offer incentives to install energy efficiency and renewable energy technologies through programs such as CPUC decisions as part of rulemaking R.19-09-009[393] and the CEC's Food Production Investment Program (FPIP) and EPIC programs.[394]
- Leverage low-carbon hydrogen programs, including the Bipartisan Infrastructure Law, for regional hydrogen hubs, hydrogen electrolysis, and hydrogen manufacturing and recycling.
- Evaluate the role of hydrogen in meeting GHG emission reductions, including policy recommendations regarding the use of hydrogen in California as required by SB 1075.
- Address cost barriers to promote low-carbon fuels for hard-to-electrify industrial applications.

Buildings

Buildings have cross-sector interactions that influence our public health and well-being and affect land use and transportation patterns, energy use, water use, and indoor and outdoor environments.[395] There are about 14 million existing homes and over 7.5 billion square feet of existing commercial buildings[396] in California. Fossil gas supplies about half of the energy consumed by end uses in these buildings. In addition to GHG emissions, fossil gas usage in buildings also produces CO_2, NOx, $PM_{2.5}$, and

[395] See Appendix F (Building Decarbonization).

[396] CEC. 2021. California Building Decarbonization Assessment. https://efiling.energy.ca.gov/GetDocument.aspx?tn=239311&DocumentContentId=72767.

formaldehyde.[397] Each year, about 120,000 new homes[398] and more than 100 million-square feet[399] of commercial buildings are newly constructed across California. These new buildings will represent between a third to half of the total building stock by mid-century.

Achieving carbon neutrality must include transitioning away from fossil gas in residential and commercial buildings, and will rely primarily on advancing energy efficiency while replacing gas appliances with non-combustion alternatives. This transition must include the goal of trimming back the existing gas infrastructure so pockets of gas-fueled residential and commercial buildings do not require ongoing maintenance of the entire limb for gas delivery. Blending low-carbon fuels such as hydrogen and biomethane into the pipeline further displaces fossil gas. Pipeline safety and reliability must be evaluated to accommodate low-carbon fuels. Figure 4-8 illustrates the energy Californians use in buildings at present compared with the Scoping Plan Scenario, which introduces alternatives to fossil gas. In that scenario almost 90 percent of energy demand is electrified by 2045, and the remaining energy demand is met with combustion of hydrogen, biomethane, and fossil gas.

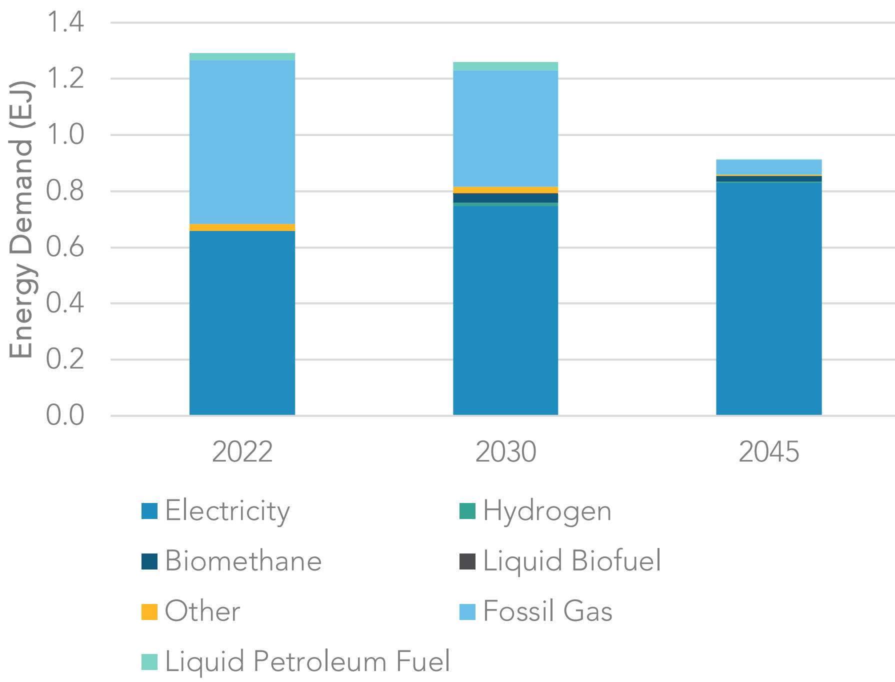
[399] Delforge, Pierre. August 11, 2021. California Forging Ahead on Zero Emission Buildings. Blog. NRDC. https://www.nrdc.org/experts/pierre-delforge/california-forging-ahead-zero-emission-buildings.

Figure 4-8: Final energy demand in buildings in 2022, 2030, and 2045 in the Scoping Plan Scenario[400]



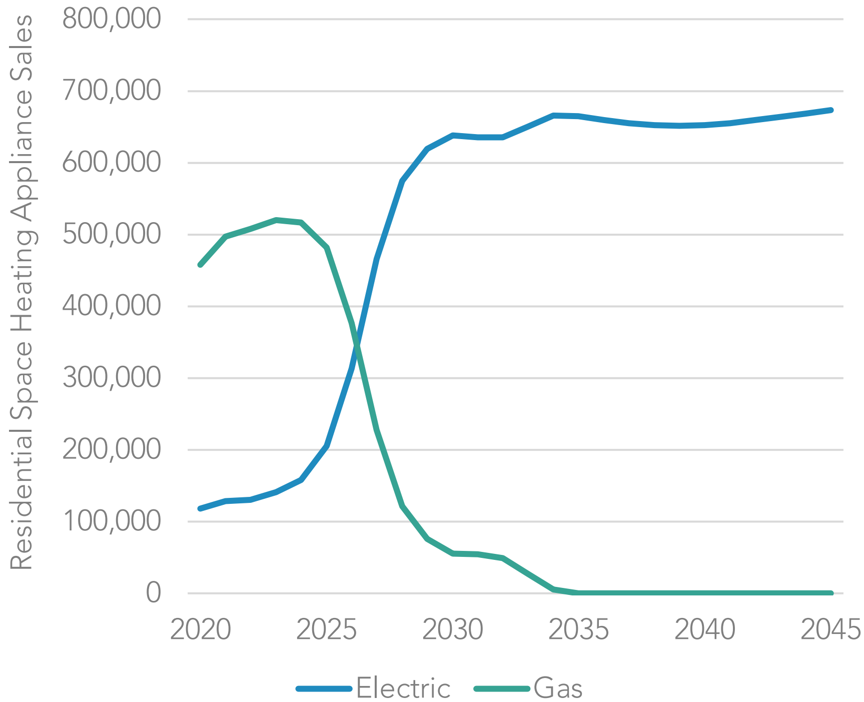
This transition is achieved when all new buildings constructed include non-combustion appliances, and appliances in existing buildings are replaced at the end of their useful life with non-combustion alternatives. Currently, electric alternatives, combined with the decarbonizing of California's grid, are the most effective alternatives, and the Scoping Plan Scenario modeled these alternatives. The Scoping Plan Scenario assumes three million all-electric and electric-ready homes by 2030 and seven million by 2035. Figure 4-9 illustrates the pace at which electric space heating appliance sales increase and gas space heating appliance sales decrease in residences in the Scoping Plan Scenario, such that by 2035 100 percent of residential home appliance sales are electric. By 2030 over six million electric heat pumps are installed statewide. The residential electric space heating appliance sales increases rapidly in the near term as new all-electric buildings are constructed and as existing buildings are renovated to utilize electric appliances. A similar transition is envisioned for other home appliances. Commercial buildings also will undergo a transition away from gas appliances to electric appliances, achieving 80 percent sales of all-electric appliances by 2035 and 100 percent by 2045. Appendix F (Building Decarbonization) describes a holistic policy approach to rapidly grow the

---

[400] *Other* fuel in the buildings sector is primarily liquid petroleum gas and waste heat.

number of zero emission appliances and buildings, to surmount the market barriers, and to prioritize an equitable transition for vulnerable communities.

Figure 4-9: Residential space heating appliance sales in the Scoping Plan Scenario



Strategies for Achieving Success

- Prioritize California's most vulnerable residents with the majority of funds in the new $922 million Equitable Building Decarbonization program, created through the 2022–2023 state budget. This would include residents in frontline, low-income, disadvantaged, rural, and tribal communities. This program is dedicated to a statewide direct-install building retrofit program for low-income households to replace fossil fuel appliances with electric appliances, energy-efficient lighting, and building insulation and sealing while also coordinating reductions in gas infrastructure in specific geographic areas.
- Achieve three million all-electric and electric-ready homes by 2030 and seven million by 2035 with six million heat pumps installed statewide by 2030.
- Expand incentive programs to support the holistic retrofit of existing buildings, especially for vulnerable communities.
- Ensure that incentive programs prioritize energy affordability and tenant protections, promote affordable and low-income household retrofits that improve habitability and reduce expenses, protect and empower small landlords and homeowners, address overlooked consumer groups, and pair decarbonization

with other critically needed renovation efforts to ensure that buildings support human health and are climate- and weather-resistant.[401]

- End fossil gas infrastructure expansion for newly constructed buildings.[402]
- Evaluate and propose, as needed, changes to strengthen the Cap-and-Trade Program.
- Strengthen California's building standards to support zero-emission new construction.
- Develop building performance standards for existing buildings.
- Adopt a zero-emission standard for new space and water heaters sold in California beginning in 2030, as specified in the 2022 State Strategy for the State Implementation Plan.
- Expand use of low-GWP refrigerants within buildings.
- Support electrification with changes to utility rate structures and by promoting load management programs.
- Increase funding for incentive programs and expand financing assistance programs focused on existing buildings and appliance replacements.
- Expand consumer education efforts to raise awareness and stimulate the adoption of decarbonized buildings and appliances, especially in vulnerable communities.
- Implement biomethane procurement targets for investor-owned utilities as specified in SB 1440 (Hueso, Chapter 739, Statutes of 2018) to reduce GHG emissions in remaining pipeline gas and reduce methane emissions from organic waste.

Carbon Dioxide Removal and Capture

Climate Change 2022: Mitigation of Climate Change,[403] a report by the IPCC released in early 2022, states "The deployment of CDR to counterbalance hard-to-abate residual emissions is unavoidable if net zero CO_2 or GHG emissions are to be achieved. The scale and timing of deployment will depend on the trajectories of gross emission reductions in different sectors. Upscaling the deployment of CDR depends on developing effective approaches to address feasibility and sustainability constraints especially at large scales." In line with that report, this Scoping Plan considers CDR as a complement to technologically feasible and cost-effective GHG emissions mitigation, and the size of its role will depend on the degree of success in reducing GHG emissions at the source across the economy.[404] The modeling shows that emissions from the AB 32 GHG Inventory sources will continue to persist even if all fossil related combustion emissions are phased out. These residual emissions must be compensated for to achieve carbon neutrality. Options for CDR include both sequestration in natural and working lands and mechanical approaches like direct air capture. Chapter 2 provides estimates on how much CO_2 removal is possible by our natural and working lands and how much must be removed by mechanical CDR.

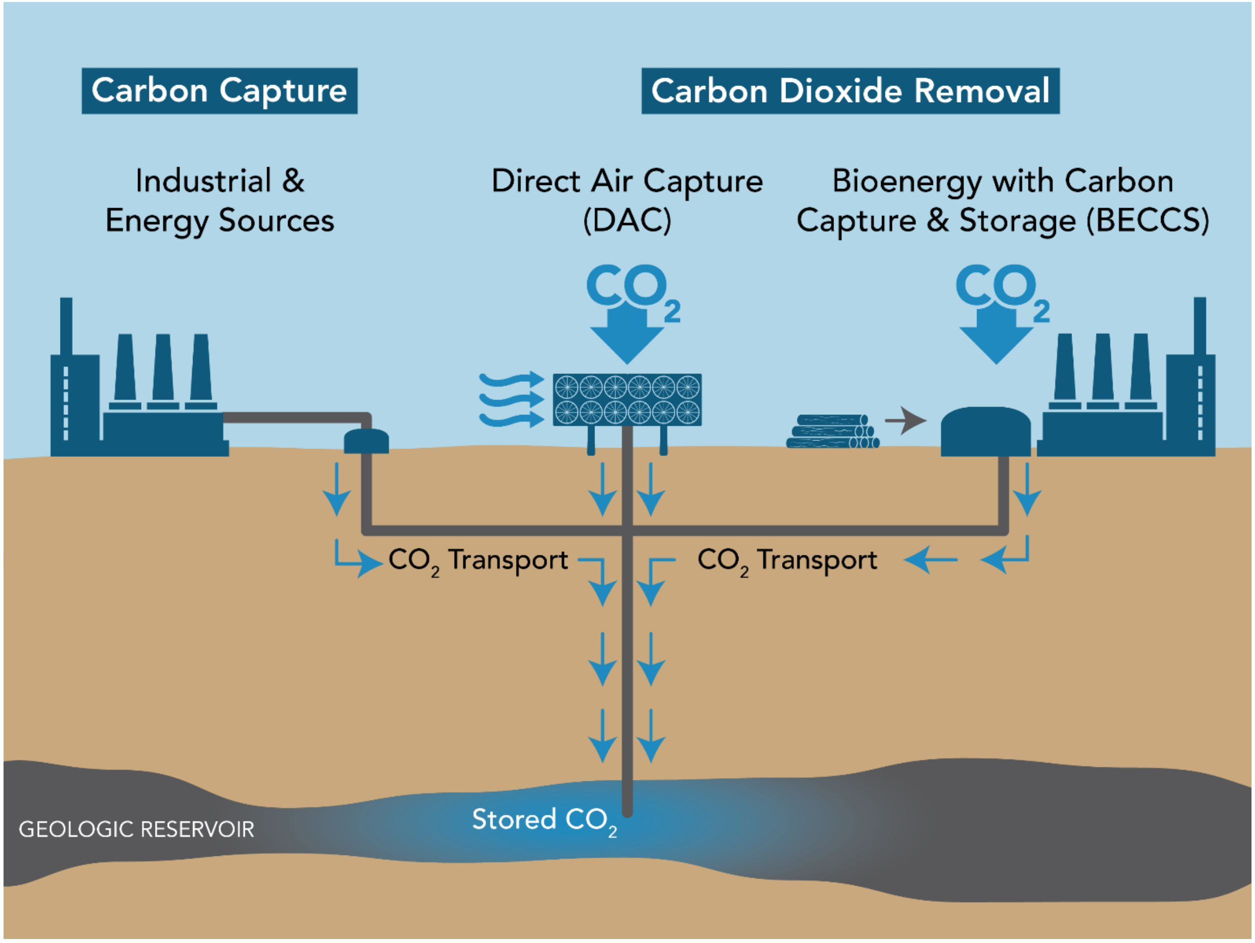
CCS, which is carbon capture from anthropogenic point sources, is described in Chapter 2 and involves capturing carbon from a smokestack of an emitting facility. Direct air capture, on the other hand, captures carbon directly from the atmosphere. Direct air capture technologies, unlike CCS, are not associated with any particular point source.

For this section, *carbon management* refers to the capture, movement, and sequestration of CO_2 through mechanical solutions for both capture at point sources and direct removal from the atmosphere through direct air capture.[405] Enabling policies and regulations across each of these steps are necessary for individual projects, and on a broader scale, for delivering reductions in support of the state's carbon neutrality and long-term carbon-negative goals. Figure 4-10 provides a graphic of the typical carbon management infrastructure.

---

[403] IPCC. 2022. *Climate Change 2022: Mitigation of Climate Change.* https://www.ipcc.ch/report/sixth-assessment-report-working-group-3/.
[404] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, F4.7. finalejacrecs.pdf (arb.ca.gov).
[405] CDR through natural and working lands is discussed in Chapter 2 and later in this chapter.

Figure 4-10: Carbon management infrastructure



Carbon dioxide removal directly from the atmosphere itself refers to a suite of carbon negative technologies that can be used to draw down ongoing and historical carbon emissions already in the atmosphere. Some CO_2 removal technologies leverage the abilities of both natural photosynthesis and mechanical removal by using biomass wastes as inputs to make low- or zero-carbon energy or fuels, all while capturing and storing produced CO_2.

Captured CO_2 from point sources or from the atmosphere is permanently stored in specialized geologic formations, typically half a mile or more underground. A recent Stanford University study estimated the state's commercial storage potential is nearly 70,000 million metric tons of CO_2, even when excluding oil and gas reservoirs.[406] California is well-positioned because few other places on the West Coast are suitable for

[406] Stanford Center for Carbon Storage. Opportunities and Challenges for CCS in California. https://sccs.stanford.edu/california-projects/opportunities-and-challenges-for-CCS-in-California.

geologic storage at scale. To inform discussion around CO_2 removal, CARB held two full-day workshops exploring the types of options for carbon capture and geologic storage and utilization in products.[407,408,409]

The modeling results provided in Chapter 2 demonstrate the targeted need for CCS on large facilities such as refineries and cement. The CCS numbers do not include the potential additional applications for producing hydrogen with biomethane, other manufacturing, electricity, or other bioenergy. If CCS is not deployed, those emissions would be released directly into the atmosphere and instead need to be addressed through CDR to achieve carbon neutrality. Although a study finds California has 76 existing electricity and industrial facilities that are suitable candidates for CCS retrofit,[410] this Scoping Plan proposes a targeted role for this technology such that it would only be used to address sectors where non-combustion options are not technologically feasible or cost-effective at this time, to the extent needed to achieve the 85 percent reduction in anthropogenic emissions as called for in AB 1279. In future updates to the Scoping Plan, there may be additional options for technologically feasible or cost-effective technologies that may be deployed, which would further reduce the need for CCS and CDR except in situations to address historical GHG emissions.

Recognizing the need for carbon capture and utilization sequestration and removal, the Legislature passed, and the governor signed, SB 905. It includes several key requirements in the development of the state's Carbon Capture Removal, Utilization, and Storage Program. The following is a summary of the work to be completed to establish and administer this program. Many of these steps will address the need to evaluate the safety and efficacy of actions to support carbon removal, sequestration, and transfer via pipelines. Note that not all of these actions are under CARB's authority.

- Review technology to evaluate efficacy, safety, viability of CCUS/CDR methodologies.
- Develop monitoring and reporting requirements and schedules.
- Develop a unified permit application.
- Develop financial responsibility requirements.
- Develop a centralized public database for project status.

- Consult with CNRA on pore space requirements as CNRA develops a framework for pore space governing agreements.
- Establish a Geologic Carbon Sequestration Group to identify suitable injection well locations, subsurface monitoring, and potential hazards that may require suspension of injection.

SB 905 also has requirements for project developers such as to develop monitoring plans and to avoid any adverse health and environmental impacts at the carbon capture location—or mitigation of unavoidable impacts as required under existing requirements. For the site of injection, there are requirements for site stability, monitoring, and reporting plans. SB 905 also bans CCS with enhanced oil recovery in California and prohibits the transfer of CO_2 via pipeline until the U.S. Department of Transportation's Pipelines and Hazardous Materials Safety Administration (PHMSA) completes its current rulemaking to update existing CO_2 pipeline safety requirements.

An often-cited example of pipeline concerns involves a CO_2 pipeline in Mississippi. On February 22, 2020, a CO_2 pipeline operated by Denbury Gulf Coast Pipelines LLC (Denbury) ruptured in proximity to the community of Satartia, Mississippi. The rupture followed heavy rains that resulted in a landslide, creating excessive axial strain on a pipeline weld (DOT 2022). The combination of weather and topography resulted in a slower dissipation of the gas. The pipeline was also carrying hydrogen sulfide, a flammable and toxic gas. The pipeline failed on a steep embankment, which had recently subsided. Heavy rains are believed to have led to a landslide, which created axial strain on the pipeline and resulted in a full circumferential girth weld failure. The PHMSA investigation also revealed several contributing factors to the accident, including but not limited to: Denbury not addressing the risks of geohazards in its plans and procedures, underestimating the potential affected areas that could be impacted by a release in its CO_2 dispersion model, and not notifying local responders to advise them of a potential failure.

As the Satartia example highlights, appropriate pipeline safety and environmental standards in California are critical to minimize any risks from CO_2 transport in the future. As such, SB 905 also tasks CNRA, in consultation with the Public Utilities Commission, to, no later than February 1, 2023, provide a proposal to the Legislature to establish a state framework and standards for the design, operation, siting, and maintenance of intrastate pipelines carrying CO_2 fluids of varying composition and phase to minimize the risk posed to public and environmental health and safety. The recommended framework shall be designed to minimize risk to public health and environmental health and safety, to the extent feasible. Because SB 905 prohibits the transfer of CO_2 via pipeline until the PHMSA completes its current rulemaking to update existing CO_2 pipeline safety requirements, CCS or CDR projects that would require a pipeline to transfer CO_2 are not feasible at this time within California.

Ultimately, and in accordance with SB 905, the merits of each CCS or CDR project must be evaluated on a case-by-case basis.[411] Deployment of CCS and CDR could support skilled jobs and workforces, including those in traditional fossil energy communities. Other co-benefits could include criteria air pollutant reductions and water production. It will be important to design projects that do not exacerbate community health impacts, include early and ongoing community engagement, and are in compliance with local, state, and federal public health and environmental protection laws. It also should be noted that, as these types of projects are an emerging area of governance, additional coordination and discussion will be needed among the various levels of authorities involved. SB 905 has already initiated this process by assigning specific agencies with tasks related to their expertise and authority.

Chapter 2 includes a more detailed discussion about the proposed role of CO_2 removal in this Scoping Plan.

Sector Transition

State,[412] national,[413,414] and global decarbonization analyses[415] indicate a significant role for carbon management infrastructure, yet relatively few projects are operational. Around the world, about two dozen large CCS projects are capturing tens of millions of metric tons of CO_2 each year, with about a dozen operating in the United States.[416] The vast majority of capacity is at industrial facilities, such as ethanol and fertilizer plants, that would otherwise vent nearly pure CO_2 into the atmosphere as a by-product of normal, non-combustion processes. Future research, development, and demonstration projects must refine and commercialize capture systems for more complex applications, especially

415 IPCC. Mitigation Pathways Compatible with 1.5°C in the Context of Sustainable Development. Chapter 2. https://www.ipcc.ch/sr15/chapter/chapter-2/. All analyzed pathways limiting warming to 1.5°C with no or limited overshoot use CDR to some extent to neutralize emissions from sources for which no mitigation measures have been identified and, in most cases, also to achieve net negative emissions to return global warming to 1.5°C following a peak (high confidence). The longer the delay in reducing CO_2 emissions toward zero, the larger the likelihood of exceeding 1.5°C, and the heavier the implied reliance on net negative emissions after mid-century to return warming to 1.5°C (high confidence).

416 Congressional Research Service. 2021. Carbon Capture and Sequestration (CCS) in the United States. R44902. https://crsreports.congress.gov/product/pdf/R/R44902?msclkid=e45e0012c25911ec8085ca575cb61e82.

for those with limited decarbonization options. It has only been in the last few years that attention has seriously turned to mechanical CDR. As new information and modeling on climate change have been made available, the science has become clearer that avoiding the most catastrophic impacts of climate change requires both reducing emissions and deploying mechanical CDR.

California is paving a path forward on a science-based carbon management infrastructure policy that can serve as an example for other jurisdictions. The LCFS, which reduces the carbon intensity of transportation fuels, includes a protocol for select carbon management projects to become certified and generate LCFS credits.[417] CCS is not a new concept or technology. Twenty years of CCS testing show it is a safe and reliable tool.[418] As mentioned in Chapter 2, while no new CCS projects have been implemented or generated any credits under the CARB CCS protocol, CCS projects have been implemented elsewhere since the 1970s. Moreover, there has been a U.S. Department of Energy CCS research program underway for more than two decades. These all form a foundation of information for future efforts. Certified projects must successfully demonstrate adherence to rigorous pre-construction, operational, and site closure standards designed to strengthen environmental performance, as described in CARB's CCS Protocol. The protocol is designed to layer on top of existing federal carbon sequestration regulations designed to protect the environment. The protocol would need to be reevaluated if CCS were to be more broadly applied across sectors beyond transportation fuel production.

Direct air capture and carbon mineralization have high potential capacity for removing carbon, but direct air capture is currently limited by high cost. Carbon mineralization may also have high potential for removing carbon from the atmosphere, but understanding of the technology is still limited.[419] Direct air capture could also be deployed at higher rates to remove legacy GHG emissions from the atmosphere. Chapter 2 contains additional information on the current status of CCS and mechanical CDR projects globally, as well as federal support of such technologies.

Strategies for Achieving Success

- Implement SB 905.

---

[417] CARB. 2018. Carbon Capture and Sequestration Protocol under the Low Carbon Fuel Standard. August 13. *https://ww2.arb.ca.gov/sites/default/files/2020-03/CCS_Protocol_Under_LCFS_8-13-18_ada.pdf*.

- Convene a multi-agency Carbon Capture and Sequestration Group comprised of federal, state, and local agencies to engage with environmental justice advocates, tribes, academics, researchers, and community representatives to identify the current status, concerns, and outstanding questions concerning CCS, and develop a process to engage with communities to understand specific concerns and consider guardrails to ensure safe and effective deployment of CCS.[420]
- Iteratively update the CARB CCS Protocol with the best available science and implementation experience.
- Incorporate CCS into other sectors and programs beyond transportation where cost-effective and technologically feasible options are not currently available and to achieve the 85 percent reduction in anthropogenic sources below 1990 levels as called for in AB 1279.
- Evaluate and propose, as appropriate, financing mechanisms and incentives to address market barriers for CCS and CDR.
- Evaluate and propose, as appropriate, the role for CCS in cement decarbonization (SB 596) and as part of hydrogen production pathways (SB 1075).
- Support carbon management infrastructure projects through core CEC research, development, and demonstration (RD&D) programs.
- Continue to explore carbon capture applications for producing or leveraging zero-carbon power for reliability needs as part of SB 100.
- Consider carbon capture infrastructure when developing hydrogen roadmaps and strategy, especially for non-electrolysis hydrogen production.
- Evaluate and streamline permitting barriers to project implementation while protecting public health and the environment.
- Explore options for how local air quality benefits can be achieved when CCS is deployed.
- Explore opportunities for CCS and CDR developers to leverage existing infrastructure, including subsurface infrastructure.
- Explore permitting options to allow for scaling the number of sources at carbon sequestration hubs.

Short-Lived Climate Pollutants (Non-Combustion Gases)

Short-lived climate pollutants (SLCPs) include black carbon (soot), methane (CH_4), and fluorinated gases (F-gases, including hydrofluorocarbons [HFCs]). They are powerful climate forcers and harmful air pollutants that have an outsized impact on climate change

[420] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, F4.9. finalejacrecs.pdf (arb.ca.gov).

in the near term, compared to longer-lived GHGs, such as CO_2. According to the IPCC's *Climate Change 2021: The Physical Science Basis,* in the near-term (i.e., 10- to 20-year time scale) the warming influence of all SLCPs combined will be at least as large as that of CO_2.[421] The United Nations Environment Programme's Global Methane Assessment[422] advises that achieving the least-cost pathways to limit warming to 1.5°C requires global methane emission reductions of 40–45 percent by 2030 alongside substantial simultaneous reductions of all climate forcers, including CO_2 and SLCPs. Action to reduce these powerful emissions sources today will provide immediate benefits—both to human health locally and to reduce warming globally—as the effects of our policies to transition to low carbon energy systems and achieve carbon neutrality further unfold.

In 2017, the Board approved the comprehensive Short-Lived Climate Pollutant Reduction Strategy (Strategy).[423] This strategy explained how the state would meet the following SB 1383-established targets:

- 40 percent reduction in total methane emissions[424] (including a separate 40 percent reduction in dairy and livestock emissions)
- 40 percent reduction in hydrofluorocarbon gas emissions
- 50 percent reduction in anthropogenic black carbon emissions
- 50 percent reduction of organic waste disposal from 2014 levels by 2020, and 75 percent by 2025, including recovery of at least 20 percent of edible food for human consumption

The state is expected to achieve roughly half of the SB 1383 targeted emissions reductions by 2030 through strategies currently in place (See Figure 4-11). As directed by the Legislature under SB 1383, state agencies focused on voluntary, incentive-based mechanisms to reduce SLCP emissions in the early years of implementation to overcome technical and market barriers. Under this "carrot-then-stick" strategy, incentives are replaced with requirements as the solutions become increasingly feasible and cost-effective. To meet legislated targets, more aggressive action is needed.

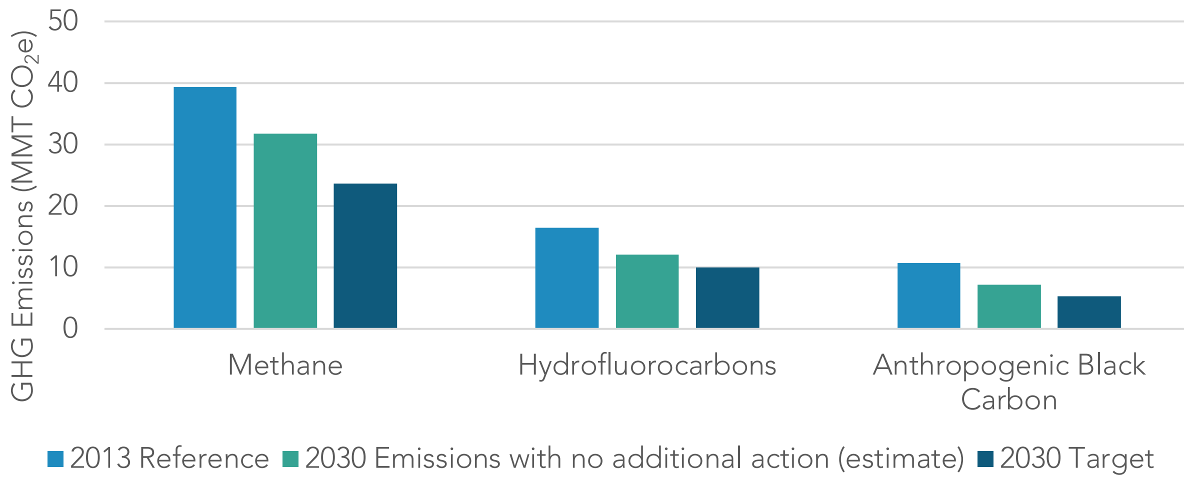
[424] All SB 1383 emissions reductions are mandated to be realized by 2030 and are relative to 2013 levels.

Figure 4-11: Expected progress toward SB 1383 targeted emissions reductions by 2030 through strategies currently in place



While the state's overall GHG emissions have declined by 9 percent over the past decade, SLCP emissions reductions have not kept pace with broader progress toward decarbonization. After growing steadily in the preceding decade, methane emissions have remained relatively flat since 2013.

HFCs are the fastest growing source of GHG emissions, primarily driven by their use to replace ozone-depleting substances and an increased demand for cooling and refrigeration.[425] Since 2005, statewide HFC emissions have more than doubled. While the rate of increase has slowed in recent years due to the state's measures, HFC emissions are still on the rise in California, and have grown by over 50 percent since 2010.[426] Globally, as temperatures rise, adoption of cooling technologies (and refrigerants) is increasing rapidly. If no measures are taken, it is estimated that HFCs will account for 9 to 19 percent of the total global GHG emissions by 2050.[427]

Methane

Human sources of methane emissions are estimated to be responsible for up to 25 percent of current warming.[428] Fortunately, methane's short atmospheric lifetime of ~12 years[429] means that emissions reductions will rapidly reduce concentrations in the atmosphere, slowing the pace of temperature rise in this decade. Further, a substantial portion of the targeted reductions can be achieved at low cost and will provide significant human health benefits. For example, the UN's *Global Methane Assessment* (2021)[430] found that over half of the available targeted measures have mitigation costs below \$21/MTCO_2e, and that each million metric tons of methane reduced would prevent 1,430 premature deaths annually due to ozone pollution caused by methane.

Following the Twenty Sixth Conference of Parties (COP26) (the United Nations Convention on Climate Change in 2021), over 110 nations have signed onto the Global Methane Pledge (Pledge)[431] to limit methane emissions by 30 percent relative to 2020 levels. The Pledge covers countries that emit nearly half of all methane and make up 70 percent of global GDP. The UN's Global Methane Assessment[432] shows that human-caused methane emissions can be reduced by up to 45 percent this decade, which would avoid nearly 0.3°C of global warming by 2045.

As shown in Figure 4-12, the three largest sources of California's methane emissions are the dairy and livestock industry, landfills, and oil and gas systems.

---

[428] IPCC. 2021. *Climate Change 2021:The Physical Science Basis.* https://www.ipcc.ch/report/ar6/wg1/.
[429] In contrast, the lifetime of CO_2 is hundreds of years. The IPCC Third Assessment Report concluded that no single lifetime can be defined for CO_2 because of the different rates of uptake by different removal processes. According to IPCC Fourth Assessment Report, the majority of an increase in CO_2 will be removed from the atmosphere within decades to a few centuries, while the remaining 20 percent may stay in the atmosphere for many thousands of years.

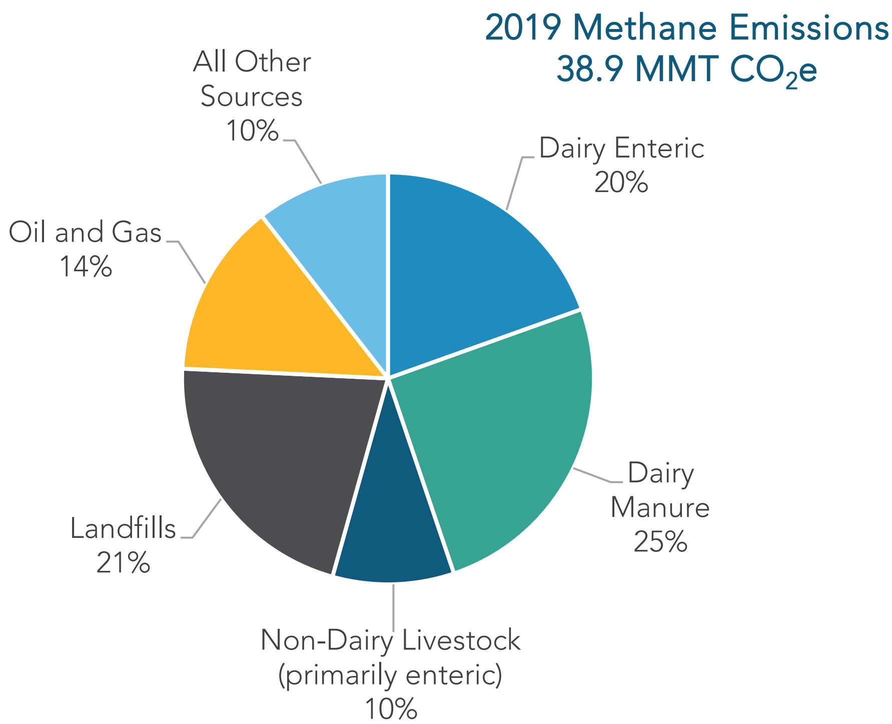
Figure 4-12: Sources of California methane emissions (2019)



Emissions from dairy and livestock operations come from two main sources: (1) enteric fermentation and (2) manure management operations, especially at dairies that employ open anaerobic lagoons that allow methane to escape into the atmosphere. Landfills, the second largest source of methane emissions, produce methane from the decomposition of organic waste. Although approximately 95 percent of all the waste that has been disposed of in the state has been deposited in a landfill that is equipped with a gas collection and control system, as required by California's Landfill Methane Regulation,[433] a portion of the methane still escapes into the atmosphere. Fugitive methane emissions can be intermittent and highly variable, both seasonally and spatially, particularly at landfills. Research has shown that landfills are complex systems and a wide range of conditions (e.g., atmospheric, operational, biological, chemical, and physical) may contribute to variability in rates of organic waste degradation, methane generation, and capture efficiency, so reducing the amount of organics deposited in landfills is critical to reducing overall landfill methane emissions. And despite the variability in individual landfill emissions, landfill gas collection and control systems remain the most effective strategy

[433] CARB. Landfill Methane Regulation. https://ww2.arb.ca.gov/our-work/programs/landfill-methane-regulation.

for reducing methane emissions from waste once it is placed in a landfill. Non-combustion methane emissions from the oil and gas sector are the third largest source of methane emissions in California. Almost three-quarters of the methane emissions from this sector come from leaks and venting from fossil gas transmission and distribution pipelines and equipment.

Hydrofluorocarbons

HFCs are synthetic GHGs that are powerful climate forcers. They are used mainly as refrigerants or heat transfer fluids in refrigeration, space conditioning, and heat pump equipment. Refrigerants are ubiquitous and are used everywhere from supermarkets, convenience stores, cold storage warehouses and wineries, to vending machines and residential and motor vehicle air-conditioners. Additionally, HFCs are also used as foam-blowing agents, solvents, aerosol-propellants, and fire suppressants. While HFCs remain in the atmosphere for a much shorter time than CO_2, the relative global warming potential (GWP) values of HFCs can be hundreds to thousands of times greater than CO_2. The mix of HFCs currently in use in California, weighted by usage (tonnage), have an average 100-year GWP of 1,700.[434] The average atmospheric lifetime of the mix of HFCs in use is 15 years.[435] Given the short average lifetimes, rapid reductions in HFC emissions can translate into near-term reductions in climate change effects.

As the global temperatures increase, the demand for cooling and refrigerants will continue to grow, as will the use of electric heat pumps to replace conventional fossil gas heating options. Unless addressed, continued use of high-GWP HFCs will perpetuate a feedback loop, where the cooling agents themselves cause additional warming.

In 2016, representatives from 197 nations signed the Kigali Amendment, which amended the existing Montreal Protocol (to reduce ozone-depleting substance production and consumption) to include a global phasedown in the production and consumption of HFCs beginning in 2019.[436] As of September 2022, 137 nations have either accepted, approved, or ratified the Kigali Amendment. On September 21, 2022, the U.S. Senate approved ratification of the Kigali Amendment, and it is expected that the United States

---

will soon join the 137 nations that have already ratified.[437] In the United States, Congress enacted the federal *American Innovation and Manufacturing (AIM) Act* in December 2020.[438] The AIM Act authorizes the U.S. EPA to address HFCs in several ways, including a national HFC phasedown that nearly mirrors the schedule of the global phasedown under the Kigali amendment.[439]

Nearly 90 percent of HFC emissions in California come from their use as refrigerants in the commercial, industrial, residential, and transportation sectors. The timescales over which the HFC emissions occur vary, depending on the type of application. Thus, strategies to reduce HFC emissions must be tailored by equipment type. CARB has several measures in place to tackle HFC emissions from the various sources shown in Figure 4-13 below. This includes the Refrigerant Management Program[440] that tracks and manages emissions from large commercial, industrial, and cold storage refrigeration facilities in the state. CARB has adopted regulations to reduce HFC emissions from consumer product aerosol propellants, semiconductor manufacturing, and small cans of automotive refrigerant.[441]

In 2018, California adopted HFC prohibitions via regulation and legislation for several sectors, including stationary refrigeration and foam end uses to backstop the partially vacated federal Significant New Alternatives Policy (SNAP) program.[442] Most recently, in 2020, CARB adopted additional measures that place GWP limits on refrigerants used in refrigeration and air conditioning equipment, which are the largest sources of HFC emissions, and are commonly used in residential, commercial, and industrial buildings. Additionally, CARB adopted a unique pilot program requiring the use of reclaimed refrigerant: the Refrigerant Recovery, Reclaim, and Reuse (R4) Program. The newly adopted HFC rules for the refrigeration and air conditioning sectors are the first of their kind in the nation.

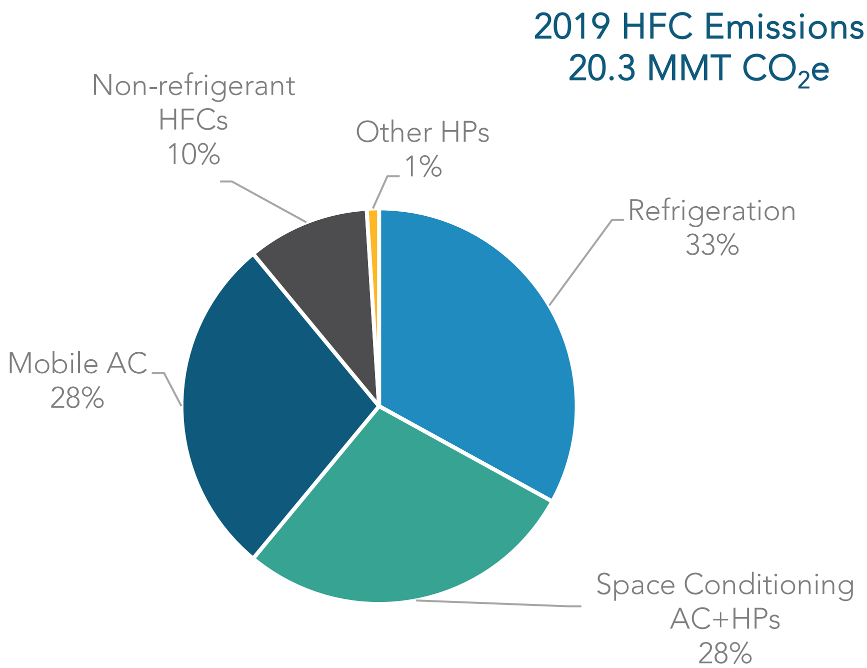
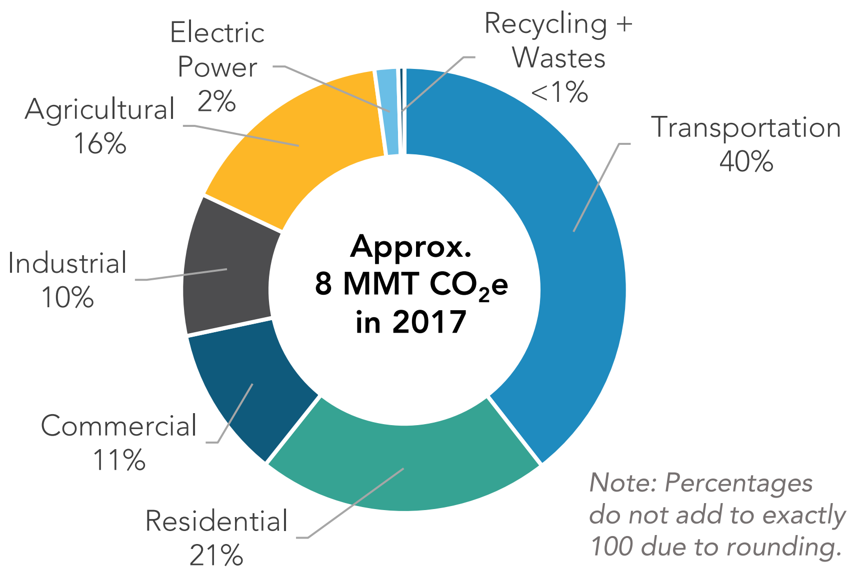
Figure 4-13: Sources of hydrofluorocarbon (HFC) emissions (2019)



Anthropogenic Black Carbon

Black carbon is not included in AB 32 or the state's AB 32 GHG inventory that tracks progress toward the state's climate targets; however, it has been identified as a powerful climate forcer and is included California's Short-Lived Climate Pollutant Reduction Strategy. The majority of anthropogenic black carbon emissions come from transportation, specifically heavy-duty vehicles, and they have decreased since 2013 due to engine certification standards and in-use rules for on-road and off-road fleets, along with clean fuel requirements and incentives, including California Climate Investments and LCFS credits. Additionally, fuel combustion for residential, commercial, and industrial applications contribute significantly to overall black carbon emissions. Approximately 95 percent of residential black carbon emissions are due to wood combustion; these emissions are being reduced through programs like the Woodsmoke Reduction Program established by SB 563 (Lara, Chapter 671, Statutes of 2017). Alternatives to agricultural burning and policies that phase out agricultural burning will also result in agricultural black carbon emissions reductions. In 2021 CARB provided a preliminary estimate of 2017 black carbon emissions (Figure 4-14).[443] This estimate will be finalized as part of a future update to the Short-Lived Climate Pollutant Inventory.

Figure 4-14: Sources of anthropogenic black carbon (preliminary 2017 estimates; AR5 100-yr GWP 900)



Sector Transition

California has long recognized the importance of mitigating non-combustion SLCPs and took several early action measures as part of a comprehensive, ongoing program to reduce in-state GHG emissions under AB 32. The early action measures included CARB's Landfill Methane Regulation,[444] Refrigerant Management Program,[445] and Oil and Gas Methane Regulation.[446]

Methane

The methane abatement strategies currently in place are projected to achieve half of the methane emissions needed to meet the overall methane reduction target of SB 1383 (40 percent reduction by 2030). The reduction target translates to a limit of less than 24 $MMTCO_2e$ in 2030 (Figure 4-15). It is anticipated that, since some sectors have fewer

[443] CARB. 2021. 2022 Scoping Plan Update – Short-Lived Climate Pollutants Workshop Presentation, September 8. https://ww2.arb.ca.gov/sites/default/files/2021-09/carb_presentation_sp_slcp_september2021_1.pdf.

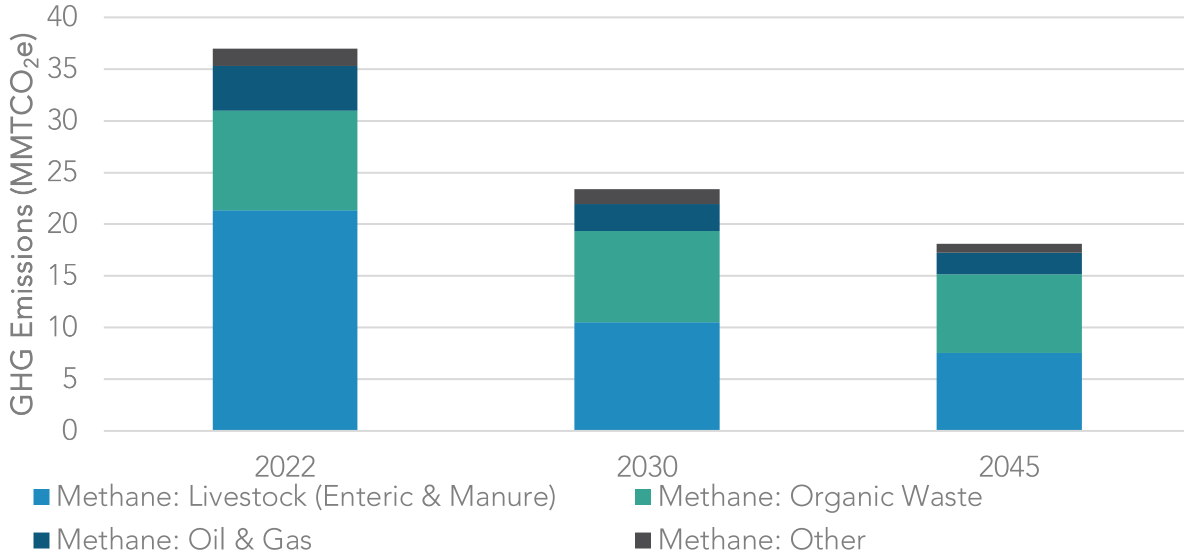
[445] Cal. Code of Regs., tit. 17, §§ 95380, et seq.
[446] Cal. Code of Regs., tit. 17, §§ 95665–77.

strategies that can be implemented to reduce methane in the near-term, other sectors will need to go beyond the 40 percent reduction to meet the target.

Figure 4-15: Methane emissions in 2022, 2030, and 2045 in the Scoping Plan Scenario[447]



Dairy and Livestock Methane

California is the largest dairy-producing state, home to one in five U.S. dairy cows. To date, methane emissions reductions from the dairy and livestock sector have mainly been driven by a decreasing animal population and the growing adoption of manure management strategies, including anaerobic digesters and conversion to dry manure systems and pasture systems. CARB recently completed a detailed analysis of the emission reductions expected by 2030 and the estimated additional investment needed to reach the dairy and livestock sector methane reduction target. [448]

Assuming no adoption of additional manure management and enteric mitigations strategies beyond the projects that have committed funding, and a continued annual animal population decrease of 0.5 percent per year through 2030, further reductions of approximately 4.4 $MMTCO_2e$ will be needed to achieve the 2030 methane emissions reduction target for the sector set by SB 1383. If the remaining reductions are met through

---

[447] The *Organic Waste* category includes methane from landfills, wastewater treatment, and compost facilities.

[448] CARB. 2021. Analysis of Progress toward Achieving the 2030 Dairy and Livestock Sector Methane Emissions Target. June. https://ww2.arb.ca.gov/sites/default/files/2021-06/draft-2030-dairy-livestock-ch4-analysis.pdf.

a mix of dairy projects in which half are dairy digesters and half are alternative manure management projects, then it is estimated that at least 420 additional projects will be necessary. Additional emissions reductions beyond this level will likely be necessary to ensure that the overall state methane emissions reduction targets are met.

Despite the considerable methane emissions mitigation potential of enteric strategies like feed additives, little progress has been made, as few products with proven mitigation potential have become commercially available, and unlike manure management strategies, there is a lack of financial incentives for their adoption.

Market conditions favoring farm consolidation and improved production efficiencies have driven reductions in the California and U.S. dairy population over the past decade. [449] These efficiency gains have allowed California to maintain production levels despite the decreasing population. If demand for dairy and beef products remains steady or increases, continued improvements in production efficiency and adoption of effective manure management and enteric mitigation strategies will be important to support dairy and livestock methane emission reductions.

Strategies for Achieving Success

- Install state of the art anaerobic digesters that maximize air and water quality protection, maximize biomethane capture, and direct biomethane to sectors that are hard to decarbonize or as a feedstock for energy.
- Increase alternative manure management projects, including but not limited to conversion to "solid," "dry," or "scrape" manure management; installation of a compost-bedded pack barn; an increase in the time animals spend on pasture; and implementation of solid-liquid separation technology into flush manure management systems.
- Implement enteric fermentation strategies that are cost-effective, scientifically proven, safe for animal and human health, and acceptable to consumers, and that do not impact animal productivity. Provide financial incentives for these strategies as needed.
- Accelerate demand for dairy and livestock product substitutes such as plant-based or cell-cultured dairy and livestock products to achieve reductions in animal populations.
- In consideration of pace of deployment of methane mitigation strategies and the scale of complimentary incentives, consider regulation development to ensure that the 2030 target is achieved, assuming the conditions outlined in SB 1383 are met.

---

[449] MacDonald, James M., Jonathan Law, and Roberto Mosheim. 2020. *Consolidation in U.S. Dairy Farming.* ERR-274. July. https://www.ers.usda.gov/webdocs/publications/98901/err-274.pdf.

Landfill Methane

Achieving the 75 percent organic waste disposal reduction target[450] of SB 1383, and maintaining that level of disposal in subsequent years, would bring annual landfill emissions in 2030 to just below the 2013 baseline. Annual methane emissions will be higher through 2030 than originally anticipated by the SLCP Strategy because the state did not achieve the anticipated reductions in organic waste disposal of 50 percent below 2014 levels by 2020. SB 1383 prohibited the organic disposal regulations from taking effect until 2022,[451] and, as a result, emissions have continued to increase.

Due to the multidecadal time frame required to break down landfilled organic material, the emissions reductions from diverting organic material in one year are realized over the course of several decades. For example, one year of waste diversion in 2030 is expected to avoid 8 $MMTCO_2e$ of landfill emissions, cumulatively, over the lifetime of that waste's decomposition.[452] Near-term diversion efforts are critical to avoid locking in future landfill methane emissions.

CalRecycle's 2020 report, *Analysis of the Progress Toward the SB 1383 Waste Reduction Goals,*[453] estimated that 8 million short tons of composting and anerobic digestion capacity will be needed to manage organic wastes, above the existing and new capacity expected to be available by 2025. The 2019 report, *Co-Digestion Capacity in California,*[454] from the State Water Resources Control Board estimated that at least 2.4 million tons of digester capacity is available at urban wastewater treatment plants if sufficient incentives or funding for collection, receiving, and processing operations are provided to enable utilization of this capacity. The CPUC approved a decision in February 2022 implementing the biomethane procurement program, which will require investor-owned utilities by 2025 to procure 17.6 billion cubic feet (BCF) of biomethane produced from organic wastes to support the landfill disposal reduction and SLCP target and reduce fossil gas reliance for

---

[450] The target is from 2014 levels by 2025.
Public Resources Code, § 42652.5. CalRecycle approved the SLCP: Organic Waste Reductions regulations (*https://calrecycle.ca.gov/organics/slcp/*) in 2020 and began implementing them in January 2022. These regulations are designed to achieve the 2025 disposal reduction and edible food recovery targets.

[452] The life cycle emissions reduction is based on anticipated diversion of 27 million short tons of organic waste from CalRecycle (2020) Analysis of the Progress Toward the SB 1383 Organic Waste Reduction Goals (*https://www2.calrecycle.ca.gov/Publications/Details/1693*). Under CalRecycle's SLCP regulations, an alternative to landfill disposal must achieve a life cycle GHG reduction of 0.3 $MTCO_2e$ per short ton of waste diverted.

[453] CalRecycle. 2020. *Analysis of the Progress Toward the SB 1383 Waste Reduction Goals.* *https://www2.calrecycle.ca.gov/Publications/Details/1693*.

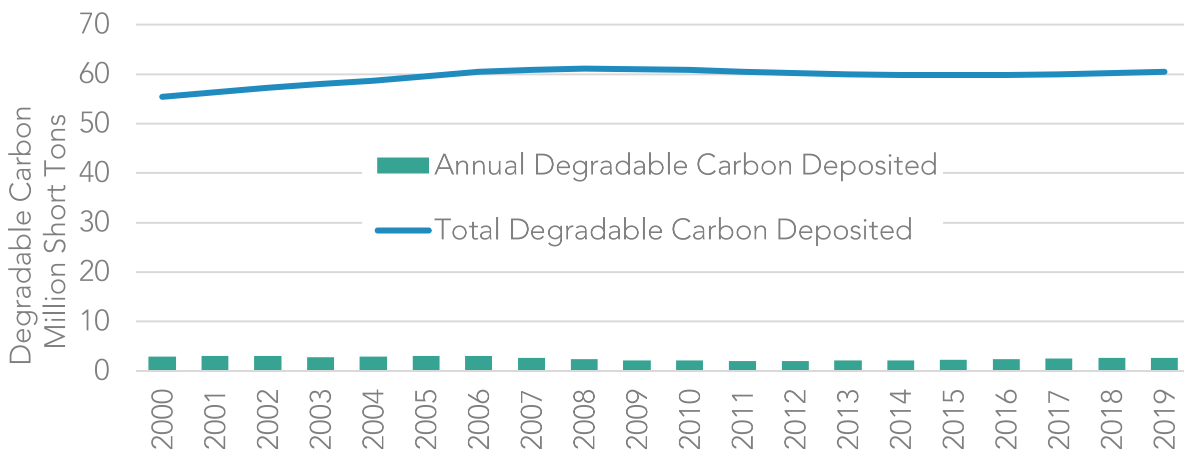
[454] State Water Resources Control Board. 2019. *Co-Digestion Capacity in California.* *https://www.waterboards.ca.gov/water_issues/programs/climate/docs/co_digestion/final_co_digestion_capacity_in_california_report_only.pdf*.

residential and commercial customers.[455] Additionally, the organic waste stream includes more than one million tons of edible food that could be recovered before it enters the waste stream through food rescue programs that combat hunger in communities throughout California.

While reducing organic waste disposal is the most effective means of achieving reductions in waste sector methane, strategies to reduce emissions from waste already in place in landfills also will play a role in achieving near-term reductions. As Figure 4-16 shows, the total degradable carbon (a measure of the amount of waste with potential to generate methane) that is accumulated from waste deposited in previous years is over 20 times greater than the amount added each year. This illustrates that even if we were able to entirely phase out landfilling of organic waste today, the existing waste in place at landfills would continue to generate methane for decades into the future.

Through a combination of improvements in operational practices, use of lower permeability covers, advanced landfill gas collection systems, and increased monitoring to detect and repair leaks, it is estimated that a direct emission reduction of 10 percent is achievable across the state's landfills by 2030. Technologies to utilize landfill gas efficiently can contribute further emission reductions in the energy sector.

Figure 4-16: Degradable carbon deposited in landfills



Strategies for Achieving Success

- Maximize existing infrastructure and expand it to reduce landfill disposal, with strategies including composting, anaerobic digestion, co-digestion at wastewater treatment plants, and other non-combustion conversion technologies.

[455] CPUC. 2022. Decision 22-02-025.

- Expand markets for products made from organic waste, including through recognition of the co-benefits of compost, biochar, and other products.[456]
- Recover edible food to combat food insecurity.
- Invest in the infrastructure needed to support growth in organic recycling capacity.
- Utilize existing digesters at wastewater treatment facilities to rapidly expand food waste digestion capacity.
- Direct biomethane captured from landfills and organic waste digesters to sectors that are hard to decarbonize.
- Implement improved technologies and best management practices at composting and digestion operations.
- Reduce emissions from landfills through improvements in operational practices, lower permeability covers, advanced collection systems, and technologies to utilize landfill gas.
- Leverage advances in remote sensing capabilities to quickly pinpoint large methane sources and mitigate leaks, improve understanding of the factors that lead to better capture efficiency, and explore new technologies and practices that can reliably improve methane control at landfills.

Upstream Oil and Gas Methane Reduction

For oil and gas production, processing, and storage, California is currently on track to achieve a 41 percent reduction in methane emissions by 2025 relative to 2013. The additional reductions needed to meet the 2030 target may be achieved by implementing additional regulatory requirements to further reduce intentional venting of fossil gas from equipment. If necessary, additional reductions from transmission and distribution facilities may be achieved by requiring the utilities to increase inspection and repair activities or further reduce emissions from pipeline blowdowns by implementing methods such as using portable compressors, using plugs to isolate sections of pipelines, flaring vented gas, routing gas to fuel gas systems, and installing static seals on compressor rods. Advances in methane detection technologies (e.g., satellites equipped to detect large methane sources) may also help to identify and mitigate methane emissions quickly across the oil and gas sector.

As California transitions away from fossil fuels, in-state oil and gas production will likely decline. This could result in an increase over time in the number of long-term idle and orphan wells (idle wells lacking a financially solvent, responsible owner) in the state. While California has regulations aimed at helping ensure operators manage their idle wells,

[456] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, F4.4. *finalejacrecs.pdf (arb.ca.gov)*.

there could likely be an increase in California's orphan well population. Plugging all orphan wells, of which there are currently over 5,000, could take decades due to the limited resources California has for orphan well plugging. The benefits from plugging wells include methane emission reductions and job creation; employment gains from well plugging and site remediation activities could help temporarily offset job losses from the oil and gas industry. The California Council on Science and Technology's 2018 report on orphan wells, *Orphan Wells in California: An Initial Assessment of the State's Potential Liabilities to Plug and Decommission Orphan Oil and Gas Wells,*[457] found that the potential cost to the state of plugging current orphan wells could be approximately $500 million, and the cost of plugging all active and idle wells could total over $9.1 billion. As oil and gas production in California declines due to reduced demand for fossil fuels, additional funding will likely be needed to cover the costs of plugging wells that have no viable operator.

Strategies for Achieving Success

- Mitigate emissions from leaks by regular leak detection and repair (LDAR) surveys at all facilities.
- Replace high emitting equipment with zero emission alternatives wherever feasible.[458]
- Have CARB and CalGEM lead a Task Force to identify and address methane leaks from oil infrastructure near communities.
- Pursuant to SB 1137, develop leak detection and repair plans for facilities in health protection zones, implement emission detection system standards, and provide public access to emissions data.
- Minimize emissions from equipment that must vent fossil gas by design (e.g., fossil gas powered compressors).
- Install vapor collection systems on high emitting equipment.
- Phase out venting and routine flaring of associated gas (gas produced as a by-product during oil production).
- Continuous ambient monitoring at fossil gas underground storage facilities to quickly detect large methane sources.
- Reduce pipeline and compressor blowdown emissions.

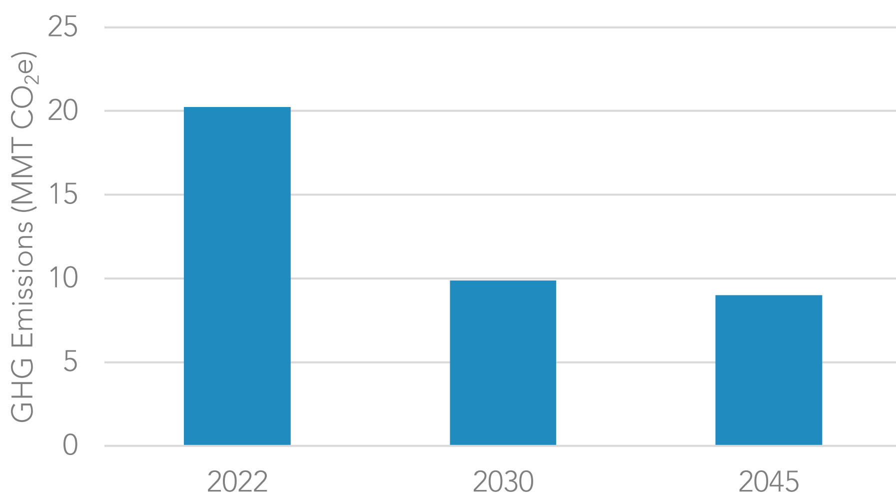
- Leverage advances in remote sensing capabilities to quickly pinpoint large methane sources and mitigate leaks.[459]

Hydrofluorocarbons

In California, all the HFC measures currently in place will help achieve more than 70 percent of the reductions needed to achieve the 2030 HFC goal and provide very significant emissions reductions by 2045 and beyond. However, new targeted measures will be needed to maintain the pace of reductions, as demand for technologies that currently predominantly use high-GWP refrigerants is anticipated to grow. Despite decarbonization efforts, high-GWP HFCs are expected to be among the last remaining persistent GHG emission sources, as shown in Figure 4-17.[460]

Figure 4-17: Hydrofluorocarbon emissions in 2022, 2030, and 2045 in the Scoping Plan Scenario



HFC emissions from new and existing sources should be addressed in tandem with building decarbonization efforts to maximize reductions.[461] As buildings are electrified in an effort to decarbonize them, the use of heat pumps for space conditioning, water heaters, and clothes dryers is expected to increase significantly. Heat pumps, while using

[460] Energy and Environmental Economics, Inc. 2020. *Achieving Carbon Neutrality.* https://ww2.arb.ca.gov/sites/default/files/2020-10/e3_cn_final_report_oct2020_0.pdf.

[461] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, NF26. finalejacrecs.pdf (arb.ca.gov).

electricity, not fossil gas, currently rely predominantly on high-GWP refrigerants. Very low- or no-GWP technologies and solutions are either available or emerging for various heat pump technologies, and likely to develop further as international efforts to mitigate HFCs continue. However, most of these technologies are still nascent in the United States. In addition, some of the alternatives cannot be used until California building codes are updated, which is currently expected at the earliest in mid-2024 for some technologies based on the recently adopted provisions in AB 209[462] requiring the California Building Standards Commission to adopt the latest safety standards for refrigerant containing equipment into California's building codes. The current updates to the building codes will allow the use of many refrigerants with lower GWPs than HFCs currently in use. However, additional building code updates are needed to expand the choices of ultra-low-GWP alternatives, and that will need to happen in the next few years. The adoption of low-GWP refrigerants must occur in parallel with building decarbonization efforts; without such efforts, the vast GHG benefits of the latter will be partially offset, and the proportion of HFC emissions from buildings will continue to grow.

Leaks from existing air conditioning and refrigeration equipment are a major source of statewide and global HFC emissions. Once installed, refrigeration and air conditioning equipment can stay in place for decades, while leaking refrigerants into the atmosphere. This makes it very important that new installed equipment use refrigerants with a GWP as low as possible. The refrigerants inside existing equipment are sometimes collectively referred to as the *installed base* or *banks* of potential HFC emissions. If released spontaneously, the existing HFC banks would equal 60 percent of all annual statewide GHG emissions in California, as illustrated in Figure 4-18.[463]

The sales prohibitions on newly produced refrigerants set forth in SB 1206 (2022) and the national/international HFC phasedown will help in reducing HFC emissions from existing equipment by restricting the supply of and increasing the value of existing high-GWP HFCs, thus enabling a circular economy. In the 2022–2023 state budget, CARB received $45 million in incentive funding for climate-friendly refrigerant technologies; this funding will be critical in shifting the market toward the best available refrigerant technologies in various sectors.

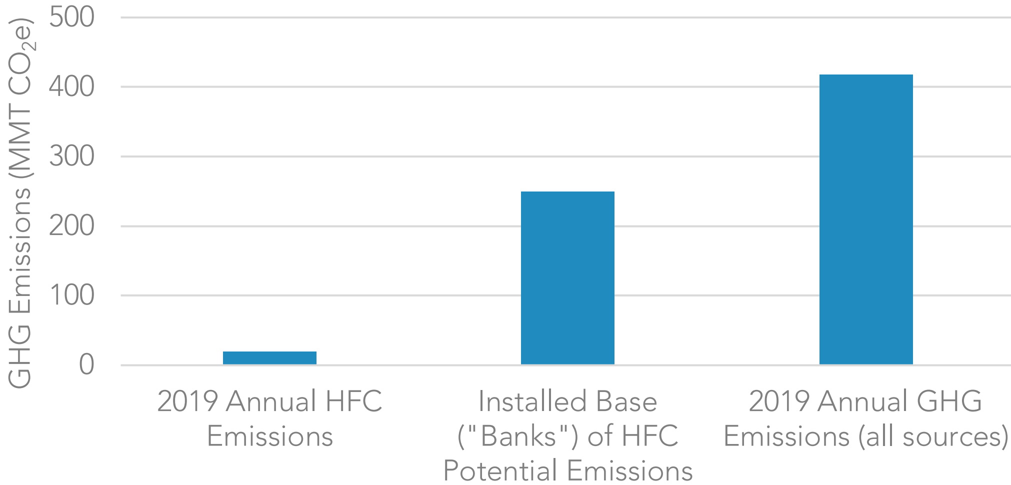
Figure 4-18: Potential emissions from refrigerants in existing equipment



Strategies for Achieving Success

- Expand the use of very low- or no-GWP technologies in all HFC end-use sectors, including emerging sectors, like heat pumps for applications other than space conditioning, to maximize the benefits of building decarbonization.[464]
- Convert large HFC emitters such as existing refrigeration systems to the lowest practical GWP technologies.[465]
- Prioritize small-scale and independent grocers serving priority populations in addressing existing "banks" of high-GWP refrigerants.[466]
- Improve recovery, reclamation, and reuse of refrigerants by limiting sales of new or virgin high-GWP refrigerants and requiring the use of reclaimed refrigerants where appropriate.[467]
- Assist low-income and disadvantaged communities in obtaining low-GWP space conditioning units to protect vulnerable communities from heat stress and wildfire smoke.[468]

[464] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, NF26. finalejacrecs.pdf (arb.ca.gov).

[466] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, JT5 and JT6. finalejacrecs.pdf (arb.ca.gov).
[467] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, JT1. finalejacrecs.pdf (arb.ca.gov).
[468] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, NF28, JT5, and JT6. finalejacrecs.pdf (arb.ca.gov).

- Accelerate technology transitions in California and the U.S. overall by collaborating with international partners committed to taking action on HFCs under the Kigali Amendment to the Montreal Protocol; this includes addressing barriers to adoption of very low- or no-GWP refrigerant technologies such as high upfront costs, shortage of trained technicians, and lag in updating safety standards and building codes.

Anthropogenic Black Carbon

Significant progress has been made since 2013 to reduce anthropogenic black carbon emissions, primarily from decreased combustion of distillate fuels in the agricultural sector, as well as improvements to provide cleaner, on-road combustion technologies. Under current strategies, anthropogenic black carbon from transportation is expected to be reduced by over 60 percent in 2030. Continued reductions in combustion emissions across all sectors from both the state's climate and air quality programs will also help reduce anthropogenic black carbon emissions going forward.

Strategies for Achieving Success

- Reduce fuel combustion commensurate with state's climate and air quality programs, particularly from reductions in transportation emissions and agricultural equipment emissions.[469]
- Invest in residential woodsmoke reduction.

In addition to SLCP emissions, some remaining non-combustion emissions are anticipated to persist in the coming decades, as shown in Figure 4-19. These include CO_2 from industrial processes such as cement manufacturing, oil and gas extraction, and geothermal electric power; N_2O from wastewater treatment, fertilizers, and livestock manure applied to agricultural soils; and other industrial, non-HFC GHG emissions.

[469] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, F1A and Appendix A (Table Summary of Direct Emission Reduction Strategies). Figure 4-19: Remaining non-combustion emissions in 2022, 2030, and 2045 in the Scoping Plan Scenario

Natural and Working Lands

California's natural and working lands (NWL) cover approximately 90 percent of the state's 105 million acres,[470] and include forests, grasslands, shrublands and chaparral, croplands, wetlands, sparsely vegetated lands, and the green spaces in urban and built environments. These lands include California Native American tribes' ancestral and cultural lands, parks and green spaces in our cities and communities, and the waters and the iconic landscapes we know and love. The diverse landscapes and biodiversity found throughout California's NWL provide a multitude of benefits to the people of California, including clean water, clean air, biodiversity, food, economic prosperity, recreational opportunities, continuation of traditional tribal ways of life, mental health benefits, and many others.

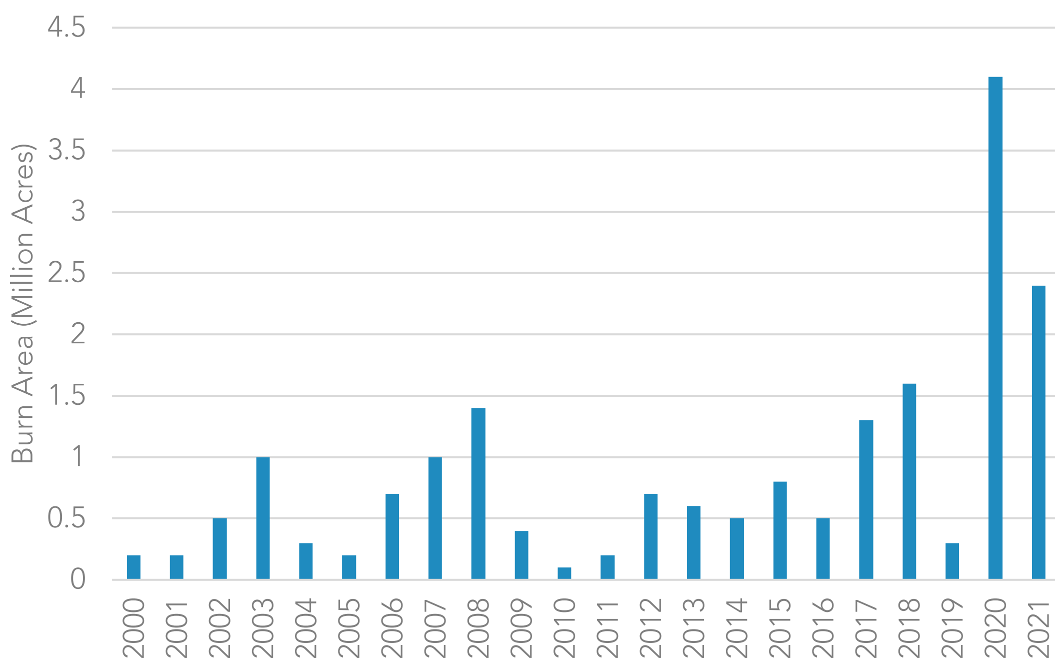
Our lands are a critical sector in California's fight to achieve carbon neutrality and build resilience to the impacts of climate change. Healthy land can sequester and store atmospheric CO_2. Healthy lands also can reduce emissions of powerful SLCPs, limit the release of future GHG emissions, protect people and nature from the impacts of climate change, and build our resilience to future climate risks. Creation of healthy lands through

[470] CNRA. 2022. Natural and Working Lands Climate Smart Strategy. https://resources.ca.gov/-/media/CNRA-Website/Files/Initiatives/Expanding-Nature-Based-Solutions/CNRA-Report-2022---Final_Accessible_Compressed.pdf.

multi-benefit and mitigation measures can also support tribal and local traditional lifeways. Unhealthy lands have the opposite effect—they release more GHGs than they store and are more vulnerable to future climate change impacts.

Climate change impacts have become more apparent in recent years and are having significant effects on communities throughout the state. One of these impacts is the much more frequent occurrence of unusually large, high-severity wildfires, which are being driven by climate change and by a recent history of fire-exclusion and land management practices that have resulted in forests with high levels of biomass. These recent large and high-severity wildfires have resulted in a significant amount of burned acreage and emissions in California (Figure 4-20).[471]

Figure 4-20: Acreage of burned wildland vegetation area



These wildfires deviate from the lower-severity fires that previously occurred at frequent intervals, around which California's forests evolved. As climate change accelerates, these large, uncharacteristic wildfires are likely to become more common and impact more of our landscapes. Climate change is also expected to have other significant effects on our lands, including more extreme droughts, floods, extreme heat, and the spread of invasive aquatic and terrestrial species, pests, diseases, and parasites. These impacts can lead

---

[471] CARB. 2022. Wildfire Emission Estimates for 2021. https://ww2.arb.ca.gov/sites/default/files/classic/cc/inventory/Wildfire%20Emission%20Estimates%202000-2021.pdf.

to negative feedback loops on human and ecological health; for example, increasing the spread of invasive species can lead to increases in pesticide use, if not managed through regulation or mitigation, which can pose risks to human health and the environment.

California's approach to climate action in the NWL sector is not solely focused on maximizing carbon stocks but instead on supporting carbon management that holistically fosters ecosystem health, resilience, provision of overall climate function, and other co-benefits.

Natural systems operate on a longer timescale than the energy and industrial sectors, and benefits from climate action on our lands can take decades to accrue. Scaling climate smart land management in California requires taking action now and playing the "long game" by establishing and maintaining consistent, patient approaches and programs.

Landscapes

For the first time, this Scoping Plan includes modeling for the NWL sector. The focus of the initial modeling is limited to seven land types that align with the those in the NWL Climate Smart Strategy.[472] Work will continue to incorporate more landscapes and management practices into the modeling over time. The initial landscapes included in the modeling for this Scoping Plan are:

- Forests
- Shrublands and Chapparal
- Grasslands
- Croplands
- Wetlands
- Developed Lands
- Sparsely Vegetated Lands

Each of these land types are a key component to the state's approach to increasing climate action in the NWL sector, as called for in Executive Order N-82-20 and AB 1757.[473] The Executive Order directs CARB to update the target for this sector in support of carbon neutrality by 2045 as part of this Scoping Plan, and to take into consideration the NWL Climate Smart Strategy. AB 1757 calls for the development of an

---

[472] CNRA. 2022. *Natural and Working Lands Climate Smart Strategy. Appendix B.* *https://resources.ca.gov/-/media/CNRA-Website/Files/Initiatives/Expanding-Nature-Based-Solutions/Appendix-B_04132022_ada.pdf*.

[473] AB 1757 California Global Warming Solutions Act of 2006: Climate Goal: Natural and Working Lands. *https://leginfo.legislature.ca.gov/faces/billTextClient.xhtml?bill_id=202120220AB1757*.

ambitious range of targets for the NWL sector to be integrated into the Scoping Plan and other state policies. It directs CARB and CNRA to work closely together to update the NWL Climate Smart Strategy, and establish an expert advisory committee to inform and advise on NWL modeling, targets, and implementation strategies.[474] Additionally, in 2021, the governor signed SB 27[475] (Skinner, Chapter 237, Statutes of 2021) into law. It directed CARB to establish CO_2 removal targets for 2030 and beyond and take into consideration the NWL Climate Smart Strategy. The governor's Executive Order, AB 1757, and SB 27 go beyond previous direction from the Legislature and past administrations. These directives emphasize the importance of quantifying land-based carbon both statewide,[476] and in programs and policies,[477] setting targets[478] for NWL to support the state's climate objectives, and advancing land management actions[479] that support the health and resiliency of these lands.

Blue carbon (also known as carbon captured and held in coastal vegetation and soils, such as seagrasses, seaweeds, and wetlands)—is also important to consider as we look at long-term climate goals. While this landscape is not currently covered by IPCC inventory guidelines or included in California's NWL Inventory, the United States was the first nation to include blue carbon in its national GHG emissions inventory. California's Ocean Protection Council and San Francisco Estuary Institute are partnering to create a new coastal wetlands, beaches, and watersheds inventory. CARB staff will utilize information from this effort and assess other available data to evaluate how this landscape may be integrated into our efforts in the future as more data become available.[480]

Trends of Carbon on Landscapes

CARB currently tracks the carbon stock changes though the Inventory of Ecosystem Carbon in California's Lands[481] (NWL Inventory), which is summarized in Chapter 1. The NWL Inventory is a key tool for tracking changes in carbon stocks across the state, and it will serve as the inventory of record for this sector, tracking sector-wide progress toward the target. The NWL Inventory provides a retrospective snapshot of the status of California's lands, and captures the gains or losses of carbon stocks that occur over time. In addition to tracking carbon stock changes, the NWL Inventory is an important tool for understanding the impacts of our efforts to increase climate action in this sector (such as those identified in this Scoping Plan and the NWL Climate Smart Strategy) on NWL carbon stocks. The inventory is also used as the foundation for Scoping Plan scenario modeling and target setting.

CARB's inventory shows that carbon stocks decreased in NWL lands from 2001 to 2011, releasing more carbon than they were storing, and then increased slightly from 2012 to 2014.[482] These trends highlight the interannual and interdecadal variability of lands and their ability to be both a source and a sink of carbon, and the importance of looking at NWL data and trends over multiyear and multidecadal time periods, as opposed to looking only at annual changes. This movement is part of the Earth's carbon cycle, where carbon transfers between the land, ocean, and atmosphere. As part of the carbon cycle, over decades or centuries, fire and plant respiration and decomposition move carbon from the land to the atmosphere, while plant growth and other processes move carbon from the atmosphere to the land. Emissions from fossil-fuel combustion are contributing to putting this cycle out of balance.

Additionally, some historic land management practices that have resulted in the loss of carbon from the soil are also contributing to the atmospheric rise of CO_2 while simultaneously exacerbating the imbalance of the water cycle, which is influenced by and linked to the carbon cycle. These emissions are also contributing to a feedback loop for California's lands: as CO_2 emissions accumulate in the atmosphere—and California experiences more warming, extreme heat events, and droughts—the risk and intensity of carbon losses also increases, which in turn transfers more carbon from the land to the atmosphere. And because forests and shrublands comprise approximately 85 percent of the carbon stocks in California, management strategies and disturbances in forest and

[481] CARB. *An Inventory of Ecosystem Carbon in California's Natural & Working Lands.* 2018 Edition. nwl_inventory.pdf (ca.gov). Accessed 3/2/2022.

[482] These trends are consistent estimates in the most recent AB 1504 reporting period.

shrubland carbon play an important role in determining whether California's lands are providing either net carbon sequestration or net emissions on an annual basis.

The gains and losses of carbon on our lands will fluctuate in the future; what is important is to restore carbon in places where it has been lost and reduce large carbon losses on our NWL through active, attentive, and adaptive management. For additional details on the nexus between NWL and GHGs, see pages 5–6 of the NWL Climate Smart Strategy.

Goals and Accelerating Nature-Based Solutions

The state's climate mitigation targets are traditionally identified by individual years, (i.e., tons of GHG emissions in 2020 or 2030). However, because NWL processes fluctuate year to year and because it can sometimes take decades for climate action to fully impact carbon in NWL, it is important to consider the statewide, long-term trends of carbon stock change when identifying how this sector contributes to California's pathway to achieving carbon neutrality. Tracking carbon stock change over a multi-decadal period is the best way to assess the full direct impact climate action has on carbon storage. Such an approach filters out fluctuations from year-to-year weather variations and multi-year natural climate cycles, such as El Niño patterns.

Current data sources and methods allow us to track only certain carbon stocks that exist on NWL. For target tracking to be successful, each carbon pool must be inventoried using a methodology that can detect changes due to management and climate change. Certain carbon pools lack the scientific data and methodologies necessary for target-setting and tracking. For example, soils in forests, shrublands, and grasslands are not included in the Scoping Plan carbon stock target because, currently, there is no way to track statewide soil carbon through time in a way that would capture the effects of increased climate action and climate change.

When considering how NWL contribute to the state's goal of carbon neutrality, all lands' carbon stock gains and losses must be considered, and the Scoping Plan target is set in these terms. It is not sufficient to aggregate climate benefits only within areas where projects, management, or climate action occur. Much of the state does not receive active or quantifiable management, but these areas still contribute to the state's overall carbon stock change and GHG emissions. To incorporate the entire carbon balance toward true carbon neutrality, the Scoping Plan target is set in terms of carbon stock change across the entire state. This incorporates all lands that both receive and do not receive active management, and includes the end result of all sequestration, emissions, and other changes to carbon on the landscape.

However, carbon stock change is not equivalent to emissions. Currently, the data and emission quantification science is not sufficient to enable inventories to comprehensively track all NWL emissions in a way that would enable us to set an NWL target in terms of statewide emissions and sequestration. There is a great need, across the entire NWL sector statewide, for more empirical data, science, and tools to track all carbon stocks across each carbon pool, and to begin to track emission and sequestration rates. As California implements AB 1757, there is an opportunity to update the data, science, and tools to enable this level of tracking and target setting in the future.

As outlined in Chapter 2, California is projected to lose carbon stocks over the coming decades, but this Scoping Plan analysis also shows that increasing the pace and scale of climate smart land management in California will reduce the carbon stock losses and GHG emissions from the NWL sector. In response to EO N-82-20 and AB 1757, the proposed target for NWL is shown in Table 4-1.

Table 4-1: Scoping Plan modeled target for NWL, based on increasing action on NWL

	Total Carbon Stock % Change from 2014
2045	-4

Achieving this target will require significant expansion of the pace and scale of climate action on California's NWL, including the following:

- Increasing climate smart forest, shrubland, and grassland management to at least 2.3 million acres a year—an approximate 10x increase in management from current levels.
- Increasing climate smart agricultural practices by at least 78,000 acres adopted a year, annually conserving at least 8,000 acres a year of croplands, and increasing organic agriculture to comprise at least 20 percent of cultivated acres in California by 2045—an approximate 7.5x increase in healthy soils practices from previous levels and a 2x increase in total acres of organic agriculture.
- Increasing annual investment in urban trees in developed lands by at least 200 percent above historic levels and establishing defensible space on all parcels by 2045.
- Restoring at least 60,000 acres, or approximately 15 percent of all Sacramento–San Joaquin River Delta (Delta) wetlands, by 2045.
- Cutting land conversion of deserts and sparsely vegetated landscapes by at least 50 percent annually from current levels, starting in 2025.

If the carbon stock target above is met, and the management actions above are implemented, the modeling for NWL indicates that California's lands will be a net source of emissions, producing approximately 7 $MMTCO_2e$ of average annual emissions.

Additional climate smart management practices and additional landscapes, such as those included in the Climate Smart Strategy and discussed below in Additional Management Strategies, have the potential to increase carbon stocks and reduce GHG emissions from NWL beyond the levels modeled for this Scoping Plan.

The purpose of the NWL target and the above estimated outcomes is to provide a numerical guide that can support the state's efforts to accelerate both near-term and long-term climate action on California's lands, prioritizing durable solutions that deliver multiple outcomes. Taking these actions over the coming decades will reduce the potential carbon losses from NWL, reduce GHG emissions from some landscape types (such as croplands and Delta wetlands), and support sequestration of GHGs from NWL between 2025 and 2045. These actions will also deliver significant benefits to Californians beyond advancing our climate goals, such as reducing wildfire emissions and their associated health impacts, increasing habitat for biodiversity, reducing urban heat island effects, reducing harmful pesticide exposure, expanding economic opportunities, and others. Additional information on several economic and health outcomes from the Scoping Plan Scenario is included in Chapters 2 and 3.

Statewide planning and target setting for the NWL sector will only create meaningful change if followed by effective on-the-ground implementation. State government cannot accomplish this implementation alone. Effective large scale climate action is dependent on partnerships among tribal, federal, state, regional, and local partners, and across governmental, private, nonprofit, and commercial sectors. The NWL sector of the Scoping Plan sets a carbon target with climate action recommendations that can be used to achieve the quantified carbon, health, and economic outcomes. Implementation of these actions must be led by local or regional partnerships that plan and execute projects appropriate to the specific conditions. The technical expertise and local knowledge of land managers and stewards in all sectors must be elevated to ensure relevant, efficient, and effective climate action.

Implementation of climate action should contribute to state targets, maximize local benefits, and alleviate environmental injustices and other social inequities. On-the-ground action is largely executed and managed by local and regional actors, but state government agencies must support communities across the state in implementing nature-based climate solutions that address statewide objectives, such as the Scoping Plan carbon target. This includes providing resources and developing frameworks, while greatly increasing capacity and technical assistance to assist and empower local partners. Examples of how this can be done are the Regional Forest and Fire Capacity Program within the forestry sector, the UC Cooperative Extension in the agricultural and forestry sectors—as well as the work of the state's 10 regional Conservancies. These programs provide strong examples to emulate as they facilitate statewide coordination, and information and resource transfer from the state to the regional and local levels. The Regional Forest and Fire Capacity Program provides funding for local and regional groups to build their organizational capacity to plan and implement wildfire and forest management projects that are informed by their own local expertise. The UC Cooperative Extension is an example of how the state provides technical assistance to local landowners and community organizations, helping them apply the latest science-based management strategies to their lands. California's regional Conservancies play a pivotal role in implementing regional conservation, restoration, and land management efforts through activities such as grant funding, science generation, and planning assistance.

The state also has identified the need to incorporate and elevate traditional indigenous knowledge into climate action on the regional and local scales. Accomplishing this requires close partnerships with tribes for mutual knowledge and resource sharing, while protecting culturally sensitive knowledge and resources. As Tribes are sovereign nations with specialized cultural knowledge and experience in managing lands, climate action on these lands that contribute to the State of California's climate targets can only be accomplished with the full participation and under the leadership of the Tribes that govern those lands.

Strategies for Achieving Success: Crosscutting Items for all NWL

- Implement AB 1757 and SB 27.
- Implement the Climate Smart Strategy.
- Accelerate the pace and scale of climate smart action, consistent with the management levels identified above, as part of a collective effort between federal, state, private, nonprofit, and individual land managers.
- Prioritize and practice equity, including through meaningful community engagement and prioritizing implementation of nature-based solutions that benefit the communities most vulnerable to climate change.[483]
- Advance multi-benefit, collaborative, landscape-level approaches that engage communities and landowners, and incorporate adaptive managements.
- Consult and partner with California Native American tribes to increase co-management and tribal management authority; restore, protect, and enhance natural cultural resources, traditional foods, and cultural landscapes; respect tribal sovereignty; and support tribes' implementation of tribal expertise and Traditional Ecological Knowledge and cultural easements.[484]

[484] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N1, N6, N16, N17, N18. *finalejacrecs.pdf (arb.ca.gov)*.

- Leverage existing innovative financial and market mechanisms, and explore new ones, between the public, private, and philanthropic sectors to secure funding of climate smart land management.
- In partnership with communities, tribes, and the private sector, expand and develop new infrastructure for manufacturing and processing of climate smart agricultural and biomass products.
- Leverage and support technical assistance providers: such as the UC Cooperative Extension and California's 98 Resource Conservation Districts, that have track records of providing technical assistance to local landowners and implementing agriculture, forestry, natural resource management, and restoration projects across the state.
- Establish and expand mechanisms that ensure NWL are protected from land conversion and parcelization (e.g., conservation easements or Williamson Act), in line with the strategies outlined in CNRA's Pathways to 30x30 California.[485,486] Pair land conservation projects with management plans that increase carbon sequestration, where feasible.
- Increase opportunities for private and philanthropic investments in nature-based climate solutions, utilizing existing voluntary and compliance carbon markets, existing state and local programs, and the California Carbon Sequestration and Climate Resiliency Project Registry established pursuant to SB 27.
- Expand monitoring and tracking of management actions and outcomes consistent with the tracking and monitoring recommendations of the Climate Smart Strategy.

Forests, Shrublands, and Chaparral

At roughly 29 million acres, forests cover 27 percent of California. Shrublands and chaparral cover 31 percent of the state; roughly 33 million acres. Both types are distinct, with their own ecological dynamics and management strategies, and are modeled within a single model that is calibrated to treat them uniquely.

Together, forests, shrublands, and chaparral support a high biodiversity of plants and animals, in addition to high levels of carbon stocks. They provide important air and water quality benefits to all Californians, as well as recreational opportunities and, for forests, harvested wood products for the state. These landscapes are fire-adapted, and historical tribal management of these lands has fostered ecosystem health and resilience. Over the past century, these lands have been impacted severely by fire exclusion, including

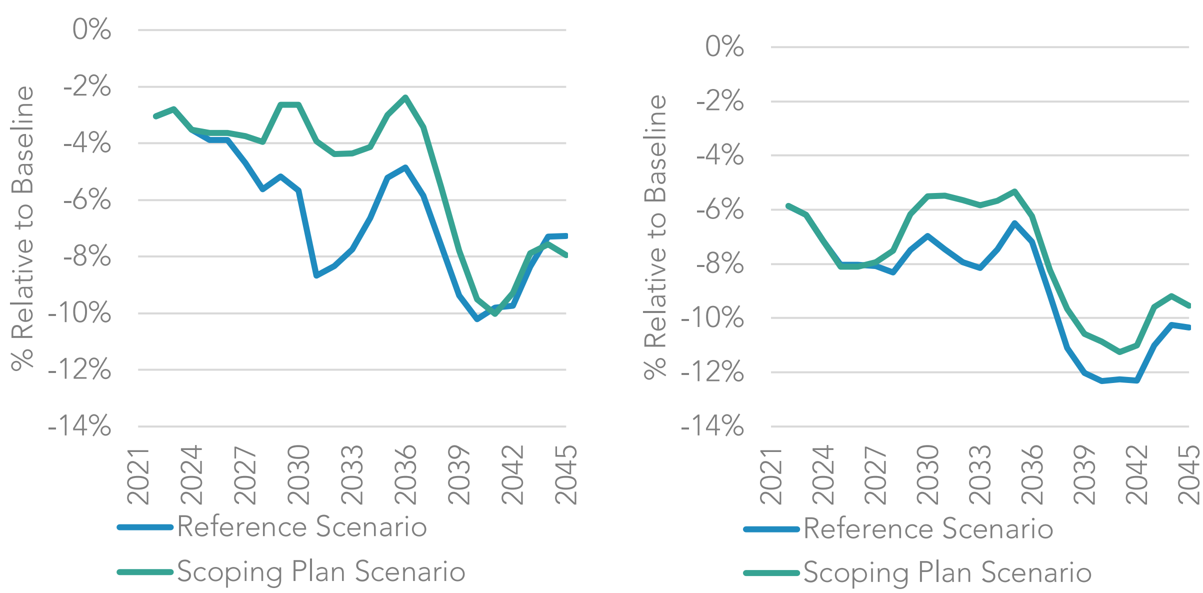
---

[485] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N5, N26, N27. finalejacrecs.pdf (arb.ca.gov).
[486] CNRA. 2022. *Pathways to 30x30 California*. https://www.californianature.ca.gov/pages/30x30.

exclusion of indigenous people's management and past management practices, which has resulted in less resilient ecosystems and communities and more destructive wildfires today. This, along with drought induced stress and mortality, has changed these landscapes from a carbon sink to a carbon source. Climate smart management can help make forests more resilient to climate change and less prone to catastrophic wildfire. Climate-smart management in shrublands and chaparral face additional challenges and uncertainty, but can still provide protection for threatened communities and natural resources. This management, if conducted on a regular basis to maintain forest health, can help reduce emissions from forests, shrublands, and chaparral, and help strengthen and maintain the co-benefits that Californians experience from them.

Under all management levels, forests and shrublands are expected to lose carbon over the next two decades due to climate change and wildfire (Figure 4-21).

Figure 4-21: Forest (left) and shrubland (right) carbon stocks by 2045[487,488]



While this decrease in carbon stocks may be inevitable, forest management under the Scoping Plan Scenario can help direct where and how carbon loss occurs. By proactively managing forests and shrublands, the loss of carbon from wildfire can be lessened as the risk of high severity fire is decreased, with the removed biomass going toward a more

[487] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N13. finalejacrecs.pdf (arb.ca.gov).
[488] This analysis is the aggregation of all forests and shrublands from all ownerships across the entire state of California.

useful purpose such as harvested wood products, bioenergy, and engineered carbon removal. Managing for a diverse and resilient forest landscape also can help forests recover more quickly so that when climate change and wildfire impacts occur, forests will be less affected and can continue to thrive and sequester carbon. Additional details on the climate benefit potential of forests and shrublands/chapparal can be found in Section 2 of the NWL Climate Smart Strategy.

Strategies for Achieving Success

- Accelerate the pace and scale of climate smart forest management to at least 2.3 million acres annually by 2025, in line with the climate smart management strategies identified in this Scoping Plan, the NWL Climate Smart Strategy, and the Wildfire and Forest Resilience Action Plan.[489]
- Establish and expand mechanisms that ensure forests, shrublands, and grasslands are protected from land conversion and that support ongoing, rather than one-time, management actions.
- In collaboration with state and local agencies, accelerate the deployment of long-term carbon storage from waste woody biomass residues resulting from climate smart management, including storage in durable wood products, underground reservoirs, soil amendments, and other mediums.
- Expand infrastructure to facilitate processing of biomass resulting from climate smart management.
- Expand permit streamlining in collaboration with state and local agencies to accelerate implementation of climate smart forest management while protecting natural resources.

Grasslands

Grasslands cover 9 percent of California, roughly 10 million acres, and are found throughout the state in various landscapes, with concentrations in the foothills surrounding the Sacramento and San Joaquin Valleys. In addition to carbon storage (primarily in the soil), grasslands provide open space, wild habitat, grazing land, and important water filtration and recharge benefits. The protection of grasslands provides an opportunity to reduce sprawl and complement VMT reduction strategies. As grasslands are susceptible to invasive species, climate smart strategies can increase grassland

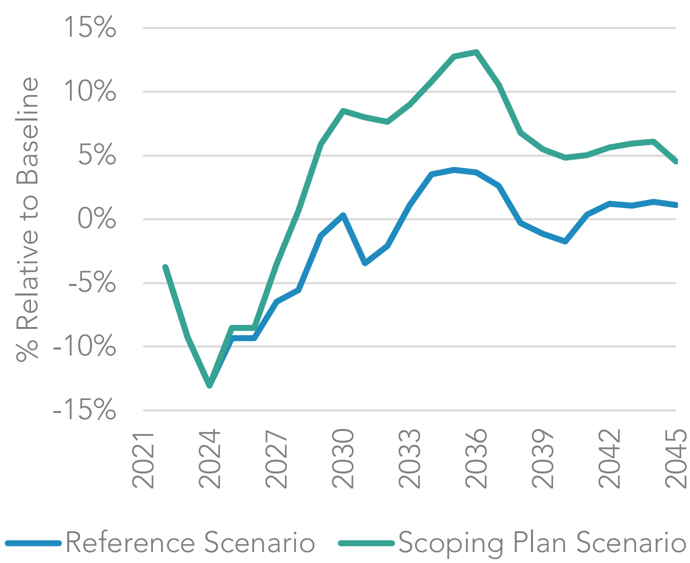
---

[489] Forest Management Task Force. 2021. *California's Wildfire and Forest Resilience Action Plan: Recommendations of the Governor's Forest Management Task Force.* https://www.fire.ca.gov/media/ps4p2vck/californiawildfireandforestresilienceactionplan.pdf.

resilience to climate change by improving species diversity and maintaining or increasing soil carbon stocks.

Modeling results show that increased fuels treatments and avoided land conversion can increase carbon stocks on grasslands by 2045, but sequestration rates fluctuate annually. Grasslands are capable of high carbon sequestration rates but are susceptible to carbon losses from wildfire and land conversion. Soil carbon is the major carbon pool on these lands, and continued future improvement of the monitoring and modeling of soil carbon is needed. Similar to forests and shrubland/chaparral, modeling alternatives that include fuels treatments resulted in greater carbon stocks compared to no management, and had lower wildfire emissions. Unlike forests and shrubland/chaparral, which have a general declining carbon stocks trend, the modeling results (Figure 4-22) show grasslands can maintain or increase carbon stocks with active management. Details on the climate benefit potential of grasslands can be found in Section 2 of the NWL Climate Smart Strategy.

Figure 4-22: Grassland carbon stocks by 2045



Strategies for Achieving Success

- Establish and expand mechanisms that ensure grasslands are protected from land conversion/parcelization and that support ongoing, rather than one-time, management actions that improve carbon sequestration.
- Deploy grassland management strategies, like prescribed grazing, compost application, and other regenerative practices, to support soil carbon sequestration, biodiversity, and other ecological improvements.

- Increase adoption of compost production on farms and application of compost in appropriate grassland settings for improved vegetation and carbon storage, and to deliver waste diversion goals through nature-based solutions.

Croplands

Croplands cover 9 percent of the state, roughly 9.5 million acres. This land is some of the most productive agricultural land in the world, and enables California to be a global leader in agriculture. Aside from developed lands, croplands are the most intensively managed landscapes in the state, and are closely tied to society through the food they produce and the constant, direct contact that people have with croplands through the course of management. In addition to food security, croplands provide considerable carbon storage in the soil and, in perennial croplands, in aboveground biomass. Climate smart practices can improve public health; for example, by reducing synthetic fertilizer and pesticide use. They also help to maintain or increase the climate resilience of cropland productivity through improved soil conditions and increased pollinator habitat.

There is also significant potential to transform this sector to increase soil carbon storage, reduce GHG emissions (Figure 4-23), and reduce pesticide exposure and health impacts. Moving to an agricultural system that improves soil health and water holding capacity reduces over-application of nitrogen, reduces the use of pesticides and fumigants, and increases biodiversity and pollinator habitat, supporting California's pathway to carbon neutrality while simultaneously improving the lives of those who live and work in the agricultural community. Croplands are intricately tied to people, communities, and their health, and through climate smart practices and cropland conservation, these lands have the potential to contribute more to society than just food.[490] The implementation of climate smart agricultural practices and diversified organic agriculture can help California achieve social and environmental benefits, like improving water use efficiency, increasing pollinator habitat, and reducing synthetic fertilizer and pesticide use.[491] Additional details on the climate benefit potential of croplands can be found in Section 2 of the NWL Climate Smart Strategy.

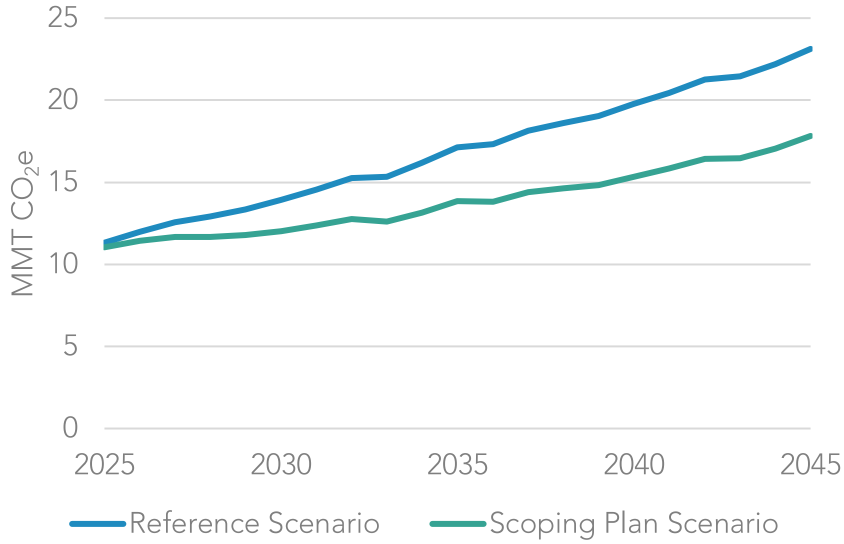
Figure 4-23: Cumulative CO_2e emissions from annual croplands in 2045[492]



CARB recognizes the complex nature of croplands, cross-sector relationships, and the need to build on this analysis to further our understanding of cropland dynamics. Many more aspects of cropland management need to be explored for potential climate benefits, such as water and nutrient use management, pest control methods, crop rotations, and other management practices. The impacts of climate change on water availability, annual/perennial crop growth, and future carbon sequestration trends are uncertain, and recent policies such as the Sustainable Groundwater Management Act may also influence cropland management in unforeseen ways. Nonetheless, it is clear that greater climate smart practice implementation can prepare California for the future and yield tangible benefits for the state.

Strategies for Achieving Success

- Accelerate the pace and scale of healthy soils practices to 80,000 acres annually by 2025, conserve at least 8,000 acres of annual crops annually, and increase organic agriculture to 20 percent of all cultivated acres by 2045.

---

[492] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N11. *finalejacrecs.pdf (arb.ca.gov)*.

- Utilize the recommendations included in CDFA's Farmer and Rancher-Led Climate Change Solutions[493] report to accelerate deployment of healthy soils practices, organic farming, and climate smart agriculture practices.
- Establish or expand financial mechanisms that support ongoing deployment of healthy soils practices and organic agriculture.[494]
- Support strategies that achieve co-benefits of safer, more sustainable pest management practices and the health and preservation of ecosystems, such as implementing the California Department of Pesticide Regulation's (DPR's) Sustainable Pest Management Work Group recommendations.[495]
- Conduct research on the intersection of pesticides, soil health, GHGs, and pest resiliency via a multi-agency effort with DPR, CDFA, and CARB.[496]
- Conduct outreach and education to develop and facilitate the increased adoption of safer, more sustainable pest management practices and tools; reduce the use of harmful pesticides; promote healthy soils; improve water and air quality; and reduce public health impacts.
- In collaboration with state and local agencies, accelerate the deployment of alternatives to agricultural burning that increase long-term carbon storage from waste agricultural biomass, including storage in durable wood products, underground reservoirs, soil amendments, and other mediums.
- Work across state agencies to reduce regulatory and permitting barriers around some healthy soils practices (e.g., composting), where appropriate.
- Utilize innovative agriculture energy use and carbon monitoring and planning tools to reduce on-farm GHG emissions from energy and fertilizer application or to increase carbon storage, as well as to promote on-farm energy production opportunities.

---

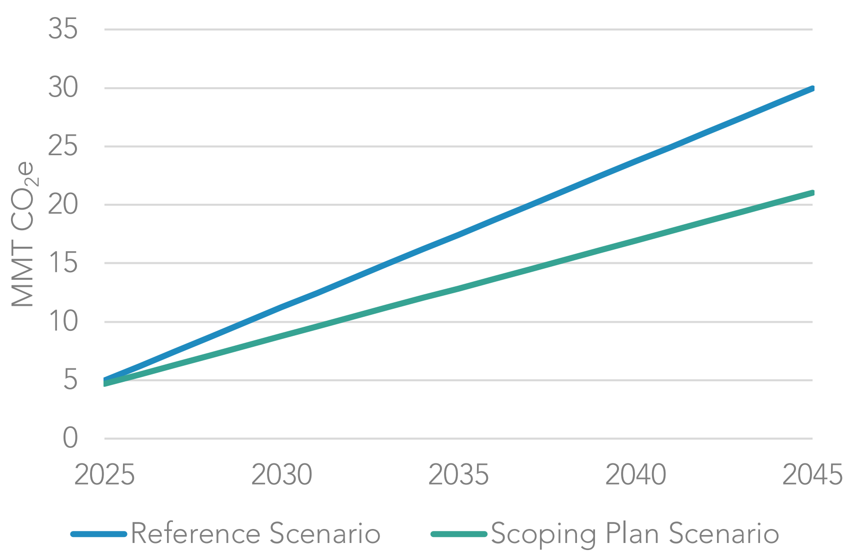
[495] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations N3, N4, N5, N7, N22. finalejacrecs.pdf (arb.ca.gov).
[496] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N11. finalejacrecs.pdf (arb.ca.gov).

Wetlands

Wetlands cover 2 percent of the state (roughly 1.7 million acres) and include inland and coastal wetlands, such as vernal pools, peatlands, mountain meadows, salt marshes, and mudflats. These lands are essential to California's communities as they serve as hotspots for biodiversity, contain considerable carbon in the soil, are critical to the state's water supply, and protect upland areas from flooding due to sea level rise and storms. Wetlands have been severely degraded through reclamation, diking, draining, and dredging practices in the past, resulting in the emissions of the carbon stored in the soils and the loss of ecosystem benefits. Climate smart strategies to restore and protect all the types of wetlands can reduce emissions while simultaneously improving the climate resilience of surrounding areas and improving the water quality and yield for the state. Restored wetlands also can reduce pressure on California's aging water infrastructure. These benefits beyond emissions reductions will help in the future, as climate change is predicted to negatively affect water supply.

Avoided conversion and restoration of Delta wetlands reduces CO_2 and methane emissions from wetlands, with GHG reductions scaling with implementation rates (Figure 4-24). Expansion of conservation and restoration efforts will generate benefits such as the conservation of biodiversity, improved water quality and supply, and reduced flood risk. Additional details on the climate benefit potential of wetlands can be found in Section 2 of the NWL Climate Smart Strategy.

Figure 4-24: Cumulative CO_2e emissions from Delta wetlands by 2045



Strategies for Achieving Success

- Restore 60,000 acres of Delta wetlands annually by 2045 to reduce methane emissions from wetlands and reverse the resulting subsidence.

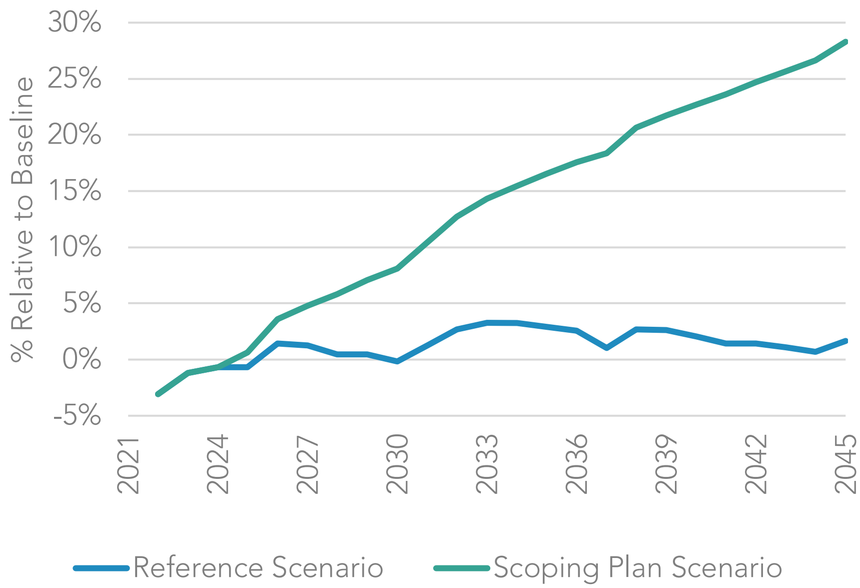
- Identify and prioritize wetland restoration efforts around climate vulnerable communities.
- Leverage other funding and institutions to support wetland restoration projects, including land trusts, local funding (e.g., San Francisco Measure AA), federal funding, and private and philanthropic funding to support wetlands restoration projects.
- Work across state agencies to reduce regulatory and permitting barriers around wetland restoration projects, where appropriate.

Developed Lands

Developed lands cover 6 percent of the state (roughly 6.8 million acres) and include urban, suburban, and rural areas, as well as transportation and supporting infrastructure throughout California. This area encapsulates the land on which the vast majority of Californians reside and call home. The vegetation within cities and communities, and along infrastructure, are all part of developed lands. This vegetation provides numerous benefits to surrounding areas, including carbon storage, air and water filtration, reduced urban heat island effect, and access to nature, aesthetics, and mental health, among others. These areas are susceptible to climate change as well, and climate smart strategies to protect and expand the urban forests, landscaping, green spaces, parks, and associated vegetation can increase their climate resilience and the benefits Californians derive from them. These strategies also have a significant opportunity to benefit disadvantaged communities, who may not have equitable access to these practices or the benefits they provide. Additional details on the climate and equity benefit potential of developed lands can be found in Section 2 and the Introduction of the NWL Climate Smart Strategy.

Urban forests have a significant potential to sequester carbon (Figure 4-25). They are vastly different from wildland forests, as they require investments to maintain and irrigate. This results in the need for a significant increase in investment to increase urban forest carbon. As urban forests become denser and management difficulty increases, the carbon stock returns on investment diminish, making it expensive to maximize carbon in urban forests. Water availability and irrigation efficiency are also an important consideration for increasing urban forest cover. As water becomes scarcer, the prioritization of irrigating trees over lawns or gardens may be required to achieve increases in urban forest carbon.

Figure 4-25: Carbon stocks in urban forests by 2045



Within wildland-urban interface (WUI) areas, defensible space can protect urban and rural communities from wildfire. Analysis results show that 48 percent of parcels are currently fully compliant with defensible space requirements. This highlights how much work needs to be done to protect communities and homes. Defensible space results in a decrease in carbon stocks, as expected when reducing fuels for wildfire.

Strategies for Achieving Success

- Increase urban forestry investment annually by 200 percent, relative to business as usual.
- Increase public awareness of urban forest benefits and, where appropriate, prioritizing irrigation of trees over lawns.
- Provide technical assistance and resources to disadvantaged communities to implement community urban greening projects to provide equitable access to the benefits of urban greening projects.[497]
- Work with state and local agencies to expand technical assistance for and enforcement of the defensible space requirements of PRC 4291 to reduce wildfire risk to homes and structures.

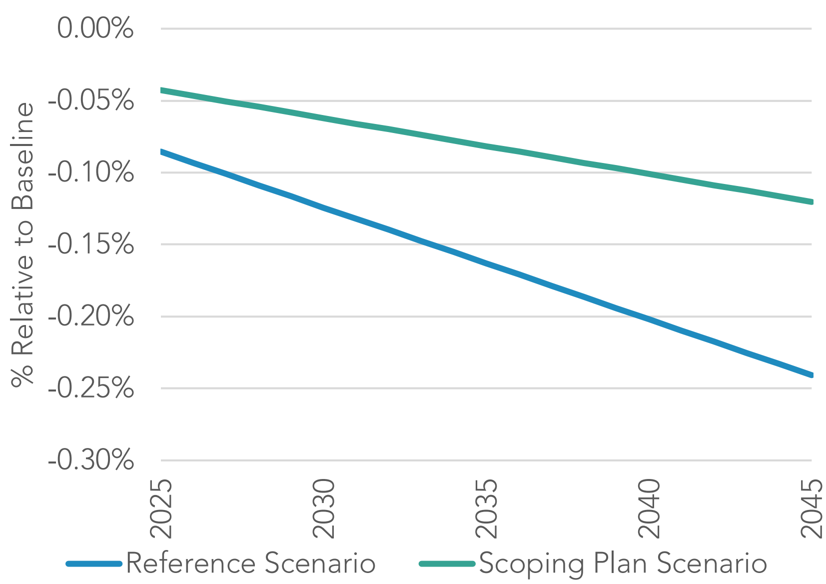
[497] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N8. *finalejacrecs.pdf (arb.ca.gov)*.

Sparsely Vegetated Lands

Sparsely vegetated lands cover 10 percent of the state, roughly 10.2 million acres, primarily in the east and southern parts of California. These lands include deserts, beaches, dunes, bare rock, and areas covered in ice and snow (e.g., higher mountain elevations). The limited carbon storage of these lands varies from bare rock and mineral soil to more vegetated areas, though severe climate limits the amount of biomass. Nonetheless, sparsely vegetated lands are important for open space and provide rare and unique habitats for endemic species and a diversity of wildlife. These lands present important recreational opportunities for Californians and serve as important protective buffers in coastal and low-lying areas. Land use change threatens these lands, and conservation efforts are important for protecting these unique areas of California.[498]

Avoided conversion of sparsely vegetated lands reduces the organic carbon lost from the soil, which is the major carbon pool in this land type (Figure 4-26). In identifying the outcomes for sparsely vegetated lands, CARB modeled avoided land conversion to another land use.

Figure 4-26: Carbon stocks in sparsely vegetated lands by 2045



Strategies for Achieving Success

- Establish and expand mechanisms that ensure sparsely vegetated lands are

[498] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N26. finalejacrecs.pdf (arb.ca.gov).

protected from land conversion, prioritizing those areas most vulnerable to climate change and loss.

Additional Management Strategies

Additional nature-based climate solutions beyond those management strategies modeled for this Scoping Plan are available for implementation, but either cannot currently be modeled and/or affect carbon and the landscape in ways that cannot currently be tracked. Nevertheless, it is important to take action even where these technical gaps exist. Some of these actions, such as cultural burning and indigenous farming practices, have been used on large scales for decades or even centuries, while others are relatively new concepts. The state nevertheless recommends implementing the additional solutions listed here to achieve potential additional climate benefits, as well as other co-benefits. These additional solutions were drawn from the NWL Climate Smart Strategy and stakeholder, tribal government, and interagency feedback.[499]

Considerations

Although these practices are recommended, because of the lack of in-depth modeling and analysis available, several considerations must be addressed when implementing them. These considerations also apply to the management strategies included in the Scoping Plan Scenario.

- Future climate change impacts are uncertain: The negative impact that climate change can have on the ability of these practices to maintain expected climate benefits is uncertain and may significantly change in the future. Climate change is expected to further diminish the already constricting growing conditions in California, with increasing droughts, more extreme weather events, and expanding disturbances from fire, insects, and disease. It is estimated that suitable habitat for many native plant and animal species could shift, creating novel ecosystems without historical precedent. Close monitoring of all practices, including no management, across our NWL will be critical to understand if and how future climate change affects outcomes and how to adapt management to meet the needs of the system under climate change.[500]

---

[499] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N24. *finalejacrecs.pdf (arb.ca.gov)*.
[500] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N15. *finalejacrecs.pdf (arb.ca.gov)*.

- Local conditions: Not every practice is applicable, feasible, or even desirable in every location across California. Implementation of these practices should account for local conditions and needs that may affect the appropriateness of that practice.
- Long-term carbon storage: The ability to sequester additional carbon into NWL is only beneficial to the climate if that carbon stays out of the atmosphere. Many of the additional practices listed here may require continual incentives or interventions to ensure permanence of carbon storage in the soil and biomass. For example, in croplands, it is difficult to estimate how much of the carbon stored by no-tillage can be released by a single subsequent tillage, but a return to conventional tillage would usually be expected to erase most gains.[501,502]
- Scaling actions: There are uncertainties on how these practices may impact both the environment and communities when significantly expanded. For this reason, it is best to take a cautious and measured approach to ramping up actions to a larger scale.
- Infrastructure and operational needs: Scaling up the implementation of some of these practices demands transformational change in the supporting infrastructure and operational frameworks. For example, increasing forest management to the degree included in the Scoping Plan Scenario will require significant changes to wood-processing infrastructure, workforce capacity, permitting processes, technical assistance, and other operational constraints. The increased application of compost to croplands, and potentially to rangelands, will require a significant increase in organic waste and dairy manure collection to increase compost supply, in line with SB 1383. This will also require additional compost production facilities as well as compost/organic waste transportation and application methods.
- Co-benefits: Many co-benefits from these practices exist beyond the climate benefits. These co-benefits include improved public and worker health; improved microbial, insect, and wildlife habitat; enhanced biodiversity; greater labor demand in the nature-based economy; and improved climate resilience.
- Labor and Economics: Many of these practices require additional labor, and an evaluation of how many more jobs are needed to carry out many of these practices

[502] Mitchell, J. P., A. Shrestha, W. R. Horwath, R. J. Southard, N. Madden, J. Veenstra, and D. S. Munk. 2015. "Tillage and cover cropping affect crop yields and soil carbon in the San Joaquin Valley." *California. Agron. J.* 107, 588–596.

is currently unknown. There will also be the need to explore the costs and economic benefits of implementing these additional practices.

- Retreatments: All of these practices have limits on how long they can enhance carbon sequestration. Many of these practices need to be periodically repeated, followed by complementary practices, or maintained through time. This increases costs and requires diligence and long-term stewardship.

Additional NWL Actions and Strategies

Below is a set of additional actions that should be taken on California's natural and working lands. Again, these practices were not modeled for this Scoping Plan, and all of the considerations listed above should be taken into account before implementing the following actions.

- Conservation of all NWL types (in line with the NWL Climate Smart Strategy and CNRA's Pathways to 30x30 California) is critical to ensuring continued carbon sequestration and provision of co-benefits from these lands for all Californians.[503]
- Reforestation following disturbance, using appropriate species, is an impactful practice that can help prevent conversion away from forestland and establish new trees to sequester carbon. The number of acres that may need reforestation following high severity wildfires is estimated to continue to increase into the future.
- Restoration of shrublands, chaparral, riparian zones, and oak woodlands across California includes a variety of practices to alter their structure and return endemic species to the areas. These unique habitats provide multiple co-benefits to the state, such as clean water, reduced wildfire risk, and biodiverse habitats for flora and fauna.
- Conservation and restoration of wetlands, beyond the Delta wetlands included in the NWL modeling, can protect these unique habitats and the climate benefits they provide. These wetland types can include but are not limited to coastal wetlands, mountain meadows, vernal pool complexes, alkali sinks and meadows, and floodplains.
- Conservation and restoration of seagrasses and seaweeds provide a number of benefits, including carbon storage and sequestration, habitat provision for many culturally and commercially important species of fishes and invertebrates, shoreline protection, and tourism opportunities.[504]

---

[503] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N26, N27. *finalejacrecs.pdf (arb.ca.gov)*.

[504] AB 32 EJ Advisory Committee. 2022 Scoping Plan Recommendations, N2. *finalejacrecs.pdf (arb.ca.gov)*.

- Prescribed herbivory utilizes various livestock to consume vegetation to reduce fuel loads across an area. This fuel management practice can be used in forests, grasslands, and shrublands as an effective alternative to herbicide use, and should be considered wherever local conditions allow.
- Urban and community greening efforts such as green schoolyards, urban farms, rain gardens, community gardens, community composting, and many more provide numerous health benefits to communities.
- Additional Healthy Soils Program practices on annual croplands such as conservation cover and crop rotation, biomass planting for borders, wind barriers, riparian areas, and improved nutrient management can improve soil health, water retention, and increase carbon stocks.
- Healthy Soils Program practices on perennial croplands and rangelands, such as compost application and alley cropping/cover cropping to improve soil health, water retention, erosion control, and biomass growth.[505]
- Stacking of these Healthy Soils Program practices, where appropriate, in perennial and annual systems, can synergistically improve soil health and provide multiple benefits.
- Mulching adds high carbon materials to croplands or fallowed lands to reduce competing vegetation and retain moisture. This practice can support other benefits such as reduced water use and reduced synthetic pesticide and fertilizer use, as well as provide a use for suitable forest and agricultural waste biomass.
- Reductions in the use of synthetic fertilizers in cropland management, generally supported by the implementation of new management tools or technologies, can lead to reductions in GHG emissions from the production and application of fertilizers. This benefit is in addition to the co-benefits of reduced chemical runoff into waterways and reduced exposure of human populations to their harmful effects.

[505] Various types of organic amendments are being researched for application to particular landscape types. For example, compost application to rangelands is a relatively new practice that has been shown to improve soil health and increase carbon sequestration in the short term, though the science on the long-term impacts of this practice is still developing and the supply of available compost may be limiting.

Chapter 5: Challenge Accepted

This chapter provides an overview of the next steps and partnerships that will be needed to successfully implement this Scoping Plan. The path forward is not dependent on one agency, one state, or even one country. It will take action on a global level to address the threat climate change poses. But, the work begins at home.[506] The state can lead by engaging Californians and demonstrating how action at the state, regional, and local levels of government, as well as action at community and individual levels, can contribute to addressing the challenge before us. We must build partnerships with academic institutions, private industry, and others to support and accelerate the transition to carbon neutrality. Ultimately, the success of this Scoping Plan will be measured by our ability to implement the actions modeled in the Scoping Plan Scenario at all levels of government and society. This will depend on a mix of legislative action, regulatory program development, incentives, institutional support, workforce and business development, education and outreach, community engagement, and research and development and deployment. Optimizing this mix will help to ensure that clean energy and other climate mitigation strategies are clear, winning alternatives in the marketplace and in communities—to promote equity, drive innovation, and encourage consumer adoption. Bold institutional action will catalyze continued research and push private investment to create jobs and bring innovative ideas to reality.

State-level Action

Achieving the targets described in this Scoping Plan will require continued commitment to and successful implementation of existing policies and programs and identification of new policy tools and technical solutions to go further, faster. California's Legislature and state agencies will continue to collaborate to achieve the state's climate, clean air, equity, and broader economic and environmental protection goals. It will be necessary to maintain and strengthen this collaborative effort, and to draw upon the assistance of the federal government, regional and local governments, tribes, communities, academic institutions, and the private sector to achieve the state's near-term and longer-term emission reduction goals and a more equitable future for all Californians.

---

[506] This "polycentric" approach to climate challenges, engaging many levels of government, was articulated in leading papers by Nobel laureate Elinor Ostrom. See, for example, Ostrom, E. 2014. "A Polycentric Approach to Coping with Climate Change." *Annals of Economics and Finance* 15-1, 97–134.

Regulations and Programmatic Development

Meeting the AB 32 2020 GHG emissions reduction target several years earlier than mandated demonstrated that developing mitigation strategies through a public process, where all stakeholders have a voice, leads to effective actions that address climate change and yields a series of additional economic and environmental co-benefits to the state. Following adoption of this Scoping Plan, state agencies will continue to update and implement new and existing programs to align with the outcomes in the plan. Community, tribal, and stakeholder engagement will be a critical part of this work. Several state agencies, including CARB, the CEC, the California State Transportation Agency (CalSTA), the CPUC, and others will need to be part of various subsequent rulemaking processes. Each of these agencies' leadership and technical staff will engage with the public through public meetings, written and oral comment, and other methods of engagement. This work will be informed by evaluations of the health, air quality, environmental, equity, and economic benefits and impacts of regulations, including an assessment of the societal cost of carbon, as required under AB 197.

Incentive Programs

As described in Chapter 1, incentive programs are one of the most important tools the state has in advancing our low carbon future, especially for climate vulnerable communities. The programs ensure clean technology and energy are accessible and are critical to closing ongoing opportunity gaps. These programs also leverage private-sector investment and build sustainable, growing markets for clean and efficient technologies, and they are particularly necessary to support GHG emission reduction strategies for priority sectors, sources, and technologies. Clean technologies are often already the best and lowest cost option over their lifetimes but incentive funding is critical to ensure that they are broadly available, especially in climate vulnerable communities. Incentives also build on California's long track record of driving innovative technology developments, and creating new industries, with targeted investment. The Inflation Reduction Act also provides a new source of funding and tax incentives that must be leveraged to help achieve the state's climate goals.

Many state funding programs are designed to achieve multiple objectives simultaneously: reduce emissions from GHGs, criteria pollutants, and toxic air contaminants; manage natural and working lands for carbon sequestration; and address health and opportunity gaps in disadvantaged communities. California's incentive programs focused on jump-starting the transition to a zero emission transportation future are a good example of this "stacked" approach. The state is investing billions of dollars through programs such as the On-Road Heavy-Duty Voucher Incentive Program and Clean Cars 4 All in order to replace the light- and heavy-duty vehicles most responsible for the state's GHG emissions and poor air quality, all while bolstering the nascent ZEV market. Further strategies aid in developing new technologies, in ramping up access for all, and in shifting to cleaner modes of transport; for instance, by supporting investments in walkable, bikeable communities and transit, as well as in vehicles. This funding strategy is, of course, paired with the regulatory approach described above.

Local Action

Local action by cities can support and amplify efforts to reduce GHGs. For example, the City of Oakland requires all new construction to be all-electric and is currently working on electrifying existing buildings.[507] In addition, starting in 2023, the City of Sacramento will require all new buildings under three stories to be all-electric, and it extends the mandate to all new construction by 2026 with some limited exemptions. The City of Sacramento also requires levels of EV charging infrastructure in new construction starting in 2023, higher than the minimum state requirements, and provides parking incentives for zero-emission carsharing and EV charging.[508] Local governments asserting this type of leadership are critical partners in supporting state-level measures to contain the growth of GHG emissions associated with the transportation system and the built environment.

California must accommodate population and economic growth in a far more sustainable and equitable manner than in the past. Good climate policy can and should create affordable and pleasant places to live, with effective transport and clean air for all—a future in which local governments and communities are central partners. Local governments have the primary authority to plan, zone, approve, and permit how and where land is developed to accommodate population growth, economic growth, and the changing needs of their jurisdictions. They also make critical decisions on how and when to deploy transportation infrastructure, and can choose to support transit, walking, bicycling, and neighborhoods that do not force people into cars. Local governments also have the option to adopt building ordinances that exceed statewide building code requirements, and play a critical role in facilitating the rollout of ZEV infrastructure. As a result, local government decisions play a critical role in supporting state-level measures to contain the growth of GHG emissions associated with the transportation system and the built environment—the two largest GHG emissions sectors over which local governments have authority.

Local governments are also frequently the source of innovative and practical climate solutions that can be replicated in other areas. Their efforts to reduce GHG emissions within their jurisdictions are vital to achieving the state's near-term air quality and long-term climate goals. Local governments must continue to take action that affirmatively

[507] City of Oakland. Building Electrification. *https://www.oaklandca.gov/projects/building-electrification*.
[508] City of Sacramento. Electrification of New Construction. *http://www.cityofsacramento.org/SacElectrificationOrdinance*.

builds the projects and expend the funds needed to further the state's collective path toward equitable emissions reductions. As such, aligning local jurisdiction action with state-level priorities to tackle climate change and the outcomes called for in this Scoping Plan is critical to achieving the statutory targets for 2030 and 2045. Local governments can implement climate strategies that can effectively engage residents by addressing local conditions and issues that also deliver local economic benefits.

Local Climate Action Planning and Permitting

California encourages local jurisdictions to take ambitious, coordinated climate action at the community scale; action that is consistent with and supportive of the state's climate goals.[509] As discussed in more detail in Appendix D (Local Actions), local jurisdictions can do much to enable statewide priorities, such as taking local action to help the state develop the housing, transport systems, and other tools we all need. Indeed, state tools—such as the Cap-and-Trade Program or zero-emission vehicle programs—do not substitute for these local efforts. Multiple legal tools are open to local jurisdictions to support this approach, including development of a climate action plan (CAP), sustainability plan, or inclusion of a plan for reduction of GHG emissions and climate actions within a jurisdiction's general plan. Any of these can help to align zoning, permitting, and other local tools with climate action.

Once adopted, the GHG emissions reductions plans detailed in CAPs can provide local governments with a valuable tool for coordinated climate planning in their community. When a local CAP complies with CEQA requirements, individual projects that comply with the CAP are allowed to streamline the project-specific GHG analysis.[510,511] Effectively, local governments that adopt a CEQA-compliant CAP enable project developers to use this streamlined approach. This saves time and resources and provides more consistent expectations for how GHG reduction measures are applied across projects in the jurisdiction. While the state encourages local governments to follow this approach, we acknowledge not all jurisdictions have the resources to develop a CAP that meets the CEQA requirements.

In addition to being required for a local CAP to comply with CEQA, local GHG reduction targets have long been recommended as part of the process of developing a climate

---

[509] This plan provides more detailed guidance and tools to local governments in Appendix D (Local Actions).

[510] Cal. Code of Regs., tit. 14, § 15183.5.

[511] California Governor's Office of Planning and Research. n.d. "General Plan Guidelines - Chapter 8 Climate Change."

action plan.[512] One challenge local jurisdictions have faced is how to evaluate and adopt quantitative, locally appropriate goals that align with statewide goals. An effective response to this challenge is to focus on goals that can help implement overall state priorities—enabling the key transformations California needs.

There are many ways that local governments can make key contributions to this transformation, depending on the characteristics of their jurisdiction and community. For example, some jurisdictions will inherently have more land capacity to remove and store carbon, whether through natural and working lands or by other means. Other jurisdictions will be host to GHG-emitting facilities that serve necessary functions and will take time to transition to clean technology (e.g., municipal wastewater treatment plants, landfills, and energy generation and transmission facilities). It is important to recognize that we will need to build new energy production and distribution infrastructure, and repurpose existing ones, for clean technology and energy before we are able to phase down existing fossil sources. There also will be a need to handle the significant amount of biomass resulting from sustainable forest management for catastrophic wildfire prevention, agricultural waste, and landfill diversion.

Regional efforts can support change too: energy and transportation systems that serve Californians do not stop at jurisdictional boundaries, and some local decisions can have ramifications for other communities. For instance, Metropolitan Planning Organizations (MPOs) can help to integrate local efforts by planning consistent with the Scoping Plan and Climate Action Plan for Transportation Infrastructure, including by removing polluting roadway capacity expansions from project pipelines and instead focusing on climate-friendly solutions. These varied capabilities and needs should be taken into account in setting targets for local climate plans. For instance, although net zero targets can often be valuable and achievable, and mitigation is important, targets should be considered in the larger context of these goals. This all means any GHG targets on a local scale should take into consideration the actions and outcomes included in this Scoping Plan. Jurisdictions considering "net zero" targets should carefully consider the implications such targets may have on emissions in neighboring communities and the ability of the state to meet our collective targets.

Jurisdictions without formal CAPs also have important opportunities within this context. These jurisdictions can still take actions that effectively translate key state plans, goals, and targets, including those articulated in this Scoping Plan for local action. For instance, state ZEV targets can advance local efforts to promote broad and equitable access to charging and fueling. Similarly, local jurisdictions can enable reduced dependence on

---

[512] Climate Smart Communities. 2014. Climate Action Planning Guide. https://cdrpc.org/wp-content/uploads/2015/05/CAP-Guide_MAR-2014_FINAL.pdf.

single-occupancy vehicles by supporting dense infill housing and transit, among other actions. Such actions can be reflected in particular project plans, in general plans, or through other local policies. Regional partnerships among these jurisdictions can also help tap resources and provide for more effective overall action.

Unlocking CEQA Mitigation for Local Success

The California Environmental Quality Act also provides important tools for lead agencies to support the achievement of the state's GHG and VMT reduction goals. Although many climate-friendly local government actions already fall into categories that may not require a full CEQA analysis, thanks to streamlining or other tools, and although certain product types (such as affordable infill housing) are generally clearly consistent with state climate goals, CEQA analyses may still sometimes be required. CEQA can be a powerful and useful tool to engage the public, identify additional opportunities to support climate efforts, and localize change. It is important that lead agencies look for ways to use CEQA to support these core purposes, ensuring that these processes do not become sources of delay but instead unlock more opportunities. The uncertainty analysis in Chapter 2 evaluates how project implementation delays can lead to missed state climate targets and continued dependence on fossil energy. Mitigation measures applied in the communities affected by projects subject to CEQA have the added benefit of improving health, social, and economic resiliency as climate impacts worsen.

Appendix D (Local Actions) explores the role of local government action and CEQA in detail. As discussed there, an important CEQA-related tool is mitigation—which can be used to further drive local action consistent with state climate goals. When a lead agency determines that a proposed project would result in potentially significant GHG impacts due to its GHG emissions or a conflict with state climate goals, the lead agency must impose feasible mitigation measures to minimize the impact. Appendix D (Local Actions) provides suggestions for prioritizing the various types of mitigation, starting with on-site GHG-reducing design features[513] and mitigation measures, such as methods to reduce VMT and support building decarbonization, access to shared mobility services or transit, and EV charging. After exhausting all the on-site GHG mitigation measures, CARB recommends prioritizing local, off-site GHG mitigation measures, including both direct investment and voluntary GHG reduction or sequestration projects, in the neighborhoods impacted by the project. This could include, for example, development of a neighborhood green space, investment in street trees, or expansion of transit services. Implementing GHG mitigation measures in the project's vicinity would allow the project proponent and the lead agency to work directly with the affected community to identify and prioritize the

[513] Cal. Code of Regs., tit. 14, § 15126.4(c)(2) and (3).

mitigation measures that meet their needs while minimizing multiple environmental and societal impacts.

Once all potential on-site and local off-site GHG mitigation measures have been incorporated to the extent feasible, Appendix D (Local Actions) provides further suggestions for prioritizing other mitigation types, including non-local off-site mitigation, and voluntary offsets issued by a recognized and reputable voluntary carbon registry (as listed on CARB's website[514]) may be appropriate. Additional in-state mitigation also may be available in the upcoming SB 27[515] (Skinner, Chapter 237, Statues of 2021) registry, which will serve as a database of projects in the state that drive climate action on natural and working lands. Lead agencies should use substantial evidence to demonstrate that the project proponent explored and prioritized investments in feasible, local mitigation prior to moving mitigation to a geography located farther away from the project.

Communities and Environmental Justice

As noted in Board Resolution 20-33,[516] it is incumbent on CARB to function as an agent of responsible social change, especially when it is clear that environmental injustices continue to persist for low-income communities, tribes, and communities of color.

State law defines *environmental justice* as the fair treatment of all people of all races, cultures, and incomes with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies.[517] Government Alliance for Race and Equity (GARE)[518] defines *racial equity* as when race can no longer be used to predict life outcomes and outcomes for all groups are improved.

For this Scoping Plan to be successful, it must address environmental justice and advance racial equity. Implementation of the plan needs to address the needs of those communities that are disproportionately burdened by climate impacts and continue to face significant health and opportunity gaps. Now, we need to ensure our actions allow these communities to not only have a seat at the table, but also inform and shape the policies

to ensure their communities thrive. With this Scoping Plan, the state also adds a new tool to identify which communities will be the least resilient in the face of selected climate impacts and will see disproportionate economic impacts as a result. As described in Chapter 3, the CVM will enable the state to target programs and policies to build resiliency in the specific regions that will feel climate impacts more acutely due to existing health and opportunity disparities leading to disproportionate economic impacts. This tool will be critical in the state's efforts to address climate impacts while accounting for environmental injustices and racial inequities. CARB will incorporate the CVM into its work as it moves forward and will share this new tool with other agencies to align our efforts. The goal is to keep expanding the CVM to incorporate additional climate impacts to better identify disproportionate economic impacts as community level data becomes available.

AB 617 is another important tool for both Air Districts and CARB to bring resources to communities that have long been disproportionately burdened by poor air quality. While AB 617 does not require local agencies to participate in the Community Air Protection Program, several AB 617 communities are finding ways to bring local land use agencies to the table to respond to community priorities. We look forward to more opportunities to foster relationships with local authorities and continued collaboration between state and air district programs.

In alignment with AB 32, and to ensure environmental justice and racial equity were integrated into this Scoping Plan, CARB reconvened the AB 32 Environmental Justice Advisory Committee (EJ Advisory Committee) to advise CARB on the development of this Scoping Plan. Since reconvening in May 2021, the EJ Advisory Committee has engaged in the following activities:

- In October 2021, the EJ Advisory Committee sent a letter to the governor requesting a timeline extension for the Scoping Plan process. In response to the EJ Advisory Committee's letter, CARB modified this Scoping Plan process[519] and committed to an active engagement with the EJ Advisory Committee following the approval of this Scoping Plan. The EJ Advisory Committee also presented to the CARB Board[520] at its October 2021 Board meeting, reiterating its request for a timeline extension, as well as sharing additional concerns about process.

[520] Argüello, M. D., K. Hamilton, S. Taylor, and P. Torres. 2021. EJ Advisory Committee Co-Chair Informational Presentation to CARB Board. October 28. https://ww2.arb.ca.gov/sites/default/files/barcu/board/books/2021/102821/21-11-4pres.pdf.

- In December 2021, the EJ Advisory Committee shared its responses to Scenario Input Questions,[521] as well as a narrative document outlining their concerns[522] around the process, the need for evaluation, and the need for a tribal representative. In response to the EJ Advisory Committee Scenario Input Questions, CARB incorporated the EJ Advisory Committee responses into the Scenario Assumptions document,[523] and modeled results from PATHWAYS.[524] In response to the EJ Advisory Committee's concerns, CARB worked diligently to appoint a tribal representative[525] in February 2022, and to outline additional opportunities for the EJ Advisory Committee to engage in the Scoping Plan process.[526]
- In March 2022, the EJ Advisory Committee presented at the joint EJ Advisory Committee / CARB Board meeting[527] and walked through their preliminary draft recommendations to inform this Scoping Plan. In April, the EJ Advisory Committee shared its revised preliminary draft recommendations[528] to inform this Scoping Plan.
- In September 2022, the EJ Advisory Committee presented at the joint EJ Advisory Committee / CARB Board meeting[529] and engaged in discussion about priority items as they relate to incorporating environmental justice into the Scoping Plan. By the end of September, the EJ Advisory Committee shared its final

recommendations[530] to inform this Scoping Plan. To the extent possible, CARB has incorporated and cited these recommendations through this Scoping Plan.

In addition to the activities listed above, Central Valley EJ Advisory Committee members hosted a successful community engagement workshop[531] in San Joaquin Valley in February 2022 with over 100 attendees. Members of EJ Advisory Committee hosted a statewide community engagement workshop[532] in June 2022 with more than 165 attendees. Throughout the EJ Advisory Committee's process, members of the Committee continued to work with their communities to ground truth their recommendations to inform the development of the Scoping Plan. The EJ Advisory Committee worked hard to ensure the voices of those communities most burdened by climate impacts were reflected in the plan. The EJ Advisory Committee will continue to play an ongoing role in the implementation of this Scoping Plan to ensure environmental justice and racial equity are prioritized in our effort to address the climate challenge before us.

To the extent possible, the EJ Advisory Committee's recommendations were integrated throughout the plan. This plan directly cites instances where there is alignment between the plan and the EJ Advisory Committee recommendations. This approach seeks to ensure there is more transparency and identify consensus that exists, as well as relevant ways equity and environmental justice are addressed in this plan and in the planning for future related implementation activities. CARB is dedicated to its efforts to ensure this plan does not leave communities behind.

As this Scoping Plan moves into the implementation phase, there will be a need to better understand how to address EJ Advisory Committee recommendations on the following topics:

- Actions under the jurisdiction of other agencies: there are certain EJ Advisory Committee recommendations that are outside of CARB's jurisdiction. As the EJ Advisory Committee continues to convene, it would be helpful to understand the

[530] EJ Advisory Committee. 2022. EJAC 2022 Scoping Plan Recommendations. September 30. https://ww2.arb.ca.gov/sites/default/files/barcu/board/books/2022/090122/finalejacrecs.pdf

role that CARB can play as it relates to the EJ Advisory Committee's recommendations for actions outside CARB's jurisdiction and coordinates with sister agencies.

- Actions that require legislative direction: there are certain EJ Advisory Committee recommendations that would require legislative action. As the EJ Advisory Committee continues to convene, it will be helpful to understand how CARB can work with the EJ Advisory Committee to share these recommendations with the appropriate members of the Legislature.
- Actions directly tied to implementation activities: This Scoping Plan is not an implementation document; it is a plan to chart a course to continue to reduce GHG emissions and achieve carbon neutrality. Once the Scoping Plan is approved, there will be follow-up action at CARB, as well as at other agencies. In these follow-up efforts, there will be a role for ongoing EJ Advisory Committee engagement.
- Actions to implement recent legislation, such as SB 905.

CARB proposes to continue to work with the EJ Advisory Committee to better understand how to move forward on EJ Advisory Committee recommendations that fall into the topics listed above and any other recommendations that were not included in this plan. It is also important to note that there are numerous recommendations where CARB shares the goals of the EJ Advisory Committee and can assist in implementation steps. Examples include the following:

- CARB shares the goal of prioritizing non-fossil energy generation and supports non-fossil projects and opportunities to locate behind-the-meter clean resources in communities of concern in programs such as the Solar on Multifamily Affordable Housing program.
- CARB will engage with agencies and academic institutions to further workforce development.
- Many other recommendations related to financial support for various energy projects, such as microgrids, are within the purview of the CPUC or local publicly owned utilities. Similarly, utility scale projects are within the jurisdiction of other agencies. However, CARB supports strategies identified in the recommendations such as offshore wind to reduce the reliance on fossil fuel generation.
- CARB is supportive of rooftop solar, although it is not within CARB's jurisdiction to determine how incentives for those projects are structured.
- CARB is supportive of strong energy decarbonization goals, recognizing that increased reliance on electrification in transportation and other sectors will create significant demand for electricity, and therefore ensuring reliability of a decarbonized grid is a critical need for the state.
- In the transportation sector, CARB is supportive of the EJ Advisory Committee's recommendations to maintain aggressive zero emission vehicle goals consistent

with its statutory mandate to ensure regulations are technologically feasible and in alignment with Governor Newsom's ZEV Executive Order (EO N-79-20). CARB looks forward to continued engagement on rulemakings that will implement these goals.

- As noted elsewhere in this plan, CARB is supportive of the Caltrans California Transportation Plan 2050 and the California Climate Action Plan for Transportation Infrastructure.
- CARB is supportive of additional public support for transit. CARB is supportive of locating EV charging in low-income communities and communities of color.
- CARB is supportive of prioritizing funding incentives for transit and heavy- and medium-duty vehicles, although CARB does believe there is an important role for incentives that support adoption of light-duty vehicles for the time being. CARB will also be opening a rulemaking on the Low Carbon Fuel Standard to ensure it continues to support clean fuels that will displace petroleum fuels and will consider the EJ Advisory Committee recommendations on this program.
- In the industrial sector, in addition to the strategies discussed more fully in this Scoping Plan, CARB continues to work with the Legislature, local agencies, and air districts to support, implement, and enforce effective reductions in emissions of GHGs and air pollutants in stationary sources. The air districts have the authority to directly issue permits addressing a facility's criteria pollutant and toxics emissions levels. These levels are set after careful permit review, under district regulation and statute. However, AB 617 directs and authorizes CARB to take several actions to improve data reporting from facilities, air quality monitoring, and pollution reduction planning for communities affected by a high cumulative exposure burden. CARB will continue to implement AB 617 and look for ways to strengthen the Community Air Protection Program.
- Considerations around the phaseout of oil and gas extraction and refining, and the role of carbon capture are discussed more thoroughly in Chapter 2.

As CARB continues to engage with the EJ Advisory Committee—in addition to the EJ Advisory recommendations that have been integrated throughout this plan—below are the following commitments that CARB is making to ensure that environmental justice is integrated in this plan and its implementation:

- Building decarbonization is a pillar of this Scoping Plan and CARB commits to working closely with state and local agencies to implement the EJ Advisory Committee recommendations that call for prioritization for residents in low-income communities and communities of color in this transition.
- CARB commits to sharing the EJ Advisory Committee's recommendations with the CEC, CPUC, and other agencies administering funds to support building

decarbonization, and to work closely with those agencies as they engage in public processes to further building decarbonization.

- CARB has committed to review the Cap-and-Trade program and determine what potential legislative or regulatory amendments could be necessary to ensure the program continues to deliver GHG reductions needed to achieve the statutory climate goals. In that process, CARB will consider the recommendations of the EJ Advisory Committee[533] and Independent Emissions Market Advisory Committee,[534] as well as others.

Critically, the EJ Advisory Committee makes numerous recommendations centered around tracking progress of the various strategies in this Scoping Plan. Currently, progress is tracked and reported in numerous ways, including the annual GHG inventory and reports to the Legislature. Part of the ongoing work of implementation, however, will include consideration of ways to provide more data and information to the public, such as rates of deployment of clean energy and technology as described in Chapter 1. CARB will also continue to collaborate with CDPH and OEHHA on health metrics to track cumulative benefits of air pollution and climate programs, especially in low-income communities and communities of color.

As noted earlier in this document, the EJ Advisory Committee will continue to play a vital role in the Scoping Plan and its implementation to ensure environmental justice and racial equity are prioritized in our effort to address the climate challenge before us. This includes ongoing EJ Advisory Committee engagement to advise CARB on the development of the Scoping Plan and any other pertinent matters in implementing AB 32. The ongoing EJ Advisory Committee will help to ensure integration of environmental justice in implementation efforts as it relates to AB 32, and also help CARB as we work toward a future where race is no longer a predictor for life outcomes.

Academic Institutions and the Private Sector

Academic institutions produce and present the latest science on both the impacts of, and actions to reduce, climate change damages. They are also leading the way by

[533] California Legislative Information. Bill Text – AB 32. Air pollution: greenhouse gases: California Global Warming Solutions Act of 2006. (AB 32, Nuñez, Chapter 488, Statutes of 2006). https://leginfo.legislature.ca.gov/faces/billNavClient.xhtml?bill_id=200520060AB32.

[534] California Legislative Information. Bill Text – AB 398. California Global Warming Solutions Act of 2006: market-based compliance mechanisms: fire prevention fees: sales and use tax manufacturing exemption. (AB 398). https://leginfo.legislature.ca.gov/faces/billNavClient.xhtml?bill_id=201720180AB398.

establishing their own climate goals and GHG emissions reductions targets.[535, 536, 537] They are incubators for innovation and knowledge in clean energy and technology and play an important role in adding to the wealth of robust information to inform policies and programs. Academic institutions have the ability to fill knowledge gaps and push us toward new frontiers. As we move forward, we will continue to see these institutions as partners and resources that can help CARB look for ways to accelerate and introduce actions to reduce GHG emissions and remove and store carbon.

As such, it will be important to maintain and enhance relationships with academic institutions, including community colleges. Community colleges are more likely to have a large proportion of first generation students or students that come from low-income communities or communities of color. The perspective of this diverse student body will be critical to inform discussions on climate change damages and mitigation efforts. This student body is also a future workforce, and courses to teach the skills for a sustainable economy are a chance to close historical opportunity gaps. Importantly, many of the students at community colleges are local residents and community members. This engagement provides another way to invest in communities across our state. The Foundation for California Community Colleges is already leading the way through innovate programs such as their Good Jobs Challenge - California Resilient Careers in Forestry.[538] These types of programs could be replicated across other sectors. CARB will evaluate how to leverage the requirements in AB 680 on workforce development in the California Climate Investments programs with the work at the Foundation for California Community Colleges.

As noted in Chapter 1, public and private partnerships will be important as we move forward in the great energy transition. But the private sector is also important in the context of research and development and deployment. Many of these companies have the resources and expertise to build and produce the clean technology and energy we will need. It was through the efforts of several private companies (Bell, Exxon, Telecom

[538] Foundation for California Community Colleges. 2022. Good Jobs Challenge. Developing Resilient Careers in Forestry for Californians. https://foundationccc.org/What-We-Do/Workforce-Development/Good-Jobs-Challenge.

Australia) that the photovoltaic solar panels in use today were developed.[539] Similarly, it was companies such as General Electric and Texas Instruments that contributed to the development of hydrogen fuel cells.[540] This Scoping Plan includes the known and emerging clean technologies and fuels available today. The private sector spirit of invention, improvement, and innovation must continue to deliver new tools in the fight against climate change.

Individuals

This Scoping Plan not only projects ambitious availability of clean technology and energy, but also includes aggressive assumptions about consumer adoption of ZEVs, heat pumps, and other energy efficiency practices, among others. When it comes to climate change mitigation, the sum of the parts matters. Only when we add up the impacts of the choices we make do we understand the true impact on GHG emissions. Today, many Californians have opportunities to choose between driving a car, taking a bus, biking, or walking. Many can choose to install a heat pump or buy an electric cooktop. Together, we can increase these opportunities and pick the future we want. We can start or transform businesses that create clean jobs, innovate new technologies, or introduce new systems. We can engage with fellow workers to support durable paths for labor in a clean economy. And we can choose to engage with our community, tribes, and our governments to advocate for change, call out challenges, and propose solutions. Our choices will help determine California's climate future. Down one path is a future of climate impacts that will continue to worsen and further increase disparities across communities. Down the other is a future that avoids the worst impacts of climate change, improves air quality—especially for the most burdened communities—and fosters new economic and job opportunities to support a sustainable economy.

Importantly, we must acknowledge that historical decisions have resulted in health and opportunity gaps for residents in low-income communities and communities of color. Not everyone has the resources or access to make these choices—to buy a ZEV, install a heat pump, or use public transit to get to work. It is here that government can help. Government, at multiple levels, can fund programs and structure policies to provide consumers with more choice and to support them in adopting cleaner technology options. Whether through affordable energy rates or assistance in purchasing zero emission vehicles and appliances, we can use the transition to a carbon neutral economy as an opportunity to close some of these persisting opportunity gaps. By acting now, we can

Re: Opposition to California Air Resources Board Proposal to Regulate Jet Fuel

Dear Chair Randolph,

As members of the aviation industry, we are writing to share our serious concern and opposition
to the recent California Air Resources Board (CARB) proposal to regulate jet fuel under its Low
309.1 Carb Fuel Standard (LCFS) Program. We believe the CARB proposal will raise the cost of jet
fuel without inducing additional Sustainable Aviation Fuels (SAF) production or use in California,
an objective the aviation industry shares with CARB. And further, the proposal to regulate jet
309.2 fuel is pre-empted by federal authority. We encourage CARB to withdraw the proposal to
309.3 regulate jet fuel and instead establish a joint CARB-industry working group to explore alternative
solutions to increase SAF production and use.

The aviation industry is committed to reducing its climate impact and achieving net zero carbon emissions by 2050, and transitioning to SAF is core to this commitment. We have long recognized that scaling up the supply of SAF and achieving net-zero carbon emissions by 2050 can only happen by working collaboratively with governments and other stakeholders across sectors. Achieving this ambition for SAF will require new and additional policy incentives, streamlined permitting processes, and close collaboration among governments, the aviation industry, the fuels industry, environmental organizations and others.

Aviation accounts for 2.6% of the U.S. greenhouse gas emissions but 5% of U.S. Gross Domestic Product (GDP) and 4.1% of California's GDP, thus exerting outsize economic impact relative to its share of emissions. U.S. civil aviation firms employ more than 380,000 California-based employees, with an overall economic impact of $194 billion.[1] Aviation is critical to driving California's economy and its rank as the 5th largest economy in the world, enabling $114 billion in annual trade flows and underpinning many of California's other significant economic drivers such as agriculture, tourism, manufacturing, banking, technology and small business.

California has established itself as an early leader in attracting investment, production, and use of SAF through the existing LCFS Program, which provides an opt-in credit for SAF that helps reduce the price difference between SAF and conventional jet fuel. Ensuring a healthy and vibrant aviation industry is essential to California's future, and leveraging CARB's early leadership on SAF can enable California leadership in the emerging SAF production industry, creating new jobs and economic development opportunities.

With this context, we express our serious concern with the proposal by CARB to regulate jet fuel
used for flights within California as an obligated fuel under the LCFS Program. This proposed
309.1 change would be unlikely to result in increased SAF production, availability, or use in California,
but would lead to higher jet fuel prices and slow down, rather than accelerate, efforts to increase

[1] The Economic Impact of Civil Aviation on the U.S. Economy, State Supplement, US Department of Transportation, November 2020

the state's SAF production and use. The primary impediment to increased SAF production and availability in California remains the higher cost of SAF for producers and buyers relative to conventional jet fuel and renewable diesel. The CARB proposal would not address this fundamental challenge or otherwise meaningfully increase SAF supply or use.

309.2 In addition to not being an effective policy tool to increase SAF production, the proposal seeks to regulate jet fuel and reduce emissions from aviation, both of which are preempted under federal law, a fact that CARB recognized when it exempted jet fuel from the LCFS in 2018.[2] Aviation, unlike many other industries, is uniquely situated in that other factors such as the safe operation and maintenance of aircraft are of great importance, which the federal government has recognized in the jurisdiction of the FAA and the EPA's Clean Air Act.

309.3 Our mutual interest is to increase SAF production, availability, and use, and the most effective way to accomplish this is to continue the positive, collaborative approach represented by the existing "opt-in" mechanism developed by CARB and the aviation community. We urge CARB to reconsider and withdraw the proposal to remove the exemption for jet fuel for intrastate flights, preserve the existing opt-in approach for SAF, and establish a joint CARB-industry working group with stakeholders across the emerging SAF ecosystem to explore alternative policy and voluntary proposals to rapidly increase SAF production, availability and use in California. We look forward to working with CARB on such measures to accelerate SAF deployment.

Sincerely,

Airlines for America® We Connect the World

RE: Low-CI Power Coalition's Comments on Proposed Low Carbon Fuel Standard Amendments.

Dear Chair Randolph and Executive Officer Cliff:

Our diverse group of low carbon fuel producers and developers, including Blue Arrow, Eco Energy, Fulcrum BioEnergy, Growth Energy, the Renewable Fuels Association, POET, Velocys, and World Energy (collectively, the "Low-CI Power Coalition") offers the following comments on the proposed amendments to the Low Carbon Fuel Standard ("LCFS") ("Proposed Regulation Order"). As reflected in the attached Appendix 1, these leading-edge companies utilize a diverse range of low carbon feedstocks and advanced process technologies to produce the low carbon fuels of the future including ethanol, renewable diesel, renewable naphtha, and sustainable aviation fuel.

These comments respond to the proposed revisions to Section 95488.8(i)(1)(C), which would allow wholesale power contracting as part of a narrow set of fuel pathways (certain hydrogen pathways and direct air capture projects). These comments explain why the proposal should apply to a broader set of low carbon intensity ("Low-CI") alternative fuels, and why excluding these fuels is arbitrary and contravenes the California Air Resources Board's ("CARB's") own policy seeking to accelerate rates of deployment of clean technology and fuels identified in the scoping plan.[1] While we are broadly supportive of many aspects of the Proposed Regulations, we are deeply concerned that the Regulation will not achieve all cost-effective emission reductions and will leave federal money that could be directed to clean energy
310.1 development in California on the table. For reasons discussed in our pre-rulemaking comments, CARB should amend Section 95488.8 to ensure that all alternative fuels can achieve incremental

[1] 2022 Scoping Plan Update, at 182.

310.1 cont. emission reductions when their alternative fuel source leads to new electricity demand.[2] This approach (the "Low-CI Proposal") is workable and consistent with CARB's objectives and stated policies supporting the optimal use of Low-CI resources to help meet California's climate goals.

DISCUSSION

I. CARB Should Expand Low-CI Power Provisions in Section 95488.8(i)(1)(C) to include a Broader Set of Tier 2 Applications.

The Low-CI Proposal is straightforward, designed to avoid any concerns about resource shuffling, and is simple to implement. As described in our June 6, 2023, comments, the Low-CI Proposal would allow for review of eligible new Low-CI power sources that are contracted by fuel pathway holders and delivered via the grid. The fuel pathway holder would be required to submit documentation as part of a Tier 2 application that it has contracted for one or more new Low-CI power sources under a power purchase agreement ("PPA") or ownership agreement.

Significantly, the contract or ownership agreement would have to meet three essential threshold requirements to ensure additionality, including a showing through the Tier 2 application process that the facility providing Low-CI electricity is not contracted with another buyer or included in a utility resource plan, a showing that the commercial online date of the facility occurs after execution of the PPA or ownership agreement, and a showing that the environmental attributes of the facility cannot be contracted, sold or transferred to any other buyer. The Low-CI Proposal did not include restrictions as to the alternative fuel because the benefits of the proposal can accrue from a range of Low-CI alternative fuels, including renewable hydrogen, renewable diesel and naphtha, ethanol, and sustainable aviation fuel. As described in our comments, the Low-CI Proposal would create additional flexibility for the sourcing of Low-CI power, and thus enable real, additional, quantifiable, verifiable, permanent, and enforceable greenhouse gas ("GHG") emission reductions. It would directly address obstacles that currently restrict pathway holders from reducing their emissions through contracting for Low-CI power sources to meet demand. The net result of integrating the Low-CI Proposal into LCFS regulation would be to achieve additional and permanent CI reductions from the same quantity of alternative fuel, thereby further decarbonizing California's transportation fuel market.

Instead of recommending adoption of the Low-CI Proposal across all alternative fuels, the Proposed Regulation Order includes only a very limited proposal to allow for the use of PPAs for Low-CI electricity for production and processing of hydrogen used directly as a transportation fuel.[3] The Initial Statement of Reasons ("ISR") acknowledges the need to support and encourage renewable and Low-CI hydrogen production to meet demand for decarbonization

---

[2] See Low CI Power Coalition comment letter submitted by Noyes Law Corporation in LCFS Pre-Rulemaking workshop (June 6, 2023), available at: https://ww2.arb.ca.gov/system/files/webform/public_comments/3666/Low%20CI%20Power%20ARB%20LCFS%20Comments%20w%20Appendices%206%20June%202023.pdf.

[3] Proposed Regulation Order at 148.

310.1 cont. in transportation and hard-to-electrify end uses.[4] It further recognizes that concerns about resource shuffling and additionality can be addressed by restricting eligibility to new or expanded capacity, delivery to the local balancing authority, and resource matching.[5] But there is no discussion justifying or explaining why the modified Tier 2 application process should be limited to hydrogen and direct air capture projects.

As there are clear benefits to be achieved through adoption of the Low-CI Proposal, and no identified justification for the Proposed Regulation Order's narrowing it to address only hydrogen and direct air capture projects, the Board should adopt the broader version proposed in the Low-CI Proposal.

a. <u>Low CI Power achieves CARB's fundamental policy goal of carbon neutrality by 2045 and will lead to material, additional emission reductions irrespective of the type of fuel that claims LCFS credit.</u>

i. Electricity demand (load) from alternative fuel producers will grow irrespective of whether the LCFS regulation allows book-and-claim for Low-CI power.

In the absence of an explanation, it is difficult to understand why the Proposed Regulation Order would forego a clear opportunity to enable incremental emission reductions that can be provided by eligible, available Low-CI alternative fuels. Under the existing LCFS procurement limitations, low carbon fuel production facilities have no practical alternatives other than to source power from a utility or other load-serving entity ("LSE"), which is likely to increase GHG emissions on a marginal basis. Direct connection of Low-CI energy (under existing regulations), is severely limiting and negates cost effective emission reductions that are otherwise available through wholesale contracting.

Marginal emission rates vary by market and are generally the greatest during peak conditions. Allowing a fuel pathway holder to enter into contracts for new, additional Low-CI power sources that are not already contracted for other purposes provides additional emission reductions regardless of the type of fuel that claims the LCFS credit. By restricting the current proposed amendments to hydrogen used as a transportation fuel, the Proposed Regulation Order is limiting potential emissions reductions, since electricity demand from alternative fuel production facilities will grow in any event, and the substantial majority of that demand will be met by system power instead of Low-CI Power.

This outcome directly contravenes the statutory requirements governing the program. Section 38510 of the California Health and Safety Code charges CARB with the responsibility for monitoring and regulating GHG emissions. Section 38560 is the primary statute that provides authority to CARB to implement the LCFS. That section provides that "[t]he state

[4] ISOR at p. 34.

[5] Id.

310.1 cont. board shall adopt rules and regulations in an open public process to achieve the maximum technologically feasible and cost-effective greenhouse gas emission reductions from sources or categories of sources, subject to the criteria and schedules set forth in this part." The proposed narrow application of the Low-CI power rules contravenes this statute because the LCFS regulation would not maximize emission reductions that are cost effective.

The purpose of the LCFS regulation is to reduce the carbon intensity of transportation fuels used in California and to "incentivize the production of low-carbon and renewable alternatives, such as low-CI electricity and renewable hydrogen, and biofuels to displace fossil fuels and allow more energy security in the transportation sector."[6] While renewable hydrogen used in fuel cell electric vehicles ("FCEVs") is without question a key resource to be supported through the LCFS, there is no need to forego opportunities to support other Low-CI alternative fuel sources. The 2022 Scoping Plan does not only call for scaling up hydrogen production, but more broadly for the "aggressive reduction of fossil fuels *wherever they are currently used in California*, building on and accelerating carbon reduction programs that have been in place for a decade and a half."[7]

The Low-CI Proposal was designed specifically to address market barriers that are currently limiting the integration of new, additional clean energy resources. It is aimed at achieving additional incremental emissions reductions at a time when accelerating climate change demands that we do so immediately, and at scale.

b. <u>A Broader Scope of Low-CI Power Rules Would not Disrupt the Availability of Clean Energy and Capacity for Other Demands.</u>

We appreciate the state has ambitious low-CI power targets and there are concerns about the ability of the state to keep up with demand for low-CI power. This Low-CI Proposal has been designed to protect power markets and to ensure availability of new power for other decarbonization strategies, such as vehicle electrification. These concerns are adequately addressed by the power contracting requirements already proposed for hydrogen and DAC. Among other requirements, the Proposed Regulation Order for Low-CI power contracting would set a quarterly balancing requirement of electricity demand from the fuel production and generation from the Low-CI power source. By proposing a quarterly balancing requirement, the proposed regulations make a fundamental distinction in how Low-CI power would be contracted under the LCFS. The proposed revisions to Section 95488.8(i) would require the fuel pathway holder to purchase energy and match that energy to load over a reporting period (i.e., a quarter). The fuel pathway holder would not need to ensure that power is "deliverable" during peak conditions. As explained below, deliverability requirements are the primary driver of delays in the power sector.

Power plants generate two products that are frequently purchased pursuant to PPAs: energy and capacity. Under the proposed revisions to Section 9588.8(i), CARB would require

[6] ISR at 6.

[7] 2022 Scoping Plan Update, Executive Summary at 1.

310.1 cont. energy matching, not capacity. Because the Proposed Regulation Order only requires energy matching, the power plants retain the ability to supply capacity to load serving entities that may need the capacity to satisfy their reliability objectives and load growth. In recent years, the timely development of new network upgrades needed to transact capacity for reliability requirements has contributed to concerns about the ability of the state to develop sufficient new power plants to meet the pace and scale of Low-CI power development contemplated in the 2022 Scoping Plan. Power plants that only require "energy-only" status are generally not affected by the same delays as projects seeking FCDS. While these "energy-only" projects must still meet interconnection requirements, these projects are generally only reliant on the interconnection facilities required for the project itself, not for network upgrades that are shared with many other interconnection customers all trying to sell capacity for reliability.

As this discussion highlights, concerns that enabling broader Low-CI power sourcing authorities to alternative fuel producers would create material risks of disrupting the market for capacity are not grounded in the details of CARB's own proposal for quarterly matching of energy. Nothing in Section 95488.8(i) requires a Low-CI power contract to provide fully deliverable capacity. Rather, the pathway applicant simply must demonstrate that over the course of a quarter, the power plant generated enough electricity to match the demand of the fuel production facility. It is anticipated that energy-only projects would be procured under the Low-CI Proposal without affecting the supply of capacity that LSEs need to meet their reliability obligations or negatively impacting known load forecasting requirements for transportation electrification.

c. <u>Power-plant Development in California Is Subject to Extensive Planning Requirements, Which Help Ensure that New Sources of Demand do Not Compete for Power at the Wholesale Level.</u>

As noted above, fuel-related electricity demand was extensively evaluated in the 2022 Scoping Plan Update and in prior iterations of the Scoping Plan process. CARB has evaluated the displacement of fossil fuels, driven by the growth of a variety of alternative fuels with varying timelines. The Scoping Plan process sets a high-level trajectory for various planning processes, including GHG target setting for the Integrated Resource Planning ("IRP") and also informs the California Energy Commission ("CEC") load forecasting process. Utilities must also account for their own projected load growth in the context of their load forecast filings to the CEC. These forecasts in turn inform the utilities' procurement of power plant capacity. The load forecasting feeds into the CPUC's IRP and the SB 100 process to ensure the utilities are planning for adequate capacity reserve margins. The load forecasting process also informs the pace and scale of new power plant development needed to meet the state's climate targets. In other words, the state has processes in place to ensure that LSEs are planning to meet various reliability and clean energy objectives, including supplying a sufficient amount of new capacity to reliably meet the state's electricity demand. As discussed above, incentivizing incremental Low-CI power demand for energy-only projects will not disrupt the state's clean energy build out

310.1 cont. because the state's load forecasting and capacity procurement processes are already designed to keep pace with the state's power needs.

d. **Broader Low-CI Power Sourcing Would Drive Clean Energy Development in Other States with Shorter Interconnection Queues, Particularly MISO Where Most of California's Low Carbon Fuels Are Produced.**

As part of its oversight of the LCFS program, CARB tracks the share of liquid biofuels produced in-state by volume and displays annual information on the LCFS Data Dashboard.[8] Over the reported years from 2011-2022, the share of in-state biofuel production has remained relatively stable at approximately 9-15%. For 2022, the share of in-state production was 14.72%. While the CARB data does not provide more granular data, it is well-known in the industry that most of the ethanol and biodiesel production in the US is concentrated in the Midwestern states while substantial renewable diesel production is located in these states but also in Texas and Singapore where Neste's renewable diesel production facility that serves the western U.S. markets is located. With reference to electricity markets, the largest concentration of US biofuels production overall is located in MISO. According to recent analysis by RMI, clean repowering-deploying clean power using existing fossil fuel power plants' interconnections- can accelerate and reduce costs for the interconnection of renewables. Overall, RMI determined that clean repowering is a 250 GW opportunity concentrated in MISO, PJM and the Southeast.[9]

Because nearly 85% of the liquid biofuel development driven by the LCFS occurs in other electricity markets (e.g., MISO, PJM, ERCOT, etc.), and while there are delays in many interconnection queues across the country, there is no evidence that creating incremental demand for Low-CI energy will exacerbate those delays in the longer term. To the contrary, encouraging incremental Low-CI power in these markets will ensure that grid operators have a broader pool of renewable energy to serve load. Moreover, there are processes in place and underway at the Federal Energy Regulatory Commission and elsewhere to ensure that utilities are meeting the demand for energy and capacity across the country. The LCFS has the potential to send long term investment signals to maximize emission reductions and expand renewable energy production to other electricity markets. CARB should not presume that interconnection delays will persist, that interconnection delays are necessarily applicable to the Low-CI energy-only projects contemplated in Section 95488.8(i), or that the concerns about competition for Low-CI power are uniform across the country. To the contrary, CARB should send positive market signals to incentivize the production of alternative fuels with Low-CI power to the greatest extent possible.

---

[8] See CARB, "LCFS Data Dashboard," Figure 10a (Share of Liquid Biofuels Produced In-State by Volume 2022), at https://ww2.arb.ca.gov/resources/documents/lcfs-data-dashboard.

Conclusion

The Low-CI Power Coalition appreciates the opportunity to comment on CARB's proposed amendments to the LCFS. We look forward to working with CARB to further tailor and ultimately implement amendments to the LCFS regulations.

Sincerely,

Graham Noyes
Noyes Law Corporation

APPENDIX 1

Low-CI Power Coalition member companies:

Blue Arrow is the exclusive technology licensee in Mexico, Brazil and elsewhere of Fulcrum Bioenergy, Inc. Blue Arrow's and Fulcrum's plants combine multiple proven and established industrial processes into a patented system that converts waste into zero-carbon synthesis crude. The syncrude is then upgraded at a refinery to zero-sulfur SAF.

Eco Energy is a leading clean energy solutions company for over three decades, focuses on reducing emissions through the promotion of low-carbon renewable fuels and products. The Eco-Energy Solar team is the trusted advisor in achieving sustainability goals for our partners by offering custom projects, including solar design and engineering. In an evolving, climate-conscious economy, Eco-Energy is leveraging its core businesses in marketing, trading, and logistics of ethanol and natural gas across the US, Canada, and abroad.

Fulcrum BioEnergy is a clean energy company pioneering the creation of renewable, drop-in transportation fuels from landfill waste, and is currently commissioning a facility in Reno, Nevada.

Growth Energy represents producers and supporters of biofuels who are working to bring consumers better choices at the fuel pump, grow America's economy, and improve the environment for future generations.

POET is the world's largest producer of biofuel and a global leader in sustainable bioproducts, creating plant-based alternatives to fossil fuels that unleash the regenerative power of agriculture and cultivate opportunities for America's farm families.

Renewable Fuels Association is a national trade association for America's ethanol industry, driving growth in sustainable renewable fuels and bioproducts for a better future.

Velocys is an international Sustainable Aviation Fuel (SAF) technology company with offices in the US and UK. Velocys' technology enables the conversion of various cellulosic feedstocks, including woody biomass residues and municipal solid waste, into low or negative carbon intensity transportation fuels. Velocys broadly offers its technology to the marketplace, and is developing the Bayou Fuels project in Natchez, MS as a commercial reference plant. Velocys has secured offtake commitments for 100% of the SAF from Southwest Airlines and IAG (parent of British Airways) with plans to supply this fuel for uplift in California.

World Energy is a low-carbon solutions provider focused on helping the world's leading companies make their net-zero commitments real. World Energy's solutions include sustainable aviation fuel, renewable diesel, and renewable naphtha, with plans to create renewable propane and green hydrogen.

Re: Proposed Low Carbon Fuel Standard Amendments To Improve Support For EV Charger Access at Multi-Family Residences

Dear Chair Randolph,

In accordance with the Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments dated January 2, 2024, Ava Community Energy (Ava) and Peninsula Clean Energy Authority (PCE) (collectively, the "Joint CCAs") submit the following comments and recommendations to the California Air Resources Board (CARB).

The Joint CCAs were encouraged to learn that CARB intends to provide more robust support for EV charging at multi-family residences (MFRs). The Staff Report: Initial Statement of Reasons (ISOR) proposed that CARB reclassify MFR EV charging as non-residential. This reclassification, in theory, is consistent with post-workshop comments submitted by CCAs during the public engagement phase of the rulemaking.[1] However, the proposed amendments to the LCFS Regulation ("Amended Regulation") are limited in nature and do not go far enough to encourage robust EV infrastructure development at MFR in California.

As default Load Serving Entities (LSE) in our respective service territories and local public agencies, the Joint CCAs are tasked with reducing GHG emissions associated with the electricity we provide to the communities we serve. The Joint CCAs' mandate to advance climate action also lends itself to a shared transportation electrification (TE) philosophy that centers around

---

[1] Joint CCAs, "Comments of the Joint CCAs on Potential Future Changes to the LCFS Program," January 7, 2022, https://www.arb.ca.gov/lists/com-attach/110-lcfs-wkshp-dec21-ws-UjFSO1Q4VmhXNFU7.pdf; Joint CCAs, "Post-workshop Comments of the Joint CCAs on Potential Changes to the LCFS Program," August 8, 2022, https://www.arb.ca.gov/lists/com-attach/91-lcfs-wkshp-jul22-ws-AHAAaVIgACcAKwdw.pdf.

broad access to TE solutions, especially for those facing significant barriers to adoption, by minimizing the cost to adopt TE technologies.

PCE's EV Ready program is a $28 million infrastructure program that offers free, no obligation technical assistance for PCE customers, $24M+ in project incentives, access to preferred pricing on EV chargers, and a trained Trade Ally network of contractors.[2] The program provides support for the design of an EV charging project from inception through installation. EV Ready also has a particular focus on supporting MF residents. Of the 1,000 charge ports installed so far, roughly 2/3 of these are in apartment buildings or condos. And another 3,000 are in process.[3]

Despite the CCAs' efforts, as well as incentives and programs offered by various other actors such as the EDUs, and agencies at the state, regional, and local level, California is not on track to hit our EV targets. And in Q4 2023, EV sales growth in California dipped for the first time in several years, challenging the assumption that consumer acceptance and continued growth of the EV market is a given.[4]

According to the California Energy Commission (CEC), "As of mid-2023, California has installed more than 91,000 public and shared chargers, including nearly 10,000 direct current fast chargers."[5] A recent analysis by the CEC identifies a need for aggressive new development of Level 1 and Level 2 MFR chargers in order to meet California's EV goals. Their recent *Assembly Bill 2127 Second Electric Vehicle Charging Infrastructure Assessment* "projects 1.01 million public and shared private chargers are needed to support 7.1 million passenger plug-in electric vehicles in 2030, and 2.11 million public and shared private chargers are needed to support 15.2 million passenger plug-in electric vehicles in 2035."[6] The CEC modeled the combined number of Level 1 and Level 2 MFR chargers needed to meet these goals and their findings are stark. They

6 *Ibid.*

estimate that California will need 313,000 new MFR chargers in MFR by 2030, and 264,000 more by 2035, for a total of 577,000 multi-family chargers.[7] This is or roughly equal to a rate of 24,000 MFR charger installations a year, every year through 2035. And according to CEC's assessment, the number of new MFR chargers needed to meet California's EV goals is larger than almost any other use case.[8]

CARB's LCFS Rulemaking presents a timely opportunity to modify an existing program to better address a growing need identified by its sister agency. The LCFS, if amended appropriately, could provide strong support for MFR EV adoption. It has the prospect of encouraging MF infrastructure development to maximize charging access for residents. It can also help alleviate cost concerns as EV fueling savings are continually eroded by increasing electric rates. As written, the Amended Regulations do not go far enough. The CCAs provide the following recommendations.

311.1
1. The Amended Regulation should be further modified to classify all multi-family EV charging as "non-residential" to provide the strongest incentive to develop EV charging access at multi-family residences;

311.2
2. The registration process for EV Fuel Supply Equipment ("FSE") should be updated to allow low-cost smart Level 1 and Level 2 EV charging outlets to generate LCFS credits; and

311.3
3. The LCFS should require that credit claimed from MF EV charging should be used to lower the cost of driving for those drivers and counter cost pressures from rising electricity rates.

Assembly Bill 2127 Second Electric Vehicle Charging Infrastructure Assessment: Assessing Charging Needs to Support Zero-Emission Vehicles in 2030 and 2035. *Figure 1 - Chargers Needed for Light-Duty Plug-In Electric Vehicles in 2030 and 2035*. Page 4. California Energy Commission. Publication Number: CEC-600-2024-00, available at: https://www.energy.ca.gov/publications/2024/assembly-bill-2127-second-electric-vehicle-charging-infrastructure-assessment.

[8] The Report forecasts that the need for Multi-Family (L1 + L2) chargers is greater than all 5 of the use case categories analyzed, except for Shared Private Workplace. Shared Private Workplace charger installation need is less than 2% higher than Multi-Family (L1 + L2). The Report forecasts that California must install the following numbers of new chargers by use case in order to meet the goal of supporting 15.2 million plug-in electric vehicles by 2035 (in descending order): Shared Private (at work) – 587,000; Multi-family (L1 + L2) – 577,000; Public (at work) – 392,000; Other Public – 475,000; DCFC – 83,000. Page 4.

1. Classifying All Multi-Family EV Charging As Non-Residential Will Make The LCFS Program More Equitable And Provide the Strongest Incentive To Develop EV Charging That Benefits Californians Living In Multi-Family Residences

As the Joint CCAs have argued in prior comments to the CARB, classifying MFR EV charging as residential under the LCFS rules, and subjecting it to the associated data reporting and registration requirements, effectively prevents entities from claiming credits generated by MFR EV charging, which in turn prevents the LCFS from being fully leveraged to support MFR EV infrastructure development.[9] Therefore the Joint CCAs were encouraged when reviewing the ISOR as it suggested that the Amended Regulation would address this issue. The ISOR includes a table which serves as a summary of the proposed amendments in the Amended Regulation. In that Table, there is a statement the Amended Regulation will "Include Multi-Family residences as non-residential."[10] However, when reading the draft language, the change is far more limited and in effect is inconsistent with the stated rationale behind the change: to provide a strong incentive to develop more MFR EV charging infrastructure.

The reason the Amended Regulation falls short is because it fails to recognize that MFR charging at assigned parking spaces needs to be a central part of the solution and incentivized by
311.1 the LCFS. According to the Amended Regulation, the only charging at MFR that will be classified as non-residential under Sections 95483(c)(1) and 95483(c)(2) is charging in shared parking spaces. Shared EV charging is suboptimal due to several practical operational, project design, and cost barriers that cannot be overcome by simply increasing LCFS incentives. As such, it will not provide meaningful support to install the number of MFR chargers the CEC forecasts that California needs. Instead, the Amended Regulation's MFR reclassification does not do enough to support MFR EV charging projects designed to maximize charging access to MF residents. To achieve this, the final Amended Regulation should classify <u>all</u> MFR EV charging as non-residential to ensure that the LCFS Program provides the strongest support possible to expand EV adoption among California's MFR communities.

Appendix E of the ISOR speaks to the purpose and rationale behind the proposed language in the Amended Regulation. Staff reasoned that "chargers at multi-family residences

---

[9] Joint CCAs, *supra* note 1.

[10] California Air Resources Board, "Staff Report: Initial Statement of Reasons," *Table 2: Summary of Proposed Regulatory Amendments to the LCFS Regulation,* December 19, 2023, page 20, https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf

(MFR) should generate LCFS credits as nonresidential charging in order to more strongly incentivize the development of and availability of charging at MFRs."[11] Appendix E continues, "[t]his change will allow EV supply equipment owners and developers to generate credits from deployment at multi-family residences, which has been identified as a sector requiring further investment."[12] Appendix E also correctly identify that the issue presented by classifying MFR charging as residential is that it designates crediting for residential charging to the Electric Distribution Utilities (EDUs) instead of EV service providers (EVSPs), meaning that currently, "the latter may not have as strong and direct an incentive to develop more EV supply equipment at MFRs *as could be most optimal and impactful"* (emphasis added).[13]

However, the Amended Regulation only provides a "strong and direct incentive" for
311.1 developing MFR EV supply equipment that is installed in a manner that is both not optimal for
encouraging MFR residents to adopt EVs, or optimal for the MFR property owners. As a result, the Amended Regulation's support for EV supply equipment at MFRs is not the most impactful. Programs like PCE's EV Ready emphasize project designs that encourage as many charging ports as possible, most of which are installed in reserved tenant parking, while limiting the need for grid or service upgrades. This design philosophy of "right-sizing" the project to suit charging needs and capacity constraints has several key advantages. It allows the MFR charging project to maximize charging access to provide the greatest incentive to consider purchasing or leasing an EV. Current and prospective tenants are given certainty they will always have charging access at home if they choose to purchase or lease an EV, a powerful motivator to adopt an EV as it is estimated that 80% of charging takes place at home. But projects that follow this design philosophy to maximize charging access will remain ineligible to claim LCFS credits under the Amended Regulation.

Right-sizing also addresses several typical concerns of MFR property owners considering
an EV charging project for their tenants. One is that EV charging will require time-consuming
311.1 and expensive grid studies and upgrades, or costly panel work. But right-sizing the project allows

[11] ISOR, Appendix E: Purpose and Rationale of Proposed Amendments for the Low Carbon Fuel Standard Requirements, *Amendments to Sections 95483(c)(1) and 95483(c)(2). Fuel Reporting Entities for Residential Electrical Vehicle Charging*, January 2, 2024, page 16, available at: https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/lcfs_appe.pdf

[12] *Ibid.*

[13] *Ibid*.

property owners to offer EV charging access to as many current and future tenants as possible while avoiding these pitfalls. And as MFR charging often occurs in parking lots and garages available to all the MF tenants, rather than near the existing individual tenants' utility meters, it is often the most cost-effective approach to install the electrical work so that the new EV load is served under a common meter and the usage is billed by the LSE directly to the property owner, not the individual tenants. This design approach allows the property owner to preserve their flexibility to reassign parking spaces to tenants as needed. Conversely, reassigning limited shared parking spaces, like guest parking, to limit it to only EV charging can be a point of friction between tenants and a property owner, especially for those tenants who do not drive an EV. Installing EV charging in shared parking spaces also creates friction opportunities between residents such as disagreements over the use of the equipment, moving vehicles to make sure that everyone who needs to charge their vehicle can, and so forth. The installation of EV charging in shared parking also triggers ADA requirements that can lead to significant delays and cost increases for the project. These are the costs and types of issues property owners simply don't want to deal with and could lead them to install a limited number of chargers that would provide limited incentive for tenants, or turn them off from pursuing an EV charging project entirely. But many of these issues are avoided if each tenant has their own charging port in their assigned parking space. But the Amended Regulation only "strongly incentivizes the development of and the availability of charging at MFRs" if the property owner decides to pursue an EV charging
311.1 project that will serve fewer tenants, is more likely to cause operational headaches, and will cost more per charging port. Therefore, the Amended Regulation should reclassify all MFR charging as non-residential to in order to strongly incentivize EVSPs to design MFR charging projects that maximize charging access for tenants and keep project costs down.

The ISOR makes it clear that the intention is to amend the LCFS to incentivize the development and availability of charging at MFRs. However, the draft Amended Regulation, by reclassifying EV charging as non-residential only if it is located in shared parking, will only provide incentives for MFR charging projects that are more costly, more time consuming to complete, and provide a weaker overall incentive for tenants to adopt purchase or lease an EV. If CARB's true intention is to provide a "strong and direct an incentive to develop more EV supply
311.1 equipment at MFRs *as could be most optimal and impactful* [emphasis added]", then the Joint CCAs propose that the final Amended Regulation must reclassify all EV charging at MFR as

non-residential. If it does not, CARB will miss an opportunity to adopt truly impactful the amendments to the LCFS program that would support level of MFR charging development that California needs to meet its EV goals.

2. Low-cost EV charging equipment should be permitted to register as Fuel Supply Equipment to generate non-residential LCFS credits

311.2 Another simple change to the LCFS regulations that the ARB should adopt to promote equitable benefit among MFR EV drivers is to allow smart Level 1 and Level 2 outlets to be registered as non-residential FSE and generate credits. There are many examples of this type of EV charging equipment on the market today that provide low-cost charging equipment options compared to standard L2 EVSE.[14] These smart outlets are also still networked, allowing the equipment to collect the data fuel reporting entities need to claim LCFS credits. Permitting these charging ports to register as FSE would also provide a strong incentive for MFR property owners to pursue EV charging projects that maximize charging access for residents while minimizing the cost of the project and the per port cost.

PCE's EV Ready program has designed 200 EV charging projects, many with smart Level 1 and Level 2 outlets for several reasons. A primary reason is that the number of MFR charging ports needed is so large that it cannot be met only with traditional Level 2 EVSE. Smart Level 1 and Level 2 outlets are a much more cost-effective and widely scalable solution. In order to provide enough charging to encourage the significant community of Californians living in MFRs to consider adopting EV technology, PCE realized designed the EV Ready guidelines to: (1) provide as much charging as possible at people's residences, particularly at their assigned parking spaces (2) provide enough charging capacity to meet their typical driving needs, and (3) avoid costly service upgrades. PCE discovered that, per day, most drivers across the state drive about 40 miles and leave their cars parked for almost 12 hours. And those EV drivers that were using Level 2 charging would leave their cars plugged in all night but only draw electricity for less than three hours. So, while Level 2 charging is still appropriate for many use cases, it is an overbuilt solution considering the low daily miles and the long dwell times, such as at MFRs. Instead, L1 and low-power L2 ports allowed PCE to design MFR projects that are much less

[14] *See* GoPowerEV, https://gopowerev.com/; Orange Charger, https://www.orangecharger.com/; Pando Electric, https://www.pandoelectric.com/; Plugzio, https://www.plugzio.com/.

likely to trigger service upgrades or utility studies, provide more charging ports for lower cost, and still provide enough charging power to meet the daily driving needs of residents.

311.2 Unfortunately, current registration restrictions do not allow owners of EV charging equipment to register smart Level 1 and Level 2 ports as non-residential EV FSE.[15] Therefore projects that utilize these EV charging options to limit project costs are unable to generate LCFS credits and leverage the program to further expand EV charging access. This highlights a disconnect between the charging options the LCFS incentivizes vs charging options available on the market that appeal to property owners for reasons of operational simplicity and lower project cost. The Joint CCAs encourage CARB to permit smart Level 1 and Level 2 ports to register as non-residential FSE to incentivize the charging options on the market today that are best positioned to encourage EV adoption among MFR communities.

3. The LCFS should require that credit claimed from MFR EV charging should be used to lower the cost of driving for those drivers to counter increasing electric rates and maintain EV cost savings.

EVs are assumed to offer a cost savings for the driver compared to an internal combustion engine (ICE) vehicle as they have lower maintenance costs and typically lower fueling costs. But as electric rates continue to rise, EVs' value proposition will continue to erode. Depending on a given ICE vehicle's fuel efficiency, there may be little or even no operational cost savings to be gained by switching to an EV. But to meet California's ZEV and climate goals, the rate of EV adoption must increase. This is especially true among MF residents who have typically faced more significant barriers to EV adoption.[16] And once they do have an EV, MF drivers also often face higher charging rates compared to SFH drivers, meaning that the value proposition was already less attractive. MFR charging on networked equipment typically includes additional fees, fees that SFH EV drivers do not have to pay to use a charger in their

---

[15] LCFS Guidance 19-04: Fueling Supply Equipment Registration. See section 4, *Non-residential EV Charging* which specifies that only Level 2 chargers with attached SAE J1772 plugs can be registered. (September 2022), available at: https://ww2.arb.ca.gov/sites/default/files/2022-09/lcfsguidance_19-04_093022.pdf

[16] Hsu, Chih-Wei and Fingerman, Kevin, "Public Electric Vehicle Charger Access Disparities Across Race and Income in California" Transport Policy, Vol. 100 at 59-67 (Jan. 2021), available at: https://www.sciencedirect.com/science/article/pii/S0967070X20309021.

home. It is important that the value proposition is not eroded further to ensure that MF residents who adopt EV technology can continue to save money on their transportation costs.

The Joint CCAs propose that the LCFS should require that the credit entities claim from
311.3 MFR EV charging projects should be allocated, at least in part, back to the EV drivers to reduce the cost of fueling. As all LCFS-eligible FSE are networked, this could be implemented by charging providers by simply crediting the accounts of drivers who live in one of the provider's MFR projects. The Joint CCAs also want to emphasize that any change to this effect must strike a balance between returning LCFS credit to EV drivers and allowing providers to retain enough of the credit to incentivize them to continue to develop MFR EV projects.

4. Conclusion

As noted above, the Joint CCAs fully support the goals and objectives of the LCFS program to reduce the carbon content of the transportation fuels in California. The Joint CCA request that CARB reclassify <u>all</u> MFR charging as "non-residential" will encourage more
311.1 equitable deployment of EV chargers where MF residents live which will provide a strong incentive for residents to consider purchasing or leasing an EV. CARB should also permit networked Level 1 and Level 2 charging ports to register as EV as they provide a lower-cost
311.2 option for MF property owners to provide charging to their tenants. The Joint CCAs also
311.3 encourage CARB to require that entities who claim credits from MFR charging use a portion of that credit to reduce the residents' fueling costs to counter the impact of rising electricity rates.

The Joint CCAs thank the ARB for taking the time to consider its recommendations and look forward to continuing to work together to advance ZEV adoption among Californians.

Subject**:** Letter of Comment on Temporary Fuel Pathway Code for Ethanol with CCS for Proposed Amendments to the LCFS, posted December 19, 2023

Dear Chair Randolph:

Life Cycle Associates would like to take this opportunity to provide our comments on the Proposed Amendments to the Low Carbon Fuel Standard Regulation, posted on December 19, 2023. This letter is focused on the development of a Temporary Fuel Pathway Code for Ethanol with Carbon Capture and Sequestration (CCS) technology.

LCFS regulation text defines the CCS technology as follows: *"Carbon capture and sequestration (CCS) project" means a project that captures CO_2 by an eligible entity specified in section 95490(a) of this subarticle, transports the captured CO_2 to an injection site, and injects and permanently sequesters the captured CO_2 pursuant to the Carbon Capture and Sequestration Protocol and as specified by section 95490 of this subarticle.*

CCS is an emerging technology in the U.S. ethanol industry. We believe that CCS technology, combined with existing and newly developing alternative fuel production facilities, offers significant environmental benefits while supporting the overall goals of the California Air Resources Board (CARB). Numerous production plants, many of which already have certified fuel ethanol pathways under LCFS for corn, corn fiber, and sorghum feedstocks, have signed agreements to develop and utilize the technology. The production facilities are pursuing CCS technology in part to further reduce their GHG emissions and meet the increasingly stringent carbon intensity (CI) reduction targets under the LCFS.

The current certification process for a CCS pathway takes multiple years, resulting in a considerable loss of potential credits during the certification period even after beginning to sequester CO_2. We understand the necessity for a thorough evaluation and approval process to ensure compliance with regulatory standards, but the extended duration can hinder the timely realization of the benefits associated with such projects.

With the expectation that CCS will become commonplace for ethanol, and potentially many other fuel production technologies destined for the California market, we ask
312.1 CARB to consider developing a temporary fuel pathway code for ethanol with CCS. The LCFS program already offers multiple temporary pathways to allow alternative fuel producers to generate a limited value from their low-CI fuel. A temporary pathway for CCS with ethanol would further encourage ethanol producers to develop CCS technology and supply even lower CI ethanol to California.

Stefan Unnasch

unnasch@LifeCycleAssociates.com
884 Portola Road, Suite A11
Portola Valley, CA 94028 USA

The amount of CO_2 captured and sequestered at an ethanol facility can be easily calculated due to a strong stoichiometric basis as demonstrated by the equation below.

$$\underset{\text{Starch}}{(C_6H_{10}O_5)_x} \xrightarrow{\text{enzymes}} \underset{\text{Glucose}}{C_6H_{12}O_6} \xrightarrow{\text{enzymes}} \underset{\text{Ethanol}}{2CH_3CH_2OH} + 2CO_2$$

Each molecule of ethanol produced via fermentation process also co-produces one molecule of CO_2, which is roughly equivalent to about 30 g CO_2/MJ reduction in the ethanol CI. However, the addition of CCS adds a marginal electricity usage for compression and transport of CO_2. This stoichiometric relationship can be utilized by CARB to determine a conservative CI for the requested temporary pathway(s), subject to verification. Following the temporary pathway, the applicant will be required to measure and monitor the quantity of CO_2 captured and sequestered as required per the provisions of the LCFS and CCS protocol. Our expectation is that this will expedite compliance with the LCFS regulation and set a standard for the industry.

We firmly believe that creation of such a temporary pathway for ethanol with CCS would contribute to meeting CARB's emissions reduction targets and serves as a model for encouraging and fostering technological advancements in the CCS technology itself. We are committed to working closely with CARB throughout the process and are ready to provide any additional information or clarification that may be required.

Thank you for your consideration in reviewing our comments and incorporating them into the final regulation. If you have any questions, please reach out to me directly.

Sincerely,

The Honorable Liane M. Randolph, Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Subject: Comment on Draft Amendments to the Low Carbon Fuel Standard (LCFS) Tier 1 Calculators

Dear Chair Randolph,

Thank you for the opportunity to comment on the Proposed Low Carbon Fuel Standard (LCFS) Amendments and updated Life Cycle Analysis (LCA) and Documentation. As a California-based consulting firm with over 10 years of experience in life cylce analysis for biofuels and alternative energy, Life Cycle Associates has actively participated in the LCFS program since its inception. We bring extensive experience in fuel life cycle anaylsis, having supported a wide variety of biofuel and alternative energy developers. Our work has been instrumental in securing government funding and approvals for numerous fuel pathways, and we have collaborated with agencies like CARB, EPA, and the states of Oregon and Washington to establish low-carbon fuel programs.

Drawing on this experience, we recommend the following minor changes to the proposed Tier 1 calculators. We believe our insights can help refine the calculators to better serve a broad range of fuel developers and accelerate the growth of alternative fuels in California.

Our specific comments and recommendations are summarized below.

Recommendation for Tier 1 Organic Waste (OW) Calculator: Recognize Diversity and Address N_2O Emissions in all Waste Treatments

It is critical that CARB recognize the complexity of organic waste management in California. The state's most recent waste characterization studies reveal a variety of organic materials ending up in landfills, from over 6 million tons of paper products to 4 million tons of food waste, over 2 million tons of wood products, more than a million tons of textiles, and over 200,000 tons of manure[1]. Moreover, the landscape of composting in California has evolved significantly since the inception of SB 1383, encompassing materials such as soiled paper products, bio-plastics, agricultural residues, and food processing wastes. These materials not only contribute to the state's compost production but are also an important part of its waste management strategy.

We support the recently added category of Recovered Organics (RO) in the Tier 1 OW calculator. However, there remains room for better accounting for emissions across all waste streams in California. Presently, only food scraps qualify for diverted N_2O credit, leaving other waste streams

[1] California Department of Resources Recycling and Recovery. (2022, November). 2021 Disposal Facility-based Waste Characterization Data Tables. Retrieved from https://calrecycle.ca.gov/wcs/dbstudy/

largely unaddressed despite their potentially significant N_2O emissions. It's worth noting that while methane holds about 30 times the potency of CO_2 over a century, N_2O is roughly 300 times more potent than CO_2 over the same period. Unlike methane, which dissipates relatively quickly, N_2O persists in the atmosphere for over a century, amplifying its long-term warming impact.

To accommodate the diverse nature of waste and the myriad waste management systems across California, the Organic Waste calculator would benefit from minor adjustments. We suggest:

313.1

- Introducing options to indicate the percentage of Other Organic Waste (OOW) diverted from composting, in addition to landfilling.
- Incorporating user inputs for site-specific baseline CH_4 emissions.
- Including user inputs for site-specific baseline N_2O emissions.

Figure 1 illustrates a potential layout for integrating these user-defined inputs.

Section 3: Static Operational Data	
3.1 Electricity Grid Region	
3.2 Grid Electricity EF (gCO_2e/kWh)

OOW - % Diverted from other Treatment	
3.11 OOW - TDOC (% dry basis)	
3.12 OOW - DANF (%)	
3.13 OOW - Decay Rate (k)	

Figure 1. Proposed location of additional user defined and site specific inputs is outline in red.

Recommendation: Align Tier 1 Calculators with CA GREET4.0 Livestock Categories

313.2 In the CA GREET4.0 RNG tab, livestock categories include Beef, Dairy Cow, Dairy Heifer, Swine, Layer, and Broiler and Turkey (refer to Figure 2). However, the Tier 1 calculator for animal manure (tier 1 DSM) presently covers only dairy cow, heifer, and swine categories. We suggest minor changes to align the tier 1 DSM with CA GREET4.0: CARB should incorporate beef and poultry manure categories into the DSM, using corresponding baseline manure management emissions described in CAGREET4.0 (Figure 3). To reflect these changes, we propose renaming the Tier 1 Dairy and Swine Manure Calculator to the Tier 1 Livestock Manure calculator.

1.3) Assumptions for Anaerobic Digestion of Animal Waste

Source of Assumptions: U.S.

U.S.

	Beef	Dairy Cow	Dairy Heifer	Swine	Layer	Broiler and Turkey
Share of Livestocks	0.0%	100.0%	0.0%	0.0%	0.0%	0.0%

Figure 2. Snapshot of CA GREET4.0 RNG Tab showing livestock categories

	Beef Feedlots [2]		Layer Operation		Broiler and Turkey Operation	
	Dry Lot	Liquid/Slurry	Anaerobic La	Poultry w/o	Pasture	Poultry w/o Litter
Manure Region Management System Usage (MS%)						
U.S. Average	100.0%	0.7%	12.9%	87.1%	1.0%	99.0%
Manure Management System MCFs						
U.S. Average	1.2%	30.4%	71.5%	1.5%	1.2%	1.5%
Direct N2O Emission Factors (kg N2O N/kg N)	0.02	0.005	0	0.001	0	0.001
N Loss Factors through Volatilization of NH3	23%	26%	54%	34%	0%	34%

Figure 3. Snapshot of CA GREET4.0 RNG Tab showing livestock categories

We also note that livestock manures, and especially poultry manure, emit significant amounts of N_2O under traditional management systems. These emissions are amplified by the increasing concentration of modern livestock and poultry operations. This concentration leads to an overabundance of nutrients, exceeding the capacity of nearby crops to absorb them. Without effective manure management solutions to distribute these excess nutrients, they accumulate in concentrated areas, creating "hotspots" with devastating environmental consequences. These consequences include, but are not limited to, the eutrophication of water bodies and the proliferation of harmful algal blooms[2].

Livestock manure-to-RNG pathways, including beef and poultry manure pathways, offer a promising solution. RNG facilities transform manure through anaerobic digestion, generating renewable natural gas (RNG) and valuable fertilizer byproducts. Distributing these byproducts efficiently addresses nutrient needs in areas beyond the immediate vicinity of the operation, reducing N_2O emissions and mitigating the impacts of nutrient concentration on watersheds.

[2] Bryant, Ray B., et al. "Poultry manureshed management: Opportunities and challenges for a vertically integrated industry." Journal of Environmental Quality 50.4 (2021): 1201-1213. https://doi.org/10.1002/jeq2.20273

Therefore, we urge CARB to consider included avoided N_2O emissions and fertilizer displacement benefits in all manure-to-RNG pathways. This would ensure accurate accounting of the environmental benefits associated with manure-to-RNG pathways, ultimately incentivizing their development and adoption.

We appreciate your attention to these comments and recommendations. Thank you for considering our input.

Sincerely,

Anna Redmond

Subject: Letter of Comment on Dairy and Swine RNG for Proposed Amendments to the LCFS, posted December 19, 2023

Dear Chair Randolph:

Life Cycle Associates would like to take this opportunity to provide our comments on the Proposed Amendments to the Low Carbon Fuel Standard Regulation, posted on December 19, 2023. This letter is focused on the proposed amendments for Dairy and Swine based RNG.

Diary and Swine RNG are potentially important feedstocks for hydrogen production. The avoided methane results in a low CI which helps to finance these facilities and support the supply of low-CI hydrogen either directly to market or as a process fuel for alternative fuel producers. While CARB is evaluating numerous comments about the generosity of
314.1 such credits, we recommend that CARB also evaluate the alignment of dairy RNG credits with the high value credit opportunities under the Hydrogen Refueling Infrastructure (HRI) provision.

Just like the HRI provides an incentive to build hydrogen stations that otherwise could not support financing of their construction, the avoided methane credits are intended to provide a financial incentive to install equipment to eliminate methane emissions that otherwise would not be regulated. Following such an intention, the HRI incentive is capped to the capital spent to build the hydrogen dispensing infrastructure. CARB should recognize the high costs for installing and operating manure Biogas Control
314.2 Systems (BCS) and not eliminate methane avoidance credits abruptly and develop an incentive (utilizing avoided methane) for dairy farms to install a BCS system to regulate their uncontrolled methane emissions in-line with the capital and operational expenditures for such BCS system(s).

Thank you for your consideration in reviewing our comments and incorporating them into the final regulation. If you have any questions, please reach out to me directly.

Sincerely,

Stefan Unnasch

California Independent Petroleum Association Comments on the Proposed LCFS 45-day Regulatory Package

Chair Liane Randolph
Board Members
California Air Resources Board

February 20, 2024

Via electronic submittal to: regulatory docket

Thank you for the opportunity to comment on this important regulatory update on behalf of the members of the California Independent Petroleum Association (CIPA)[1]. CIPA represents nearly 300 crude oil and natural gas producers, royalty owners, and service and supply companies who all operate in California under the toughest regulations on the planet.

The LCFS regulatory package released in early January contains the complete package of material for the pending amendments[2]. The materials include a proposed updated LCFS regulation and appendices, including an update Table 9—*Carbon Intensity Lookup Table for Crude Oil Production and Transport*. The proposed regulation also solidifies the role of the Innovative Crude crediting program to incent the reduction of greenhouse gases (GHGs) from in-state production activities.

CIPA is appreciative of the staff recommendation to retain the Innovative Crude credit provisions through 2040. This regulatory signal allows for significant capital flows to occur in the near-term and GHG reductions to occur continually for the next 16 years, while assisting the retention of high-value jobs within the State. We are however disappointed to see the results of the latest OPGEE model as provided in the proposed Table 9, as they do not seem to reflect stakeholder input on the differences with in-state production as compared to other less regulated jurisdictions. CIPA is also discouraged by the lack of real transparency in that process.

The 2022 Update to the AB 32 Scoping Plan clearly shows that, even in 2045, California will continue to consume significant volumes of crude oil to fuel the legacy fleet of ships, planes, trains and vehicles that remain in California, even with the State's all-in push for zero-emission technology[3]. California in-state crude, produced under the State's Cap-and-Trade, Low Carbon Fuel, and Oil/Gas Methane regulations should be prioritized as the primary feedstock of choice. The results of the latest update, do not accomplish this anti-leakage approach to the LCFS. CIPA remains strongly opposed to any LCFS amendments in which in-state crude is replaced with

---

[1] The mission of CIPA is to promote greater understanding and awareness of the unique nature of California's oil and natural gas resources, and the independent producers who contribute actively to California's economy, employment and environmental protection.
[2] https://ww2.arb.ca.gov/rulemaking/2024/lcfs2024
[3] https://ww2.arb.ca.gov/sites/default/files/2022-12/2022-sp_1.pdf

imported crude either by direct regulation or indirect impact such as inaccurate values for crude carbon intensity scores. A true and successful LCFS would not shift emissions, tax-base and jobs to other jurisdictions.

Stability of the Innovative Crude Program

315.1 CIPA doesn't see the need to end LCFS crediting, as is proposed in the amendment package, of large capital projects that are built to meet the goals of the Program by continually reducing GHG emissions year-after-year, thus reducing a key economic feedstock's carbon intensity. Nonetheless, the staff proposal to retain the Innovative Crude credits option under the LCFS is an important policy signal to the market. The Scoping Plan's approach to allow the demand for fuels lead the market rather than attacking local supply, allows for the transportation and byproduct feedstocks to not be relied up only through increased imports.

We have supported our members in these GHG-reducing endeavors for years. As long as there is demand for liquid fuels, California should be promoting GHG reduction projects for in-state oil and gas extraction given it is the only crude oil that is compliant with California's climate program.

CIPA members are actively deploying carbon reduction strategies including renewable energy to replace both electricity and thermal loads, in addition to, carbon capture and sequestration, which is rightly not subject to the deadline assigned other Innovative Crude credits. Replacing thermal loads, as allowed under the Regulation, has significant direct local air quality benefits in the state's most impacted communities, and if properly designed, permitted and built, can reduce costs and strain on the state's electrical grid.

OPGEE and Table 9 Updates

The OPGEE scores for California produced crude have moved higher on average, even though
315.2 CARB has claimed success for reducing industry emissions on several fronts, including implementation of the Oil/Gas Methane rule. This is incongruent, especially given that foreign CI scores have proportionally decreased compared to in-state production even though it can't be shown that new or additional emission controls have been enacted.

The OPGEE model continues to use of foreign default values that are not enforceable or verifiable, two hallmarks of California's climate regulations—Cap-and-Trade and the LCFS. Additionally, the California oil/gas methane rule has been shown to reduce in-state fugitive methane emissions from local producers.[4]

CIPA has been actively engaged in this process and previously submitted comments to the OPGEE model update under earlier LCFS workshops. Those comment go into great detail about the need to get the science right BEFORE policy decision are made, and describe a model in which the regulatory framework of California is ignored.[5,6] We incorporate those comments by reference and provide these additional thoughts.

We have requested a transparent analysis evaluating the *global* impact of replacing California crude, with its methane monitoring rules, flaring rules, vapor recovery rules and short pipeline transport distances with the equivalent volume of less regulated, long-distance transported

foreign crude. Such an analysis needs to consider all the emission reduction efforts highlighted in the previous CIPA OPGEE letters to CARB

The OPGEE model overestimates the CI of California crude oil, and underestimates the CI of foreign crudes, most notably those from Saudi Arabia and Ecuador, the two largest suppliers of oil to California. The data support the common-sense conclusion that California's demand for oil is best met by locally produced, locally regulated, and lesser greenhouse gas emitting oil than those foreign sources which require long transport distances in addition to non- or under-reported greenhouse gas emissions and environmental protections.

Summary

As shown in the State's officially adopted climate planning document, California will need petroleum and natural gas fuels for many years. During this time, California should not only prioritize in-state supply but incent its carbon intensity reduction.

The last barrel of oil used in California, should be produced in-state with all the local, regional and statewide environmental, health and safety and labor standards ensured to be used. California environmental and worker leadership cannot include looking the other way through direct or indirect promotion of foreign crude supplies.

Thank you.

Sincerely,

Rock Zierman
Chief Executive Officer
California Independent Petroleum Association

Re: Port of Oakland Comments on Proposed Amendments to Low Carbon Fuel Standard

Dear California Air Resources Board Staff:

The Port of Oakland (Port) appreciates the opportunity to review and comment on California Air Resources Board's (CARB) amendments to the Low Carbon Fuel Standard (LCFS). The Port is a public enterprise agency, operating a seaport, an airport (Oakland International Airport (OAK)), and commercial properties along the Oakland waterfront. The Seaport and the Airport are both essential transportation infrastructure serving the San Francisco Bay Area, the State of California, and the nation. The Port is also a public utility, providing electricity to both the Seaport and Airport.

OAK is in East Oakland, which has a mix of residential neighborhoods, heavy industrial land uses, and major transportation infrastructure. California's CalEnviroScreen tool identifies East Oakland as a pollution-burdened area with elevated levels of diesel particulate matter and other toxic air contaminants. In addition, the Council of Environmental Quality's Climate and Economic Justice
316.1 Screening tool identifies East Oakland as a disadvantaged community. The Port requests that CARB include electric ground support equipment (eGSE) as a lookup pathway in the LCFS program. This would accelerate airport electrification, support the Port's transition to zero emission program, and further the goals of the LCFS program.

The Port incorporates zero emissions operations and climate resiliency considerations into its planning, management, development, and operations to support its zero emission goals, reducing air quality impacts to the environment and adjacent communities. The LCFS program allows entities that provide low carbon intensity fuel to generate credits and sell to high carbon intensity fuel producers and then invest the proceeds into projects that further reduce the carbon intensity of transportation fuel.

The Port has been participating in the LCFS program since 2019, generating credits for ocean-going vessel shore power, electric cargo handling equipment

PORT OF OAKLAND

(eCHE), and electric light-duty, medium-duty, and heavy-duty vehicles at the Seaport and electric light-duty vehicle charging at the Airport. The Port generates about 5,800 credits per quarter.

316.1 cont. In 2019, the Port initiated discussions with CARB on including eGSE in the LCFS program as a lookup pathway. Following recommendations from CARB, OAK and other California airports sponsored the California Airports Council (CAC) Environmental Working Group in hiring a consultant to develop an Energy Economy Ratio (EER) for eGSE using the same methodology that CARB used to develop the EER value for eCHE. CAC's consultant developed the EER and submitted the report to CARB in 2021 (see Attachment 1). Following multiple correspondences and meetings, CARB decided not to include an eGSE category in 2022 and encouraged individual airports to apply through the Tier 2 pathway process. However, the Tier 2 pathway process is long and labor intensive and requires annual verification. This has proven to be a barrier, which in turn has slowed the adoption of eGSE at airports.

It is noteworthy that Oregon's Department of Environmental Quality included eGSE in its LCFS equivalent, Clean Fuel Program using the data developed by California airports. Oregon Clean Fuel Program has similar goals of reducing fuel carbon intensity. More information can be found here: https://www.oregon.gov/deq/ghgp/cfp/pages/cfp-overview.aspx#:~:text=DEQ%20gradually%20lowers%20the%20amount,meet%20the%20annual%20reduction%20goal.&text=The%20Clean%20Fuels%20Program%20encourages,reduction%20goals%20for%20that%20year.

The Port respectfully requests that CARB reconsider including eGSE into the LCFS Program as a lookup pathway using the EER value that has already been developed and submitted. Inclusion of eGSE aligns with CARB's objectives to promote investment in disadvantaged communities and incentivizes more electric infrastructure and electric equipment. Including eGSE as a lookup pathway would further Port and State decarbonization goals and accelerate infrastructure upgrades that will continue improving air quality for the East Oakland community and other communities located near California airports.

We appreciate the opportunity to provide comments. Please contact me at 510-627-1198 if you have any questions.

Thank you,

Colleen Liang
Director of Environmental Programs and Planning

FROM:	Sarah Johnson, California Airports Council
SUBJECT:	Development of EER Values for eGSE in the California LCFS Program

Energy Economy Ratios for Electric Ground Support Equipment in the Low Carbon Fuel Standard

The California LCFS program allows owners of charging infrastructure or electric equipment to generate credits for many different equipment categories, including forklifts, on-road trucks, yard tractors, cargo handling equipment, and shore power for marine vessels. Electrified airside ground support equipment (eGSE) is not precluded from participation in the program. However, because no energy economy ratio (EER) for this equipment category exists in the LCFS regulation, there are only two mechanisms by which eGSE can generated credits; 1) use of a site-specific EER-adjusted Tier 2 pathway, or 2) use of an EER of 1.0 in lieu of an equipment-specific EER. Both options introduce burdens to eGSE fleets, limiting participation in the LCFS program. In fact, no eGSE currently generates LCFS credits. Given the sustainability efforts and commitments by airports and airlines in California, eGSE represent an important equipment category for further electrification of California's transportation sector.

The most effective way to include eGSE in the LCFS program is to establish one or more defensible EER values that can be added to the LCFS regulatory text and/or used in an EER-adjusted Tier 2 pathway without requiring site-specific data collection and verification of the EER on an ongoing basis.

Previous analyses have established EERs in one of two ways:

1. Predicting emissions based on the average speed of the equipment. This is the basis of EER values for electric on-road trucks and yard tractors.
2. Correlating average activity and engine loads to CO_2 emissions and fuel consumption. This is the methodology used to calculate EER values for the electric cargo handling equipment (eCHE) and electric ocean-going vessel (eOGV) categories. It is used for applications where average speed does not properly characterize engine performance because of significant changes in engine load at low- or zero-speed.

The approach to developing EERs for eGSE follows the same basic methodology as used by CARB staff for these other categories. The approach for eCHE and eOGV EER development is described in CARB Staff's Attachment D to the "Notice of Public Availability of Modified Text and Availability of Additional

Documents and Information," related to the 2018 Proposed Amendments to the Low Carbon Fuels Standard Regulation and to the Regulation on Commercialization of Alternative Diesel (Attachment D). These prior analyses referenced emissions inventories developed for the Port of Long Beach as the source of equipment activity data. The source of equipment activity data for this analysis is CARB's OFFROAD model.

A. Methods

1. eGSE Power Requirements

The OFFROAD model provides data on populations, fuel consumption, engine work, and load factors, for a wide range of GSE types. For this analysis, the engine efficiency for each GSE type and fuel combination is calculated from the OFFROAD model data as follows:

$$Efficiency_{type,fuel} = CF * \left(\frac{E_{fuel} * \sum_{ModelYear} \sum_{HP\ Bin} FuelUse}{LF_{type,fuel} * \sum_{ModelYear} \sum_{HP\ Bin} HPhr} \right)^{-1}$$

Equation 1. Calculation of Engine Efficiency for GSE by Equipment Type and Fuel

Where:

E_{fuel} is the energy density of the base fuel type (diesel, gasoline, or natural gas) in MJ/gallon on a lower heating value basis

FuelUse is the annual fuel consumption for each model year and HP bin combination in gallons/year

LF is the load factor for a particular combination of GSE type and fuel

HPhr is the total horsepower hour per year of activity reported by the OFFROAD model for each model year and HP bin combination, before applying the load factor. The OFFROAD model reports this value as "Horsepower_Hours_hhpy"

CF a conversion factor of 2.6845 MJ per hp-hr

Efficiency is the average thermodynamic efficiency of the engine

Currently, CARB's EER calculation methods assume no energy loss during battery charging or conversion of energy to useful work. To be consistent with prior calculation methods, it is similarly assumed that no losses occur for eGSE. Therefore, the inverse of conventional engine efficiency can be used to estimate EERs for each equipment type and fuel.

Date: February 5, 2021

2. Application to Specific Ground Support Equipment

Table 1 presents the fuel consumption, activity, and load factors for each GSE type and fuel combination, as reported by the CARB OFFROAD model[1]. Note that the OFFROAD model data presented in ORION2017 does not contain data for portable diesel equipment (e.g., pre-conditioned air units, ground power units, generators). The OFFROAD2007 model does include information on portable diesel GSE, so average horsepower, activity, and load factors from OFFROAD2007 were used to calculate estimated EER values for these portable diesel equipment categories.

Table 1. Fuel Consumption (MJ/yr), HP-hr per year, and Load Factors for eGSE Types

	Fuel (MJ/yr)			Total hp-hr/yr (LF not included)			Load Factors

[1] See attached supporting spreadsheets detailing OFFROAD model values and analysis.

EER values for eGSE were estimated by applying the values in Table 1 to the function in Equation 1. The EER for each equipment type and fuel is the inverse of the engine efficiency resulting from Equation 1. Combined EERs for each fuel type are calculated by weighting each GSE category EER based on Operating Hours per year, following the eCHE methodology.

GSE were grouped into two categories: Mobile and Portable, based on the primary fuel and type of GSE. Gasoline and spark-ignited natural gas and propane are the dominant fuel types for Mobile equipment while diesel is the dominant fuel type for Portable equipment. Consequently, the proposed EER for Mobile equipment is 4.2 and based on EERs for gasoline equipment. The proposed EER for Portable equipment is 2.9 and based on EERs for diesel equipment.

Table 2. Fuel Consumption and Calculated EER for eGSE Types

Group	GSE Category	Total Fuel Consumed (gal/yr)			EER		
		Gasoline	Diesel	Nat Gas	Gasoline	Diesel	Nat Gas
Mobile	Aircraft Tug - Narrow Body	476,800	430,627	-	4.0	2.6	n/a
Mobile	Aircraft Tug - Wide Body	500,952	450,271	-	3.8	2.6	n/a

Portable	Generator	51,772	4,376,131	-	4.1	2.9	n/a
Portable	Air Start Unit	25,163	1,303,079	-	4.0	2.6	n/a
				Mobile (Operating Hour Weighted)	**4.2**	2.6	3.3
				Portable (Operating Hour Weighted)	4.0	**2.9**	n/a

3. Alternative Data Source Considered

Data from the Airport Cooperative Research Program, Report 149 (ACRP 149)[2] were also considered as an source of information to estimate EERs. ACRP 149 is "a guidance document that provides a potential update to the current set of default ground support equipment (GSE) fleet and activity data used for passenger and cargo aircraft and a protocol to improve the accuracy and consistency of data collection for airport GSE activity."[3] However, while ACRP 149 provides recommended load factors for emissions inventories, it does not provide values for equipment activity, rated engine horsepower, or fuel consumption. To implement the same methodology as described in Attachment D, values for rated engine horsepower and annual operating hours for each GSE type and fuel were taken from the OFFROAD model. Composite horsepower ratings for each GSE category were calculated on a population weighted basis across all fuel types using OFFROAD population values.

The relationship between CO_2 emissions factors and engine brake horsepower presented in Figure 1 of the Attachment D document was then used to calculate CO_2 emissions, implied diesel fuel consumption, and the resulting EERs. Results of this analysis are summarized in Table 3.

This approach is limited because the relationship between CO_2 and engine brake horsepower developed for diesel engines is applied to a composite of all fuel types described in the OFFROAD model. However, the resulting EERs for Mobile and Portable equipment are 4.1 and 2.9, respectively, and are nearly identical to the results from the previously described approach. This suggests that the EER values of 4.2 and 2.9 for Mobile and Portable equipment presented previously are reasonable, robust when using different approaches and data sources.

Portable	Air Start Unit	0.47	363	171	502	9.0	2.5	65,441
						Mobile (Operating Hour Weighted)	4.1	
						Portable (Operating Hour Weighted)	2.9	

B. Recommendations

The EERs shown in Table 2 represent a wide range of GSE types and fuels with contributions that vary in proportion to the overall activity and emissions. The dominant fuel and associated engine type combinations (spark-ignited vs compression-ignited) vary by group; defined here as Mobile and Portable groups. Thus, the final recommended EERs for eGSE are separated into the two equipment groups and weighted based on the operational hours reported in the OFFROAD model. Specifically, it is recommended that Mobile eGSE be assigned an EER of 4.2 and a gasoline baseline, while Portable eGSE be assigned an EER of 2.9 and a diesel baseline.

Finally, it should be noted that some airside equipment are already captured under other LCFS categories. For example, medium- and heavy-duty trucks, buses, light-duty cars and trucks, and forklifts already have established EERs. It is recommended that equipment in those categories continue to use the EERs already established.

Re: Use of LCFS Holdback funds in the Proposed 2024 Low Carbon Fuel Standard Amendments

Dear Chair Randolph and Members of the Air Resources Board:

Ecology Action is a 501(c)3 nonprofit based in Santa Cruz, California focused on reducing emissions at scale and has done extensive work with energy efficiency retrofits and EV infrastructure across California. Ecology Action specializes in developing equitable EV infrastructure deployment and EV demand generation approaches in hard-to-reach markets such as affordable multifamily and small business. Our most recent projects are “direct installation” of EV charging in affordable multifamily properties via the CEC REACH 1.0 and 2.0 grant programs and with PG&E on their Multi-Family Housing and Small Business Direct Install Pilot (MSDI) using LCFS holdback funds. Ecology Action is unique as we act as both a community-based organization (CBO) and a program implementer.

317.1 We strongly support the ARB staff’s proposal to increase the amount of hold back proceeds benefiting priority communities to 75% by January 2025. We support staff’s efforts to expand the scope of how LCFS holdback proceeds can address the unique barriers faced by disadvantage communities such as using holdback proceeds to fund managed charging and V2X applications. This will open new pathways for equity customers to tap into the emerging value stream from managed and bi-directional charging as a grid support service.

LCFS holdback funds create unique opportunities to design programs that better serve the equity market. This is in contrast to some other highly constrained and historically regulated EV funding sources. One example is the ability to create programs which pair vehicle incentives along with EV infrastructure delivering a complete solution. Another is providing of end-to-end technical assistance support for site hosts in priority communities. Ecology Action has learned from its more than 20,000 energy efficiency “direct installation” projects completed that even if 100% of the cost of an intervention is covered by incentives, hosts would not be able to realize the adoption without in-depth technical assistance to overcome other persistent barriers they face (e.g. lack of EVSE expertise, necessity for the property staff to not be distracted from their primary business imperatives). Direct installation is one example of a solution that provides additional support. It is a ‘one-stop shop’ approach much like that which CARB has used, but with the addition of technical assistance providing construction project management to assure project completion.

One of the key impediments to equitable deployment of EV infrastructure faced by the utilities is that current allocations for technical assistance under the Transportation Electrification Framework (TEF) appear to be extremely underweighted. While consumer incentives are extremely important in creating and expanding markets, right-sized technical assistance is critical to meet the staff’s proposed 75% equity benefit goal. To help cover this gap left by the TEF, we encourage CARB to assure that the Amendment language being considered now be crafted to assure that the following recommendations can be adopted.

317.2 1. Allow LCFS holdback proceeds to fund technical assistance that is directly paired with the TEF statewide incentive program dollars so that underserved participants can receive the end-to-end, vendor neutral technical assistance they need to electrify. This includes system design, business model and payment settlement selection, permitting, contractor selection, construction management services, activation and staff/driver training.

317.3 2. Allow the continued, and encourage the expanded, use of nonprofit and for-profit third-party implementers for deployment of holdback-funded initiatives. This is in compliment to the utilities own teams that are implementing a portfolio of very effective programs. Third party implementers have been used extensively for utility-funded energy efficiency and demand response program implementation for more than two decades and often bring essential nimbleness and innovation at costs that are often less than traditional approaches. The CPUC's energy efficiency and other DER programs implemented by IOUs and CCAs can be used as real-world benchmarks for setting the appropriate balance between technical assistance and incentive dollars required to reach the State's equity and scaling objectives.

317.4 3. Focus LCFS funds on electrification of small, essential EV fleets that serve priority communities. (e.g. foodbanks, paratransit, elder meal delivery, small business fleets in underserved communities). Holdback proceeds should fund, in a single offering, the triad of 1.) end-to-end vendor neutral technical assistance 2.) vehicle incentives and 3.) infrastructure incentives. This bundled offering is essential for scaling small equity fleets. Likewise, it is important that incentives for Class 1 & Class 2 vehicles are eligible for holdback proceeds, beyond the current Class 3-8 vehicles covered by CARB's ISEF program.

317.5 4. We encourage the Amendment to expressly state that a key purpose of LCFS proceeds is to demonstrate and pilot deployment innovations as a way to inform and shape future iterations of TEF funding.

The State of California has ambitious goals for equity, air quality improvement and GHG reduction. Ecology Action truly believes the State can make a meaningful contribution to all three with the thoughtful deployment of the LCFS holdback funds as outlined here.

If you have any questions regarding our comments, please don't hesitate to contact me.

Subject**:** Letter of Comment on Ethanol Pathway in GREET, Issue with Biogenic VOC for Proposed Amendments to the LCFS, posted December 19, 2023

Dear Chair Randolph:

318.1 Life Cycle Associates would like to take this opportunity to provide our comments on the dry mill corn ethanol pathway under CA LCFS. We wish to draw attention to an issue regarding the treatment of biogenic VOC emissions within the ethanol production and T&D phases, which have been incorrectly categorized as fully oxidized GHG emissions. Both the prior and current versions of GREET have incorporated fugitive VOC emissions as fully oxidized GHG emissions, thereby adding to the carbon intensity of corn ethanol's well-to-tank phase. Such miscalculation within GREET1 models has carried forward to CA-GREET models as well, permeating this issue to CA LCFS.

Given that the VOC's carbon source is inherently biogenic, it logically follows that it should be designated as carbon-neutral for the purposes of carbon intensity calculations, warranting a reevaluation of its current treatment within the model. The non-combustions VOC emissions at the production plant as well as during the T&D phase are calculated per the equation below:

Equation 1. Total VOC emissions Dry Milling Corn Ethanol w/o Corn Oil Extraction.

$$VOC \ \left(\frac{g\ CO2e}{MMBtu}\right) = \left(\frac{(\mathbf{2.239})}{76{,}330} \times 1.001 \times 1e^{6} \times 1.000\right) \times \frac{44}{14} + (6.667 + 13.082) \times \frac{44}{14} \times 0$$

Compared to its predecessor, the 2019 simplified sfe calculator correctly excluded the T&D VOC fugitive emissions as GHG emissions. However, the fugitive VOC emissions as GHG from the production phase were still incorrectly retained, resulting in a CI of about 0.087 g/MJ. The same calculation has been carried forward in the proposed simplified SFE calculator, as shown in Table 2 below.

Stefan Unnasch
1. 650.461.9048 direct
unnasch@LifeCycleAssociates.com
884 Portola Road, Suite A11
Portola Valley, CA 94028 USA

Table 1. Corn Ethanol Evaporative Emissions

CA-GREET4.0 Emission Factors and Specifications				
Category	Sub-Category	Name	Value	Unit
Fuel Production	Process Fuel	Natural Gas Combustion in Boiler	75,496	gCO_2e/MMBtu NG (LHV)
	Chemicals and Enzymes	Chemicals	2.02	gCO_2e/MJ ethanol (LHV)
		Cellulosic Enzymes Used	525	gCO_2e/lb enzyme (normalized)
	Coproducts	Default Distiller's Oil Moisture Content	1%	%W/%W
	Evaporative Emissions	Standard Value	0.0867	gCO_2e/MJ EtOH
	Denaturant	Default Blend Value	2.5%	%V/%V

There are two key issues to be corrected in the above calculation and thus the ethanol CI calculator.

1. Incorrect oxidation of VOC
The fully oxidized conversion of the VOC from the production phase currently utilizes the standard factor of approximately 44/14, where 14 refers to the molecular weight of an average VOC molecule. However, the VOC fugitively emitted during ethanol production is essentially an ethanol molecule with a molecular weight of 46, not 14. Thus, the correct fully oxidized fugitive VOC emission should use the factor of (44/46) instead of (44/14).

2. It's all biogenic
Most importantly, the origin of carbon in these fugitive VOC emissions is strictly biogenic. As all other biogenic carbon flows are treated carbon neutral under the ethanol pathway, these fugitive emissions should also be zeroed out and not be included in the ethanol pathway altogether.

Overall, the correct equation to calculate the GHG emissions from the fugitive VOC emissions is as follows:

$$VOC\ \left(\frac{g\ CO2e}{MMBtu}\right) = \left(\frac{(2.239)}{76{,}330} \times 1.001 \times 1e^{6} \times 1.000\right) \times \frac{44}{\mathbf{46}} \times \mathbf{0} + (6.667 + 13.082) \times \frac{44}{14} \times 0 = \mathbf{0}\ \frac{\boldsymbol{g\ CO2e}}{\boldsymbol{MMBtu}}$$

Correcting for this reduces the corn ethanol pathway CI by about 0.087 g/MJ as shown in the Table *1*. This may seem like a small number, but it should be noted that this is a systematic error which affects each and every certified corn ethanol pathway and every gallon of corn ethanol sold in California, and it also affects the Inflation Reduction Act (IRA). Over the total volume of corn ethanol sold, such a small change in CI generates a significant impact for the LCFS program. It is also critical from a consistency perspective to treat the emissions from all biogenic sources equally.

Note that the same issue applies to other biofuel pathways including biodiesel and renewable diesel. CARB has already zeroed out the GHG impact of the transport VOC emissions for these pathways based on comments we provided several years ago. However, since the source of VOC in the ethanol plant is not clearly identified as biogenic ethanol, CARB has not acted on the ethanol production component, which clearly appears to be fugitive ethanol.

Life Cycle Associates has previously shared this comment with Argonne National Laboratory as well as with CARB. The response from ANL was in agreement with the comments, however owing to their priorities, ANL has deferred this change to future. Our previous comment letter to

Stefan Unnasch
1. 650.461.9048 direct
unnasch@LifeCycleAssociates.com
884 Portola Road, Suite A11
Portola Valley, CA 94028 USA

CARB also describes in detail the exact calculation with references to the specific sheets and cells within the prevailing CA-GREET and GREET1 model.

More importantly, the GREET model defines the basis for GHG calculations under the LCFS. Scholars, students, analysts, and of course affected parties look to the model to define the methods for GHG analysis. So, simple math errors do not support confidence in the program and should be corrected to avoid misunderstandings.

Thank you for your consideration.

Subject: Letter of Comment on Avoided Methane from Organic Materials and Renewable Power for Process Fuel for Proposed Amendments to the LCFS, posted December 19, 2023.

Dear Chair Randolph:

Life Cycle Associates would like to take this opportunity to provide our comments on Proposed Amendments to the Low Carbon Fuel Standard Regulation, posted on December 19, 2023. This letter is focused on two key components of the proposed amendments: Avoided Methane from Organic Materials and Renewable Power for Process Fuel.

Organic Feedstocks

319.1 • CARB is considering that all U.S. landfills are capped and that all U.S. landfill methane emissions are capped up to 75% and that only 25% can be considered leaked and potentially avoided. According to the U.S. EPA, even capped landfills cannot capture more than 50% of its LFG, and that there are numerous landfills in CA and the U.S. which are NOT capped at all. Therefore, CARB's assumptions in the Tier1 OW calculator is conservative.

319.2 • The Tier1 OW calculator is limited to CNG production via anaerobic digestion. We recommend that the calculator should apply to all fuels including hydrogen, FT jet, and others and not be limited to CNG via anaerobic digestion. Digestate from AD systems also becomes CO_2 just like feedstock into gasification systems and CARB should not delay the adoption of these technologies.

319.3 • We recommend that CARB provide more clarity on the definition of material that was diverted from a landfill versus material that otherwise would be composted as the counterfactual will be difficult to prove. A methane avoidance emission factor that represents the potential alternative fates of landfilling and composting with decomposition to CO_2 will allow for greater clarity in defining the avoided emissions from organic materials.

Processing Power

319.4 • That the small amount of power used for processing includes energy used for pumps, compressors and electronic control systems, etc. We recommend that CARB allows the use of grid power with book and claim of RECs for process power used to make hydrogen. These loads do not require large grid drawdown and only use for plant controls, pumps and processing and should not receive any different treatment than power used for electrolysis, especially for projects located in California.

Consequences of Biomass Disposal

I have seen the consequences of inaction on biomass some of them are well known. SB1383 has led the challenges in the handling of urban biomass including wood chips. I don't need to look far to see the consequences. Alongside the roads everywhere you see piles of wood chips, no doubt the consequence of SB1383 and landfill fees that have risen. Better enforcement cannot force the round wood chip into the square hole. Technologies such as the utilization of biomass need to be actively considered and cannot wait another decade. Organic material provides an ideal energy source for synthetic aviation fuel, hydrogen, and other fuels and this resource needs to be examined.

Figure 1. Slash piles from commercial lumber operations are not stored for long periods of time as new trees must be grown.

Stefan Unnasch
1.650.461.9048 direct
unnasch@LifeCycleAssociates.com
884 Portola Road, Suite A11
Portola Valley, CA 94028 USA

Figure 2. Biofuel policies could eliminate illegally dumped woodchips which accumulate along CalTrans freeway interchanges. High tipping fees and the challenges associated with composting make biomass energy an attractive option. No integrated polies are in place to deal with the fire hazards such as the Eucalyptus tree that overlooks the scene.

Avoidance Credit for Recovered Organics

The proposed regulation and the associated Tier 1 calculators now allow recovered organics to also generate avoided methane credit similar to urban landscape waste diverted away from landfills. Such an inclusion can be seen in the instruction manual of the OW calculator as shown below:

Field Name	Instructions
2.1 Organic Waste Feedstocks	Select feedstock(s) used by the fuel pathway. "Food Scraps" (FS) is the organic portion of municipal solid waste (MSW) that consists of wastes derived from plants or animals for the explicit preparation for consumption by humans or other animals that is predominantly disposed by landfilling. This includes inedible waste from foods processed or consumed at residences, hospitality facilities (hotels, restaurants, amusement parks, stadiums, special events, etc.), institutions (hospitals, schools, prisons, etc.), and grocery stores. Food scraps do not include liquid wastes, fat/oil/grease (FOG) materials, or other by-products of industrial food processing, manufacturing, and distribution facilities. "Urban Landscaping Waste" (ULW) is organic MSW material collected from landscaping activities, including leaves, grass, branches, and stumps. "Recovered Organics" (RO) is the organic fraction of mixed MSW that is manually or mechanically separated from the waste stream, typically at a materials recovery facility or transfer station. Any other organic waste feedstocks may be modeled as "Other Organic Waste" (OOW).

Similar to the FS or OLW waste pathways, the RO waste pathway also earns an avoided fugitive emissions from landfilling. The RO represents the waste that is separated from the aggregate waste stream at a recovery facility.

Stefan Unnasch
1.650.461.9048 direct
unnasch@LifeCycleAssociates.com
884 Portola Road, Suite A11
Portola Valley, CA 94028 USA

319.5 However, the regulatory text, particularly the section § 95488.9.(f) (2), does not clearly reflect the same. A simple reading of this provision seems not to include avoided methane credit generation for recovered organics. We propose modifying the language in the following section to accurately reflect inclusion of recovered organics towards generating avoided methane emissions from landfilling.

(2) A fuel pathway that utilizes an organic material may be certified with a CI that reflects the reduction of greenhouse gas emissions achieved by the voluntary diversion from decomposition in a landfill and the associated fugitive methane emissions, provided that:

(A) The organic material that is used as a feedstock would otherwise have been disposed of by landfilling, and the diversion is additional to any legal requirement for the diversion of organics from landfill disposal.

(B) Any degradable carbon that is not converted to fuel is subsequently treated in an aerobic system or otherwise is prevented from release as fugitive methane. Upon request, the applicant must demonstrate that emissions are not significant beyond the system boundary of the fuel pathway.

(C) The baseline quantity of avoided methane reflected in the CI calculation is additional to any legal requirement for the avoidance or capture and destruction of biomethane.

For additional consistency we also recommend addition of "recovered organics" in all places which specify or define "organic waste" for the purposes of methane credit generation. Few of such places are shown below as examples:

- Tier 1 Classification

GREET~~3~~4.0 model to calculate the pathway CI. The Tier 1 classification includes, but is not limited to, the following fuel pathways:

(1) Ethanol derived from starch or fiber in corn kernels or grain sorghum, and sugarcane;

(2) Biodiesel produced from feedstocks including but not limited to oilseed crop-derived oils; rendered animal fat, distiller's corn oil, distiller's sorghum oil, and used cooking oil;

~~(3)~~ Renewable ~~Diesel~~diesel, renewable naphtha, alternative jet fuel and renewable propane produced by hydrotreatment of feedstocks in a stand-alone reactor, including ~~but not limited to~~ oilseed crop-derived oils, rendered ~~tallow~~animal fat, distiller's corn oil, distiller's sorghum oil, and used cooking oil~~;~~

~~(4)~~(3) ~~LNG and L-CNG from North American fossil natural gas;~~, also known as Hydroprocessed Ester and Fatty Acid (HEFA) Fuels;

~~(5)~~(4) Biomethane from North American landfills, anaerobic digestion of wastewater sludge, dairy and swine manure, and food, urban landscaping waste, and other organic waste~~.~~; and

February 20, 2024

The Honorable Liane Randolph, Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95814

Re: Comments on Proposed Low Carbon Fuel Standard Amendments and associated Initial Statement of Reasons

Dear Chair Randolph:

Brightmark LLC ("Brightmark") appreciates the opportunity to submit comments on the Proposed Low Carbon Fuel Standard Amendments and associated Initial Statement of Reasons (ISOR) posted on December 19, 2023, and updated on January 2, 2024 ("Proposed LCFS Amendments"). We appreciate the California Air Resources Board (CARB) engaging with stakeholders regarding changes and updates to the Low Carbon Fuel Standard (LCFS) program.

California's leadership in climate action through aggressive reduction targets and corresponding programs, like the LCFS, accomplishes actual pollution reduction and public health benefit outcomes by establishing market certainty to drive private investment. The state's leadership and programs provide key solutions to the global climate challenge, however, more needs to be done.

The Proposed LCFS Amendments are **insufficient** to maintain and increase investment in the LCFS program and **risk stranding existing assets** that have relied on the program.

The credit market has shown, through price dips, not price increases, following the release of the Proposed LCFS Amendments in December 2023 that the proposed changes are insufficient. Current LCFS prices as of February 11, 2024, reached the lowest point in over a year, indicating that CARB has not gone far enough in the Proposed LCFS Amendments regarding Carbon Intensity (CI) targets, CI step-down, and the Auto Acceleration Mechanism (AAM). This trend in credit market decreases following CARB proposed rule announcements includes after the February 2023 workshop and after posting of the Standardized Regulatory Impact Assessment (SRIA) in September 2023. If the current prices were to continue, there is a real threat of stranded assets for current investments that limit, if not eliminate, future investment.

CARB needs to utilize the three main levers: (1) CI targets, (2) CI step-down, and (3) AAM to stabilize credit prices at a level that will sustain current investments and lead to future investments. Increased program ambition is critical for continued methane reduction and growth in all low-carbon fuels.

1725 Montgomery Street, Floor 3
San Francisco, CA 94111
415-810-0448
Brightmark.com

Based on the Proposed LCFS Amendments, Brightmark recommends the following policy changes:

- A 2030 CI target of 40%,
- A CI step-down of 10% from the current regulation of 12.5% to 22.5% in 2024 to address current oversupply issues and increases in the bank that will occur in 2024.
  - If not administratively possible, then a CI step-down of 10% from the current proposal of 13.75% to 23.75% in 2025.
  - Increases of credits in the bank in 2024, because of delayed rule implementation, are causing downward price pressure needing immediate attention.
- An AAM, using similar mechanics laid out by AJW at the May 23, 2023 Workshop (May Workshop), to help avoid future oversupply situations, with the following changes:
  - Allow for a cumulative Credit/Deficit (C/D) bank trigger, instead of waiting for annual C/D numbers, and adjust the C/D ratio from 1.0 to 0.8
  - Allow for the AAM to be triggered as early as 2025
- A full credit true-up process that includes both
  - a true up while generating credits using the temporary pathway and
  - an annual true-up during the annual fuel pathway report process.

Brightmark Overview

Brightmark was founded in 2016 with the mission of solving some of the greatest environmental challenges facing the United States. One of these solutions is capturing methane emissions from organic waste and producing biogas and digestate through the natural process of anaerobic digestion. Agricultural activities contribute approximately 30% to total U.S. greenhouse gas (GHG) emissions, a significant portion attributable to methane emissions from animal waste.[1]

Brightmark operates over 30 net-negative carbon intensity projects on dairy farms across the U.S., including in California. Through these projects, Brightmark derives RNG from biogas that has been captured from organic waste streams and is cleaned and conditioned to achieve the quality standards necessary to blend with or substitute for geologic natural gas. We work with dairy farmers to harness the energy potential of their dairy manure, provide them with solutions to meet their greenhouse gas reduction goals, and enhance farm profitability. We are committed to reimagining waste and building projects that benefit farms, their dairy, their communities, and the planet.

These facilities provide a win/win scenario for farmers and local communities; they help address methane emissions from organic waste produced locally and turn that waste into renewable energy and fertilizers. To date, our projects have offset over 850,000 metric tons of CO2eq.

[1] U.S. Department of Agriculture Economic Research Service, citing the U.S. Environmental Protection Agency *Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2021*, April 2023 (EPA 2023).

1725 Montgomery Street, Floor 3
San Francisco, CA 94111
415-810-0448
Brightmark.com

The LCFS program, and the certainty it provides to the market, is a key factor in the long-term success of projects like these in addressing environmental challenges. The CARB LCFS workshops throughout 2022 and 2023 highlighted the success of the LCFS, showing that the program is over-performing and helping California meet its reduction goals sooner than originally targeted.

California Leadership in Climate Solutions Should Lead to More Aggressive Targets

California has a long history of supporting aggressive actions to address environmental challenges, like climate change. Governor Newsom has called for an even more aggressive approach to achieve climate neutrality. As CARB has stated, "[s]ignificant reductions in transportation emissions are needed to achieve state's air quality and climate goals."

During the Oil Price Information Service LCFS & Carbon Markets Workshop, ICF presented a scenario analysis that included the current bank of credits with a step-down of 7.25% and found that a CI reduction target of 40% was achievable in 2030 without the credit bank going negative.

The credit bank is projected to reach 28-30 million credits through the end of 2024 reporting, with the bank projected to increase in size by up to 6-8 million credits in 2024 alone. The current proposed 5% CI step-down will still lead to an increase in the bank in 2025, but a step-down of 10% will offset most, if not all, of the bank increase in 2024. This will stabilize the size of the bank to maintain credit prices at levels that will sustain and increase investment in the LCFS.

We believe the reduction target should be 40% by 2030, combined with a step-down of 10% in 2024. Because of the delay in LCFS rule implementation, the credit bank increases through 2024 do not seem to be addressed in the CI targets and step-down proposals. If not administratively possible in 2024, then a 10% step-down in 2025 should be implemented. As with California's Renewable Portfolio Standard program, the industry rises to the occasion with aggressive targets.

According to the ISOR, the LCFS provides environmental and public health benefits. Appendix A shows that projected positive environmental and health benefits, on a 2021$/gallon basis in 2026 and 2030, are comparable to significantly higher credit prices than what we see now. And historically, the potential LCFS impact on gas prices is insignificantly less than other exogenous impacts on crude prices (the main driver of gas prices) and California refinery disruptions and issues, see Appendix B.

In addition to the environmental and public health benefits, an increasingly stringent target provides market and regulatory certainty. Participants in the LCFS program have already demonstrated the ability to invest in long-term assets that drive CI reduction targets that exceeded expectations. Brightmark supports higher targets to increase credit demand and maintain a diverse fuel and credit generation mix.

An Auto Accelerator Mechanism Provides an Appropriate Guardrail Against Low Prices and Increases Investor Certainty

In addition to a near-term 2024 or 2025 adjustment to the range of 23-24% and tightening the stringency to achieve a minimum 40% reduction by 2030, CARB should adopt a target accelerator mechanism to reduce the likelihood of future oversupply scenarios. An accelerator mechanism is not a substitute for appropriate changes in the targets, but it does offer an attractive additional tool to CARB if they wish to minimize future minor target-adjustment rulemakings. The key term here is "future oversupply scenarios." The LCFS is already oversupplied, with that oversupply projected to increase by 30-40+% higher from now through 2024. It is important that a sufficient step-down is implemented where the AAM would not be triggered in the first year after the new amendments (2026).

The details of the accelerator mechanism mechanics proposed by AJW at the May Workshop are well thought out and administratively feasible. A high credit-to-deficit (C/D) ratio and a high bank-to-deficit (B/D) ratio are important signals indicating an imbalance in credit supply and demand fundamentals. We encourage CARB to allow for a cumulative Credit/Deficit (C/D) bank trigger instead of waiting for annual C/D numbers. Also, as proposed, the C/D ratio should be adjusted from 1.0 to 0.8. If the B/D ratio can be triggered, then the bank is too large. However, if a C/D ratio is between 0.8-1, then there will not be a significant enough decrease in the bank to impact prices and lead to future investment.

A dual trigger, consisting of both a C/D ratio and a B/D ratio, as proposed by AJW, will likely strike an appropriate balance and only activate when there is a high likelihood of systemic long-run oversupply. The proposed trigger values should be reassessed appropriately based on historical data from the CA LCFS system. Once the trigger conditions are met, responding with a jump ahead in compliance targets is a straightforward and transparent way to increase stringency. Aligning the timing of correction with the existing process to address significant undersupply (through the Credit Clearance Market) is appropriate and straightforward.

320.1
- **Policy recommendation:** To address current and anticipated credit oversupply that threatens the viability of RNG projects, a more aggressive carbon intensity target with an increase to at least 40%

320.2
- **Policy recommendation:** A CI step-down of 10% from the current regulation of 13.75% to 23.75% in 2025 to address current oversupply issues and increases in the bank that will occur in 2024. This level of ambition should also be implemented in Q3 or Q4 of 2024, if administratively possible.

320.3
- **Policy recommendation:** in the AAM,
  - allow for a cumulative Credit/Deficit (C/D) bank trigger, instead of waiting for annual C/D numbers, and adjust the C/D ratio from 1.0 to 0.8, and
  - allow for the AAM to be triggered as early as 2025.

Brightmark.com

Accurate Credit Accounting

A full credit true-up remains necessary to properly recognize the true environmental performance of all pathways. Brightmark appreciates the inclusion of a credit true-up process in the rule language and wants to clarify that it is a full credit true-up both during temporary pathway and annual true up process, consistent with the recommendations submitted by the RNG Coalition in September 2023.

This recommendation would incentivize RNG producers to continuously make improvements to, and find efficiencies in, their existing production processes to improve their carbon intensity score, thus resulting in the continued reduction of GHG, even from operational facilities (which, may yield the greatest value for the LCFS program). As to underperformance, which can be impacted by a variety of external factors separate and apart from the facility itself, a true-up mechanism will allow producers to make the required adjustments and disclosures without the need for CARB staff to generate and process Notice of Violations (NOVs).

320.4
- **Policy recommendation:** A full credit true-up process that includes both a true up while generating credits using the temporary pathway and an annual true up during the annual fuel pathway report process.

Focusing on Solving the Problem

The goal of the LCFS is to reduce the carbon intensity of transportation fuels through greenhouse gas emission reductions. The LCFS is currently the only market with the economic incentive to develop carbon negative projects, including dairy biomethane. Dairy digester projects, due to the low energy density feedstock and higher required residence time, among other reasons, result in higher costs per MMBtu produced.

320.5 The success and market certainty of the LCFS program should be based on increasing the demand for credits, not limiting fuels and credit generation. Increasing demand for credits will result in greater overall emission reductions and a more diverse and stable credit pool. Avoided methane crediting should continue in LCFS until a realistic and proven replacement policy is implemented. Significant investments have been made in existing and future projects based on the current rules and trust in the LCFS program that emission reductions from these projects would be valued for delivering positive outcomes.

320.6 Brightmark supports the continued alignment of deliverability requirements for RNG with that of the federal Renewable Fuel Standard program. Biomethane projects that theoretically have the ability to deliver to California should be included, as the program currently operates. Current rules require that a project's CI score measure the additional carbon impact of traveling further in the CI calculation. Gas pipelines, contrary to the transmission power grids, can deliver biomethane from the East Coast to the West Coast.

1725 Montgomery Street, Floor 3
San Francisco, CA 94111
415-810-0448
Brightmark.com

320.7 While Brightmark prefers the current rule mechanisms for avoided methane and book and claim deliverability continue as is, we can support the proposed rule language applying to projects that break ground after December 31, 2029, to phase out pathways for crediting biomethane used in CNG vehicles after December 31, 2040, and pathways for biomethane used to produce renewable hydrogen would be eligible to receive credits until December 31, 2045.

Market and Regulatory Certainty

The success of the LCFS to date shows the market's ability to deliver together in partnership with CARB. The LCFS, at its core, is a market-based, fuel-agnostic regulation that does not pick winners and allows for all fuels to compete.

Market and regulatory certainty are based on trust in California as a reliable place to sell low-carbon fuel and credits to meet and exceed climate goals. However, to continue to achieve aggressive targets, CARB must promote a long-term, stable environment to encourage investors and teams to create new and maintain existing CI-reducing projects. This requires that credit prices maintain a level for capital recovery of previous and future investments.

320.8 An unfounded concern is that LCFS credit prices will adversely impact fuel prices. Appendix A illustrates that projected environmental and public health benefits, on a 2021$/gallon basis in 2026 and 2030, are comparable to significantly higher credit prices than what we see now. Appendix B shows that historically the potential LCFS impact on gas prices is insignificantly less than other exogenous impacts on crude prices (the main driver of gas prices) and California refinery disruptions and issues.

The ultimate goal of California and the market participants, like Brightmark, is decarbonization and eventual carbon neutrality of not only transportation, but all sectors of the economy. To reach this goal, California needs negative CI fuels for transportation and negative CI biogas for other uses (power, thermal, etc.). In-state and out-of-state RNG production are connected, the same developers that develop instate projects develop out-of-state projects. Current RNG production's success will lead to developing additional RNG projects necessary to decarbonize the non-transportation sectors to achieve long-term goals.

Negative CI fuels require significant economic incentives and market certainty, which has eroded with current LCFS prices. Long-term depression of credit prices will lead to stranded assets and lack of private investment in decarbonizing California's economy. CARB should send a strong signal by dramatically increasing the LCFS reduction targets and help return certainty to the market.

Appendix A – Quantification of Environmental Benefits

The following values are taken directly from the ISOR for total emission reductions and annual monetized environmental benefits.

all in 2021$	2026	2030
CO2 Emission Reduced (MMT)	13	20
5% Discount Rate	$254	$438
3% Discount Rate	$852	$1,368
2.50% Discount Rate	$1,250	$1,997
CH4 Emissions Reduced (MT)	314,024	292,597
5% Discount Rate	$288	$304
3% Discount Rate	$601	$640
2.50% Discount Rate	$816	$800
Health Benefits Total Benefits	$141	$129

The table below shows the combined environmental and health benefits per metric tonne (MT) of CO2e reduced.

Per MT CO2e Reduced in 2021$	2026	2030
5% Discount Rate	$32.8	$31.9
3% Discount Rate	$76.4	$78.2
2.50% Discount Rate	$105.8	$107.1

With the proposed CI targets of 21% and 30% by 2026 and 2030, that results in 0.0024 and 0.0034 deficits generated per gallon of gasoline. The table below compares monetized environmental and health impact per gallon (in 2021$) with the LCFS credit price impact per gallon. The range of credit prices shown are $50, $100, and $150 in nominal dollars that are converted to 2021$ with a range of 2.5%, 3%, and 5% discount rates.

$/gallon Positive Environmental and Health Impact – 2021$		
	2026	2030

RE: Low Carbon Fuel Standard Missing Key Programs to Drive SAF Uplift as Key Components to Reach California's Climate and Regional Air Quality Goals

Dear Chair Randolph,

As you know San Francisco International Airport (SFO) is a global leader of sustainable aviation fuel (SAF) uplift, using ten million gallons of neat SAF delivered last year. Receipt of this fuel was exclusively enabled by CARB's 2018 Low Carbon Fuel Standard Rulemaking that incentivized SAF beyond any other state or country. Since this adoption, SFO and the Sustainable Aviation Fuel (SAF) Coalition we launched that is comprised of airlines, airports, conventional and alternative aviation fuel producers, and other nonprofit and government partners, has met with CARB staff and leadership to compel additional programs to sustain the state's SAF leadership. Further, the SAF Coalition teamed with the Speaker of the Assembly, Robert Rivas, to author the widely supported AB1322, which passed unanimously through the California Legislature, to gap analyze SAF programs that could ensure California's continued SAF competitiveness. While SFO respects the bold decarbonization vision that CARB outlined in its 2022 Scoping Plan Update, we write today to humbly request that CARB team with key members of our aviation industry, as AB1322 requested, to develop a far broader playbook than that proposed in this 2024 Low Carbon Fuel Standard (LCFS) Rulemaking to ensure the state meets Governor Newsom's 20% clean fuels adoption for the aviation sector, estimated at 1.5 billion gallons of SAF by 2030.

California and CARB must model a complete program that addresses the greenhouse gas and criteria air emissions across all sectors. Aviation efforts are falling short of our European
321.1 counterparts. SFO aligns with our industry peers to urge CARB to align LCFS policy across both hydrogen and SAF to allow for book and claim accounting for low-CI electricity and RNG inputs via the use of Power Purchase Agreements (PPAs). SAF and hydrogen are both nascent industries and the state should equally allow the indirect accounting for both technologies.

SFO continues to encourage CARB to consider LCFS and other levers that can materialize new markets to recognize SAF's non-CO2 benefits, as outlined in previous communications with CARB, the California Natural Resources Agency (CNRA), the Bay Area Air Quality Management District, and GoBiz. These positive externalities include improvements to air quality, economic development through green jobs, and wildfire risk reduction, and are detailed in industry studies and should be represented in the LCFS, Scoping Plan, further CARB

Rulemaking, GoBiz programs and/or CNRA incentive structures. A recent Airport Cooperative Research Program (ACRP), administered by the Transport Research Board of the U.S. National Academies of Sciences, found that a 50% SAF blend could reduce by nearly 40% oxides of sulfur and PM reductions of up to 65%. A more recent measurement campaign found that SAF produced via the alcohol-to-jet pathway could reduce non-volatile PM by up to 97%.

The California aviation sector utilizes four billion gallons of conventional jet fuel annually. By creating new programs that enable airlines to switch to SAF, California can reduce aviation GHG emissions by 50-80% on a lifecycle basis. If aircraft in California uplifted just 5% SAF by 2025, greenhouse gas emissions avoided from those flights would total up to 2 million metric tons of CO2. Without growing AJF use, aviation sector emissions are expected to grow to over 25% of California's emissions by 2040, as other sectors (e.g., buildings, road transport) have full decarbonization pathways.

SFO has set a goal of expanding SAF use by its airlines to 5% by 2025. And while we are on our way, hitting 1% last year, achieving this goal will require 200 million gallons of SAF per year (MGY) by 2025, or 16 new SAF plants. As this goal of 200 MGY represents only about one-third of California's 2019 renewable diesel supply, it requires a rapid scaling of SAF production to be achieved.

SAF is being commercialized and is scalable, but volumes are currently small, with roughly 15 million gallons used exclusively in California last year, compared to 2.5 billion gallons of biodiesel and renewable diesel consumption. The key factor limiting SAF growth is the total monetary value that SAF producers receive when compared to that available to producers of alternative fuels to serve the on-road market. This has been quantified and detailed in a 2020 submittal by Graham Noyes ("Cap and Rack Cost" + LCFS cost) and is recognized by the industry to be approximately $0.40 per gallon. To that end, we request that CARB further review LCFS through its Public Workshops and consider revising the regulations to overcome the disparity in policies between the production of renewable diesel and SAF. Doing so will send the price signal producers need to secure investment capital to expand their facilities and increase supply to airlines uplifting SAF in California. It also offers a lifeline to renewable diesel fuel producers that exclusively serve the on-road sector, which is now obligated to increasingly electrify through State Executive Order and regulation to retrofit and retool plants for a future of aviation fueled by SAF.

With quotas and targeted SAF incentives announced and growing in Canada, the United Kingdom, Sweden, Norway, and the European Union, we hope that CARB will consider expanding the LCFS credit for SAF. Doing so will help power aviation's contribution to California's continued post-COVID and wildfire recovery in a way that keeps our state climate-competitive and fuels our industry's energy transition. While other states are starting to develop more robust SAF tax credits and incentive programs, CARB must grow SAF's LCFS credit value, or pursue other programs that can scale (not hinder) SAF as a key waypoint in California's climate emergency response planning and create a lasting legacy for our state.

We stand ready to support CARB's leadership, side by side with our airline and SAF producer peers, through the development of a mutual and robust SAF campaign that we hope you'll take on through this LCFS Rulemaking.

Very truly yours,

Ivar C. Satero
Airport Director

RE: Comments of Joby Aviation on the Proposed Amendments to the Low Carbon Fuel Standard

Joby Aviation appreciates the opportunity to provide comments on the California Air Resources Board's (CARB) Proposed Amendments to the Low Carbon Fuel Standard (LCFS).

About Joby Aviation

Joby's mission is to help the world connect faster and more easily with the people and places that matter most by delivering a new form of clean, quiet, electric vertical take-off and landing (eVTOL) aerial transportation. Building on recent advancements in energy storage, microelectronics, material science, and software, we are developing an all-electric aircraft with zero operating emissions that will transport a pilot and four passengers at speeds of up to 200 mph, while also having the ability to take off and land vertically.

Developing sustainable mobility solutions has never been more needed given the threat that climate change poses to our communities and to our planet. According to the U.S. Environmental Protection Agency (EPA), the top source of CO2 emissions in the U.S. is the transportation sector. We expect the electrification of transportation to accelerate and extend to the skies in the decade ahead, representing a bright spot where technology, economy, and sustainability converge. Applying electrification to small aircraft unlocks new degrees of freedom in aircraft design that were not possible with traditional, combustion engines.

Our aircraft has been specifically designed to achieve a considerably lower noise footprint than that of today's conventional aircraft or helicopters. It is quiet at takeoff and near silent when flying overhead, blending seamlessly into the environment. This will allow us to operate from new skyport locations nearer to where people live and work, in addition to utilizing the more than 5,000 heliport and airport infrastructure facilities already in existence in the U.S. alone.

Joby is headquartered in Santa Cruz, CA with over 1,400 employees across California. In 2022, we completed the construction of our pilot production lines in San Carlos and Marina, CA, and we began manufacturing our production prototype aircraft. We are excited to support the clean transportation and climate goals of our home state.

Zero-Emission Aviation is Key to Meeting California's Climate Goals

The combustion of aviation and other transportation fuels releases substantial amounts of greenhouse gasses into the atmosphere. The transportation sector has the highest dependency on oil over any other sector, with over 90% of energy coming from fossil fuels.[1] At the same time, the aviation industry is undergoing rapid expansion due to the increasing popularity and accessibility of flying. The rise of low-cost carriers and a growing middle-class population worldwide have fueled a surge in air travel demand. Joby strongly supports the broader accessibility of flying as a mode of transportation. We also believe that eVTOL will play an important role in replacing internal combustion vehicles on the road. However, there is a challenge in ensuring minimizing the environmental impacts while reaping the undeniable benefits of increased mobility and connectivity.

For this reason, California and CARB have already created goals to reduce emissions from aviation. These include:

1. 20% of aviation fuel demand met by electricity (batteries) or hydrogen (fuel cells) by 2045; and
2. Sustainable aviation fuel meeting most or the rest of 2045 fuel need.[2]

These goals are ambitious, but Joby and others in the aviation sector are working to ensure that zero-emission aviation becomes a reality in California. In order to advance these goals, CARB will need to utilize every tool available to unlock zero-emission and sustainable aviation technologies and fuels. This includes the LCFS, which will play an important role in incentivizing a less carbon-intensive aviation industry. CARB should seek to streamline the participation of the aviation sector in the LCFS, such as by creating Tier 1 or Lookup Table participation pathways for electric aviation. It is also important that CARB initiate a rulemaking process to implement its aviation goals.

Joby Supports a Stronger LCFS Program

[1] See Data from the International Energy Agency: https://www.iea.org/energy-system/transport
[2] CARB 2022 Scoping Plan at p.73. Available at: https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf

322.1 Joby supports increasing the carbon intensity (CI) reduction target of the LCFS program to at least 30 percent by 2030 and also increasing stringency in later years. As emphasized in the 2022 Scoping Plan Update, the aviation sector holds an important role in California's ambitious journey toward carbon neutrality by 2045, and the LCFS program is a critical instrument in facilitating the decarbonization of aviation.

Beyond setting a more ambitious yet attainable CI target for 2030, it is imperative to structure the LCFS program to be adaptable to market dynamics, ensuring support for continued investments in the cleanest low-carbon technologies. The inclusion of a compliance target "auto-acceleration mechanism," capable of automatically adjusting to
322.2 expedite investments if the LCFS program surpasses expectations, serves as a strategic measure to maximize California's potential for emissions reduction in the transportation sector. This multifaceted approach aligns with Joby's commitment to sustainable aviation and complements the broader initiatives aimed at achieving California's environmental objectives.

Conclusion

Joby is excited to continue to work with CARB on achieving California's zero-emission aviation and larger climate goals.

Sincerely,

/s/ George Kivork

Chief, Industrial Strategies Division
California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: AMP AMERICAS COMMENTS ON PROPOSED LOW CARBON FUEL STANDARD AMENDMENTS

Dear Mr. Botill:

Thank you for the opportunity to comment on the Proposed Amendments to the Low Carbon Fuel Standard ("LCFS"). Amp Americas ("Amp") appreciates the California Air Resource Board's ("CARB's") leadership on addressing climate change and the significant success the LCFS program has had in decarbonizing transportation. Amp especially appreciates CARB staff's thorough and ongoing stakeholder engagement throughout the LCFS amendment process, and in particular on issues related to dairies and renewable natural gas ("RNG").

Amp strongly supports amending the LCFS to ensure its ongoing success as a driver of investment in a broad array of low carbon fuels, including dairy RNG. Accordingly, we offer the following comments, which are further elaborated upon below:

323.1
- Stronger near-term targets than proposed are necessary to address the ongoing accumulation of credits and drive additional investments in low carbon fuels projects in the near term. We recommend:

323.2
  - **A step down to at least 23%** carbon intensity reduction, to take effect as soon as the regulation takes effect in Q3 2024, rather than 2025. If the step down is not effective until 2025, we recommend a 25% step down effective January 1, 2025.

323.3
  - **A 2030 target of at least 35%,** in order to drive the outcomes laid out in the 2022 Scoping Plan. We note that approximately 3 percentage points of the target are required to counteract the change in diesel baseline, which without adjustment, effectively reduces program ambition by 3 percentage points.

323.4
- We support the addition of an auto acceleration mechanism (AAM) to the program, and encourage minor adjustments that would allow it to be more responsive to market conditions:

323.5
  - The **AAM should take effect as soon as the regulation does**, with the first test occurring in 2026 to evaluate 2025 performance.

323.6
  - The **AAM trigger should be 1x quarterly deficits**, rather than 3x, in recognition that 1) the LCFS is now a liquid and mature market, and 2) that liquid and mature markets are in surplus conditions when inventory is greater than 0.6x quarterly demand.

323.7
  - There should be **no limit to applying the AAM in consecutive years**.

323.8
- **We urge CARB to follow the deep and sound science and maintain avoided methane crediting for all RNG pathways.**

323.9 • We **support efforts to develop RNG pathways for zero emission vehicle ("ZEV") fuels and stationary sources**, and encourage CARB to **enable book-and-claim delivery for RNG-to-power plants** to further support this transition.

323.10 • We **support the proposed true-up provisions and recommend CARB allow true-ups during the Temporary CI period for any pathway using a Temporary CI.**

323.11 • We include various other technical comments and recommendations to bolster the ability of the program to continue driving investment in low carbon transportation fuels and greenhouse gas emissions reductions, including allowing the regulation to **automatically incorporate new carbon capture, removal, utilization and sequestration (CCRUS) pathways** if and when new CCS Protocols are developed pursuant to Senate Bill 905.

In addition to these recommendations on the proposed amendments, we appreciate the opportunity to comment on the proposed CA-GREET 4.0 model and revised Tier 1 calculators. We reiterate our comments shared previously on the calculator,[1] and specifically that:

323.12 • All biomethane pathway calculators should include the option to model biogas-to-electricity carbon intensity scores.

323.13 • Applicants should be allowed to account for actual fugitive methane performance.

323.14 • The avoided emissions boundary should include biogas flared during normal operations.

323.15 • The volatile solids table should be updated to include new technologies.

ABOUT AMP

Founded in 2011, Amp develops, owns, and operates RNG facilities that convert dairy waste into carbon-negative renewable energy. Over our history, Amp's projects have prevented over 1.7 million metric tons of carbon equivalent emissions. In 2022 alone, our projects abated approximately 480,000 metric tons of carbon equivalent emissions, and we plan to rapidly expand our impact over the next several years.

As a pioneer in the dairy RNG industry, Amp registered the first 5 dairy RNG-to-CNG pathways in California's LCFS program, and we were the RNG supplier for the first 11 dairy RNG-to-hydrogen pathways. Our experience developing, operating, and reporting on these and other assets gives us a unique perspective on the impact CARB policy has on investment and project development activity related to low carbon fuels. Our projects and resulting methane and carbon dioxide reductions have been made possible by CARB's leadership in decarbonizing transportation, and we encourage CARB to continue to support the policy decisions that have made it so successful.

LCFS CRITICAL TO ACHIEVING SB 1383 METHANE REDUCTION TARGETS

California is a global leader in efforts to slash potent super pollutants, including methane from dairies and other sources. Since the finalization of the *Short Lived Climate Pollutant ("SLCP") Reduction Strategy* in 2017, the state has seen significant investment in projects to mitigate methane emissions, notably from dairy manure management. For example, for decades prior to development of the SLCP Reduction Strategy, the state had only a handful of dairy digesters to mitigate methane emissions, but over the few

[1] https://www.arb.ca.gov/lists/com-attach/360-lcfscalculators23-ws-UTBVPgZ3U19QIgNq.pdf

years since the adoption and implementation of the SLCP Reduction Strategy, California now has over 200 dairy digesters built or under development. Hundreds more projects are under development nationally, delivering significant additional SLCP reductions and creating a broader supply of available RNG to replace fossil natural gas (virtually all of which is imported from out-of-state) and decarbonize California's transportation and other sectors in alignment with the state's strategy to achieve carbon neutrality under the *2022 Climate Change Scoping Plan Update*.

A key element driving this success has been the LCFS. The SLCP Reduction Strategy specifically highlights the LCFS and federal Renewable Fuel Standard as critical programs to enable ongoing development of dairy digesters in California.[2] Without credits generated under the LCFS and RFS programs, or other significant ongoing state incentives, additional dairy manure methane mitigation projects are unlikely to be developed in California.[3] This was a clear finding in the March 2022 review report, *Analysis of Progress toward Achieving the 2030 Dairy and Livestock Sector Methane Emissions Target*. Among other takeaways, the report finds that the LCFS can ensure the long-term operation and financial stability of digester projects[4] and that alternative manure management projects are unlikely to be implemented without subsidies.[5]

This successful framework can continue driving investment in methane mitigation in order to meet our statutory emissions reduction targets, provided that the LCFS is strengthened to maintain a strong investment signal and continues to allow for methane mitigation projects to be developed by (1) increasing overall program ambition in line with the 2022 Scoping Plan, (2) preserving the science-based accounting for avoided methane associated with RNG pathways, and (3) preserving book-and-claim delivery for RNG so it can continue to reach its current transportation fuels markets and extending book-and-claim to allow RNG to serve other target end markets in transportation and stationary uses.

Maintaining current provisions for dairy RNG pathways maintains the investment case under which investors allocated capital to the LCFS program and avoids emissions backsliding. CARB engineered a program to draw private dollars rather than allocate public funds to its SLCP Strategy goals. In order to maintain trust with investors and continue to drive private investment, CARB cannot change the rules and strand investment in capital already deployed. Not only is preserving the rules for dairy digesters important for statewide carbon goals and the LCFS program, but investment in digesters is required to achieve the state's methane mitigation goals and supporting initiatives under SB 1383. The state's Renewable Gas Standard directs utilities to procure biogas from projects utilizing organics diverted from landfills in line with SB 1383 obligations, and explicitly relies on dairy biogas projects continuing to be supported by the LCFS.[6] Thus, several state priorities are at risk with the proposed changes to the dairy RNG rules and overly conservative proposal for overall program ambition by 2030.

https://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M454/K335/454335009.PDF

STRONGER NEAR-TERM TARGETS NEEDED TO SUPPORT ONGOING INVESTMENT

The ongoing development and operation of low carbon fuel projects, including dairy RNG projects, requires programs like the LCFS to provide and maintain a strong and clear market signal sufficient to attract capital for new projects and to maintain operations at existing RNG facilities. In previous comments,[7] we have advocated for a step-down in CI average reductions to at least 19% in 2024, and CI reduction targets of at least 35% in 2030, and urged that targets be in-line with emissions reduction targets in statute or identified in the 2022 Scoping Plan Update (e.g., 40-48% reduction).

323.2 cont. While the proposed amendments include a step-down to about 19%, *the step-down as proposed wouldn't take effect until 2025.* During the third quarter of 2023, the credit bank grew by 2.25 million credits and ended the quarter with a balance of 20.4 million credits. With no change to targets in 2024, if credit supply and demand continue their current rate of growth, the bank could be 38 million by the end of 2024, almost 6 times quarterly deficit generation. If credit supply were to remain constant at Q3 2023 values, with no step down in 2024 (a wildly conservative scenario), the bank would still reach 30 million credits and represent more than 4 quarters' worth of deficits. These outcomes do not account for the recently revised diesel carbon intensity, which will lead to additional credit generation beginning in 2025. With a bloated credit bank to begin with, the market will be hopelessly saturated and getting worse by multiple percentage points and millions of additional banked credits.[8]

If the bank is allowed to reach these levels, prices will remain depressed for an extended time. Investment in new LCFS credit generating projects has already slowed or frozen, and while projects that were green-lit in a higher price environment continue to come to market, new projects are not starting. If low prices persist, new supply growth will stop. In several years, when targets accelerate, the market could snap to undersupply and squeeze prices past the cap. In order to prevent this situation, targets must reflect the market's ability to bring in new supply.

The proposed increase in stringency to 18.75% (growing program targets by 50% vs. 2023), if executed immediately for the full year 2024 (not an option proposed) would only balance the market for this year. However, in 2025, supply growth will once again outstrip demand growth as projects currently under construction are brought online. With surplus conditions continuing, the bank will continue to build, and we will remain in a low price environment – meaning no new investment will materialize.

Together, these trends demonstrate that a greater step down is necessary to maintain orderly functioning of the LCFS market, reverse the trend of accelerating growth in the credit bank, and to avoid further weakening the signal to invest in new projects and GHG reductions. **Accordingly, we encourage amendments that would have the step-down to 23% take effect in 2024 or alternatively, to increase the step down to ~25% if it were to take effect only in January 2025.** Our recommendation is in-line with the analysis presented by ICF, showing levels needed to return balance to the credit bank and stabilize prices**.** We also reiterate our call to set 2030 CI reduction targets of at least 35%, and align program goals with levels required to achieve the goals of the Scoping Plan.

---

[7] For example, see: https://ww2.arb.ca.gov/system/files/webform/public_comments/3751/Amp%20LCFS%20May%202023%20Workshop%20Comment%20Letter%20vF.pdf

[8] ICF, *Analyzing Future Low Carbon Fuel Targets in California*, February 2024

We appreciate that CARB has evaluated three scenarios for program rules and targets, showing high prices and a leveling, declining bank in its proposed scenario. We do not have access to all of CARB's inputs to provide specific feedback, but it is clear that the market disagrees with the output of CARB's forecasts, as reflected in the price of credits since the ISOR was released. The market believes the LCFS market will remain in surplus for the foreseeable future, and credit prices have been trading down since the proposed amendments were released. At the current price level in the low $60s per ton, with the proposed program target levels, most capital providers have stopped investing and going forward will not allocate dollars for further investment in California low carbon fuels projects for at least the next few years.

ADJUSTMENTS TO THE AUTO ACCELERATION MECHANISM WILL MAKE IT MORE EFFECTIVE

323.5 cont. The demonstrated market response implies two things. First, and most importantly, the step-down quantum is insufficient to clear the current supply of available credits. If the market had confidence in the AAM, we might see some price recovery, rather than a continuing decline in credit prices. So the second implication of the market response is that the market believes the AAM as proposed will be insufficient to correct the for the low ambition in the targets. Accordingly, in addition to strengthening the step-down and pulling it forward to Q3 2024, Amp strongly encourages CARB to adjust the AAM, so that it takes effect sooner and is more responsive to changing market conditions.

323.4 cont. Amp strongly supports development of an AAM, which will help to strengthen the program and potentially help to avoid future potential market weakness driven by as-yet unforeseen trends in low carbon fuels supplies. While the market is currently overachieving its targets, there is a long way to go to reach 2045 goals. Ironically, when overachieving the targets in the near term leads to sustained price weakness, it will inevitably lead to sustained periods of underachievement and high prices. If the market subsequently swings from undersupply to oversupply, prices will be volatile, undermining public confidence in the program and jeopardizing long term goals. An AAM can help provide a clear, ongoing signal that there will be a market for low carbon fuels, providing greater certainty to investors and incentivizing continuous investments in clean fuels and ongoing greater emissions reductions, provided that it is designed appropriately.

323.5 cont. As noted above, however, together with the proposed step-down approach, the AAM is insufficient to reverse an accumulating credit bank over the next several years, and therefore stands to miss on its promise. Accordingly, Amp recommends adjusting the AAM as follows:

- The **AAM (and step-down) should take effect as soon as the regulation does (e.g. Q3 2024).** This would imply the first test would take effect in May 2025, and the first year the target could be accelerated would be 2026. If the regulation becomes effective in 2025, the first test should occur in May 2026.
- 323.6 The **AAM should be triggered when credits exceed one quarter of demand**, rather than 3x quarterly demand.
- 323.7 There should be **no limit to applying the AAM in consecutive years** if the specified thresholds are met.

323.6 cont. The AAM is by its nature conservative, requiring both a significant and growing credit bank in order to be triggered. Accordingly, there is no reason to wait an additional year after the step-down takes effect

323.6 cont. for the AAM to potentially apply, or for that matter, to introduce a year between periods when the AAM may potentially trigger again. If a significant credit bank persists and continues to grow – even during a year in which targets were accelerated by operation of the step-down or the AAM – that demonstrates that further acceleration of the targets is warranted.

A credit bank that is too large has a seriously detrimental effect on the market. Especially when a large number of credits is held by few players – as is the case now and for the last several years – those players can draw on their holdings and not buy or generate additional credits. This leads to price weakness and tells potential future suppliers not to invest. Even if the market were to supply fewer new credits than compliance obligations require (i.e., market balance is in deficit) the large bank can prevent prices from signaling to suppliers the need to invest. So, what is the right level? Drawing corollaries from similar markets, stores rarely exceed 15-25% of annual demand or 0.6-1.0x quarterly demand in U.S. grain[9] and energy markets (see data for crude oil and natural gas below). We note as well that the federal RFS program allows for an effective bank maximum of 0.8x quarterly demand in the form of its rule allowing 20% carryover of RIN balances (and deficits).

U.S. Crude Oil Storage as Share of Quarterly Demand 2008-2023[10,11,12,13]

	Ending Stocks of Crude Oil (Barrels)	Crude Oil + NGL Quarterly Production (Barrels)	Quarterly Supplied Petroleum Products (Barrels)	Quarterly Storage Divided by Next Quarter Demand
Max	1,208,001,846	1,832,932,500	1,937,512,923	0.72x
Median	1,055,914,615	1,139,179,000	1,801,268,000	0.59x
Mean	1,052,450,337	1,149,569,945	1,801,178,655	0.59x
Min	782,771,000	593,810,000	1,653,659,000	0.43x

[9] Zulauf, et al. University of Illinois. *Stock-to-Use Ratios of US Corn, Soybeans, and Wheat Since 1960.* June 2021.
[10] Crude oil inventory: http://www.eia.gov/dnav/pet/pet_stoc_wstk_dcu_nus_w.htm
[11] Crude production: http://www.eia.gov/dnav/pet/pet_crd_crpdn_adc_mbbl_m.htm
[12] NGL production: https://www.eia.gov/dnav/pet/hist/LeafHandler.ashx?n=PET&s=M_EPL2_FPF_NUS_MBBLD&f=M
[13] Crude consumption ("U.S. Weekly Product Supplied"): http://www.eia.gov/dnav/pet/pet_cons_wpsup_k_w.htm

323.6 cont. **U.S. Natural Gas Storage as Share of Quarterly Demand 2010-2023**[14,15,16]

	Lower 48 Natural Gas Inventory (Bcf)	U.S. Natural Gas Gross Withdrawals (Bcf)	U.S. Natural Gas Total Consumption (Bcf)	Quarterly Storage Divided by Next Quarter Demand
Max	3,864	11,626	9,433	0.51x
Median	2,750	8,255	6,951	0.39x
Mean	2,732	8,828	7,054	0.39x
Min	1,308	6,535	4,959	0.23x

Would a tighter allowance on the size of the bank present a risk to the operation of the LCFS program? We see little reason to believe so. The biggest quarterly deficit ever seen in the program was 13% of deficits for the quarter (Q2 2018). Were we to see this level of shortfall again, it would take almost 8 quarters of sustained deficit at this record level to draw down a bank balance of 1x quarterly deficits and it would take 23 quarters to draw a bank balance of 3x quarterly deficits. **Implementing a reasonable 1x quarterly deficits trigger would be a clear signal to the market of CARB's intent to reach its goals with very little risk to overall program effectiveness.**

AVOIDED METHANE AND BOOK AND CLAIM DELIVERY FOR BIOGAS CRITICAL TO ACHIEVING METHANE REDUCTION GOALS

323.8 cont. Avoided methane crediting is critical for both financing digester project development and long-term operating viability. Dairy digester projects cost tens to hundreds of millions of dollars and take 2-3 years to develop and construct, followed by up to two years to receive provisional pathway scores. Avoided methane crediting provides the source of revenue for these projects that pays for their beneficial impact and allows developers to invest. If in the future, farm methane emissions are regulated directly, milk buyers will foot the bill for reducing emissions through milk prices or government will directly subsidize digesters. Until then, avoided methane crediting is the only way to support digester development, ongoing operations, and associated emissions reductions. **We strongly encourage CARB to maintain avoided methane crediting for all RNG pathways, and to not phase out CNG or hydrogen pathways unless and until direct regulation renders avoided methane non-additional.**

As noted above, the LCFS has proven a successful model – likely the most successful in the world – in achieving methane reductions from the agricultural sector. This success stems directly from avoided methane crediting as part of lifecycle GHG emissions accounting for biomethane pathways. Methane crediting is both scientifically accurate and proven effective in supporting project development and driving significant methane reductions. Given this demonstrated success and scientific accuracy, a number of new programs are taking a similar approach to California's, including the Inflation Reduction Act and other programs based on the Argonne National Laboratory (ANL) Greenhouse gases, Regulated Emissions, and Energy use in Technologies (GREET) model.

[14] Natural gas storage: https://ir.eia.gov/ngs/ngs.html
[15] Natural gas production ("Natural Gas Gross Withdrawals") http://www.eia.gov/dnav/ng/ng_prod_sum_a_epg0_fgw_mmcf_m.htm
[16] Natural gas consumption: http://www.eia.gov/dnav/ng/ng_cons_sum_dcu_nus_m.htm

323.8 cont. Still, project infrastructure and equipment have a finite life. If avoided methane crediting goes away, not only will new projects not be built, but existing projects will shut down because they cannot pay operating costs and costs to maintain and extend the life of equipment. If existing projects shut down, we will backslide to pre-LCFS methane emissions at dairies. Our existing projects and projects currently under construction prevent about 700,000 MT per year of carbon reduction that would revert to venting.

Backsliding has happened before. Some of Amp's largest projects were originally biogas-to-electricity projects that were shut down by prior owners due to failed economics. CARB should not assume that once a digester project is developed, methane emissions are permanently abated, and it should not change accounting for avoided methane emissions until clear mechanisms are in place to ensure avoided methane emissions remain avoided.

323.16 Additionally, as described in our previous comments,[17] California imports nearly all of its natural gas,[18] and any biomethane injected into the pipeline system under the LCFS serves to displace fossil natural gas that otherwise would be imported into the State. The North American natural gas system does not mirror the fractured and isolated electricity markets in the western U.S. Instead, the gas system is deeply interconnected, and long ago moved away from point-to-point service, instead creating trading hubs and flexible receipt and delivery points to give customers a variety of options in the market.

Fossil natural gas operates on a system very similar to book-and-claim, in which buyers of fossil gas do not buy the molecules injected by their supplier, but rather instantaneously take receipt of a pre-agreed amount of gas, based on a mass-balance corresponding to the amount their supplier injected elsewhere in the system. These systems already work well for natural gas supplies across the continent and in the LCFS, and they should continue to be leveraged to cost effectively and efficiently support decarbonizing California gas end uses. RNG under the LCFS should be treated no less preferentially than compared to fossil natural gas, and **book-and-claim eligibility should be maintained for all RNG pathways**.

AMP SUPPORTS DEVELOPING RNG FOR STATIONARY SOURCES, ZEV FUELS

The proposed phaseout of avoided methane crediting and book-and-claim eligibility for combustion-based or hydrogen-based pathways is counter-productive and not supported by science. Still, we appreciate that California is moving towards zero emission vehicles ("ZEVs"), as required by the Advanced Clean Cars II and Advanced Clean Fleets regulations, and the Scoping Plan highlights a priority to develop additional renewable gas supplies to help decarbonize stationary sources. Amp supports California's overall decarbonization goals and its efforts to develop RNG supplies to decarbonize stationary sources in all sectors of the economy. Provisions in the proposed amendments help support transitioning RNG to ZEV fuels and stationary sources, but we encourage additional steps to further assist the transition, specifically:

[17] https://www.arb.ca.gov/lists/com-attach/125-lcfs-wkshp-nov22-ws-VzZcN1EgAg5QOghr.pdf
[18] According to the California Energy Commission, "California continues to depend upon out-of-state imports for nearly 90 percent of its natural gas supply…" https://www.energy.ca.gov/data-reports/energy-almanac/californias-natural-gas-market/supply-and-demand-natural-gas-california

323.17
- **Do not phase out avoided methane crediting and book-and-claim eligibility for all RNG pathways, including RNG-to-hydrogen**.

323.18
- **Allow RNG book-and-claim eligibility for electricity production at power plants** to charge electric vehicles ("EVs").

323.19
- **Allow RNG book-and-claim eligibility for process energy for any transportation fuel pathway,** in order to align with the Scoping Plan and begin to shift RNG away from transportation to stationary sources.

323.20 Enabling book-and-claim delivery for RNG sourced from projects in North America to be eligible for both hydrogen production *and* electricity generation would align with state goals around ZEVs and maintain equal treatment among ZEV options – including both hydrogen and electricity. We recommend making this change in Section 95488.8(i)(2) to expressly allow book-and-claim delivery for biomethane used to produce electricity for transportation purposes.

323.21 We recommend making a similar change to Section 95488.8(h) to expressly allow book-and-claim delivery for biomethane used for process energy (e.g., in cement production). This will serve as another mechanism to promote shifting RNG from transportation to stationary applications.

A significant portion of the LCFS value generated from RNG flows to the stations that distribute fuel, and this same dynamic would apply to RNG-to-electricity-to-EV pathways, accelerating EV adoption by injecting additional LCFS value into the EV ecosystem.

AMP SUPPORTS AMENDMENTS RELATED TO CREDIT TRUE UP

323.10 cont. Amp strongly supports the proposed amendments regarding "credit true up after annual verification." For RNG pathways specifically, which encompass living, biological systems, several parameters are beyond the control of a pathway holder – including temperature, herd count, changes to the manure volatile solid content, unplanned equipment downtime, evolving energy efficiency due to equipment age, force majeure events, or other changes in dairy operations beyond the operator's control including manure collection practice, water usage, dairy feed – can impact a number of variables that affect the CI of a pathway. Due to these unpredictable and uncontrollable factors, verified pathways may deviate from provisional pathways through no fault of the project developer or operator. The true up provisions will protect the environmental integrity of the program and maintain rigorous accounting and verification, while allowing flexibility to accommodate reasonable uncertainties.

323.22 In addition, Amp supports credit true up between temporary CI and certified (e.g. provisional or non-provisional) CI values, as previously proposed by CARB staff. Essentially all dairy RNG pathways utilize a Tier 2 process today, which currently takes about 18-24 months for approval and means that dairy RNG projects use a Temporary CI score for about 2 years. The Temporary CI score is -150, where the average dairy RNG project is -313, meaning these projects fail to get credit for approximately 40%[19] of their emissions reductions for 2 years. This also reduces credit availability in the program, increasing the cost of compliance for regulated entities. By allowing a true up between temporary CI and certified CI values, CARB would help alleviate concerns related to pathway process delays, assist in avoiding complicated

[19] https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/fuelpathways/current-pathways_all.xlsx accessed 2/19/2024; simple average of Dairy Manure feedstock pathways; diesel baseline of 87 gCO2e/MJ in 2024

323.22 cont. storage agreements, provide reliable deliveries to fleets by avoiding buildup of stored gas inventory, allow more direct sales of RNG to smaller local fleets, and motivate additional project development. **CARB should allow true-up for the verified actual CI of projects during the pathway registration period.**

323.23 We applaud CARB's attempts to make the Tier 1 calculator more usable by dairy projects and to shorten the period during which a Temp CI would be required. Our comments stand even if this initiative is successful. There is simply no equitable argument to deny dairy RNG projects credit for their verified impact however long the Temporary CI period may last.

ADDITIONAL PROVISIONS TO SUPPORT AN ONGOING, SUCCESSFUL LCFS

Finally, Amp offers the following comments and questions on various provisions included in the proposed amendments:

<u>Less Intensive Verification</u>

323.24 We support the concept of "Less Intensive Verification" in Section 955011(h), given that the verification
323.25 process can often be completed remotely. However, we oppose applying the rules only to electricity transactions identified in section 95500(c)(1)(E). Amp recommends that less intensive verifications be applied for all quarterly fuel transaction reports ("QFTR") identified in Section 95500(c)(1). This would be consistent with the CARB Regulation for the Mandatory Reporting of Greenhouse Gas Emissions, Title 17 of the California Code of Regulations ("CCR") Section 95130(a)(1), while allows for less intensive verification services for the following two years if the less intensive verification criteria are met. Verification site visit for a QFTR primarily consists of a visit to an entity's headquarters or other location of central data management and comprises reviewing electronic records. The site visit can easily be done virtually, as we successfully observed during COVID. The third-party verifier could still have discretion to determine that a conventional verification is necessary if project-specific facts indicate a less intensive verification will not suffice. Allowing less intensive verifications for QFTRs will reduce travel requirements, costs and associated emissions.

<u>Deficit Obligation Calculation</u>

232.26 We support the deficit obligation concept in Section 95486.1(g), given the variability of biological carbon
323.27 intensity scores. We recommend that this starts with the 2024 fuel transaction year instead of the 2025 fuel transaction year. If the Regulation goes into effect at the start of 2025, the new provision can be easily implemented prior to verification being completed by August 2025.

<u>Measurement Accuracy</u>

323.28 The measurement accuracy section under Section 95488.8(j) was moved to Section 95491.2(a), however the old section is still cited three times in Sections 95481(a), 95491.1(c)(1)(K), and 95491.1(c)(1)(2)(E). This creates ambiguity that would be helpful to correct.

<u>Missing Data Provisions</u>

323.29 The proposed "Missing Data Provisions" in Section 95491.2(b)(2)(B) Table 13 are based on a data year, however data substitution is often required to be completed monthly to determine fuel allocations for Pathways with multiple fuel pathway codes. If missing data substitution is required to be completed annually instead of monthly, it will create issues with monthly fuel allocation and dispensing for

323.29 cont. pathways, as well as quarterly fuel transaction reporting, which will require quarters 1, 2, and 3 to be re-opened and re-reported every year.

Amp requests that the use of "reasonable temporary methods" continue to be allowed to address missing data, which allows for operational realities and engineering best practices to be used. As the majority of data being substituted is continuous data (e.g. 15-minute data), data substitution using data directly prior and after is likely to be more accurate than a 30-day average or highest/lowest value over a one- to two-year time period. As the reports that fall under 95491.2 are all required to undergo third party verification, it ensures that all "reasonable temporary methods" are deemed conservative and accurate.

Force Majeure Events

323.30 Section 95491.2(b)(3) provides updated force majeure event requirements, including a requirement to report operational data during force majeure events when submitting the quarterly or annual verification. Reporting entities already report operational data to the verification body during the verification process as well as to CARB upon request. Therefore, it is unnecessary to also provide this operating data for force majeure events during the quarterly and annual reporting process.

Carbon Capture Protocols

323.11 cont. We encourage CARB to allow additional carbon capture, removal, utilization and sequestration ("CCRUS") protocols to be utilized as they are developed, pursuant to SB 905 or if the CCS Protocol is updated otherwise. Enabling a wider array of CCRUS pathways to be deployed will help reduce industrial sector emissions and emissions associated with several different transportation fuel pathways, including biogas. However, the definition of a "carbon capture and sequestration project" and provisions in Section 95490 refer to geologic sequestration and transport of CO_2 to an injection site, which implies only geologic sequestration projects would be eligible. We encourage amendments to avoid limiting future eligibility of CCRUS projects, should new CCRUS protocols be developed.

Thank you again for your collaboration with stakeholders through this public process, the opportunity to comment on the proposed regulatory amendments. We appreciate your consideration of these comments and work to amend and strengthen this critical program.

Sincerely,

Cassandra Farrant

Re: Hy Stor Energy Comments on Proposed 2024 Low Carbon Fuel Standard (LCFS) Regulation

Dear California Air Resources Board:

Thank you for the opportunity to provide comments on the proposed low-carbon fuel standard amendments. Hy Stor Energy LP respectfully submits the following comments, which are intended to facilitate the adoption of clean hydrogen in low-carbon transportation fuels, which include sustainable aviation fuel (SAF), power-to-liquids, and renewable diesel, and would help scale up a low-carbon fuel industry that would supports the decarbonization of the U.S. economy.

Hy Stor Energy, a company headquartered in Jackson, MS, was formed for the purpose of developing and advancing renewable hydrogen production, storage, and delivery at commercial scale in the United States. Pursuing a multi-regional platform strategy focused on critical locations with the right geography and geology uniquely suited to favorable renewable power generation, underground hydrogen storage, and distribution networks for regional and global market access. Hy Stor Energy's first major project, the Mississippi Clean Hydrogen Hub, is under active development. It will be centered on the development of world-scale underground hydrogen storage capability, with approximately 70,000 acres of land in sixteen Mississippi counties and two Louisiana parishes under Hy Stor Energy's control, seven salt domes, and nine salt caverns fully permitted for underground hydrogen storage. Hy Stor Energy will soon announce a second project in the western United States positioned to be the leading renewable hydrogen supply hub serving the U.S. West and California markets.

Renewable hydrogen is an essential tool for the energy transition and will play a significant role in enabling California to achieve its net-zero goal by 2045. Renewable hydrogen is both an important transportation fuel for fuel cell electric vehicles as well as a necessary feedstock for many low and zero-carbon transportation fuels including SAF, power-to-liquids, renewable diesel, renewable methanol, and renewable ammonia. Enabling the LCFS eligibility of renewable hydrogen as both a transportation fuel in FCEVs as well as a feedstock liquid transportation fuel will enable greater adoption of low-carbon liquid fuels and drive emissions reductions in both the near and long term.

Hy Stor Energy respectfully suggests that the California Air Resources Board (CARB) modify the LCFS amendments to make the following amendments to the LCFS staff draft.

555 Tombigbee St
Suite 101
Jackson MS 39202
(888) 542-6074
www.hystorenergy.com

I. Allow book-and-claim delivery of low-CI electricity for electrolytic hydrogen production used as a feedstock in liquid transportation fuels.

II. Allow book-and-claim delivery of low-CI hydrogen in dedicated hydrogen pipelines outside of California for transportation fuel sold into the California market.

III. Allow delivery of low-CI electricity via book-and-claim for electrolytic hydrogen production in the Renewable Hydrogen Refinery Credit Program.

324.1 **Allow book-and-claim delivery of low-CI electricity for electrolytic hydrogen production used as a feedstock in liquid transportation fuel.**

Allowing book-and-claim delivery for low-CI electricity would maximize the potential for renewable hydrogen adoption and emissions reductions. Low-CI hydrogen will support the production of low and zero-carbon liquid transportation fuels, which are critical to decarbonizing the hard-to-decarbonize markers of heavy-duty surface transportation, aviation, and maritime transportation.

Furthermore, permitting book-and-claim delivery for low-CI electricity will match the treatment CARB has extended to renewable natural gas (RNG), which allows for the utilization of book-and-claim delivery of RNG, including for RNG used in the production of liquid transportation fuels.

324.2 **Allow book-and-claim delivery of low-CI hydrogen in dedicated hydrogen pipelines outside of California for transportation fuel sold into the California market.**

Currently, there are no dedicated hydrogen pipelines in California. Our goal as a nation and Hy Stor Energy's goal as an early mover in the production and distribution of green hydrogen is to facilitate the build-out of a national clean hydrogen economy. This will necessarily include the buildout of a robust hydrogen pipeline backbone to support the scale up of low-CI hydrogen adoption and drive down costs across the entire hydrogen value chain. Limiting eligible dedicated hydrogen pipelines to the California state borders would dramatically stunt the development of the hydrogen market both within California and the region. The optimal policy would be to allow book-and-claim delivery of low-CI hydrogen in any dedicated hydrogen pipeline serving as a feedstock for any fuel being consumed in California. A robust book-and-claim system will allow the delivery of low-CI hydrogen to catalyze market adoption of low and zero-carbon liquid transportation fuels including sustainable aviation fuels, power-to-liquids fuels, and renewable diesel in the critical hard-to-decarbonize industries in California and nation-wide.

324.3 **Allow delivery of low-CI electricity via book-and-claim for electrolytic hydrogen production in the Renewable Hydrogen Refinery Credit Program.**

In order to decarbonize medium to large scale facilities GW scale electrolysis projects will be required. As the current program is designed, requiring onsite renewable generation restricts the program to small-scale projects due to land constraints where refinery facilities are currently located. Allowing for the

HY STOR ENERGY

555 Tombigbee St
Suite 101
Jackson MS 39202
(888) 542-6074
www.hystorenergy.com

delivery of low-CI electricity via book-and-claim for electrolytic hydrogen production would allow refineries to utilize this program to lower emissions. Without this amendment, this program will likely continue to be underutilized.

Conclusion

Hy Stor Energy is committed to catalyzing low and zero-carbon solutions to enable California to meet its climate goals. We appreciate the CARB staff's work on the development of the proposed rule and their commitment to improving the LCFS. We look forward to continuing to work with CARB staff on this critically important effort.

Sincerely,

Laura L Luce
Founder & CEO
Hy Stor Energy LP

Re: Comments on Proposed LCFS Amendments to Sections 95481, 95482, 95483, 95483.2, 95483.3, 95484, 95485, 95486, 95487, 95486.1, 95486.2, 95488, 95488.1, 95488.2, 95488.3, 95488.5, 95488.6, 95488.7, 95488.8, 95488.9, 95488.10, 95489, 95490, 95491, 95491.1, 95495, 95500, 95501, 95502, 95503 of title 17, California Code of Regulations

Ladies and Gentlemen:

I am writing on behalf of TES US Development LLC ("TES") to share our company's perspective on key aspects of the Proposed Amendments to the Low Carbon Fuel Standard ("LCFS") regulation relevant to electrofuels (e-fuels) producers. TES respectfully requests the California Air Resources Board ("CARB") consider the following topics in the LCFS update, to advance California's transition to cleaner transportation fuels and in furtherance of California's climate goals:

1) **Definition of Biomethane and Synthetic Natural Gas:**

325.1 The current and proposed amendments to the LCFS regulation do not clearly define biomethane or renewable natural gas, specifically what CARB considers "synthetic natural gas derived from renewable resources" and whether synthetic natural gas derived from renewable resources of non-biogenic origin (e.g., industrial waste stream or captured CO_2) would be considered biomethane or renewable natural gas. The promotion of recycled carbon fuels is a key contributor towards energy diversification and decarbonization of the transportation sector, especially for drop-in fuels that can significantly reduce emissions in the near future with existing fleet and infrastructure. In addition, such fuels contribute to the avoidance of CO_2 emitted to the atmosphere due to the use of waste streams of non-biogenic origin which are unavoidable and an unintentional consequence of industrial processes.

The current and proposed amendments to the LCFS define Biomethane as "methane derived from biogas, or synthetic natural gas derived from renewable resources" but do not define "renewable resources." The proposed LCFS amendment also includes a new definition for Renewable Natural Gas, defined as "an alternate term for biomethane," so for the purposes of commenting, we will refer to the term biomethane.

TES recommends that LCFS include a standalone definition for "renewable resources" to clearly define the feedstocks that are allowed in low carbon fuel pathways and extend the scope to include a broader range of sources beyond the traditional "biogenic sources," in accordance with the established federal practices. As an example, the United States Department of Energy ("DOE") Office of Energy Efficiency & Renewable Energy defines renewable carbon resources as *"carbon-based resources that are regularly regenerated, either via photosynthesis (e.g., plants and algae), or through regular generation of carbon-based waste (e.g., the non-recycled portion of municipal solid waste, biosolids, sludges, plastics, and* CO_2 *and industrial waste gases)."* TES recommends expanding LCFS to adopt a similar approach towards the applicability of synthetic natural gas and other e-fuels.

TES would like to highlight the state, federal, and international level recognition of the importance of carbon capture, utilization, and storage ("CCUS") strategies in achieving climate goals and urges CARB to consider how limiting “renewable resources” to biogenic sources would exclude leveraging existing industrial waste streams via carbon capture to produce low carbon fuels.

2) **Book-and-Claim Eligibility**

325.2 TES recommends CARB expand the pathways that can apply book-and-claim accounting (“B&C”), which currently includes low-CI electricity, biomethane or low-CI hydrogen, to include any low-CI methane pathways. The current and proposed LCFS limits B&C accounting to biomethane based on feedstock rather than physical product characteristics or CI. Given the overarching intent of LCFS to support California’s transition to low carbon fuels and drive GHG emissions reductions, TES recommends CARB consider revising B&C restrictions to be feedstock agnostic, and instead limit B&C eligibility based on fuel product (e.g., electricity, methane or hydrogen pathways, where infrastructure exists to support indirect accounting, and use depends upon common carrier infrastructure) and pathway CI.

3) **Availability of Fuel Pathways**

325.3 TES would like to note that the current LCFS regulation does not include any Tier 1 or Temporary fuel pathways specific to synthetic natural gas or other e-fuels with CO_2 conversion. TES recommends CARB develop either a Temporary or Tier 1 pathway for synthetic fuels or e-fuels that convert CO_2 to common products (e.g., methane, methanol, liquid hydrocarbon fuels). This would help support technology developers and fuel producers to bring these low-CI, drop-in fuels to market, thereby accelerating California’s transition away from fossil fuels.

We appreciate your review and consideration of our recommendations, and we are ready to provide assistance as needed to support the development of e-fuels and the decarbonization of the transportation sector.

Sincerely,

Cynthia Walker
President
TES US Development

RE: Comments On Proposed Low Carbon Fuel Standard Amendments

Remora values the chance to share input on the Staff Proposed Amendments to the California Air Resources Board's (CARB) Low Carbon Fuel Standard (LCFS). Our commitment extends to collaborating with CARB, its State agency partners, and all stakeholders to contribute innovative climate solutions with broad-reaching benefits in California and beyond.

About Remora & Mobile Carbon Capture Technology

Remora designs and manufactures an **innovative engine exhaust technology that captures carbon dioxide (CO_2) directly from heavy, hard-to-decarbonize mobile sources**, including Class 8 heavy-duty vehicles (semi-trucks). Using Remora's mobile carbon capture and storage (MCCS) technology, semi-truck exhaust is diverted to a carbon capture unit, which aims to capture approximately 80% of CO_2 emissions generated by the semi-truck (as well as approximately 75% of nitrous oxide emissions), before the exhaust is released into the atmosphere. The captured CO_2 is compressed, stored onboard, and then offloaded at designated sites that are co-located at refueling or cargo-loading infrastructure sites. All captured CO_2 can be safely and permanently disposed of via underground sequestration or utilized within other products and industries.

Semi-trucks are essential to our economy, delivering over 70% of goods that Americans use. Unfortunately, semi-trucks are also extremely high greenhouse gas (GHG) emitters and difficult to decarbonize. The approximately two million semi-trucks in operation today emit approximately 340 million metric tons of CO_2 per year. In addition, these high-emitting semi-trucks will be on the roads for decades to come, given the investments made by companies to purchase these vehicles and the need for these vehicles to support supply chain needs across the United States. Remora's MCCS technology has the power to decarbonize existing trucks and, if coupled with the use of biofuels, can result in semi-truck operations with a negative carbon intensity score.

To date, Remora has partnered with numerous nationally significant companies, including three in the Fortune 10 and numerous in the Fortune 500, to install its carbon capture equipment on their semi-trucks. Market demand for Remora's technology is extremely high as companies seek to reduce their CO_2 emissions. Remora's MCCS technology, and that developed by other MCCS companies, is uniquely poised to offer major decarbonization benefits while also supporting the growth of small businesses, helping to remedy environmental justice injustices and inequalities, advancing further innovations in CCS technology, and more, as described further below:

- Air Quality Benefits: Remora's MCCS technology acts as a filter on engine exhaust. Along with capturing CO_2, it demonstrates the potential to drastically improve air quality by reducing toxic air pollutants like nitrogen oxides by approximately 75%. These benefits could immediately serve low-income and disadvantaged communities that are most affected by vehicle emissions due to their proximity, in many cases, to highways and other major roadways.

- Scalable Impact: The decarbonizing impact of Remora's technology has the potential to rapidly scale. Each Remora MCCS unit is equivalent to removing approximately 30 passenger vehicles from the road per year. Remora's carbon capture units can capture and store 1,000,000 metric tons of CO_2 annually just by installing MCCS units on about 7,500 semi-trucks. With millions of semi-trucks in the United States, the opportunity for MCCS is enormous and increases further when utilized for other mobile sources of CO_2 emissions.

Remora's device and other mobile carbon capture technologies can quickly address the most difficult sectors to decarbonize, including heavy-duty trucking, vessel shipping, and rail. Remora has signed on to group comments with the Mobile Carbon Capture Coalition, which shows the breadth of the industry and the additional work being done across the world.

Remora Supports a Strong LCFS

California's transportation sector is the State's largest source of both greenhouse gas emissions and air pollution, accounting for more than half of statewide GHG emissions.[1] Rapidly driving down these emissions is a critical element of California's strategy to achieve carbon neutrality. As described in the 2022 Scoping Plan Update, the transition to zero-emission technology will take time as internal combustion vehicles will remain on the roads in California for decades to

[1] See Draft 2022 Scoping Plan Update, pg. 147.

come. The modeling for the Scoping Plan indicates that even in 2045, significant volumes of liquid fuels, including fossil fuels, are likely to remain in California's transportation fuel mix.[2] Solutions that can significantly reduce—and even fully eliminate—greenhouse gas emissions from California's transportation sector will be key.

326.1 Remora supports CARB's accelerated carbon intensity (CI) reduction target of 30% by 2030 as proposed by Staff in these LCFS amendments. Remora encourages CARB to consider even more
326.2 ambitious CI targets to drive California towards its climate goals. For this reason, Remora also supports the inclusion of an auto-acceleration mechanism that will increase the stringency of
326.3 LCFS if the program over-performs. This mechanism will help to ensure that California will continue to achieve emissions reductions and will provide additional incentives for investment in clean transportation fuels and technologies.

LCFS should be positioned to incorporate Mobile Carbon Capture Technologies

Given the scale and scope of the challenge to meet California's GHG reduction targets, the State cannot afford to limit any approaches that can contribute to this effort. As CARB works to refine
326.4 LCFS, **Remora urges CARB to ensure that it optimally positions California to reap the benefits that innovative and proven technologies like MCCS can provide**.

Incorporating additional technologies into the existing CCS Protocol within the LCFS Regulation, which recognizes the role CCS can play in decarbonizing the production of transportation fuels, will be key.

By incorporating MCCS into the LCFS, California can work towards even more ambitious transportation decarbonization targets, which will provide climate, air quality, and public health benefits to Californians.

Remora appreciates the opportunity to submit comments, and we look forward to continuing to work with you and all stakeholders in California on this critically important effort.

Sincerely,

Alexandra Frumar

Re: Comments regarding proposed amendments to the Low Carbon Fuel Standard

Dear Chair Randolph,

Thank you for the opportunity to provide comments on the proposed amendments to California's Low Carbon Fuel Standard. Environmental Defense Fund (EDF) appreciates the work CARB staff has dedicated to amending the Low Carbon Fuel Standard. EDF looks forward to continuing to engage in this rulemaking and supporting the successful decarbonization of California's transportation sector.

As we have stated in previous comments during the informal workshop process, updating LCFS to increase the program's ambition and efficacy will be integral to ensuring California can deliver the outcomes and emissions reductions envisioned in the final Climate Change Scoping Plan, as well as achieve carbon neutrality by 2045.

327.1 We are pleased to see that this proposal strengthens the CI reduction benchmarks both pre- and post-2030. Alongside this increased rigor, EDF hopes to see amendments that will sustain the LCFS's role in promoting the use of lower carbon alternatives to petroleum fuels, thus bringing substantial health, economic, and environmental benefits. To that end, we offer the following comments regarding four aspects of the proposed LCFS amendments: 1) crediting for manure biogas, 2) hydrogen crediting and usage, 3) crediting for medium- and heavy-duty vehicle charging, and 4) sustainable decarbonization of the aviation sector.

1. Crediting for Manure Biogas

Agriculture, particularly the dairy industry, is a major source of California's methane emissions. Almost 25% of California's total methane emissions are estimated to come from dairy manure. Addressing dairy manure methane emissions is a key action needed to meet California's climate goals. We applaud the state for establishing a specific methane reduction for the dairy and livestock sectors in SB 1383 (Lara, 2016). California dairy farmers, as price takers, have little market power to pass costs associated with methane reduction solutions on to the consumer, we therefore also recognize the important role that programs such as the LCFS continue to play in incentivizing and supporting reductions in livestock methane sources.

327.2 We appreciate CARB's stance that capturing methane from landfills, dairies, and wastewater is critical to achieving climate targets, and we are aligned with CARB's preference for biomethane to be used to produce low-carbon intensity hydrogen and electricity. We agree that attention is needed to ensure methane capture projects are not abandoned as LCFS transitions away from combustion vehicles towards hard-to-decarbonize sectors.[1]

Manure biogas systems, when operated and installed in a responsibly maintained farm system, are a proven technology that can address existing sources of agriculture methane (from dairy manure storage systems) while replacing fossil fuel-derived methane. Given the large number of liquid manure systems that exist on California (and US) dairies, continuing to include manure biogas systems—as part of an environmentally comprehensive farm nutrient management system—in the LCFS is a powerful tool to drive agriculture methane reductions from existing sources. Continued eligibility is important to meet California's climate goals and drive further agriculture methane reductions across the US.

Today, the LCFS is the most impactful market-based tool to incentivize livestock farmers to adopt methane capture technologies. However, as with any program, it is not perfect. We cannot focus on solving methane, a global climate pollutant, without also ensuring meaningful improvement in the local environment and community.

Addressing Local Pollution

Sources of on-farm methane leakage need to be properly managed.

327.3 While they are an important tool for capturing methane, the leakage of methane and the resulting net methane emissions relative to the counterfactual must be considered. EPA acknowledges in its RNG Operations Guide that "fugitive emissions of methane, depending upon their magnitude, can negate the climate and environmental benefits of RNG projects." While methane's negative impact on climate is commonly discussed, methane can also be dangerous to human health at the local level, as a precursor to ozone.[2] Ozone, even at relatively low levels, can cause health effects including inflammation and damage of the airways and further aggravating lung diseases such as asthma, emphysema, and chronic bronchitis.[3]

---

[2] https://unece.org/2010/presentations/Importance%20of%20Methane%20for%20Ozone.pdf
[3] https://www.epa.gov/ground-level-ozone-pollution/health-effects-ozone-pollution

One of the largest sources of methane leakage in digester biomethane production comes from improper digestate management.[4] Digestate is the effluent that comes out of the digester, which contains nutrients that can fertilize crops. It is common in the United States for digestate to be held in open storage pits or lagoons. Although the manure has been digested, and most of the biogas has been captured in the digester, digestate still produces some methane which is emitted if the digestate is stored in an open lagoon or storage tank. Residual methane emissions from the digestate are estimated to be between 0.2-5.9% of that captured in the digester.

Covering digester effluent storage captures this residual methane, which can be flared or added to the digester biogas, enhancing the carbon market value when it is used for energy. An impermeable cover on the digestate can reduce residual methane emissions by 90%.[4] There are also developing technologies that can capture the ammonia and concentrate it, making it easier to land apply or potentially be sold to generate additional revenue.[5,6]

Another large source of methane leakage is from the processing of biogas – to produce renewable natural gas sufficient to meet natural gas pipeline standards. Methane leakage from the processing of biogas is estimated to be in the 2 – 4% range up to as much as 15%.[7] Methane leakage in the transmission and distribution of natural gas has been estimated to be in the range of 0.4 - 0.9%.[8]

Local air quality impacts that result either directly or indirectly from anaerobic digestion must be addressed.

327.4

One of the most significant local air pollutants of concern surrounding biogas systems is ammonia. Approximately 80% of ammonia emissions in the United States, encompassing emissions from both natural sources and human activities, are from agricultural sources. Notably, around 60% of these national emissions stem from livestock manure.[9] Ammonia is a health concern, as it has the potential to form fine particulate matter (PM2.5), which can lead to respiratory and pulmonary issues in nearby communities.[10] Ammonia emissions also present an environmental risk contributing to soil acidification and/or eutrophication in downwind ecosystems.[11]

During anaerobic treatment or storage, manure organics decompose in an oxygen-free environment and produce methane, ammonia, and other gases. In open-system manure storage

11 https://www.sciencedirect.com/science/article/pii/S0301479722018588?via%3Dihub

or treatment lagoons, as the manure undergoes anaerobic decomposition, most of these compounds are lost to the atmosphere. If the anaerobic decomposition takes place in an enclosed environment (such as a covered lagoon or anaerobic digester), the methane degases from the liquid phase and is captured under the cover where it can be collected and flared or used as a fuel. However, the ammonia stays in the solution and hence the dissolved ammonia becomes concentrated inside the anaerobic digester, particularly relative to that remaining dissolved in an open lagoon.

Once the digestate from the anaerobic digester or covered lagoon is discharged from beneath the cover into an open lagoon or storage tank, the ammonia is lost to the atmosphere in the same quantity or perhaps somewhat higher quantities, relative to that lost in an open lagoon, presenting a serious health risk to downwind communities.

Any tax credit generated from biogas created from manure in covered lagoons or anaerobic digesters for hydrogen production should be predicated upon the management of the digestate to reduce ammonia losses. Keeping the digestate in an enclosed system would greatly reduce the loss of ammonia from the digestate as well as allow for the capture of the residual methane in the digestate. The residual methane could be added to the digester biogas and used as fuel. An impermeable cover on the digestate reduces ammonia losses by 55-100% and residual methane emissions by 90%[4] while a permeable cover is estimated to reduce ammonia by 40-80%.[12]

Crediting should be contingent upon meeting specific standards to further reduce local environmental impacts.

As discussed, farm systems can have a negative impact on local communities, specifically around air pollutants, odors, and other downwind ecosystem and water concerns. Producers of
327.4 biomethane from digesters should have a robust system in place to participate in LCFS to ensure the digester and its nutrients are managed properly. Third-party vetted Nutrient Management Plans (NMP) and Comprehensive Nutrient Management Plans (CNMP) are utilized in many states to reduce the environmental footprint of livestock operations. In New York State for instance, certified nutrient management planners help farmers create farm plans and verify they are followed throughout the year.[13] This standard goes beyond what EPA requires and adds assurance to communities that best management practices are followed, even in emergencies.

For farmers using digesters, compliance with relevant USDA NRCS standards, including both USDA NRCS Nutrient Management (Code 590)[14] to ensure digestate nutrients are well-managed and USDA NRCS Anaerobic Digester Conservation Practice Standard (CPS) for Anaerobic Digesters (Code 366) is paramount. This guidance outlines standard practices to improve air

---

[12] https://extension.colostate.edu/topic-areas/agriculture/best-management-practices-for-reducing-ammonia-emissions-lagoon-covers
[13] http://nmsp.cals.cornell.edu/publications/extension/CAFOCNMPNY2023.pdf
[14] https://datcp.wi.gov/Documents/NM590Standard2015.pdf

quality by reducing greenhouse gas emissions and objectionable odors from manure or agricultural waste, and/or to reduce transport of pathogens to surface water.[15] These practices apply where biogas production and capture are components of a waste management system plan or a comprehensive nutrient management plan, and sufficient and suitable organic feedstocks are readily available. This practice outlines standards for system design, cover, etc., as well as gas collection, transfer, control, utilization, and monitoring/safety requirements, including criteria for maintenance of air quality, but does notably leave out the control of ammonia emissions, which should be addressed per earlier information.

Without these guardrails, programs like LCFS could encourage the build-out of additional digesters with no oversight into how they are managed – potentially leading to harmful methane leaks and other air pollutants, including ammonia, which can negatively affect local air, soil, and water quality and in turn, harm local communities.

Deliverability

Beyond accelerating the capture of manure methane emissions on California livestock farms, the LCFS, in its current form, has also helped address methane emissions from manure across the US. Under the current regulation, the LCFS allows for indirect accounting of biomethane injected into the North American natural gas pipeline without a deliverability requirement. This enables farm systems across the country to participate in supplying biomethane for the LCFS. However, CARB's proposed changes include new deliverability requirements for natural gas pipeline injection.

327.5 *Indirect accounting without a deliverability requirement should continue, provided that out-of-state biogas systems contribute to the overall improvement of the local environment and community.*

Continuing to allow indirect accounting of biomethane without a deliverability requirement, serves to lift the conversation on manure methane emissions across the country and push other states to engage in how to address agriculture methane emissions. Since methane emissions are a global pollutant, the current LCFS regulation helps reduce methane emissions in a broader context than just California.

As the supply of RNG from manure digestion represents less than 1.5% of current natural gas production, limiting deliverability will decrease the number of offset credits available for the LCFS.[16] Another implication of limiting delivery is the quenching effect it would have on

[15] https://www.nrcs.usda.gov/sites/default/files/2023-04/366-NHCP-CPS-Anaerobic-Digester-2023.pdf
[16] https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gas-emissions-and-sinks

livestock methane capture across large sections of the US as well as the amount of low CI hydrogen produced.[17]

As the market regulator, CARB has the ability and responsibility to ensure that out-of-state manure biogas systems are being implemented in a manner that protects local water quality and air quality, and meaningfully reduces the impact of livestock on local communities. It's imperative that CARB utilize its authority to ensure full compliance with LCFS regulations to not only ensure fraud is prevented in indirect accounting, but that biogas producers contributing to local pollution are held accountable. Biogas systems are complex operations and if farm systems are not currently meeting equivalent environmental regulations and expectations to those followed by California biogas systems, out-of-state biogas systems should not be eligible for participation in the LCFS.

There are numerous examples across the US of manure biogas systems that, upon reaching the current technology end-of-life, are no longer being used and manure methane emissions are again being released into the atmosphere. Without ongoing appropriate economic incentives, farms will not continue to operate manure biogas systems and will not reinvest in the technology. CARB needs to consider how best to address manure biogas systems when they reach the end of the ten-year avoided methane crediting period.

2. Hydrogen Crediting and Usage

Hydrogen is a short-lived, indirect greenhouse gas (GHG) that causes warming by increasing the concentrations of GHGs in the atmosphere.[18] At least 15 scientific publications over the past two decades, including two IPCC assessment reports, have cautioned about the climate impacts of hydrogen emissions in the context of a potential hydrogen economy.[19]

Around 30% of molecular hydrogen (H_2) emitted into the atmosphere chemically reacts with the naturally occurring hydroxyl radical after a few years. This reaction ultimately increases the amounts of short-lived greenhouse gases including methane, tropospheric ozone, and stratospheric water vapor. Recent advancements in chemistry-climate modeling have led to the quantification of hydrogen's full atmospheric warming effects using multiple models—leading to a doubling of earlier warming potency estimates. The latest science suggests that hydrogen emissions are 30-40 times more powerful at trapping heat over the following 20 years than carbon dioxide for equal mass, and 8-12 times more powerful over a 100-year period.[18]

Hydrogen is notoriously hard to hold onto given its small molecular size and is emitted throughout the value chain from both operational releases and leakage. Currently, sensors with

---

[17] https://gasfoundation.org/wp-content/uploads/2019/12/AGF-2019-RNG-Study-Full-Report-FINAL-12-18-19.pdf
[18] https://acp.copernicus.org/articles/23/13451/2023/acp-23-13451-2023.html
[19] https://www.nature.com/articles/s41467-022-35419-7

the speed and sensitivity necessary to quantify emissions are not widely available; and in the absence of direct measurement data, several studies have estimated emissions from venting, purging, and leakage at various stages of the value chain and in total,[20] finding a wide range in emissions anywhere from <1% to 20%. Thanks to DOE funding, advanced sensor equipment is currently under development, with early models just entering the market this year. These sensors will enable empirical measurements of hydrogen emissions from existing infrastructure in the near future.

Operational and fugitive hydrogen emissions should be excluded from receiving LCFS credits.

327.6 Due to hydrogen's warming impacts, it is critical to exclude "wasted" gas from operational practices (i.e., vented or purged hydrogen) from being able to claim the LCFS credit. Similarly, detectable levels of unintentional emissions (i.e. leaks) should also be immediately excluded. These lost volumes can easily be determined by comparing the known inputs with their calculated outputs of hydrogen energy to be sold, and these loss rates should be reported alongside the claimed volumes to improve the data collection around hydrogen emissions. In the near future, as high-precision sensors become more readily available, hydrogen producers will be able to measure small leaks along with their calculated lost volumes. CARB can thus stipulate that all levels of fugitive emissions will eventually be excluded from receiving LCFS credits.

Hydrogen emissions should be factored into CA-GREET.

327.7 Because of its well-documented role as an indirect greenhouse gas, hydrogen must be factored into life cycle assessments through the CA-GREET model. Argonne has already been exploring the inclusion of hydrogen emissions into the GREET model. This can be done by using GWP values of 37 for GWP20 and 12 for GWP100.[21]

While the GREET model currently does not include hydrogen's warming effects, it does include estimated loss rates throughout the value chain. We recommend that hydrogen's GWPs be applied to the current loss rates, and then as empirical measurements become available, the loss rates should be updated regularly. Hydrogen producers can also account for hydrogen emissions via a mass balance calculation of what they expect to produce versus what they actually produce.

327.6 *Producers should be required to submit and comply with hydrogen emission management plans.*

To both verify the amount of wasted hydrogen gas and as an incentive to control hydrogen emissions, producers should be required to submit hydrogen emission management plans. These will likely include a commitment to using the best available sensor technology to detect

[20] https://www.frontiersin.org/articles/10.3389/fenrg.2023.1207208/full
[21] https://acp.copernicus.org/articles/23/13451/2023/

leaks, and operational best practices to mitigate leakage such as tightening valves and seals, establishing a leak detection and repair program, and incorporating technology to recombine vented, purged, and residual hydrogen with oxygen back into water. Management plans should also disclose whether you are using venting, flaring, and purging practices and state how a facility is verifying final volumes to ensure tax credit compliance.

Hydrogen should be deployed responsibly by targeting the hard-to-abate sectors.

Due to hydrogen's leakage risks combined with the relative energy intensity involved in its production, processing, and distribution, hydrogen use should be limited to hard-to-abate applications. The U.S. National Clean Hydrogen Strategy and Roadmap[22] states the importance of targeting "strategic, high-impact uses for clean hydrogen," including "the industrial sector (e.g., chemicals, steel, and refining), heavy-duty transportation, and long-duration energy storage."

Based on data from available scientific literature and hydrogen supply chain models, we know that light-duty vehicles can be more effectively decarbonized, with greater climate benefits, via EV batteries.[23] On average, powering a hydrogen fuel cell vehicle requires three to four times (and up to nine times) more energy than an electric battery.[24] In addition to the energy needed to convert renewable electricity into hydrogen fuel — and then back again through a hydrogen fuel cell — hydrogen also requires additional energy-intensive processes, such as compressing or liquefying hydrogen for transport and storage. In contrast, renewable electricity does not require conversions into a different state and is significantly less energy-intensive for transmission, distribution, and end use.

On the other hand, using hydrogen to produce fuels for aviation and maritime shipping – both
327.9 hard-to-abate end uses with limited opportunities for electrification – are clearly "no regrets"
opportunities that should be prioritized through the LCFS.

<u>3. Crediting for Medium- and Heavy-Duty Vehicle Charging</u>

Medium- and heavy-duty vehicles are responsible for a disproportionate amount of greenhouse gas (GHG) emissions and local pollution relative to the size of their population. In California, despite the fact that trucks are just seven percent of all vehicles in the state, they emit nearly 33% percent of particulate matter, 25% percent of nitrogen oxides (NOx), and nearly 9% percent of greenhouse gas emissions[25] from the transportation sector; electrifying these vehicles will therefore produce outsized climate and local air pollution benefits. This is particularly important in the state's disadvantaged communities, because while the health impacts, which can

---

[22] https://ww2.arb.ca.gov/ghg-inventory-graphs
[23] https://blogs.edf.org/energyexchange/wp-content/blogs.dir/38/files//2023/01/Methodology-for-H2-Energy-Intensity-Blog.pdf
[24] https://blogs.edf.org/energyexchange/2023/01/30/rule-1-of-deploying-hydrogen-electrify-first/
[25] https://ww2.arb.ca.gov/ghg-inventory-graphs

negatively affect “every organ in the body,”[26] are experienced to some extent all across the state, “low-income and communities of color…are often disproportionately affected by emissions from freight movement due to their proximity to transportation infrastructure,”[27] such as ports, railyards, and freight corridors. Because of this disproportionate impact, there is an urgent need to electrify medium- and heavy-duty vehicles in these neighborhoods.

327.10 *The proposed expansion of the Clean Fuel Reward program will further incentivize and streamline the adoption of medium- and heavy-duty electric vehicles.*

EDF supports the proposal to change the scope of the statewide Clean Fuel Reward program from a light-duty rebate to a medium and heavy-duty rebate. The focus on new and used rebates for medium- and heavy-duty trucks that are exempted from the Advanced Clean Fleets regulation will chart a path towards electrification for the segments of the trucking sector that are most challenging to transition. This program will be particularly important for small fleets and independent owners/operators, for whom up-front purchase price can be a major barrier to electrification.

327.10 *LCFS crediting for medium- and heavy-duty vehicle charging will support the deployment of necessary infrastructure to help California realize the full benefits of the Advanced Clean Trucks and Advanced Clean Fleets rules.*

While the goals embedded in the Advanced Clean Trucks and Advanced Clean Fleet regulations – setting sales and purchase targets for zero-emission vehicles – are crucial components for a sustainable, equitable transportation future, the benefits will not be realized without adequate charging that is sufficient in number and well-designed to support the medium- and heavy-duty vehicles in the state. As such, EDF views the introduction of a new medium- and heavy-duty vehicle Fast Charging Infrastructure (MHD FCI) credit as critical for this effort. The operational variation of medium- and heavy-duty vehicles necessitates a wide diversity of charging equipment and capabilities. Given the diversity of charging needs, the 10 years of crediting will be one of many state-supported funding solutions necessary to transition fleets effectively and affordably throughout the state.

327.12 *CARB should remove the minimum nameplate power rating requirement for the MHD FCI program.*

EDF recommends that CARB modify the proposed eligibility requirements for participating in the MHD FCI program to remove the requirement that each charger (also referred to as Fueling Supply Equipment or FSE) “must have a minimum nameplate power rating of 250 kW.” While some electric trucks and buses will rely on direct current fast chargers (DCFCs) with nameplate capacities of 250 kW or greater, many will not need this level of charging. This is particularly

[26] https://www.ucsusa.org/resources/cars-trucks-buses-and-air-pollution#toc-effects
[27] https://ww2.arb.ca.gov/sites/default/files/2021-09/Proposed_2020_Mobile_Source_Strategy.pdf

true for fleets operating out of and charging at private depots which may have shorter duty cycles and can spread their charging overnight and/or several daytime blocks with lower-power DCFC or level-2 charging. Removing the 250 kW requirement would allow these fleets to optimize their charging based on their own operational needs, resulting in grid-beneficial charging behavior, while still remaining eligible for the program. Consistent with this recommendation, CARB should also remove or modify the limitation that no more than ten chargers per applicant per site would be eligible for credits. The proposed 10 MW cap per customer per site is a sufficient constraint on individual customers accumulating credits while retaining the flexibility for applicants to deploy chargers in number and capacity consistent with their needs. Otherwise, applicants would potentially be incentivized to oversize chargers' nameplate capacity to maximize credit eligibility.

4. Sustainable Decarbonization of the Aviation Sector

For almost a decade, EDF has been working to reduce harmful pollution from aviation to mitigate climate change and deliver public health benefits utilizing alternative fuels. This includes engagement in climate policy at the International Civil Aviation Organization (ICAO), leading and participating in expert working groups developing ICAO's Sustainability Framework for Sustainable Aviation Fuel (SAF) – an effort that builds heavily on California's Low Carbon Fuel Standard (LCFS). We were also deeply involved in the inclusion of SAF tax credits in the federal Inflation Reduction Act (IRA).

The proposed LCFS reforms include changes that will significantly impact California's efforts to decarbonize the aviation sector and warrant thorough consideration. Expanding the scope of the Low Carbon Fuel Standard (LCFS) program to include aviation fuels beyond the existing voluntary opt-ins for alternative jet fuels[28] is a necessary step towards achieving carbon neutrality in California by 2045 and will likewise support collective climate ambition. The structured deployment of sustainable aviation fuels (SAF) in California is crucial for the civil aviation sector to reach the International Civil Aviation Organization (ICAO)'s global goal of net-zero climate impact by 2050.

The following recommendations are relevant in evaluating how to sustainably transition from the uptake of conventional fossil jet fuel to the uptake of alternative jet fuel in the State.

327.13 *All fossil jet fuel provided in California should generate deficits under the LCFS, not only intrastate flight fuel burn.*

We respectfully encourage CARB to extend a reformed LCFS beyond the proposed amendment of CCR §95482(c)(1)(2), and instead, cover all fossil jet fuel uplifted in California to ensure the

---

[28] Important to note, 'alternative jet fuels' denotes a broader category than does 'SAF.' Per definitions established at the federal and international levels, 'SAF' refers solely to fuels produced using renewable energy sources, wastes and residues and meet sustainability criteria.

greatest degree of climate benefits. Whereas the modified text makes conventional fossil jet fuel subject to LCFS regulation only for intrastate flights, we recommend instead that CARB delete altogether the exemption §95482(c)(1)(2), "Conventional jet fuel or aviation gasoline."

The broader coverage of all flights – whether intrastate, interstate, or international -- is consistent with the generally applicable language of Gov. Schwarzenegger's Executive Order S-01-07 establishing the LCFS applicable to all transportation fuel providers in California. It is also consistent with the authority CARB exercised in the 2018 LCFS reform when it included alternative jet fuel as an opt-in fuel entitled to generate credits, providing the necessary steppingstone towards more comprehensive action now.

Furthermore, an amended LCFS covering only intrastate flights could pose a serious risk of invalidation under federal law. CARB could easily sidestep this risk by removing the exemption language and thus treating fossil jet fuel as part of the general suite of transport fuels subject to LCFS regulation.

On this front, CARB needs to act now – and act prudently. Postponing the effective start date until 2028 would be a missed opportunity we cannot afford. Planning for intrastate-only aviation coverage – and with such a long delay - would be neither legally viable in the face of federal preemption nor commensurate with the climate emergency.

In terms of emissions quantities, intrastate flights represent a mere 10% of emissions from jet fuel uplifted in California, or around 6% of the total aviation emissions from flights to and from California.[29] In a scenario of LCFS coverage limited to intrastate flights, Governor Newsom's requested "aggressive 20% clean fuels target for the aviation sector" in 2030 translates to emissions reductions on the order of 1% of California's aviation emissions.[30] This is far too small a quantity to achieve meaningful benefits for climate action or for human health.

327.14 *CARB must protect workers' and airport-adjacent communities' health by regulating jet fuels' aromatic content and thus mitigating particulate matter pollution.*

Fuel-related emissions from landing and take-off operations disproportionately affect local communities as well as workers within the airport envelope. Communities living in proximity to

---

[29] Based on 2020 inventory data available at: https://ww2.arb.ca.gov/sites/default/files/classic/cc/inventory/ghg_inventory_scopingplan_sum_2000-20.pdf
[30] https://www.gov.ca.gov/wp-content/uploads/2022/07/07.22.2022-Governors-Letter-to-CARB.pdf?emrc=1054d6

airports are exposed to elevated levels of ultrafine particles (UFP) and are at risk of adverse health effects, a critical issue upon which CARB needs to act without further delay.[31]

While alternative aviation fuel blends have the potential to reduce harmful aviation emissions by reducing aromatic content, such an outcome will not happen unless additional regulations are enforced. Furthermore, the gradual scale-up of alternative aviation fuels means that a fuel swap will help only marginally in the near term - if at all - which is insufficient to protect overburdened communities already suffering decades' worth of accumulated adverse health effects.

To deliver tangible near-term public health benefits, CARB should not only extend the scope of LCFS-covered jet fuel but, California should also undertake complementary action to regulate jet fuel composition. Jet fuel aromatic content could be reduced by hydrotreating conventional jet fuel while tapping on IRA's generous clean hydrogen subsidies to cushion price impacts and GHG emissions penalties.[32] This is a near-term measure that could slash PM2.5 emissions without adversely affecting safety, i.e., in a manner that would be fully compatible with existing federal airworthiness certifications.

327.15 *The prohibition on converting forested land into agricultural production should extend to also protect wetlands and grasslands.*

As noted in Appendix E: Rationale, section W(5), "It is vital that the LCFS program limit deforestation and land use change as a result of feedstock production as much as possible." The proposed new §95488.9(g), Sustainability Requirements for Crop-Based and Forestry-Based Feedstocks, takes a step toward installing the needed guardrails. Notably, the requirement that all domestic and imported feedstocks be traced to their point of origin has a more comprehensive coverage than any other domestic tracing requirement to date. However, the text is incomplete in fulfilling its purpose outlined in the ISOR(II)(F), "reduce the risk that rapid expansion of biofuel production and biofuel feedstock demand could result in deforestation or adverse land use change."

Direct land use change (DLUC) can occur on land cover types other than only forest. High-carbon-stock and high-biodiversity land types include grasslands and wetlands as well; bringing these lands into bioenergy feedstock cultivation is every bit as dangerous as bringing forests into

---

[31] For a more detailed description, a literature review, and an overview of options on how to tackle $PM_{2.5}$ emissions from aviation see EDF's letter to the U.S. Environmental Protection Agency from April 4, 2022:
https://downloads.regulations.gov/EPA-HQ-OAR-2019-0660-0207/attachment_1.pdf

[32] In recent filings, EDF has underscored the vital importance of reducing climate and health harming pollution from hydrogen production. See: https://www.edf.org/sites/default/files/2023-09/Petition%20for%20Rulemaking%20-%20Hydrogen%20Production%20Facilities%20-%20CAA%20111%20and%20112%20-%20EDF%20et%20al.pdf

cultivation. These natural land conversion emissions are non-negligible: the soil carbon released from plowing alone can be greater than the entire lifecycle carbon intensity of fossil jet.[33]

Therefore, the first sentence of §95488.9(g), “Crop-based and forestry-based feedstocks must not be sourced from land that was forested after January 1, 2008,” should be modified to protect grasslands, wetlands, and peatlands in addition to forested land.

By removing the deficit-generating exemption for all fossil jet fuel provided in California, regulating jet fuels' aromatic content, and protecting a broad range of natural lands from agricultural conversion, CARB can deliver on deep decarbonization and public health goals now.

CARB’s upcoming decision on LCFS reform offers a golden opportunity to lay down the foundation for the high-integrity SAF needed to make real progress in transforming the aviation sector’s outlook for climate action in California. Including the aviation sector under the LCFS is urgent, and we can’t afford to miss this opportunity to deliver on deep decarbonization and public health goals.

Regulating fossil aviation fuels under the LCFS will ensure that the environmental attributes associated with the use of alternative jet fuels are claimed on California’s emissions ledger, rather than under other jurisdictions through indirect accounting systems. The emissions reduction benefits from the use of alternative aviation fuels take place upstream of fuel combustion, i.e., within sectors counted toward California’s GHG inventory (or equivalent inventory for imports).

Covering aviation fuels under the LCFS will also ensure that the aviation sector shares responsibility for a portion of the cost of deploying SAF in California, rather than leaving road transportation end-users to subsidize the aviation sector (a dynamic driven also by the federal Renewable Fuel Standard). Even so, the impact on airfare prices of expanding the scope of the LCFS to aviation should be modest because (1) generous federal subsidies are available to offset increased manufacturing expenses, and (2) air carriers have the ability to shield themselves against marginal price signal pass-throughs from jet fuel providers.

In parallel to striking out §95482(c)(1)(2), CARB would also need to recalibrate the increase in stringency of the LCFS carbon intensity targets to account for the uptick in aviation’s sectoral demand. This task is already under deliberation and should be relatively straightforward, though it is no less time-sensitive than the other components of LCFS analysis.

---

[33] Estimates from Spawn et al, 2019, Environ. Res. Lett. 14 045009. There is a wide geographic variation in both the size and sensitivity of affected carbon stocks that would need to be evaluated on a case-by-case basis. Still, the primary source of land conversion in the United States is grassland to cropland, in which disruption of soil organic carbon stocks makes it a larger emissions source than conversion of the Brazilian Cerrado.
https://iopscience.iop.org/article/10.1088/1748-9326/ab0399/pdf

Thank you for your consideration of these comments. EDF looks forward to continuing to work with CARB to update the LCFS. If you have questions or would like to discuss any of these recommendations, please contact Katelyn Roedner Sutter at kroedner@edf.org.

The Honorable Liane Randolph
Chair, California Air Resources Board
1001 I St, Sacramento, CA 95814
Sacramento, California 95814

February 20, 2024

Re: Low Carbon Fuel Standard

Dear Chair Randolph:

328.1 We, the 51 undersigned clean fuel businesses and related organizations, write to emphasize our support for the key proposed amendments to the Low Carbon Fuel Standard (LCFS) and urge adoption of several additional amendments that will allow the state of California to effectively achieve climate and clean air goals.

We stand ready to follow your leadership to address the dire threat of climate change. The LCFS drives reductions in greenhouse gases (GHG), supports a rapid phase-out of petroleum, and bolsters a transition to electrification everywhere feasible. Also, as partners in California's transportation decarbonization efforts, we strongly support the conclusions in the *Initial Statement of Reasons* supporting science-based analysis. By doing so, the LCFS is well positioned to encourage the billions of dollars of investment required to implement the California Air Resources Board's (CARB's) *2022 Scoping Plan for Achieving Carbon Neutrality* in the transportation sector.

There is no more effective and immediate step we can be taking to address climate change now than to aggressively and rapidly reverse emissions of fugitive methane from all sectors, including society's organic waste streams through renewable natural gas (RNG) projects.

Many RNG projects in planning and construction across North America currently rely on LCFS
328.2 revenues to be built, operated, and provide a return on investment for debt service. We are pleased that CARB, via the just-released *Proposed Amendments to the Low Carbon Fuel Standard Regulation,*[1] is proposing to allow projects that break ground by December 31, 2029 to
328.3 retain the current approach to book and claim and avoided methane accounting. We are also supportive of the proposal that for projects that break ground after December 31, 2029, deliverability rules won't be modified until January 1, 2041 for pathways which include biomethane used in CNG vehicles and January 1, 2046 for biomethane used for hydrogen production. While these existing accounting rules are well functioning and do not need to be deviated from, we look forward to working with CARB to increase stakeholder understanding on these topics and plan for new accounting rules once more implementation details are developed.

Outstanding Problem: Making LCFS a Functional Program Requires a Strong CI Curve

328.4 We remain concerned that the proposed carbon intensity (CI) compliance curve falls short of stimulating the market and needs to be significantly strengthened to draw down the Program's credit bank which recently hit a new high of over 20 million surplus credits, with ICF forecasting that the program will have a bank of about 29-30 million credits by the end of 2024.[2] In fact, ICF continued to state, "[T]he proposed [CARB] CI step-down will slow the bank build by about 50%

[1] "Appendix A-1; Proposed Regulation Order; Proposed Amendments to the Low Carbon Fuel Standard Regulation," California Air Resources Board, January 2, 2024
[2] "Analyzing Future Low Carbon Fuel Targets in California; Response to Staff Report," Page 3, ICF, February 2024

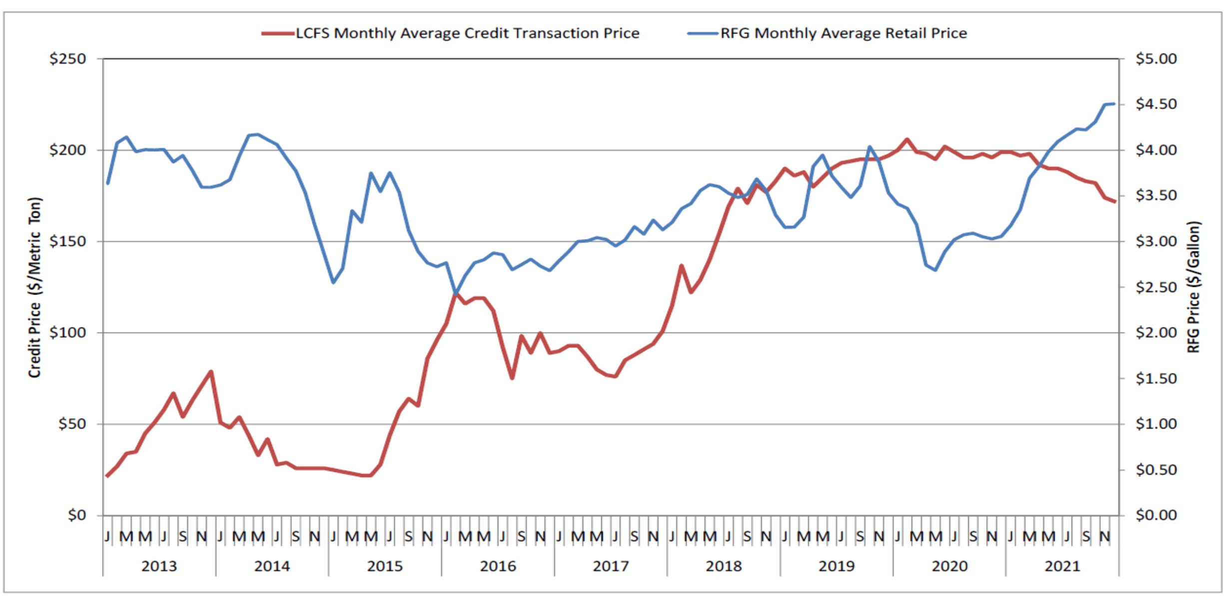
compared to previous years; however, the credit bank is still likely to grow by nearly 4 million credits by the end of 2025."

The primary reason for the substantial surplus in credits is the increasing supply of renewable diesel fuel due to additional projects coming online and various projects passing significant milestones. Without changes, this will continue to drive the credit bank up and keep LCFS prices depressed for multiple years. In fact, we are seeing the same occurrence in Oregon's program with a steady increase in renewable diesel going there, causing credit prices to fall as more credits are flowing into that market.

328.4c cont. The oversupply of credits in the market hurts existing and proposed projects, but additionally it sends a signal to investors that we should not invest. In fact, based on the spot and futures markets, Wall Street believes California has lost its urgency to decarbonize transportation. Investment banks are viewing credits as stranded assets over proactively investing in production projects that move California closer to its climate and clean air goals. And while the Program has been successful in driving down carbon intensity of transportation fuels, this situation also demonstrates the need to tighten the CI curve so that the market can move off its eight-year low credit price of $55, when the credit bank by the end of this year will have enough credits for nearly 2 years' worth of compliance and is still growing.

It is important to note that research[3] has concluded there is not a causal relationship between the LCFS and prices at the pump. Analysis of market prices demonstrates that the LCFS is not a significant driver of retail fuel prices in California, as the primary driver is the cost of crude oil. Lower carbon fuels are displacing Californians' exposure to foreign crude and delivering alternatives that bring home cost savings, in addition to the California jobs required to build low carbon fuel supply, clean fuel networks, and maintenance infrastructure of clean fuel vehicles. This conclusion is consistent with that in the ISOR on pages 82-83. This graph shows this lack of causal relationship over time:

Figure 1: LCFS Credit Price and Retail Gasoline Price[1]



[3] "Low Carbon Fuels Standards; Market Impacts and Evidence for Retail Fuel Price Effects," Bates White Economic Consulting, April 2022

In conclusion, the LCFS program must be fixed to be functional, but won't achieve California's climate goals if the CI curve is not effective.

Solution

328.4a cont. We urge CARB to set an ambitious compliance curve course that immediately draws down the credit bank and ensures a steady market to 2030. We support the ICF conclusion on the step-down for 2025 that "[A] CI [reduction] of 25% in 2025 is likely needed to ensure that the credit bank reverses and that the bank is drawn down to a level that is in line with a credit bank of only two quarters' worth of deficits. This level of stringency, while seemingly high, is likely what is needed to achieve CARB's stated intent of correcting for the 'near-term over-performance' of the program."[4] 328.4b We are also supportive of at least a 41% CI reduction target by 2030, which to our industry's extensive quantitative modeling[5] concludes that implementing the above strategy would increase the current approximate $55 credit price to $100-$120 by the end of 2025 and maintain at least that price through 2030.

Additional Amendments

Additional RNG-related changes are also needed to improve investor confidence and increase the pace of methane emissions abatement. We urge CARB to please consider:

328.5

- A full credit True-up remains necessary to properly recognize the true environmental performance of all pathways. Approvals take 18 months or more which puts financial hardship on a project and those in the entire value chain. A project would be able to apply its actual CI performance retroactively to the start of a project and thus eliminate the need to store gas. The project would be eligible to claim the full benefit of its project CI even when starting with the temporary pathway (also known as the project start up period);

328.6

- The Auto Acceleration Mechanism should be able to trigger as early as 2026. This would dynamically respond in the event of future sustained and significant underestimation of CI reduction targets by further tightening the stringency and complement the updated overall stringency of the program, complement existing mechanisms to avoid credit shortfalls, and better ensure that opportunities to deliver additional reductions of carbon and air pollutants are not foregone;

328.7

- We support the revised Tier 1 calculators and urge improving pathway processing times. The current review delay of over a year deters future investment and decreases return on investment of projects that California needs. For example, a multi-million dollar project built today must endure an 18-month administrative review on average to certify the project's LCFS pathway. Certification should be performed in less than a six-month window.

The success of the LCFS is due to the broad portfolio of clean fuels working together to achieve substantial emissions reductions. Unwinding these successful partnerships would strand billions

[5] "Analyzing Future Low Carbon Fuel Targets in California; Initial Results for Accelerated Decarbonization, Central Case," ICF, June 2023

of dollars in clean technology investment, delay transportation decarbonization, and extend the period where petroleum is the dominant fuel in California.

328.8 The LCFS must remain fuel-neutral, driven by CARB's science-based analysis, capable of incentivizing real-world investment, and focused on performance-based GHG outcomes. Remaining true to these core concepts will ensure California leads the world in rapid transportation sector decarbonization.

Subject: Low Carbon Fuel Standard (LCFS) Comments

Dear Chair Randolph,

FirstElement Fuel (FEF) is pleased to provide these comments on the proposed changes to the LCFS program detailed in the Staff Report: Initial Statement of Reasons (December 19, 2023)[1]. FEF, as you may know, is the largest retail hydrogen refueling station (HRS) provider in California, due to the state's aggressive greenhouse gas emissions policies married to appropriate market incentives embodied in the Low Carbon Fuel Standard (LCFS) regulatory framework. We provide these comments not only as a market participant but also as an enabler of California's hydrogen transportation ambitions and as a business dependent on its success.

First and foremost, we commend you and your staff for the thoughtful proposal, which reflects a balance between strict regulatory goals and economic reasonableness. Due to the large scope of changes, however, some areas regarding hydrogen deserve further refinement to enable greater implementation. These areas are discussed below.

Increased Stringency and Step Down
329.1 We agree with staff's recommendation of the 30% reduction in carbon intensity (CI) by 2030
329.2 and a 90% reduction in CI by 2040. However, we are concerned that the historically low credit
prices[2] will continue through 2025, so urge bringing the one-time 5% CI step down forward
sooner (e.g., at rule adoption through OAL) as well as the auto acceleration mechanism (AAM).
329.3 The delay in hearing the rule and any further delays in implementation will further stifle any
329.4 private investments in cleaner transportation fuels, especially HRS. We request the Board
implement the 5% step down and AAM sooner than the proposed date of 2025.

Light-Duty (LD) Hydrogen Refueling Infrastructure (HRI) Pathway
The existing LD HRI program has been working as intended, with HRS development solving the chicken-or-egg dilemma of vehicle adoption or fuel availability coming first. The HRI program was meeting or exceeding all of its goals laid out by the CARB Board and LCFS Staff through 2021 while there was a healthy balance of LCFS credit deficits in the marketplace that in turn buoyed LCFS credit prices. The *Program Goals*, and concomitant positive results, are summarized below.

---

[1] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf
[2] https://r.search.yahoo.com/_ylt=AwrgzbOD88tlcAQAl.ZXNyoA;_ylu=Y29sbwNncTEEcG9zAzIEdnRpZAMEc2VjA3Ny/RV=2/RE=1709074564/RO=10/RU=https%3a%2f%2fww2.arb.ca.gov%2fresources%2fdocuments%2fmonthly-lcfs-credit-transfer-activity-reports/RK=2/RS=yu36..J0ANG2sS86H065qyHr788-

329.5 1. *Accelerate the development of hydrogen refueling infrastructure capacity*.
The installed capacity of HRS in California more than doubled between 2019, when the HRI program was initially implemented and mid-2022 when LCFS credit prices dramatically fell.

329.6 2. *Unlock private investment as a greater share of hydrogen refueling station capital expenditures.*
The share of public funding for HRS fell from an average of ~70% of project capex *plus* Operation & Maintenance support to ~30% of project capex and an elimination of Operation & Maintenance support.

329.7 3. *Enable hydrogen station operators to retail hydrogen at a price more indicative of a full-fledged market.*
The average retail price of hydrogen fell to an all-time low in the months following the implementation of HRI, with FEF retailing hydrogen at $12/kg + tax, nearly price-parity with gasoline.

329.8 4. *Encourage the development of commercial-scale hydrogen stations with higher capacity, capable of supporting growth in the marketplace, including more vehicle classes (such as Medium-Duty hydrogen vehicles).*
As a result of the hydrogen station development spurred by the HRI program, California leads the world in higher-performing, higher-capacity hydrogen stations. Furthermore, setting the capacity cap at 1,200 kg/d in the LD HRI program has led to the development of stations that are robust enough to serve medium-duty (MD) fuel cell electric vehicles (FCEVs), such as large pickup trucks or delivery vans, thus enabling another vehicle segment.

329.9 5. *Encourage good performance of hydrogen refueling stations in the marketplace.*
The "uptime" requirement in the HRI program has incentivized FEF to make significant investments in R&D and engineering to improve equipment performance and uptime, which has also led to the creation of jobs and workforce training.

329.10 6. *Reduce the CI and increase the renewable content of hydrogen sold into the mobility sector.*
As a result of the LD HRI program, FEF increased the renewable content of our hydrogen on average from 33% to over 70% and reduced our CI to zero. CARB data suggests that other hydrogen station operators followed similar trends during the first several years of the LD HRI program.

The single factor that has caused the LD HRI program to fall short of its goals in recent months is the imbalance of LCFS credits in the marketplace which has depressed LCFS credit prices. Depressed LCFS credit prices have resulted in a near standstill of LD HRS development, a dramatic increase in retail hydrogen prices throughout the state, and a reduction in performance by several hydrogen refueling station operators (while FEF continues to make strides in improving hydrogen station performance, nearly every other hydrogen station operator in California has seen a reduction in performance).

Several historical outcomes of the LD HRI program performance and participation suggest that the program *as originally designed* is well-balanced and was extremely successful at achieving its targeted goals if there was a healthy balance of LCFS credits-to-deficits in the marketplace. For example:

- There was never a "gold rush" to develop HRS, suggesting that the incentive was appropriate and not overly generous;
- The program was effective in hitting all 6 of its goals very shortly after implementation (this can be tracked with data), suggesting that the program was effectively designed; and
- When LCFS credit prices fell dramatically in 2022, the program stopped incentivizing the development of HRS and the retail price of hydrogen rose, again suggesting that the incentive was appropriate and not overly generous.

329.11 So, we agree with the staff recommendation to extend the LD HRI program but urge elimination of the new constraints imposed on the program, namely the more restrictive 10-year crediting period, the 600 kg/d capacity cap, and crediting only if within low-income, rural and disadvantaged communities (DACs). The specific justifications for each are summarized below:

- Limiting LD HRI crediting to 10 years creates risk and uncertainty for the continued operation of LD/MD HRS and hydrogen fuel availability beyond 10 years that could inhibit FCEV adoption. This uncertainty will also further limit private investment in HRS. We urge the CARB to maintain the efficacy of the existing LD HRI program by keeping 15 years crediting duration.
- Reducing the station capacity eligible for LD HRI crediting from 1,200 kg/d to 600 kg/d will severely undersize stations at sub-economic size. The LD HRI Capacity Cap was originally established at 1,200 kg/d to support HRS with at least three (3) dispensers as the minimum viable size. As MD hydrogen trucks are introduced, these will typically fill at the neighborhood fueling stations established under the LD HRI program rather than HD HRS stations along freeways (i.e., truck stops). Each MD FCEV may fill with twice the amount of hydrogen as each LD FCEV, making HRS capacity established under the existing LD HRS program even *more* important today than ever. We urge the CARB to maintain the lasting benefits of the LD HRI program by keeping the station Capacity Cap at 1,200 kg/d.
- Supporting stations with HRI crediting only in low-income, rural and DACs will hinder the fueling network coverage that is essential to FCEV adoption. Many practical constraints already limit the viable locations for new HRS, so adding the additional location requirements will certainly cause gaps. Furthermore, environmental justice advocates have argued that HRS would not benefit but rather create *further burden* to these communities by enabling greater traffic, congestion and idling fossil-fueled vehicles in those areas due to a station. A better solution is to enable greater ZEV incentives for those communities rather than requiring infrastructure.

We urge the Board to simply extend the LD HRI program "as is" and revisit in a few years to ensure the program is operating as intended and serving disadvantaged communities. We also request grandfathering on-going CEC projects awarded under the existing LD HRI program since

329.11 cont. these projects have been delayed due to the pandemic, the recent financial crisis in California, and the historically low credit prices.

Heavy-Duty HRI

329.12 The hydrogen industry stakeholders have worked with staff to draft a workable HD HRI program, and for the most part, we agree with the resulting capacity credit outline. From our experience over 10 years as the largest developer and operator of LD HRS, now looking toward HD HRS, we expect the 6,000 kg/d station Capacity Cap and 2.5% HD HRI Market Cap to be sufficient and the CARB action to establish the HD HRI program to be similarly effective as the existing LD HRI program.

329.13 However, for the same reasons elaborated above, we urge staff to create the new HD HRI pathway incorporating the parameters proven effective in the existing LD HRI pathway rather than the more restrictive current proposal. In particular, we urge a 15-year HRI crediting period, rather than the proposed 10-year limitation, and the elimination of the location requirements.

329.14
- Limiting HD HRI crediting to 10 years creates risk and uncertainty for the continued operation of HD HRS and hydrogen fuel availability beyond 10 years, which could inhibit HD FCEV adoption, especially amongst commercial fleets operating HD FCEV seeking long-term certainty in their operations. With the higher cost of HD HRS and long-term investment horizon of commercial fleets, the need for at least 15-year HRI crediting period is even more essential for HD HRS. We urge the CARB to establish efficacy in the HD HRI program with a 15-year crediting duration.

329.15
- Limiting HD HRI to locations within one mile of a ready or pending FHA Alternative Fuel Corridor, next to truck parking, or having received funding from a state or federal competitive grant program are too restrictive, unnecessary and will hinder the fueling network coverage that is essential to commercial fleet adoption of HD FCEV. Many existing truck stops fueling diesel truck fleets are further than 1 mile from FHA Alternative Fuel Corridors and not adjacent to truck parking, and we know that there are existing HD HRS locations that will serve significant truck volumes that are also NOT within one mile of a FHA corridor (e.g., the 60 Freeway and warehousing centers in the Inland Empire). We urge the location restrictions be removed entirely, or at least increased to a more reasonable five (5) miles with exceptions that allow for local or regional funding (as opposed to only state or federal) programs since there are Air District grant programs that vet station locations in their grants.

329.16 We recommend the Board adopt the HD HRI with a 15-year crediting period and without the location constraints, or at least allow the Executive Officer case-by-case discretion in the location approval.

Decarbonizing Hydrogen Fuel: 80% Renewables by 2030

329.17 The LCFS policy with HRI pathways has proven effective for the rapid decarbonization of hydrogen fuel. Per LCFS reporting, the hydrogen sold for transportation in California was rapidly decarbonized after the HRI was established, to 33 gCO2e/MJ average in 2022[3]. In contrast, the electricity in the California grid in 2022, at 77 gCO2e/MJ, was more than double the carbon

[3] https://ww2.arb.ca.gov/resources/documents/low-carbon-fuel-standard-reporting-tool-quarterly-summaries

329.17 cont. intensity[4]. So, we know that reducing the *carbon intensity* of hydrogen fuel to mitigate climate change is an effective weapon, and we also recognize that renewable sources for hydrogen production will be the ultimate pathway for transportation. However, the needed scale and cost of renewable-source hydrogen feedstocks take time to develop, at the project level as well as at utility scale with renewable power generation. Requiring 80% renewable content by January 1, 2030 is too soon and may prove counter-productive to the primary intent of LCFS policy to decarbonize fuels. We urge the Board to keep the existing 40% requirement for renewable content and conduct periodic check-ins on the average renewable content before mandating an increase.

Station Capacity Modeling: HyCAP and HyScape

329.18 Although not addressed in the regulatory package, we understand and agree the modeling for HD HRS capacity using the HyCAP model is essential for determining the HD HRS capacity credits, while continued use of the HyScape model is appropriate for determining the LD HRS capacity credits. However, we urge staff to provide certainty in the LCFS regulation that multi-use stations serving LD/MD and HD FCEV will be eligible to certify into both the LD HRI and HD HRI pathways. Furthermore, we recommend this be implemented with an iterative approach using both HyScape (LD/MD) and HyCAP (HD) models to ensure consistent and equitable treatment. We are involved with the NREL working group for HyCAP, and are confident in the implementation of this approach.

Finally, we wish to thank the CARB Board and staff for allowing us to comment. The LCFS is the most important regulation for the hydrogen refueling infrastructure industry, and the HRI programs are the keys to our continued viability. We look forward to working through these issues with staff prior to Board adoption.

Sincerely,

Matt Miyasato, Ph.D.
Chief Public Policy & Programs Officer
FirstElement Fuel

Sacramento, California 95814

Re: Proposed Low Carbon Fuel Standard Amendments

Dear Mr. Botill,

Divert is an impact technology company with a mission to protect the value of food. Based in Concord, Massachusetts with significant operations within California, we were founded in 2007 with the purpose of creating innovative and efficient solutions toward eliminating food waste. We are passionate about proving that environmental sustainability can be as good for business and consumers as it is for the planet. To that end, Divert is focused on decarbonizing unconsumed food through source reduction, food rescue, and recycling.

Divert operates 13 facilities across the U.S., and works with over 5,400 retail stores. Divert works across the retail food supply chain, implementing training protocols and technology to track food and gather data about what is wasted and why. Divert provides insights that enable our customers to change behaviors and ultimately reduce waste through source prevention and rescue programs. For inedible food, Divert created the first FDA Food Safety Modernization Act (FSMA)-compliant reverse logistics process to aggregate wasted food and transport it to one of Divert's anaerobic digestion facilities at no additional cost and with negative carbon intensity. At these anaerobic digestion facilities, before it's digested, wasted food is processed through a proprietary depackaging system to remove excess moisture and unwanted contaminants – such as wrappers, stickers and rubber bands – that make this commercially generated organic material unsuitable for composting. Divert's facilities capture the biogas naturally released during anaerobic digestion, which is captured and purified into renewable natural gas.

We work towards our purpose every day, and have achieved successes to:

- Use our technology platform to optimize the reduction of food waste generation for the retail food industry, which is the largest generator of food waste in the U.S.
- Cultivate partnerships with retailers and food banks to increase donations for unsold food that meets food donation guidelines but would otherwise be bound for the landfill.
- Establish ourselves as the largest processor of food waste in the U.S., converting food waste to renewable natural gas via proprietary liquefaction and anaerobic digestion.

Divert is committed to helping California reduce short-lived climate pollutants through the rescue, recovery, and recycling of food waste. As California continues to achieve its food waste reduction and carbon neutrality goals, Divert is:

- Partnering with Feeding America, local food banks, and a private retailer to service over 900 California based stores to identify and facilitate the rescue of unsold food to provide to local communities and families in need.
- Providing California food retailers access to Artificial Intelligence (AI) and Internet of Things (IoT) technology to maximize source reduction and improve the proper handling and freshness of perishable goods.
- Expanding food waste processing and anaerobic digestion capabilities with a new California food waste to energy facility that makes carbon negative renewable natural gas (RNG).

We are supportive of the efforts made by the California Air Resources Board (CARB) and the State of California to achieve its carbon-neutrality goals and offer comments to the Low Carbon Fuel Standard Amendment below.

330.1 **Avoided Methane Crediting Should Continue in LCFS and Remain Available to Those Addressing The goals set forth in SB 1383 or Until a Realistic and Proven Replacement Policy is Implemented**
SB 1383 requires the state to achieve a reduction in SLCP emissions, including a 40 percent reduction in methane, by 2030.[1] In its 2022 Scoping plan, CARB outlines its SLCP related emissions achievements, while noting that these reductions have not kept pace with the broader progress towards California's decarbonization goals.[2] The document states that "more aggressive action is needed" to meet the state's legislative goals.[3]

As CARB has acknowledged, the emission impacts of SLCP's are especially strong over the short term, and timely action on reducing these pollutants can have an immediate beneficial impact on climate change and public health.[4] Achieving reductions in SLCP's would help reduce ambient levels of ozone and particulate matter and the cardiovascular and respiratory effects associated with air pollution, and many of these benefits would accrue in disadvantaged communities, which are often located near sources of SLCP emissions.[5]

SB 1383 requires a 40 percent methane reduction target by 2030, but by 2025 the state is expected to remain roughly 8 million tons short of anaerobic digestion or composting capacity.[6] Scaling up California's organic waste recycling infrastructure is crucial to achieving the adopted goals and such infrastructure can be incredibly costly to local jurisdictions. Private businesses can help the state achieve these goals with project investments both inside and outside of California.

Despite the state's need to reduce short lived climate pollutants and to scale organics processing infrastructure, the Proposed Rule has outlined a plan to phase out the avoided methane crediting in the LCFS program. This phase out is premature and leaves an incredible amount of uncertainty for investors that are looking to scale organics processing solutions that promote decarbonization within the state. These types of projects are often reliant on LCFS crediting and it would be counterproductive to propose

[1] California State Legislature, "SB 1383 - Short-lived climate pollutants: methane emissions: dairy and livestock: organic waste: landfills" 2015
[2] California Air Resources Board, "Final 2022 Scoping Plan Update", Page 224
[3] ID

[5] California Air Resources Board, "Short-Lived Climate Pollutant Reduction Strategy", Page 13
[6] Governing Magazine (March 10, 2022), "It's Time America stopped Throwing Out Food Waste"

an arbitrary phase out of avoided methane crediting without a detailed plan for developing a replacement policy or continuing to provide a similar credit to projects that are working to help the State achieve the goals set for in SB 1383. To continue with a phase out will lead to significant project uncertainty, an increased potential for stranded assets, and could discourage future investment within the state of California.

We continue to support CARB analyzing phase-out of avoided methane crediting once replacement policies are in place. However, we do not support the Proposed Amendment's *required* phase-out of avoided methane crediting *without* a suitable replacement policy. Divert would recommend that CARB work with industry stakeholders to determine what alternative incentives are needed to advance projects that directly achieve the state's SLCP emissions reduction goals.

330.2 **Tier 1 Calculator: Recognition of Methane Benefits of RNG Projects Diverting Organic Material from Landfills Should be Revisited and Expanded**

Both CARB and US EPA have mandatory emission control requirements for landfills that help reduce methane emissions, yet research literature suggests that many landfills still contribute methane emissions at rates that are much higher than previously estimated.[7] A 2019 study by NASA JPL estimates that landfills' contribution to the state's methane emissions is double current estimates – approximately 41% of all methane point source emissions in California.[8]

LCFS can help address methane from organic waste handling through better recognition of the benefits of RNG projects that divert organics from landfills and into dedicated digesters. Better quantification of the methane benefits of avoided landfilling and incenting such reductions in the LCFS should be a key focus for CARB, rather than considering arbitrary dates for eventual sunsetting of avoided methane crediting.

We support and appreciate the change for years 1-3 in the *Tier 1 Calculator Biomethane from Anaerobic Digestion of Organic Waste* acknowledging the fact that significant methane emissions occur from open face of the landfill. However, maintaining the 75% assumed capture rate for the remaining years is inaccurate and does not align with current science, most notably EPA's October 2023 EPA findings that 61% of methane from landfilled food waste escapes to the atmosphere (39% capture rate).[9]

Given that EPA was the source for prior capture rate assumptions (with the 75% capture coming from a 1997 EPA study), EPA's much more robust and up-to-date findings should be immediately adopted and the 2023 EPA findings of 39% capture rate incorporated into the Tier 1 calculator.

330.3 **Tier 1 Calculator: Adjust Calculation Innaccuracy Related to Fugitive Methane from Biogas Upgrading**

---

[7] This fact should be noted by those that believe a mandate to control is the sole solution that should be employed for other sources of fugitive methane, such as agricultural manure methane emissions.

[8] Duren, R.M., Thorpe, A.K., Foster, K.T. et al. California's methane super-emitters. Nature 575, 180–184 (2019). https://doi.org/10.1038/s41586-019-1720-3

[9] United States Environmental Protection Agency, Office of Research and Development, October 2023, *Food Waste Management: Quantifying Methane Emissions from Landfilled Food Waste* https://www.epa.gov/system/files/documents/2023-10/food-waste-landfill-methane-10-8-23-final_508-compliant.pdf

330.3 cont. As written, the CI score Tier 1 Calculation for fugitive methane emissions from biogas upgrading potentially creates a significant amount of inaccuracy. The calculator estimates tail gas emissions, which is a very small number, by subtracting two very large numbers - the digester gas heating value and the RNG and flared gas heating value - from each other. This can mean that an error as small as 1% in the digestor gas flow or methane content can recreate calculation errors as large as or larger than the entire CI contribution from factors like tailpipe emissions, pipeline transport, or fuel station compression which have been meticulously calculated.

The intent to accurately measure fugitive methane emissions is understood and effort should be made to ensure knowledge of what these fugitive emissions are, but we believe that a static assumption for fugitive losses in the upgrader would lead to more accuracy over the long term. A static assumption would also create less of a need for true-ups against fully certified CI scores due to measurement fluctuations within typical device uncertainty. We would welcome the opportunity to work with CARB to determine how this static assumption can be created and suggest that it potentially be based on technology type or vendor documentation.

330.4 **A Full Credit True-up Remains Necessary to Properly Recognize the True Environmental Performance of RNG Pathways**

We support the Proposed Amendment's inclusion of a "Credit True Up" after Annual Verification. When implemented properly, such a concept can ensure that the LCFS program correctly accounts for the full GHG benefits all fuel pathways produce. However, we believe the Proposed Amendment's true up

330.5 language may be mis-drafted as it appears to *not* allow true ups during the temporary pathway period.

This is confusing because, at both October 2020 and August 2022 LCFS Workshops, CARB Staff proposed providing a credit true up to correct for under crediting to pathway holders *only* during the period where a project is using temporary CI scores at the outset of their credit generation. At the time, CARB workshop material stated that such a limited true up would help reduce the pressure on CARB from developers to process LCFS applications quickly.

330.4 cont. We continue to support a full true up to verified actual CI performance for all pathways (temporary, provisional, and fully certified).[10] As an anaerobic digester is going through its application period, it is often assigned a carbon intensity score that substantially underestimates the greenhouse gas benefit (and associated lost revenue) during the project's startup period. This will lead to increased pressure on CARB developers to process LCFS applications quickly - something that CARB was actively hoping to avoid - as digestor operators scramble to make their investments viable. If pathways were allowed to fully "true up" their LCFS credit generation to their actual CI score, once that score was able to be calculated based on actual greenhouse gas performance data, these problems can be resolved.

330.5 cont. The current LCFS regulation requires an annual verification to determine the true CI score, relative to the certified CI score. But the result of that annual verification is that pathway holders can only give up credits if their actual CI score goes up—they cannot also gain credits if their verified CI score goes down. We believe that, absent some manipulation or misrepresentation, the exchange should go both ways. With proper safeguards around the timing of the true up and potentially some requirement to hold credits in

---

[10] See the Renewable Natural Gas Coalition's comment letters from prior workshops dated January 7, 2022, August 8, 2022, and September 18, 2022.

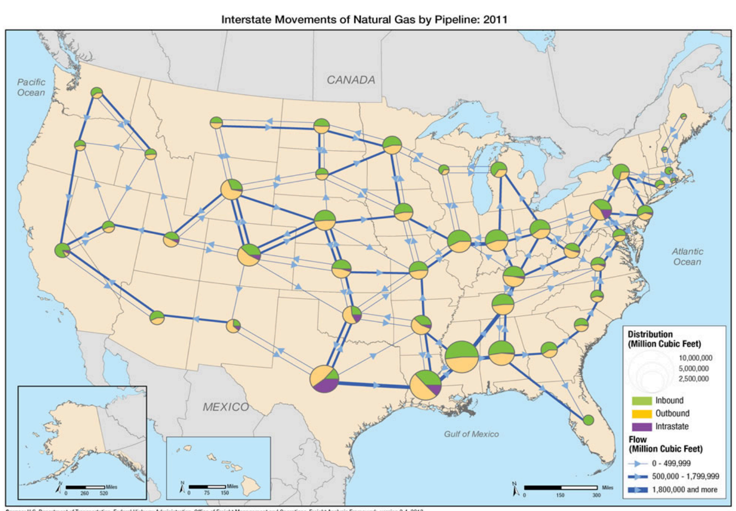
330.5 cont. reserve, this policy can serve to encourage very low carbon pathways whereas the current policy discourages very low carbon fuels in favor of less variable fuels.

330.6 **Because it is Physically Interchangeable with Fossil Natural Gas, Renewable Natural Gas can be Distributed in the Same, Longstanding Natural Gas Pipeline System that has Served California for Decades. This System Can Move Gas Across North America, therefore, a 50% Flow Requirement is Arbitrary and Unjustified.**

In the Proposed Rule, CARB staff is proposing a deliverability requirement on biomethane projects and is requiring projects to demonstrate that eligible biomethane is carried through common carrier pipelines that physically flow within California or toward end use in California 50% of the time on an annual basis. Divert understands that this requirement would be put in place to ensure that California is making progress on the State’s methane reduction targets, but the requirement would be detrimental to projects that are aimed at helping the state realize its short lived climate pollutant goals.

Natural gas currently flows throughout the United States depending on shifts in production, demand, weather, export pricing, and natural gas balancing. All major North American gas pipelines are interconnected, sharing gas flow and balancing, which can be contrasted with the power sector that is a more balkanized grid with limits on wheeling between regions—despite the efforts mentioned above to increase interconnection of the power grid.

When RPS limitations were developed, gas was just beginning to come from all over the country to California. The map below shows cross-country flows, dating back to 2011, illustrating the interconnectedness of the natural gas pipeline system in the United States.[11]



Since the RPS provisions were developed, the gas system has only grown more interconnected. For example, natural gas now flows from the Northeast region to all areas of the United States, from Texas to

[11] U.S. Department of Transportation Federal Highway Administration, *Interstate Movements of Natural Gas by Pipeline: 2011 Map*, https://ops.fhwa.dot.gov/freight/freight_analysis/nat_freight_stats/interstatenatgas2011.htm (last modified Mar. 23, 2020).

330.6 cont. California, and from the Rockies to California. The entire pipeline system in the United States is interconnected and in many cases is now bidirectionally flowing.

Natural gas has long been distributed through pipeline systems tracking volumes being injected and withdrawn throughout the entire system. These volumes are carefully tracked, as the pipeline system typically has state and federal oversight and third-party pipelines have metering throughout the system. Not only does this create a robust and liquid market for physical gas delivery across North America, that market already optimizes moving gas from supply to demand in a least cost (and lowest GHG)[12] fashion.

Given the interconnected nature of the US Gas pipeline, deliverability requirements can create a difficult burden on producers of natural gas to prove compliance. In addition, it will limit the production of biomethane for use in organics processing and in sectors that are hard to electrify. We strongly recommend that CARB avoid implementing deliverability requirements and instead maintain the status quo of the program to allow for book and claim for RNG Programs across North America. As California currently sets the precedent for the nation's decarbonization efforts, it is crucial that the state accept book and claim requests for projects across North America to better incentivize states to decarbonize. As new states adopt LCFS programs, it is important to consider what such a precedent would create as they adopt policies championed by CARB. Instead, Divert would welcome the opportunity to work with CARB to better explain the ramifications of such a policy move and discuss alternatives for a productive outcome.

330.7 **Increased Program Ambition as it is Critical for Continued Methane Reduction and Growth in All Low Carbon Fuels**

We support the effort that CARB staff has taken to outline future scenarios that set forth carbon intensity reduction goals for 2030 and beyond, however we feel that the biggest barrier to continued LCFS-driven methane reduction is the Proposed Rule's lack of overall ambition. Given the LCFS credit surpluses seen over the past two years and as CARB staff has highlighted in several of their recent workshops, the LCFS program has significantly exceeded expectations and low carbon fuels are coming to the market quicker and in greater volumes than previously anticipated. With this success, a significant step-down in the Annual Carbon Intensity (CI) Benchmarks is critical at this time. Based on all recent market information to date in 2024, the program will have produced many more credits than deficits. This will cause the bank to continue to build rapidly, prices to fall, and low-carbon investment to decline.

We urge CARB to adopt goals to reduce this trend and promote a healthy market. To accomplish this goal, CARB must adopt the appropriate stringency trajectory for the CI Benchmarks. Throughout this rulemaking process, a diverse group of clean fuel voices have contracted with the consulting firm ICF to independently prepare and submit an analysis of what program targets are feasible. In their analysis they are recommending that:

---

[12] Moving gas requires additional energy and emissions from compression stations and potential methane leakage. These factors are already correctly accounted for in the LCFS CI modeling, which assumes physical gas flow from source to sink, regardless of the ability to trace actual molecule path. This provides a fair and appropriate disincentive that recognizes GHG disbenefits of moving gas from projects located farther from California, all else equal.

A 2025 Target of >25% is Needed to Address Current Oversupply Issues. This Level of Ambition Should also be Implemented in Q3 or Q4 of 2024, if Administratively Possible.

330.7a cont. The ICF work demonstrates that increasing the program's benchmarks to set a 25% CI reduction below the 2010 Baseline in 2025 would be sufficient to begin to draw down the credit bank, reestablish a demand for additional expansion in low carbon fuel supply, and therefore drive additional greenhouse gas
330.7b abatement. Further, starting the step-down as soon as possible and avoiding unnecessary bank build is crucial. We recommend that CARB target the step-down to occur on 7/1/2024 to a level of 25% below the 2010 baseline and maintain that level through 12/31/2025 (assuming CARB elects to retain the updated 2010 diesel baseline value).

330.7c *A 2030 Target of >30% can be Achieved with a Lower Credit Price Trajectory than Predicted in CARB's Modeling of the Primary ISOR Scenario*

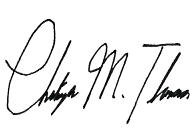
ICF's work shows significantly different LCFS credit price outcomes than CARB's ISOR analysis of the primary scenario. We believe that ICF's outlook is better informed by the true near-term supply outlook across all low carbon fuels and a better understanding of the potential other areas of public policy support (e.g., federal biofuel policy). Given that this deeper understanding demonstrates that it is possible to achieve greater mid-term reductions, we recommend that CARB continue to target at least a 30% CI reduction by 2030.

Conclusion
By considering the above recommendations, CARB staff has the opportunity to inspire further innovation in the low-carbon fuel sector while ensuring that the state does not prematurely reverse its historic emissions reduction accomplishments. These suggestions will strengthen the LCFS program by:

- Incorporating new innovations in emissions reduction and inspiring additional carbon reduction operational improvements.
- Ensuring that the LCFS program prioritizes the removal of short lived climate pollutants by keeping incentives in place to develop necessary organics infrastructure
- Creating opportunities for a cohesive and uniform RNG marketplace across North America

We would welcome an opportunity to discuss these suggestions further and additionally talk through our operations to provide further context to our suggestions. If you have any questions, please do not hesitate to contact me at cthomas@divertinc.com or at 202-421-1107. We are eager to collaborate further on this critical effort.

Sincerely,



Chris Thomas
Vice President of Public Affairs

DEFENSORES DEL VALLE CENTRAL
PARA EL AIRE Y AGUA LIMPIO

CENTRAL VALLEY DEFENDERS
FOR CLEAN AIR AND WATER

February 20, 2023

Liane M. Randolph, Chair
California Air Resources Board
1001 “I” Street
Sacramento, CA 95814

Submitted via CARB’s online Comment Submittal Form

Re: San Joaquin Valley Community Resident Opposition to the Proposed LCFS Amendments

Dear Chair Randolph and members of the CARB board,

We are Defensores del Valle Central para el Agua y el Aire Limpio (Central Valley Defenders for Clean Air and Water) a group of residents from the San Joaquin Valley who have come together out of the need to defend our right to healthy neighborhoods. Our mission is simple, to promote and enforce policies and practices that decrease pollution, degradation of the environment, and other negative impacts from dairies on vulnerable communities and the region.

For almost two years, our group has played an active role in ensuring the concerns of our communities, regarding the proliferation of factory farm gas and its harmful effects on our health, are addressed by CARB in the LCFS rulemaking update. Unfortunately at every turn, CARB staff ignores our concerns and blatantly tries to erase our lived experiences and the impacts we live with every day, from the expansion of factory farm gas infrastructure, like digesters and pipelines near our communities.

331.1 As Environmental Justice communities in a region with poor air quality, high levels of asthma and other respiratory illnesses, a lack of public health infrastructure, and many of us without clean and affordable drinking water, we demand that CARB eliminate avoided methane crediting and use the power the legislature gave them to initiate a rulemaking to directly regulate emissions from manure.

331.1 cont. Below you will find a collection of comments from a few members of Defensores urging you to think about how staff proposals, that did not mention any community concerns, must and should take those concerns into account in this rulemaking.

"I have lived in Pixley, CA for over 47 years. I have come to this body in Sacramento, over Zoom, the phone, and some of you have even visited Pixley to hear our stories. Unfortunately, it seems like you have not heard or listened to the yells from our community. One mile north of Pixley is a dairy digesters cluster where factory farm gas is being produced. The smell of ammonia and concentrated cow manure has only gotten worse in Pixley. We are surrounded by dairies and their digesters, the truck traffic in our community keeps getting worse, and people in our community are suffering from the air quality impacts. There are three generations of people in my family that use a CPAP machine, my 36-year-old son, my 11-year-old grandson, and myself, Sadly, this is not a unique story in my community, in fact respiratory illnesses have become a "normal" thing for us. This is why we need your leadership more than ever because our communities can not wait."

Maria Arevalo, Pixley

"I live in Santa Nella and was raised in the Central Valley. Since the inception of digesters, there has never been any intention of actually engaging communities in this process. In the past, meetings did not provide translation, outreach was not conducted, and materials were not accessible to non-English speakers. Now, you ask us to attend workshops and you meet with us, only to not mention our concerns in your documents at all. In addition to ignoring what the community has to say and trying to erase us from your record, there was not one mention of public health in your document and the already existing problems many SJV communities face. You are contaminating our air, water, and all for companies that are not even in our communities. We have needs in our communities to improve our local air quality and not line the pockets of investors who have never had to live with the smell day in and out. We ask the board to consider public health for all over profit for some."

Patricia Ramos-Anderson, Santa Nella

"CARB must regulate the dairy industry. We have to endure the flies, the odors, and the air quality impacts. Many people in my community live with Asthma. The dairy industry impacts our air and water quality. I worry about our safety and our health. CARB must have regulations on the dairies manure."

Josefa Gonzalez, Pixley

"I stand with my partners in community demanding justice for our communities that are already overburdened with pollution. We do not need more mechanisms in our communities to make us sick, you should be investing in community-identified measures to improve the health of our air."
Tere Ochoa, Los Banos

"I've been living here since 1960. Hillcrest arrived in 2002 with over 3,000 cows. In 2012 they

331.1 cont. *were out of compliance with Merced County with over 8,000 cows. Our Town population is only a little bit over 4,000. I've gone to the Board of Supervisors in Merced County to complain with a group of citizens as well but it goes and it falls on deaf ears. In January 2024, CARB could start a rulemaking for the regulation of methane, but to this day we have not heard any desire from staff of the board to begin this process. California Regulators have not adequately evaluated this program as to local air and small communities so we implore your help communities, just like Pixley and Planda and any other small town that just want to breathe."*

David Rodriguez, Planada

We thank you for your time and consideration and look forward to a better program that does not disproportionately impact our communities.

Sincerely,

Defensores del Valle Central Para el Aire y el Agua Limpio
Central Valley Defenders for Clean Air and Water

SUBJECT: SUPPORT Proposed Amendments to the Low Carbon Fuel Standard Regulation

Dear Chair Randolph and Honorable Board Members,

CALSTART appreciates the opportunity to submit comments on the proposed amendments to the Low Carbon Fuel Standard (LCFS) program. Since its initial implementation in 2011, the LCFS program has allowed California to decrease carbon in the state's fuel pool and accelerated new technology and alternatives to petroleum fuel. The program has also served as a valuable incentive program in helping bring new companies and their ideas for zero-emission fuels and technology into the state's fuel market.

CALSTART and our Origins

CALSTART, headquartered in California, is a globally renowned 501(c)3 nonprofit organization dedicated to the advancement of zero emission vehicle and infrastructure technology. With a global member consortium of more than 300 technology, government, industry, and community partners, CALSTART has worked for 30+ years to accelerate the commercialization and deployment of advanced technologies and solutions. Through policy development, incentive program administration, and first-of-its-kind deployment partnerships, CALSTART has designed and managed programs that drive the market for clean transportation technologies needed to achieve critical greenhouse gas and criteria pollutant emission reduction goals.

Comments on the Proposed Amendments to the Low Carbon Fuel Standard

In July of 2022, Governor Newsom wrote a letter to California Air Resources Board (CARB) Chair Randolph[1] pushing for "greater opportunities to reduce our dependence on fossil fuels to achieve our air quality and climate targets," and continue the diversification of fuels away from petroleum in the transportation sector. Part of his ask was to evaluate and consider an increase in the stringency of the LCFS. Shortly thereafter the CARB Board approved the 2022 update to the Scoping Plan including increasing the stringency of the 2030 greenhouse gas (GHG) reduction target to 48 percent below 1990 emissions and putting the state on track to achieve carbon neutrality by 2045, or earlier. CALSTART strongly supports CARB's efforts to increase its ambition to deliver needed GHG reductions to help stave off the most serious impacts of climate change—impacts that disproportionately harm our most vulnerable populations.

Increased Stringency

To that end, CALSTART believes there are opportunities to improve the proposed amendments to deliver additional greenhouse gas emissions reductions. There are two key adjustments that CARB can make to the stringency as part of the 15-day change process. Specifically, by increasing the step-down and pulling forward the effective date for triggering the Auto Acceleration Mechanism (AAM) CARB can deliver additional reductions in GHG emissions. These reductions will be lost with the current proposal and by doing so will send a clear, and supportive market signal to continue investments in clean fuels.

332.1 The proposed 5% step-down in stringency does not go far enough considering the size of the cumulative credit bank, which is anticipated to increase its rate of growth as new clean fuels come to market. CALSTART strongly encourages the step-down must be increased by ***at least*** seven percent (7%), translating into a 2030 target of at least thirty-two percent (32%) reduction in the carbon intensity (CI) relative to the 2010 baseline. While a 7% step-down will likely leave many credits in the cumulative credit bank, this single adjustment will translate into millions of additional tons of greenhouse gas emission reductions and strengthen the market in the process.

332.2 As designed, the first year that the AAM could impact program stringency is 2028---which is far too long in the event the cumulative bank continues to grow. The concept and need for the AAM is to respond to clear overperformance of the program and to send an unambiguous signal to investors that the program will respond to opportunities to deliver additional GHG reductions. The AAM should be based on 2025 data with the trigger assessment occurring in May 2026, and the AAM being applied in 2027 providing the applicable conditions are met, thus increasing program stringency for 2027. Relying on 2025 as the first eligible year for triggering the AAM is appropriate as one of the main objectives of the step-down is to bring the program into balance. Therefore, assessing the impact of the step-down on the market based on 2025 data, including the cumulative bank and the rate of credit to deficit generation, is aligned with the principles of the program. With this approach, the AAM could potentially increase the stringency of the program in 2027 and 2029 (i.e., triggered twice prior to 2030), better ensuring that potential emission reductions are not left on the table in the event the program continues to overperform following the Board's adoption of the amendments. Furthermore, it is important to note that the 3:1 ratio (i.e., cumulative bank/average quarterly deficits) proposed by staff that would trigger the AAM is likely inadequate. For example, in 2022, a year where there is consensus that the LCFS was overperforming, the AAM would not have been triggered using CARB's current proposal.

Support Full Range of Medium/Heavy Duty Zero Emission Transportation

332.3 CALSTART strongly supports staff's proposal to change the Clean Fuel Reward program from a focus on new light-duty EV rebate, to rebates for new and used medium- and heavy-duty zero emission trucks that are exempted from the Advanced Clean Fleets regulation. CALSTART believes this will be hugely impactful in transitioning currently unregulated fleets. Additionally, CALSTART is appreciative of the proposal to expand ZEV infrastructure crediting to the medium- and heavy-duty sector to support ZEV infrastructure needed for medium- and heavy-duty ZEVs. However, there are areas where CALSTART believes the regulation needs additional consideration and
332.4 modification. CALSTART recommends that CARB create parity between how the Fast-Charging Infrastructure and Hydrogen Refueling Infrastructure credits are treated under the program. The proposed regulation gives preferential treatment to hydrogen stations over electric vehicle charging stations when assigning the CI for capacity credits. We

332.5

encourage CARB to harmonize hydrogen refueling and EV charging. Additionally, CALSTART recommends that the geographic restrictions be modified. ZEV charging behavior does not necessarily mirror conventional fueling, nor that of light duty charging infrastructure. Specifically, MHD ZEV charging can be located where vehicles are domiciled and used, which may not be within one mile of a highway corridor. While the current proposal will support regional and long-haul trucks by incentivizing infrastructure along freight corridors, CALSTART believes the LCFS should support the full range of truck vocations, including drayage and short haul.

Conclusion

The LCFS program continues to be one of the best drivers for reduction of carbon in fuel and opportunities to incentivize and promote investments in cleaner fuel and zero-emission infrastructure. It is a necessary program to ensure the reduction of carbon intensity in the transportation sector while adoption of ZEV is accelerated. The basis of the program should be adopted by other states in the country, and CALSTART will continue to push for multi-state adoptions based on California's LCFS program's successes.

Thank you for your time and consideration. Please feel free to reach out if there are any comments or questions.

Trisha Dellolacono
Head of Policy
CALSTART

The Honorable Liane M. Randolph, Chair
California Air Resources Board
1001 I Street
Sacramento, CA 95814

RE: Comment on Draft Amendments to the Low Carbon Fuel Standard (LCFS) Regulation

Dear Chair Randolph,

On behalf of the Low Carbon Fuel Coalition Working Group on Biomass, we appreciate the opportunity to provide comments on the Draft Amendments to the LCFS Regulation. Our working group supports the overall objectives of the LCFS program and would like to express our specific recommendations for enhancing the inclusion of biomass feedstocks in the regulation.

Expanding Forestry Waste Feedstocks for Emission Reductions:

We strongly support the inclusion of additional waste feedstocks (§95488.8.g), specifically focusing on forest residues removed for forest fire fuel reduction or forest stand improvement as included in *§95488.8.g:*

(1) Pathways Utilizing a Specified Source Feedstock. In order to be eligible for a reduced CI that reflects the lower emissions or credit associated with the use of a waste, residue, by-product or similar material as feedstock in a fuel pathway, fuel pathway applicants must meet the following requirements.

a. Specified Source feedstocks include:

3. Small -diameter, non-merchantable forestry residues removed for the purpose of forest fire fuel reduction or forest stand improvement and from a treatment where no-clear cutting occurred; Municipal solid waste that is diverted from landfill disposal;

While the proposed regulation includes some forestry residues, we propose expanding this section to encompass all materials generated from essential forest management practices to adequately respond to the urgency of California's wildfire crisis, the resulting threat to human life, and the massive GHG and criteria pollutant emissions from wildfires and open burning. California's 2021 Wildfire and Forest Resilience Action Plan underscores the critical need to dramatically expand intensive forest management to mitigate wildfire risks [1]. The plan emphasizes the role of large-scale thinning and other management activities in reducing long-term greenhouse gas (GHG) emissions and air pollution associated with catastrophic wildfires. This aligns with the ambitious goal of managing 2.3 million acres of Natural Working Lands (NWL) set by the CARB 2022 Scoping Plan[2]. Utilizing residues from these activities as biomass feedstocks not only supports wildfire prevention but also offers a lower-emission alternative to traditional fuels. However, the ambiguous language in the proposed regulation will inhibit or preclude biomass utilization.

The current language presents three challenges:

[1] California's Wildfire and Forest Resilience Action Plan. California Wildfire Task Force. April 2022. Retrieved from https://wildfiretaskforce.org/wp-content/uploads/2022/04/californiawildfireandforestresilienceactionplan.pdf
[2] California Air Resource Board - 2022 Scoping Plan for Achieving Carbon Neutrality, November 16, 2022

- **Ambiguity:** Vague terms like "small-diameter, non-merchantable" hinder feedstock evaluation and create uncertainty for developers.

333.1
- **Inconsistency:** Lack of alignment with established federal and international standards (RFS, RSB) represent a challenge for securing eligible feedstocks under multiple regulatory frameworks.
- **Rigidity:** Failure to recognize that California is experiencing a wildfire crisis that the State and Federal Governments have recognized requires massive fuel reduction activities that will result in increasing quantities of forest biomass that must be open burned if the material cannot be utilized in a beneficial manner.

For example of this ambiguity and inconsistency, please see the table below:

Standard	Thinnings description	Definition/Questions
Proposed California language	Small -diameter, non-merchantable forestry residues	How will "non-merchantable" be interpreted since thinnings can generally be sold albeit at a much lower value than saw timber.
RFS	Pre-commercial thinnings	Pre-commercial thinnings are trees, including unhealthy or diseased trees, removed to reduce stocking to concentrate growth on more desirable, healthy trees, or vegetative material that is removed to promote tree growth.
RSB	Early/non-commercial thinnings	Thinnings performed for sivacultural or ecological reasons; including pre-commercial thinnings (i.e., thinnings of trees with a typical breast height diameter (DBH) below 10 inches.)

To address the challenges and encourage necessary biomass utilization in California we propose:

1. **Expand eligible feedstocks:** Include all forestry residues from forest management practices approved by the authorized tribal, federal, state or local agency.

333.2
2. **Adopt clear, consistent definitions:** Align with established standards for terms like "thinnings" and "residues" where possible, while still allowing flexibility for site specific forest management practices.
3. **Stakeholder Engagement:** Gather input from diverse groups to refine definitions and implementation procedures that will maximize forest health.

Additional Considerations:

- **Clearcut materials:** We propose revising the total exclusion of clearcut-derived biomass wastes and residues. Tightly regulated clearcutting practices ensure sustainability[3], and utilizing these residues offers environmental benefits without encouraging further clearcutting. Furthermore, the rationale for this exclusion has not been supported by stakeholder interaction at CARB workshops.

---

[3] California Forest Practice Rules in Title 14 of the California Code of Regulations (CCR) Section 921.3(c)(1)

- **Pre-2008 plantations:** Similar to the 2015 Compliance Offset Protocol, consider including materials from pre-2008 plantations meeting California's Forest Practice Rules[4].

Inclusion of Agricultural Residues Under Waste Definition:

We strongly support the proposed inclusion of additional waste biomass under §95488.8.g. Additionally, we urge for the explicit definition and inclusion of agricultural residues such as crop residues including
333.3 corn stover, wheat straw, sugarcane trash and bagasse, orchard prunings, and vineyard prunings, and orchard trees.

CARB's website acknowledges the current practice of burning these residues, which contributes to GHG emissions and air pollution[5]. Burning leads to GHG emissions and air pollution. By utilizing these materials as fuel feedstocks, we can convert waste into a valuable resource while reducing emissions.

Therefore, we recommend explicitly defining agricultural residues as eligible waste feedstocks within the LCFS program. This clarity will facilitate their incorporation and promote investments in diverse fuel types.

Inclusion of Lumber Mill Residue Under Waste Definition:

333.4 We strongly urge CARB to support the inclusion of lumber mill waste as a waste feedstock. This prevents landfilling and aligns with the broader environmental goals of the LCFS program.

Attestation Requirements for Waste Feedstocks:

333.5 We appreciate the importance of maintaining a rigorous chain of custody for all waste feedstocks and support the amended text under §95488.8.g.D regarding supplier attestation letters:

> ***Requirements for Feedstock Attestation Letter***. *Each specified source feedstock supply chain entity must maintain a specified source feedstock supplier attestation letter. Supply chain entities supplying biogas or biomethane used as a feedstock must follow the requirements under section 95488.8(i)(2). The specified source feedstock supply chain entities include points of origin, collectors, aggregators, traders, distributors, and storage facilities that participate in the supply chain from point of origin to the fuel producer for specified source feedstocks. The attestation letter must attest to the veracity of the information supplied, declare that the information accurately represents the specified source feedstock(s), and conform to the requirements of this subsection. The specified source feedstock attestation letter must make the following specific attestations:*

However, we seek clarity and flexibility on the specific definitions introduced in this requirement. For example, regarding traceability to "point-of-origin", we suggest clarifying the language to define the point-of-origin for biomass wastes as the location where the waste or the residue was generated. In this case, forestry residues would be traced to the specific timber stand, and lumbermill waste to the lumbermill. Bills of lading, already used for chain of custody purposes, should be an acceptable verification method.

---

[4] Section 5.2.1(e)(1)(D)
[5] https://ww2.arb.ca.gov/our-work/programs/agricultural-burning

333.6 We recognize potential challenges in applying these requirements to certain feedstocks, like sawdust, where tracing the origin throughout the entire supply chain might be impractical or infeasible. Therefore, we urge CARB to consider a more flexible approach for such specific cases. This flexibility could involve:

- Alternative verification methods: Accepting alternative forms of documentation or verification mechanisms suitable for the specific feedstock type.
- Focus on key points: Prioritizing attestation requirements on critical stages of the supply chain, such as initial collection and final delivery, rather than demanding origin details for every intermediary step.
- Tiered approach: Implementing a tiered system where the level of detail required in the attestation letter varies depending on the feedstock type and potential risks associated with its origin.

By adopting a more nuanced approach, we can ensure the integrity of the program while also fostering the utilization of diverse and potentially important waste feedstocks.

Sustainability Requirements:

We acknowledge the importance of establishing sustainability requirements for crop-based and forestry-based feedstocks under §95488.9.g to safeguard environmental integrity within the LCFS program:

> *(g) Crop-based and forestry-based feedstocks must not be sourced on land that was forested after January 1, 2008. A forest is as defined in section 95481 or where they are protected by international or national law or by the relevant competent authority for nature protection purposes.*
>
> *All crop-based and forestry-based feedstocks used for LCFS fuel pathways must meet the following sustainability requirement:*
>
> (1) *Maintain continuous third-party sustainability certification under an Executive Officer approved certification system.*
>
> (A) *All feedstocks at the point-of-origin must be certified by January 1, 2028. Fuel quantities reported under fuel pathways utilizing feedstocks not certified by January 1, 2028 must be assigned the ULSD carbon intensity found in Table 7-1 of the LCFS regulation.*
>
> (B) *The Executive Officer will review and may approve certification systems based on the following criteria:*

However, we raise concerns regarding the potential impact of mandatory third-party certification on forestry residues essential for wildfire prevention, particularly those originating from unmanaged lands.

333.7 While we agree with the principle of ensuring sustainable sourcing, applying a uniform certification requirement might pose undue challenges for wildfire abatement efforts. Unlike residues from managed forests, those obtained from unmanaged lands often lack established management practices and readily available certification pathways. The prohibitive expense of acquiring individual certifications for each instance of wildfire fuel reduction could hinder critical activities essential for forest health and wildfire abatement.

Therefore, we urge CARB to consider a nuanced approach that acknowledges the unique circumstances surrounding wildfire abatement residues.

Inclusion of Biomass as a Process Fuel:

333.8 We advocate for the inclusion of biomass as a process fuel within the LCFS program, recognizing its potential to contribute to GHG emission reductions and energy diversification.

The omission of biomass derived process fuels creates several missed opportunities for utilizing biomass and decarbonizing California's transportation sector**.** Biomass can be a valuable source of process heat, power, and combined heat and power (CHP) in facilities like:

- Biomass gasification plants
- Corn ethanol facilities with CHP (utilizing corn stover or other biomass)
- Facilities requiring low-carbon intensity (CI) power

As a practical example, the current Tier 1 calculators for the sugarcane ethanol pathway only consider "externally sourced biomass," excluding the use of biomass within the production process itself. This narrow definition fails to capture the full potential for emission reductions and sustainable biomass utilization.

Therefore, we recommend explicitly including biomass process fuels within the LCFS program, and updating the proposed tier 1 calculators to include both internally and externally sourced biomass.

Urgency for Clear Biogenic Carbon Accounting Guidance for Biomass Feedstocks:

The proposed LCFS regulation lacks crucial details regarding how the carbon intensity (CI) of biomass feedstocks will be determined. This omission presents a significant hurdle for developers of biomass-to-fuel pathways.

Biogenic carbon accounting plays a vital role in calculating the overall CI of a pathway, which will ultimately determine a project's economic viability.

We urge CARB to urgently provide comprehensive guidance on biogenic carbon accounting for all biomass feedstocks within the LCFS program. Ideally, this guidance should:

333.9

- Establish categories of biomass: By establishing clear categories for biomass types, considering factors such as their origin, properties, and potential uses, CARB can streamline the process of biogenic accounting. For instance, forestry residues and agricultural wastes represent major biomass categories that can be further refined based on geographical sources and potential alternative fates. Categories of biomass should include thinnings and slash, wildfire risk removal material, agricultural residues, urban wood waste, and purpose grown biomass.

- Align with established federal policies: Harmonizing with existing biogenic carbon accounting frameworks under programs like the RFS, where GREET serves as the accepted modeling tool and biogenic carbon is treated as carbon neutral, would streamline processes and promote clarity for developers.
- Acknowledge wildfire abatement contributions: Recognize the unique context of forestry materials sourced for wildfire abatement. Thinning and utilizing these materials can significantly reduce uncontrolled wildfire emissions, leading to orders of magnitude greater CO_2 savings compared to the biogenic carbon sequestered in the feedstock itself due to the avoidance of collateral damage from catastrophic wildfires. A nuanced approach that factors in this mitigation potential is crucial.
- Offer flexible and practical pathways: Allow for flexibility for accommodate diverse feedstock types and projects.

Clear guidance will attract investment to biomass-to-fuel projects, accelerating California's transition to a lower carbon intensity transportation sector.

The Low Carbon Fuel Coalition Working Group on Biomass is committed to working collaboratively with CARB to refine and implement these recommendations. We look forward to discussing these recommendations with you further and working together to strengthen the LCFS program.

Antelope Valley Transit Authority

February 20, 2024

Rui Chen
California Air Resources Board (CARB)
1001 I Street
Sacramento, CA 95814

Re: Antelope Valley Transit Authority Comments on the Proposed Low Carbon Fuel Standard Amendments

Dear Mr. Chen:

Antelope Valley Transit Authority (AVTA) appreciates the opportunity to comment on the California Air Resources Board (CARB) proposed amendments for the Low Carbon Fuel Standard (LCFS). AVTA supports CARB's initiatives to advance California's climate change goals, including propelling the growth of the nascent heavy-duty charging infrastructure and zero emission vehicle (ZEV) market through
334.1 the LCFS. We encourage CARB to provide more specificity around requirements to receive DC Medium-and Heavy-Duty Fast Charging Infrastructure (MHD-FCI) credits, in order to ensure accuracy and allow for greater participation in the program.

About Antelope Valley Transit Authority

AVTA is a transit agency with 30 years of experience providing mobility and access to over 450,000 residents of the surrounding Antelope Valley region and northern Los Angeles County. AVTA operates a fleet of 100 buses for transit service with 83 fully electric buses dedicated for local service, 19 electric On Request Microtransit Ride Service (ORMRS) vans and 24 electric coaches dedicated to commuter service for over one million rides annually (post COVID ridership). AVTA is the first transit authority in the United States to achieve a 100% zero-emission fleet, and it accomplished this goal in 2022.

The Importance of MHD-FCI Credits and Specifications in Requirements

The LCFS is a critical program for advancing California's climate objectives, including the expansion of electric vehicle charging infrastructure. The funds generated from LCFS credits have had a powerful impact on AVTA's ability to operate and grow, and MHD-FCI credits will allow AVTA to further expand its DC charging network to accommodate its growing fleet and help the state meet its climate and transportation electrification goals.

42210 6th Street West | Lancaster, California 93534 | 661.945.9445 | avta.com

334.1 cont. The proposed amendments contain areas in which the language is ambiguous in regards to some aspects of the criteria for eligibility for MHD-FCI credits. In particular, § 95486.3(b)(1)(B)(2) states that proposed MHD-FCI chargers must be "located within one mile of a reading or pending electric vehicle Federal Highway Administration Alternative Fuel Corridor or on or adjacent to a property used for medium or heavy-duty vehicle overnight parking." It is unclear what form of measurement is used to determine the one-mile distance from an Alternative Fuel Corridor – options include a straight-line or "as the crow flies" distance (the length of the straight-line drawn from the station to the nearest exit on the Corridor), or a driving distance (the distance measured along the route a vehicle takes from the Corridor to the station). If a station is greater than one mile driving distance from a corridor due to road logistics, but it is less than a mile straight-line distance from the corridor, it is unclear whether the station would meet the criteria for MHD-FCI credits.

334.2 AVTA recommends that the one-mile requirement be measured using a straight-line distance and that this be explicitly stated in the language, both for clarity and accuracy, as well as to favor a slightly more inclusive policy with the added effect of promoting more heavy duty infrastructure development in the state. Heavy duty infrastructure is a nascent market that needs additional support in order to reach the state's transportation electrification and climate goals, and allowing for greater participation in this program is one way of providing such support.

It is for these reasons that we propose the following changes:

- Specify the means of measuring a one mile distance in § 95486.3 (b)(1)(B):

  "The proposed MHD-FCI chargers must be:
  1. Located in California; and
  2. Located within a one mile straight-line distance* of a reading or pending electric vehicle Federal Highway Administration Alternative Fuel Corridor or on or adjacent to a property used for medium or heavy-duty vehicle overnight parking, or has received capital funding from a State or Federal competitive grant program that includes location evaluation as criteria."
  *The length of the straight line from the charging station to the nearest exit on the Corridor.

We Appreciate the Transparent Amendment Process

We are grateful for your time and consideration of these comments. We look forward to working with you to support a renewed, strengthened LCFS that will keep the state on track to meet and exceed its climate goals. Please do not hesitate to reach out if you have any questions about AVTA or these comments.

Sincerely,

Judy Vaccaro-Fry, MBM, MPA

Executive Summary

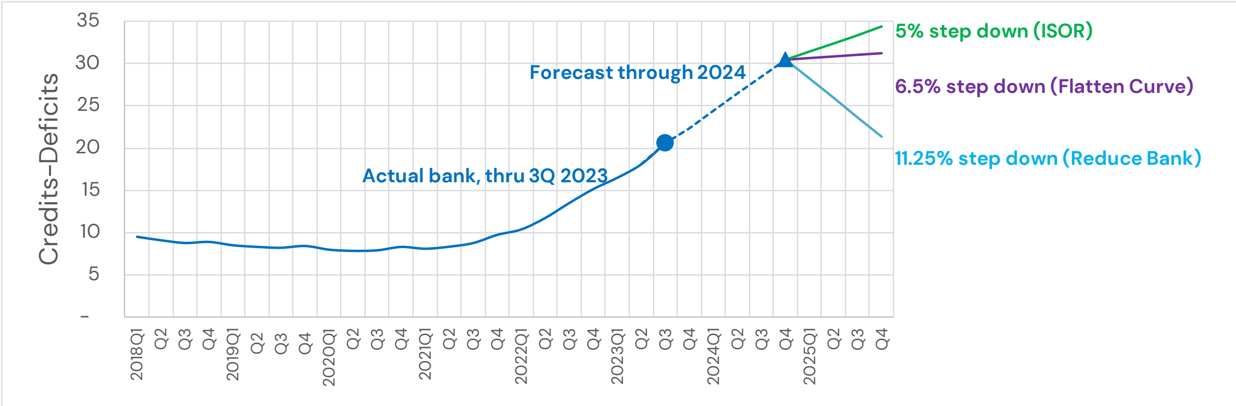
The California Air Resources Board staff released the Staff Report: Initial Statement of Reasons outlining many proposed amendments to the LCFS program in December 2023. The Staff Report identified three key areas of change with respect to carbon intensity targets: 1) increased stringency by 2030 (from 20% to 30% CI reduction), 2) a step down of 5% in the carbon intensity reduction required in 2025 (yielding an 18.75% carbon intensity reduction requirement compared to the 13.75% reduction scheduled), and 3) the introduction of an Automatic Acceleration Mechanism.

ICF previously reported that in an Accelerated Decarbonization *Central Case* a carbon intensity reduction target of 41-44% for 2030 is achievable for California's Low Carbon Fuel Standard program. ICF reached this conclusion based on expected fuel volumes and carbon intensity reductions for a wide array of low carbon fuel pathways. The work presented here, however, was prepared in direct response to the Staff Report and accompanying documentation published in December 2023. ICF modified and updated our analysis by focusing on a) an *ISOR Case*, b) the step down in 2025, c) the Automatic Acceleration Mechanism, and d) credit pricing.

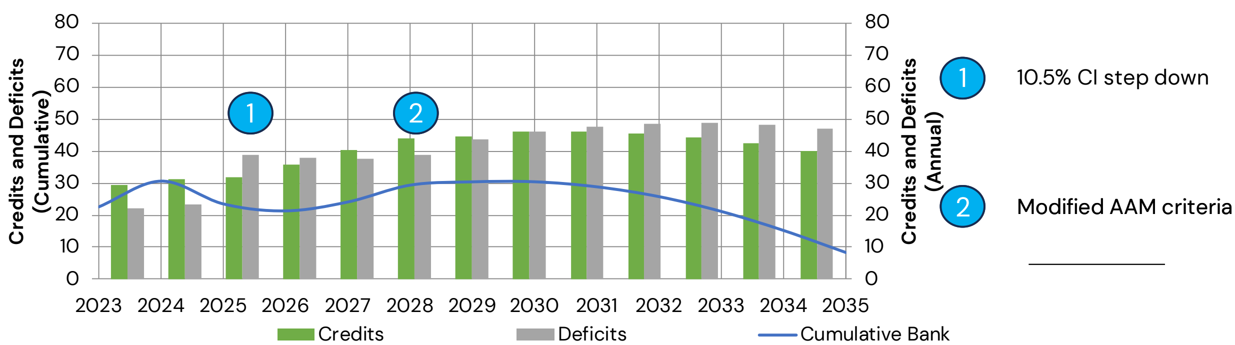
ICF developed the *ISOR Case* by modifying certain aspects of our modeling with the express intent of aligning more closely with the restrictions or constraints included in modeling done by Staff in support of the proposed amendments. ICF removed both the potential for a 15 percent blend of ethanol with gasoline and any pathways in the analysis that generated credits via the implementation of climate smart agriculture practices at the farm level. ICF also constrained renewable natural gas deployment in line with proposed changes to deliverability requirements and avoided methane emissions accounting. Lastly, ICF updated the carbon intensity value for ultra-low sulfur diesel in our analysis to align with the higher value published by Staff. ICF made other minor modifications to our analysis to reflect market developments that occurred over the course of the project.

335.1 ***ICF recommends a step down of 10.5% to 11.5% in 2025 to achieve a target credit bank equivalent of 2-3 quarters worth of deficits.*** This level of stringency is likely what is needed to achieve the stated intent of correcting for the "near-term over-performance" of the program. ICF's analysis indicates that the credit bank will likely continue to build significantly in 2025 if the step down is limited to 5%. ICF analysis suggests that a 6.5% step down is needed to ensure that the credit bank build is flattened in 2025.

335.1 cont.



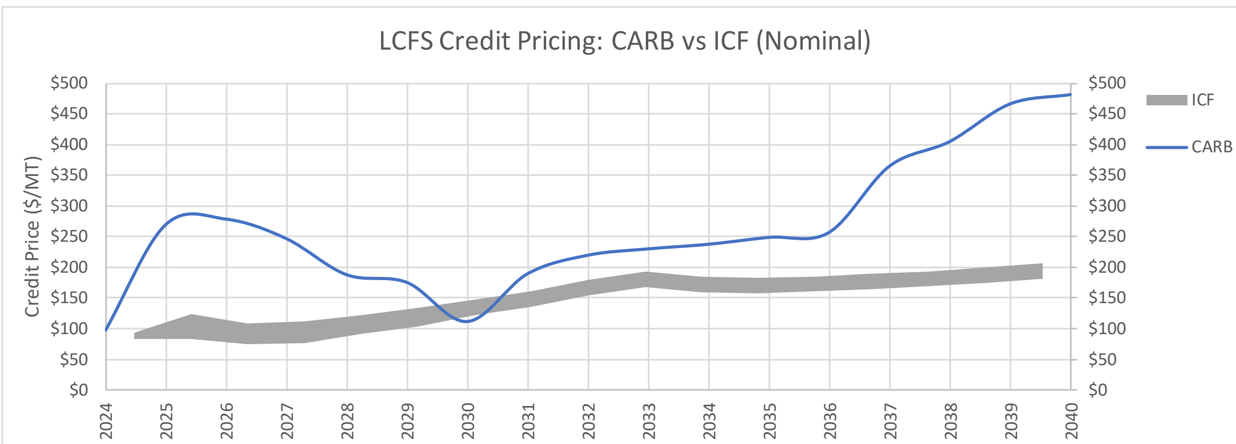
335.2 ***ICF recommends that the Automatic Acceleration Mechanism be considered for implementation as soon as 2026, rather than waiting until 2028. ICF also recommends that the first criteria for the Automatic Acceleration Mechanism be modified such that the mechanism is enacted when the credit bank is more than 2.5 times greater than the quarterly deficits generated in a given year*** (down from the proposed value of 3 times). The figure below shows the results of ICF's modeling using the *ISOR Case*.



The figure above has a shape and curve that ICF thinks is more in line with a successful Low Carbon Fuel Standard program i.e., one that maintains a tighter credit-deficit balance and is flexible enough to respond to market conditions in the near-term future (pre-2030), while enabling California to achieve its long-term GHG reduction targets. ICF's view of the market suggests that a focus on an "ideal" credit bank from pre-2021, quantified using a threshold of 3 quarters worth of deficits, is misguided and may lead to a market that "swings" up and down (as measured by the credit bank) more than necessary, thereby creating market uncertainty for active and would-be participants. Major investments by regulated parties in the last several years have likely improved their respective line of sight on credit generation, thereby reducing the need to carry such a large credit bank.

335.3 ***ICF recommends that Staff make more transparent the credit price modeling so that stakeholders can understand better what is driving the magnitude of credit pricing and the patterns emerging from the data.*** Staff used an internal estimate of credit pricing as

335.3 cont. one of the primary reasons for dismissing a higher carbon intensity reduction target in 2030. Staff claim that a higher target will lead to higher costs faced by consumers associated with pass-through compliance costs. However, Staff's forecasting is flawed and effectively implies that the Low Carbon Fuel Standard program will bear the entire cost of subsidizing low carbon fuel production. This analysis is overly pessimistic because it overlooks the substantial value of the Clean Fuel Production Credit via the Inflation Reduction Act, robust pricing from the federal Renewable Fuel Standard, moderate commodity pricing (e.g., for gasoline and diesel), and increasing California carbon allowance prices. The figure below shows a range of ICF forecasted credit prices in grey compared to the Staff credit price forecast in blue line.[1]



ICF makes three observations associated with the comparison between Staff's forecast and our forecast:

1. In the near-term future (by 2025), Staff is forecasting a four-fold increase in credit pricing. This forecasted credit price spike coincides with the introduction of the Clean Fuel Production Credit and other substantial Inflation Reduction Act incentives that will be flowing to the low carbon fuel market and reducing pressure on the Low Carbon Fuel Standard program.
2. In a post 2030 environment, though the two curves are showing similar patterns of increasing credit prices, Staff's forecast is still $60-65/ton higher than ICF.
3. Post-2035, Staff's forecasts are suggesting that a credit price of $250 to nearly $500/ton is needed to achieve program compliance. There is no reason that the credit price should ever need to be that high to induce the investments necessary to achieve compliance based on ICF modeling.

[1] Staff's credit price forecast has been adjusted to nominal dollars, as ICF has found this is how stakeholders tend to view the market (rather than adjusting pricing to some real-dollar basis).

1 Introduction

The California Air Resources Board (CARB) has proposed more ambitious carbon intensity (CI) targets to increase the stringency of the Low Carbon Fuel Standard (LCFS), with the intent of achieving more significant greenhouse gas (GHG) emission reductions in support of California's pursuit of economy-wide carbon neutrality no later than 2045. With respect to CI targets, CARB has proposed three key areas for change:

1. Increased CI stringency by 2030, increasing the target from 20% to 30% by 2030.
2. Additional 5% CI reduction in 2025 from the current CI target, also referred to as the step down. This step down in 2025 will yield an 18.75% CI target in 2025. The step down in 2025 is "in response to the near-term over-performance."
3. Introduction of an Automatic Acceleration Mechanism (AAM) that is designed to trigger a more stringent CI standard in the event of the market over-performing in the future (with over-performance measured by two criteria).

ICF is supporting a coalition of interested parties representing a diverse mix of low carbon fuel producers seeking to understand the potential carbon intensity reduction that could be achieved assuming the likely aggregate deployment of low carbon fuels and supporting technologies. Previously, in an Accelerated Decarbonization *Central Case*, ICF found that a carbon intensity target of 41-44% for 2030 is achievable based on expected fuel volumes and carbon intensity reductions for a wide array of fuel pathways.[2]

The initial stages of this project were focused on defining an ambitious CI target for 2030. However, the work presented here is in response to the Staff Report: Initial Statement of Reasons[3] and accompanying documentation published by CARB, and ICF has modified the analysis accordingly. The work presented here focuses on a) an *ISOR Case*, b) commentary on the step down in 2025 supported by ICF analysis, c) review of the AAM in light of likely low carbon fuel deployment to California out to 2030 (and beyond), and d) commentary on LCFS credit pricing.

As noted elsewhere, ICF's modeling differs from the modeling conducted by CARB staff using the California Transportation Supply (CATS) model. More specifically, CATS is described as a "transportation fuel supply optimization model" that "minimizes the cost of supplying fuel to meet demand in each year." In other words, given certain modeling constraints, namely a specific CI reduction trajectory and associated policy constraints, the

---

[2] In a *High Case* reflecting updated science and analysis, additional cost effective GHG reduction opportunities, and alignment with proposed federal policies, ICF reported that a carbon intensity reduction of 43% to about 57% could be achieved by 2030.

[3] Available online at https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf.

CATS model optimizes compliance accordingly. The CATS model is designed to answer the question: *What is the least-cost compliance pathway associated with a CI target of X in year Y?* ICF notes that CARB has used scenario modeling in previous analysis supporting amendments to the LCFS program and has provided no rationale for switching to an optimization model. ICF maintains that an optimization model is not the right approach for target setting because it puts an out-sized impact on the modeling inputs that are used to solve for what is more likely to be a preconceived outcome. Scenario modeling, when done correctly is more useful to understand market outcomes as they might be, rather than how the author(s) wants them to be.

2 ICF Analysis of the Staff Report

Developing an ICF *ISOR Case*

After reviewing the Staff Report and engaging in a peer-exchange with CARB staff, ICF made several changes to our modeling approach with the intent of aligning more closely with the work done by CARB and the resulting proposed regulatory structure. ICF refers to this as an *ISOR Case*. As a reminder, ICF was previously focused on the CI reduction that was achievable by 2030. In this *ISOR Case*, ICF sought to focus on details that were not available prior to the Staff Report, including the 2025 CI step down and the implementation of the Automatic Acceleration Mechanism. While still standing behind the modeling and assumptions previously employed, ICF made the following changes to the supply-demand for low carbon fuels to more closely align with CARB's modeling approach:

- ***E15 Blending Removed.*** ICF removed the opportunities for E15 blending in the modeling. CARB has signaled that they did not include E15 consumption in their modeling because it is not yet approved as a fuel for sale in California. ICF maintains that E15 should be included in the modeling given the high likelihood of approval before 2030 and the interest in E15 to help reduce retail gasoline pricing in line with SB X1-2 ("discussion of methods to ensure an adequate, affordable, and reliable fuel supply"). However, for the purposes of evaluating the 2025 CI Step Down, E15 blending was excluded.
- ***Climate Smart Agriculture Removed***. ICF removed LCFS credit generation attributable to climate smart agriculture from our modeling because CARB has indicated that they did not include this in their modeling, and ICF's intent in the ISOR Case is to align initial assumptions or modeling boundary conditions to the extent feasible with CARB. This had an impact on credit generation associated with liquid biofuels, including ethanol, biodiesel, renewable diesel, and renewable jet fuel. ICF maintains that California will likely find itself as a disadvantage compared to other states considering incentivizing GHG emission reductions at the farm-level. However, although ICF believes climate smart agriculture has the potential to

provide significant additional CI reductions and will be implemented in the LCFS subsequent to 2028, this was removed from our modeling for this analysis.

- ***Constrained RNG Deployment.*** ICF constrained RNG deployment based on changes to deliverability and avoided methane emissions accounting consistent with the Staff Report. The constraints also account for lower credit pricing in the near-term future because of the over-supply of credits occasioned by the current LCFS targets, thereby restricting investment opportunities. [4]
- ***Updated CI value for ULSD.*** ICF updated the CI value for diesel in 2025 based on the revised value published by CARB--the CI of ULSD increased from 100.45 g/MJ to 105.76 g/MJ. ICF modeling suggests that this will have a material impact on the program because biomass-based diesel (i.e., biodiesel and renewable diesel) have displaced more than 50% of ULSD in California. Without a concomitant change in the CI of biodiesel or renewable diesel, ICF analysis suggests that this will yield substantially more credit generation than previously forecast.

ICF made other minor modifications to our analysis based on the market developments that occurred over the course of the project. For instance, ICF revised upward our renewable diesel projections as a result of additional projects coming online, various projects passing significant milestones, and data released by CARB related to deliveries to California through 3Q 2023. ICF also made modifications to the average carbon intensity of fuels based on data available for 2023, including for ethanol, biodiesel, renewable diesel, renewable jet fuel, renewable natural gas, and electricity.

2025 CI Step Down

ICF views the 2025 CI step down as a critical juncture for the program. In our modeling, we first evaluated the following:

1. What is the impact of the proposed 5% CI reduction step down, yielding an 18.75% CI target in 2025?

As of the end of 3Q 2023, the credit bank surpassed 20 million credits, with a bank build of 2.25 million credits in the most recent quarter for which data are available. ICF forecasts that the program will have a bank of about 29-30 million credits by the end of 2024. ICF analysis suggests that the proposed CI step down will slow the bank build by about 50% compared to previous years; however, the credit bank is still likely to grow by nearly 4 million credits by the end of 2025.

[4] Note that ICF's initial assessment indicates that this constraint may restrict California's ability to achieve its methane reduction targets included in SB 1383. It is conceivable that SB 1383 targets are still met; however, this would likely require changes to procurement rules under SB 1440.

335.1 cont. ICF then sought to determine two things with our analysis:

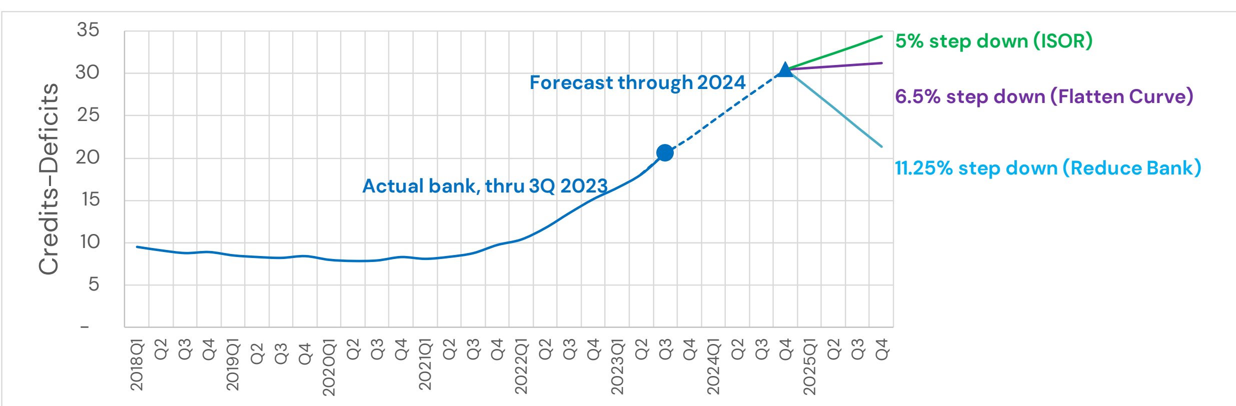
2. What CI step down is necessary to flatten the credit bank in 2025?
3. What CI step down is necessary to decrease the bank of credits to two quarters' worth of deficits?

With respect to the former, ICF modeling sought to identify the level of CI reduction that would be needed for the step down to *at least* flatten the curve of growing credits. ICF analysis shows that a CI of 20.25% in 2025 is likely needed to ensure that the credit bank does not continue to build.

With respect to the latter, ICF sought to identify the level of CI reduction that would be needed for the step down to reduce the bank of credits to about two quarters' worth of deficits in 2025. ICF analysis shows that a CI of 25% in 2025 is likely needed to ensure that the credit bank reverses and that the bank is drawn down to a level that is in line with a credit bank of only two quarters' worth of deficits. This level of stringency, while seemingly high, is likely what is needed to achieve CARB's stated intent of correcting for the "near-term over-performance" of the program.

The figure below illustrates the three aspects of the 2025 CI step down evaluated by ICF: the blue line shows the current credit bank inventory (20 million credits), the dotted blue line shows ICF forecasted credit bank by the end of 2024 (30 million credits), the green line shows the likely growth of the credit bank using CARB's proposed step down in 2025 (5% step down to 18.75% CI reduction), the purple line shows what ICF analysis indicates is needed to flatten the credit bank (6.5% step down to 20.25% CI reduction), and the light blue line shows that a CI step down of 11.25% to a 25% CI step down is needed to restore the program to an appropriate credit bank balance.

Figure 1. ICF analysis of the CI step down in 2025



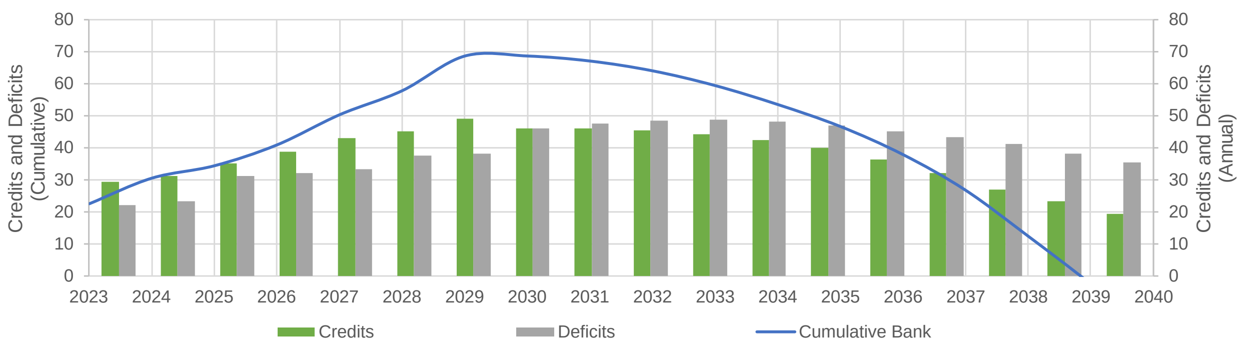
ICF recommends a step down of 10.5%-11.5% to reduce the cumulative bank of credits to the range of 2-3 quarters' worth of deficits by the end of 2025.

Automatic Acceleration Mechanism

The AAM is designed to accelerate the stringency of the LCFS program when certain criteria are met. CARB defined two criteria in the Staff Report: 1) when the credit bank is more than 3 times greater than the quarterly deficits generated in a given year and 2) when credit generation exceeds deficit generation. The Staff Report also indicates that the first year during which the CI reduction schedule can be impacted is in 2028, based on data from 2027.

Building on commentary regarding the CI step down in 2025, ICF's analysis indicates that if CARB keeps the 5% CI step down in 2025, that the credit bank will build in 2025, 2026, and 2027. In fact, by the end of 2027, ICF analysis suggests that the credit bank will reach 45-50 million credits. This will trigger the AAM in 2028 (based on 2027 data). ICF analysis suggests that the bank will be triggered again in 2030 (based on data for 2029)-getting the program to a 39% CI standard by 2030. The figure below shows the credit and deficit generation annually (green and grey bars, respectively) and the associated credit bank (blue line) using CARB's CI trajectory, including the CI step down in 2025, and the AAM as proposed.

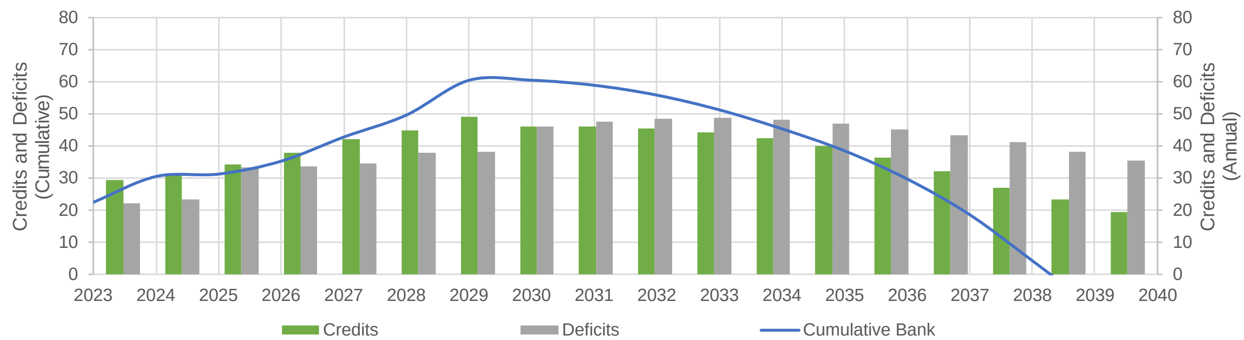
Figure 2. Credit-Deficit Balance in the ICF ISOR Case



In the long-term future, the AAM modifies the trajectory of the program post-2030. However, the short-term impact is muted-the CI step down does not achieve the objective of reversing the credit bank, and delaying the AAM until 2028 slows credit growth, but does not reverse the credit bank build until 2031. The shape of the curve in the figure above is appropriate, but the magnitude of the credit bank is too high to drive higher credit prices.

335.2 cont. Implementing a more stringent CI step down in 2025 will reduce credit generation but will still likely lead to credit generation post-2025, and the AAM will be inadequate to reverse the credit bank build until 2030.

335.2 cont. Figure 3. Credit-Deficit Balance in the ICF ISOR Case, with 6.5% CI stepdown in 2025

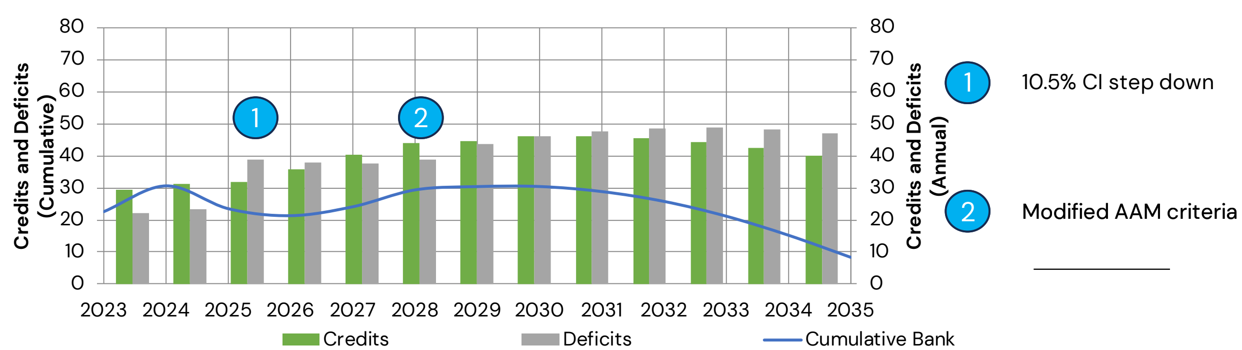


ICF analyzed the ISOR Case using the following assumptions:

- A CI stepdown of 10.5% in 2025 that would require a CI reduction of 24.25%. We adjusted the targets between 2026 and 2030 linearly while maintaining the 30% CI reduction in 2030 and post-2030 CI reduction schedule included in the Staff Report.
- An AAM that is implemented similarly as to what is used in the Staff Report, but adjusting the threshold to being triggered when the credit bank is more than 2.5 times greater than the quarterly deficits generated in a given year.

The figure below shows the results of the ISOR Case using the parameters described above.

Figure 4. ICF ISOR Case with larger CI step down and modified AAM



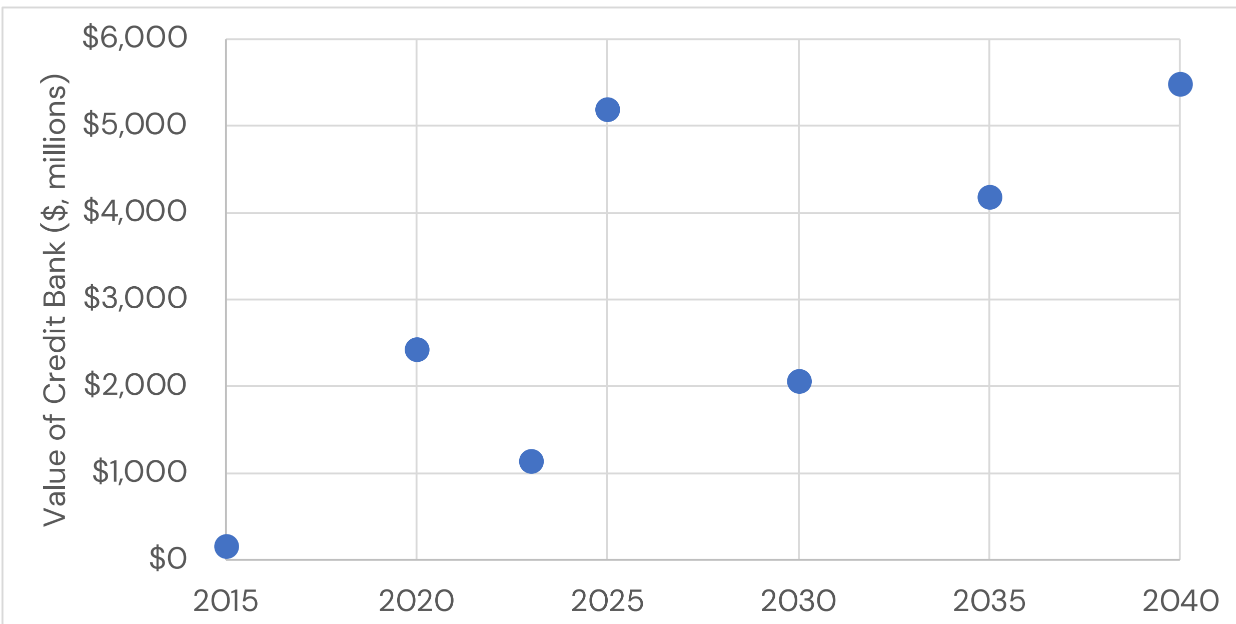
The figure above has a shape and curve that ICF thinks is more in line with a successful LCFS program i.e., one that maintains a tighter credit-deficit balance and is flexible enough to respond to market conditions in the near-term future (pre-2030), while enabling California to achieve its long-term GHG reduction targets. A similar trajectory can be achieved with a shallower step down in 2025, but with an AAM that comes into place in 2026 and an even lower threshold of the first criteria that would trigger the AAM (e.g., lowering the value from 2.5 to 2.0).

ICF recommends that the AAM be considered for implementation as soon as 2026, rather than waiting until 2028, regardless of the 2025 CI step down.

ICF Commentary on AAM Trigger Criteria 1

335.4 ICF disagrees with the underlying presumption that the AAM should be triggered at the proposed threshold i.e., when there are three quarters' worth of deficits in the bank. Based on information presented at the May 23, 2023 modeling discussion, the AAM design is looking to program data from prior to 2021 as an indicator of an "ideal" bank of credits. ICF views this as a critical mistake with respect to how the market is likely to unfold in the future. From a market perspective, if we consider the credit bank as a measure of the risk that regulated parties (i.e., refiners) bear in order to do business in California, then the credit bank should be measured in dollars, not credits/deficits. The figure below shows the estimated value of the credit bank in five-year increments from 2015 to 2040. The data for 2015 and 2020 are based on data reported by CARB for both deficits and credits; whereas the data for 2025 to 2040 is based on the deficit generation in ICF's analysis of the proposed CI reduction trajectory and the credit price reported by CARB in the Staff Report. All values are reported in real dollars using 2021 as the basis year ($2021).

Figure 5. Estimated value of LCFS credit bank as a proxy for refiner risk tolerance



A target credit bank of three quarters worth of deficits in 2015 would have been valued at $140 million; by 2020, the value of the bank grew to $2.4 billion. In 2023, ICF estimates that a credit bank with three quarters worth of deficits is valued at $1.1 billion. Based on CARB's forecasted credit price, the value of a credit bank of three quarters worth of deficits in 2025 would rise to $5.2 billion before collapsing back to $2.1 billion in 2030. The higher pricing reported by CARB in 2035 and 2040 yields an "ideal bank" valued at $4.2 billion and $5.5 billion. When viewed from the lens of dollars tied to risk, rather than risk tied to a specific credit bank, the target bank of three quarters worth of deficits does not make

335.4 cont. sense. By 2035, for instance, petroleum products will have decreased substantially due to efficiency gains, increased liquid biofuel blending, and transportation electrification. ICF estimates that gasoline consumption may decrease by up to 50% by 2035, while ULSD consumption could decrease by as much as 85% by 2035 (compared to 2022 consumption). Why would an industry that has lost so much market share increase the value of its risk burden by nearly a factor of four over that same time frame?

In line with ICF's hypothesis that the AAM should consider the "ideal credit bank" in terms of managed risk (as measured in dollars' worth of exposure), we also believe that the proposed AAM fails to recognize the evolution of the market post-2020. Consider that in 2018:

- The average CI of ethanol was nearly 70 g/MJ
- Biodiesel volumes were averaging around 5% blend rates in California
- There were 2-3 renewable diesel producers delivering product to California
- The first fuel pathway for RNG from animal manure was submitted and approved by CARB
- EVs represented just 7% of new light-duty vehicle sales
- Off-road electrification applications generated about 500,000 credits

Most of the refiners in the LFCS program had limited visibility with respect to LCFS credit generation and were forced into a position of purchasing LCFS credits from a limited market. As a result, refiners generally opted to build substantial credit banks as part of their compliance strategy. This strategy enabled other market participants to benefit via an increased credit price. However, in the interim years, refiners have made substantial investments that give them a clearer line of sight in their credit generation. The table below highlights the key investments that six refiners have made since 2018; these refiners represent what ICF estimates to be more than 90% of the obligation in the LCFS program. This is not meant to be an exhaustive list, rather it illustrates key investments that will impact LCFS credit generation moving forward.

335.4 cont

Obligated Party	Key Investment since 2018
Marathon	• Retrofitted Dickinson facility for RD production • Martinez Renewables joint venture with Neste in California • Acquired RNG platform (LF Bioenergy)
Chevron	• Acquired REG, largest biodiesel producer in US • Converting diesel hydrotreating unit for renewable diesel / renewable jet fuel production at El Segundo • Investments in RNG platforms including California Bioenergy, Brightmark Energy • Acquired natural gas fueling assets via deal with Mercuria
PBF[5]	• St. Bernard Renewables project in Louisiana producing RD
Valero	• Expanded Diamond Green Diesel (a joint venture with Darling Ingredients) at Norco, Louisiana • Commissioned Port Arthur project with expected completion in 2025
Phillips 66	• On the verge of completing Rodeo Renewed project at San Francisco Bay Area refining complex, converting to renewable fuels entirely
BP	• Expanded co-processing capabilities at Cherry Point • Purchased RNG platform via Archaea acquisition

It is clear from this table that there is a much clearer line of sight to LCFS credit generation for regulated parties today in 2024 than there was in 2018. The view of the credit-deficit balance from pre-2021 will not be a good indicator of how the market will evolve moving in 2025 and beyond.

ICF recommends that the first criteria for the AAM be modified such that the mechanism is enacted when the credit bank is more than 2.5 times greater than the quarterly deficits generated in a given year.

LCFS Credit Pricing

ICF views the LCFS credit price as part of a broader set of environmental commodities available to low carbon fuel producers. ICF models environmental commodities using an approach that assumes the marginal cost of compliance is determined by the value of subsidy needed to offset the difference between low carbon fuel production costs and the conventional fuels that they replace i.e., gasoline and diesel. The complicating factor related to determining marginal compliance costs is the multiple subsidies available and the

[5] Shell sold its Martinez Refinery and related logistics assets to PBF in 2021.

associated "loading order" of those subsidies with respect to various fuels. ICF's modeling assumes the value for low carbon fuel producers is generated via multiple streams, including federal tax credits or incentives, federal policies like the Renewable Fuel Standard, and then state level programs like California's LCFS program.

- ***Federal tax incentives***: ICF considers two types of tax incentives, the Blenders Tax Credit and the Clean Fuel Production Credit (CFPC) from the Inflation Reduction Act (IRA).
    - The BTC is available to blenders that blend biodiesel or renewable diesel into the transportation fuel supply and is valued at $1.00 per gallon of eligible fuel blended. The current version of the BTC will expire at the end of 2024. The BTC is not adjusted for inflation.
    - The CFPC is a carbon intensity-based production tax credit that replaces and expands upon the BTC. The CPFC is codified in the Inflation Reduction Act and is often referred to as the Sec 45z credit. It is valued at up to $1.00 per gallon of eligible fuel; however, in order to qualify, an eligible fuel must be produced in the United States and meet a maximum carbon intensity threshold of 50 kgCO2e/mmBtu. The CFPC is calculated as follows:[6]

$$CFPC = \$1.00\ x\ \left(1 - \frac{CI_{fuel}}{50}\right), (\max \$1.00)$$ [7]

- ***Renewable Fuel Standard***: Most transportation fuels generate value via the Renewable Fuel Standard and generate RINs (or Renewable Identification Numbers), the currency and compliance tracking mechanism for the federal program. There are several RIN buckets in the program: D6 RINs, D5 RINs, D4 RINs, and D3 RINs. The RIN designation is tied to two key factors: a) the feedstock used to produce the renewable fuel and b) the GHG emission reductions attributable to the fuel. <u>It is important to note that while there is a GHG emission reduction requirement or threshold within each RIN bucket, fuels are not differentiated by their carbon intensity score the way that they are in the LCFS program.</u>
- ***California Cap at the Rack (CAR)***: Renewable diesel producers to date have received some share of the value of displacing a gallon of ULSD in the Cap-and-

[6] Note that the GREET model referenced in the IRA is the version of the model developed by Argonne National Laboratory (ANL) and not the CA-GREET model used by CARB to regulate the LCFS program. The CI for renewable diesel in the CA-GREET model is *higher* than the CI for renewable diesel in the GREET model for several reasons, but most notably because CARB's model assumes a higher CI adder for land use change (LUC), specifically for soybeans.

[7] ICF assumes that the CI of the marginal gallon of eligible fuel will have a CI score of 35 kg/mmBtu, yielding an incentive of $0.30 per gallon of 30 cpg. The CFPC is adjusted for inflation from 2022 pursuant to the IRA.

Trade program, which is quantified as CAR. Generally speaking, renewable diesel is the only low carbon fuel that has benefitted significantly from California Carbon Allowance (CCA) pricing, which has helped to maintain profitability of renewable diesel production in light of falling LCFS credit prices.

- ***California LCFS Credit Price***: The LCFS credit price serves as a subsidy for low carbon fuel production, with the understanding that many low carbon fuels cost more to produce than their conventional counterparts. The value of the LCFS credit price can be represented by the cost per ton to deliver the last or marginal unit of low carbon fuel to California in any given year, after accounting for revenue from other subsidies.

ICF modeling calculates the LCFS credit price as the difference between the low carbon fuel cost of production (inclusive of any costs to deliver the fuel to California) minus any other revenue streams that the low carbon fuel would otherwise receive. For example, in the case of renewable diesel, the production costs, $C_{production}$, would include the feedstock costs associated with producing the fuel, the fixed and variable production costs, and any logistical costs associated with bringing the fuel to California.

$$C_{production} = C_{feedstock} + C_{fixed} + C_{variable} + C_{logistics}$$

The revenue streams, *R*, for renewable diesel exclusive of the LCFS credit price, including the commodity value of the fuel, the value of the D4 RIN, any tax credits (e.g., the Blenders Tax Credit, BTC), and some share (α) of the value of displacing a gallon of ULSD in the Cap-and-Trade program, which is quantifies as Cap at the Rack (CAR).

$$R = Commodity + Fed \quad al\ Tax\ In \quad ives + \quad RIN + \alpha \quad CAR$$

In this example, the LCFS credit price needed to bring that gallon of renewable diesel (*LCFS Credit Price*$_{RD}$) to California would be calculated as the difference between the production costs and the revenue streams:

$$LCFS \qquad Pri\ \ e_{RD}\left(\frac{\$}{ton}\right) = \frac{C_{production} - R}{}$$

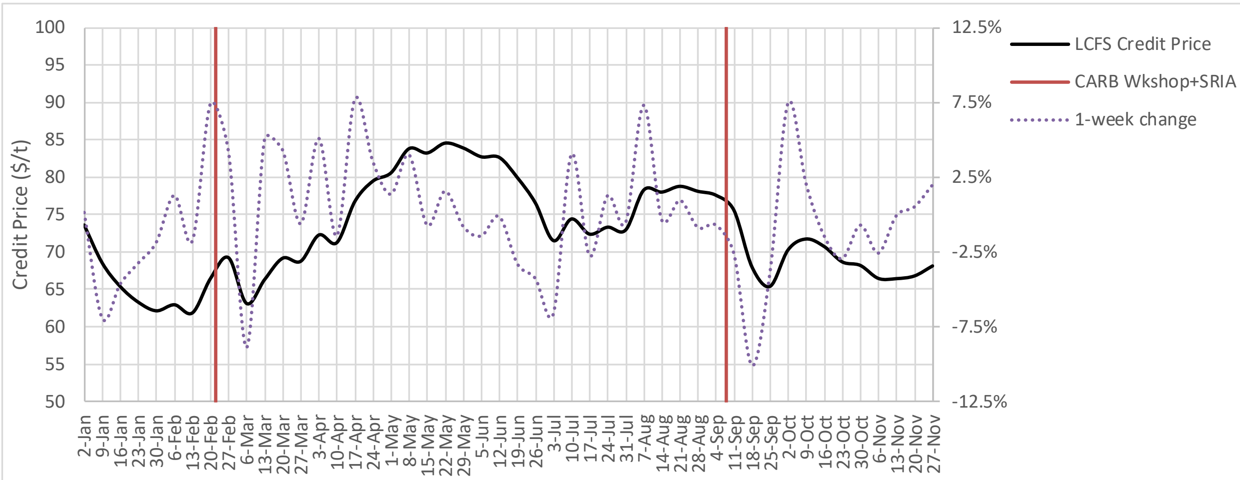
The LCFS credit price in any given year (t) can be approximated as the maximum LCFS credit price amongst low carbon fuels (fuels) delivered to California:

$$LCFS \qquad Pri\ \ e_{t}\left(\frac{\$}{ton}\right) \approx Max_t^{fuels}\{LCFS \qquad Pri\ \ e_{fuels}\}$$

LCFS Credit Pricing in response to CARB Proposals

Prior to the Staff Report, CARB staff had two significant opportunities to communicate to the market their intentions with respect to increasing the stringency of the LCFS program. The figure below shows the weekly LCFS credit price for Type 1 transfers reported by CARB from January to late November 2023 (black line), with a range of $60 to $85 per ton over that time frame. The dotted purple line shows the change from week to week on a percentage basis. The two largest week-over-week decreases in LCFS credit pricing for 2023 occurred after the February 22, 2023 LCFS workshop and when the Staff Regulatory Impact Assessment (SRIA) for the LCFS was made publicly available. In both cases, CARB signaled its intention to advance a proposal with a 30% CI standard in 2030.

Figure 6. ICF analysis of LCFS credit prices in response to CARB announcements



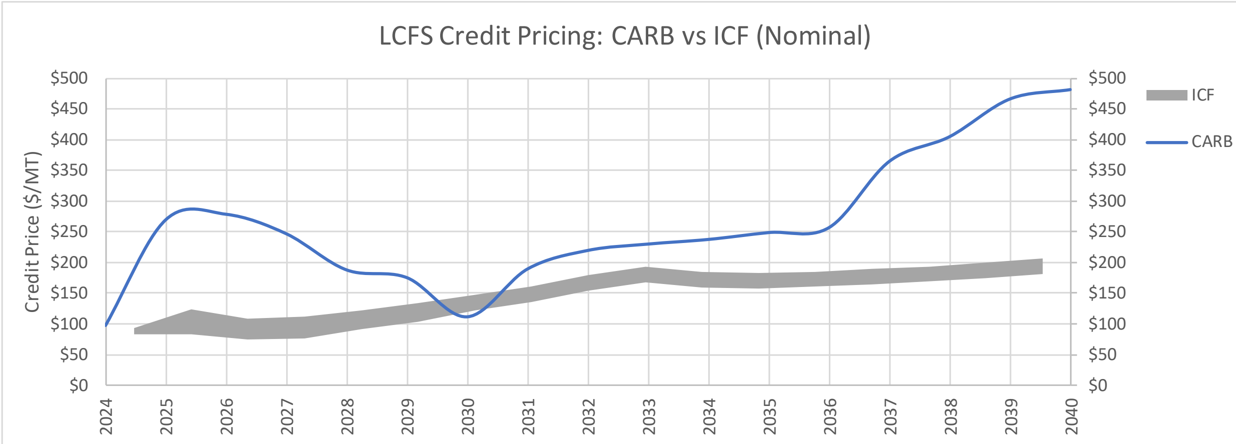
While ICF cautions against overreacting to spot price movements in any market, these movements can be a helpful indicator of market sentiment. In this case, the market was likely hoping for a more stringent standard. This conclusion is bolstered more forcefully in the market reaction after the Staff Report was issued, with credit prices in early 2024 decreasing to below $60/t for the first time in more than five years.

LCFS Credit Pricing: CARB vs ICF

335.3 cont. CARB's forecasted LCFS credit pricing has a variety of caveats associated with it; however, CARB staff use the LCFS credit pricing as one of the primary reasons for dismissing a higher CI reduction target in 2030 because of potential consumer impacts associated with pass-through compliance costs. However, the CARB forecasting is flawed and effectively implies that the LCFS will bear the entire cost of subsidizing low carbon fuel production. This is misaligned with market factors given the significant supplemental value of the Clean Fuel Production Credit via the IRA, robust RIN pricing, moderate commodity pricing (e.g., for gasoline and diesel), and increasing CCA prices.

The figure below shows a range of ICF forecasted LCFS credit prices in grey compared to the CARB LCFS credit price forecast in blue line. The CARB LCFS credit price forecast has been adjusted to nominal dollars, as ICF has found this is how stakeholders tend to view the market (rather than adjusting pricing to some real-dollar basis).

335.3 cont. Figure 7. Comparison of CARB and ICF LCFS credit pricing forecasts (nominal dollars)



ICF makes three observations associated with the comparison between CARB's forecast and our forecast:

4. In the near-term future (by 2025), CARB is forecasting a four-fold increase in LCFS credit pricing. This credit price spike coincides with the introduction of the CFPC and other IRA incentives flowing to the market. [8]
5. In a post 2030 environment, though the two curves are showing similar patterns of increasing credit prices, CARB's forecast is still $60-65/ton higher than ICF.
6. Post-2035, CARB's forecasts are suggesting that a LCFS credit price of $250 to nearly $500/ton is needed in order to achieve program compliance. There is no reason that the credit price should ever need to be that high in order to induce the investments necessary to achieve compliance based on ICF modeling.

[8] The CFPC will apply to a broader set of fuels than the BTC; however, many fuels that were receiving the $1.00 per gallon benefit of the BTC will be reduced to what ICF estimates is more like $0.30 per gallon. Historically, after the removal of the BTC (via expiration of the incentive based on some timeline defined in statute) the D4 RIN price has increased to accommodate the lost value. ICF analysis suggests that the RIN price has increased and helped to recover as much as 75% of the lost value. ICF assumes a similar dynamic will emerge for RIN pricing as the BTC transitions to the CFPC. The transition from the BTC to the CFPC will also likely reduce imports into the United States. Despite these potential changes, ICF analysis of available supply of low carbon fuels to California will not require such a dramatic increase in LCFS credit pricing, as highlighted in the text.

Appendix

Background on ICF Modeling

ICF models the CI reductions that could be achieved using the structure of the LCFS program. The modeling is driven by the demand for transportation fuel in California, which is a function of many variables including but not limited to economic growth, vehicle miles traveled (VMT), vehicle fleet turnover, and the expected compliance with complementary policies that impact transportation fuel demand. ICF's modeling is initiated using documentation associated with the EMissions FACtor model (EMFAC)[9] that is publicly available for download. The EMFAC model is "developed and used by CARB to assess emissions from on-road vehicles including cars, trucks, and buses in California." The EMFAC model enables ICF to characterize top-level transportation fuel demand in California given baseline consideration of the aforementioned key factors, like VMT and fleet turnover. Although EMFAC2021 incorporates expected compliance with several regulations that decrease fossil fuel demand, like the Advanced Clean Truck (ACT) Rule and the Innovative Clean Transit (ICT) Rule, it does not include expected compliance with Advanced Clean Cars II (ACC2) or Advanced Clean Fleet, which were adopted by the Board in 2022 and 2023, respectively. ICF has modified EMFAC2021 to ensure compliance with ACC2 and ACF. ICF then pairs the fleet turnover and fuel demand functions of EMFAC with supply-cost curves for low carbon fuels, including ethanol, biodiesel, renewable diesel, and renewable natural gas (RNG).

ICF previously modeled multiple scenarios for this project and framed each as *Accelerating Decarbonization* in the transportation sector using a diverse array of low carbon fuel strategies that are viable in the timeframe contemplated. Within this framework, ICF presented a Central Case and High Case(s).

- *Accelerating Decarbonization, Central Case*: ICF's primary focus is this case, whereby we limited our consideration of low carbon fuel strategies that require expanded deployment, reasonable technological advancement, and limited, if any, substantive policy changes.
- *Accelerating Decarbonization, High Case(s)*: In these cases, ICF considered additional strategies and/or policy changes that would lead to higher deployment of low carbon fuels and/or greater CI reductions over the course of the analysis. These included but were not limited to reductions in indirect land use change (ILUC) accounting, resumption of FFV manufacturing by OEMs, and relaxation of

[9] ICF is using the most recent version of EMFAC, EMFAC2021 (v1.0.2) as a starting point for our modeling. The EMFAC model is available for download online.

deliverability requirements for electricity used as a transportation fuel and as a processing fuel. Together, these represent a more expansive market and aggressive outlook for decarbonizing the transportation sector.

Stakeholder Outreach

ICF retains exclusive decision-making with respect to the parameters that are included in (or excluded from) the modeling in this project. However, as part of the development of our modeling, we sought (and will continue to seek) input and feedback from stakeholders that are uniquely positioned to characterize trends, constraints, and opportunities across various low carbon fuels. ICF conducted interviews with stakeholders from various low carbon fuel providers. Through these conversations, ICF introduced the broader project objectives and ICF's modeling approach to help stakeholders understand the key drivers for our analysis. ICF then led a discussion guided by the following questions:

- ***Deployment***. What are expected changes in the industry that will increase or decrease the deployment of a particular fuel or fuel/vehicle combination? These generally include supply and demand considerations and should account for opportunities and barriers to the extent feasible. What is the timeframe associated with any changes?
- ***Carbon intensity.*** What is the current and projected carbon intensity of the fuel under consideration? Are there any California-specific policy or regulatory changes that can be accommodated to help achieve these reductions? What is the rate at which these carbon intensity changes are likely to occur?
- ***Demand from Other Markets***. Where are the developments likely to occur? Are there any specific advantages or disadvantages associated with delivering these solutions to California that ICF needs to consider? To what extent will other (existing or potential) low carbon fuel markets be advantaged or disadvantaged as it relates to these solutions as a function of their corresponding geography?

Lastly, it is important to note that ICF developed the modeling framework used in this study based on publicly available tools and data—we have purposefully excluded any proprietary data or considerations as part of this analysis.

Sacramento, California 95814

Re: Proposed Low Carbon Fuel Standard Amendments

Dear Chair Randolph:

Bunge is the world's largest oilseed processor by crush volume capacity. Bunge buys and processes agricultural commodities, turning them into products used in the food industry, animal feed, and the renewable diesel industry. Bunge is also an industry leader in sustainability, embracing climate-focused decision making and setting ambitious goals. For instance, we are well on our way to meeting our commitment to eliminate deforestation and native vegetation conversion from our supply chain in 2025 and are helping to accelerate industry-wide progress through sector initiatives that seek to create common alignment and scalability on deforestation goals. Bunge's robust traceability and monitoring systems give us unprecedented insight into our supply chain. We achieved 82 percent traceability for soy in Brazil's high-risk areas in 2022, helping us achieve our 2025 commitment. Further, we have already achieved 100 percent traceability in our direct supply of soy in priority areas in South America. We are leveraging our experience working with farmers and incentivizing sustainable practices through the use of technology and data to scale our efforts across the wider agribusiness sector in many geographies where deforestation is a higher risk.

In general, Bunge supports the Low Carbon Fuel Standard ("LCFS") and the California Air Resources Board's ("CARB's") proposed 2024 amendments. Bunge recognizes the challenges that climate change poses to the world, as well as to Bunge's business and agriculture overall. The LCFS has addressed climate change by driving demand for lower-carbon fuels. Bunge applauds the success of CARB's LCFS implementation, which has increased volumes of low-carbon fuels such that California's overall petroleum fuel use has fallen by 1.3 billion gallons since 2019. Meanwhile, the carbon intensity ("CI") of the state's transportation fuels has declined 12.63 percent from 2010 levels.

Bunge appreciates the opportunity to comment on the amendments that CARB is proposing to update the LCFS in 2024. As a leader in renewable fuels and sustainable practices, Bunge broadly supports the proposed amendments. However, Bunge is concerned about aspects of CARB's proposed sustainability certification requirements. Bunge encourages CARB to clarify and/or modify the amendments to address these issues before finalizing the rule, as discussed further below.

Bunge Supports the LCFS, and CARB's Decision to Reject a Cap on Crop-Based Fuels

336.1 Bunge commends CARB for proposing amendments that generally maintain and strengthen the LCFS as a market-based system that drives emissions reductions by using science to identify the CI of various fuels. Specifically, Bunge supports CARB's decision to reject an arbitrary cap on crop-based fuels. An arbitrary cap would have run counter to CARB's science-based approach, as we underscored in our March 15, 2023 letter in response to CARB's February 2023 public workshop. Still, we understand and appreciate CARB's desire to further address indirect land use change in the program. Indeed, impacts on land use change are driving Bunge's existing efforts to guarantee its supply chains are deforestation free. We appreciate that CARB's proposal seeks to address sustainability concerns through efforts to demonstrate that crops used in the program are deforestation-free, rather than by adopting an arbitrary cap on crop-based fuels.

Bunge Encourages CARB to Adjust Its Sustainability Certification Rules for Feasibility

In general, Bunge echoes the comments of the National Oilseed Processors Association ("NOPA"), which represents Bunge and others in the industry. Like NOPA, Bunge is concerned about the details of CARB's proposed requirement that crop- and forestry-based feedstocks "maintain continuous third-party sustainability certification" to demonstrate they were not "sourced on land that was forested after January 1, 2008." *See* Proposed Regulation Order at § 95488.9(g).

In particular, Bunge has reservations about the feasibility of implementing certifications requiring high traceability with U.S. and Canada producers, for whom such certifications remain relatively foreign because deforestation risk is remote for these producers. U.S. Department of Agriculture data illustrates the low domestic deforestation risk: U.S. producers actually planted fewer acres of land as corn, soybeans, and wheat in 2022 than in 1980, as highlighted in NOPA's comment letter. If deforestation were a reality or risk, one would expect more acres of land planted in recent years, which would indicate that forested land had been cleared for crops. Instead, U.S. farmers today produce higher crop volumes on the same amount of land—or slightly less—than forty years ago. Programs like the federal Renewable Fuel Standard do not require third-party sustainability certification, recognizing the low deforestation risk in the U.S.
336.2 and Canada. Requiring low-risk U.S. and Canada feedstocks to undergo certifications that are

336.2(cont'd) suited to and designed for high-risk regions like South America could disadvantage some of the lowest-risk growers without attendant sustainability benefits.

We appreciate the value and utility of sustainability certifications. In fact, in our March 2023 letter, we suggested that CARB study certification options rather than pursue an arbitrary cap on crop-based fuels, reinforcing Bunge's commitment to sustainability. Still, Bunge believes such certifications are most useful and relevant in high deforestation risk contexts. For example, Bunge has found that certifications are valuable in parts of South America, such as Brazil, where the threat of deforestation has been an issue the industry has had to address. In these regions, Bunge has substantial experience tracing products from the point of origin to certify them as deforestation-free and thus compliant with sustainability requirements like the European Union's Renewable Energy Directive ("RED"). Specifically, Bunge has certified products in high-risk deforestation regions like South America using systems from the Round Table on Responsible Soy ("RTRS"), Biomass Biofuel Sustainability Voluntary Scheme ("2BSvs"), and International Sustainability and Carbon Certification ("ISCC"). Certifications that trace soy to the
336.2 (cont'd) farm level have clear value in the Gran Chaco in Argentina and Paraguay and the Cerrado in Brazil, where there is significant agricultural expansion pressure. But in the U.S. and Canada, tracing soy to the farm level has little to no sustainability benefit because there is very little expansion pressure caused by agriculture, meaning deforestation risk is low.

With this context in mind, Bunge is concerned that these full traceability systems are less workable in the North American context, particularly on the implementation timeline that CARB is proposing. CARB's proposal requires crop-based feedstocks be certified at the point of origin by January 1, 2028. For a certification system to be approved, it must have been recognized by a government for at least 24 months. In other words, market participants have less than four years to implement certifications, and any certification scheme used must be recognized by a government now or in the very near future due to the 24-month criterion. Based on the
336.3 European experience implementing RED, it is difficult to imagine development and implementation of a certification system that complies with CARB's proposed requirements within the proposed time frame. We are concerned that it will not be possible to develop new schemes that meet CARB's listed criteria on such a tight timeline and then implement those schemes. Factoring in the required two years of government recognition makes this even less feasible.

With these difficulties in mind, Bunge encourages CARB to consider workable solutions that guarantee LCFS feedstocks are deforestation free. For instance, CARB might consider altering
336.4 the timeline and governmental-recognition requirement to give industry, the agency, and growers time to advance certification systems that are feasible in the North American context. The industry needs time to develop a risk-based approach that does not over burden the supply

336.4(cont'd) chain with full traceability to the farm when the risk of deforestation in some areas of the world, such as the United States and Canada, is much lower than in others.

Bunge commends CARB's commitment to addressing climate change through its proposed LCFS amendments. Bunge also appreciates CARB's commitment to maintaining the science-based integrity of the LCFS, as demonstrated by the agency's rejection of an arbitrary cap on crop-based fuels. We look forward to working with CARB to make sure any sustainability certification requirements and timelines are feasible while also accomplishing the goal—which Bunge shares—of deforestation-free fuels.

Sincerely,

Robert Coviello
Chief Sustainability Officer and Government Affairs

Comment 346 for Proposed Low Carbon Fuel Standard Amendments (lcfs2024) - 45 Day.

First Name	Chelsea
Last Name	Lee
Email Address	chelsea@betterworldgroup.com
Affiliation	Coalition to Fix the LCFS

Subject	Fix the Low Carbon Fuel Standard - Prioritize Zero Emission Investments

Comment

On behalf of more than three dozen cross-sectoral organizations, w
respectfully submit the attached critical process and substantive
337.1 recommendations for CARB to fix the LCFS. We urge CARB to provide
non-voting, informational Board hearing, which will allow for more
time and the opportunity for meaningful public and Board
engagement. This need for more engagement opportunities is
underscored by the major deficiencies that remain in the current
proposal. We urge CARB to prioritize fixing the LCFS this year in
the following ways:

A. Reign in bogus credits that are depressing the credit price,
337.2 distorting markets, and harming people and ecosystems by:
 - Eliminating avoided methane crediting for fuel derived
from livestock manure.
337.3 - Capping the use of lipid biofuels.

B. Leverage the LCFS to achieve a zero-emissions future for all
337.4 Californians by:
 - Creating ZEV multipliers to boost electric school bus ar
electric public transit bus and rail system deployments.
 - Following through with the inclusion of intrastate jet
337.5 fuel as a deficit generator and starting to analyze the path towar
including California's share of the fuel used in interstate and
international flights.
 - Allowing credits for zero-emission transportation fuels
337.6 used for ocean-going vessels, and simplifying the process for
credits for shore power installations serving electrified harbor
crafts and for dispensing green hydrogen.

Sacramento, CA 95814
cotb@arb.ca.gov

Re: Fix the Low Carbon Fuel Standard - Prioritize Zero Emission Investments

Dear Chair Randolph and Members of the Board,

On behalf of the undersigned advocates, we respectfully submit the following critical process and substantive recommendations that CARB must take to ensure the LCFS aligns with and truly advances our state's zero-emission transportation priorities.

The LCFS is an important financing component of private and public sector transportation electrification investments that California needs to achieve the successful implementation of its landmark clean transportation regulations, like the Advanced Clean Fleets, Advanced Clean Cars II, and Advanced Clean Trucks rules, which CARB itself developed and approved.

Despite its unique potential to support these life-saving regulations, the LCFS proposed by staff is misaligned with electrification goals, worsens environmental injustices, and will continue to founder from a glut of lipid-based biofuels and livestock biogas that will undercut the credit price. CARB must spend more time to ensure that the policy fulfills its unique role in helping secure California's zero-emission transportation future without further exacerbating harm to vulnerable communities. The April workshop must feature a robust discussion about these core program issues and not just focus on biofuels certification and auto adjustment mechanisms for credits. We also request a hybrid workshop format that allows in-person attendance and offers Spanish translation to ensure the discussion is accessible to impacted communities.

We request an informational Board hearing before a vote.

In previous regulation processes, the Board has followed the release of a staff proposal with a non-voting, informational Board hearing. Considering that the LCFS is a complex policy with long-lasting and far-reaching impacts, deviating from this standard practice will rob the public of the opportunity for meaningful engagement and the Board of the opportunity to give direction. In addition, many Board members are new to the role, and 10 of 16 Board members have not previously participated in a major update to the LCFS. The Board will reach a stronger decision if members are given an opportunity to ask questions and provide direction to staff in an informational meeting before they are asked to vote. A non-voting hearing will give also the Board and staff more time to meaningfully engage with the Environmental Justice Advisory Committee, whose eight recommendations rooted in environmental justice principles were not properly considered in staff's proposal. Providing one additional informational hearing for both the public and Board to analyze and engage is especially crucial given that staff's current proposal is vastly different from what they had presented in previous workshops and at the September 2023 Board meeting. Finally, holding a non-voting meeting this year will still meet the timing requirements of the Office of Administrative Law and enable 2025 implementation.

CARB has the opportunity to finally align the LCFS program with all of California's other zero-emission transportation laws, regulations, and investments. The Board needs more public engagement opportunities to ensure successful alignment, and getting it right in this rulemaking is critical.

Critical changes to the LCFS are needed in this rulemaking.

The need for more engagement opportunities is underscored by the major deficiencies in the staff proposal that the Board must fix in this rulemaking. On behalf of our diverse coalition of advocates, we urge CARB to prioritize fixing the LCFS this year in the following ways:

- Reign in bogus credits that are depressing the credit price, distorting markets, and harming people and ecosystems by:
  - Eliminating avoided methane crediting for fuel derived from livestock manure.
  - Capping the use of lipid biofuels.
- Leverage the LCFS to achieve a zero-emissions future for all Californians by:
  - Creating ZEV multipliers to boost electric school bus and electric public transit bus and rail system deployments.
  - Following through with the inclusion of intrastate jet fuel as a deficit generator and starting to analyze the path toward including California's share of the fuel used in interstate and international flights.
  - Allowing credits for zero-emission transportation fuels used for ocean-going vessels, and simplifying the process for credits for shore power installations serving electrified harbor crafts and for dispensing green hydrogen.

In conclusion, we request that CARB ensure the April workshop is comprehensive and accessible and that it hold an informational non-voting hearing to allow greater public and Board engagement before the vote. This will ensure appropriate Board direction, ultimately producing the best policy possible for achieving CARB's zero-emission transportation future with the greatest benefits for environmental justice communities.

Thank you for your consideration of our requests. We look forward to further collaborating with CARB on improving the LCFS and securing a zero-emission transportation future for all Californians.

Sincerely,

Daniel Chandler

Board Comments Home

February 20, 2024

California Air Resources Board
1001 I Street
Sacramento, CA 95815

RE: Proposed Low Carbon Fuel Standard Amendments

Dear California Air Resources Board Members and Staff:

Thank you for the opportunity to provide comments and recommendations to the California Air Resources Board (CARB) on its proposed Low Carbon Fuel Standard (LCFS) Amendments. We recognize the significant undertaking of initiating revisions to a program with diverse stakeholders and critical importance to the State's ability to meet its zero-emissions transportation goals and regulatory deadlines, and commend CARB staff on their thoughtful and deliberative process since initiating this rulemaking.

Headquartered in San Francisco, CA, Prologis, is the global leader in logistics real estate, with a portfolio of over 1.2 billion square feet across four continents and approximately 2.8% of global GDP flowing through our properties each year. Prologis leases modern warehousing and distribution facilities to customers, which include manufacturers, retailers, transportation companies, third-party logistics providers, and other enterprises. Our large, flat rooftops have enabled us to build out commercial solar installations to serve onsite and offsite load with clean energy and battery storage, helping our customers reduce their emissions and placing us second in the U.S. for corporate on-site solar.

Prologis' Mobility business is helping transform the fleet and logistics industry and enabling our customers to transition to zero-emissions through industry-leading electric vehicle (EV) charging technology and solutions. With roughly 180 million square feet of industrial real estate across our California portfolio, the opportunity for us to help our customers with this transition is significant, and we are developing dedicated charging infrastructure at Prologis sites to support their medium- and heavy-duty (MHD) fleets across last mile, drayage, and other applications. In addition to providing charging solutions at our own properties, we offer electrification services at non-Prologis buildings and are developing multi-fleet charging hubs serving areas with dense concentrations of warehouses.

Prologis echoes the comments submitted by the Joint MHD EV Infrastructure Parties focused on the proposed amendments to the LCFS as they focus on MHD-FCI Shared charging sites or "hubs," of which we are a signatory. We believe that ensuring concurrent growth of both hub and MHD-FCI Private on-site "depot" models for fleet charging in California is integral to the successful electrification of the goods movement sector, and welcome the opportunity to submit Prologis' additional recommendations.

338.01

Remove the §95486.3(b)(3)(A)(2) 0.5% criterion to avoid unintended consequence of penalizing individual fleets for having common service providers and avoid creating conflicts with the regulatory framework of the South Coast Air Quality Management District's (SCAQMD) Indirect Source Rule (ISR).

Section §95486.3(b)(3)(A)(2) states "*If estimated potential MHD-FCI credits from an individual applicant's approved stations exceed 0.5 percent of deficits in the most recent quarter for which data is available, the Executive Officer will not approve additional MHD-FCI pathways or accept additional applications from* *that applicant until the applicant's estimated potential MHD-HRI credits are less than 0.5 percent of deficits."*

An individual applicant can be providing charging services at more than one private charging site for private fleets unrelated to each other, as is the case for Prologis and other industrial property owners that are investing in charging infrastructure on-site to serve their tenants' fleets. For example, Prologis leases warehousing and distribution space to a diverse customer base of 6,700 businesses across our global portfolio. In California alone, Prologis owns more than 900 buildings where, from one site to the other, different fleet operators lease real estate and assets, including charging infrastructure. It would not be fair to penalize one private fleet because of their association with other unrelated fleets through a common service provider. This creates an impediment for warehouse operators implementing mitigation measures in line with the ISR's requirements, such as EV fleet adoption and on-site charging infrastructure deployment, as well as fleet conversion towards Advanced Clean Fleets (ACF) deadlines.

338.02

Remove the Section §95486.3(b)(3)(A)(3) 1% criterion to avoid an unintended consequence of penalizing individual fleets for maximizing competitiveness and compliance efficiencies by charging their fleets at their natural domicile locations.

Section §95486.3(b)(3)(A)(3) states *"If estimated potential MHD-FCI credits from approved private MHD-FCI stations exceed 1 percent of deficits in the most recent quarter for which data is available, the Executive Officer will not approve additional private MHD-FCI pathways and will not accept additional applications for private MHD-FCI stations until private MHD-FCI stations' estimated potential MHD-HRI credits are less than 1 percent of deficits."*

Having different rules for Private vs. Shared will create operational and potentially SCAQMD ISR compliance inefficiencies for our customers who need to electrify at their "home" fleet domicile location.

Grant equitable access to book-and-claim accounting for EV charging microgrids.

Section §95488.8(i)(2)(A) states *"RNG injected into the common carrier pipeline in North America (and thus comingled with fossil natural gas) can be reported as dispensed as bio-CNG, bio-LNG, or bio-L-CNG, or as an input to hydrogen production, without regards to physical traceability."*

MHD charging projects are in a difficult position: they are extremely capacity and energy intensive, second only to data centers in light-industrial real estate,[1] making them time-consuming to connect to the grid, yet they require accelerated schedules to meet fleet electrification mandates and avoid stranding EV assets. Projects in this predicament look to on-site generation with energy storage as solution to meet fleet electrification objectives ahead of utility connections, with a coproduct of resiliency for critical fleet operations when the utility connection is eventually established in parallel. However, due to the exceptional energy intensity of industrial MHD charging projects on limited footprints, dispatchable power-dense on-site generation such as fuel cells or linear generators can sometimes be the only feasible technical solution remaining that can fit the available real estate and meet the energy demand.

This important EV charging pathway for biomethane (whether RNG or hydrogen in its final delivered form for on-site generation) is not only a more energy efficient pathway for biomethane, but also has

[1] According to Prologis benchmarks of typical alternative uses for comparable properties

significantly lower NOx emission profile than CNG vehicle application in sensitive disadvantaged communities around ports for example[2], yet only CNG vehicle fueling projects are incentivized with book-and-claim LCFS accounting from RNG energy sources.

338.03 As Prologis has recommended in prior comment letters, CARB should grant equitable access to biomethane book-and-claim LCFS accounting for MHD EV charging projects investing in on-site RNG/hydrogen generation that add resiliency and accelerate around transmission and distribution upgrade delays. We ask that CARB consider amending 95488.8(g)(1)(A)(2) to read as follows:

"Biomethane supplied using book-and-claim accounting pursuant to section 95488.8(i)(2) and is claimed as feedstock in pathways for bio-CNG, bio-LNG, bio-L-CNG, hydrogen via steam methane reformation, ***and electricity generation for co-located EV charging****;"*

Further, we suggest a revision of Section §95488.8(i)(2) to explicitly state:

"(2) Book-and-Claim Accounting for Pipeline-Injected Biomethane Used as a Transportation Fuel or to Produce Hydrogen ***or to generate Electricity****. Indirect accounting may be used for RNG used as a transportation fuel or to produce hydrogen* ***or to generate Electricity*** *for transportation purposes (including hydrogen that is used* ***either*** *in the production of a transportation fuel* ***or in the generation of electricity for transportation purposes****), provided the conditions set forth below are met:*

> *(A) RNG injected into the common carrier pipeline in North America (and thus comingled with fossil natural gas) can be reported as dispensed as bio-CNG, bio-LNG, or bio-L-CNG, or as an input to hydrogen production,* ***or as an energy source for electricity generation****, without regards to physical traceability. Entities may report natural gas as RNG within only a three-quarter time span. If a quantity of RNG (and all associated environmental attributes, including a beneficial CI) is pipeline-injected in the first calendar quarter, the quantity claimed for LCFS reporting must be matched to natural gas sold in California as RNG no later than the end of the third calendar quarter. After that period is over, any unmatched RNG quantities expire for the purpose of LCFS reporting.*
>
> *(B) Biomethane reported under fuel pathways associated with projects that break ground after December 31, 2029, injected into the common carrier pipeline, and claimed indirectly under the LCFS program for use as bio-CNG, bio-LNG, or bio-L-CNG in CNG vehicles or as an input to hydrogen production* ***or as an energy source for electricity generation*** *for transportation purposes, must demonstrate compliance with the following requirements:*
>
> *1. Starting January 1, 2041 for bio-CNG, bio-LNG and bio-LCNG pathways, and January 1, 2046 for biomethane used as an input to hydrogen production* ***or electricity generation****, the entity reporting biomethane must demonstrate that the pipeline or pipelines along the delivery path physically flow from the initial injection point toward the fuel dispensing facility at least 50 percent of the time on an annual basis. Entities may report natural gas as RNG within only a three-quarter time span. If a quantity of RNG (and all associated environmental attributes, including a beneficial CI) is pipeline-injected in the first calendar quarter, the quantity claimed for LCFS reporting must be matched to natural gas sold in California as RNG no later than the end of the third calendar*

[2] 0.059 gNOx/mile for a battery electric truck supported by linear generators vs. 0.317 gNOx/mile for a CNG truck per industry SME calculations provide to Prologis

quarter.

After that period is over, any unmatched RNG quantities expire for the purpose of LCFS reporting."

Prologis believes these recommendations will further enhance CARB's proposed improvements to the LCFS program to align with the State's transportation electrification goals and ensure they reflect the multiple use cases supporting logistics sector fleets, including both MHD-FCI Private and Shared charging, as well as address the realities of utility energization delays and resiliency risks for charging projects.

Thank you for considering our recommendations, and we welcome the opportunity to further discuss our views with the Board and staff. Please do not hesitate to contact me at amoch@prologis.com or 571-895-5763 for more information or to discuss our comments in further detail.

Respectfully submitted,

Alexis Moch

Subject	End LCFS Support for Manure Digesters

Comment

February 20, 2024

Dear Governor Newsom and Members of the California Air Resources Board,

The Campaign for Family Farms and the Environment appreciates the opportunity to comment on the Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments. CFFE is a coalition of state and national organizations, including Dakota Rural Action Iowa Citizens for Community Improvement, Land Stewardship Project, Missouri Rural Crisis Center, Food & Water Watch and Institute for Agriculture and Trade Policy. Our organizations work together as CFFE to change policies that promote consolidation in animal agriculture at the expense of independent family farms, rural and urban economies, workers and an open, fair and competitive food system.

Our members have witnessed the shift in the structure of the livestock sector away from independent diversified farms to industrialized animal feeding operations in their communities. These factory farms concentrate animals and their waste, burdening surrounding communities with air and water pollution. A report by Food & Water Watch called Factory Farm Nation: 2020 Edition provides many examples of what happens to communities when livestock and their waste is concentrated in specific regions. Jus one example of FWW's findings illustrates the problem: hogs on factory farms in Duplin County, North Carolina produce the same weight in manure as residents of Boston. But unlike human sewage, hog and other livestock waste is not treated before being released into the environment. Around the country, neighbors of these facilities report odors and other health impacts, and losing the ability to spend time outdoors. Anaerobic digesters are touted by the industry as a win-win solution that creates usable energy whi reducing the environmental impact from the management of massive quantities of manure. But communities around the country know that this technology is far from a real solution. Instead, digesters allow factory farms to not only remain a burden on surrounding communities, but often to grow even larger.

Unfortunately, California's preference for manure-derived biogas the LCFS program is driving the expansion and entrenchment of factory farms and dirty biogas projects farm beyond California, including into our communities. The LCFS has become a lucrative financing tool for factory farm biogas. It is driving the construction of more factory farms and factory farm biogas projec in states far from California, causing severe harm to air, water, public health, rural economies, and overall quality of life.

The current flaws in the LCFS, such as "avoided methane crediting and inaccurate life cycle assessments, not only enable pollution but disproportionately harm low-income communities and communitie of color who live near factory farms and manure digesters. This i in stark contrast to the environmental justice commitment set by California.

CFFE believes that climate change is a serious challenge that requires a dramatic response. This crisis demands more than highl speculative market-based schemes that will allow polluters to kee polluting and let agribusiness pay farmers less for their crops a livestock. A serious plan to address agriculture and climate chan must address structural issues, not just attempt minor improvemen in environmental performance in a highly consolidated, industrialized factory farm system. Factory farms require huge quantities of feed, water, chemical inputs and energy and manage manure in a way that drives greenhouse gas emissions. California' climate programs must support a dramatic transition in how we rai animals for food that is centered on independent family farms and sustainably managed grazing systems.

Using California's climate programs, including the LCFS, to suppo expensive manure management projects on confinement operations fails to make this necessary structural change, and instead props up and expands the factory farm system. Prioritizing grazing over factory farm manure management would increase the sequestration o carbon in pastures, and also avoid the emissions from industrialized animal operations' feed production and liquid manu storage. Manure lagoons not only emit high amounts of methane and nitrous oxide, but they are also highly vulnerable to natural disasters such as hurricanes and floods. And confinement operatio decouple grazing animals from grasslands, requiring more syntheti fertilizers for feed production, which drives further emissions.

In addition to these overarching concerns about LCFS' support for manure digesters, we urge you to prioritize the following changes to the standard:

- Eliminate "avoided methane crediting"

- Address inaccuracies in the Life Cycle Assessment that ig associated up and downstream greenhouse gas emissions from factor farm gas production

- Remove the 10-year "grace period" for factory farm gas pr

- Stop double counting by allowing factory farm gas project for and claimed by other programs to sell LCFS credits as well.

For practices related to manure management, including anaerobic digesters, the LCFS calculation should evaluate not only the risk of increased ammonia emissions and water pollution from disposal digestate, but also the potential that the contract will lead to increase in the total number or density of livestock raised on the site. The potential for LCFS funding to lead to more animals bein raised on an operation with a digester, and the increase in enter emissions and carbon emissions from feed production related to th increase, should be incorporated into a new LCFS scoring system f manure-derived biogas.

The California Air Resources Board (CARB) has the opportunity to adopt new rules that would realign the LCFS with California's environmental justice commitments and stop rewarding factory farm around the country for their pollution. CARB's Environmental Justice Advisory Committee has presented a clear alternative that CARB should incorporate to align the LCFS with California's environmental justice commitments and end the state's support of environmental harm in communities across the country.

We appreciate the opportunity to comment on this critical subject

Sincerely,

Campaign for Family Farms and the Environment

February 20, 2024

Dear Governor Newsom and Members of the California Air Resources Board,

The Campaign for Family Farms and the Environment appreciates the opportunity to comment on the Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments. CFFE is a coalition of state and national organizations, including Dakota Rural Action, Iowa Citizens for Community Improvement, Land Stewardship Project, Missouri Rural Crisis Center, Food & Water Watch and Institute for Agriculture and Trade Policy. Our organizations work together as CFFE to change policies that promote consolidation in animal agriculture at the expense of independent family farms, rural and urban economies, workers and an open, fair and competitive food system.

339.1

Our members have witnessed the shift in the structure of the livestock sector away from independent diversified farms to industrialized animal feeding operations in their communities. These factory farms concentrate animals and their waste, burdening surrounding communities with air and water pollution. A report by Food & Water Watch called *Factory Farm Nation: 2020 Edition* provides many examples of what happens to communities when livestock and their waste is concentrated in specific regions. Just one example of FWW's findings illustrates the problem: hogs on factory farms in Duplin County, North Carolina produce the same weight in manure as residents of Boston. But unlike human sewage, hog and other livestock waste is not treated before being released into the environment. Around the country, neighbors of these facilities report odors and other health impacts, and losing the ability to spend time outdoors. Anaerobic digesters are touted by the industry as a win-win solution that creates usable energy while reducing the environmental impact from the management of massive quantities of manure. But communities around the country know that this technology is far from a real solution. Instead, digesters allow factory farms to not only remain a burden on surrounding communities, but often to grow even larger.

Unfortunately, California's preference for manure-derived biogas in the LCFS program is driving the expansion and entrenchment of factory farms and dirty biogas projects farm beyond California, including into our communities. The LCFS has become a lucrative financing tool for factory farm biogas. It is driving the construction of more factory farms and factory farm biogas projects in states far from California, causing severe harm to air, water, public health, rural economies, and overall quality of life.

The current flaws in the LCFS, such as "avoided methane crediting" and inaccurate life cycle assessments, not only enable pollution but disproportionately harm low-income communities and communities of color who live near factory farms and manure digesters. This is in stark contrast to the environmental justice commitment set by California.

CFFE believes that climate change is a serious challenge that requires a dramatic response. This crisis demands more than highly speculative market-based schemes that will allow polluters to keep polluting and let agribusiness pay farmers less for their crops and livestock. A serious plan to address agriculture and climate change must address structural issues, not just attempt minor improvements in environmental performance in a highly consolidated, industrialized factory farm system. Factory farms require huge quantities of feed, water, chemical inputs and energy and manage manure in a way that drives greenhouse gas emissions. California's climate programs must support a dramatic transition in how we raise animals for food that is centered on independent family farms and sustainably managed grazing systems.

Using California's climate programs, including the LCFS, to support expensive manure management projects on confinement operations fails to make this necessary structural change, and instead props up and expands the factory farm system. Prioritizing grazing over factory farm manure management would increase the sequestration of carbon in pastures, and also avoid the emissions from industrialized animal operations' feed production and liquid manure storage. Manure lagoons not only emit high amounts of methane and nitrous oxide, but they are also highly vulnerable to natural disasters such as hurricanes and floods. And confinement operations decouple grazing animals from grasslands, requiring more synthetic fertilizers for feed production, which drives further emissions.

In addition to these overarching concerns about LCFS' support for manure digesters, we urge you to prioritize the following changes to the standard:

- Eliminate "avoided methane crediting"

339.2
- Address inaccuracies in the Life Cycle Assessment that ignore associated up and downstream greenhouse gas emissions from factory farm gas production

339.3
- Remove the 10-year "grace period" for factory farm gas producers

339.4
- Stop double counting by allowing factory farm gas projects paid for and claimed by other programs to sell LCFS credits as well.

339.5 For practices related to manure management, including anaerobic digesters, the LCFS calculation should evaluate not only the risks of increased ammonia emissions and water pollution from disposal of digestate, but also the potential that the contract will lead to an increase in the total number or density of livestock raised on the site. The potential for LCFS funding to lead to more animals being raised on an operation with a digester, and the increase in enteric emissions and carbon emissions from feed production related to the increase, should be incorporated into a new LCFS scoring system for manure-derived biogas.

The California Air Resources Board (CARB) has the opportunity to adopt new rules that would realign the LCFS with California's environmental justice commitments and stop rewarding factory farms around the country for their pollution. CARB's Environmental Justice Advisory Committee has presented a clear alternative that CARB should incorporate to align the LCFS with California's environmental justice commitments and end the state's support of environmental harm in communities across the country.

We appreciate the opportunity to comment on this critical subject. If you have questions or need more information, please contact Patty Lovera at pattylovera20@gmail.com.

Sincerely,

Campaign for Family Farms and the Environment

Re: Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments (lcfs2024)

To Esteemed Responsible Officials:

Our organization Biofuelwatch appreciates the opportunity to submit this brief letter to the California Air Resources Board (CARB) as comment on the Notice of Public Hearing to Consider Proposed Low Carbon Fuel Standard Amendments (LCFS Rulemaking)[1]. Biofuelwatch[2] is an international organization that works to increase public understanding and civic engagement on the land-use implications of climate policy. We have a particular focus on the environmental harms and social inequities of large-scale industrial bioenergy projects, and we work extensively on addressing the negative ecological and social outcomes of policy and actions that are justified as being beneficial to the global climate, yet carry with them risks and threats to public health and safety, economic stability and natural resources. Due to circumstance, more than an innate desire, we have developed extensive experience with the negative real-world outcomes due to the Low Carbon Fuel Standard (LCFS). In particular, over the last nearly four years our
340.1 organization has been deeply engaged on what we assess to be the extremely irregular governance of the conversion of two refineries in the San Francisco Bay Area to manufacturing liquid biofuels, the Phillips 66 Rodeo Renewed Project (Phillips 66 Project)[3] being one of those controversial refinery conversion projects and the Marathon-Neste biofuel refinery joint venture in Martinez (Marathon-Neste Project)[4] being the other.

The California Air Resources Board (CARB) has unfortunately played a key role in the irregular governance of the refinery conversions, not only as a regulator but as a political player. For all intents and purposes

[1] https://ww2.arb.ca.gov/rulemaking/2024/lcfs2024
[2] http://www.biofuelwatch.org.uk/
[3] https://www.contracosta.ca.gov/RodeoRenewed
[4] https://www.marathonmartinezrenewables.com/

CARB has acted to protect the stranded assets of large transnational energy corporations, and has put aside local community and global climate justice concerns about the refinery conversions. Our organization has arrived at the harsh conclusion that in doubling down on climate false solutions like liquid biofuels CARB is failing in the objective of reforming the LCFS in order that the mechanism effectively be a tool for mitigating climate change. Unfortunately, there are numerous and severe harms arising from the LCFS mechanism that CARB staff have refused to recognize throughout the discussions regarding the current LCFS Rulemaking effort.

Though the postponement of the scheduled March 21 board hearing on the LCFS Rulemaking may have been in response to public concern about the LCFS in concept and deed, not the least of which are the inadequate current amendments to the LCFS requirements, we are attentive to how the agency may be once again working to dilute public participation in a significant rulemaking process.

We hope that the board will hear what has been shared over the last several years of workshops and processes around the LCFS. We also know that the board heard a great deal about the problems with the LCFS as the 2022 Scoping Plan was developed, and that current deliberations around cap-and-trade have also exposed major problems with the incentive mechanism. The unfortunate truth is that fatal flaws are embedded within the LCFS. The current amendments do not address these fatal flaws. For our organization and for the communities we work with around the state, the nation and around the world, it is horrifying to us that a high-profile markets-based mechanism, one that California authorities celebrate as an example of global climate leadership to be emulated by other jurisdictions, is in many instances not actually helping, and is instead making the climate situation worse faster.

Purpose and Rationale for LCFS Amendments Addressing the Evidence That Increased Production of Crop-based Liquid Biofuels Presents to Global Forests Fails to Meet the Moment

This comment letter will remain within the relatively limited handrails of the nexus between forests and bioenergy. This can include many topics related to the LCFS, but for the most part this letter will address **liquid biofuels**, and the related LCFS credit pathways currently in effect, such as the Phillips 66 pathway for making '*renewable diesel*' specifically with a feedstock of soy oil from Argentina that is imported by ocean tanker to their refinery in Rodeo, California.

340.2 It is obvious to anyone with experience in the manufacture of liquid biofuels that these energy products present serious threats to forest ecosystems and the communities dependent on them. It has long been understood that any increase in demand for high deforestation risk commodities for use in feed, food, or for fuel will drive deforestation. This most certainly includes liquid biofuels.

Actually, CARB goes so far as to admit that these types of concerns need to be addressed. In the description of the Purpose and Rationale of Proposed Amendments[5], staff go so far as to emphasize the need to "mitigate the concerns regarding deforestation and other unintended environmental impacts."

This is not the only effort of CARB staff to try to assuage the concerns about the well-known fact that increasing demand for high deforestation risk feedstocks such as soy to make liquid biofuels is a driver of land use change, biodiversity loss and environmental degradation. The Purpose and Rationale goes on to explain that "(T)he growing demand for crop- and forest-based feedstocks for use in the LCFS program produce an increasing risk of deforestation and use of land with a high biodiversity value to meet this

[5] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/lcfs_appe.pdf

demand. It is vital that the LCFS program limit deforestation and land use change as a result of feedstock production as much as possible."

Though some might be relieved to see that CARB is showing so much concern about these critical matters,
340.3 the problem is that CARB is out of touch with current understanding of the imperative to stop deforestation. Limiting deforestation is simply not enough. CARB is so completely out of touch with global efforts on these matters that this failing needs to be addressed in this comment letter.

For instance, even though the statement is considered anodyne and toothless by many experts with experience addressing the drivers of deforestation and working to halt the loss of primary forest globally, the Glasgow Leaders Declaration on Forest and Land Use[6] that was signed during COP 26 in Scotland in 2021 is explicit in describing the need to "**halt and reverse forest loss and land degradation**." The objective is not to 'limit' deforestation. This is not just a semantical difference. Halting and reversing forest loss is the global standard, whereas simply aspiring to limit deforestation and land use change is by simple definition allowing for the loss of forest to continue. Earth living systems cannot afford more forest loss.

Thus, from the outset CARB has failed global forests with the description of these matters in the Purpose and Rationale for the amendments. This is inexcusable for an agency that has in many instances claimed to have expertise over tropical forest-based climate mitigation strategies, even though California is not host to tropical forests.

Prohibiting Palm Oil Based Fuels Is Long Overdue and Is Simply Not Enough

Our organization noted that CARB has finally taken steps to more explicitly prohibit the use of palm oil or palm derivative fuels in the LCFS program. However, we still take issue with the assignment of higher Carbon Intensity (CI) scores as a disincentive. First and foremost, the reliance of the LCFS on CI is essentially a case study in the manner in which CARB obfuscates climate science, as the concept of CI ignores the climate science fundamental that emissions are cumulative. Just like with cap-and-trade CARB embarks upon technocratic carbon accounting formulas that fail to take into account the most basic underpinnings of the climate problem: that emissions are cumulative and that we are working with a rapidly diminishing carbon budget. The LCFS still fails to pass the climate science smell test.

That said, CARB has long relied on disincentives in the market-based mechanism. It is actually quite remarkable that after all this time CARB is offering to clearly ban palm oil and palm derivative based fuels. Congratulations! However, this is not enough. The global policy debate has already moved on from palm to discuss the imperative of also banning soy as a feedstock for making liquid biofuels. As it can be said, *soy is the new palm*. But CARB is as behind the times on this matter, just as it is in aspiring to 'limit' deforestation as opposed to rising to the global standard to 'halt and reverse deforestation.' The prohibition of palm oil-based liquid biofuels is long overdue, and it is simply not enough.

Sustainability Certification Systems Are Proven Ineffective

In answer to concerns about the LCFS incentivizing global deforestation by incentivizing demand for high deforestation risk feedstocks, CARB decides to play a card from several decades ago: require certification to guarantee 'sustainability.' Unfortunately, CARB has apparently failed to look at what is happening with certification standards globally, much less at home in California.

---

[6] https://webarchive.nationalarchives.gov.uk/ukgwa/20230418175226/https://ukcop26.org/glasgow-leaders-declaration-on-forests-and-land-use/

The fact is that certification has not helped companies meet commitments to keep deforestation out of their supply chains.

As a window into this dynamic regarding the failures of certification schemes to guarantee sustainability, which is not a new phenomenon, Greenpeace International published a report in March 2021, nearly three years ago now, titled Destruction: Certified[7].

340.4 The purpose of the report is to assess the effectiveness of certification for land-based commodities as an instrument to address deforestation, land degradation and other ecosystem conversion and human rights abuses. **The analysis in the report shows that certification is a weak tool to address global forest and ecosystem destruction**.

Among the certification schemes evaluated in the report are the International Sustainability and Carbon Certification, the Round Table on Responsible Soy, and the Forest Stewardship Council (FSC). Though CARB does not name any of these specific schemes, experienced stakeholders can predict exactly where this proposal for certification will lead. This without even beginning to address the total lack of regulation of the certifying entities that would be responsible for the implementation of any certification scheme.

340.5 With decades of experience working on the development and implementation of certification schemes our organization is adamant in our position that the plan to require certification of high deforestation risk commodities for qualification for the LCFS is not only inadequate, it is bound to fail.

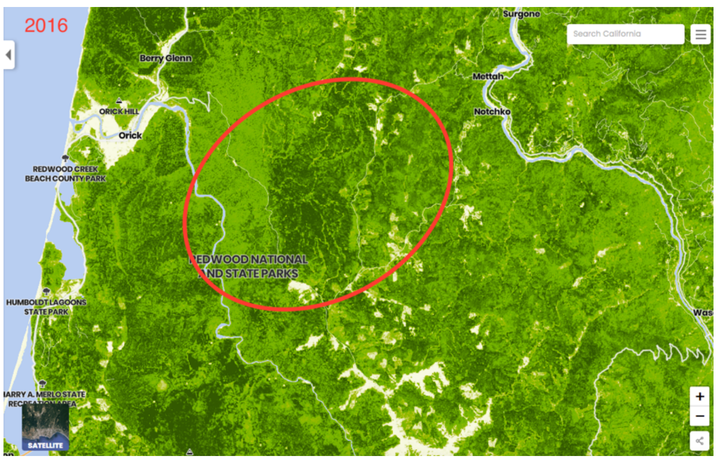
Forest Stewardship Council Weakened Standards to Certify Clearcutting in the Redwoods as Sustainable
As an example of why certification standards have failed as an instrument for addressing sustainability challenges with land-based commodities one has to travel no further than the redwood temperate rainforest ecosystem, Northern California's own globally important forest. In 2012, the FSC, in the face of strong community opposition, and after weakening their standards to allow clearcutting, certified Green Diamond Resource Company (GDRC). Interestingly enough, the GDRC clearcuts are visible from space.

This image above is of the southern boundary of the Redwood National and State Park system and the clearcut holdings of Green Diamond Resource Company in Humboldt County. The National Park, to the

[7] https://www.greenpeace.org/international/publication/46812/destruction-certified/

right side of the frame in dark green, is a UNESCO World Heritage site, ostensibly subject to the management protocols of the Man and Biosphere framework, which would normally include a significant buffer zone between the industrially managed holdings and the globally relevant protected area. Yet, as can be seen with the review of the image, the clearcutting is happening right up to the boundary of the Redwood National Park/World Heritage site. Despite a rhetorical emphasis on the importance of protecting forests as a climate mitigation tool CARB has remained silent about the intensive logging right up to the boundary of a World Heritage site in California. FSC certifies this logging as 'sustainable.'

Another set of maps, 'before and after,' from the California Forest Observatory[8], focused on Green Diamond Resource Company holdings to the north of the Redwood National Park, shows how clearcut logging can be certified sustainable. You can see the circle in the 2016 map below, highlighting an area of mostly intact second growth forest that is/was in the immediate vicinity of the Redwood National and State Park matrix. There can be no questioning the biological and climate value of this forest.



Unfortunately, as the 2020 map below shows, this area was aggressively logged by GDRC in the space of five years, leaving clearcuts visible from space. The products from this logging were certified and marketed as 'sustainable' by FSC. This is not the first time that CARB staff have received this evidence. CARB arguments that certification is a solution for avoiding forest loss and ecosystem degradation ignore reality.

[8] https://forestobservatory.com/

340.6 ***The Carbon Intensity, Environmental Repercussions and Climate Impacts of the Soy Oil Feedstock from Argentina Specified in the Phillips 66 Credit Pathway Are Grossly Underestimated***

It is unfortunate that when the imperative of halting global deforestation has become more acute than ever that such a grossly inadequate fuel pathway Life Cycle Analysis[9] was submitted with the Phillips 66 Application for an LCFS credit pathway for making 'renewable diesel' from soy imported from Argentina.

The assessment of Indirect Land Use Change (ILUC)[10] tried to apply a methodology from the Midwest United States to Argentina, though the quality of the assessment is so poor it is hard to discern exactly how the methodology was applied. This assessment of Indirect Land Use Change failed completely to address the most contemporary science when it comes to calculating ILUC.

The conclusion in the Application materials that deforestation from the expansion of the agriculture frontier is no longer an issue of concern for the soy sector in Argentina flies in the face of common knowledge. Indeed, this facile conclusion is refuted by simple and easy to find studies[11] from the Environment Ministry of the Government of Argentina that make it clear that the expansion of soy agriculture, which is closely related to the cattle industry, remains one of the major drivers of deforestation in the country. The assessments of the feedstock climate impacts as provided in the Application were woefully deficient.

Considering the urgency of the situation, an item that would serve CARB staff and leadership to take into consideration is the recently published report from the European organization Transport and Environment titled "Halt Deforestation-Driving Soy Biofuels Before it is Too Late."[12]

In this report clear arguments are made that soy must be considered a high-ILUC risk feedstock (something that the recent LCFS Rulemaking fails to do) and that **in order to protect global forests an aggressive**
340.7 **phase out of palm and soy-based biofuels is needed immediately**. There are many lessons to be learned from the European experience on these matters of global deforestation and biofuels, and CARB staff and leadership need to take measures to update the approach to assessing the climate impacts from high deforestation risk feedstocks like soy.

Much more research and analysis need to be done about the viability and environmental repercussions of granting a special climate value to making liquid biofuels from soy. The available evidence shows that this is not a climate solution. By rushing forward with these credit pathways for making liquid biofuels from commodities like soy CARB is running the risk of elevating California climate policy to become a driver of global deforestation.

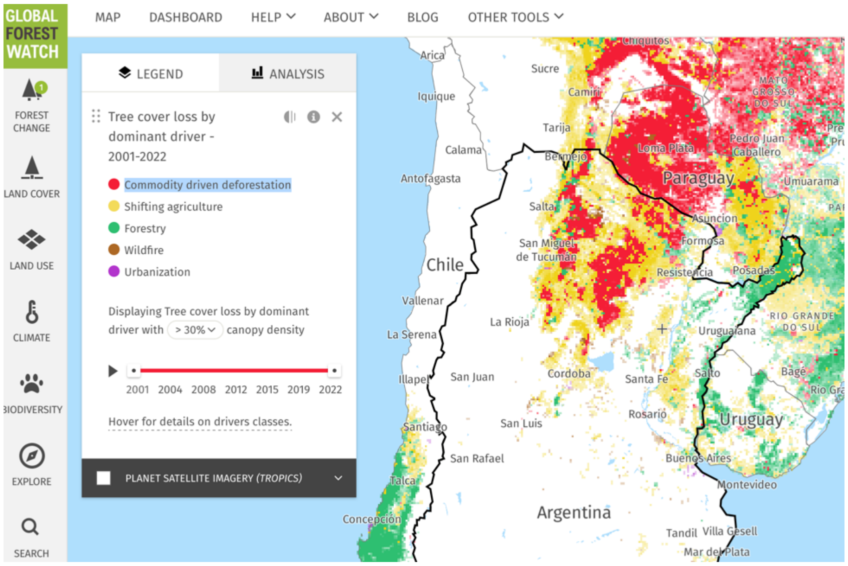
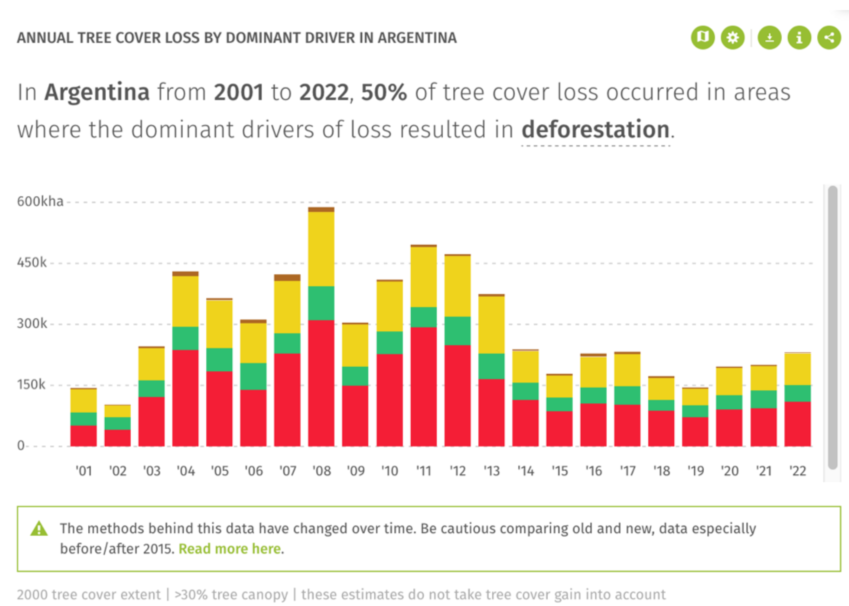
Global Forest Watch Data Describes Commodity Driven Deforestation in Argentina



This data is easily accessible from the Global Forest Watch portal[13]. The map image above shows in red the tree cover loss attributable to 'commodity driven deforestation since the year 2001 until 2022, the last year for which data is currently available. In the graph below commodity driven deforestation is again shown in red. The year 2022 saw the greatest amount of annual deforestation in Argentina since 2013.



Clearly the issue of deforestation in Argentina remains acute, despite the facile treatment of the matter by CARB in the Phillips 66 LCFS credit pathway application. The recently proposed amendments are also completely inadequate. The hard and sad truth is that by falsely characterizing liquid biofuels as a climate solution California climate policy is contributing to the market dynamics that drive global deforestation.

---

340.8 ***The Public Health Disaster Resulting from the Expansion of the Soy Agroindustry Is Being Ignored***

Over the last decades the soy agroindustry has expanded in Argentina at a breathtaking rate. This expansion has extended throughout Southern South America more broadly, especially in the region reaching north from Argentina into Paraguay, Bolivia and Brazil. This industrial monoculture model has relied almost exclusively on varieties of soy that are genetically modified organisms that are engineered to be resistant to pesticides, namely the "Round Up Ready" varieties, which are engineered to confer tolerance to glyphosate and dicamba, both of which are associated with a host of serious human health hazards and environmental risks. Unprecedented amounts of these pesticides have been applied across the region, sprayed by hand, by vehicle and by airplane. This has resulted in a tragic and intensifying public health crisis across the area that has hosted this exponential expansion of the soy agroindustry model.

The situation has gotten so desperate that communities that self-identify as "*los pueblos fumigados*" – the fumigated peoples – have begun to organize to address the indiscriminate use of toxic pesticides across the region, and to free themselves from an industrial model that is poisoning their families and their environment[14]. This public health crisis is totally ignored by the LCFS and the formulas used to give a CI value to different feedstocks. The LCFS design discriminates against affected communities; in the rush to put a price on carbon and to protect the stranded assets of multi-billion-dollar transnational energy corporations, California is embracing known false solutions like liquid biofuels. The externalities of these resource intensive high emissions feedstocks are thrust on rural and indigenous communities, which are forced to shoulder the burden of a climate mechanism that fails to take their well-being into account.

Once again it is marginalized communities that are paying the price of California's climate hubris.

Why is this happening? Is it disinterest? Or ignorance? Why is the State of California doubling down on the promotion of liquid biofuels as a climate solution? The status quo is untenable and the expansion of the production and use of these energy products is climate suicide.

The board of directors of CARB must take responsibility for the monster they are unleashing on the world. To turn a blind eye to the evidence that is being presented regarding the real-world impacts of these crop-based liquid biofuel products, whether it be '*sustainable aviation fuel*' or '*renewable diesel*,' is immoral. Doubling down on a poorly designed incentive mechanism to avoid publicly having to admitt to the defects of these failed technologies would be worse than irresponsible. The time to correct course is now.

We demand extensive reformulation and redesign of California's failing markets-based approach to climate, the LCFS being first up for review, revision and reframing. We remain available to meet with board members that are looking for more information about these matters of global relevance and local significance.

Sincerely,

Gary Graham Hughes

Subject: Comments on the California Air Resources Board Proposed Amendments to the Low Carbon Fuel Standard

Dear Dr. Laskowski:

Southern California Gas Company (SoCalGas) values the opportunity to provide feedback on the Proposed Amendments (Proposed Amendments) to the Low Carbon Fuel Standard (LCFS). The LCFS has played a critical function in decarbonizing the transportation sector and will continue to serve a crucial role in promoting the adoption of lower carbon transportation fuels to reduce greenhouse gas (GHG) emissions. To meet California's ambitious GHG reduction targets outlined in the 2022 Scoping Plan, CARB should foster a stable, long-term environment that encourages investment in methane capture projects essential for reducing emissions from sources including landfills, dairies, and wastewater. As highlighted in the Staff Report's Initial Statement of Reasons, "Capturing methane from California's sources is critical for achieving climate targets, including those set by SB 32, SB 1383, and AB 1279."[1]

We commend CARB for thoughtfully incorporating a smooth transition to fuels supporting zero-emission vehicles while maintaining support for clean fuels that have driven the emission reductions thus far in the program. Without additional support and direction for new programs, however, the proposed incentive adjustments may not be sufficient to encourage investments in biomethane and the infrastructure necessary to achieve carbon neutrality by 2045.

341.1 As such, SoCalGas's comments highlight the following: 1) CARB should establish a complimentary policy such as an industrial clean fuels standard to promote the growth of the biomethane market for use in hard-to-electrify sectors; and 2) the proposed deliverability requirements support rapid buildout of biomethane capture projects.
341.2

[1] Proposed Amendments to the Low Carbon Fuel Standard Staff Report: Initial Statement of Reasons; (ISOR) at 30.

341.1 cont.

1) CARB should establish a complimentary policy such as an industrial clean fuels standard to promote the growth of the biomethane market for use in hard-to-electrify sectors

SoCalGas appreciates that the Proposed Amendments recognize the need for more methane capture projects in California to reduce short-lived climate pollutants (SLCP) emissions.[2] We agree with CARB staff that immediate action to curtail these potent emissions will yield local health benefits and mitigate global warming as we transition to low-carbon energy systems and pursue carbon neutrality.[3]

More specifically, the proposed modifications to avoided methane crediting maintain a pathway for projects established before 2030 to recover initial capital costs of methane capture. These projects constitute some of the most cost-effective investments for carbon reduction in the state and merit fortification.[4] A complementary program to advance the deployment of biomethane beyond the transportation sector is essential to the sustainability of methane capture projects post-crediting phase-out.

We support the policy direction outlined in CARB's 2022 Scoping Plan for the long-term deployment of biomethane for hydrogen production and its expanded use in stationary sources. To sustain this momentum, the State should establish a clear pathway with concrete milestones and appropriate offramps before the complete phase-out of avoided methane credits. Since California's industrial sector is a significant contributor to natural gas consumption and greenhouse gas emissions, incentivizing biomethane use in sectors beyond transportation becomes crucial.[5] CARB could achieve this by opening the current LCFS program to stationary sources or using the current LCFS program as a model to create a new Industrial Clean Fuel Standard program. This new standard would aim to institute a set of gradually declining emissions-based targets for regulated entities, empowering the industrial sector to reduce emissions through diverse approaches including electrification, procuring low and zero-carbon fuels, carbon capture and sequestration, and enhancing energy efficiency. CARB should also evaluate pathways to utilize other programs such as the Cap-and-Trade Program to support the transition of biomethane into other sectors.

The ongoing success of the LCFS program is pivotal to fortifying the biomethane market, especially as its applications extend beyond transportation. To support a robust biomethane market with competitive pricing and a consistent supply, SoCalGas recommends expediting discussions on potential initiatives, such as an Industrial Clean Fuel Standard or expanding the utilization of

[3] ISOR at 29.
[4] CARB, California Climate Investments 2022 Mid-Year Data Update, September 2022, indicates that investments in dairy digesters and diverted organic waste cut carbon emissions by approximately $9 and $10 per ton, respectively. CARB's 2021 Annual Report on Climate Investments also showed that investments in organic waste to energy were the most cost-effective of the State's climate investments; at 119.
[5] California Industrial Energy Efficiency Market Characterization Study, XENERGY Inc., December 2001, available at http://www.calmac.org/publications/California%20Ind%20EE%20Mkt%20Characterization.pdf; at 3-22.

341.1 cont. other program funds like Cap-and-Trade for biomethane procurement. The proposed amendments to the avoided methane crediting underscore the need for establishing a complementary policy before 2030. This proactive measure not only incentivizes the market to lower prices but also provides clear guidance and procedures for funding opportunities, encouraging businesses to invest in biomethane projects.

As championed by CPUC-supported programs[6], the benefits of biomethane procurement are based on the avoided costs of well gas, encompassing upstream interstate transmission, and the avoided social cost of methane. Hence, it is crucial for CARB, as a regulatory body, to adopt programs that equally incentivize multiple cost-effective means of decarbonization to more rapidly achieve net-zero goals, benefiting society at large.

341.2 cont.

2) The proposed deliverability requirements support rapid buildout of biomethane capture projects

SoCalGas appreciates that CARB's proposed revisions to deliverability requirements acknowledge the importance of sustaining existing procurement agreements with out-of-state biomethane projects. The Proposed Amendments will encourage and expedite the expansion of biomethane capture projects throughout this decade, aligning with the imperative to reduce methane emissions.[7] California will need both in-state and out-of-state supplies of biomethane to decarbonize hard-to-abate sectors, including cement and steel manufacturing, as well as promoting methane capture and GHG emissions throughout the west, since GHG emissions are a global pollutant rather than a local pollutant. An uninterrupted flow of biomethane into California is a strategic imperative that fosters its adoption across diverse economic sectors over time.

Furthermore, the Book-and-Claim (B&C) deliverability approach not only supports the production of clean fuel sources that mitigate global pollutants but facilitates the cost-effective procurement of biomethane in support of California's clean energy policies and prioritization of energy security for all Californians. This is crucial for maintaining affordability while decarbonizing challenging sectors. As biomethane phases out of the LCFS, its limited availability for hard-to-abate sectors underscores the need for current policies to concentrate on boosting both production and demand. Allocating funds for developer incentives and consumer programs can drive greater end-use applications, bolstering production. Hence, it is critical for CARB to maintain biomethane B&C provisions in future policies supporting biomethane. Such a measure is essential to maintaining the positive momentum and success attained in the realm of affordable and reliable procurement thus far.

Conclusion

SoCalGas is grateful for the chance to offer feedback and to participate in discussions with CARB and stakeholders during the LCFS Program regulatory update. We are dedicated to a unified and

[6] Decision 22-02-025, Finding of Fact 16 at 53.
[7] Draft EIA at 18.

collaborative shift towards cleaner energy and acknowledge CARB's thoughtful consideration given to all stakeholders throughout this process. We eagerly anticipate continued engagement with staff to collaboratively establish a framework for expeditiously transitioning biomethane for use in other sectors.

Respectfully,

/s/ Kevin Barker

(Comment submitted electronically)

RE: The Importance to California's Climate Goals of Enabling Power-to-Liquid Fuel Producers to Source Low-Carbon Intensity Electricity via Book-and-Claim Accounting

Dear Chair Randolph,

The signatories of this letter are pleased to submit comments recommending a modification to the California Air Resources Board's ("CARB") proposed amendments to the Low Carbon Fuel Standard ("LCFS"). We support CARB's LCFS program, as it sends a market signal to decarbonize the transportation sector, is performance based, and provides long-term policy stability that supports investment. However, we respectfully request that CARB maintain LCFS policy stability for the clean fuels industry and preserve the eligibility of facilities that
342.1 produce Power-to-Liquid ("PtL") fuels to source low-carbon intensity electricity ("Low-CI Electricity") via book-and-claim accounting. PtL fuels, also known as eFuels, electrofuels or synthetic fuels, are drop-in replacement fuels for use in airplanes, ships and motor vehicles that do not trigger the costs or delays inherent to engine or infrastructure changes. Specifically, we request that CARB preserve the current renewable energy certificate ("REC") system for electrolytic hydrogen and enable the sourcing of energy for PtL fuel production via book-and-claim accounting.

342.2

CARB's proposed LCFS regulatory amendments are highly damaging to the nascent PtL industry in that the new proposed regulatory structure would require that PtL facilities source grid mix power both for PtL hydrogen and for their other energy needs. This structure would inhibit the growth of PtL fuels and the expansion of new sources of renewable power. One of the key benefits of PtL fuels is their deep reduction in carbon intensity (over 90%) compared to fossil fuel incumbents. The deep CI reduction hinges on reliance on carbon-free electricity. CARB's LCFS regulations, if they fail to allow book-and-claim mechanisms for PtL fuel producers' electricity procurement, will undercut the tremendous potential of PtL fuels to contribute to the decarbonization of internal combustion vehicles ("ICVs") and, importantly, the aviation sector. Indeed, the proposed LCFS regulatory change impedes fulfillment of the goals of CARB's 2022 Scoping Plan to dramatically decarbonize transport and power and reduces the likelihood that California will achieve its goal to displace 80% of its fossil jet fuel supply with sustainable aviation fuel ("SAF"). It also makes it very challenging to achieve the on-road and jet fuel CI reduction target of 90% by 2045 that CARB has proposed.

PtL has the potential to be an ultra-low carbon fuel alternative to petroleum derived transportation fuels and to scale rapidly - ***but only to the extent that PtL producers are allowed to source Low-CI Electricity***. PtL fuel producers do not use biomass feedstocks for production

342.2 cont but instead utilize carbon dioxide (CO_2) that would otherwise be emitted as waste and water as their only feedstocks to produce PtL transportation fuels. To convert water to hydrogen via electrolysis, PtL facilities require a substantial amount of power, which needs to come from carbon-free sources in order for the resulting fuels to achieve deep CI reductions. Due to this electricity demand, the proposed regulatory changes would dramatically increase the CI of PtL fuels (i.e., to a level at or above the petroleum baseline CI value) and perpetuate the use of fossil jet fuel and other petroleum-based fuels in the broader transportation sector. This will effectively stunt the innovative PtL industry, the importance of which has already been recognized in the road, aviation and maritime sectors and in other jurisdictions such as the European Union and United Kingdom (i.e. ReFuelEU Aviation, FuelEU Maritime, EU RED, and UK RTFO programs).

<u>CARB's Proposed Change to the Existing LCFS Regulation</u>
342.1 cont **<u>Is Highly Detrimental to PtL Fuels</u>**

Under §95488.8(i)(1)(A)-(B) of the existing LCFS Regulation, book-and-claim accounting is authorized for Low-CI Electricity supplied as a transportation fuel or to produce hydrogen through electrolysis if that hydrogen is used either as a transportation fuel or in the production of another transportation fuel (e.g., SAF). Through these provisions, PtL facilities are explicitly authorized to source Low-CI Electricity from the grid to produce hydrogen that is used in the production of PtL fuels. Under these existing LCFS provisions, Low-CI electricity can be sourced flexibly through the use of RECs or via a qualifying Green Tariff program.

The proposed LCFS regulatory revisions that CARB released on December 22, 2023, would dramatically narrow the power-sourcing landscape for PtL producers. The proposed amendments would revoke the current authorization to source Low-CI Electricity for electrolysis through the REC mechanism. To source Low-CI Electricity, the proposed regulations would instead require a PtL facility to construct a wind, solar or other renewable generation project and directly connect that power generation source behind the utility meter to the PtL fuel facility, which is typically impractical. CARB's regulatory proposal will severely inhibit the growth of a liquid fuel technology that holds great promise for scaling and, as noted above, is not dependent upon biomass feedstocks. By changing its policy this significantly with no notice to the industry or delayed phase-in, CARB will also undermine investor confidence in the continuity of its policy structure and thereby deter investment in ***all clean fuel facilities and technologies***, including game-changing fuels like PtL fuels.

<u>Policy Support for Expanding Power Sourcing Flexibility within the LCFS</u>

We appreciate that other considerations have informed CARB's development of the proposed LCFS amendments. In particular, we recognize that CARB is seeking to adhere to a strategy of aggressive electrification to reduce GHG emissions from the transportation sector and is seeking to support the growth of hydrogen fuel cell electric vehicles (FCEVs) through this regulatory proposal. By this comment letter, we do not seek to detract from CARB's electrification strategies and for the reasons discussed herein, we consider our proposed revision to the proposed LCFS amendments to be fully consistent with these strategies. However, we do think it important to bring to CARB's attention the difficulty of decarbonizing the aviation sector
342.2 cont without enabling PtL fuel producers to access Low-CI Electricity via the grid. It is only through

the ability to source zero-emission electricity from renewable energy resources that PtL facilities will be able to obtain ultra-low CI scores (e.g., < 10 gCO_{2e}/MJ) for their fuels, substantially reduce GHG emissions on a lifecycle basis and generate LCFS credits.

This past November, The International Council on Clean Transportation ("ICCT") published a white paper assessing the feasibility of meeting the targets in the Biden Administration's SAF Grand Challenge based on "resource availability, production costs, technology readiness level, and policy support."[1] ICCT's white paper emphasized the importance of PtL SAF in meeting the 2050 SAF Grand Challenge goal of 35 billion gallons, as follows:

> *We find that the near-term 2030 production target can be met with sustainable resources, but the 2050 target will be far more challenging to reach. In the longer-term, biomass volumes will need to be supplemented with a combination of other fuel sources or fuel burn reduction to meet the energy needs of the entire U.S. aviation sector. . . .*
>
> *E-fuels, or synthetic aviation fuels produced from renewable electricity, could help to bridge the supply gap in later years. . . .Though the technology remains in the demonstration phase, e-fuels have gained significant interest in Europe and other markets due to their 'drop-in' advantages and theoretically unlimited supply. For example, the EU has adopted an e-fuel mandate of 1.2% of aviation fuel, averaged over 2030 and 2031, and 5% of aviation fuel volumes by 2035 (European Commission, 2023). These e-fuels are estimated to be costlier than most biomass-derived SAFs in the near-future, but their costs could rapidly come down as electrolyzer technology matures and the cost of renewable electricity declines (Zhou et al., 2022). . . . With the use of policy incentives, including the IRA's 10-year production tax credits for hydrogen and carbon capture, utilization, and storage (CCUS), e-fuels will likely become cost-competitive within a much shorter timeframe.*[2]

Conclusion

Due to the importance of Low-CI Electricity to the production of PtL fuels, and the importance of PtL fuels to meeting both California's 2045 carbon neutrality goal and California's specific goals to displace fossil jet fuel with SAF, we respectfully recommend that CARB modify the proposed LCFS amendments such that PtL facilities are authorized to procure Low-CI Electricity for electrolytic hydrogen production and their other energy needs via book-and-claim accounting.

Thank you for the opportunity to provide comments on this important topic.

Re: Proposed Low Carbon Fuel Standard Amendments

Dear Board Members,

As a broad coalition of clean fuel producers committed to building a robust alternative jet fuel industry and decarbonizing aviation, we appreciate the opportunity to comment on the proposed changes to the California Low Carbon Fuel Standard (LCFS). We strongly support the CA LCFS program and applaud CARB's proposal to better align the program with the bold vision outlined in the 2022 Scoping Plan Update. Here, we comment specifically to express our strong support for CARB's proposal to eliminate the exemption for intrastate fossil jet fuel use under the LCFS, which is a critical step to enhance the market signal for sustainable aviation fuel (SAF).

Our organizations recognize and appreciate the state's continued leadership in the adoption of clean fuels in the aviation sector—one of the most difficult to decarbonize. In the 2018 LCFS rulemaking, CARB initiated inclusion of SAF in the program on an opt-in, credit-generating basis, which has since been replicated in other LCFS jurisdictions.[1] Unfortunately, while a helpful first step in providing some value for SAF under the LCFS, a stronger market signal is needed. The slow uptake of SAF in California can be traced, in part, to state regulatory rules, including the lack of an obligation on fossil jet fuel under the LCFS.[2]

California has rightfully set ambitious targets for aviation and for SAF specifically: Governor Newson recently called for 20% clean fuels adoption in the aviation sector,[3] the state legislature has estimated a need for at least 1.5 billion gallons of SAF blending by 2030,[4] and the 2022 CARB Scoping Plan states that 80% of all aviation fuel demand will need to come from SAF by 2045.[5] Given California's aggressive goals in the aviation sector and its recognition in the proposal that the LCFS should actively encourage transitioning the use of low carbon fuels to hard-to-decarbonize sectors in the coming decades, we urge CARB to better align the aviation provisions with the ambition that will be needed to achieve the state's goals.

Accordingly, we ask that CARB significantly strengthen the signal for SAF in the proposal provisions that would impact the aviation sector. Specifically, we suggest that CARB consider the following revisions to the proposal:

343.1
343.2

1. Include all fossil jet fuel as a deficit generator under the LCFS.
2. Accelerate the obligation to begin in 2025, rather than 2028.

---

[1] Both [Oregon Clean Fuels Program]() and [Washington Clean Fuels Standard]() currently exempt fossil jet fuel from generating deficits and allow SAF to generate credits on an opt-in basis.

[3] *See* California Office of the Governor, Governor's Letter to Chair Randolph. July 22, 2022. https://www.gov.ca.gov/wp-content/uploads/2022/07/07.22.2022-Governors-Letter-to-CARB.pdf?emrc=1054d6
[4] *See* AB1322 (Rivas) *available at* https://leginfo.legislature.ca.gov/faces/billNavClient.xhtml?bill_id=202120220AB1322. AB 1322was passed by the California assembly in 2022 and later vetoed by Governor Newsom, who, in his veto letter, supported the legislature's intent with the bill and ordered CARB to develop a "plan to reduce greenhouse gas emissions through the production and use of sustainable aviation fuels by July 1, 2024". Governor Newsom's veto letter *available at* https://www.gov.ca.gov/wp-content/uploads/2022/09/AB-1322-VETO.pdf?emrc=7598b6
[5] *See* CARB, 2022 Scoping Plan for Achieving Carbon Neutrality. December 2022. https://ww2.arb.ca.gov/sites/default/files/2022-12/2022-sp_1.pdf. Page 73. The Scoping Plan scenario envisions 20% of aviation fuel demand met by electricity (batteries) or hydrogen (fuel cells) in 2045, with sustainable aviation fuel meeting the remaining 80%.

343.3 3. Allow for book-and-claim accounting of low-CI electricity and RNG for SAF production, a regulatory approach that is already in place for electric vehicle charging.

343.4 4. Utilize the LCFS to encourage long term adoption of SAF in the aviation sector by adopting provisions that will help realize the additional air quality and climate benefits SAF can provide the state, including by developing mechanisms to credit the non-CO2 climate benefits of SAF.

343.5 5. Finally, we offer new legal analysis, attached, to show that California enjoys ample authority to obligate all jet fuel uplifted in California, in line with its treatment of other transportation fuels[6]

Please see our detailed comments and rationale for each below.

1. Include all jet fuel as a deficit generator under the LCFS.

The current proposal to remove the exemption only for intrastate jet fuel is an important step in the right direction but is far from sufficient to meet state goals for the aviation sector. Removing the exemption for intrastate jet fuel SAF will help by partially eliminating the LCFS rack fee benefit that currently applies to replacements for obligated fuels but not for SAF, thereby increasing the market signal for SAF production.[7] However, an obligation on roughly 10% of the jet fuel pool cannot be expected to close the gap between current uptake and the state's goals. Indeed, CARB's own modeling suggests that SAF blending could reach about 100 million gallons in 2030 and about 200 million in 2045 as a result of the current proposal.[8] While these volumes represent encouraging growth from today's volumes, they still fall far short of state goals, which would require roughly 800 million gallons of SAF to meet Gov. Newsom's 20% clean fuels adoption target, 1.5 billion gallons in 2030 to meet the AB 1322 goal, and 3.2 billion gallons by 2045 to meet the 2022 Scoping Plan target. As noted by the International Council on Clean Transportation (ICCT), obligating only intrastate jet fuel would have "a minimal impact on the program due to the small size of this fuel pool and would fail to meaningfully promote aviation decarbonization."[9]

343.1 To boost the impact of the aviation provisions and put California on a path to achieving its aviation decarbonization goals, we encourage CARB to remove the exemption for all jet fuel uplifted in California. While anything that closes the incentive gap under the LCFS between jet and diesel substitutes (including obligating only a portion of jet fuel as proposed) will be directionally helpful in increasing SAF supply by reducing the opportunity cost for producers who choose to make SAF, obligating all jet fuel uplifted in CA will have a much more significant impact in sending an investment signal for SAF and driving SAF use in the state.

If CARB maintains a focus on obligating only intrastate jet fuel use, we suggest that CARB obligate all jet fuel combusted in California, as outlined in the September 20, 2023 Board meeting, when CARB staff stated that intrastate jet fuel would include not only flights within California, but also the portion of jet fuel combusted in California from other flights that start or end in California. Such a provision need not be overly precise or require direct regulation of or reporting from aircraft operators. Rather, existing data and tools could be used to develop a rough estimation of intrastate fuel use.[10]

---

[6] *See* Attachment to our comments (Attachment_Legal Analysis_CARB LCFS Authority to Obligate Jet Fuel.pdf)

[7] SAF credit generation under the LCFS has consistently been less than 1% of credit generation for very similar renewable diesel. This is in part because of regulatory disincentives to SAF, such the LCFS rack fee and the state Cap-at-the-Rack cost under the Cap-and-Trade program, both of which increase the cost of fossil diesel, and the federal RFS program which awards 1.7 RINs per gallon of renewable diesel compared to just 1.6 per gallon of SAF. While the total size of the incentive gap varies, the BAAQMD analysis estimated it in 2020 at about $0.42 per gallon advantage for producing renewable diesel versus SAF, of which the LCFS represented about $0.14. An obligation only on intrastate jet fuel—a small fraction of the total pool—would reduce the LCFS disparity only marginally. New federal incentives under the Inflation Reduction Act, such as the SAF Blender's Tax Credit (40B) and the Clean Fuels Production Credit (45Z) can in theory make up much of that difference, but given that those expire in 2025 and 2027, respectively, they do not send a robust investment signal for needed SAF production. *See* CA LCFS Data Dashboard, Figure 2 at https://ww2.arb.ca.gov/resources/documents/lcfs-data-dashboard; *See also* Bay Area Air Quality Management District (BAAQMD), Sustainable Aviation Fuel: Greenhouse Gas Reductions from Bay Area Commercial Aircraft. The methods used by Graver et al. could be extended with a simple additional calculation to attribute fuel burn from either takeoff or landing (whichever occurs in California) plus a fraction of the cruising fuel burn equal to the fraction of the route's distance that lies within the state.

2. **Accelerate the obligation to begin in 2025, rather than 2028.**

343.2 CARB states that the proposal to delay the elimination of the exemption for fossil fuel jet fuel until 2028 is meant to provide "sufficient time for potential producers of alternative jet fuel to add capacity for the anticipated increased demand of alternative jet fuel"[11] However, such a delay is unnecessary, and we urge CARB to consider an earlier implementation date. We note that British Columbia has already added an obligation for all fossil jet fuel beginning in 2026, coupled with a volumetric SAF mandate beginning in 2028.[12] In addition, the proposal trails the ambition of both the ReFuel EU SAF mandate beginning in 2025 as well as the recently announced SAF mandate in Singapore beginning in 2026.[13]

Given that CARB is only proposing an obligation for jet fuel and not an actual SAF requirement, consistent with the LCFS, there is technically no need for lead time to increase SAF production capacity because the structure of the LCFS program allows for compliance via credits generated outside of aviation—credits which are readily available today.[14] In addition, CARB has already provided a five-year window for growth since making SAF an opt-in credit generator in 2019, during which time SAF volumes recorded under the LCFS have increased five-fold, despite a global pandemic and the continued regulatory disadvantages for SAF producers under both the LCFS and the Cap and Trade program.[15] Nevertheless, SAF continues to lag far behind similar ground transportation fuels under the LCFS. This gap should not be misinterpreted as a signal that the SAF market or SAF technologies are insufficiently mature to support an obligation for aviation, but rather should serve as evidence that the lack of an LCFS obligation for aviation has steered producers toward more lucrative opportunities serving road transportation.[16]

In any event, our organizations are confident that there will be enough production capacity to meet demand beginning in 2025. In the last year alone, global SAF capacity has increased by over 300 million gallons from a single producer and the International Air Transport Association estimates 2024 SAF production to triple to over 500 million gallons, or 1.5 million metric tonnes.[17] In the U.S., SAF production capacity has expanded by at least 70 million gallons, with new facilities including LanzaJet's Freedom Pine Fuels[18] and Montana Renewables Great Falls plant[19] coming online. Additional expansions are in the pipeline, including concrete, near-term plans for expansions from Diamond Green Diesel,[20] Montana Renewables,[21] and California's own World Energy.[22] Most importantly, there are roughly 3 billion gallons of renewable diesel consumed in the U.S. each year, 80% of which is produced domestically,[23] and half of which could easily be transitioned to SAF production—where it would produce additional benefits to both climate and local air quality— if additional policy incentives were put in place under the LCFS to level the playing field for SAF. In sum, there is sufficient SAF production capacity and CARB need only send an appropriate market signal.

[23] *See* https://ethanolproducer.com/articles/epa-2375-billion-rins-generated-in-2023. RIN data, which measure consumption of renewable diesel, underestimate domestic production capacity because a fraction of domestically produced fuels are exported.

We urge CARB to maintain its role as a leader in LCFS policy by accelerating its fossil jet fuel obligation to 2025.

3. Allow for book-and-claim accounting of low-CI electricity and RNG for SAF production.

343.3 We are supportive of the existing policy to allow book-and-claim accounting for low-CI electricity and RNG inputs to the production of low-CI hydrogen, and we applaud CARB's proposal to expand access through the use of power purchase agreements (PPAs) for low-CI electricity. However, we strongly believe that the same access should be expanded to SAF. At minimum, we urge CARB not to eliminate the existing allowance for indirect accounting for low-CI electricity to produce hydrogen that is used in the production of fuels, including SAF.

CARB's arguments for providing additional flexibility to low-CI hydrogen when directly used as a transportation fuel apply equally to SAF. Both low-CI hydrogen and SAF are young technologies with nascent markets that displace hard-to-electrify end uses like powering aircraft. The 2022 CARB Scoping Plan calls for significant growth in the use of both and, in the aviation sector, envisions even greater growth for SAF—from less than 1% of jet fuel consumption today to 80% in 2045.[24]

Despite these parallels, current and proposed LCFS rules for indirect accounting of low-CI energy systematically disadvantage SAF relative to hydrogen. Hydrogen producers have access to emissions reductions from process energy—low-CI electricity and RNG—that SAF cannot access. This is counter to state goals for SAF uptake and aviation decarbonization. We urge CARB to promote equity between future fuels like SAF and hydrogen and allow indirect accounting of RNG and low-CI electricity—both as a direct
343.3 input to SAF and as an input to hydrogen for use in SAF.

4. Utilize the LCFS to encourage long term adoption of SAF by adopting provisions that will help realize the additional air quality and climate benefits SAF can provide the state, including by developing mechanisms to credit the non-CO2 climate benefits of SAF.

We applaud CARB for thinking dynamically about alternative fuels and their impacts on climate, environment, and society. We urge CARB to acknowledge the additional, uncounted positive externalities that come from substituting fossil jet fuel with SAF and consider ways to better account for them under the LCFS.

First, while both light and medium/heavy-duty transportation are expected to electrify over the coming decades (although on different timetables), aviation will take much longer to transition to decarbonize, and SAF is expected to be the chief decarbonization lever for the foreseeable futures. The 2022 Scoping Plan scenario envisions 100% sales of zero emissions vehicles for light duty transport by 2035 and for medium/heavy duty transport by 2040, but for aviation sees only 20% alternative propulsion by 2045.[25]

343.4 Second, SAF provides additional air quality benefits that have not been fully considered by CARB. CARB notes that the current proposal would result in reductions in oxides of nitrogen (NO_x) and fine particulate matter (PM 2.5).[26] In addition, a recent synthesis of emissions measurement campaigns by the Airport Cooperative Research Program (ACRP), administered by the Transport Research Board of the U.S. National
343.4 Academies of Sciences, found that a 50% SAF blend could reduce by nearly 40% oxides of sulfur,[27] which are known to have significant negative effects on exposed populations, and which are present in greater proportions in fossil jet fuel than other transportation fuels like diesel. Additionally, other studies have found greater reductions in PM than the 55% cited in the SRIA. The ACRP study found PM reductions of

up to 65%, and a more recent measurement campaign found that SAF produced via the alcohol-to-jet pathway could reduce non-volatile particulate matter by up to 97%.[28]

343.4 Third, California's environmental justice communities have explicitly asked CARB to support displacement of fossil jet fuel with SAF, both in the formal recommendations to CARB of the Environmental Justice Advisory Committee[29] and in person, at the September 28th, 2023 Board meeting. Communities that live near and work at airports are some of the most vulnerable in California — of the ten busiest airports in the state, four are located within SB 535 designated disadvantaged communities, and another four are immediately adjacent.[30] These communities have long borne the disproportionate health impacts of unmitigated fossil jet fuel combustion.

Fourth, jet fuel causes unique contributions to global climate change that are unrecognized by the LCFS—harms that SAF can mitigate. Emerging research indicates that particulate matter reductions from SAF reduce aviation's non-CO_2 climate impact, specifically the climate forcing from "contrail cirrus" impacts (the combined warming from contrails and contrail-induced cirrus). The current best estimate from the most recent comprehensive study is that the climate impact from contrail cirrus is nearly twice the impact from CO_2.[31] Even the low end of current estimates–which show that contrail cirrus causes roughly half the total warming of CO_2– warrants consideration of potential mitigation opportunities from SAF.[32] One recent study cited found that a 50% SAF blend could reduce contrail cirrus climate impacts by over 20%. An eventual shift to 100% SAF could reduce the climate impact of contrail cirrus by 50%.[33] While continued scientific uncertainty around the size of the non-CO_2 climate impacts makes them difficult to precisely quantify, the direction of those impacts—less warming when SAF is used—is known.

We strongly believe that these additional benefits—which align closely with state goals and priorities and accrue only to SAF—justify action by CARB to prioritize the use of SAF. And as CARB has noted, transitioning fuels to other sectors in the long term requires that market signals transition first.[34] Under the current proposal, the market signal improves marginally, but is not likely to be enough to meet the state's goals. Accordingly, we encourage CARB to consider additional measures to credit those benefits. For example, CARB should consider applying a credit multiplier for SAF on the basis of the most conservative estimates of non-CO_2 climate benefits of SAF. (The European RED II program, currently provides a multiplier of 1.2x for SAF.) Alternatively, CARB might develop a "CO_2 equivalent" metric to account for these benefits in terms of carbon intensity and incorporate them into the CA-GREET model, as has been suggested by the European Commission in its recent study on how to address the non-CO_2 climate impacts of aviation.[35]

5. <u>California Enjoys Ample Authority to Obligate All Jet Fuel Uplifted in CA</u>

While some stakeholders have long asserted that CARB does not have legal authority to include jet fuel as an obligated fuel due to unarticulated claims of federal preemption in the sector, this claim has to date not been addressed on the merits and we hope this proposal catalyzes more detailed understanding among stakeholders of the scope of CARB's authority over aviation. As further outlined in the attached legal analysis and summarized below, it is clear that CARB enjoys ample authority to obligate both intrastate and all jet fuel uplifted in California (interstate and international) under the LCFS program.[36] None of the statutes that have been cited by stakeholders—the Clean Air Act, the Federal Aviation Act, or the Airline Deregulation Act, serve as a source of preemption or a barrier to CARB promulgating an aviation obligation that is commensurate with the state's goals in the aviation sector.

Here, we address each of those statutes in turn.

a) Clean Air Act

The Clean Air Act does not preempt an obligation on jet fuel under the CA LCFS, whether applied to intrastate jet fuel use or to all fossil jet fuel uplifted in the state. Importantly, courts analyzing preemption are "highly deferential to state law in areas traditionally regulated by the states" such as air pollution prevention and related public health measures.[37]

While Section 233 of the Clean Air Act does give EPA explicit preemptive authority on the regulation of emissions **<u>from aircraft engines</u>**, this provision is simply not relevant to the regulation of fuels.[38] Notably, the Ninth Circuit interprets the preemptive scope to cover only regulation of aircraft or aircraft engines, and has not extended preemption beyond that scope to include the regulation of jet fuel.[39] Indeed, a reading that Section 233 preempts regulation of jet fuel would be contrary to the plain meaning of the statute, the structure of the Clean Air Act, and EPA's longstanding interpretation of its authority over aviation. By its terms, section 233 refers to engine and aircraft standards promulgated under Section 231, not to fuel standards. And the underlying structure of the Clean Air Act certainly distinguishes between engine and fuel standards, with separate provisions for engine/vehicle standards under Sections 202 (on road vehicles/engines), 213 (nonroad vehicles/engines) and Section 211 (fuels for use in on road and nonroad vehicles/engines). To read Section 233's preemption provisions as somehow applying to aircraft fuels would be wholly inconsistent with this statutory structure.

Such an interpretation would also be inconsistent with EPA's long-held interpretation of its authority as extending only to aircraft/engine standards, with the Federal Aviation Administration (FAA) then having authority to promulgate fuel standards for any pollutant for which EPA has made an endangerment finding under Section 231 of the Clean Air Act.[40] Indeed, just last year the EPA reiterated this position, noting in its final endangerment finding for leaded aircraft fuels that EPA's only role was to make an endangerment finding and promulgate an engine standard for lead. Aviation fuel standards, EPA reiterated, were left to FAA.[41] Simply put, the Clean Air Act cannot preempt California from issuing fuel standards for aviation that EPA itself lacks the authority to issue.

---

[36] We note that, in the Canadian context, British Columbia has determined that any jet fuel sold in the province is subject to provincial regulation.

[37] 14 Exxon Mobil Corp. v. United States EPA, 217 F.3d 1246, 1255 (9th Cir. 2000).

[38] See 42 U.S.C. § 7573 (stating that" No State or political subdivision thereof may adopt or attempt to enforce any standard respecting emissions of any air pollutant from any aircraft or engine thereof unless such standard is identical to a standard applicable to such aircraft under this part.")

[39] See California v. Department of Navy, 624 F.2d 885, 888 (9th Cir. 1980); California ex rel. State Air Resources Bd. v. Department of Navy, 431 F. Supp. 1271, 1285 (N.D. Cal. 1977) (narrowly interpreting the "field" regulated as the "structure or performance of aircraft engines").

[40] *See* EPA, Advance Notice of Proposed Rulemaking on Lead emissions From Piston-Engine Aircraft Using Leaded Aviation Gasoline, 75 Fed. Reg. 22445-22446 (April 28, 2010) (explaining in EPA rulemaking that although EPA has authority under the Clean Air Act to regulate fuels used in motor vehicles and nonroad vehicles, fuels used exclusively in aircraft engines are regulated by FAA); see also EPA, Advance Notice of Proposed Rulemaking on Regulating Greenhouse Gas Emissions Under the Clean Air Act, 73 Fed. Reg. 44434 (July 30, 2008) ("Section 211(c) authorizes regulation of vehicle fuels and fuel additives (excluding aircraft fuel)…").

[41] *See* EPA, Finding That Lead Emissions From Aircraft Engines That Operate on Leaded Fuel Cause or Contribute to Air Pollution That May Reasonably Be Anticipated To Endanger Public Health and Welfare, 88 Fed. Red. 72372-72404 (October 20, 2023). (EPA states, "pursuant to 49 U.S.C. 44714, the FAA has a statutory mandate to prescribe standards for the composition or chemical or physical properties of an aircraft fuel or fuel additive to control or eliminate aircraft emissions which the EPA has found endanger public health or welfare under section 231(a) of the Clean Air Act.")

Further, even if EPA theoretically had authority to regulate jet fuel, the proposal does not run afoul of the preemption provisions under Section 233 of the Clean Air Act because the LCFS is not an "emission standard" applicable to aircraft and aircraft engines. Under the U.S. Supreme Court's definition of emission standard, the LCFS is not an emission standard because it does not restrict how much of a given pollutant an engine may emit, it does not require equipment of a certain pollution control device, or mandate emission control design features.[42] Further, as reinforced in a recent order from the U.S. District Court for the Central District of California, the LCFS is not an aviation emission standard because regulated entities (fuel suppliers) can comply by taking action unrelated to the purchase of SAF and the LCFS does not serve as an attempt to compel the purchase of SAF.[43]

b) Federal Aviation Act

The Federal Aviation Act grants broad authority to the FAA that has been generally held to "preempt the field" of aviation safety and airspace management.[44] However, the preemptive scope of the FAA Act is not limitless, and courts have determined that states may still regulate certain aspects of aviation operations that do not directly intrude on the FAA's domain.[45] With respect to fuels, the FAA's domain includes both the general authority to approve aviation fuels[46] and the specific statutory authority, under Section 44714[47], to prescribe "standards for the composition or chemical or physical properties of an aircraft fuel or fuel additive to control or eliminate aircraft emissions" which the Environmental Protection Agency (EPA) has determined endanger public health or welfare.[48]

The inclusion of jet fuel as an obligated fuel under the CA LCFS would not intrude on the FAA's regulatory domain. While the CA LCFS would establish standards for the lifecycle carbon intensity of jet fuel and incentivize the use of some fuels approved by FAA over others, it would **not mandate or prohibit the use of any particular jet fuel approved by the FAA**, nor would it set any of its own requirements on the composition of fuels. The FAA could—and should—exercise its own authority under Section 44714 to set a federal emissions standard on fossil jet fuel,[49] with which the LCFS obligation on fossil jet fuel would work in tandem. [50]

Importantly, an obligation on jet fuel is not equivalent to a mandate for SAF, and obligated upstream fuel providers are free to comply with LCFS credits from numerous sources. While we believe an obligation on fossil jet fuel—particularly all fossil jet fuel uplifted in the state—will meaningfully increase the market signal for SAF production and use in the state, the ultimate means of compliance with the LCFS is up to obligated parties, and aircraft operators will not be required to use SAF under the proposal.

c) Airline Deregulation Act (ADA)

Finally, some stakeholders have claimed that the ADA preempts California from obligating fossil jet fuel under the LCFS. The ADA expressly prohibits states from enacting or enforcing "a law, regulation, or other provision having the force and effect of law related to a price, route, or service of an air carrier that may provide air transportation . . . ."[51] However, although obligating jet fuel as a deficit generator under the LCFS may increase the cost of fuel uplifted by an airline, those impacts are likely outside the scope of ADA

[50] *See Rocky Mountain Farmers Union v. Corey*, 258 F. Supp. 3d 1134, 1152-53 (E.D. Cal. 2017) (holding LCFS was not preempted where and state efforts to reduce GHG emissions complemented and supported the EPA's efforts).
[51] 49 U.S.C. § 44713(b)(1). The exceptions do not apply to the proposal to include jet fuel in the LCFS

preemption,[52] impose such a tenuous burden on an air carrier's price or services that it would not trigger preemption,[53] or are simply too difficult to link causally to changes in carrier prices, routes or services, given the complexity of airline ticket and fuel pricing. Fundamentally, an LCFS obligation on jet fuel would not
343.5 entail any specific regulation of price, routes, or services, and is therefore not preempted by the ADA. Notably, the Central District of California recently held that the South Coast Air Quality Management District's Warehouse Indirect Source Rule does not run afoul of the ADA because it only has an indirect connection to carrier prices, services, or routes.[54]

To further insulate the aviation provisions from potential legal challenge, we recommend that CARB designate jet fuel suppliers as the reporting entity—as currently proposed. Designating fuel suppliers as the
343.5 reporting entity aligns with existing LCFS precedent for other fuel types and merely ensures that upstream aviation fuel suppliers are treated in the same fashion as all other transportation fuel suppliers in the California economy. This is significant, as case law around aviation preemption distinguishes between regulations targeted specifically at aviation and regulations that merely apply to upstream "inputs" to many sectors of the economy, including aviation.

d) Dormant Commerce Clause

In addition to preemption challenges, another potential challenge to the LCFS that could arise is the "dormant Commerce Clause" of the U.S. Constitution, which limits the state's authority to enact or enforce laws that burden interstate commerce. However, the LCFS has already been upheld against dormant Commerce Clause challenges.[55] Because the burden on jet fuel providers would not seem appreciably different from the burden imposed by the LCFS on other fuel providers, a court may be hard pressed to reach a different result if a dormant Commerce Clause challenge to the Proposal were brought.

Finally, we emphasize that CARBs attempt to avoid conflict with federal laws by isolating intrastate jet fuel is unnecessary. When Congress determines that a uniform national standard is needed, federal law preempts state regulation everywhere—including regulations internal to a state, such as obligating intrastate jet fuel under the LCFS. The proposal's limitation to intrastate jet fuel use offers only marginal protection from challenges, while dramatically weakening the impact of the obligation and threatening the achievement of the state's aviation decarbonization goals. Accordingly, we strongly suggest that CARB eliminate the distinction between intrastate and interstate jet fuel and obligate all jet fuel uplifted in California under the LCFS.

****

Thank you for the opportunity to comment on this LCFS Rulemaking. Please don't hesitate to reach out if you have any questions.

Sincerely,

[52] 17 See Nat'l Federation of the Blind v. United Airlines, Inc., 813 F.3d 718, 727-28 (9th Cir. 2016) (noting that the Ninth Circuit has narrowly interpreted "service" to mean an air carrier's transportation service).
[53] *Supra*. Note 15
[54] *Supra*. Note 43 (noting that the rule is not preempted because it applies to all warehouses and not only air carrier warehouses, that potential increased costs for air carriers are not sufficient as increased costs do not interfere with the air carrier/customer relationship, and that the rule does not require specific prices or fundamentally differ from other generally applicable regulation that affects an air carrier's cost of compliance.)

Best Regards,
Graham Noyes
Noyes Law Corporation

Infinium Operations, LLC ("Infinium") is pleased to submit comment recommending specific modifications to the California Air Resource Board's ("CARB") proposed amendments to the Low Carbon Fuel Standard ("LCFS"). We strongly support CARB's LCFS program. However, we respectfully request that CARB revisit its proposed power sourcing structure as applied to power-to-liquid fuels which are also known as eFuels". In the same way that electric vehicles must utilize zero carbon power to be carbon neutral, eFuels must b produced from zero carbon power to be carbon neutral. We respectfully recommend that CARB follow its own precedent by allowing eFuels to source low carbon intensity ("Low-CI") power in the future in the same manner as electric vehicles do today.

INFINIUM™

February 20, 2024

The Honorable Liane M. Randolph
Chair
California Air Resources Board

(Comment submitted electronically)

RE: Infinium Operations, LLC's Recommendations that would Enable California to Harness the Profound Decarbonization Potential of eFuels

Dear Chair Randolph,

Infinium Operations, LLC ("Infinium") is pleased to submit comments recommending specific modifications to the California Air Resources Board's ("CARB") proposed amendments to the Low Carbon Fuel Standard ("LCFS"). We strongly support CARB's LCFS program as it sends a strong market signal to decarbonize the transportation sector, is performance based, and
344.1 provides long-term policy stability that supports investment. However, we respectfully request that CARB revisit its proposed power sourcing structure (the "Proposed Structure" or "Proposed Regulations") as applied to power-to-liquid fuels ("PtL Fuels") which are also known as eFuels. In the same way that electric vehicles must utilize zero carbon power to be carbon neutral, eFuels must be produced from zero carbon power to be carbon neutral. We respectfully recommend that CARB follow its own precedent by allowing eFuels to source low carbon intensity ("Low-CI") power in the future in the same manner as electric vehicles do today.

As further examined in this comment, the Proposed Structure precludes the recognition of greenhouse gas ("GHG") emission reductions that are achieved by sourcing Low-CI power that is delivered over the grid to produce eFuels. By effectively mandating that eFuel production facilities source only grid power that includes fossil-based power except in rare circumstances, the Proposed Structure prevents both the growth of the eFuel industry and the expansion of new sources of renewable power. These policy outcomes undercut the tremendous potential of eFuels to decarbonize internal combustion vehicles ("ICVs") and jet engines; run counter to the goals of CARB's 2022 Scoping Plan to dramatically decarbonize transport and power; and reduce the likelihood that California will achieve carbon neutrality by 2045.

Recommended Changes

Infinium respectfully requests the following modifications to the Proposed Structure:

344.2 1. Allow eFuel production facilities to utilize the book-and-claim power sourcing system that is currently authorized for battery electric vehicles and electrolytic hydrogen to source Low-CI power via book-and-claim to produce electrolytic hydrogen and to produce drop-in fuels from hydrogen and carbon dioxide.

344.3 2. Establish a book-and-claim accounting system for hydrogen pipelines that is applicable outside California.

344.4 3. Establish a book-and-claim accounting system for carbon dioxide pipelines that is applicable outside California.

344.5 4. Revise the proposed Alternative Fuel definition to account for drop-in eFuel alternatives for gasoline and diesel fuel.

About Infinium

Infinium's mission is to decarbonize the transportation sector through the production of eFuels, an ultra-low carbon fuel alternative to petroleum derived transportation fuels. Infinium eFuels are drop-in replacements for use in planes, ships and motor vehicles without the need for costly infrastructure changes. Infinium's proprietary technology utilizes carbon dioxide (CO_2) that would otherwise be emitted, renewable power, and water as feedstocks to produce transportation fuels (e.g. eSAF, eDiesel and eNaphtha), with substantial reductions in lifecycle GHG emissions as compared to fossil-based alternatives.

Infinium's strategic and financial investors, include affiliates of Amazon, NextEra Energy, Mitsubishi Heavy Industries, SK Ventures, and AP Ventures- leading companies that are interested in both reducing their carbon footprints and innovating solutions to current environmental issues.

Infinium operates the first commercial drop-in eFuel facility in the world from its plant in Corpus Christi, Texas which will provide eFuels to Amazon's middle mile trucking fleet. Infinium announced a second commercial eFuel facility in West Texas called Project Roadrunner, which will be the largest in the world when it begins production in 2026. Project Roadrunner will produce primarily Infinium eSAF and smaller volumes of eDiesel and eNaphtha. Anchor partners include American Airlines as a sustainable aviation fuel ("SAF") off-taker and Breakthrough Energy Catalyst providing project equity investment.

How Can eFuels Help California Achieve Carbon Neutrality?

eFuels are renewable transportation fuels that are unique in that none of the energy content of the fuel comes from the input raw materials such as crude oil or biological sources (i.e., fuel feedstocks). The raw materials to produce eFuels are water and carbon dioxide that have no accessible energy value. Instead, the energy content in eFuels originates from renewable electricity applied during production to create hydrogen via electrolysis and subsequently reacted with CO_2 to yield eFuels such as eSAF, eDiesel and eNaphtha. In this respect, eFuels provide a method to convert renewable energy into a drop-in replacement fuel for ICVs and long-haul jets without the need to extract energy or release additional carbon from fossil crude oil or biomass-derived feedstocks.

eFuels have been recognized as a foundational fuel pathway in the policy framework of many jurisdictions and have also been recognized as a vital solution by non-governmental organizations ("NGOs") and think tanks. eFuels (with lifecycle GHG emission reductions exceeding 90% if produced using zero CI energy) provide the most effective means to substantially decarbonize internal combustion vehicles ("ICVs") and long-haul jets, and the drop-in nature of eFuels allows harnessing the massive value and capabilities of existing vehicles and liquid fuel infrastructure (e.g. storage and distribution systems).

The underlying logic of utilizing eFuels has been demonstrated by analysis completed by the University of California Institute of Transportation Studies ("ITS") in a report that charted California's likely course to carbon neutrality in the transportation sector. As stated in the Executive Summary, "The purpose of this study is to provide a research-driven analysis of possible policy options that could, if combined, put the state on the pathway to a carbon-neutral transportation system by 2045."[1]

The ITS report's authors deployed an aggressive suite of policies to accelerate and maximize the speed and scale of the transportation electrification to create the scenario for their analysis. Nonetheless, the Driving California's Transportation Emissions to Zero report concluded that a significant number of ICVs will remain on the road beyond 2035 and even beyond 2045 and these vehicles will require a substantial continued supply of liquid fuels. The ITS report recognized the resiliency of ICVs in terms of vehicle life and reached the conclusion that while total energy demand for transportation would drop substantially due to the efficiency of electric vehicles, ***almost half of all transportation energy demand in California would still be met by liquid fuels in 2045 as is reflected by the following figure from the ITS report***.[2] Importantly, the methodology of the ITS report limited the demand for SAF to fuel uplifted for intrastate flights in California only,[3] thus the report's fuel demand forecast did not account for approximately 90% of aviation fuel demand in California.

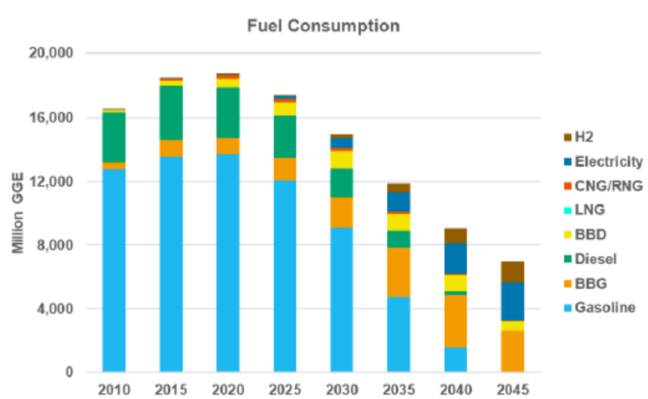

Figure EX-2. CO_2 emissions and fuel consumption projections in the LC1 scenario. The near-zero CO_2 emissions target is reached by 2045, with nearly all fossil fuels replaced by electricity, hydrogen, and biofuels at that date. (MMT, million metric tonnes; SAF, sustainable aviation fuel; H2, hydrogen; CNG/RNG, compressed natural gas/renewable natural gas; LNG, liquefied natural gas; BBD, bio-based diesel, including biodiesel and renewable diesel; BBG, bio-based gasoline, including ethanol blends and drop-in gasoline replacement fuels)

Driving California's Transportation Emissions to Zero

[1] See Institute of Transportation Studies, "Driving California's Transportation Emissions to Zero," (April 2021), available at https://escholarship.org/uc/item/3np3p2t0 , Executive Summary at p. 1, and Figure EX-2.
[2] Id.
[3] Id. at p. 395.

A close review of the ITS fuel forecasts for 2045 highlights the critical importance of low carbon liquid fuels to California's goal of achieving carbon neutrality:

- With reference to BBG (Bio-based Gasoline), ITS projected that the demand for this type of fuel would approximately double between 2025 and 2045 from 1.2 BGY to 2.4 BGY (in GGE, Gasoline Gallon Equivalent).
    - It is important to note that in the current market, ethanol is the only commercialized Bio-based gasoline and is restricted to a maximum blend level of 10%. Flex fuel vehicles can utilize blends of up to 85% but represent a small portion of the ICV fleet.
    - Thus, unless a drop-in Bio-gasoline is commercialized or eFuel is utilized, fossil-based gasoline would be the only fuel option and preclude achievement of California's carbon neutrality goal.
- With reference to BBD (Bio-based Diesel), the ITS report projects demand for this type of fuel will decline from approximately 930 MGY to 625 MGY (GGE).
    - However, as previously noted, the ITS report only evaluated demand for intrastate jet fuel in its analysis. If aviation fuel for interstate and international fuel is included, the demand for BBD in 2045 would increase to approximately 4.6 BGY or continued fossil jet fuel usage would be necessary to enable air travel.
    - Thus, if California considered all jet fuel uplifted in the State, it would be necessary to expand bio-based diesel usage by a factor of over 7x, a strategy that the ITS report deemed infeasible due to biomass feedstock supply constraints. eFuels will have a significant role in filling this void, given concerns regarding feedstock supply.

The European Union has Integrated eFuels into their Climate Policies

Consistent with the ITS analysis, the European Union ("EU") has determined eFuels to be an essential solution in the transport sector toward achieving the Union's carbon neutrality goals.

The EU RefuelEU Aviation program mandates steadily increasing blends of SAF for flights originating and departing in the EU with a sub-mandate for eFuels of 35% by 2045, as depicted in this chart.[4] In the road sector, under the Renewable Energy Directive ("RED"), eFuels must be blended to a minimum of 1% by 2030, with member countries planning to adopt higher quotas of up to 5.5%. In the marine sector, under the FuelEU Maritime program, eFuels are expected to play an outsized role in meeting the sector decarbonization mandate of 80% reduction in GHG emissions by 2050.

[4] See TOPSOE, "The Outlook for SAF," Timeline 3: The Course of Legislation, available at "https://www.topsoe.com/sustainable-aviation-fuel/saf-outlook".

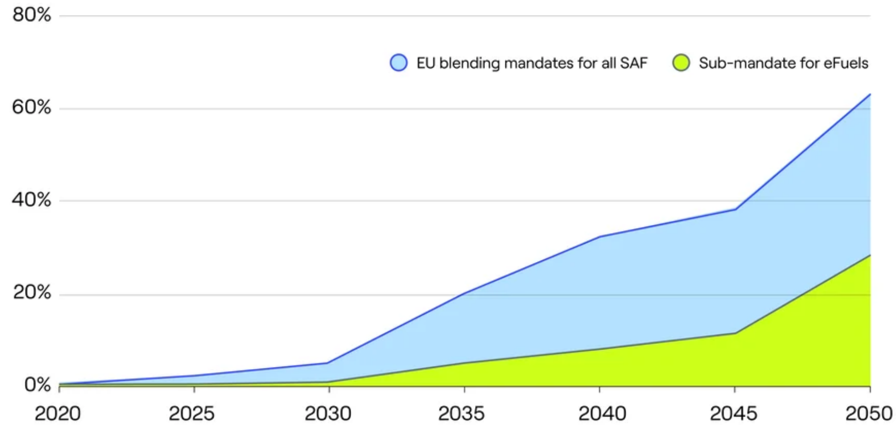

Chart: EU blending mandates for all SAF and sub-mandate for eFuels

The International Council on Clean Transportation has Recognized the Importance of eFuels

This past November, The International Council on Clean Transportation ("ICCT") published a white paper assessing the feasibility of meeting the targets in the Biden Administration's SAF Grand Challenge based on "resource availability, production costs, technology readiness level, and policy support."[5] ICCT's white paper emphasized the importance of eSAF in meeting the 2050 SAF Grand Challenge goal of 35 billion gallons, as follows:

> *We find that the near-term 2030 production target can be met with sustainable resources, but the 2050 target will be far more challenging to reach. In the longer-term, biomass volumes will need to be supplemented with a combination of other fuel sources or fuel burn reduction to meet the energy needs of the entire U.S. aviation sector. . . .*
>
> *E-fuels, or synthetic aviation fuels produced from renewable electricity, could help to bridge the supply gap in later years. . . .Though the technology remains in the demonstration phase, e-fuels have gained significant interest in Europe and other markets due to their 'drop-in' advantages and theoretically unlimited supply. For example, the EU has adopted an e-fuel mandate of 1.2% of aviation fuel, averaged over 2030 and 2031, and 5% of aviation fuel volumes by 2035 (European Commission, 2023). These e-fuels are estimated to be costlier than most biomass-derived SAFs in the near-future, but their costs could rapidly come down as electrolyzer technology*

[5] O'Malley, J., Pavlenko, N., & Kim, Y.H. (2023). Meeting the SAF Grand Challenge: Current and Future Measures to Increase U.S. Sustainable Aviation Fuel Production Capacity. International Council on Clean Transportation. Available at https://theicct.org/wp-content/uploads/2023/11/ID-37-%E2%80%93-SAF-Grand-Challenge-white-paper-letter-40036-v3.pdf.

matures and the cost of renewable electricity declines (Zhou et al., 2022). . . . With the use of policy incentives, including the IRA's 10-year production tax credits for hydrogen and carbon capture, utilization, and storage (CCUS), e-fuels will likely become cost-competitive within a much shorter timeframe.[6]

Low-CI Power Sourcing is Essential to the Success of eFuels

344.6 As noted by ICCT, eFuels are costlier than most biomass-derived SAF currently and in the near future. However, there is an opportunity to reduce the cost of eFuels as electrolyzer technology matures and the cost of renewable electricity further declines. Success in driving down the cost of both wind and solar power has been an enormous success story that has been led in the US by California policy. Similarly, California's 2022 Scoping Plan contained ambitious goals to expand supply and demand for hydrogen while driving down prices.

eFuels are uniquely well-situated to benefit from further reductions in the cost of renewable power and electrolyzers but the tremendous potential of this industry's growth will be stunted by the policy change in the Proposed Structure. Under §95488.8(i)(1)(A)-(B) of the existing LCFS Regulation, book-and-claim accounting is authorized for Low-CI Electricity supplied as a transportation fuel or to produce hydrogen through electrolysis if that hydrogen is used either as a transportation fuel or in the production of another transportation fuel (e.g., SAF). Through these provisions, eFuel production facilities are explicitly authorized to source Low-CI Electricity from the grid to produce hydrogen that is used in the production of eFuels. Under these existing LCFS provisions, Low-CI electricity can be sourced flexibly through the use of Renewable Energy Certificates ("RECs") or via a qualifying Green Tariff program.

The proposed LCFS regulatory revisions that CARB released on December 22, 2023, would dramatically narrow the power-sourcing landscape for eFuel producers. The proposed amendments would revoke the current authorization to source Low-CI Electricity for electrolysis through the REC mechanism. To source Low-CI Electricity, the proposed regulations would instead require an eFuel facility to construct a wind, solar or other renewable generation project and directly connect that power generation source behind the utility meter to the eFuel facility, which is typically impractical and infeasible. CARB's regulatory proposal will severely inhibit the growth of a liquid fuel technology that holds great promise for scaling and, as noted above, is not dependent upon biomass feedstocks. By changing its policy this significantly with no notice to the industry or delayed phase-in, CARB will also undermine investor confidence in the continuity of its policy structure and thereby deter investment in ***all clean fuel facilities and technologies***, including game-changing fuels like eFuels.

Book-and-Claim Power Sourcing Recommendation

Due to the importance of Low-CI Electricity to the production of eFuels, and the importance of eFuels to meeting both California's 2045 carbon neutrality goal and California's specific goals to displace fossil jet fuel with SAF, we respectfully recommend that CARB modify

[6] *Id.* at 21.

344.6 cont. the proposed LCFS amendments such that eFuel production facilities are authorized to procure Low-CI Electricity for electrolytic hydrogen production and their other energy needs via book-and-claim accounting.

344.7 Under existing LCFS provision §95488.8(i)(1)(A)-(B), Low-CI electricity supplied as a transportation fuel, e.g., used to power BEVs, can be sourced flexibly through the use of RECs or via a qualifying Green Tariff program. Under these provisions, it is also required that the electricity be supplied to the grid within the same balancing authority as where the EVs are charged or in compliance with CPUC §399.16, that all environmental attributes be retired with limited exceptions, and that the RECs be used within three quarters of when the RECs were generated.

As is currently the case for electrolytic hydrogen that can utilize RECs to obtain Low-CI power, CARB should restore and authorize this same power sourcing structure for eFuels that meets the requirements established by §95488.8(i)(1)(A)-(B). See Exhibit A for illustrative regulatory language that is aligned with this comment's recommendations.

344.8 Infinium also requests that the proposed definition for Alternative Fuel be revised to include the range of eFuel types including eDiesel, and eNaphtha / eGasoline. As drafted, the definition for Alternative Fuel includes fuels that are not CaRFG and 'diesel fuel'. However, for example, diesel fuel, as defined under California Code of Regulations, title 13, section 2281(b), includes any fuel that is commonly or commercially know, sold or represented as diesel fuel. As a result, any drop-in non-petroleum alternative such as eDiesel could be classified as 'diesel fuel' under this broad definition. See Exhibit A for illustrative regulatory language that is aligned with this comment's recommendations.

Infinium's Pipeline Recommendations

344.9 **Hydrogen:** Infinium supports CARB's proposal to provide a 'book-and-claim' accounting approach for low-CI hydrogen. To meet California's GHG reduction targets and support the eFuel industry, it is essential to utilize book-and-claim to preserve the CI attribute of hydrogen that is transported in multi-source/multi-use distribution systems, where Low-CI hydrogen is comingled with conventionally produced hydrogen. A robust book-and-claim system for hydrogen will ensure that the low-carbon attributes of the hydrogen are retained and applied to end-uses where the most environmental benefit can be derived. This sends the necessary long-term signal for low-CI hydrogen to play a meaningful role in decarbonizing transportation.

344.10 One key improvement to the LCFS proposal that Infinium supports is to eliminate the requirement that eligible hydrogen must be supplied to California in a dedicated pipeline as proposed in §95488.8(i)(3)(A). This requirement places an unnecessary constraint on a nascent market and will stifle investments at a time when massive capital outlays are needed to bring low-carbon hydrogen to scale. There are no dedicated interstate hydrogen pipelines to California. This requirement therefore favors only in-state hydrogen pipelines and fails to recognize the value of using hydrogen as a feedstock to produce eFuels out of state and imported for use in California. Section 95488.8(i)(3) specifically indicates the intention that the low-CI hydrogen book-and-claim approach should be applied to hydrogen used in "Alternative Fuel Production", but this proposed

344.10 cont. eligibility requirement precludes alternative fuel facilities out of state from realizing these benefits. We anticipate that eFuel production facilities will be located in fuel producing regions across North America, be connected to regional hydrogen pipelines, and must necessarily lower their CI by utilizing low-CI hydrogen. We urge CARB to adopt a wider worldview that acknowledges the need for a multi-jurisdictional supply chain for low-CI hydrogen.

We specifically request that CARB modify §95488.8(i)(3)(A) as follows:

> Low-CI hydrogen is injected into a dedicated hydrogen pipeline physically connected to ~~California~~ a distribution system or a production facility that provides transportation fuel to California.

344.11 **Carbon Dioxide:** Infinium recommends that book-and-claim be similarly established for carbon dioxide transported by pipeline with the following proposed regulation:

> *Book-and-Claim Accounting for Pipeline-Injected carbon dioxide Used in Alternative Fuel Production.* Indirect accounting may be used for carbon dioxide used to produce alternative fuel for transportation purposes provided the conditions set forth below are met:
>
> (i) Carbon dioxide is injected into a dedicated carbon dioxide pipeline physically connected to a production facility that provides alternative fuel to California
>
> (ii) To substantiate carbon dioxide quantities injected into the pipeline as an input to alternative fuel production, the pathway application and subsequent Annual Fuel Pathway Reports must include the following documents linking the environmental attributes of carbon dioxide in kg with corresponding quantities of carbon dioxide in kg withdrawn from the pipeline: monthly invoices showing the quantities of carbon dioxide (in kg) sourced and the unredacted contract by which the fuel pathway holder obtained the environmental attributes.

Thank you for the opportunity to provide comments. Should you have any questions or would like additional information, please feel free to contact me at dzaziski@InfiniumCo.com.

With kind regards,

David Zaziski, Ph.D.
Vice President, Policy & Government Affairs

The following proposed regulatory text is provided for illustrative purposes with deleted text as compared to the Proposed Regulations indicated by ~~strike-outs~~ and inserted text indicated by underlining.

344.12 **§ 95481. Definitions and Acronyms.**

(…)

"Alternative Fuel" means any transportation fuel that is not fossil CaRFG, fossil diesel fuel, or fossil jet fuel including those fuels specified in section 95482(a)(3) through (a)(13).

(…)

"PtL Fuel" means a synthetic hydrocarbon fuel that is produced from water, captured CO_2 and electricity, and that can replace or be blended into CARBOB, CaRFG, diesel fuel or jet fuel.

(…)

344.13 **§ 95488.8. Fuel Pathway Application Requirements Applying to All Classifications.**

(…)

(i) Indirect Accounting for Low-CI Electricity, Biomethane, PtL Fuel and Low-CI Hydrogen.

(1) *Book-and-Claim Accounting for Low-CI Electricity Supplied as a Transportation Fuel, Direct Air Capture projects, or Used to Produce PtL Fuel or Hydrogen.* Reporting entities may use indirect accounting mechanisms for low-CI electricity supplied as a transportation fuel, for PtL Fuel supplied as a transportation fuel, for hydrogen production and processing for transportation purposes (including hydrogen that is used in the production of a transportation fuel), or for direct air capture projects, provided the conditions set forth below are met:

(A) For electricity used as a transportation fuel, for PtL Fuel production, or as an input to hydrogen production delivered through the grid without regard to physical traceability if it meets all requirements of this subarticle. The low-CI electricity must be supplied to the grid within a California Balancing Authority (or local balancing authority for PtL Fuel or hydrogen produced outside of California) or alternatively, meet the requirements of California Public Utilities Code section 399.16, subdivision (b)(1). Such book-and-claim accounting for low-CI electricity may span only three quarters. If a low-CI electricity quantity (and all associated environmental attributes, including a beneficial CI) is supplied to the grid in the first calendar quarter, the quantity claimed for LCFS reporting must be matched to grid electricity used as a transportation fuel

344.13 cont.

or for hydrogen or PtL Fuel production no later than the end of the third calendar quarter. After that period is over, any unmatched low-CI electricity quantities expire for the purpose of LCFS reporting.

(B) Low-CI electricity used as a transportation fuel or used for hydrogen or PtL Fuel production for transportation purposes can be indirectly supplied through a green tariff program (including the Green Tariff Shared Renewables program described in California Public Utilities Code Section 2831-2833) or other contractual electricity supply relationship that meets the following requirements:

1. Electricity is generated by, or supplied under contract to, the pathway applicant for all environmental attributes of the claimed electricity. In order to substantiate low-CI electricity claims, the applicant must make contracts available to the Executive Officer, upon request, to demonstrate that the electricity meets the requirements of this subarticle. Generation invoices or metering records are required to substantiate the quantity of low-CI electricity produced from the renewable assets. Monthly invoices must be unredacted copies of originals showing electricity sourced (in kWh) and contracted price;

2. All electricity procured by any LSE for the purpose of claiming a lower CI must be in addition to that required for compliance with the California Renewables Portfolio Standard (described in California Public Utilities Code sections 399.11-399.32~~)~~ or, for hydrogen or PtL Fuel production for transportation purposes outside of California,) in addition to local renewable portfolio requirements;

3. Renewable energy certificates or other environmental attributes associated with the electricity, if any, are not issued credits or claimed under any other voluntary or mandatory program with the exception of the federal RFS, and the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800). Retirement of renewable energy credits for the purpose of demonstrating Green Tariff Shared Renewables procurement to the California Public Utilities Commission does not constitute a double claim.

(C) For direct air capture projects ~~or for hydrogen used as a transportation fuel~~, low-CI electricity must meet the following criteria:

344.13 cont.

1. The low-CI electricity must be supplied to the grid within the local balancing authority where the electricity is consumed or delivered to that local balancing authority without substitution consistent with the requirements of California Public Utilities Code section 399.16, subdivision (b)(1).

2. The pathway holder or the project operator must be the first contracted entity for procuring the low-CI electricity.

3. Low-CI electricity must be supplied by new or expanded low-CI electricity that begins new or expanded production on or after January 1, 2022, or within three years of the start of the hydrogen production facility or direct air capture project, whichever is later.

4. Such book-and-claim accounting for low-CI electricity may span only one quarter. If a low-CI electricity quantity (and all associated environmental attributes, including a beneficial CI) is supplied to the grid in the first calendar quarter, the quantity claimed for LCFS reporting in the same calendar quarter. After that period is over, any unmatched low-CI electricity quantities expire for the purposes of LCFS reporting.

5. Any renewable energy certificates or other environmental attributes associated with the energy are not issued credits or claimed produced, or are retired and not claimed under any other voluntary or mandatory program with the exception of the federal RFS, incentives under the Infrastructure Investments and Jobs Act or the Inflation Reduction Act, and the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800).

RE: MN8 Comments on Proposed Low Carbon Fuel Standard Amendments

Dear CARB staff and board,

345.1 MN8 Energy LLC (MN8) appreciates CARB's ongoing effort to update the Low Carbon Fuel Standard (LCFS) regulation. MN8 is largely supportive of the Proposed Regulation Order (The Order) and appreciates the opportunity to offer these comments.

MN8 develops, owns, and operates renewable energy generation facilities, battery energy storage systems (BESS) and electric vehicle (EV) charging stations. Today, we provide clean, affordable energy to over 200 world-class enterprise customers, with an operating fleet of over 850 energy projects and approximately 3 gigawatts (GW) of solar photovoltaic (PV) and BESS capacity spread across 28 US states. We are also partnering with various customers, such as OEMs and fleet operators, to develop EV charging solutions with the goal of delivering a reliable and high-quality experience to EV drivers that will enable widespread EV adoption.

Strengthening the LCFS Carbon Intensity Targets

345.2 MN8 supports CARB's proposed amendments to increase California's LCFS carbon intensity (CI) benchmarks. California has not updated its LCFS annual CI benchmarks since 2018 and the state has made significant progress in technology development and Zero-Emission Vehicle (ZEV) infrastructure deployment since the last update. MN8 appreciates CARB staff's (Staff) in-depth analysis and engagement with stakeholders to determine appropriate benchmark updates. We agree with Staff's assessment that a reduction in the CI of transportation fuel of at least 30% by 2030 and 90% by 2045 is both achievable and necessary to meet the state's goal in transportation decarbonization and beyond. Increasing the stringency of the LCFS CI targets and implementing an automatic acceleration mechanism will provide the market with a strong incentive to make long-term investments in low carbon transportation infrastructure.

Proposed Amendments to the LCFS ZEV Infrastructure Crediting Program for Light-Duty Fast Charging Infrastructure (LD-FCI)

345.3 MN8 recommends that CARB delay implementing a requirement that stations be built in low-income (LIC) or disadvantaged communities (DAC), or at least ten miles away from the nearest fast charger, to be eligible for the LD-FCI pathway. There remain substantial

345.3 cont. additional infrastructure needs across the LD charging space – the state needs 39,000 public DCFCs by 2030, and 85,000 by 2035, and had installed around 10,000 as of the end of 2023 and just over 1,000 over the course of 2023[1]. This means that the average rate of public DCFC buildout needs to achieve approximately four times the rate realized in 2023 over the period spanning 2024-2030 to meet the state's goals; this will require a rapid acceleration of deployments. These infrastructure needs include but are not limited to LICs and DACs. FCI can serve an important role in achieving the rapid and widespread public DCFC infrastructure deployment needed by the state. CARB should therefore delay implementation of any locational constraints around LD-FCI eligibility until a later rulemaking, if and when it finds that the state is clearly on pace to meet its immense DCFC deployment needs.

345.4 MN8 also cautions against the proposed amendment to limit the maximum number of eligible chargers in the LD-FCI program to four per site. Limiting the number of eligible chargers at a participating site could discourage the build-out of larger charging hubs that will be needed in certain locations to provide a more accessible and reliable service to drivers. As EV adoption rises, public charging stations must have adequate charging capabilities to support current and future demand, which will require sites far larger than four charging ports in high-traffic locations.

Support of a new FCI program for medium- and heavy-duty EVs

345.5 MN8 supports CARB's proposed amendments to expand the ZEV Infrastructure Fueling Pathways for Medium- and Heavy-Duty (MHD) vehicles. Expanding LCFS ZEV credit generation to the MHD vehicle sector will complement existing policies in California including the Advanced Clean Truck (ACT) and Advanced Clean Fleet (ACF) rules to support a rapid transition to ZEVs in the MHD sector. MN8 appreciates CARB's willingness to consider stakeholder feedback in proposing that credits can be generated through both public and private ZEV refueling infrastructure, since both of these categories will be critical in enabling a rapid transition in the MHD space. Given the substantial capital costs of installing MHD ZEV refueling infrastructure, the state's objectives to achieve rapid fleet turnover from internal combustion engine vehicles to ZEVs, and because MHD ZEV adoption is only just beginning, it is important that FCI applies to all business models and use cases for MHD infrastructure.

345.6 MN8 opposes the proposed amendments to limit MHD FCI to sites located within one mile of a Federal Highway Administration Alternative Fuel Corridor (AFC) or on or adjacent to a property where medium- and heavy-duty vehicles are parked overnight, or which have received capital funding from a state or federal competitive grant program that included location evaluation as a criteria."[2] Various charging solutions are likely to be necessary to serve the MHD space that would not be covered by this rule – for

California Energy Commission. Publication Number: CEC-600-2024-003

[2] Proposed Low Carbon Fuel Standard Amendments, Appendix A-1: Proposed Regulation Order (Proposed Sections for Amendments), Section 95486.3(b)(1). Medium- and Heavy-Duty Fast Charging Infrastructure Pathway Eligibility

345.6 cont. example, off-site charging opportunities at cross docks and warehouse facilities where trucks do not park overnight but would benefit from “convenience charging” opportunities as they wait for their cargo to be loaded and/or unloaded, or public and private charging depots located near demand centers (e.g., warehouse clusters) but are not necessarily on or adjacent to premises where MHD vehicles park overnight. Excluding these sorts of infrastructure from FCI would remove an important incentive for the industry to build out critical charging infrastructure.

Thank you again for your leadership in implementing the LCFS in California. MN8 appreciates the opportunity to provide feedback on this important program.

Regards,

Brian Kee

Re: Proposed Low Carbon Fuel Standard Amendments

Dear Board Members,

346.1

LanzaJet thanks CARB for the opportunity to comment on the proposed changes to the California Low Carbon Fuel Standard (LCFS). As longtime supporters of the CA LCFS program, LanzaJet is encouraged by CARB's proposal to better align the program with the ambitious path laid out in the 2022 Scoping Plan. We echo parallel comments submitted by a broad coalition of sustainable aviation fuel (SAF) producers, including LanzaJet, in strongly supporting CARB's proposal to eliminate the exemption for intrastate fossil jet fuel under the LCFS.[1] We comment separately to stress the importance of that key next step in enhancing the market signal for SAF and also to provide insights on other key provisions in the proposal.

LanzaJet is an industry-leading SAF producer using a proprietary alcohol-to-jet (ATJ) process to convert any source of low-carbon, sustainable ethanol into ASTM-compliant SAF and renewable diesel. Following a decade of technology development and demonstration, LanzaJet was launched in 2020 with a clear mission—to scale the SAF market and enable meaningful decarbonization of the aviation sector. LanzaJet recently completed construction of a first-of-a-kind commercial scale SAF facility in Soperton, Georgia, U.S., and we are pursuing a pipeline of SAF projects to meet our goal of 1 billion gallons of domestic production by 2030. LanzaJet's equity investors include LanzaTech, Suncor, Mitsui, British Airways, and Shell, and financial support has been provided by ANA and Microsoft.

LanzaJet recognizes and appreciates California's continued leadership in the adoption of clean fuels in the aviation sector—one of the most difficult to decarbonize. In the 2018 LCFS rulemaking, CARB initiated inclusion of SAF in the program on an opt-in, credit-generating basis, which has since been replicated in other LCFS jurisdictions.[2] Unfortunately, while a helpful first step in providing some value for SAF under the LCFS, a stronger market signal is needed. The slow uptake of SAF in California can be traced, in part, to state regulatory rules, including the lack of an obligation on fossil jet fuel under the LCFS.[3]

California has rightfully set ambitious targets for aviation and for SAF specifically: Governor Newson recently called for 20% clean fuels adoption in the aviation sector,[4] the state legislature has estimated a need for at least 1.5 billion gallons of SAF blending by 2030,[5] and the 2022 CARB Scoping Plan states that

80% of all aviation fuel demand will need to come from SAF by 2045.[6] Given California's aggressive goals in the aviation sector and its recognition in the proposal that the LCFS should actively encourage transitioning the use of renewable fuels to hard-to-decarbonize sectors in the coming decades, we urge CARB to better align the aviation provisions with the ambition that will be needed to achieve the state's goals.

Accordingly, we urge CARB to significantly strengthen the signal for SAF in the proposal provisions that would impact the aviation sector. Specifically, we suggest that CARB consider the following revisions to the proposal:

346.2 1. Include all fossil jet fuel as a deficit generator under the LCFS.
346.3 2. Accelerate the obligation to begin in 2025, rather than 2028.
346.4 3. Allow indirect accounting of low-CI electricity and RNG for SAF production, a regulatory approach that is already in place for electric vehicle charging.
346.5 4. Allow book-and-claim use of SAF as proposed for hydrogen used as a transportation fuel.
346.6 5. Further strengthen proposed increases to the stringency of the program.
346.7 6. Align the definition of renewable diesel with the definition used by the EPA Renewable Fuel Standard Program (RFS).
346.8 7. Adopt the proposed rules for feedstock traceability with provisions to avoid increasing administrative burdens.
346.9 8. Utilize the LCFS to encourage long term transition of biofuels into hard-to-decarbonize sectors like aviation.

Please see our detailed comments and rationale for each below.

1. Include all jet fuel as a deficit generator under the LCFS.

The current proposal to remove the exemption only for intrastate jet fuel is an important step in the right direction, but far from sufficient to meet state goals for the aviation sector. Currently, the LCFS provides a "rack fee" benefit that accrues to replacements for obligated fuels, like renewable diesel, but not to SAF.[7] This benefit, in conjunction with other state and federal regulatory rules, systematically disincentivizes SAF production, leading SAF credit generation under the LCFS to be consistently less than 1% of credit generation for very similar renewable diesel.[8] While removing the exemption for intrastate jet fuel SAF will help by partially eliminating the LCFS rack fee benefit, an obligation on roughly 10% of the jet fuel pool cannot be expected to fully close the gap nor to substantially increase the market signal for SAF production. Indeed, CARB's own modeling suggests that SAF blending could reach about 100 million gallons in 2030 and about 200 million in 2045 as a result of the current proposal.[9] While these volumes represent encouraging growth from today's volumes, they still fall far short of state goals, which would require roughly

---

[6] *See* CARB, 2022 Scoping Plan for Achieving Carbon Neutrality. December 2022. https://ww2.arb.ca.gov/sites/default/files/2022-12/2022-sp_1.pdf. Page 73. The Scoping Plan scenario envisions 20% of aviation fuel demand met by electricity (batteries) or hydrogen (fuel cells) in 2045, with sustainable aviation fuel meeting the remaining 80%.

[7] Under the LCFS, suppliers of obligated fuels like diesel face a compliance cost, part of which they pass through to purchasers of fuel "at the rack". This rack fee narrows the gap between the cost of fossil and renewable fuels, increasing the willingness to pay for the latter.

[8]. Besides the LCFS rack fee, additional regulatory disincentives to SAF include the state Cap-at-the-Rack cost under the Cap-and-Trade program, which similarly narrows the price gap between fossil and renewable diesel, and the federal Renewable Fuel Standard (RFS) program which awards 1.7 RINs per gallon of renewable diesel compared to just 1.6 per gallon of SAF. While the total size of the incentive gap varies, the BAAQMD analysis estimated it in 2020 at about $0.42 per gallon advantage for producing renewable diesel versus SAF, of which the LCFS represented about $0.14. An obligation only on intrastate jet fuel—a small fraction of the total pool—would reduce the LCFS disparity only marginally. New federal incentives under the Inflation Reduction Act, such as the SAF Blender's Tax Credit (40B) and the Clean Fuels Production Credit (45Z) can in theory make up much of that difference, but given that those expire in 2025 and 2027, respectively, they do not send a robust investment signal for needed SAF production. *See* CA LCFS Data Dashboard, Figure 2 at https://ww2.arb.ca.gov/resources/documents/lcfs-data-dashboard; *See also* Bay Area Air Quality Management District (BAAQMD), Sustainable Aviation Fuel: Greenhouse Gas Reductions from Bay Area Commercial Aircraft. October 2020. *available at* https://www.baaqmd.gov/news-and-events/page-resources/2020-news/121120-saf-report.

[9] CARB, Appendix C-1 Standardized Regulatory Impact Assessment, September 2023. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/appc-1.pdf. Figure 4, page 18.

800 million gallons of SAF to meet Gov. Newsom's 20% clean fuels adoption target, 1.5 billion gallons in 2030 to meet the AB 1322 goal, and 3.2 billion gallons by 2045 to meet the 2022 Scoping Plan target. As noted by the International Council on Clean Transportation (ICCT), obligating only intrastate jet fuel would have "a minimal impact on the program due to the small size of this fuel pool and would fail to meaningfully promote aviation decarbonization".[10]

To boost the impact of the aviation provisions and put California on a path to achieving its aviation decarbonization goals, we encourage CARB to remove the exemption for all jet fuel uplifted in California. While anything that closes the LCFS incentive gap between jet and diesel substitutes (including obligating only a portion of jet fuel as proposed) will be directionally helpful in increasing SAF supply, obligating all jet fuel uplifted in CA will have a much more significant impact in sending an investment signal for SAF and driving SAF use in the state.

346.2 If CARB maintains a focus on obligating only intrastate jet fuel use, we suggest that CARB obligate all jet fuel combusted in California, as outlined in the September 20, 2023 Board meeting, when CARB staff stated that intrastate jet fuel would include not only flights within California, but also the portion of jet fuel combusted in California from other flights that start or end in California. Such a provision need not be overly precise or require direct regulation of or reporting from aircraft operators. Rather, existing data and tools could be used to develop a rough estimation of intrastate fuel use.[11]

2. Accelerate the obligation to begin in 2025, rather than 2028.

CARB states that the proposal to delay the obligation for fossil fuel jet fuel until 2028 is meant to provide "sufficient time for potential producers of alternative jet fuel to add capacity for the anticipated increased demand of alternative jet fuel"[12] However, such a delay is unnecessary, and we urge CARB to consider an earlier implementation date. We note that British Columbia has already added an obligation for all fossil jet fuel beginning in 2026, coupled with a volumetric SAF mandate beginning in 2028.[13] Given that CARB is only proposing an obligation for jet fuel and not an actual SAF requirement, consistent with the LCFS, there is technically no need for lead time to increase SAF production capacity because the structure of the LCFS program allows for compliance via credits generated outside of aviation—credits which are readily available today. In addition, CARB has already provided a five-year window for growth since making SAF an opt-in credit generator in 2019, during which time SAF volumes recorded under the LCFS have increased five-fold, despite a global pandemic and the continued regulatory disadvantages for SAF producers under both the LCFS and the Cap and Trade program.[14] Nevertheless, SAF continues to lag far behind similar ground transportation fuels under the LCFS. This gap should not be misinterpreted as a signal that the SAF market or SAF technologies are insufficiently mature to support an obligation for aviation, but rather should serve as evidence that the lack of an LCFS obligation for aviation has steered producers toward more lucrative opportunities serving road transportation.[15]

346.3

In any event, LanzaJet is confident that there will be enough production capacity to meet demand beginning in 2025. In the last year alone, global SAF capacity has increased by over 300 million gallons from a single producer and the International Air Transport Association estimates 2024 SAF production to triple to over

[14] *See* CA LCFS Data Dashboard, Figure 2 at https://ww2.arb.ca.gov/resources/documents/lcfs-data-dashboard
[15] On regulatory disincentives, see footnote 8. On technology and market maturity, several SAF pathways have already been commercialized. A total of 8 pathways for SAF production have been approved under ASTM 7566, and 3 additional coprocessing pathways have been approved under ASTM D1655. *See* https://www.caafi.org/focus_areas/fuel_qualification.html.

500 million gallons, or 1.5 million metric tonnes.[16] In the U.S., SAF production capacity has expanded by at least 70 million gallons, with new facilities including LanzaJet's Freedom Pines Fuels[17] and Montana Renewables Great Falls plant[18] coming online. Additional expansions are in the pipeline, including concrete, near-term plans for expansions from Diamond Green Diesel,[19] Montana Renewables,[20] and California's own World Energy.[21] Most importantly, there are roughly 3 billion gallons of renewable diesel consumed in the U.S. each year, 80% of which is produced domestically,[22] and half of which could easily be transitioned to SAF production—where it would produce additional benefits to both climate and local air quality— if additional policy incentives were put in place under the LCFS to level the playing field for SAF. In sum, there is sufficient SAF production capacity and CARB need only send an appropriate market signal. We urge CARB to maintain its role as a leader in LCFS policy by accelerating its fossil jet fuel obligation to 2025.

3. Allow indirect accounting of low-CI electricity and RNG for SAF production, a regulatory approach that is already in place for electric vehicle charging.

LanzaJet supports existing policy to allow indirect accounting for low-CI electricity and RNG inputs to the production of low-CI hydrogen, and we applaud CARB's proposal to expand access through the use of power purchase agreements (PPAs) for low-CI electricity.[23] However, we strongly believe that the same access should be expanded to SAF. At minimum, we urge CARB not to eliminate the existing allowance for indirect
346.4 accounting for low-CI electricity to produce hydrogen that is used in the production of fuels, including SAF.

CARB's arguments for providing additional flexibility to low-CI hydrogen when directly used as a transportation fuel apply equally to SAF. Both low-CI hydrogen and SAF are young technologies with nascent markets that displace hard-to-electrify end uses like powering aircraft. The 2022 CARB Scoping Plan calls for significant growth in the use of both and, in the aviation sector, envisions even greater growth for SAF—from less than 1% of jet fuel consumption today to 80% in 2045.[24]

Despite these parallels, current and proposed LCFS rules for indirect accounting of low-CI energy systematically disadvantage SAF relative to hydrogen. Hydrogen producers have access to emissions reductions from process energy—low-CI electricity and RNG—that SAF cannot access. This is counter to state goals for SAF uptake and aviation decarbonization. We urge CARB to promote equity between future fuels like SAF and hydrogen and allow indirect accounting of RNG and low-CI electricity—both as a direct input to SAF and as an input to hydrogen for use in SAF.

4. Allow book-and-claim use of SAF, as proposed for hydrogen used as a transportation fuel

[22] *See* https://ethanolproducer.com/articles/epa-2375-billion-rins-generated-in-2023. RIN data, which measure consumption of renewable diesel, underestimate domestic production capacity because a fraction of domestically produced fuels are exported.

[23] *See* CARB, Staff Report: Initial Statement of Reasons (ISOR). December 19, 2023. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf. Page 34.

[24] *See* CARB, 2022 Scoping Plan for Achieving Carbon Neutrality. December 2022. https://ww2.arb.ca.gov/sites/default/files/2022-12/2022-sp_1.pdf. Page 73.

LanzaJet also supports the proposal to allow book-and-claim accounting for low-carbon intensity hydrogen used as a transportation fuel. We agree with CARB's rationale for allowing hydrogen book and claim: that physical delivery is impractical for large scale production that is sent to several off-takers through shared
346.5 pipelines.[25] However, the same rationale also applies to SAF, and we strongly recommend that the offtake opportunities provided by book and claim should be available to all pipeline-fungible liquid and gaseous fuels.

All of the arguments given by CARB in the Initial statement of Reasons for extending book and claim to low-CI hydrogen also apply to SAF.[26] Like hydrogen, the SAF market is nascent, and relies on large scale production, pipeline deliveries, and multiple off-takers for economies of scale. In the aviation sector, both hydrogen and SAF serve the same end use—transportation fuel for aircraft.

The 2022 Scoping Plan sees SAF as the essential key to meaningful decarbonization of aviation through 2045—displacing 80% of the fossil fuels used by the sector. Despite that, current and proposed LCFS rules for book and claim that exclude SAF make it much more logistically difficult and carbon intensive for jet fuel suppliers to provide their customers with emissions reductions from SAF than it would be from hydrogen.

5. Further strengthen proposed increases to the stringency of the program.

LanzaJet supports the proposed measures to increase the stringency of the LCFS program and encourages CARB to boost stringency even more. We believe that near-term efforts to quickly boost LCFS prices back
346.6b to meaningful levels are essential, and we therefore urge CARB to 1) aim for a 6 or 7% stepdown in the CI
346.6c reduction target in 2025, rather than the proposed 5%, and 2) move implementation of the auto adjustment mechanism forward from 2028 to 2027. Additionally, we suggest that CARB increase the 2030 CI reduction
346.6d target—currently at 20%-- even beyond the proposed 30%. A recent study by ICF found that a 42% CI reduction by 2030 is both feasible and necessary to support progress toward the 2022 Scoping Plan goals.[27]

6. Align the definition of renewable diesel with the definition used by the EPA RFS program.

LanzaJet believes that the proposed definition of "renewable diesel" is unintentionally limited to certain production processes (hydrotreating or Fisher-Tropsch) and feedstocks (lipids, biocrudes, or gasified biomass).[28] The proposed definition would arbitrarily exclude renewable diesels produced via alcohol-to-fuels pathways as well as via other non-enumerated feedstocks. We urge CARB to let lifecycle analysis, guided by the latest science, determine eligibility for credit generation under the LCFS and broaden the definition to include objective criteria, as was the case with the former definition.

346.7 Specifically, we suggest that CARB expand the definition of renewable diesel to align with the EPA definition of a non-ester renewable diesel under the federal RFS program:

"A fuel or fuel additive that meets the Grade No. 1–D or No. 2–D specification in ASTM D975 (incorporated by reference, see § 80.12) and can be used in an engine designed to operate on conventional diesel fuel;"[29]

[25] *See* CARB, Staff Report: Initial Statement of Reasons (ISOR). December 19, 2023. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf. Page 34.
[26] *See* CARB, Staff Report: Initial Statement of Reasons (ISOR). December 19, 2023. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf. Page 30.
[27] *See* ICF, Analyzing Future Low Carbon Fuel Targets in California. June 2023. Submitted to CARB June 30, 2023.
[28] *See* CARB, Appendix A-1 Proposed Regulation Order (Proposed Sections for Amendments). January 2, 2024. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/lcfs_appa1.pdf. Page 22.
[29] *See* 40 C.F.R. § 80.2

7. Adopt the proposed rules for feedstock traceability with provisions to avoid duplicative administrative burdens.

In principle, LanzaJet supports the additional proposed guardrails on crop-based feedstocks—the sustainability of our SAF is paramount to us. However, we urge CARB to ensure that these requirements do not add additional undue administrative burden to reporting entities. SAF producers participate in a variety regulatory programs and incentives beyond the CA LCFS, including the federal Renewable Fuel Standard (RFS) program, incentives under the Inflation Reduction Act, the International Civil Aviation Organization's Carbon Offsetting Reduction Scheme for International Aviation (CORSIA), and others. As such, SAF producers, like other low carbon fuel producers, are already subject to multiple, separate sets of detailed regulations for tracking, verifying, and independently certifying the details of feedstock production and procurement. Given that we do not believe any producer would produce a biomass-based transportation fuel only for the LCFS market, we urge CARB to avoid adding a new, bespoke, and duplicative administrative burden under the LCFS. We strongly request that CARB explicitly allow for the new
346.8 feedstock tracking and certification requirements to be met by existing certification schemes, such as EPA Quality Assurance Plans under the RFS program, International Sustainability and Carbon Certification (ISCC) or the Roundtable on Sustainable Biofuels (RSB).

6. Utilize the LCFS to encourage long term transition of biofuels into hard-to-decarbonize sectors like aviation.

We applaud CARB for thinking dynamically about existing biofuel resources, and considering ways to encourage diversions into sectors where they will be most needed to meet 2022 Scoping Plan goals. A key example of this type of thinking is CARBs proposals aimed at pivoting biomethane from its current end-use as a road transportation fuel into hard-to-decarbonize applications like industry and flexible power generation.[30] We strongly urge CARB to apply the same thinking to the aviation sector and use the LCFS to encourage the diversion of biofuels from road transport—including both renewable diesel and ethanol—to aviation.

346.9 We believe there is ample justification for CARB to prioritize a long-term transition of biofuel resources to SAF:

First, while both light and medium/heavy-duty transportation are expected to electrify over the coming decades (although on different timetables), aviation will take much longer to transition to decarbonize, and SAF is expected to be the chief decarbonization lever for the foreseeable futures. The 2022 Scoping Plan scenario envisions 100% sales of zero emissions vehicles for light duty transport by 2035 and for medium/heavy duty transport by 2040, but for aviation sees only 20% alternative propulsion (hydrogen or electric) possible by 2045.[31] In short, SAF is California—and the world's—only viable option for meaningful decarbonization in the aviation sector before mid-century.

Second, SAF provides additional air quality benefits that have not been fully considered by CARB. CARB notes that the current proposal would result in reductions in oxides of nitrogen (NO_x) and fine particulate matter (PM 2.5).[32] In addition, a recent synthesis of emissions measurement campaigns by the Airport Cooperative Research Program (ACRP), administered by the Transport Research Board of the U.S. National Academies of Sciences, found that a 50% SAF blend could reduce by nearly 40% oxides of sulfur,[33] which are known to have significant negative effects on exposed populations, and which are present in greater

[32] *See* CARB, Staff Report: Initial Statement of Reasons (ISOR). December 19, 2023. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2024/lcfs2024/isor.pdf. Page 57.
[33] Airport Cooperative Research Program, Alternative Jet Fuels Emissions Quantification Methods Creation and Validation Report. August 2019. Page 10. *Available at* http://www.trb.org/Publications/Blurbs/179509.aspx

proportions in fossil jet fuel than other transportation fuels like diesel. Additionally, other studies have found greater reductions in PM than the 55% cited in the SRIA. The ACRP study found PM reductions of up to 65%, and a more recent measurement campaign found that SAF produced via the alcohol-to-jet pathway could reduce non-volatile particulate matter by up to 97%.[34]

Third, California's environmental justice communities have explicitly asked CARB to support displacement of fossil jet fuel with SAF, both in the formal recommendations to CARB of the Environmental Justice Advisory Committee[35] and in person, at the September 28th, 2023, Board meeting. Communities that live near and work at airports are some of the most vulnerable in California: of the ten busiest airports in the state, four are located within SB 535 designated disadvantaged communities, and another four are immediately adjacent.[36] These communities have long borne the disproportionate health impacts of unmitigated fossil jet fuel combustion.

Fourth, jet fuel causes unique contributions to global climate change that are unrecognized by the LCFS—harms that SAF can mitigate. Emerging research indicates that particulate matter reductions from SAF reduce aviation's non-CO2 climate impact, specifically the climate forcing from "contrail cirrus" impacts (the combined warming from contrails and contrail-induced cirrus). The current best estimate from the most recent comprehensive study is that the climate impact from contrail cirrus is nearly twice the impact from CO2.[37] Even the low end of current estimates–which show that contrail cirrus causes roughly half the total warming of CO2– warrants consideration of potential mitigation opportunities from SAF.[38] One recent study cited found that a 50% SAF blend could reduce contrail cirrus climate impacts by over 20%. An eventual shift to 100% SAF could reduce the climate impact of contrail cirrus by 50%.[39] While continued scientific uncertainty around the size of the non-CO2 climate impacts makes them difficult to precisely quantify, the direction of those impacts—less warming when SAF is used—is known.

We strongly believe that these additional benefits—which align closely with state goals and priorities and accrue only to SAF—justify action by CARB to prioritize the production and use of SAF. As CARB has noted, transitioning fuels to other sectors in the long term requires that market signals transition first.[40] Under the current proposal, the market signal for SAF would improve marginally, but not nearly enough to overcome existing disincentives and pivot biofuel production toward SAF. Therefore, we encourage CARB to consider additional measures to credit the additional climate and air quality benefits. For example, CARB should consider applying a credit multiplier for SAF based on the most conservative estimates of non-CO_2 climate benefits of SAF. (The European RED II program, currently provides a multiplier of 1.2x for SAF.) Alternatively, CARB might develop a "CO_2 equivalent" metric to account for these benefits in terms of carbon intensity and incorporate them into the CA-GREET model, as has been suggested by the European Commission in its recent study on how to address the non-CO2 climate impacts of aviation.[41]

LANZAJET

346.10 We also urge CARB to consider carefully how to account for the lifecycle emissions involved in a pivot—rather than an expansion—of biofuels toward the aviation sector. As light and medium/heavy duty road transportation electrify, the 2022 Scoping Plan envisions a 94% reduction in demand for ethanol in California's transportation sector by 2045—an absolute decline of 1.6 billion gallons per year of biofuel.[42] This presents a key opportunity to expand SAF production; at the national level, the 17B of ethanol currently blended into gasoline each year could become 10 billion gallons per year of SAF—more than triple the amount envisioned in the 2022 Scoping plan and the SAF Grand Challenge—with no net new ethanol demand.[43] The emissions factors for land use change (LUC) under the LCFS are based largely on a shock in emissions from the initial land conversion, annualized over a project horizon of 30 years.[44] However, if there is no net new ethanol demand, there can be no new land use change. As long as ethanol production does not substantially increase, LanzaJet recommends CARB maintain consistency with the assumptions that underlie the current LUC carbon intensity values by phasing out LUC emissions once emissions are amortized over the full 30-year project horizon land use change emissions have been fully accounted for. With nearly half of that amortization period over and the current rulemaking extending to 2045, LanzaJet believes it would be appropriate for CARB to include provisions for phasing out ILUC emissions in 2040, 30 years after the 2010 rulemaking, particularly for feedstocks like ethanol where significant demand destruction is forecasted and the "demand shock" rationale for ILUC cannot be reasonably maintained.

Subject	Hy Stor Energy's Comments on Proposed Low Carbon Fuel Standard Amendments

Comment

Dear California Air Resources Board,

Thank you for the opportunity to provide comments on the proposed low-carbon fuel standard amendments. Hy Stor Energy LP respectful submits the following comments, which are intended to facilitate the adoption of clean hydrogen in low-carbon transportation fuels, which include sustainable aviation fuel (SAF), power-to-liquids, and renewable diesel, and would help scale up a low-carbon fuel industry that would supports the decarbonization of the U.S. economy.

Sincerely,

Hy Stor Energy LP

Re: Hy Stor Energy Comments on Proposed 2024 Low Carbon Fuel Standard (LCFS) Regulation

Dear California Air Resources Board:

Thank you for the opportunity to provide comments on the proposed low-carbon fuel standard amendments. Hy Stor Energy LP respectfully submits the following comments, which are intended to facilitate the adoption of clean hydrogen in low-carbon transportation fuels, which include sustainable aviation fuel (SAF), power-to-liquids, and renewable diesel, and would help scale up a low-carbon fuel industry that would supports the decarbonization of the U.S. economy.

Hy Stor Energy, a company headquartered in Jackson, MS, was formed for the purpose of developing and advancing renewable hydrogen production, storage, and delivery at commercial scale in the United States. Pursuing a multi-regional platform strategy focused on critical locations with the right geography and geology uniquely suited to favorable renewable power generation, underground hydrogen storage, and distribution networks for regional and global market access. Hy Stor Energy's first major project, the Mississippi Clean Hydrogen Hub, is under active development. It will be centered on the development of world-scale underground hydrogen storage capability, with approximately 70,000 acres of land in sixteen Mississippi counties and two Louisiana parishes under Hy Stor Energy's control, seven salt domes, and nine salt caverns fully permitted for underground hydrogen storage. Hy Stor Energy will soon announce a second project in the western United States positioned to be the leading renewable hydrogen supply hub serving the U.S. West and California markets.

Renewable hydrogen is an essential tool for the energy transition and will play a significant role in enabling California to achieve its net-zero goal by 2045. Renewable hydrogen is both an important transportation fuel for fuel cell electric vehicles as well as a necessary feedstock for many low and zero-carbon transportation fuels including SAF, power-to-liquids, renewable diesel, renewable methanol, and renewable ammonia. Enabling the LCFS eligibility of renewable hydrogen as both a transportation fuel in FCEVs as well as a feedstock liquid transportation fuel will enable greater adoption of low-carbon liquid fuels and drive emissions reductions in both the near and long term.

Hy Stor Energy respectfully suggests that the California Air Resources Board (CARB) modify the LCFS amendments to make the following amendments to the LCFS staff draft.

555 Tombigbee St
Suite 101
Jackson MS 39202
(888) 542-6074
www.hystorenergy.com

I. Allow book-and-claim delivery of low-CI electricity for electrolytic hydrogen production used as a feedstock in liquid transportation fuels.

II. Allow book-and-claim delivery of low-CI hydrogen in dedicated hydrogen pipelines outside of California for transportation fuel sold into the California market.

III. Allow delivery of low-CI electricity via book-and-claim for electrolytic hydrogen production in the Renewable Hydrogen Refinery Credit Program.

Allow book-and-claim delivery of low-CI electricity for electrolytic hydrogen production used as a feedstock in liquid transportation fuel.

Allowing book-and-claim delivery for low-CI electricity would maximize the potential for renewable hydrogen adoption and emissions reductions. Low-CI hydrogen will support the production of low and zero-carbon liquid transportation fuels, which are critical to decarbonizing the hard-to-decarbonize markers of heavy-duty surface transportation, aviation, and maritime transportation.

Furthermore, permitting book-and-claim delivery for low-CI electricity will match the treatment CARB has extended to renewable natural gas (RNG), which allows for the utilization of book-and-claim delivery of RNG, including for RNG used in the production of liquid transportation fuels.

Allow book-and-claim delivery of low-CI hydrogen in dedicated hydrogen pipelines outside of California for transportation fuel sold into the California market.

Currently, there are no dedicated hydrogen pipelines in California. Our goal as a nation and Hy Stor Energy's goal as an early mover in the production and distribution of green hydrogen is to facilitate the build-out of a national clean hydrogen economy. This will necessarily include the buildout of a robust hydrogen pipeline backbone to support the scale up of low-CI hydrogen adoption and drive down costs across the entire hydrogen value chain. Limiting eligible dedicated hydrogen pipelines to the California state borders would dramatically stunt the development of the hydrogen market both within California and the region. The optimal policy would be to allow book-and-claim delivery of low-CI hydrogen in any dedicated hydrogen pipeline serving as a feedstock for any fuel being consumed in California. A robust book-and-claim system will allow the delivery of low-CI hydrogen to catalyze market adoption of low and zero-carbon liquid transportation fuels including sustainable aviation fuels, power-to-liquids fuels, and renewable diesel in the critical hard-to-decarbonize industries in California and nation-wide.

Allow delivery of low-CI electricity via book-and-claim for electrolytic hydrogen production in the Renewable Hydrogen Refinery Credit Program.

In order to decarbonize medium to large scale facilities GW scale electrolysis projects will be required. As the current program is designed, requiring onsite renewable generation restricts the program to small-scale projects due to land constraints where refinery facilities are currently located. Allowing for the delivery of low-CI electricity via book-and-claim for electrolytic hydrogen production would allow refineries to utilize this program to lower emissions. Without this amendment, this program will likely continue to be underutilized.

Conclusion

Hy Stor Energy is committed to catalyzing low and zero-carbon solutions to enable California to meet its climate goals. We appreciate the CARB staff's work on the development of the proposed rule and their commitment to improving the LCFS. We look forward to continuing to work with CARB staff on this critically important effort.

Sincerely,

Laura L Luce

CITY OF PALO ALTO

February 20, 2024

Honorable Chair Liane Randolph and Honorable Board Members California Air Resources Board 1001 I Street
P.O. Box 2815
Sacramento, CA 95812

Re: City of Palo Alto Comments on California Air Resources Board's Amendments to the Low Carbon Fuel Standard Regulations

Dear Chair Randolph and Honorable Board Members:

The City of Palo Alto ("Palo Alto") respectfully submits these comments to the California Air Resources Board ("CARB") regarding amendments to the Low Carbon Fuel Standard ("LCFS") regulation as drafted in the Proposed Regulation Order posted on December 19, 2023.

City of Palo Alto provides a broad array of city services to the residents and businesses in Palo Alto, including the operation of a Compressed Natural Gas (CNG) fueling station that serves the community. This station is registered with the CARB under the LCFS regulation.

348.1 Even though it is small station, dispensing ~200,000 terms/year, the LCFS regulation requires Palo Alto to contract with a CARB accredited Verifier to provide verification of services for fuel dispensed by the CNG station. The cost of this verification services is ~$8,000, plus staff time to manage the verification process; we have received verifier quotes as high as $19,000. We believe this level of cost and effort is not commensurate with the value, especially for small station that is expected to receive just 40 LCFS credits in 2023, currently valued at ~$3,000. As such, we would like to request CARB consider exempting small CNG dispensers like Palo Alto from need for verification.

Palo Alto would like to hereby earnestly request CARB to consider exempting smaller CNG stations operated by governmental entities from the verification process, as the costs largely outweigh the benefit when applied to these small and not-for-profit entities dispensing standard fuel such as CNG.

We appreciate the Board's consideration of our request.

Respectfully submitted,

Shiva Swaminathan

Re: SEIU-USWW Public Comments on Proposed Low Carbon Fuel Standard Amendments

Our Union & Member Communities

SEIU United Service Workers West (USWW) represents nearly 45,000 janitors, security officers, entertainment & stadium workers across California, including thousands of workers at LAX, SFO and other airports throughout the state. Our membership primarily consists of workers within low-wage industries, including aviation. Many of our members reside in communities near major airports and within their flight paths. For decades, these communities - largely Black and Brown - have endured exposure from an array of toxic pollutants produced by airport operations, adding on to the decades of environmental racism these cities and neighborhoods have faced from other sources.

SEIU USWW recognizes the detrimental health impacts on our membership and communities produced by commercial aviation's dependency on fossil fuel consumption. For years, we've fought to raise industry standards at the bargaining table, but more recently have been expanding our commitment to confronting the environmental racism and inequity that our members and their communities face as a result of this industry's continued and ever-expanding operations.

California's LCFS & Commercial Aviation's Immense Privilege

349.1 It is for these reasons that we are excited to see CARB taking steps to decarbonize aviation by finally ending the industry exemption and incorporating conventional jet fuel (CJF) into the Low Carbon Fuel Standard. This is long overdue: Sustainable Aviation Fuel (SAF)[1] has been a credit-generating fuel under the LCFS for years, but it's difficult to imagine airlines prioritizing a meaningful transition to more sustainable fuels while their older, polluting fuels continue to draw hundreds of millions of dollars worth of subsidies and savings from the state.

The carveout for CJF saves the airlines an estimated \$110 to \$360 million each year on the cost of that fuel.[2] The exemption from sales & use taxes for fuel used in international flights cost state and local governments nearly \$300 million last year[3], and the jet fuel exemption from excise taxes saves airlines about \$29 million a year.[4]

This heavily subsidized, minimally regulated dynamic for aviation will have to be changed in order to transition to a sustainable industry and meet California's ambitious climate goals. It's simply a matter of when and how.

Intrastate Jet Fuel in the LCFS - A Great *First* Step

SEIU USWW is encouraged to see CARB continuing to move forward on a proposal to subject conventional jet fuel to the LCFS standards - a direction that our union has been on the record in support of for years now.[5] We know that the agency has been exploring the concept since at least 2021,[6] and are happy to see this idea move toward implementation. This is a great first step, but we do want to emphasize that it can't be the last one. The latest proposal will only cover fuel used in intrastate flights - flights that represent an extremely small portion of overall emissions from aviation activity: just 3% of emissions nationally, and less than 6% in California.

California's aviation sector accounted for about 34 million metric tonnes of CO_2 emissions in 2018, and only about 2 million were the result of intrastate flights.[7] Nationally, intrastate flights make up only about 3% of CO_2 emissions in the United States. Nearly two-thirds of domestic aviation's CO_2 emissions - 112 million metric tonnes in 2019 - come from domestic flights, but of that, only 6 million comes from intrastate flights.

We view any progress toward reckoning with aviation's climate impact on California residents and communities as both welcome and overdue, but this should be the beginning of a much more comprehensive effort that California is uniquely positioned to lead on. Intrastate flights are a drop in the bucket (though still a very important departure from the status quo), and ending there runs the risk of greenwashing the industry's outsized climate impact by focusing our state policy solutions for aviation on such a small fraction of fuel and emissions.

349.2 CARB needs to set a clear path toward bringing jet fuel used in any flights combusted over California into the LCFS, not just the flights that begin and end in our state. A policy that stops short of that needs to also include some kind of commitment toward obligating more of the fossil jet fuel as time goes on. Ongoing analysis of the supply of SAF and growth in the aviation sector needs to take place so that CARB can increase the obligated fuel beyond this current rulemaking. Without a plan to take on more than just intrastate flights, growth in overall aviation activity stands to outpace any gains made in discouraging the continued use of fossil jet fuel.

Implementation Delay to 2028 is Unnecessary

Currently, CARB is proposing a 2028 implementation date for the obligation of intrastate jet fuel under the
349.3 LCFS.[8] Given that the proposal has been scaled back significantly to just fuel used in intrastate flights, we feel that this kind of delay is excessive and unnecessary. The intrastate limitation means that over 90% of the industry's fossil jet fuel is still exempt from the LCFS, four years of additional grace period for the small share of fuel that will be obligated by the latest proposal is gratuitous. By 2028, SAF will have been eligible for LCFS credits for nearly a full decade - it is clear at this point that significant and urgent action is needed in order to encourage the industry to take their transition away from fossil fuels much more seriously.

Just a few years ago, the industry and the Biden administration both committed to SAF production goals of at least 3 billion gallons a year by 2030 - a figure that would total not even 7% of US jet fuel consumption in 2023, and stands to amount to an even smaller proportion of what that total would be in

---

[5] SEIU USWW, "Re: CARB Draft 2022 Climate Change Scoping Plan Update," 6/23/2022

[6] CARB, Public Workshop: Potential Future Changes to the LCFS Program, 12/7/2021

[7] Zheng & Rutherford, ICCT, "Reducing aircraft CO_2 emissions: The role of U.S. federal, state, and local policies," February 2021

[8] CARB, Staff Report: Initial Statement of Reasons, 12/19/2023

2030.[9] If the scope of the LCFS' jet fuel obligation does not expand beyond intrastate flights, a delay to 2028 is unjustified. A policy that is no more ambitious than the industry's own plans and projections will do little to actually encourage a shift away from fossil fuels that wouldn't have occurred already.

SAF Needs Strong Guardrails

Given how far out we are from truly zero-emission solutions at commercial scale in aviation, the industry
will have to rely on Sustainable Aviation Fuel in the near term. But as supply ramps up, smart policy is
349.4 necessary to ensure that this short-term bridge fuel doesn't create long-term problems. The industry has
consistently worked to dilute sustainability standards for SAF[10], and there is a real possibility of the market
being flooded with SAF that fails to significantly reduce lifecycle greenhouse gas emissions. Taking on
SAF as a bridge fuel only makes sense when paired with strong guardrails. A cap on crop-based
feedstock would be ideal, as well as a strong framework for assessing the sustainability of SAF feedstock.
Even now, the industry has been pushing for changes at the federal level that would undermine the ways
in which the overall emissions impacts of SAF are assessed.[11] CARB's evolving policies on aviation must
ensure that we are not simply trading problematic fossil fuels for problematic SAF.

Next Steps

349.5 At SEIU USWW we strongly support efforts to incorporate conventional jet fuel into the LCFS program and will continue to advocate for this kind of policy - though we believe that CARB can and should still include the fuels used in interstate and international flights in current proposals. Falling short of that, CARB should reopen the LCFS rulemaking a couple years from now to chart that path. Within the current rulemaking though, we find the proposed 2028 implementation date excessively generous given the minimal share of flights affected by limiting the program's obligations to intrastate flights only, and are calling for this to be pulled back to 2025 or removed entirely. Finally, we believe a cap on crop-based SAF feedstock is warranted, and as clarity increases with respect to the supply chain for Sustainable Aviation Fuel we hope to see stronger sustainability criteria for SAF feedstock within the LCFS. It should be an ongoing concern for CARB to fight the industry's efforts to undermine the ways in which the emissions impact of different feedstock is assessed.

We believe that meeting California's ambitious climate goals will require a sober-minded view of the sources of carbon emissions, and that decarbonizing aviation is a necessary challenge that our state must overcome. We are encouraged by this policy as a first step and optimistic about the legal viability of this direction. We look forward to continued and increased collaboration with CARB in the years to come as we work to bring true accountability to an industry with so many stakeholders in our workplaces and communities.

Sincerely,

David Huerta

CALIFORNIA CARBON SOLUTIONS COALITION

Building Climate Smart Solutions for California

February 20, 2024

California Air Resources Board
P.O. Box 2815
Sacramento, CA 95812
[submitted electronically]

RE: Comments on the Proposed Amendments to the Low Carbon Fuel Standard Regulation

The California Carbon Solutions Coalition appreciates the opportunity to provide comments on the Proposed Amendments to the Low Carbon Fuel Standard.

350.1 The California Carbon Solutions Coalition is the state's leading business and labor organization working to support the rapid deployment of carbon capture, removal, utilization and sequestration (CCUS) technologies to reduce greenhouse gas emissions and deliver high-quality jobs for Californians.

California's 2022 Climate Change Scoping Plan identifies CCUS and direct air capture (DAC) technologies as critically needed tools to support achievement of California's climate goals. A number of industries across California are actively investing in CCUS and DAC projects and technologies. As recognized in the December 19, 2023 Initial Statement of Reasons, the LCFS is a key policy driver for the rapid deployment of these technologies.[1] As CARB proceeds with implementation of an updated LCFS program it is crucial to ensure the timely review and approval of applications submitted pursuant to the "Carbon Capture and Sequestration Protocol (CCS Protocol) under the Low Carbon Fuel Standard."

350.2 Additionally, the Coalition supports the proposal in § 95490 (a)(2)(A) of the proposed regulation that direct air capture projects must be physically located in the United States to be eligible under the CCS Protocol.[2] This proposal will effectively align the LCFS with national efforts currently underway, including major federal incentive funds, to capture the climate, economic and jobs benefits that these projects can deliver.

The Coalition appreciates the opportunity to comment on the Proposed Amendments to the Low Carbon Fuel Standard and looks forward to continuing to work with CARB to ensure that CCUS technologies can meaningfully contribute to the achievement of California's climate goals.

Sincerely,

Virgil Welch
Director

Re: Maas Energy Works Public Comments on the Notice of Public Hearing to Consider Proposed Low Carbon Fuels Standard Amendments

Dear Chair Randolph:

Maas Energy Works (MEW) is North America's largest developer of dairy manure digesters, and one of the two major such companies active in California. Our facilities generate renewable natural gas (RNG) and electricity use as carbon-negative vehicle fuel. Working with our partner families in the California dairy industry, Maas develops projects that support the California Air Resources Board's (CARB) goal of greenhouse gas (GHG) emission reductions. They also protect regional air and water quality, create local jobs, and provide a new revenue stream along with other meaningful benefits to the dairy.

351.1 Thank you for the opportunity to provide comments to CARB on the Proposed Low Carbon Fuel Standard Amendments as presented by CARB staff on December 19, 2023. We fully support the comments submitted by the Coalition for Renewable Natural Gas, which has provided a detailed and authoritative response to the full set of issues raised in this process.

We would like to bring particular attention to the following points in RNC Coalitions comment, using the numbering system from their letter.

351.2 **1.1 Target Setting** The market is oversupplied to a degree that the proposed rule changes will not sufficiently rebalance. The surplus credits will continue to build for years, even more so with the proposed CI change to ULSD. We request CARB refer to the excellent analysis prepared by ICF and described in the RNG Coalition's letter, with the accompanying recommendations regarding changes to the timing and degree of annual CI targets.

351.3 **2.1.1, 2.1.2, and 2.1.3. Avoided Methane** The US dairy RNG industry has been largely built upon capturing fugitive methane emissions and receiving credits for turning those emissions into transportation fuel. Without a way of monetizing those reductions, future investments in digesters are at risk. While we appreciate that the draft rule gives dairy RNG projects a long time before phasing out avoided methane crediting, CARB is still signaling that its goal is to end avoided methane crediting—even if those methane reductions remain additional, verifiable, and voluntary. We would prefer CARB communicate that avoided methane crediting will remain valid under the LCFS for as long as the reductions are additional—just like any other fuel. We note that the European Union's Renewable Energy Directive, Argonne-GREET, and many other leading protocols assign avoided methane benefits to RNG, and we ask CARB not to be the leader in tearing down an industry that CARB has done so much to build up.

351.4 **2.2 Credit True-Up** CARB's proposed true-up mechanism should be helpful in allowing RNG projects to claim the full value of the verified emissions reductions created the project at the end of each verification

MAAS ENERGY WORKS

1730 South Street
Redding, CA 96001
www.maasenergy.com

351.4 cont. cycle—but only at the risk of 4x penalties if the verified score comes in too high. By itself, this change will reduce or delay revenues to digester projects but is at least helpful in providing a way to avoid triggering Notices of Violation (NOVs) in the LCFS program. But the original intention of the credit true-up, as discussed in CARB workshops, was to allow for projects to receive the full value of their verified emissions reductions, full stop. We do not understand why CARB did not extend this same verified, science-based true-up logic to the startup period. Projects that are forced to use a Temporary Fuel Pathway Code should be automatically entitled to later the full value of their emission reductions if and when the underlying data has been validated or verified. As it is, the startup revenue delays, lost credits, risk of NOVs, and regulatory uncertainty are pushing our company and many other developers to question whether supplying carbon-negative RNG to the LCFS program is still a good investment. By making the Credit True Up apply to the initial startup period, CARB can solve one of these problems favorably and accurately. The 4x penalties might be tolerable if there was a full true up in place, but without full accounting for the emissions reductions that our projects generate, the 4x penalty is just punitive.

351.5 **2.3.3 Book and Claim** Book and claim accounting for natural gas deliveries is standard across the RNG industry in North America and much of Europe. We ask CARB not to create new obstacles to the delivery of RNG which will confuse and inhibit production or RNG and/or abatement of dairy methane. Again, the message coming from CARB in these kinds of proposed changes is that RNG should expect more regulatory downsides. Such messages make it very hard to take risks on future projects.

351.6 **3. Auto Accelerator Mechanism** We applaud the AAM as a needed tool to balance supply and demand in the LCFS market. Due to the large and rapidly growing oversupply in the market, we urge that the mechanism be triggered earlier. As proposed, it cannot be triggered earlier than 5/15/2027 and the impacts of this mechanism might not be felt for months or even years after that date. Our company is already needing to pause investments in this sector until demand is more certain.

351.7 **Review of Missing Data Substitution**. CARB, like many regulatory bodies, has previously recognized the use of "reasonable temporary methods" to address data gaps, noting operational realities result in varying gaps that can be reliably filled in reasonable ways that consider the context of each situation. RNG Coalition urges CARB to continue to allow those participating in the LCFS to be able to use "a reasonable temporary method," rather than prescribing the limited data substitution tactics specified under 95491.2(b)(2)(B)'s Table 13 or resorting to an "Executive Office approved alternate method."

We appreciate CARB's hard work and devotion to improving the LCFS program. We appreciate the dedication of CARB LCFS staff in preserving the integrity of the program. Thank you, again, for the opportunity to comment on the draft rule.

Warmly,

Daryl Maas

Board Comments Home

February 20, 2024

California Air Resources Board

1001 I Street

Sacramento, CA 95814

RE: CARB Proposed 2024 LCFS Amendments

I'd like to voice my concerns with the Proposed 2024 LCFS Amendments and the associated rulemaking. These concerns revolve around an underestimation of the degree of tightening needed to drive higher credit prices, and a departure from the technologically neutral stance that formed the basis of the LCFS. I also have one question on the future of Electric Vehicle crediting which will be more pertinent in future years.

Proposed CI Targets

352.1 Overcompliance is clearly seen in recent data, with the credit bank set to increase to around 24mm MT by the end of 2023 and over 31mm MT by the end of 2024 (assuming no changes are made to 2024 targets). Data for the 3rd Quarter of 2023 demonstrated a 15.6% CI reduction, which exceeds the 2026 statutory reduction target. In just a few years, LCFS compliance has moved three years ahead of schedule.

In light of this data, the 2025 step change as proposed will not go far in rebalancing the market. The proposed 18.75% CI reduction target for 2025 would result in about equal credits and deficits assuming pretty conservative trends for biomass-based fuels, RNG, and electric vehicles. If this turns out to be true, the LCFS credit market will remain severely oversupplied due to the large credit bank until at least 2028, when the AAM can begin to respond. Until then, the credit bank will weigh on prices, decarbonization investments, and climate outcomes.

While these assumptions are far from a sure thing, history tells us that technology has adapted quickly to LCFS, and that overlapping local, state, and federal incentives for making this technology economical are quite powerful together. The biggest obstacle to accelerated technological progress seems to be underestimation of its potential. The rulemaking in 2018 seemed quite ambitious at the time but proved to be the opposite. The current rulemaking, on the other hand, feels conservative even at its onset.

The credit bank is in the process of reaching a full year's worth of deficits. The AAM is a fine instrument for automatically adapting to future developments, but CARB should act now to address current situation if it indeed seeks to support the market. A step change to 22.75% in 2025 would reduce the credit bank by approximately 28mm MT vs the current proposal. This is necessary if CARB seeks to reduce the LCFS credit bank by a meaningful amount before EV adoption begins shifting the market back into surplus before 2030, assuming the 30% target in 2030 remains in place. While I don't expect an

352.1 cont. AAM trigger would be necessary if such a move would be made, I also cannot predict what unexpected advances or setbacks in decarbonized transportation might surface.

If it is the desire of CARB to keep prices around current levels (between $50 and $80) I think the current proposal would be adequate. While the market will remain oversupplied, I believe the prospect of the AAM triggering in later years will draw in investor interest when credits drop significantly below this range, with the possibility of higher prices in the 2030's. This rulemaking strategy also has its merits, as it would help avoid rising compliance and fuel costs which could pose a political risk to the LCFS and other state-level environmental programs such as Cap-and-Trade and ACCII, among others. And to the extent that LCFS is meant to find least-cost pathways to low carbon transportation, this path would truly emphasize the 'least-cost' aspect, with competition likely to drive the cost of low-carbon fuels lower.

I'd be happy to share my model assumptions with CARB if requested.

Concern Regarding Existing Modeling

352.2 Regarding the CATS model, I'd like to highlight what I view to be an improper implementation of the credit bank. While the bank has nominally been included, banked credits are only made available at the price ceiling where the supply of credits is effectively unlimited already. This effectively means the CATS model ignores the entire bank. In reality, banked credits will be available at much lower prices, especially when considering the lack of ambition around this proposed rulemaking. Correcting this assumption would show much lower credit prices going forward, even leaving the rest of the CATS model unchanged.

I also believe the CATS model is showing a misunderstanding of the state of the renewable diesel market. California is already consuming more RD than the CATS long-term projections of RD supply. I don't have specific recommendations for fixing the model, but suggest interpreting the results with extreme caution in light of this.

Technological Neutrality

352.3 I find the moves to limit crediting to particular decarbonization technologies as concerning for the integrity of the program going forward. To preserve an efficient market, the rules must be clearly established and enforced. The developments needed to decarbonize transportation (or any industry) require long periods of time to fund, deploy, and operate to be financially viable. Inconsistent rules add economic and regulatory risk to that process, and will make investment more expensive and more short-term focused. I do not believe this is the intention of the CARB, but it is a likely consequence of proposed changes to RNG, biomass-based fuels, and electric forklifts.

LCFS and the CA-GREET model have effective and scientifically rigorous means for evaluating technology, and in many ways already address the criticism of various technologies. Adapting these methodologies to new science and evidence is entirely appropriate, but disregarding them or creating parallel, inconsistent methodologies is not.

352.3 cont. I urge ARB to eliminate its unscientific changes to its rules meant to favor some technologies over others, and instead strongly reaffirm its science-driven rules-based technological neutrality. To the extent that existing pathways do not properly reflect compliance with the LCFS CI targets, corrections for this should be made primarily through the established program mechanisms – updating CA-GREET and adjusting the annual CI reduction targets.

The Future of ZEV Crediting

352.4 Lastly, I have a question about Zero-Emission Vehicle crediting in the future with respect to ACCII. As the regulation goes into effect that requires a certain percentage of new car sales be Zero-Emission Vehicles, will LCFS crediting be adjusted to reflect the fact that each ZEV is not replacing an ICE vehicle? As soon as 2026, the status quo baseline alternative to purchasing and operating 100 new ZEVs will be purchasing and operating a fleet of 65 new ICE vehicles and 35 new ZEV vehicles. The overall fleet of vehicles will also shift more towards ZEV vehicles, making the concept that each ZEV displaces one ICE's worth of gasoline incorrect. How does LCFS plan to incorporate this into their crediting methodology, and is this consistent with other technologies?

Thank you for considering my comments. I greatly appreciate the hard work involved in managing this program, as well as the transparency which has allowed me to have and voice these reflections and opinions.

Sincerely,

Eric Mintzer

Sacramento, CA 95814

RE: Tesla Comments on CARB's Proposed Low Carbon Fuel Standard Amendments (Dec. 19, 2023)

Dear Chair Randolph and Members of the Board:

Pursuant to the California Air Resources Board's (CARB's) Proposed Low Carbon Fuel Standards (LCFS) Amendments (Dec. 19, 2023), Tesla respectfully submits the following comments. Tesla incorporates by reference its written comments in response to previous 2022 Scoping Plan and LCFS workshops and presentations.[1] [2] [3]

Tesla continues to support CARB and the state of California in defending the state's authority to implement the LCFS. In response to the Proposed Regulation Order and Initial Statement of Reasons (ISOR) released on December 19, 2023, Tesla provides comments highlighting, inter alia, amendments that support the maintenance of programmatic stringency, enhance public benefits and infrastructure investments, modernize the program and ease administrability.

To provide an understanding of the level of importance of each of our suggested amendments, our comments are divided into three sections. The sections are: Section II) Essential Amendments (changes that Tesla believes to be essential to LCFS stabilization and success), Section III) High-priority Amendments (changes Tesla believes will significantly improve the adoption of EVs and result in emissions reductions sought), and Section IV (Amendments that should be included if time permits though could be completed in a future regulatory cleanup). These three levels of prioritization are based upon a view of where EV (all classes) adoption stands, economic influences, the influence CARB's programmatic decisions have on other US states, balancing the need to finalize new regulations with CARB Staff resource availability and other considerations.

I. Background

a. Tesla's Mission and its California Manufacturing Footprint

Tesla's mission is to accelerate the world's transition to sustainable energy. Moreover, Tesla believes the world will not be able to solve the climate change crisis without directly reducing air pollutant emissions

---

[2] https://www.arb.ca.gov/lists/com-attach/4195-scopingplan2022-BmVcO1IMAyMGYwBv.pdf
[3] https://www.arb.ca.gov/lispub/comm2/iframe_bccomdisp.php?listname=lcfs-wkshp-feb23-ws&comment_num=111&virt_num=98

- including carbon dioxide and other greenhouse gases - from the transportation and power sectors.[4] To accomplish its mission, Tesla designs, develops, manufactures, and sells high-performance fully electric vehicles and energy generation and storage systems, installs, and maintains such systems, and sells solar electricity.[5] Consistent with this effort, in May, 2023, Tesla was ranked as the world leader in the transition to vehicle electrification.[6]

Tesla currently produces and sells four fully electric, zero emissions light-duty vehicles (ZEVs): the Model S sedan, the Model X sport utility vehicle (SUV), the Model 3 mid-sized sedan, and the Model Y mid-sized SUV. As an EV-only manufacturer, as the U.S. Environmental Protection Agency (EPA) recognized in its *2023 Automotive Trends Report*, Tesla had by far the lowest carbon dioxide emissions (0 g/mi) and highest fuel economy (120 miles per gallon) of all large vehicle manufacturers in MY 2022.[7] Additionally, in December 2022, Tesla initiated delivery of its Tesla Semi Class 8 day cab truck[8] and in December 2023, delivery of its electric pickup truck, the Cybertruck.[9]

Tesla is the largest manufacturing employer in California and employs more than 42,500 people in state. California is home to both Tesla's global design headquarters in Hawthorne, as well as its global engineering headquarters in Palo Alto. Tesla manufactures and assembles vehicles, advanced 4680 lithium-ion battery cells, and battery packs at its factories in Fremont, CA.[10] It also produces Megapack, a utility-scale grid storage battery, at its factory in Lathrop, CA.[11] In 2021 alone, Tesla's investment in California helped deliver $10.4 billion ($28.5 million per day) to California's gross state product.[12]

Importantly, Tesla is not only a manufacturer but is also continuing to grow its large network of retail stores, vehicle service centers, collision centers, and electric vehicle charging stations to accelerate and support the widespread adoption of electric vehicles (EV).[13] Tesla has over 60 stores and galleries and over 45 Service Centers in California. Tesla also operates the country's largest and most reliable public EV charging network. Since 2012, Tesla has invested heavily in siting, building, operating, and maintaining charging infrastructure. In 2013, Tesla had just eight Supercharger Stations in North

[13] See, 86 Fed. Reg 43726, 43799 (Aug. 10, 2021) ("Electrification of the vehicle fleet is likely to affect both the number and the nature of employment in the auto and parts sectors and related sectors, such as providers of charging infrastructure.").

America. Today, Tesla owns and operates the largest DCFC network in the world, known as the Tesla Supercharging network.[14] In California, Tesla has 440 Tesla Supercharger locations with over 6,600 charging stalls.

b. Tesla's Class 8 Truck – the Tesla Semi

Tesla's first heavy duty vehicle, a Class 8 truck, is designed from the ground up to be the most efficient and safest truck on the market. The Tesla Semi will have an outsized impact on reducing GHG, particulate matter (PM), and (nitrogen oxides) NO_X emissions from goods movement and transportation. The Semi comes in two models with ranges of 300 and 500 miles respectively and demonstrates that an all-electric truck can meet virtually any duty cycle when paired with the Semi charging system that Tesla is developing.

Combination trucks – of which the vast majority are semi-trucks – account for just 1.1% of the total fleet of vehicles on the road in the U.S.. As EPA recognizes, because combination trucks have high fuel consumption due to their weight and heavy utilization, they account for approximately 25% of all U.S. vehicle GHG emissions.[15] Accordingly, rapidly electrifying the heavy-duty truck segment is an essential part of transitioning the world to sustainable energy.

On December 1, 2022, Tesla announced delivery of its first Semi trucks and has subsequently deployed a fleet of the vehicles with PepsiCo.[16] Since unveiling the Tesla Semi, a significant number of fleets with substantial freight needs have placed reservations for the truck, indicating broad industry demand for heavy-duty electric vehicles.[17] These fleets will be deploying the Tesla Semi in a wide range of applications, including but not limited to, manufacturing, retail, grocery and food distribution, package delivery, dedicated trucking, rental services, intermodal, drayage, and other applications. Companies with operations throughout North America representing every major trucking sector and category of the economy have reserved the Tesla Semi, ranging from food service to logistics to retail.[18]

The reason for this strong interest is clear – the economics of electrified heavy-duty vehicles are compelling for end-users, particularly sophisticated and economically rational operators. Tesla estimates that the time to recoup the investment in a Tesla Semi, given the operational savings it provides customers compared to a conventional Class 8 truck, will be approximately two to three years (Class 8 diesel trucks have a 15-year average lifetime). With the per mile operational costs being so much cheaper than diesel trucks, economic minded operators will maximize the use of their electric trucks and quickly expand the number of electric trucks in their fleets.

[18] See EPA, Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles: Phase 3, Draft Regulatory Impact Analysis (Draft RIA) (April 2023) at 52-59.

Tesla has set an annual Semi North American production goal of 50,000.[19] This production rate will represent a level of approximately 20% of 2022 Class 8 domestic annual sales.[20]

c. BEV Deployment Growth Necessitates Stringency and Continued Programmatic Support of All BEV Classes, including Light-Duty and Heavy-Duty

In the ISOR, CARB recognizes that the increasing deployment and market share of electric vehicles and the accompanying buildout of EV charging enable the ability to strengthen the CI reduction benchmarks of the LCFS.[21] Tesla believes the path of EV adoption can support even further reductions in both the CI reduction benchmarks and a greater near-term step down in 2025.

As the agency should be aware, numerous manufacturers have announced increased EV production goals that encompass rapid deployment between now at 2030.[22] These announcements have continued

to expand with Toyota, Hyundai, JLR, and Subaru, among others, recently announcing new commitments on BEVs.[23] As of the fall of 2023, automakers and battery manufacturers had committed $115 billion to expand the production of EVs and batteries inside the U.S. and across North America.[24]

While some in the fossil fuel industry along with manufacturers struggling to efficiently produce electric vehicles have suggested a retrenchment on EV deployment, any such pronouncements have been flat wrong.[25] In late 2023, the U.S. Energy Information Administration's (EIA) figures reported EV sales were 17.7% of U.S. sales already outpacing the anticipated market share projected by EPA for MY 2026.[26] While the entire U.S. vehicle market was up 13% YoY over 2023, the EV market was up almost 50%

YoY.[27] BloombergNEF predicts a 32% YoY growth rate for 2024.[28] These results are consistent with other projections of rapid EV sales growth. A recent study published in the Proceedings of the National Academies of Science (PNAS) found that consumer valuation of increased range and lower prices will lead EVs to being the majority of vehicles sold by 2030.[29] Some analysts predict that by 2026 60% of new models will be EVs.[30] Still other analysts project that EVs could even account for 90% of sales by 2027.[31]

Most importantly in terms of light-duty EVs, Veloz's Q4 2023 EV Market Report shows that in 2023,[32] California recorded the highest EV share of total car sales, with 25 percent of all vehicles sold being EVs – nearly three times the national average.[33] Further, California's recent adoption of the ACC II rule, setting a 100 percent ZEV sales standard by 2035, will also accelerate BEV adoption. Tesla also expects the deployment of medium- and heavy-duty EVs to scale rapidly. The depth and pace of electrification technology deployment that has already occurred and will be accelerated through market forces and numerous other state and federal policies is impressive. Electric truck deployment, like other technologies, will follow an S curve leading to a rapid pace of adoption in the next decade. Indeed, many manufacturers have rapidly placed innovative technology across major portions of their new vehicle offerings in only a few model years.[34] BEV technology will continue to follow similar paths, and deployment has already been shown to outperform the traditional S curve.[35]

The BEV market is dynamic and changing rapidly. One recent report published two months *before* passage of the Inflation Reduction Act (IRA) found that revenue from the electric truck market was growing at a compound annual growth rate of 54%.[36] In another example, NREL has found economics will drive much faster adoption with ZEV sales possibly reaching 42% of all medium- and heavy-duty trucks by 2030.[37] It even projects out a scenario where ZEV sales reach >99% by 2045, and 80% of the

sector transitions to ZEVs by 2050, reducing CO2 emissions by 69% from 2019.[38] A new analysis views the heavy-duty haul market as 50% electrifiable right now.[39] Still other analyses have found that most "market segments have the potential to be fully mature by 2025, with EV models available from multiple companies, including the majority of major OEMs that currently have 90% market share of the in-use fleet."[40] Further, it is predicted the pace of electrification in the truck sector will increase rapidly over the next decade.[41] Recent sales suggest this pace of adoption is already occurring.[42]

These estimates do not take into account the BEV sales impacts that will result from California's newly adopted Advanced Clean Fleets (ACF) program. [43] ACF will require last mile delivery and yard trucks to transition to ZEVs by 2035, work trucks and day cab tractors must be zero-emission by 2039, and sleeper cab tractors and specialty vehicles must be zero-emission by 2042.[44] Moreover, the ACF rule has accelerated the rate of BEV deployment under the original ACT rule to embrace an end to combustion truck sales in 2036.[45] In California, the original ACT rule is estimated to require the deployment of 100,000 heavy-duty ZEVs in 2030 and 300,000 by 2035.[46]

353.1 Finally, CARB should consider the role that new federal incentives may play in deployment of heavy-duty electric vehicles. Federally, numerous heavy-duty electrification grants, demonstration programs, incentives, and infrastructure incentives were included in the Infrastructure Investment and Jobs Act of

353.1 cont. 2021.[47] The IRA also has established programs, such as the Clean Heavy-Duty Vehicles Program, to address climate change by reducing GHG emissions and improve the air quality through the acquisition and use of zero-emission vehicles.[48] The program directs EPA to award a total of $1 billion through grants and rebates to eligible recipients (e.g., states and municipalities) to replace existing heavy-duty vehicles with clean zero-emission vehicles and develop zero-emission vehicle infrastructure. The funding can be applied to up to 100% of the incremental costs of replacing an eligible heavy-duty vehicle with a zero-emission vehicle. It can also be used for other activities such as purchasing, installing, operating, and maintaining infrastructure needed to fuel or maintain zero-emission vehicles. The federal government also recently launched its Commercial Clean Vehicle Credit providing up to $40,000 per truck in tax credits.[49]

CARB should ensure it utilizes the universe of manufacturers' significant public EV deployment commitments in implementing a stringent LCFS, and the agency can mitigate any retrenchment in those commitments by maintaining an adequate light-duty Clean Fuel Rewards program as discussed in Section II.c.i. below.

II. Essential Amendments to Reinvigorate the LCFS Program and Support Light through Heavy Duty BEV Deployments

353.2

a. Tesla Supports Strong Program Stringency (30% minimum by 2030)[50]

Tesla applauds CARB's long-term vision of setting a 90% reduction target by 2045. This cements California as the clear leader in the transportation decarbonization policy space, with the farthest-forward decarbonization target of any transportation decarbonization program globally. It also sets California on a path to reach Net Zero by 2045, as envisioned by Executive Order B-55-18.

The compliance curve, step change, and auto acceleration mechanisms must all work in unison, and Tesla encourages CARB to increase the stringency of the 2030 target beyond 30% if our below recommended changes to the step-change and auto acceleration mechanism are not implemented.

353.3

b. Correcting The Supply-Demand Imbalance Necessitates a Regulatory Step Change of at least 12%

As discussed earlier, the current LCFS market is not functioning in a sustainable manner. There is simply a glut of credits on the market that has driven down pricing, making the LCFS less supportive of electrification efforts in California. As a near term solution to address these issues, CARB should implement a step change of at least 12%, implemented as quickly as possible.

---

[47] See, DOE, Alternative Fuel Data Center, Bipartisan Infrastructure Law (Infrastructure Investment and Jobs Act of 2021) *available at*. https://afdc.energy.gov/laws/infrastructure-investment-jobs-act

[49] https://www.irs.gov/credits-deductions/commercial-clean-vehicle-credit#:~:text=Businesses%20and%20tax%2Dexempt%20organizations,powered%20by%20gas%20or%20diesel)
[50] See UC Davis Updated fuel Portfolio Scenario Modeling to inform 2024 Low Carbon Fuel Standard Rulemaking here. Updated Fuel Portfolio Scenario Modeling to Inform 2024 Low Carbon Fuel Standard Rulemaking (escholarship.org)

353.3 cont. In the past year of reported data, the actual CI reduction has gone from -13.11% (against a -10% target) in Q4 2022 to -15.61% (against a -11.25% target) in Q3 2023, resulting in the differential between target and actual increasing from -3.11% to -4.36%. A simple linear extrapolation of this trend would result in a CI differential of -6.41% by Q1 of 2025.[51] However a response to adopt a 7% step change would not result in a declining credit bank or be reflected in a substantive credit price stabilization. The combination of continued EV adoption with the diesel pool approaching 100% justifies a significant step change of at least 12%.

The step change should be increased in stringency to adjust for the change being proposed by CARB in this rulemaking to the diesel benchmark from 100.45 gCO2e/MJ to 105.76 gCO2e/MJ. Because the diesel credit pool is now more than 50% renewable, an increase in the diesel benchmark results in more overall credit generation per gallon consumed in the whole pool. Going forward, in the absence of limits to first generation biofuels, it is widely expected that the renewable content of the diesel pool will continue increasing until it approaches 100%. This increase in renewable content will amplify the effects of this benchmark change. We recommend CARB model these effects and increase the step change stringency correspondingly.

Just as speed to implementation of the rule changes is critical to health of the program, so too is speed to implementation of the step change. The difference between a 2024 implementation and a 2025 implementation could result in a bank size growing millions of MT higher. Such a large bank increase could require years to rebalance, lowering demand for newly generated credits during that period. By allowing such a large supply and demand imbalance and the creation of such a large total bank, many smaller credit-generating companies who have been critical to the success of the program thus far could experience financial hardship, potentially resulting in lower credit generation in future years as they slow or cease operation. Further, delaying a step change, to use a BEV analogy, sends a message to participants that California is taking its foot off the accelerator, engaging regenerative breaking. This effectively implies that the state leading the climate fight in the U.S. feels it has done enough near-term and is willing to sacrifice additional emissions reductions and reinvestment when it is critically needed.

353.4

c. EV Automaker Contributions to Emissions Reductions Are Deserving of Base Credit Allocations to Revitalize the Clean Fuel Reward (CFR) Program as the CFR was Envisioned

In addition to Tesla's investments noted above in the introduction and Section II, it is expected that Automakers will invest more than $500B globally throughout the electrification value chain.[52] As similarly mentioned in a joint response filed by Tesla and others to the 2022 Scoping Plan, automakers enjoy comparatively strong relationships with consumers and act as primary distributors of information regarding the consumer and environmental benefits of EVs. Automakers also guide consumer preferences by providing compelling EV products, which are primarily responsible for the emissions reductions associated with EV adoption. Despite this significant and unique role in the transition to EVs,

[51] Using actual CI reduction calculation methodology from Figure 1 of the LCFS dashboard: https://ww2.arb.ca.gov/resources/documents/lcfs-data-dashboard;Using reported actual data from the LCFS Quarterly Data Spreadsheet: https://ww2.arb.ca.gov/resources/documents/low-carbon-fuel-standard-reporting-tool-quarterly-summaries

[52] See Auto OEMs to Invest US$515 Billion in EV-Related Technologies and Upgrades…here. https://www.prnewswire.com/news-releases/auto-oems-to-invest-us515-billion-in-ev-related-technologies-and-upgrades--but-supply-chain-challenges-remain-301550827.html

353.4 cont. EV automakers may only generate limited incremental LCFS credits, and only if other stakeholders have not already registered to generate such credits. Furthermore, the value of the incremental credits structurally depreciates as improvements are made to the carbon intensity of California's electric grid. This existing structure provides a weak and diminishing incentive for EV manufacturers to make additional allocations to- or investments in- California based on LCFS, and it does not reflect the relative contributions of EV manufacturers in the transition to EVs. As such, CARB should establish a structure that shifts base credit generation for residential EV charging to automakers for the purpose of implementing a functional CFR Program, creating a more inclusive program in which the roles of different stakeholders are more evenly balanced while still ensuring programmatic goals are met. Such a change would reward EV manufacturers for the use of their products—a powerful complement to the existing ZEV sales mandate and an incentive to invest in more capable and desirable EVs.

Tesla continues to support the reinvestment of LCFS electrification credit revenue back into the program to support further electrification. CARB LCFS regulations provide utilities a relatively diverse menu of base credit spending categories which historically included offering a light-duty (LD) Clean Fuel Reward (CFR) program. Far from "bankrupt," by Tesla's estimates, the CFR program has in excess of $420M[53] in LCFS credits intended for LD EV incentives held by utilities today. CARB should provide EV automakers with base credit allocations to revitalize the CFR program, touched upon further below. Lastly, CARB should consider requiring all clean fuel providers (E.G. hydrogen producers or Biofuels Producers) to reinvest funds generated through the sales of LCFS generated credits back into CA LCFS efforts as only electricity is required to reinvest and track today.

353.5

i. Revitalize the Light Duty California Clean Fuel Reward (CFR) Program with Efficient and Sustainable Modifications including EV Manufacturer Base Credit Allocations

CARB staff's proposal to fundamentally change the CFR program from one that supports on the hood incentives for LD vehicles to one focused on medium and heavy-duty vehicles was an unexpected change to the program that was not discussed in any of the preliminary workshops. It is fundamentally problematic to utilize base credits from residential light duty EV charging to fund medium and heavy-duty programs. While the CFR program was obviously flawed, Tesla believes that it can be salvaged, improved, and turned into a consistent pool of funds to support on the hood incentives for light duty electric vehicles. Automakers have decades of experience administering incentives. CARB should welcome EV manufacturers willing participation to create CFR programmatic efficiencies and recognize that the proposal to abandon the LD CFR and reallocate funding to MHD is premature, particularly with extensive existing MHD incentive support. Moving these funds into supporting medium and heavy-duty vehicles that are "exempted from Advanced Clean Fleets regulation"[54] as CARB intends, will essentially provide additional funds for the same pool of vehicles that are currently supported by CARB's HVIP Program, which currently has over $480M of funding available.[55] Further, these truck fleets (unlike California's light duty EV drivers), will already be getting base credits for fleet charging that will reduce their total cost of ownership.

[53] $450,540,222 in total program costs reported for 2020, 2021, and 2022: https://cleanfuelreward.com/reporting;
[54] Appendix E: Purpose and Rationale of Proposed Amendments for the Low Carbon Fuel Standard Requirements at 14.
[55] See https://californiahvip.org/funding/

353.5 cont. That said, the CFR program was not as effective as it could have been. Automakers know more about their delivery plans than anyone and can leverage that knowledge to plan ahead, creating a revitalized LCFS program. By granting base credit revenue to EV manufacturers, administrative efficiencies can be gained, creating a program that relies on lower administrative fees and provides on-the-hood incentives. Having completed substantive and ongoing analysis to understand why the CFR failed and how it could have succeeded (and can succeed) if established with EV manufacturers as the credit recipient, Tesla is confident that a revitalized program could remain solvent, support an incentive for all line makes, including new market participants, and continue to support consumer decisions to purchase LD EVs in pursuit of LCFS goals. Tesla supports the continuation of the LD Clean Fuel Rewards Program with EV manufacturers responsible for operationalizing the program through receipt of non-holdback credits similarly to how utilities are receiving those now.

Should CARB establish a similar CFR MHD program or reallocate funds intended for LDV to MHD as proposed, Tesla recommends that CARB provide the Executive Officer with the authority to adjust any MHD program including credit allocation. The challenging history of the CFR is long and creating flexibility to correct course when expectations and outcomes do not match is essential. CARB has presented no support or justification as to why a CFR for MHD vehicles will not face the same problems that the LD CFR experienced when funded simply through the utilities use of credits. In order for a MHD CFR focused program to succeed, the way this program is funded needs to be reimagined.

353.6

d. Implement Rule Changes in 2024, Being Careful to Not Sacrifice Stringency

With a supply and demand imbalance of over 6 million MT per year, as of the last reported data,[56] the speed in which CARB implements new rules is of vital importance to market participants. With actual reductions in carbon emissions exceeding 15%,[57] surpassing expectations since 2020, and seeing LCFS credit prices fall since that time from ~$200 to a low of $57 so far this year,[58] delaying a stringency increase and step-change will likely continue to suppress credit values, market confidence and investment in clean fuels in California. While every quarter delay matters, Tesla encourages CARB staff to continue to focus on rules that correct near-term credit pricing in support of reinvestment in emissions reducing efforts.

353.7

e. Improve the Automatic Acceleration Mechanism (AAM)

The inclusion of an Automatic Acceleration Mechanism (AAM) is an important and welcome step towards balancing the safeguards in the program. The program already includes multiple safeguards to help rebalance the program if it is underachieving its targets, including a Credit Clearance Market, Advanced Credits, Carryback Credits, and Accumulated Deficits. The AAM is an important counterbalance safeguard for times when the program is overachieving its targets.

During times of program overachievement, the AAM, as currently envisioned, requires two full years to take effect.

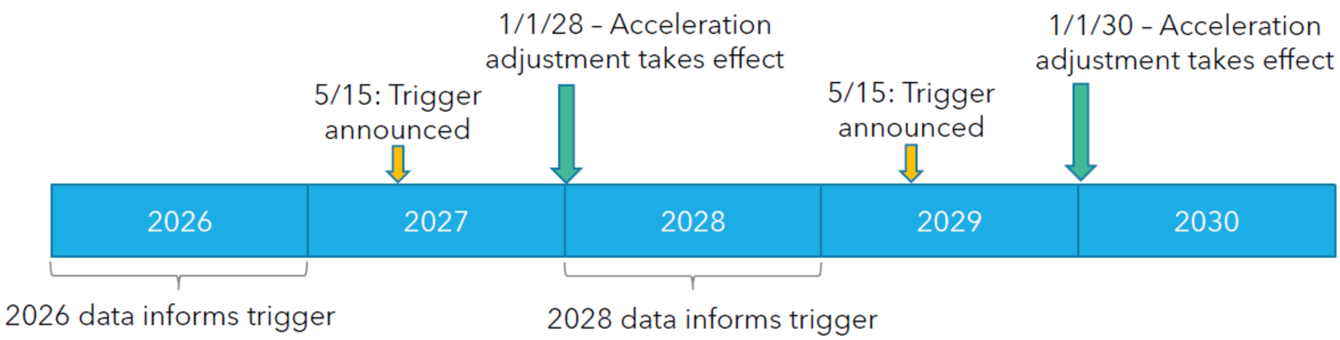
[57] https://ww2.arb.ca.gov/resources/documents/low-carbon-fuel-standard-reporting-tool-quarterly-summaries
[58] See California Low Carbon Fuel Standard Credit Price from July 2020 through February 13, 2024, https://www.neste.com/investors/market-data/lcfs-fuel-standard-credit-price

353.7 cont.



The current draft rule also sets the AAM's first year of implementation as 2027, with benchmark changes taking effect in 2028 at the earliest. Tesla's primary ask is for the first year of AAM implementation should be in 2026, using 2025 data for the trigger, with the changes to the benchmark being implemented in Q3 of 2026 if triggered.

III. High Priority Amendment Recommendations

353.8 **a. Update the Light Duty BEV Energy Efficiency Ratio (EER) and Provide a Pathway for OEM-Specific EERs**

CARB should also use this rulemaking as an opportunity to update the Energy Efficiency Ratio (EER) for Light Duty Battery Electric Vehicles (LD BEV). The current 3.4 EER was adopted by CARB in 2011 and has not been updated in the 13 years since. As described in the 2011 Initial Statement of Reasons (ISOR) (Appendix A, Page 67),[59] the 3.4 EER was an average of the EERs of two vehicle comparisons. The first was a PHEV-to-ICE comparison between a 2011 Chevy Volt compared to a 2011 Chevy Cruze (93 MPGe combined fuel economy / 28.3 MPG combined fuel economy = 3.29 EER). The second was a BEV-to-ICE comparison between a 2011 Nissan Leaf and a 2011 Nissan Versa (99 MPGe combined fuel economy / 28.4 MPG combined fuel economy = 3.49 EER). The fuel economy numbers can be viewed on www.fueleconomy.gov. The 28.3 MPG fuel economy for the Chevy Cruze was presumably a simple average of the automatic transmission versions of the three engine trims offered. The 28.4 MPG fuel economy for the Nissan Versa was presumably a simple average of the automatic transmission versions of the two engine trims offered. Given the immense change in EV adoption in recent years, and the remarkable improvements in the efficiency of EVs today, it is simply inappropriate to use an EER that is 13 years old. As an illustrative example, a 2024 Hyundai Ioniq 6 has a 140 MPGe, which is a 40% improvement on the 2011 Nissan Leaf.

If CARB were to keep the 2011 (existing) EER methodology and simply update the calculation using the most current version of the cars included in that calculation, the EER would rise from 3.4 to 3.8. However, for the first comparison between a PHEV and ICE vehicle, CARB chose the Chevy Volt and Chevy Cruze; unfortunately, General Motors ceased production of both vehicles in 2019.[60] In leu of

[59] https://ww3.arb.ca.gov/regact/2011/lcfs2011/lcfs2011.htm
[60] https://www.cbsnews.com/news/chevy-volt-discontinued-chevrolets-last-volt-rolls-off-the-assembly-line/

353.8 cont. these vehicles, CARB would need to add another comparison. A similar comparison can be done between the 2024 Prius Prime, which achieves a 127 MPGe combined fuel economy,[61] and the conventional ICE 2024 Toyota Corolla (both are classified as compact cars), which achieves a 28.5 MPG combined fuel economy across the simple weighted average of the automatic transmission versions of the two non-hybrid engine trims. This is a PHEV-to-ICE EER of 4.46. Nissan continues to sell the Leaf and the Versa. The Nissan Leaf energy efficiency has improved from 99 MPGe in 2011 to 111 MPGe for the 2024 model year.[62] The Nissan Versa energy efficiency has improved from 28.4 MPG in 2011 to 35 MPG for the automatic transmission version of the only engine trim.[63] This translates to an EER of 3.17 for BEV-to-ICE. Using the simple average of the BEV and PHEV EERs, we arrive at an overall Light Duty EER of 3.8. Another apt comparison would be the Hyundai Ioniq 6 and the Hyundai Elantra. As stated earlier, the Ioniq 6 gets 140 MPGe, while the Elantra's weighted average of the automatic transmission versions of the two non-hybrid engine trims is 35 MPG. This is a BEV-to-ICE EER of 4. Using a sales-weighted BEV-to-ICE ratio would likely result in an EER over 4.0.

California would not be alone in modernizing its EERs for LD BEVs. Canada's Clean Fuel Regulations use a 4.1 EER for light duty EV Charging. This was calculated based on the ratio of the sales-weighted average efficiencies of electric vehicles to the sales-weighted fuel efficiency of the ICEVs in the same class, with efficiency data came from the 5-cycle testing procedure.[64] The Netherlands' Energy Transport Regulation currently uses an EER of 4.0.[65] The European Union recently passed the third version of its Renewable Energy Directive (REDIII). This directive increases the targets for EU member states transportation GHG reductions and guides them to use a 4.0 EER.[66] Updating the EER is important to ensure that electric vehicle charging is properly credited and continues to be incentivized appropriately. Utilizing a higher EER can support a steeper step change and a steeper compliance curve for this program.

In addition, CARB should allow an OEM to submit an application for an EER based upon that OEM's real-world fleet. CARB has created a precedent for this by approving the Lime scooter Tier 2 pathway which included a company-specific EER factor.[67] Allowing OEMs to submit applications for company-specific EERs would better reflect the actual efficiency of electric vehicles in the market and allow those vehicles to be properly credited. This would also incentivize each OEM to focus on improving vehicle efficiency.

353.9

b. Update the Medium and Heavy-Duty BEV Energy Efficiency Ratio

[61] https://www.fueleconomy.gov/feg/Find.do?action=sbs&id=47501
[62] https://www.fueleconomy.gov/feg/Find.do?action=sbs&id=46973
[63] https://www.fueleconomy.gov/feg/Find.do?action=sbs&id=47236

[65] https://www.rijksoverheid.nl/documenten/kamerstukken/2022/12/22/beantwoording-kamervragen-over-wijziging-van-de-stimuleringsfactoren-in-de-regeling-energie-vervoer
[66] https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=CELEX%3A32023L2413&qid=1699364355105
See also, https://www.europarl.europa.eu/doceo/document/ITRE-AM-729929_EN.pdf
[67] https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/fuelpathways/comments/tier2/b0467_cover.pdf

353.9 cont. While not quite as dated, the current 5.0 EER for Heavy Duty battery electric vehicles is also due for an update. This EER was set during the 2018 rulemaking and the methodology for calculating this EER is described in the ISOR Appendix H, Section E.[68] Unlike the Light Duty EER calculation, which was based on just two vehicle comparisons, the MHD EER calculation is based on an analysis of a number of papers comparing the efficiency of transit buses, drayage trucks, parcel trucks, and many other MHD vehicle types. Tesla believes this more comprehensive EER methodology is preferable and encourages CARB to update the MHD EER based on the current state of vehicle efficiency research.

In the current EER table (Table 5) CARB has Light and Medium Duty electric vehicles lumped together into a single EER and Heavy Duty EERs as another single EER. Light Duty vehicles are defined as vehicles with a GVWR of 8,500 pounds or less, while Medium Duty Vehicles are defined as vehicles with a GVWR between 8,501 and 14,000 pounds. Anything over 14,001 pounds GVWR is classified as Heavy Duty. This combining of Light and Medium duty in the EER table conflicts with the combining of Medium and Heavy Duty in the Fast Charge Infrastructure (FCI) program. As part of the EER update, Tesla encourages CARB to either create a separate EER for Medium and Heavy Duty BEVs or allow for OEM-specific EERs.

353.10

c. Remove the Unnecessary Third Party Verification for Non-Residential EV Charging

Proposed section 95501 of the amendments includes a proposal to expand third party verification for EV charging transactions. While Tesla appreciates the intent of CARB staff's proposal, it is unnecessary to create a separate third-party verification program regime for non-residential electricity transactions related to EV charging. Commercial EV charging infrastructure transactions fall under the purview of the CA Department of Agriculture, Division of Measurement Standards (DMS), under its state weights and measures program. CA DMS is responsible for verifying the accuracy of commercial EV charging infrastructure in California. This includes both a field verification process carried out by the CA counties as well as type evaluation program. It is unnecessary for LCFS to add additional verification requirements given the accuracy of commercial EV charging transaction is already regulated and verified in CA. We therefore recommend that no additional third-party verification is necessary for EV charging transactions.

353.11

d. Amendments to the Medium and Heavy-Duty Fast Charge Infrastructure Program

Tesla agrees that medium and heavy duty FCI pathways are important for accelerating the transition of electrifying trucking in California. Tesla supports CARB's inclusion of a HD-FCI pathway in the proposed amendments and appreciates CARB's inclusion of depot charging as an eligible pathway. Initial Tesla Semi customers will initially be focused on charging infrastructure located in the internal depots. These trucks utilize "hub and spoke" operations or go through other internal depots during their operations. The cost of infrastructure is one of the main determining factors for how many trucks a customer is willing to purchase. The HD-FCI will incentivize customers to build out the necessary charging infrastructure to support their fleet transitioning to electric trucks on an expedited timeline.

353.12

i. Remove Geographic Restrictions for MHD FCI

[68] https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2018/lcfs18/apph.pdf

353.12 cont. The geographic restrictions included in the proposed amendments for the HD FCI should be removed. There are limited locations in California with the power available to support truck charging at scale. Given the cost, and more importantly, the time constraints that come with bringing new capacity to power constrained locations, charging developers must be able to locate their locations where it makes the most sense from a business perspective. Alternatively, CARB should change the one mile from the corridor limit to five miles. This will at least expand the number of suitable charging locations to develop.

CARB's justification for including the restriction to within one mile of a major freight corridor is to "bring cleaner air for communities living adjacent to these areas currently heavily impacted by diesel truck pollution." Siting medium and heavy-duty chargers is a balancing act between land costs, availability of land near freeways, availability of land without zoning restrictions, and, perhaps most importantly, the challenge in finding 5 MW or more of grid capacity where the local utility is willing to install interconnects on a quick timeline. Because the Venn diagram overlap of these needs is already small, we do not believe CARB should be adding additional geographic restrictions to further limit the number of qualifying sites. Limiting eligible charging locations will only serve to slow down that process and subject all communities, including Environmental Justice communities to continued diesel pollution.

Different trucks have different driving patters – class 4 trucks might deliver milk to grocery stores early in the morning and then sit charging for the rest of the day; this would best be served by slower chargers in the location where these trucks are parked most of the time. Class 8 trucks might be traveling all day long, with multiple driving shifts between the ports and warehouses; this would best be served by fast chargers along a major freight corridor. Some trucks will be fleet vehicles while others will be driven by independent-owner operators. Trying to overlay a "one size fits all" geographic restriction on MHD-FCI will only serve to slow the deployment of these chargers.

353.13

ii. Eliminate or Increase the 10 Charger Per Site Limit for MHD FCI

For MHD-FCI sites, CARB is proposing limits of no more than 10 charging posts per site. This artificial limitation should be removed. Charging developers that are focused on the medium and heavy-duty truck sector are developing sites that are far bigger than 10 posts for good reason.[69] In order to support

---

[69] See e.g., Bloomberg News, Tesla Wants to Build a Semi Truck-Charging Route From Texas to California (August 1, 2023), (describing a proposal for charging infrastructure that included at least 12 chargers per site) *available at* https://www.bloomberg.com/news/articles/2023-08-01/tesla-semi-truck-charging-route-pitched-at-100-million?embedded-checkout=true; Canary Media, Big electric-truck charging depots are coming soon to California (January 26, 2024) (an overview of three truck charging depots being built by WattEV, including two in the Central Valley which will have a combined 192 chargers and a third site in Blythe with 66 chargers),*available at* https://www.canarymedia.com/articles/ev-charging/big-electric-truck-charging-depots-are-coming-soon-to-california; (Forum announcing a new charging depot in Port of Long Beach with 25 chargers) Forum Mobility Announces New Charging Depot for Electric Drayage Trucks in the Port of Long Beach (November 30, 2023) *available at* https://www.prnewswire.com/news-releases/forum-mobility-announces-new-charging-depot-for-electric-drayage-trucks-in-the-port-of-long-beach-302001230.html; TerraWatt Infrastructure Accelerates Rollout of EV Fleet Charging Solutions Across Inland Empire (October 10, 2023), (Terrawatt announcing two sites capable of charging over 500 trucks utilizing 40MW of power) *available at* https://www.prnewswire.com/news-

353.13 cont. the transition to truck electrification being driven by policy and regulations in California, it is vitally important that there are large charging depots available to truck operators. These charging sites can support fast charging for regional and long-haul trucking but can also serve other truck operations where operators are able to sit and charge for longer periods of time. These charging locations will make electric trucking possible for companies looking to electrify longer routes, as well as smaller operators who are unable to accommodate charging in their depots. If CARB is unwilling to remove this limitation entirely, Tesla suggests increasing the charger post number to 100 or at least remove or increase the limitation for shared depots and fleet depots which will be the majority of initial charging developments in the coming years.

353.14

iii. Increase 10 MW Limit to 15 MW per Site with Exceptions up to 24 MW

For the same reasons stated above that the 10 charger per site limit should be removed, CARB should also remove the overall site capacity limit of 10 MW. 10 MW is simply not enough power to support the charging stations needed to meet California's electric truck deployment goals. CARB should increase the 10 MW cap for sites to at least 15 MW and allow an exception by the Executive Officer for up to 24 MW for sites.

353.15

iv. Raise 2.5% cap for MHD FCI to 5%

The MHD-FCI program is limited to 2.5% of the previous quarter deficits. At today's deficit levels, this would fall dramatically short of the charging requirements in the state. Additional support is needed to attract the scale of private capital required, particularly at this nascent stage of the market.

We suggest increasing the 2.5% cap, particularly in the early years of the program. As truck and charging infrastructure deployments grow, CARB might consider reducing the cap in a future rulemaking. Tesla supports increasing the cap to 5% to provide the support necessary to begin to build a charging network that will enable the market to take off. Solving the chicken-and-egg infrastructure problem by using FCI to provide assurances to MHD infrastructure developers in advance of vehicle adoption is critical to the success of ACF, ACT, and the Scoping Plan. Encouraging the early adopters (e.g., shared depots and some fleets) to build the infrastructure to accommodate full electrification is critical even if the initial vehicle deployments are lower. This will help expedite the time frame for increasing the fleet's adoption rate of electric trucks. In the near future, turnaround time for new electric truck orders will be measured in weeks and the lack of infrastructure will delay adoption. Helping fleets move early will allow them to quickly add to their fleet after gaining comfort with the technology.

353.16

i. Harmonize Hydrogen and EV Charging CIs for Capacity Credits

CARB currently gives preferential treatment to hydrogen stations, despite showing no signs of commercial success, over electric vehicle charging stations when assigning the CI for capacity credits. Hydrogen stations utilizing the HCI pathway receive a CI of the "Company-wide weighted average CI for dispensed hydrogen during the quarter or 0 g/MJ, whichever is greater" while electric vehicle charging

---

releases/terawatt-infrastructure-accelerates-rollout-of-ev-fleet-charging-solutions-across-inland-empire-301951648.html

353.16 cont. stations utilizing the FCI receive a CI of the "California average grid electricity carbon intensity" regardless of whether the EV charging company is utilizing 0 CI RECs for the rest of their charging.

CARB should treat Hydrogen and EV charging equally by either giving hydrogen HRI capacity credits a CI of the last reported industry average, or by allowing EV charging FCI capacity credits to be generated off of a 0 CI if the company is using REC matching for the rest of their charging.

353.17 **ii. Ownership Clarification**

Tesla suggests that CARB clarify that "private MHD-FCI stations" includes fleets owned by entities in the government, private and non-profit sectors.

e. Amendments to the Light Duty Fast Charge Infrastructure (FCI) Program

353.18 The light duty FCI program has played an important role in driving the expansion of electric vehicle charging infrastructure throughout California. It has been key driver of making the economics of charging station development pencil out by providing developers with some incentives before utilization picks up. This has made certain charging locations economic to build months or years ahead of when they would have been built without this support. Importantly, as utilization grows at these locations, dependence on this program wanes as they move to base credit generation. As California seeks to dramatically expand its charging infrastructure to support its EV growth trajectory, it is critically important that this program remains robust and effective. Tesla offers the below comments on amendments to this program.

353.19 **i. CARB should Maintain a 2.5% Light Duty FCI Cap, Removing the 0.5% Cap Change**

CARB is proposing reducing the total amount of available FCI credits from 2.5% of deficits to 0.5%. Tesla believes that it is too early to declare "mission accomplished" on light duty electric vehicle charging. In the technology adoption life cycle, we are now past the early adopters and into the mainstream of car buyers. These buyers tend to be more risk-adverse and more concerned with the availability of reliable charging infrastructure. It is crucial that we continue to maintain a positive charging experience for these mainstream customers so that we can continue to advance the full electrification of the transportation sector. Light Duty FCI credits continue to play an important role in solving in the "chicken and the egg" problem of the tension between EV vehicle deployment and EV charger deployment. The CEC modeling of ACC2 shows a need for 83,000 DCFC in public locations by 2035 which is a daunting increase from the 10,000 public DCFC today and is significantly more than what a 0.5% cap can incentivize. CARB should keep the 2.5% cap in place to ensure continued incentives flow to charging infrastructure developers to build new chargers ahead of demand.

353.20 **ii. Remove Geographic Restrictions and Station Size Limitations**

CARB is proposing additional geographic restrictions for LD-FCI projects, where "station must be located in California in a low-income or disadvantaged community, or at least 10 miles from the nearest direct current fast charger open to the public with a nameplate capacity equal to or greater than 150 kW."[70]

[70] APPENDIX A-1 Proposed Regulation Order Proposed Amendments to the Low Carbon Fuel Standard Regulation at 105.

353.20 cont. CARB's logic for these geographic restrictions is to "help fill refueling gaps in the State."[71] However, these amendments effectively limit LD FCI stations to rural areas because there are very few non-rural locations that are not located ten miles from an existing DCFC station. This amendment is operationally unworkable, requiring real time checking of federal maps (e.g., Alternative Fuel Data Center) on a daily, monthly, or even quarterly basis to see if the planned station remains within ten miles of some other public DCFC station.

Given the need for charging throughout California, CARB should remove all geographic limitations on this program. If our recommendation for no geographic restrictions is not acceptable, we recommend the new LCFS use United States Treasury Department and Internal Revenue Service (IRS) guidance on station eligibility for the 30C alternative fuel vehicle fueling property tax credit, which was designed to support the deployment of EV charging infrastructure in non-urban (rural) communities across the US and updated in the Inflation Reduction Act.[72] The U.S. Department of Energy has also published a clear mapping tool that shows which census tracts meet IRS definition of non-urban census tracts.[73] Compared to having a 10 mile from existing DCFC as a way to encourage DCFC in rural areas, the federal definition of non-urban census tracts is easily understood, stable, and remains in effect through 2030 until the Census Bureau updates determinations of urban and non-urban areas.[74]

CARB is also proposing to reduce the maximum site limit from 6 MW to 1 MW and adding a cap on the number of charging posts at a site to 4. Tesla believes that CARB should not add these additional restrictions. Tesla's largest location in Coalinga, California has 168 charging posts with a capacity of 16 MW. Charging companies have the best data to make informed business decisions about where to deploy new chargers and often the optimal decision is to add new chargers to an existing location which customers already find convenient, rather than adding a new site somewhere else. Adding restrictions on the size of the site and number of posts will result in suboptimal charger placement. Charging providers should continue to be incentivized to identify where charging infrastructure will be needed and build ahead of the demand with the support of the capacity credits. If charging is only built when needed, it is the customer who suffers because they are forced to wait for charging at chargers that are busy while new relief charging is being developed.

The 6 MW cap was implemented because CARB was worried that charging companies would build "white elephant" projects where they deployed dozens of chargers in whatever location was the cheapest to build, rather than in locations that were convenient for drivers. This concern has proven to be unfounded, as thousands of chargers have been built all over California in locations that are best optimized for both cost and customer convenience. This policy has directly enabled California's charging infrastructure to have a fighting chance to stay ahead of demand and ensure California EV drivers are able to live, travel and work throughout California. It is, therefore, unnecessary to add additional size and geographic restrictions today.

---

[71] Appendix E: Purpose and Rationale of Proposed Amendments for the Low Carbon Fuel Standard Requirements at 37.

[72] https://www.irs.gov/pub/irs-drop/n-24-20.pdf

[73] https://experience.arcgis.com/experience/3f67d5e82dc64d1589714d5499196d4f/page/Page/

[74] https://www.irs.gov/pub/irs-drop/n-24-20.pdf

353.21 Note: in the draft regulation CARB incorrectly listed the section for amendment as "Subsection 95486.2(b)(1)(E)1" – it should be "Subsection 95486.2(b)(2)(E)(1)".

353.22 **f. Tesla Supports Efforts to Protect Against Fraud in Biofuel Markets**

CARB is proposing additional guardrails to the use of crop-based feedstocks in the production of biofuels. Tesla supports efforts to remove palm oil as a qualifying feedstock and requirements to track crop-based and forestry-based feedstocks to their point of origin.

Tesla is involved in the European fuel credit markets, such as the German THG program and Netherlands HBE program, and has seen how the flood of allegedly fraudulent biofuels into the European Union has caused the prices of those programs to fall, harming companies who are producing actual carbon reductions. One study found that imported used cooking oil represented 80% of consumption and that "a large share of these imports could be fraudulent" sourced from "repurposed virgin palm oil."[75] With the European Union now investigating those allegedly fraudulent sources of biofuels, there are concerns that these feedstocks will flow to other biofuels markets with less stringent safeguards. California is a leader in transportation decarbonization and as such we hope CARB will work with EU regulators as well as other North American regulators with LCFS programs to harmonize biofuel feedstock verification and tracking requirements to prevent these allegedly fraudulent biofuels from flowing to whichever LCFS program has the most lax regulations.

353.23 **g. Book-and-Claim Accounting for Hydrogen Could be Catastrophic and Requires Further Analysis prior to Implementation**

CARB is proposing rules which would allow Book-and-Claim Accounting for hydrogen injected into pipeline systems. Tesla is concerned that CARB has not fully taken into account the potential detrimental effects on our climate from such a provision. Hydrogen itself is a greenhouse gas with a global warming potential 33 times that of carbon dioxide on a 20 year timeframe.[76] As opposed to simply putting renewable electrons directly into a battery electric vehicle for motive power, hydrogen production from electrolysis uses that renewable electricity to split water and produces hydrogen, a greenhouse gas, some of which inevitably leaks into the atmosphere, furthering climate change. Because hydrogen is the smallest molecule, it is more susceptible to leakage than any other greenhouse gas. Leakage of hydrogen into the atmosphere during production, storage, distribution, and dispensing counteracts some of the potential carbon reductions. We hope that CARB staff will further study this issue and release a full analysis of the impacts of such a decision before it is implemented.

IV. Technical Amendment Improvements to Modernize the Policy if Time Allows:

353.24 **a. Reduce Geofencing Radius for Incremental Credit for Residential Charging**

CARB Guidance Document 19-03 sets a geofencing radius of 220 meters (M) around all registered non-residential EV charging FSEs, using a 4 decimal point prevision. Within that 220 meter radius, automakers are not allowed to apply incremental crediting to home charging. This is an issue in dense

[75] https://www.transportenvironment.org/discover/biofuels-from-unsustainable-crops-to-dubious-waste/
[76] https://www.gov.uk/government/publications/atmospheric-implications-of-increased-hydrogen-use

353.24 cont. locations like cities where home charging takes place near registered non-residential EV chargers. With thousands of non-residential EV chargers deployed across the state, these geofencing radii have begun morphing into a patchwork that has nearly blotted out entire cities.

Tesla recommends CARB update the geofence radius from 220M to 20M at most. Improvements in GPS systems since adoption of the 220M radius provide assurance that double counting will not take place. A 2021, MIT Technology review revealed that "Once the signals are processed by a receiver, GPS is generally accurate to within five to 10 meters. Now the system is in the middle of a years-long upgrade to GPS III, which should improve its accuracy to one to three meters (see chart)."[77] The review goes on to recognize that additional accuracy, down to the centimeter, may be possible with the assistance of ground-based augmentation. Without fully knowing where ground-based augmentation may be in use to create higher accuracy, Tesla urges CARB to adopt a conservative radius of 20 meters at this time.

353.25 **b. Smart Charging Provision Modifications**

The current LCFS regulations include a pathway for generating incremental credits by using smart charging. This pathway is designed to incentivize shifting electricity use for EV charging to the times when marginal greenhouse gas emission rates of grid electricity are lower than the average emission rate. Tesla believes that this pathway is important for the continued acceleration of grid decarbonization. California has hit some key grid decarbonization milestones in the past few years, with the entire grid operating on 100% renewable electricity for brief periods throughout the day. As we ramp up renewables further, we will need companies to utilize the smart charging pathway to help flatten the Duck Curve.[78]

We encourage CARB to explore regulatory changes that would encourage more companies to utilize the Smart Charging pathway. One change could be to allow companies offering whole home renewable power systems with solar, storage, and EV charging to combine the systems to act as a virtual power plant, using the rooftop solar to charge the home storage battery during the day and discharging the home storage into the EV at night to lower grid pull during high emissions periods. We look forward to a future when more homes have such integrated systems and can be combined to provide grid services and time-shifting carbon reduction. Another change could be to allow for the use of hourly RECs, matched to offset specific carbon reductions against the hourly grid carbon intensity, rather than being matched against the yearly average carbon intensity. This would encourage the development of hourly RECs and would create a market that would put a price on hourly grid carbon intensity and incentivize investment in grid assets that reduce emissions during the highest intensity hours.

353.26 **c. Repayment of Accumulated Deficits with a 10% Interest Rate**

The current LCFS regulation[79] requires obligated parties to repay accumulated deficits with an interest rate of 5% applied. Given the higher interest rates we are seeing now, this low rate may incentivize

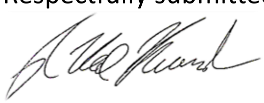
[77] See MIT Technology Review located here, https://www.technologyreview.com/2021/02/24/1017805/hyper-accurate-global-positioning-available-worldwide/#:~:text=Once%20the%20signals%20are%20processed,three%20meters%20(see%20chart).
[78] https://www.energy.ca.gov/sites/default/files/2022-10/CEC-500-2022-013.pdf
[79] §95485(c)(5)(A)

353.26 cont. some obligated parties to hold off on purchasing credits as the interest rate applied to these deficits would be below their cost of capital. Tesla recommends increasing this interest rate to 10%.

Conclusion

353.27 In conclusion, Tesla supports CARB adopting a stringent standard, at least 30% by 2030 with at least a
353.28 12% step change and an effective AAM in 2026 that limits implementation delays. Further, Tesla believes that the CFR Program should continue to support LD EV deployment and would remain solvent and create efficiency if base credits were allocated to EV automakers to support the program. While
353.29 Tesla supports alterations to LD through MHD FCI crediting, overall, FCI regulations for electrification
353.30 should generally mirror those provided to hydrogen producers. Lastly, we urge CARB to modernize the regulations through updates to EERs and others. Section IV changes are necessary to support scientific integrity however could be postponed should CARB have insufficient resources to make these changes while getting the regulations adopted and enforceable in 2024.

Respectfully submitted,



Thad Kurowski
Public Policy & Business Development

Re: Comments on the December 19th Initial Statement of Reasons

Submitted electronically

Chairwoman Liane M. Randolph
California Air Resources Board
1001 I Street
Sacramento, CA 95814

The Clean Fuels Alliance America (Clean Fuels)[1] and California Advanced Biofuels Alliance (CABA)[2] appreciate the opportunity to provide comments on the December 19th proposed changes to the Low Carbon Fuel Standard (LCFS) as presented in the Initial Statement of Reasons. Clean Fuels and CABA have been longtime supporters of the state's overall climate and air quality improvement goals and have collaborated frequently with CARB staff toward achieving those goals. We continue to support California's efforts to decarbonize its economy, especially the transportation sector, with a comprehensive all-of-the-above suite of measures.

Our California member producers and marketers support over 3,900 well-paying jobs in the state and about $960 million in economic activity each year. Further, the biodiesel, renewable diesel, and sustainable aviation fuel supplied to the state by our California and national members are collectively the single largest source of GHG reductions in the LCFS, providing nearly half[3] (about 45%) of the carbon reductions since 2017, more than any other fuel including electricity, and 42% since the start of the LCFS. Our fuels have grown to the point where nearly 60% of each gallon on average of diesel fuel consumed in the state in 2023 consisted of our industry's low-carbon fossil diesel replacement fuels.[4] Our sustainable replacements for petroleum diesel have been a major factor in driving California's continuing transformation towards being carbon neutral. In short, the LCFS would not be the success it is today, and one the state is looking to export to other jurisdictions, without the key role our diesel replacements have played. More to the point, our liquid

[1] Clean Fuels (formerly the National Biodiesel Board) is the U.S. trade association representing the entire supply chain for biodiesel, renewable diesel, and sustainable aviation fuel. The name change reflects our embrace of all the products Clean Fuels members and the U.S. industry are producing, which include biodiesel, renewable diesel, sustainable aviation fuel, and Bioheat® fuel for thermal space heating. Our membership includes over 100 farmers, producers, marketers, distributors, and technology providers, and many are members of environmental organizations supportive of state and local initiatives to achieve a sustainable energy future.
[2] California Advanced Biofuels Alliance is a not-for-profit trade association promoting the increased use and production of advanced biofuels in California. CABA represents biomass-based diesel (BMBD) feedstock suppliers, producers, distributors, retailers, and fleets on state and federal legislative and regulatory issues.
[3] Biodiesel and renewable diesel provided almost 60% of the LCFS credits in Q3 2023. See LCFS Quarterly Data Spreadsheet (dated January 31, 2024).

cleanfuels.org

petroleum replacement fuels remain the only viable, large-scale, cost-effective alternatives for the next several decades to decarbonizing the most difficult-to-electrify sectors: heavy duty on- and off-road, marine, rail, and aviation.

Previous Comments

Clean Fuels and CABA have been keenly aware of how significant this rulemaking is to its members and the clean fuels industry as a whole. We have actively participated throughout the workshops in the pre-rulemaking process to provide information and perspective on how staff's proposal may impact the industry. In addition to this comment letter, please refer to our previous comments submitted for the May 31/June 2 virtual meeting, the May 23 workshop on Auto-Acceleration Mechanisms, and the February 22 workshop to discuss potential changes to the LCFS to address previous discussions that did not make it into the ISOR but are potentially still on the table as future modifications are considered.

Strengthen the CI Reduction Targets

354.1 Clean Fuels and CABA are generally supportive of CARB's proposal to strengthen the CI reduction
354.2 targets in 2030 and 2035 but we reserve comment on the feasibility of a 2045 target due to the lack of data to support a target that far out into the future. We are also generally supportive of the addition of the step-down and auto acceleration mechanisms to provide ways to firm up credit prices as quickly as possible. We further believe that additional adjustments can and should be made to maximize the GHG reductions and benefits provided by the LCFS and the credit prices that are necessary for the clean fuels market to thrive.

Request: As further discussed in the report submitted by ICF[5], Clean Fuels and CABA respectfully request that the Board direct CARB staff to establish:

354.3
- A Carbon Intensity (CI) reduction target between 41 – 44% for 2030.

354.4
- An initial step down of 10.5% to 11.5% in 2025 to achieve a target credit bank equivalent of two to three quarters worth of deficits.

354.5
- An Automatic Acceleration Mechanism (AAM) implementation that can be triggered in 2026, with a modification to enact the AAM when the credit bank is more than 2.5 times greater than the quarterly deficits generated in a given year.

354.6 In addition, we urge CARB to maintain the technology neutrality that has enabled the success of the LCFS program. Clean Fuels and CABA believe that this combination of revisions can further boost the effectiveness of the LCFS program.

Introduction of Sustainability "Guardrail" Provisions

Clean Fuels and CABA were surprised by the introduction of sustainability provisions in the ISOR,
354.7 especially since that was the first time anyone had seen them. At no time during the informal rulemaking process did anyone have a chance to vet, workshop, or provide feedback on these provisions, which is a far cry from how CARB typically engages with its stakeholders. It is especially concerning since the implementation of these provisions will have a significant negative impact to
354.8 our members as they are potentially burdensome, duplicative, and infeasible as proposed.

---

[5] Analyzing Future Low Carbon Fuel Targets in California: Response to Staff Report, ICF Resources, February 2024.

Our members are eager to work with CARB staff to work through the many details surrounding this topic, including but not limited to – having a proper length of time to gather and submit information, considering similar certification programs that can be modified to streamline the verification process, and planning for any potential next steps once these provisions are complied with. There must be a collaborative and transparent process to produce sustainability provisions that will meet the interests of both CARB and the clean fuels industry.

Request:

354.9
- The Board should direct CARB staff to assemble a small workgroup of affected parties to develop the implementation guidance for these provisions.

354.10
- The Board should direct CARB staff to exempt any feedstocks that are grown on land that was already in production prior to 2007 from being subject to these sustainability provisions. Since they were already in agricultural production prior to 2007, those lands involve no deforestation whatsoever, the primary concern raised by CARB staff during the workshop process and ostensibly the reason the sustainability provisions were proposed. These domestic feedstocks already meet the qualification criteria to generate RINs in the federal Renewable Fuel Standards, which were established to address similar sustainability concerns. It makes complete sense that the LCFS align with these existing federal requirements that the clean fuels industry already understands and complies with.

354.11
- As an alternative to the previous bullet, the Board should direct CARB staff to draft implementation guidance for any feedstocks that are proven to be low deforestation risk and could be exempted, that considers:
  - the different environmental impacts of different feedstocks;
  - alignment with the certifications that are already required for producers selling into the Canadian or European markets to avoid expensive and unnecessary duplication of effort; and
  - using a mass balance approach or equivalent for feedstocks that are co-mingled prior to biofuel processing.

Exemption for Jet Fuel

354.12
Clean Fuels and CABA believe that prior to the availability of sustainable aviation fuel (SAF), exempting jet fuel from the LCFS program seemed logical. However, the landscape has dramatically shifted with new facilities coming online in the very near future. In light of this evolving reality, it is perplexing that the proposed amendments continue to exempt intrastate jet fuel until January 1, 2028. Such a delay would be severely counterproductive since urgent market signals are crucial for capitalizing on the momentum the industry is currently experiencing.

Request: The Board should direct CARB staff to advance the repeal of the exemption to January 1, 2025. This would offer essential support urgently needed to transition the aviation sector toward cleaner, more sustainable practices. Furthermore, we advocate for removing the exemption of all jet fuel, not solely intrastate, as continuing reliance on petroleum jet fuel amidst cleaner alternatives is entirely unnecessary, especially for years 2025, 2026, and 2027 when the industry has already announced projects that could fulfill the entire SAF obligation for all three years.

Update GTAP-BIO

Clean Fuels and CABA would like to re-emphasize that the ILUC model, GTAP-BIO, is not being updated during this rulemaking while all other key models used to calculate lifecycle emissions are being updated or are new (GREET 4.0, HyCap, OPGEE). Previous comments submitted by Clean Fuels and CABA throughout the workshop process highlight the many reasons why this gross inequity must be resolved during this rulemaking.

354.13 Despite many years of stakeholder requests, CARB has not revisited GTAP-BIO, electing to continue using the 2014 version of GTAP-BIO, which in turn uses nearly two decade old datasets, compared to the 2022 version that reflects the most updated and granular data available based on real-world observations developed over many years. The failure to use the latest science quite frankly puzzles our members and continues to be a significant point of frustration regarding the assignment of CIs for biofuel producers. An update to the ILUC modeling would be a welcome effort that can complement and inform the discussions about environmental impacts from biofuels and the design of the sustainability provisions as described above. Using the latest version, the ILUC impact from soy would be decreased from the current 29.1 g CO2e/MJ to less than 10, a 67% reduction from the current value and an 84% reduction from CARB's original value set in 2011. It is counter-intuitive and nonsensical that CARB propose guardrail sustainability provisions in this rulemaking without first making sure the regulation reflects the most current science available.

354.14 Request: The recent announcement to postpone the Board hearing from March to a future meeting provides a great opportunity for CARB to update the GTAP datasets in line with the above. The Board should direct CARB staff to update GTAP immediately to be incorporated into the current rulemaking..

Penalty for Underestimating a CI

354.15 Clean Fuels and CABA believe that the proposed changes to how CARB will treat a CI score that is verified to be higher than their approved value is overly punitive. CI scores are dependent on a multitude of feedstock assumptions and operating conditions and pathway holders make their best faith effort when they compile the pertinent model inputs for their pathway applications. They include the best data available to them, in addition to a reasonable margin of safety to cover fluctuations throughout the fuel's lifecycle.

354.15 Credits that were illegitimately generated due to having a higher CI at the time of verification compared to their approved value should absolutely be replaced, but at a one to one ratio, not at a four to one ratio. CARB provides no justification in the ISOR to warrant the additional penalty, and no justification has been provided by CARB that documents underestimation of CI scores is a rampant issue. If a pathway holder's underestimation is due to demonstrable misconduct, then CARB can use its existing enforcement and penalty authority to address that situation. But unintentional shortfalls made in good faith that are relatively minor should not be subject to this penalty.

Request: The Board should direct CARB staff to remove the quadrupling of the number of credits that need to be retired against the illegitimate credit generation due to an underestimation of a CI.

Incorrect Tallow value in CA-GREET

Clean Fuels and CABA are concerned that the proposed CA-GREET 4.0 model contains an incorrect value for emissions related to the energy inputs for beef tallow rendering process. This

354.16 error first appeared in GREET 2016 and was identified by the Argonne National Laboratory[6] and corrected in GREET 2017. The difference is about 8 gCO2e/MJ, about double what it should be. However, this correction was not made to CA-GREET 3.0 nor to CA-GREET 4.0.

GREET 2022 updated the energy use for rendering with data from another 46 rendering facilities. The values were broadly in line with the data from the original 25 plants that were used to generate the data in the GREET models from 2014 to 2021.

354.16 Request: The Board should direct CARB staff to update CA-GREET 4.0 with the correct energy inputs for the beef tallow rendering process as contained in GREET 2022.

Conclusion

Clean Fuels and CABA thank CARB staff for their continued efforts to strengthen the LCFS and provide the vision for the program to meet California's carbon neutrality goals. For this rulemaking, we support the proposed increases in the CI targets but feel that even more can be done to strengthen the program and the market by making additional adjustments to the step-down and automatic acceleration mechanisms. We are deeply concerned by the lack of transparency regarding the process to add sustainability provisions to the LCFS but stand ready to work with CARB to address those concerns in a collaborative way in the future. We support the repeal of the exemption of jet fuel as soon as possible. We strongly believe that the latest science should be used to estimate ILUC and to calculate the CI for tallow pathways and that updating GTAP and GREET will help. Finally, we would like to endorse and incorporate by reference the comments filed by members and affiliates of Clean Fuels and CABA, including but not limited to ADM, Darling Ingredients, and the National Oilseed Processors Association. Thank you for your consideration of these comments. We look forward to continuing our strong collaboration with CARB and staff.

Sincerely,

RE: Amendments to the LCFS Program

Chair Randolph:

355.1 On behalf of the California Transit Association, I write to you today to voice our support for the Low Carbon Fuel Standard (LCFS) amendments package released by the California Air Resources Board (CARB) on December 19, 2023 and to elevate the specific, but currently unaddressed, priorities of our transit and rail agency members. The Association represents over 230 member organizations from across California's transit industry, which includes 85 transit and rail agencies in the state.

Through our work to advance the implementation of the Innovative Clean Transit and In-Use Locomotive regulations and our steadfast support for federal and state investments in zero-emission transit vehicles across modes, the Association and our members have been consistent partners with CARB in promoting and accelerating the deployment of zero-emission vehicle (ZEV) technologies in public transportation
355.2 applications. In an era of significant financial constraints at state and local levels, we view the LCFS program as a vital incentive for encouraging transit and rail agencies to take early and expansive actions to further clean their fleets and as a critical funding source for offsetting the persistently high costs of zero-emission operations. We thank CARB for its efforts to continuously improve this program to the benefit of program participants and formally request a series of changes to the amendments package as
355.3 it moves forward. Additionally, we request that CARB continue to review options to further support transit and rail agencies that participate in the LCFS program. The specific changes we request would address current disparities in credit generation between pre-2011 fixed guideway systems and post-2010 fixed guideway systems, administrative challenges related to registration and reporting of electricity usage from the fuel service equipment (FSE), and the scope of reporting of electricity usage.

<u>Disparities in Credit Generation</u>

355.4 The LCFS program currently affords pre-2011 fixed guideway systems fewer credits

355.4 cont. for their electricity usage than post-2010 fixed guideway systems due to disparities in CARB's Energy Economy Ratio. We understand that this current disparity reflects modeling performed by CARB at the beginning of the LCFS program, which established a baseline that treated all rail in place at that time as existing, and rail constructed after as new. CARB posited then that new rail would reduce significantly more VMT than existing rail. We believe this distinction and justification is arbitrary and does not reflect the reality that rail – no matter when it was constructed – significantly reduces VMT and that the level of VMT reduction at any one point in time or segment of service may vary depending on a series of exogenous factors.

With rail agencies facing operations funding shortfalls and higher expenses, the Association implores CARB to increase the level of credit generation for pre-2011 fixed guideway systems to bring it into alignment with post-2010 fixed guideway systems. The additional credits generated from this change will be vital as rail agencies work to continue to provide service with diminished local funding sources.

Administrative Challenges in Reporting

355.5 The LCFS program currently requires non-residential EV charging industries and agencies generating credits from grid electricity to report the quantity of electricity (in kWh) from the FSE, or electric charger.

As an Association, we are concerned with the administrative constraints associated with registering and reporting from each individual FSE. Several transit agencies have designed for an overhead charging system that will implement power cabinets (power source), and depot pantographs (dispenser to conductively charge on top of buses). The overhead charging design is a 3-to-1 ratio (3 pantographs to 1 power cabinet or 3 buses connected to 1 charger). With this, we have concerns about how data will be reported from this type of design, and the need to register and report from each individual charger (power cabinet) and/or pantograph (dispenser). To manage this type of overhead charging system, several transit agencies are also planning to implement a charge management system (CMS) software to efficiently manage charging cycles optimally for getting buses ready for service each day and at its most cost effective. These CMS platforms are still in their infancy stages, with most vendors being third- party to charger manufacturers. It is currently unknown how a third-party vendor's CMS platform will manage multiple charger manufacturers (interoperability) data components and if proprietary parameters will impact data communication when exporting this data. At this time, to maximize credits using time-of-use energy consumption, our members would need to report from the meter/utility bill.

Loss of Credit (Energy Loss/Line Loss)

355.6 Since January 2022, several transit agencies have experienced an overall loss of energy or line loss from what's reported at the meters to what's been reported at the FSEs. At full deployment, this loss can equate to hundreds of thousands of dollars in credit loss per quarter and millions of dollars in credit loss annually. Reporting with an energy loss or line loss (consumption in kWh) also doesn't accurately reflect the well-to-wheel GHG analysis

355.6 cont. for running a battery electric bus in-service.

In closing, we greatly value our partnership with CARB in advancing the deployment of zero-emission vehicle technologies. We thank you for your consideration of our requested changes to the LCFS program.

If you have any questions, please feel free to contact me at (916) 446-4656 or michael@caltransit.org.

Sincerely,

Michael Pimentel
Executive Director

RE: Preliminary Staff Report Proposed Low Carbon Fuel Standard ("LCFS") Amendments

We are pleased to provide comments on proposed changes to biogas-based electricity crediting in response to the Preliminary Staff Report Proposed Low Carbon Fuel Standard ("LCFS") Amendments.

We commend ARB for recognizing the important role that dairy manure biogas-to-electricity fuel pathways play in decarbonizing California's transportation sector. We believe that there are several changes that ARB could make to reduce barriers for small biogas to electricity generators to participate in the program; and to adjust restrictions related to book-and-claim of renewable natural gas into an offsite generator and create a temporary pathway for all dairy biogas-to-electricity projects.

Adjust Requirements for Small Biogas-to-Electricity Facilities

As they are currently designed, annual verification requirements for dairy biogas to electricity fuel pathways are cost prohibitive to small electricity generators and effectively shut out a large portion of the state's small and medium dairy operations from participating in a program that could provide meaningful support to decarbonization efforts.

356.1 For facilities with a total nameplate capacity of less than 150 kW, we encourage ARB to consider the following changes to the LCFS program:

- **Simplified Lookup Table Pathway for dairy biogas-based electricity**
  For small facilities looking for a simple way to participate in the LCFS, CARB could offer a Lookup Table Pathway option, with a CI score set at the lower of the score of the highest currently approved dairy manure to electricity fuel pathway in the program or 0. After ensuring that facilities meet a minimum eligibility criteria, projects would then be able to be approved for immediate participation into the program.

356.2
- **Remove the Third-Party Verification Requirements**
  The requirement to have a third-party verifier review the AFP report is an excessive burden for small facilities and can often exceed the credit revenue available from the program, a problem exacerbated by the recent low level of LCFS prices. While low LCFS prices strain the economics for dairy biogas-to-electricity generators of all sizes, that dynamic combined with the cost burden of annual verification particularly disadvantages smaller farms.

356.3
- **Simplify the Annual Fuel Pathway Report**
  The data requirements of the Annual Fuel Pathway Report can be onerous for a small

operation. Specifically, the data requirements for raw biogas flow, methane content, and sub metered electricity usage are difficult to obtain and can be costly relative to the size and production of smaller facilities. WREGIS already certifies RECs based on exported electricity consumption. In combination with the recommendations above, more reasonable data requirements for small dairies for AFP reporting would go a long way to making the LCFS more viable for smaller dairy biogas-to-electricity facilities.

356.4 **Allow for Book & Claim of RNG to Off-Site Electric Generators**

ARB currently recognizes that "Low-CI electricity used as a transportation fuel can be indirectly supplied" through book-and-claim accounting, typically by pairing a renewable energy credit ("REC") with electric vehicle charging. ARB separately currently recognizes book-and-claim accounting for renewable natural gas ("RNG") injected into a commercial distribution pipeline and paired with compressed natural gas ("CNG") fueling in California.

Yet to generate RECs from low-CI electricity derived from dairy biogas, ARB requires that the generator of the electricity in California that consumes the biogas is co-located with the digester from which it is produced.

We re-iterate our proposal submitted in prior comments in June 2023, in response to ARB's May 2023 LCFS Workshop, encouraging ARB to enable book-and-claim accounting of RNG to be eligible for electricity generation. This approach not only aligns with CARB's existing book-and-claim accounting framework but is also consistent with ARB's objectives of supporting the transition to zero emission transportation.

356.5 **Establish a Temporary CI Pathway for Dairy Biogas-to-Electricity and a Credit True-Up Mechanism**

In contrast to other low carbon transportation fuels in the LCFS program, no Temporary CI Pathway exists for dairy biogas-to-electricity projects. Despite the fact that dairy biogas-to-electricity pathways fully reduce methane in the same manner as dairy biogas-to-RNG pathways, ARB treats them differently in this respect.

The lack of a Temporary CI Pathway prevents beneficial projects from receiving revenue until the Provisional CI is achieved, a process that can last from many months to a year or more. The extensive timeline for projects to receive even a Provisional CI means ARB in parallel should revise the true-up language to apply to Temporary CI scores.

We thank you again for the opportunity to provide these comments, and we look forward to continued engagement with ARB staff.

Sincerely,
Bridge To Renewables, Inc.

RE: Proposed amendments to the Low Carbon Fuel Standard Regulation under Division 3, Chapter 1, Subchapter 10, Article 4, Subarticle 7 (Low Carbon Fuel Standard) under Title 17, California Code of Regulations

California Air Resources Board Members and staff:

I am writing on behalf of Nuseed Americas, Inc.

Nuseed is a global agriculture innovator enabling the transformation of select crops into renewable and traceable sources of lower-carbon energy, and plant-based nutrition. Nuseed's proprietary solutions contribute to solving global challenges like food security, human nutrition, and climate change. By unlocking the intrinsic value and commercial potential of omega-3 canola, carinata, sorghum, sunflower, and energy cane to deliver VALUE BEYOND YIELD®, Nuseed empowers growers and end-use customers to rapidly scale today to meet current and emerging demand for generations to come.

Established in 2006, Nuseed has 10 locations in Australia, Europe, North America, and South America, including three proprietary innovation centers, more than 400 employees, and sales in more than 30 countries. Nuseed is the seed technologies platform of Nufarm Limited.

We appreciate and recognize the significant amount of time, energy and effort by all (staff and stakeholders) to develop the proposed changes to the LCFS program in accordance with the adopted scoping plan. This has been a significant undertaking and while some may wish to single out certain items or proposals as lacking and needing changes or adjustments, it is important to acknowledge how the overall proposal significantly improves air quality, reduces carbon loading and positively impacts climate change.

357.1 To that end, Nuseed applauds the increase in stringency of carbon intensity reductions from 20% below 2010 baselines to 30% by 2030 and a 90% reduction by 2045. Comparing this step to previous actions, from 2015, when the Board readopted the program, to 2018 when the 10% target was increased to 20% (and extended from 2020 to 2030), critics raised concerns about the availability of alternative fuels and its impact on the state's economy and derided the goals as unachievable.

Yet as CARB's own data shows, time and again biofuel manufacturers and suppliers were able to overachieve and deliver biofuel volumes at a rate faster than the agency required or predicted possible and at competitive pricing with existing fossil fuels. The renewable fuel industry has proven it can meet the targets CARB sets.

As a developer of carinata that is grown on fallow land between crop rotations and does not compete with existing food or feed crops, we are ready and eager to help the industry achieve the next set of targets, particularly as the state moves to phase in intrastate aviation fuel for compliance. Sustainable Aviation Fuel (SAF) is available today as a drop in fuel and has already been used in California as airlines were able to opt into the program. As the need for SAF grows, we can deliver new innovative feedstocks that add to the supply of existing sources of feedstocks already approved for use.

357.2 In addition to the increase in stringency, we also support the development of the Automatic Acceleration Mechanism (AAM). This addition to the program allows the state to more nimbly respond to the biofuel (and ZEV) industry's ability to "overcomply." As noted in the ISOR, the AAM would help bolster market stability in the event that transportation fuel decarbonization grows rapidly. This kind of market adjustment sends a strong signal to companies like ours that are putting significant resources into developing new feedstocks with low and ultra-low carbon intensities.

357.3 It is in that vein, that we note with interest the sustainability provisions added to §95488.8(g). Nuseed has been working with international sustainability standard setting bodies like RSB for sometime. While the section lays out in detail how the entities should be structured and the path for their approval by the Executive Officer, a number of details remain to be developed. We would welcome the opportunity to share our experiences in working with international sustainability groups on data collection and reporting. 357.4 We also believe there is a robust discussion to be had on the positive impacts crops like ours can have on soil retention and improvement and the potential in on-farm carbon sequestration. As CARB looks at innovative ways to sequester carbon, like direct air capture, the agency should also embrace data driven climate smart agriculture's ability to store carbon at the farm level.

Thank you again for your leadership and for the opportunity to provide comments.

Sincerely,

Scott R. Hedderich
North America Policy & Government Affairs Director

Subject	LCFS Comment of H Cycle

Comment	Attached please find the Low Carbon Fuel Standard comment of H Cycle. A short summary is included below. Thank you for the opportunity to provide this comment. Best Regards, Graham Noyes Noyes Law Corporation H Cycle, LLC ("H Cycle") is pleased to submit comments pertaining to the California Air Resources Board's ("CARB") proposed amendments to the Low Carbon Fuel Standard ("LCFS Proposal" or "Proposal"). We support CARB's LCFS program as it sends a powerfu market signal to decarbonize the transportation sector, is performance based, and provides long-term policy stability that supports investment. However, we respectfully encourage CARB to take advantage of this LCFS rulemaking to make regulatory changes that incentivize deployment of low carbon intensity ("Low-CI") waste-to-hydrogen production facilities that can simultaneously catalyze more organics diversion, reduce emissions of the short-lived climate pollutant ("SLCP") methane, create a distributed hydrogen production network and drive federal dollars to California to accelerate hydrogen production expansion.

(Comment submitted electronically)

RE: H Cycle's Recommendations to Leverage the Low Carbon Fuel Standard Program to Accelerate Achievement of SB 1383 Diversion, Reduce Methane Emissions, Rapidly Scale Distributed Hydrogen and Attract Federal Funding to California

Dear Chair Randolph,

H Cycle, LLC ("H Cycle") is pleased to submit comments pertaining to the California Air Resources Board's ("CARB") proposed amendments to the Low Carbon Fuel Standard ("LCFS Proposal" or "Proposal"). We support CARB's LCFS program as it sends a powerful market signal to decarbonize the transportation sector, is performance based, and provides long-
358.1 term policy stability that supports investment. However, we respectfully encourage CARB to take advantage of this LCFS rulemaking to make regulatory changes that incentivize deployment of low carbon intensity ("Low-CI") waste-to-hydrogen production facilities that can simultaneously catalyze more organics diversion, reduce emissions of the short-lived climate pollutant ("SLCP") methane, create a distributed hydrogen production network and drive federal dollars to California to accelerate hydrogen production expansion.

<u>LCFS Recommendations</u>

H Cycle has identified three modifications to the LCFS Proposal that will increase organics diversion, decrease methane emissions, accelerate development of distributed hydrogen production, and attract federal funding:

358.2

1. CARB should respond to the Little Hoover Commission's findings regarding the State's current failure to meet SB 1383 organic diversion targets by modifying LCFS regulations to support SB 1383 implementation by recognizing real-world methane emission reductions achieved by diverting additional organic waste from landfills to produce hydrogen. This recommended action also supports the goals outlined in the Advanced Clean Fleets Rule that will require availability of renewable hydrogen derived from waste feedstocks to supply the eventual zero emission fleets.

358.3

2. Given the massive scale of hydrogen ambition established by the 2022 Scoping Plan and the minimal hydrogen demand that exists from fuel cell electric vehicles ("FCEVs"), CARB should extend the eligibility of electricity book-and-claim to Low-CI hydrogen that is used in the production of an alternative fuel. Related to

358.3 cont. this, due to the importance of attracting federal funding to California including Inflation Reduction Act ("IRA") funds for Low-CI hydrogen, CARB should more closely align LCFS electricity book-and-claim accounting requirements with IRA Section 45V's utilization of environmental attribute certificates ("EACs"). This alignment would provide hydrogen producers with the flexibility to source Low-CI power utilizing Power Purchase Agreements ("PPAs") and/or unbundled Renewable Energy Certificates ("RECs").

358.4 3. CARB should clarify its intent under proposed LCFS §95488.8(i)(1)(C)(2) as this proposed provision states, "The pathway holder or the project operator must be the first contracted entity for procuring the low-CI electricity." Prior to adoption of the LCFS Proposal, CARB should revise the language to clearly indicate what is meant by the phrase "first contracted entity" and ensure that this provision does not establish an impossible condition in California or other markets.

The Critical Nature of Low-CI Hydrogen

The 2022 Scoping Plan recognized the critical role that new technologies and low carbon intensity ("Low-CI") hydrogen must play in California's drive to carbon neutrality and emphasized the need to identify and remove market and implementation barriers that impede California's transition away from fossil fuels:

> *We must avoid making choices that will lead to stranded assets and incorporate new technologies that emerge over time. Importantly, given the pace at which we must transition away from fossil fuels, we absolutely must identify and address market and implementation barriers to be successful. The scale of transition includes adding four times the solar and wind capacity by 2045 and about 1,700 times the amount of current hydrogen supply.*[1]

In addition to charting a course away from fossil fuels and toward massive hydrogen expansion, the 2022 Scoping Plan also identified the challenge of relying solely on electrolytic hydrogen to achieve California's goals. The Draft Scoping Plan included an estimate that 40 GW of solar capacity would be required to support only electrolysis to produce all hydrogen in the Proposed Scenario. The Final Scoping Plan substantially reduced the anticipated on-grid solar capacity down to 10 GW. This reduction was necessary due to a high degree of uncertainty as to whether this level of on-grid solar capacity expansion was feasible. The solution reached in the Final Scoping Plan was to integrate steam methane reformation of biomethane and biomass gasification with carbon capture and sequestration to produce hydrogen, along with off-grid solar.[2] As discussed in the following section of this comment, H Cycle's new technology is uniquely situated to produce additional and particularly beneficial hydrogen for California from landfill diversion on a distributed scale while at the same time reducing methane emissions.

[2] Id. at p. 88-89, and footnote 151.

H Cycle is the Leading Company in Organic/Biogenic Waste-to-Hydrogen

H Cycle is a California company based in Concord that was founded in 2021. H Cycle is a developer of low-cost, low-carbon hydrogen production facilities that deploy an advanced waste-to-hydrogen thermal conversion technology. H Cycle is currently developing multiple projects in California. H Cycle facilities will be capable of utilizing a diverse composition of waste feedstocks including post-separated organic fractions of municipal solid waste, agricultural residues, and woody biomass from wildfire risk reduction projects to produce Low-CI hydrogen. The successful development of these projects will reduce methane emissions from landfill disposal and other waste streams and facilitate achievement of California's waste diversion targets under Senate Bill 1383 ("SB 1383"). The H Cycle process delivers Low-CI hydrogen that can be used as a fuel for decarbonizing hard-to-abate sectors such as low-carbon fuel production, heavy-duty trucking, and sustainable aviation. H Cycle is excited to work with CARB and local communities to deploy our solution and support the State in meeting its climate, sustainability and air quality goals.

H Cycle is the first company to have received a favorable Article 2 determination from CalRecycle. The Short-Lived Climate Pollutants Waste Reduction Regulations ("SB 1383 Regulations") identify specific technologies that constitute recovery of organic waste and other technologies that are categorized as landfill disposal.[3] If a technology or activity is not specifically identified in either subsection (a) or (b) of 14 CCR Section 18983.1, an interested party may request CalRecycle to perform an evaluation of its technology to determine if it constitutes a reduction in landfill disposal, in accordance with the Article 2 requirements.[4] For a technology or recovery process to constitute a reduction in landfill disposal, it must reduce the physical presence of organic waste in landfills and reduce greenhouse gas ("GHG") emissions. Pursuant to the CalRecycle and CARB evaluation process, H Cycle's technology was determined to exceed the benchmark ERF for composting and also met other SB 1383 Requirements and was therefore determined to be "a reduction in landfill disposal" by CalRecycle on January 11, 2024.[5] See Attached Exhibit A for the H Cycle Article 2 determination.

H CYCLE'S ANALYSIS AND RECOMMENDATIONS

358.2 cont. ***Recommendation 1:***

CARB should utilize the findings and recommendations of the Little Hoover Commission regarding the current statewide shortfall and inability to meet organic diversion targets under SB 1383 to inform its LCFS regulatory amendments and to take remedial action to reduce methane emissions from organics that continue to be landfilled in the State.

Discussion:

The Little Hoover Commission is an independent state oversight agency. By statute, the Commission is a bipartisan board composed of five public members appointed by the governor,

[3] Recovery at 14 CCR Section 18983.1(b); landfill disposal at 14 CCR Section 18983.1(a).
[4] 14 CCR Section 18983.2.
[5] See CalRecycle, "Public Notice: Consideration of a Technology Determination for H Cycle Pursuant to Article 2 of the SB 1383 Regulations," at https://www2.calrecycle.ca.gov/PublicNotices/Details/5287, "Request for Action," download available at https://www2.calrecycle.ca.gov/PublicNotices/Documents/15520.

358.2 cont. four public members appointed by the Legislature, two senators and two assemblymembers. When the Commission was established in 1962, the Legislature declared its purpose to be:

> "… promoting economy, efficiency and improved services in the transaction of the public business (…) and in making the operation of all state departments, agencies and instrumentalities, and all expenditures of public funds, more directly responsive to the wishes of the people as expressed by their elected representatives…"[6]

In its letter presenting the report entitled "Reducing California's Landfill Methane Emissions: SB 1383 Implementation," to Governor Newsom and to members of the California Senate and Assembly, Chair Pedro Nava emphasized the following:

> *Combatting climate change is perhaps the defining issue of our era, and California has long been a leader in that fight. In 2016, the state enacted a landmark reform in this area by passing SB 1383, which required the state to reduce the amount of organic material deposited into landfills. The stakes could not be higher. As it decomposes, organic material produces methane, which is extraordinarily efficient at trapping heat and contributing to climate change. In the effort to constrain climate change, no short-term step is as important as reducing methane emissions. The livability of our planet depends on it.*
>
> *Yet California is falling short of its goals. The state missed its 2020 target, and is poised to miss its 2025 goal. Local governments – the front-line warriors in this fight – are struggling to implement the state's program.*
> *(…)*
> *The recommendations in this report present a critical opportunity to advance California's fight against climate change. We hope and believe you will consider this report in that light – as a plea to fix what is wrong in the pursuit of a noble and critical challenge.*[7]

The Little Hoover Commission 1383 report noted that the State completely failed to meet its target in 2020 of a 50% reduction below 2014 levels in that the amount of organic waste sent to landfills in 2020 actually increased by one million tons over the 2014 baseline. The report forecast that the 2025 target of a 75% reduction is unattainable and estimated that the State will fall short of the target by approximately 8 million tons per year.[8] (For reference, this would be the equivalent of approximately 54 one-unit H Cycle facilities. H Cycle is permitting its first one-unit facility in the City of Pittsburg.) The 2025 forecast in the report was based on CalRecycle's analysis of the amount of organic waste that would be received in 2025 and the testimony of CalRecycle's leadership to the Commission. The CalRecycle analysis found that the state would only have sufficient composting, anaerobic digestion, co-digestion, biomass electricity and mulching facilities to process 10 of the 18 million tons that would need to be processed by these types of facilities in 2025.[9]

[9] Id. at p. 10; citing at Little Hoover 1383 Report to footnote 11: CalRecycle, "Analysis of the Progress Toward the SB 1383 Organic Waste Reduction Goals" (August 18, 2020). p. 7-15. https://www2.calrecycle.ca.gov/Publications/Download/1589.

358.2 cont. The Little Hoover 1383 report recommended that the State implement a temporary pause on SB 1383 and take a series of steps during the temporary pause to the get the organics diversion policy on track. The report noted that more than 100 local jurisdictions have sought an extension of the deadline for compliance.[10] The report examined Low-CI hydrogen and found that Low-CI hydrogen is not sufficiently commercialized in California to be deployed at scale or to play a significant role in meeting the SB 1383 target for 2025 and stated as follows:

> *Work on future use of hydrogen in California should and will continue. In 2022, the Legislature passed a bill requiring that by June 2024 the California Air Resources Board evaluate "the development, deployment, and use of hydrogen." But while low- carbon hydrogen has promising implications for the future, it would be unrealistic and unreasonable to expect even the state government to meet the procurement requirements with hydrogen by 2025 given the factors noted above. Presenting it as a feasible alternative for local governments to have in place by 2025 is setting them up to fail.*[11]

Given the centrality of hydrogen's role in the 2022 Scoping Plan and California's strategy to achieve carbon neutrality by 2045, CARB should take this LCFS rulemaking opportunity to accelerate technologies like H Cycle's that can both help California achieve the methane reduction goals that underlie SB 1383 and expand its Low-CI hydrogen production capacity. Because of the severe failure and current inability of the State to meet SB 1383 organics diversion targets, CARB should deviate from its standard approach to LCFS lifecycle analysis that utilizes California legal requirements to serve as baseline for analysis. The tremendous shortfall that has already occurred in landfill diversion of organics necessitates a different approach so that California's most potent transportation program can be leveraged to help reduce methane emissions immediately. The following proposed regulatory changes would institute a short-term program designed specifically to accelerate landfill diversion and commercialize technologies that can enable California to solve its methane crisis. To fulfill its obligations under SB 1383 and other statutes, CARB must acknowledge the reality that California is currently not capable of diverting 75% of organics from landfills for the litany of reasons detailed in the Little Hoover 1383 report that has caused over 100 jurisdictions to request compliance extensions.

Summary of Recommended LCFS Amendments under H Cycle Recommendation 1

CARB should make a number of targeted amendments to the LCFS Proposal to address the landfill methane crisis facing the State:

A. **Modify §95488.9(f) to authorize a technology that produces a transportation fuel determined by CalRecycle and CARB to meet the Article 2 standard to simultaneously receive a qualifying LCFS pathway score under the LCFS with a pathway CI score that is aligned with the Article 2 determination.**
B. **Modify §95488.9(f) so that new technologies can continue to receive LCFS pathway scores that are consistent with Article 2 determinations until California attains the SB 1383 statewide organics diversion target of 75%.**

[10] Id.
[11] Id. at p. 14-15.

358.2 cont. **C. Modify §95488.9(f) such that subsequent to California attaining the SB 1383 statewide organics diversion target of 75%, fuel pathways that are based on the diversion of organic waste will receive LCFS fuel pathways based on reductions achieved that are greater than the emissions reduction from composting organic waste (0.30 MTCO2e per short ton organic waste).**

H Cycle's proposed approach would be administratively efficient, would enhance the coordination between CalRecycle and CARB in the recognition of technologies that can enable California to bridge the 1383 organics diversion gap and would advance the commercialization of hydrogen. The attached **Exhibit B** provides recommended text to implement this recommendation.

H Cycle recognizes that the proposed revisions to the LCFS regulation would be exceptions to CARB's general approach to life cycle analysis modeling of carbon intensity reductions which is to only recognize GHG reductions that are additional to legal requirements. However, the findings of CalRecycle and the Little Hoover 1383 report conclusively establish that California is likely to miss its 2025 statewide target *by eight million tons of organics* and that the result of this landfilling of organics in excess of SB 1383 targets is that massive quantities of the powerful SLCP methane will be released into the atmosphere in 2025 and subsequent years. The Little Hoover 1383 report provides compelling evidence of the impact of persistent organics in California landfills in that 30 (of the state's 436) landfills and 2 compositing facilities are super-emitters, have persistent methane plumes, and are the source of almost half of landfill methane emissions.[12]

While consistency is the preferred general rule in regulatory development, there is no valid climate policy reason for CARB not to recognize real-world methane reductions from diverted landfill organics in its LCFS program that occur before SB 1383 organics diversion targets are achieved. Such SLCP reductions are additional reductions that California and the planet desperately need. If climate change is indeed the kind of existential crisis described in the Scoping Plan and a large body of California statutes, now is the time to leverage the LCFS program to incentivize H Cycle and other developers of technologies that can convert organic wastes into transportation fuels. It is certainly not the time to sunset crediting for qualified Article 2 technologies when municipalities are desperately searching for viable outlets for landfill-diverted organics and H Cycle is the only Article 2 approved technology that exists.

358.3 cont. ***Recommendation 2:***

Given the massive scale of hydrogen ambition established by the 2022 Scoping Plan and the extremely small market share of fuel cell electric vehicles ("FCEVs") CARB should extend the eligibility of electricity book-and-claim to Low-CI hydrogen that is used in the production of an alternative fuel. Related to this, due to the importance of attracting federal funding to California including Inflation Reduction Act ("IRA") funds for Low-CI hydrogen, CARB should more closely align LCFS electricity book-and-claim accounting requirements with IRA Section 45V's utilization of environmental attribute certificates ("EACs"). This would include allowing hydrogen producers the flexibility to source Low-CI power utilizing PPAs and/or unbundled RECs.

[12] Id. at p. 23-24.

358.3 cont. ***Discussion:***

H Cycle would like to first acknowledge and express its support and appreciation for CARB's decision to expand the eligibility of hydrogen to utilize Low-CI electricity beyond electrolytic hydrogen to Low-CI hydrogen that meets the requirements established by §95488.8(i)(3). We commend CARB for establishing a technology-neutral eligibility standard that recognizes the value of hydrogen derived from biogenic sources, including the derivation of hydrogen from organic waste diverted from landfills.

However, we must also express our concern that in the LCFS Proposal, CARB has severely restricted how hydrogen can be used as a fuel under the LCFS while maintaining eligibility for book-and-claim power sourcing. Under the existing regulations, book-and-claim can be utilized for qualifying hydrogen that is "for transportation purposes (including hydrogen that is used in the production of a transportation fuel)" under existing §95488.8(i)(1). Under the LCFS Proposal, book-and-claim can only be utilized for "hydrogen used as a transportation fuel" under proposed §95488.8(i)(1) and §95488.8(i)(1)(C).

We have raised this issue in discussions with CARB and have been advised that the rationale for the restriction is the concern that there is a limited amount of Low-CI power currently available in California and there are limits to the rate of Low-CI power supply expansion. Due to these concerns regarding Low-CI power scarcity, the LCFS Proposal is intended to ensure sufficient supply of Low-CI power for zero emission vehicles ("ZEVs") including battery-electric vehicles ("BEVs") and FCEVs. We respect this concern but in the current rulemaking, it is our perspective that the restriction to supplying FCEVs will preclude the massive growth of hydrogen supply (1,700x) that CARB is seeking to achieve by 2045 to meet California's climate and air quality goals.

The market reality is that by limiting Low-CI book-and-claim to neat/unblended hydrogen used in FCEVs, CARB has shrunk the addressable hydrogen market demand drastically. In order to develop multiple facilities in California during the 2020's, H Cycle and other hydrogen producers must raise sufficient capital to secure each site, comply with environmental reviews, permit the facility, procure necessary equipment, hire workers and build and commission the facility. The fundamental question from investors is, "What is the anticipated return on investment for the capital provided in the form of equity or debt to the project?" According to the scenario spreadsheet developed by E3 that underlies the 2022 Scoping Plan, in 2024 there will be a very small FCEV sector in California that includes 8,168 light-duty FCEVs; 410 medium-duty FCEVs, 1,230 heavy-duty FCEVs, and 53 FCEV buses.[13]

Returning to the vantage point of the investor, there is likely to be little interest in investing in new hydrogen production facilities that are forced to choose whether:

- To build in remote areas, far-removed from hydrogen demand, in order to co-locate with solar or wind power generation to reduce the CI of their energy input,
- To sell hydrogen only to the very small and distributed FCEV fleet that currently exists in California, or,

[13] See CARB Scoping Plan at p. 189, footnote 332 which provides the underlying information to Figure 4-2, "Transportation fuel mix in 2022, 2030, and 2045 in the Scoping Plan Scenario." The Scoping Plan footnote states, See https://ww2.arb.ca.gov/sites/default/files/2022-11/2022-sp-PATHWAYS-data-E3.xlsx for transportation fuels by year.

358.3 cont.

- To source grid-mix power that may result in a CI score that reduces their federal IRA 45V incentives and California LCFS crediting.

The same investor is likely to be substantially more interested in investing in a Low-CI facility that has the flexibility to supply hydrogen that is used in the production of an alternative fuel. We note that there is more expansive flexibility in the existing LCFS section 95488.8(i)(1) that allows Low-CI power sourcing for electrolytic hydrogen producers that supply "hydrogen that is used in the production of a transportation fuel." While we recognize that hydrogen supplied to produce transportation fuel extends to hydrogen used in petroleum refineries, we also recognize that CARB is working to phase down the supply of fossil fuels to speed the reduction of both GHG and criteria pollutant emissions.

We therefore limit our recommendation to "hydrogen that is used in the production of an alternative fuel." H Cycle's focus is on decarbonization and thus the company is focused on supplying hydrogen to the low carbon fuel market. This is a diverse and growing market that includes power-to-liquid ("PTL") fuels, renewable diesel and sustainable aviation fuel ("SAF"), and each of them has significant needs for hydrogen inputs to production.

Under existing LCFS provision §95488.8(i)(1)(A)-(B), Low-CI electricity supplied as a transportation fuel, e.g., used to power BEVs, can be sourced flexibly through the use of renewable energy certificates ("RECs") or via a qualifying Green Tariff program. Under these provisions, it is also required that the electricity be supplied to the grid within the same balancing authority as where the EVs are charged or in compliance with CPUC §399.16, that all environmental attributes be retired with limited exceptions, and that the RECs be used within three quarters of when the RECs were generated.

As is currently the case for electrolytic hydrogen that can utilize RECs to obtain Low-CI power, CARB should authorize this same power sourcing structure for Low-CI hydrogen that meets the requirements established by §95488.8(i)(3). Hydrogen producers must necessarily comply with the requirements of IRA Section 45V which, when finalized, will impose strict requirements on power sourcing for Low-CI hydrogen. Due to the substantial value that attaches to 45V crediting for hydrogen producers, and the associated potential inflow of federal funding to the State, CARB should authorize either the use of RECs pursuant to §95488.8(i)(1)(A)-(B), or environmental attribute certificates as authorized under Section 45V.

The expansion of low-CI power would facilitate California's receipt of federal funds that are available through the Inflation Reduction Act, Bipartisan Infrastructure Law, and other federal programs. These funding opportunities hinge upon CARB's continuing to enable the sourcing of Low-CI Power via RECs. If CARB instead limits Low-CI Power sourcing to neat hydrogen supplied to FCEVs, H Cycle will be required to source grid-mix power. The sourcing of grid mix power will substantially increase the H Cycle's CI score and correspondingly reduce H Cycle's ability to generate LCFS credits. Without the additional value derived from LCFS credits, H Cycle will have a more difficult time siting its facilities in California where permitting requirements cause substantial expense and time delays, and it is generally more expensive to site and operate a facility.

358.4 cont. ***Recommendation 3:***

CARB should clarify its intent under proposed LCFS §95488.8(i)(1)(C)(2) as this proposed provision states, "The pathway holder or the project operator must be the first contracted entity for procuring the low-CI electricity." Prior to adoption of the LCFS Proposal, CARB should revise the language to clearly indicate what is meant by the phrase "first contracted entity" and ensure that this provision does not establish an impossible condition in California or other markets.

Discussion:

CARB should clarify its intent under §95488.8(i)(1)(C)(2*)* regarding the use of PPAs for bundled Low-CI power sourcing for hydrogen production, with regard to the "first contracted entity" requirement, because California law does not allow "direct access" for manufacturers as end-use retail customers to procure competitive wholesale power supplies.[14] Other than direct hard-wiring of power supplies, entering into PPAs to source Low-CI power indirectly via community choice aggregators ("CCAs") or other load-serving entities represent hydrogen producers' only authorized opportunity to source Low-CI power from renewable generators at a competitive cost, versus procuring grid power from their utility plus unbundled RECs at enormous cost. If CARB's intent is to allow hydrogen producers to access this lower-cost, Low-CI power and thereby promote the development of more hydrogen production in the State, then the language should be modified to remove the first contracted entity requirement, so hydrogen producers can contract indirectly via CCAs and other load-serving entities to arrange such Low-CI power supplies.

---

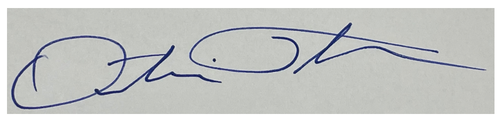
[14] See DIVISION 1. REGULATION OF PUBLIC UTILITIES [201 - 3297] *(Division 1 enacted by Stats. 1951, Ch. 764.);* PART 1. PUBLIC UTILITIES ACT [201 - 2120]; *(Part 1 enacted by Stats. 1951, Ch. 764.)*
CHAPTER 2.3. Electrical Restructuring [330 - 400.3] (Chapter 2.3 added by Stats. 1996, Ch. 854, Sec. 10.);
ARTICLE 6. Requirements for the Public Utilities Commission [360 - 380.5] (Article 6 added by Stats. 1996, Ch. 854, Sec. 10.).

Conclusion

358.5 Non-electrolytic hydrogen technologies and pathways have the potential to be a meaningful contributor to the State's and CARB's goals in the latest LCFS Proposal, and H Cycle believes the foregoing recommendations are strongly needed to ensure the projects have a fair shot at being financially viable to make such contributions. Supporting waste-to-hydrogen as a technology and commercial pathway, brings many benefits including a) supporting the State's current law in SB 1383; b) supporting the adoption of ZEVs in the CARB's Advanced Clean Fleets rules; c) achieving local air emissions reductions of NOx, particulate matter, etc. as a result of ZEV displacement of fossil-fueled vehicles; and d) job growth and investment tax base from new facilities. The LCFS Program and policies in the LCFS Proposal will play a key role in securing these benefits.

We appreciate the opportunity to submit these comments, and are available for further discussions on these important issues.

Sincerely,



Quentin Foster
VP, Policy and Government Affairs

EXHIBIT A

REQUEST FOR ACTION

To: Rachel Machi Wagoner
Director

From: Cara Morgan
Deputy Director, Materials Management and Local Assistance Division

Request Date: December 8, 2023

Decision Subject: Consideration of a Technology Determination for H Cycle Pursuant to Article 2 of the SB 1383 Regulations

Action By: January 16, 2024

Summary of Request
This Request for Action presents staff's analysis of a technology determination application pursuant to Article 2 of the SB 1383 Regulations (14 CCR Section 18983.2.), conducted in consultation with the California Air Resources Board (CARB). Action is needed to (1) determine whether the proposed technology, submitted by H Cycle and described below, constitutes a reduction in landfill disposal by reducing the physical presence of organic waste in landfills and reducing greenhouse gas (GHG) emissions and (2) to determine whether to publish a description of H Cycle's proposed technology on CalRecycle's website.

Background
The Short-Lived Climate Pollutants Waste Reduction Regulations (SB 1383 Regulations) identify specific activities and technologies that constitute recovery of organic waste (14 CCR Section 18983.1 (b)) and others that are considered landfill disposal (14 CCR Section 18983.1 (a)). If a technology or activity is not specifically identified in either subsection (a) or (b) of 14 CCR Section 18983.1, an interested party may request CalRecycle to perform an evaluation of its technology to determine if it constitutes a reduction in landfill disposal, in accordance with the Article 2 requirements (14 CCR Section 18983.2.).

For a technology or recovery process to constitute a reduction in landfill disposal, it must reduce the physical presence of organic waste in landfills and reduce greenhouse gas (GHG) emissions. To meet the requirements under Article 2 (14 CCR Section 18983.2 (a)(3)), the permanent lifecycle GHG emission reductions of a proposed technology or process must be equal to or greater than the emission reductions from composting organic waste (0.30 metric tons of carbon dioxide equivalents ($MTCO_2e$) per short ton organic waste), referred to herein as the "benchmark." The methodology used to calculate the permanent lifecycle GHG emission reductions from composting organic waste (or benchmark) is set out in Section 19883.2 and described in CARB's Calculation of the Lifecycle Greenhouse Gas Emission Reduction Benchmark for the Organic Waste Reductions Regulation.

To conduct the required lifecycle analysis of a technology or process, CalRecycle, in consultation with CARB staff, evaluates its GHG emission impacts as described in 14 CCR Section18983.2 (a)(1)-(a)(3). An applicant must submit a complete set of assumptions, data, and other information that is sufficient to estimate the GHG emissions and permanent lifecycle GHG emission reductions of their technology or process. CalRecycle staff, in consultation with CARB, must evaluate the information submitted in an application within 30 days of receipt and inform the applicant whether the application is complete. Upon receiving all required information and deeming an application complete, CalRecycle and CARB staff conduct an evaluation of the technology or process and determine, within 180 days, if it will permanently reduce GHG emissions by at least 0.30 $MTCO_2e$ per short ton of organic waste. As authorized by 14 CCR Section 18983.2 (a)(1)(I), CalRecycle may request additional information to clarify and validate the information provided in an application. If CalRecycle determines that a proposed technology or process constitutes a reduction in landfill disposal, Section 18983.2 (b) mandates that a description of the operation be posted on CalRecycle's website.

Applicability of the Article 2 Technology Determination

Under the SB 1383 regulations, jurisdictions are required to provide organic waste collection services to all residents and businesses to divert these materials away from landfills and to recycling and recovery activities such as composting, anaerobic digestion, animal feed, and land application. The regulations provide a pathway for processes that are not specified in the SB 1383 regulations, to be deemed a reduction in landfill disposal. An Article 2 technology determination allows a facility to count as a reduction in landfill disposal for purposes of the SB 1383 Regulations if it can show it achieves the required GHG emission reductions. The Article 2 technology determination is not a guarantee that a project can be built or meets other requirements of state or federal law. Further,

i) The Article 2 technology determination is not an endorsement of a technology or process. The determination is solely an evaluation of the lifecycle GHG emission impacts of a proposed operation, technology, or process using the methods and assumptions described in 14 CCR Section 18983.2.
ii) An Article 2 technology determination made by the department pursuant to 14 CCR Section 18983.2 is a factual determination and does not constitute a permit or a permit approval. Further, although a technology or process may constitute a reduction in landfill disposal under the criteria set out in Section 18983.2, the operation must still comply with all other statutory and regulatory requirements. A technology or process deemed to constitute a reduction in landfill disposal pursuant to Article 2 may still be considered landfill disposal under other laws, such as AB 939 (PRC Section 40120.1).
iii) An Article 2 technology determination does not serve any role in the permit approval process.
iv) An Article 2 technology determination is made on the basis of the information presented in the Article 2 application and clarifying information submitted at the request of the department. The determination is limited to the specific activities, operations, and assumptions presented in the Article 2 application. If the technology, activities, operations, or processes differ

from the application as described in herein and on the department's website, the determination is not applicable.

a. If a facility is found to be operating in a manner that differs from the description posted on the department's website and is not otherwise engaged in one of the activities specified in 14 CCR 18983.1(b), any organic waste processed by the facility does not constitute a reduction in landfill disposal.

Applicant: H Cycle

H Cycle is a developer that intends to build and operate multiple facilities in California to produce hydrogen from organic waste. H Cycle previously applied for an Article 2 technology determination in 2022. The previous application lacked information specifying the operational controls that would prevent a facility using H Cycle's technology from deviating from the feedstock scenarios and other operating assumptions, which could impact whether it permanently reduces greenhouse gas emissions by at least 0.30 MTCO2e per short ton of organic waste. Because CalRecycle is required to make a determination upon a "proposed operation," and requires operational controls demonstrating how a proposed technology will operate in practice to permanently reduce GHG emissions, CalRecycle found that the application did not sufficiently demonstrate permanent reductions in greenhouse gas emissions to warrant a finding that the operation described constituted a reduction in landfill disposal. Subsequently, H Cycle submitted an application on July 17, 2023, which included operational controls and monitoring and verification procedures to verify the greenhouse gas emission reductions are achieved.

Staff Analysis

Application Review Process

CalRecycle received an Article 2 application from H Cycle on July 17, 2023. In accordance with Section 18983.2 (a)(2), staff reviewed the application, in consultation with CARB, and performed a completeness review. After reviewing the application, in consultation with CARB, CalRecycle determined that it was complete at its August 15, 2023, Monthly Public Meeting. CalRecycle notified H Cycle of the completeness finding.

CalRecycle and CARB staff reviewed all the information and calculations provided by the applicant and confirmed that, under the specific processes and assumptions identified in H Cycle's application, the permanent lifecycle GHG emission reductions are equal to or greater than the emission reductions from composting organic waste (0.30 $MTCO_2e$/short ton organic waste). CalRecycle and CARB reviewed the methodology utilized to determine the emission reduction factor (ERF) of H Cycle's proposed process under the three feedstock scenarios described below. H Cycle provided key performance data based on its preliminary engineering design, which provides data on heat and mass balances, utility needs, product yields, and other key metrics utilized to calculate the life cycle greenhouse gas (GHG) emissions from the waste processing and hydrogen production process, the avoided fugitive methane emissions from landfilling, avoided emissions due to hydrogen production (i.e., the GHG emissions that do not occur because a conventional fossil fuel is replaced by waste-derived hydrogen), and emissions due to transportation. Below is CARB's technical summary.

Summary of Hydrogen Production Process

H Cycle's application proposed that facilities utilizing its technology will convert approximately 85,000 to 133,000 short tons per year of organic waste from material recovery facilities (MRFs) into hydrogen using Omni Conversion Technologies' thermal conversion process, a sour-gas-shift reactor, and a pressure swing adsorption system. The hydrogen is intended for use at refineries or in fuel cell electric vehicles. The process described in the application is organized into four units: the feedstock preparation unit, the waste conversion unit, the hydrogen production plant, and a utility and water unit.

At the feedstock preparation unit, the material is shredded; most inert materials and plastics are removed using manual sorting, screening, magnetic and eddy current separators and air classifier; and the material is dried to 10 percent moisture content using steam from a boiler and heat recovered from the process. At the waste conversion unit, the prepared feedstock will be transformed into syngas using a non-combustive thermal conversion process. The syngas (a mixture of primarily hydrogen, carbon monoxide, and some methane) goes through a second high-temperature conversion step to maximize yield. Particles are removed from the syngas and converted to a non-hazardous slag, which can be used as a recycled product or disposed.

The syngas is finally sent through a series of cleaning and scrubbing steps to remove chlorine and nitrogen species and remaining solids. The syngas is then compressed and fed into the hydrogen production unit, which uses a sour-gas-shift reactor where steam reacts with syngas forming a hydrogen-rich gas and converting carbon monoxide to carbon dioxide. The resulting gas is treated to remove sulfur species and purified in a pressure-swing adsorption system to generate hydrogen gas of at least 99.97 percent purity, the International Standards Organization (ISO) specification level for use in a hydrogen fuel cell.

A utility and water unit comprised of oxygen production, steam generation, and wastewater treatment supports various stages of the process. Condensate wastewater from the plant is cleaned and disposed to the local sewer. Offgas is recycled and combusted in a boiler equipped with emissions controls to generate additional steam for use on-site.

Feedstock Scenarios

H Cycle developed three illustrative feedstock scenarios, based on characterization and lab sampling of specific sources collected from MRFs. The three scenarios differ primarily by moisture content of the organic waste, which in turn impacts process energy demand. For each feedstock scenario, the application provides the quantity of each waste type, as-received, as-fed to the process, and the total annual throughput in tons.

1. Low-moisture scenario: the waste feedstock is composed of a mixture of construction and demolition waste and post-MRF non-recyclable fibers (15 percent moisture as-received).
2. Medium-moisture scenario: the waste feedstock is composed of residential black bin organics post primary processing at a MRF or transfer station, further processed by H Cycle to high organic content (39 percent moisture as-received).

3. High-moisture scenario: the waste feedstock is composed of material obtained from a high-diversion organic MRF containing the expected worst-case maximum 9 percent plastic (45 percent moisture as-received).

The life cycle GHG emissions analysis is based on the assumption that the feedstocks processed in H Cycle's projects will fall within the boundaries of these scenarios and do not exceed them in terms of moisture or plastic content.

Based on the as-fed composition, H Cycle used a process model to determine the anticipated throughput of the facility and resulting process energy demand, hydrogen and slag yields for each feedstock scenario. Key inputs and outputs are summarized in Table 1.

Table 1. Key Process Performance Metrics

Input or Output (per short ton of organic waste feedstock)	Feedstock 1 Low Moisture	Feedstock 2 Medium Moisture	Feedstock 3 High Moisture
Natural Gas Input (MMBtu/ton)	0.74	1.44	1.39
Electricity Input (MWh/ton)	0.93	0.63	0.59
Slag Output (kg/ton)	151.60	102.56	145.86
Hydrogen Output (kg/ton)	73.16	47.03	43.76

System Boundary and Emissions

The life cycle GHG emissions analysis includes the emissions reduction from avoided landfill disposal, the emissions reduction due to products displaced by hydrogen (i.e., the GHG emissions that do not occur because a conventional fossil fuel is replaced by waste-derived hydrogen), the process emissions from the waste processing and hydrogen production process, and the emissions due to transportation. Key assumptions, data sources, and calculations are summarized below:

1. Avoided landfill emissions
   H Cycle used the Landfill Emission Reduction Factor Tool developed by CARB to calculate avoided GHG emissions from landfilling each organic waste type. The weighted average was calculated for each feedstock scenario.

2. Avoided product displacement emissions
   H Cycle estimated the avoided GHG emissions that could result from displacing fossil fuels with hydrogen derived from conversion of organic waste. H Cycle estimates 30 percent of the product will be used in heavy-duty fuel cell electric vehicles to displace diesel and the remainder will be used at refineries to displace fossil gas-derived hydrogen.

3. Process emissions
   Energy use included fossil natural gas, grid electricity, and diesel used at the H Cycle facility, and at hydrogen vehicle fueling stations to compress, store, and dispense fuel. Process emissions also included the emissions associated with

the production of material and chemical inputs used at the H Cycle facility (e.g., catalysts, potassium carbonate, activated carbon, and zeolite). Life cycle emission factors were obtained from CA-GREET3.0. Fugitive, leaked, and vented emissions were calculated by assuming one percent of generated methane and carbon monoxide may leak from flanges, valves, or other parts of the processing equipment and emissions during the storage of post-processed waste for up to 3 days in aerobic conditions may be vented. Emissions from conversion of plastics were calculated using the emission factor from the U.S. EPA's Waste Reduction Model (WARM), 2.33 $MTCO_2e$ per short ton.

4. Transportation emissions for slag disposal and hydrogen product delivery
   H Cycle assumed a maximum distance of 200 miles per trip for both the disposal of slag material at a landfill or delivery of hydrogen product to an end use. H Cycle calculated the emissions from diesel in heavy-duty trucks to transport slag for disposal in 21-ton capacity trucks and to transport compressed hydrogen to a fueling station or refinery in 0.4-ton capacity tube trailers. Capacity and fuel economy factors used in the calculation are from CA-GREET3.0. Note that the system boundary does not include transport of organic waste from a MRF, under the assumption that the H Cycle facility will be the same distance or nearer to the organic waste supplier than the nearest landfill that would otherwise dispose of the organic waste feedstock.

Example calculation of avoided emissions from product displacement:

$$\text{Displacement} = CCCC_{\text{displaced fuel}} \times EEEEEE \times ww \times CC$$

Where, $CCCC_{dddddddddddddddddd\ ffffdddd}$ is the carbon intensity of the conventional fuel, e.g., diesel; $EEEEEE$ is the energy economy ratio, a ratio that represents the efficiency of a fuel as used in a powertrain as compared to a reference fuel; ww is the energy density of hydrogen; and CC is the unit conversion from metric tons (MT) to kilograms (kg) and grams (g) to MT. Values are from CA-GREET3.0. Displacement for hydrogen (H_2) that is used to displace diesel in a heavy-duty electric fuel cell vehicle is given by:

$$\text{Displacement} = 99.76\,\frac{gCCCC_2e}{\text{MJ}_{\text{diesel}}} \times 1.9\,\frac{\text{MJ}_{\text{diesel}}}{\text{MJ}_{\text{H2}}} \times 120\,\frac{\text{MJ}_{\text{H2}}}{\text{kg}_{\text{H2}}} \times \frac{1000\ \text{kg}_{\text{H2}}/\text{MJ}_{\text{H2}}}{10^{6}\text{g}CCCC_2\text{e}/\text{MT}CCCC_2\text{e}} = \mathbf{2222.77}\,\frac{\text{MT}CCCC_2\text{e}}{\text{MT}_{\text{hydrogen}}}$$

A similar calculation is performed to determine displacement for H_2 used in refineries, with $EEEEEE = 1$ and $CCCC_{dddddddddddddddddd\ ffffdddd} = 99.4$. Displacement resulting from use of 30% H_2 in vehicles and 70% in refineries is calculated by:

$$\text{Displacement} = (30\% \times 22.7) + (70\% \times 11.9) = \mathbf{1111.22}\,\frac{\text{MT}CCCC_2\text{e}}{\text{MT}_{\text{hydrogen}}}$$

This factor is then adjusted to the short ton organic waste basis for inclusion in the ERF.

Key Assumptions

- Waste feedstock is prepared within one day of delivery to the H Cycle facility.
- No additional pre-processing steps are required at the MRF or transfer station that supplies organic waste.

- No hazardous waste will be accepted, and organic material as received will have a maximum moisture content of 45 percent.
- Prepared organic feedstock is stored for no more than 3 days and contains no more than 9 percent plastic by mass.
- At least 30 percent of the hydrogen product will be used in fuel cell electric vehicles.
- Slag material will be transported for landfill disposal no more than 200 miles from the conversion facility.
- Hydrogen products will be transported for end use no more than 200 miles.
- Process energy demand does not exceed the values stated in the application.
- Product yields achieved are greater than or equal to the values stated in the application.

Final Emission Reduction Factor

The final ERF was determined by adding (a) the avoided methane emissions from not landfilling the waste and (b) the avoided GHG emissions associated with product displacement, and subtracting both (c) the process emissions and (d) transportation emissions. The resulting ERF reflects the life cycle GHG emissions reduction from processing one short ton of mixed organic waste versus depositing the same amount of material into a landfill. Note that while the total GHG emissions per year are accounted for in these calculations (including fossil CO2 emissions from plastic conversion), they are divided by the tons of organic waste processed only (i.e., excluding tons of plastic and other inert materials), as specified in the regulations.

A summary of the emissions by life cycle stage and final ERF for each feedstock scenario is provided in Table 2.

Table 2. Emission reductions and final ERF for each feedstock scenario, expressed in $MTCO_2e$/short ton of organic waste processed.

Feedstock Scenario	Avoided Landfill (a)	Product Displacement (b)	Process Emissions (c)	Transport Emissions (d)	Final ERF
1	0.20	1.08	(0.45)	(0.06)	**0.78**
2	0.26	0.69	(0.37)	(0.04)	**0.55**
3	0.06	0.65	(0.36)	(0.03)	**0.31**

Monitoring and Verification Procedures

The H Cycle application includes “Feedstock Quality Control” and “Monitoring and Verification” sections that identify operational and contractual controls, recordkeeping and reporting procedures, and methods for CalRecycle to monitor and verify that a facility using the H Cycle technology is continually operating consistent with what is represented in this Article 2 application.

Without the following additional monitoring and verification procedures and controls, CalRecycle cannot validate that the technology described in H Cycle's application will continually achieve the permanent lifecycle reduction in greenhouse gas emissions equal to or greater than 0.30 $MTCO_2e$/short ton of organic waste that therefore constitutes a reduction in landfill disposal. Any finding by CalRecycle that the H Cycle technology as described in the application constitutes a reduction in landfill disposal is contingent upon these monitoring and verification procedures and controls being in place.

1. Conduct waste characterization analyses of each contracted source of municipal solid waste (MSW) feedstock and of as-fed feedstock materials, at least quarterly, using the following protocol:
    a. Collect and photograph 200-pound samples per ASTM[1] D5231 – 92.[2]
    b. Conduct a bulk density test of each sample per ASTM E11090 – 19.[3]
    c. Pass materials through a fine screen (screen size to be consistent with that which is utilized for as-fed feedstocks) and continue hand sorting overs into subcomponent categories listed in (d).
    d. Hand sort each sample into subcomponents categories including but not limited to, yard waste, food waste, paper products, plastics, glass, hazardous waste, and ferrous and non-ferrous metals. Photograph and weigh each subcomponent category and maintain records.
    e. Create laboratory samples for moisture content analysis by recreating a weighted average mixture of the subcomponent categories, properly storing the samples to not allow evaporation of water content prior to testing. The laboratory samples shall be prepared in a manner consistent with the standards of the independent laboratory utilized and shall not contain the fines removed via the fine screen unless fines are included in as-fed feedstock. These samples shall be sent to an accredited ISO/IEC 17025[45] laboratory to measure moisture content.
2. Maintain and make available to the department, upon request, records of all slag material and any other co-products or waste produced, including but not limited to residuals removed from feedstocks, liquids produced onsite, hazardous waste outputs, and any constituents removed from the hydrogen gas produced. Records shall include a description and quantity of each material produced, the name of the landfill(s) where each material is disposed, quantity of material transported for any other use, and distance transported for each of these uses.
3. For each quarter in operation when reporting in the Recycling and Disposal Reporting System pursuant to CCR Title 14, Section 18815.1 through 18815.13, upload a document to the Recycling and Disposal Reporting System that includes the following:

---

[1] ASTM International, formerly known as American Society for Testing and Materials.
[2] ASTM D5231-92(2016), *Standard Test Method for Determination of the Composition of Unprocessed Municipal Solid Waste*
[3] ASTM E1109-19, *Standard Test Method for Determining the Bulk Density of Solid Waste Fractions*
[4] International Organization for Standardization/International Electrotechnical Commission:
ISO/IEC17025:2017 general requirements for the competence of testing and calibration laboratories.

   a. The total quantity of feedstock as-received and the total quantity of feedstock as-fed to the reactor over the quarter.
   b. The results of waste characterization and moisture content analyses conducted, including the quantity of plastic contained in the as-fed feedstock.
   c. Total utility energy consumption reported in units of kWh/ton of organic waste as-fed.
   d. Total natural gas consumption reported in million British thermal units per ton of organic waste as-fed.
   e. Description, quantity, disposition, and location of disposition of all slag material and any other co-products or waste produced, including but not limited to residuals removed from feedstocks, liquids produced onsite, and any hazardous waste in as-received feedstock.
   f. The total quantity of hydrogen produced, the distance the hydrogen is transported to its destination, and the end use of the hydrogen.
4. The project proponent includes operational aspects to implement monitoring and verification procedures 1, 2 and 3, as identified above in this RFA, in the operating document required for a solid waste facilities permit.
5. Monitoring by the Local Enforcement Agency:
   a. CalRecycle to provide technical assistance to Local Enforcement Agency.
   b. If the operating document is altered, CalRecycle will be notified by the Local Enforcement Agency.
6. H Cycle will participate in CARB’s Low Carbon Fuel Standard (LCFS) Program and will be subject to annual reporting to CARB and third party verification of its carbon intensity (CI) score which includes:
   a. Feedstock quantity, moisture content, and amount of plastics contained in the as-fed feedstock materials.
   b. Energy consumption.
   c. Assessment of calibration procedures.
   d. Quantity of produced hydrogen used as transportation fuel.
7. If the facility utilizing the H Cycle technology, as described in the application, is operating outside the parameters identified in this application and RFA averaged over the reporting quarter, the facility shall notify CalRecycle within seven business days of submitting the quarterly RDRS report.

These additional monitoring and verification procedures will enable CalRecycle to validate that the technology as described in the application constitutes a reduction in landfill disposal on an ongoing basis for a specific operation. If these procedures are not followed, any determination that the technology does represent a reduction in landfill disposal will not be applicable as CalRecycle cannot be certain that the requisite GHG reductions are being met to constitute a reduction in landfill disposal. Any waste sent to such a facility likely will be deemed disposal.

Feedback from Interested Parties

As part of CalRecycle’s commitment to transparency in decision making and program development, the H Cycle application documents, with confidential and proprietary information redacted, were made available for public review and comment. An email message was sent via the SB 1383 Short-Lived Climate Pollutants listserv which provided instructions for submitting comments to CalRecycle. The 30-day public comment period was held from August 15, 2023, through September 16, 2023. All comments received are attached to this RFA (see attachments 3-20).

Summary of Staff Analysis

CalRecycle staff, in consultation with CARB, reviewed H Cycle's application and found the permanent lifecycle GHG emissions reduction is equal to or greater than the emissions reduction from composting organic waste (0.30 $MTCO_2e$ per short ton organic waste), and can be determined to be a reduction in landfill disposal under the analysis and methodology prescribed by regulation in 14 CCR Section 18983.2. The additional monitoring and verification procedures and controls identified above will allow CalRecycle to validate that the technology described in H Cycle's application will continually achieve the permanent lifecycle reduction in greenhouse gas emissions equal to or greater than 0.30 $MTCO_2e$/short ton of organic waste that therefore constitutes a reduction in landfill disposal.

Options

1. Find that the proposed H Cycle technology is a reduction in landfill disposal because the technology meets the benchmark reduction required by regulations to constitute a reduction in landfill disposal pursuant to 14 CCR Section 18983.2(a)(3). Staff is directed to publish a description of this technology on CalRecycle's website as required by 14 CCR Section 18983.2(b).
2. Find that the proposed H Cycle technology is not a reduction in landfill disposal because it fails to meet the benchmark reduction required by regulations to constitute a reduction in landfill disposal pursuant to 14 CCR Section 18983.2(a)(3).

Action

Based on the information and analysis provided in this Request for Action, including the above-noted monitoring and verification procedures, and as required by section 18983.2, I hereby determine that the proposed H Cycle technology is:

✓ Option 1: A reduction in landfill disposal and direct staff to publish a description of this technology on CalRecycle's website.

☐ Option 2: Not a reduction in landfill disposal.

Dated: 1/11/2024

Signed By: Rachel Machi Wagoner, Director

Exhibit B

LCFS Proposed Amendments

(…)

§ 95488.9. Special Circumstances for Fuel Pathway Applications.

(…)

(f) Carbon Intensities that Reflect Avoided Methane Emissions from Dairy and Swine Manure or Organic Waste Diverted from Landfill Disposal.

(1) A fuel pathway that utilizes biomethane from dairy cattle or swine manure digestion may be certified with a CI that reflects the reduction of greenhouse gas emissions achieved by the voluntary capture of methane, provided that:

(A) A biogas control system, or digester, is used to capture biomethane from manure management on dairy cattle and swine farms that would otherwise be vented to the atmosphere as a result of livestock operations from those farms.

(B) The baseline quantity of avoided methane reflected in the CI calculation is additional to any legal requirement for the capture and destruction of biomethane.

(2) Prior to January 1, 2025, a fuel pathway that utilizes an organic material diverted from a landfill may be certified with a CI that reflects the reduction of greenhouse gas emissions determined in the approval of an Article 2 of the SB 1383 Regulations (14 C.C.R. 18983.2) technology determination by CalRecycle conducted in consultation with CARB if the permanent lifecycle GHG emissions reduction is equal to or greater than the emissions reduction from composting organic waste (0.30 $MTCO_2e$ per short ton organic waste).

(3) Until California attains its statewide organics diversion goal of 75% under SB 1383, ~~A~~a fuel pathway that utilizes an organic material may be certified with a CI that reflects the reduction of greenhouse gas emissions achieved by the ~~voluntary~~ diversion from decomposition in a landfill and the associated fugitive methane emissions, provided that:

(A) The organic material that is used as a feedstock would otherwise have been disposed of by landfilling~~, and the diversion is additional to any legal requirement for the diversion of organics from landfill disposa~~l.

(B) Any degradable carbon that is not converted to fuel is subsequently treated in an aerobic system or otherwise is prevented from release as fugitive methane. Upon request, the applicant must demonstrate that emissions are not significant beyond the system boundary of the fuel pathway.

(C) The baseline quantity of avoided methane reflected in the CI calculation is additional to any legal requirement for the avoidance or capture and destruction of biomethane in a landfill.

~~(4)~~ Upon a determination that California has attained its statewide organics diversion goal of 75% under SB 1383, ~~A~~ a fuel pathway that utilizes an organic material may be certified with a CI that reflects the reduction of greenhouse gas emissions achieved by ~~the voluntary~~ mandatory diversion ~~to a~~ if the permanent lifecycle GHG emissions reduction is equal to or greater than the emissions reduction from composting organic waste

~~(A) The organic material that is used as a feedstock would otherwise have been disposed of by landfilling, and the diversion is additional to any legal requirement for the diversion of organics from landfill disposal.~~

~~(B) Any degradable carbon that is not converted to fuel is subsequently treated in an aerobic system or otherwise is prevented from release as fugitive methane. Upon request, the applicant must demonstrate that emissions are not significant beyond the system boundary of the fuel pathway.~~

~~(C) The baseline quantity of avoided methane reflected in the CI calculation is additional to any legal requirement for the avoidance or capture and destruction of biomethane.~~

(5) Carbon intensities that reflect avoided methane emissions from dairy and swine manure or organic waste projects are subject to the following requirements for credit generation:

(A) *Crediting Periods.* Avoided methane crediting for dairy and swine manure pathways as described in (f)(1) above, and for landfill-diversion pathways as described in (f)(2) above, is limited to three consecutive 10 years crediting periods, counting from the quarter following Executive Officer approval of the application. The pathway holder must formally request each subsequent crediting period for the project through the LRT-CBTS. The Executive Officer may renew crediting periods for fuel pathways certified before January 1, 2030, for up to three consecutive 10-year crediting periods. For pathways for bio-CNG, bio-LNG, and bio-L-CNG used in CNG vehicles associated with projects that break ground after December 31, 2029, the Executive Officer may only approve avoided methane crediting through December 31, 2040. For pathways for biomethane used to produce hydrogen that break ground after December 31, 2029, the Executive Officer may only approve avoided methane crediting through December 31, 2045.

(B) Notwithstanding (A) above, in the event that any law, regulation, or legally binding mandate requiring either greenhouse gas emission reductions from manure methane emissions from livestock and dairy projects or diversion of organic material from landfill disposal, comes into effect in California during a project's crediting period, then the project is only eligible to continue to receive LCFS credits for those greenhouse gas emission reductions for the remainder of the project's current crediting period. The project may not request any subsequent crediting periods.

(C) Notwithstanding (A) above, projects that have generated CARB Compliance Offset Credits under the market-based compliance mechanism set forth in title 17, California Code of Regulations Chapter 1, Subchapter 10, article 5 (commencing with section 95800) may apply to receive credits under the LCFS. However, the LCFS crediting period for such projects is aligned with the crediting period for Compliance Offset Credits, and does not reset when the project is certified under the LCFS.

Re: Proposed Low Carbon Fuel Standard Amendments

Disclaimer: The opinions expressed herein are our own and do not necessarily reflect the views of The Johns Hopkins University.

Liane M. Randolph
Chair, California Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Chair Randolph:

We are researchers at the Johns Hopkins Center for a Livable Future (CLF) based at the Bloomberg School of Public Health in the Department of Environmental Health and Engineering. The Center for a Livable Future investigates the interconnections among diet, food production, public health, and the environment. Since 1996, the Johns Hopkins Center for a Livable Future has applied a public health lens to the ecological, economic, and social considerations across the food system.
359.1 While the Low Carbon Fuel Standard (LCFS) has potential to support environmental justice and a transition to renewable fuel sources in California's transportation sector, we are concerned that a specific element of the Proposed LCFS Amendments will negatively impact the health of Californians and Americans alike. Specifically, we believe that the inclusion of the avoided methane credits in the Proposed LCFS Amendments would threaten public health and deepen environmental injustices by incentivizing and further entrenching the industrial food animal production (IFAP) model.

We call on the California Air Resources Board (CARB) to eliminate avoided methane crediting, as recommended by its own Environmental Justice Advisory Committee (EJAC) (CARB 2023).

The avoided methane credits incentivize growth of and further entrench the industrialized model of food animal production, which has been demonstrated to threaten public health.

IFAP is a term referring to the predominant system of meat, milk, and egg production in the U.S., characterized by confining thousands of animals in small areas and the resulting concentration of massive quantities of manure. The Environmental Protection Agency (EPA) and Centers for Disease Control (CDC) have documented that these large animal operations pose significant public health and environmental risks, particularly in surrounding communities (US EPA 2013; CDC 2018). These facilities are disproportionately sited in low-income communities, as well as in non-white communities (US EPA 2013; CDC 2018). Public health concerns stem from human exposures to air pollution, as well as drinking water and soil contamination. EPA recently analyzed the literature documenting health effects of direct emissions from animal production facilities and found that residential proximity to them is linked to asthma, decreased lung function, mortality, odor annoyance, and gastrointestinal illness (US EPA 2023).

359.1 cont. The Proposed LCFS Amendments state that digester operators that join the program before 2030 can receive payment for the avoided methane credits until 2060, creating an enormous incentive for biodigester expansion in the next six years. Further, evidence suggests that the economic viability of these operations requires a significant number of animals (Anderson et al. 2013, Barbera et al. 2019; US EPA 2023). Given public health concerns related to the operation of these IFAP facilities, such an expansion may have implications for human exposures to IFAP related pollutants.

We are concerned that the avoided methane credits incentivize wet manure management systems, which pose known public health concerns. These systems use pits or tanks to store liquid waste and a connected system of pipes to transport it. The tanks and pipes are both susceptible to failures and breaches—now more common as heavy rainfall and flooding become more frequent and intense due to climate change. These failures and breaches may release pathogens, nitrates, and other pollutants into surface water and groundwater supplies (Burkholder et al. 2007). Exposure to these contaminants have been linked to an increased risk of cancer, diabetes, thyroid disease, and birth defects (Burkholder et al. 2007; Jones et al. 2016; Inoue-Choi et al. 2015; Temkin et al. 2019). Furthermore, wet manure management systems are associated with high levels of nitrous oxide and methane emissions, which contribute to climate change and are associated with increased asthma attacks (Glibert 2020).

Due to the water contamination and air pollution caused by wet manure management systems, the American Public Health Association (APHA) has called on federal and state governments to "prohibit the installation of new liquid manure handling systems, including waste lagoons" and to phase out existing wet manure management at IFAP facilities (APHA 2019). Unfortunately, the Proposed LCFS Amendments, through avoided methane crediting and the resulting negative carbon intensity for biogas, would do the opposite.

The avoided methane credits do not reduce burdens on environmental justice communities and workers.

The avoided methane credits run counter to one of the key intentions of the Proposed LCFS Amendments which is to promote investment and improve air quality in disadvantaged communities (CARB 2023). In a study of North Carolina counties with many IFAP operations, average ammonia concentrations, linked to the health effects listed above, have been found to be two and a half to three times higher in environmental justice communities compared to the entire study region (Quist et al. 2022). Additionally, IFAP operations are associated with declining infrastructure, property values, and sense of cohesion—all of which have the opposite impact of community investment (Donham et al. 2007).

The EJAC, whose membership comes from Many disadvantaged communities with significant exposure to air pollution, concluded that IFAP facilities do not promote investment or improved air quality in disadvantaged communities (EJAC 2023). CARB must honor the recommendations of EJAC in order to follow through with its own commitments to reducing pollution burdens in environmental justice communities.

359.1 cont. The practice of burning biogas on-site for electricity production poses safety and public health risks to workers. These can include explosions, asphyxiation, and disease from bacteria, viruses, and parasites in manure (Westenbroek and Martin II 2019). Many agriculture workers are not protected by US labor laws (Lydersen 2022); California has the opportunity to protect those workers from these risks by prohibiting the burning of biogas in its LCFS regulations.

In conclusion, the California Air and Resources Board must eliminate avoided methane crediting, included in the Environmental Justice Scenario, in order to mitigate the public health risks described above. CARB has stated its commitment to transition to clean fuels and to improve air quality in the transportation sector in California. We believe that a solution to improved air quality in the transportation sector cannot include regulations that harm air quality in the agricultural sector. Given that CARB does not have the authority to implement air quality mitigation measures, it should be particularly cautious about including any measures in the LCFS that pose a public health risk to air quality.

Sincerely,

Allie Wainer, MS

Re.: Proposed Low Carbon Fuel Standard Amendments

Dear Rajinder Sahota,

Background

AFCC and its member companies welcome the opportunity to provide comments on the CARB proposed low carbon fuel standard amendments.

AFCC is a collaborative government affairs effort organized by the Kilpatrick Townsend & Stockton law firm and American Diversified Energy. AFCC was created to address policy and advocacy gaps at the federal and state levels with respect to renewable chemicals, bioplastics/biomaterials, cell-cultured food ingredients, alternative proteins, single cell protein for food and feed, enzymes, alternative fuels, biobased products and sustainable aviation fuels sectors. AFCC member companies work on food and fiber supply chain security and sustainability, renewable chemicals, industrial biotechnology, bioplastics and biomaterials, and biofuels.

Areas of Importance for Amending the LCFS

The amendments to the LCFS are focused on expanding the definition of renewable biomass to include woody biomass, forest residuals, sawdust, and ensuring these are treated in any LCA model as carbon neutral which is aligned with the enacted federal definition of carbon neutrality. Furthermore, amendment to the areas of risk of wildfire should be expanded and producers qualify for the LCFS for sustainable aviation biofuels, advanced biofuels, cellulosic biofuels, marine biofuels, hydrogen and ammonia. Innovation in these areas continues to grow, as such LCFS should account for these technologies correctly.

§ 95481. Definitions and Acronyms.

360.1 "California-modified Greenhouse Gases, Regulated Emissions, and Energy use in Transportation model (CA-GREET)" is a modified version of Argonne National Lab's Greenhouse Gases, Regulated Emissions, and Energy use in

Transportation (GREET) model used to evaluate well-to-wheel GHG emissions in the LCFS. The CA-GREET model is periodically updated, and includes a version number suffix, e.g., CA-GREET4.0.

360.1 cont

It is recommended to amend the definition as: Projects will occur in CA and developers should not be in a position to build a project with no GHG guidance.

360.2 Individual cases exist for developers such as: 1. Wildfire, there need to be details on areas with wildfire risk. 2. Thinnings to increase surrounding tree growth. 3. Agricultural residues. 4. Lumbermill and sugar mil waste. 5. Waste should have zero iLUC, similar to UCO. 5. Counterfactuals are consistent with carbon neutrality.

(20)"Biomass" means non-fossilized and biodegradable organic material originating from plants, animals, or micro-organisms, including: products, byproducts, residues and waste from agriculture, forestry, and related industries; the non-fossilized and biodegradable organic fractions of industrial and municipal wastes; and gases and liquids recovered from the decomposition of nonfossilized and biodegradable organic material.

It is recommended to amend the definition as: align with federal enacted law for the definition of carbon neutrality.
Expand CARB's definition of biomass to include: Federal use of GREET. Support CARB's efforts in supply chain tracking, consistent with RED, Federal requirements. Carbon neutrality is Federal law, align Carb with Federal definition.

360.3 **§ 95481. Definitions and Acronyms. Definition of Renewable Hydrogen**

Renewable Hydrogen" means hydrogen derived from

(1) electrolysis of water or aqueous solutions using renewable electricity;

(2) catalytic cracking, oxidation or steam methane reforming of biomethane or other renewable hydrocarbons; or

(3) thermochemical conversion of biomass, including the organic portion of municipal solid waste (MSW).

It is recommended to amend the definition as: Hydrogen derived from thermochemical conversion of biomass, including the bio-genic portion of municipal solid waste (MSW) or landfill diverted MSW which contains biogenic and non-biogenic/non-recyclable material.

§ 95481. Definitions and Acronyms. Definition of Biomethane

360.4 *It is recommended to have a distinct definition of renewable natural gas to include methane derived from other renewable sources, such as methane derived from renewable resources such as bio-genic and non-biogenic components in the landfill-diverted MSW.*

Methanation uses H2 and CO2 to create synthetic methane and becomes a method for bulk hydrogen storage and bulk hydrogen transportation via existing natural gas pipelines.

360.5 **§ 95488.1(c). Tier 1 calculator for hydrogen**

Proposal to include Tier 1 calculator for

1. Electrolysis

2. Steam methane reformation using RNG or North America Natural Gas

It is recommended to include thermochemical conversion of landfill diverted MSW (biogenic and non-biogenic component) with carbon capture in Tier 1 pathway for hydrogen.

Thermochemical conversion of organic component of MSW is well accepted technology for producing renewable hydrogen. Approval of CARB for landfill diverted MSW as feedstock for thermochemical conversion technology with carbon capture under Tier 1 pathway, will support rapid deployment of these projects.

360.6 **§ 95488.8. Fuel Pathway Application Requirements**

Applying to All Classifications. section (g) Specified Source Feedstocks (1) (A) subsection 3 be amended to read as follows:

~~Small-diameter, non-merchantable~~ Any forestry residues and byproducts removed as part of a forest fire fuel reduction, ~~last~~ stand improvement or slash/tops from a treatment (including harvests) ~~where no-clear cutting occurred;~~ from forest lands that meet applicable federal, state or local regulations; Municipal solid waste that is diverted from landfill disposal;

360.7 **§ 95488.8. Fuel Pathway Application Requirements Applying to All Classifications.**

It is recommended to amend as:

(4) Areas at risk of wildfire include: thinnings to increase surrounding tree growth, agriculture residues, lumber mill and sugar mill waste, wasts should have zero ILUC – similar to UCO, and counterfactuals are consistent with carbon neutrality. Carbon neutrality aligns with federal definition.

§ 95488.8(g). Specified Source Feedstocks
1. MSW diverted from landfills will be added under specified feedstock
360.8 sources.
2. Robust chain of custody documentation that traces MSW to the point of origin is required.

It is recommended that the definition of MSW diverted from landfill to include non-biogenic components/ non-recyclable components such as plastic. Considering 48% of landfill waste is non-biogenic (by mass, ref 2023 R&D GREET model), landfill diverted MSW represents a valuable untapped, sustainable, and renewable clean energy resource when carbon capture is implemented.

360.9 **§ 95488.8 (i)(1)(A)-(B).**
The proposed LCFS regulatory revisions that CARB released on December 22, 2023, would narrow the power-sourcing landscape for Power-to-Liquid (PtL) producers. We urge CARB to retain and expand the language which prescribes low-carbon intensity electricity (Low-CI electricity) can be sourced flexibility through the use of RECs or via a qualifying Green Tariff program. Therefore, AFCC and its member companies propose the following:
(i) add to the LCFS regulation a definition of the term "power-to-liquid fuel," with the term defined to mean transportation fuel that is produced from captured carbon dioxide, water, and low-carbon intensity (low-CI) electricity; and (ii) make low-CI electricity used in the production of such fuel, including power-to-liquid sustainable aviation fuel (PtL SAF), eligible for book-and-claim accounting. Indirect accounting mechanisms are warranted for the production of PtL SAF and other PtL fuels, and perhaps more importantly, would promote the scale-up of the PtL fuels industry. PtL SAF in particular has the potential to make a significant contribution to the decarbonization of California's aviation sector.

§ 95488.8(I)(3). Expanding Book and Claim to low CI Hydrogen used in FCVs and alternative fuel production for use in transportation
1. Book and claim for low CI hydrogen injected into dedicated pipelines of hydrogen, which are physically connected to California.
2. Such hydrogen can be used in direct transportation or in the further process of production of alternative fuel.
3. CI of hydrogen for Well to Wheel Analysis is defined as <= 55 gCo2e/MJ (CI-45) for gaseous H2 and <= 95 gco2e/MJ (CI-79) for liquid hydrogen if transported as liquid before pipeline injection.
4. All the projects operational post Dec 31, 2023 are eligible for book and claim.

360.10 *It is recommended that under Book and Claim for hydrogen the requirement of demonstration of deliverability to take effect from Jan 1st, 2041, similar to RNG criteria.*

360.11 **§ 95491 (d)(4)(D). Book and Claim accounting for Low-CI electricity used in production of Hydrogen and direct air capture projects**

1. Low-CI electricity supplied by new or expanded low-CI projects that begin production on or after January 1, 2024, or
2. Within three years of the start of the hydrogen production facility or direct air capture project, whichever is later.
3. Book and claim accounting at qtrly matching, any unmatched CI electricity quantities produced will expire for LCFS reporting.

It is recommend: The carbon intensity of grid-sourced electricity to be evaluated according to the generation portfolio of the PPA (power purchase agreement) without regard to the Three Pillars (Incrementality, Temporal matching, Deliverability).

Electric power requirement for thermochemical conversion pathway, including balance-of-plant, is substantially less than the power required for other pathways. Considering the energy of the product, hydrogen fuel, the majority comes from feedstock (MSW). GHG emissions associated with process energy inputs (grid power) shall be included in the lifecycle hydrogen CI. Technology improvements will result in further efficiencies including industrial heat recovery and sharing.

360.12 **Renewable Natural Gas (RNG) – Importance of the Transportation Market Segment to Avoid Phase Out for Biomethane and Hydrogen**

The CARB proposed amendments seek to phase out avoided emission pathways for projects that break ground after December 31, 2029, for biomethane used as a transportation fuel through 2040 and for biomethane used to produce hydrogen through 2045. While we understand that CARB's intention here is to begin to transition biomethane away from the transportation sector – this will have impact on both short term and long term investments, and the underlying rational is being construed by some as science-driven rather than a policy decision concerning the phase out of combustion in transportation. AFCC and its member companies do not support the phaseout of avoided emission credits. CARB should be explicit that the policy decision to discontinue recognition and eligibility of avoided methane emissions in vehicle pathways should not be interpreted as a departure from the established rigorous science of accounting for the benefits of avoiding methane emissions which continues to be appropriate for non-vehicle sectors. AFCC and its member companies recognize that avoided emission credits for biogas to electricity projects remain, and applaud CARB for recognizing the value of these projects by proposing to retain this aspect of the program.

Conclusion

360.2 cont AFCC and its member companies are requesting forest residuals or hazardous fuels to be treated as carbon neutral feedstocks for producers of biofuels. We respectfully ask CARB to have consistency in its regulatory development of standards to that of other states, federal agencies, and international policies, for ease of adoption, and not create market confusion.

Sincerely,

Rina Singh, PhD.
Executive Vice President, Policy
Alternative Fuels & Chemicals Coalition

Re: Clearing Service Provider Five-Day Rule Amendment

Xpansiv, through an affiliate, acts as an Account Administrator for Minneapolis Grain Exchange's Clearing Service Provider Account in the LCFS Program. Xpansiv is submitting these comments in its capacity as market operator for the CBL Platform, which provides a venue for participants to transact LCFS Credits.

Dear Ms. Sahota,

Xpansiv operates the market infrastructure to rapidly scale the world's energy transition. The company runs the largest spot exchange for environmental commodities, including carbon credits and renewable energy certificates. It is the premier provider of registry infrastructure for energy, power, and environmental markets and operates the largest independent platform for managing and selling solar renewable energy credits in North America.

Last year, Xpansiv partnered with the Minneapolis Grain Exchange ("MGEX"), an eligible Clearing Service Provider ("CSP") under § 95483.1(a)(3) in the LCFS Regulation, to launch the first exchange traded spot LCFS contract on the CBL Platform ("CBL"), where MGEX holds participants' LCFS credits in its LRT-CBTS account that are transacted on CBL. The contract launched in July 2023 and has been well received by the market with over 175,000 LCFS credits cleared across a diverse array of counterparties.

While the market has responded positively to the contract, Xpansiv has observed, in its role as operator of CBL, operational challenges that limit participation and create barriers to adoption.
361.1 As a result, Xpansiv would like to re-submit comments encouraging the ARB to reconsider the requirement that a clearing service provider only hold LCFS credits for up to 5 days in the LRT-CBTS for spot exchanges.

Provision § 95483.1(a)(3)(B) restricts CSPs to holding LCFS credits in an LRT-CBTS account for "up to five days". We believe that an extended holding period would provide participants with an increased opportunity to leverage an exchange to market their credits. In the 2018 Final Statement of Reasons, CARB noted, in response to CBL's comments, that "five days are sufficient to facilitate a transfer" and would "minimize the time period during which credits are locked out of a credit market". As a spot exchange where buyers and sellers transact credits, CBL provides a platform where market participants can access liquidity in the market, as

361.1 cont. opposed to getting "locked out" of it. Approved Participants log into CBL to actively market their LCFS credits. In many instances, the process of listing orders, negotiating, matching with a counterparty, settlement and delivery, takes longer than five days. The CSP account holding period not only covers "facilitation of transfer" of LCFS credits, but the entire lifecycle of a transaction. In addition, participants leverage the CBL LCFS spot contract to set and maintain active bid-ask spreads and hedge their LCFS credit positions in a transparent and efficient way. This requires LCFS credits to be held in a CSP account for longer than five days. The inability to do so has disrupted market participants' ability to make a consistent market during all trading hours, resulting in a less liquid marketplace.

We suggest amending § 95483.1(a)(3)(B) to read "A clearing service provider cannot own credits but can hold LCFS credits for up to thirty days for clearing purposes only." This maintains a reasonable time limit on credit holdings, but also gives participants flexibility in marketing LCFS credits through a spot exchange-based medium. We believe this adjustment will allow firms more flexibility to assess market conditions and utilize an open and competitive marketplace for trade execution and price discovery. This would result in a more liquid marketplace, which benefits all LCFS participants.

We appreciate the California Air Resources Board's ongoing efforts to continue to assess and improve this market-based mechanism. The proposed modification would help enhance an already successful program that is setting the standard for similar regulated low carbon fuel markets across the Americas.

Xpansiv respectfully submits these comments for consideration and thanks the California Air Resources Board for the opportunity. Please direct all follow-up questions and inquiries to policy@xpansiv.com.

Respectfully,

Yaniv Lewis

RE: Rulemaking Regarding Amendments to LCFS

The Brazilian Sugarcane and Bioenergy Industry Association (UNICA) appreciates the opportunity to submit feedback on the proposed amendments to the Low Carbon Fuel Standard being considered later this year.

UNICA applauds California policymakers who have long led the nation on environmental conservation and climate change. The current deliberations over the future of the LCFS again reflect innovative thinking and continue the state's tradition of introducing change that can change the direction of the nation. It is in this spirit that we share our unwavering belief that our product is part of the carbon-reducing vision you seek. California was thoughtful in 2011 when it put biofuels to work. California's climate policy reach goes way beyond the west coast geographic limits, so today, perhaps more than ever, CARB's technical evaluation of biofuels needs to be fair for the different sources of energy, especially those willing to bring in scientific evidence to support their claims.

With this in mind, we only ask that in your deliberations that Brazilian ethanol is scored fairly and accurately so that California residents can continue to enjoy the environmental benefits derived from the world's more efficient, environmentally friendly biofuel. A careful review of the data will again demonstrate that Brazilian ethanol should continue contributing to the state's climate goals, not only in road transportation, but in hard to abate sectors, with the use of sugarcane advanced fuels for sustainable aviation fuels (SAFs) and hydrogen technologies.

As reflected in the staff report, there is a significant opportunity for emissions reduction in the aviation sector and UNICA is well positioned to supply this transition. Meeting this demand requires building out significant new supply capacity, and with appropriate LCFS incentivizes and collaboration among the world's largest ethanol producers we are confident that California can provide proof of concept and market leadership for the global economy.

362.1 We respectfully request that the update of the factors/ inputs presented below are included in the rulemaking process, not only because there is new data and scientific literature to support them but to give Brazilian biofuels a fair score in the LCFS program, which will help with the state's carbon neutrality goals. The items UNICA would like to request to be updated are summarized here. A detailed explanation along with supporting references follows below.

INPUT	ASK
Primary Farming Data	Update farming input values based on truly verified primary data
Farming Energy + Mechanized Harvesting	Update mechanization to a conservative 95% rate in all states of the Center- South region of Brazil
Straw Yield	Update straw yield to 140 kg (dry) per ton of sugarcane (fresh weighted), in line with re- cent literature
N2O from Applied N	Update values to 0.006 kg-N20-N/kg N-fert applied according to Tier2 evidence.
N2O and CH4 from vinasse transportation	Eliminate emissions of N2O and CH4 from vi- nasse transportation
Credits for electricity surplus	Credits from electricity surplus must con- sider the marginal (natural gas, diesel) in- stead of average of the grid
Logistical Routes	Allow Brazilian mills to register different routes with different CIs
Maritime Backhaul Penalties	Reduce or eliminate backhaul penalties, subjecting maritime logistics to the verification procedures
Regenerative Agriculture	Recognize climate-smart agriculture techniques for crop-based biofuels, including in Brazil
By Products Optimization	Establish credit values for displacement of natural gas by biomethane

Sugarcane Farming Data – update farming input values with thoroughly verified primary data, differentiating production patterns in the US and Brazil.

Inspired by LCFS the RenovaBio program developed the most complete and updated database on biofuels production patterns in Brazil. The RenovaBio Program is a national policy guided by three strategic axes: 1) Decarbonization Targets; 2) Efficient Biofuel Production Certification; and 3) Decarbonization Credit (CBIO). In the first axis, each year, the government sets national targets for ten years, which are cascaded down to the fuel distributors, who are the obligated party of
362.1 cont the policy. In the second axis, producers voluntarily certify their production and receive, as a result, energy-environmental efficiency scores (NEEA). These scores are multiplied by the volume of biofuel sold, which results in the amount of CBIOs that a given producer may issue and sell in the market, which is the third axis.[1]

The biofuel certification process follows several steps to ensure the reliability of the NEEA and of the program. First, the producers collect and organize information on agricultural and indus- trial phases to be ascribed into a GHG calculator (RenovaCalc) developed by the National Agency of Petroleum Biofuels and Natural gas (ANP). Each input data needs to be traceable and verifiable

[1] ANP. Renovabio - https://www.gov.br/mme/pt-br/assuntos/secretarias/petroleo-gas-natural-e-biocombustiveis/renovabio-1

(up to the farm level) since each value will be audited in a third-party verification process by companies registered and accredited by ANP[2]. A detailed certification protocol has been published by ANP to assure the reliability and homogeneity of the information. After that, the application is submitted to public consultation and then is verified by ANP before the NEEA is approved and the biofuel is certified.

The certified NEEA is valid for three years, after that the biofuel producer must submit a new certification process again. Also, to remain active and in compliance with the program, producers are required to update the calculator yearly.
It is important to clarify that for the biofuel to be considered eligible, the area of cultivation of the raw material that originated it must meet three criteria:

1. No deforestation of native vegetation after Dec/2017 (validated by satellite images).
2. The Rural Environmental Registry (CAR) must be valid.
3. The cultivated area is in a municipality listed in the Agroecological Zoning of the crop.

As for the reported information regarding the inputs used in the biomass production phase, these have two distinct origins, namely:

Primary data: areas where the raw material is cultivated, whose reported data on the inputs were confirmed through the presentation of documentation in the external audit process carried out by the inspection firm.

Standard penalized input: areas where the raw material is cultivated, which could not be proved through the presentation of documentation. These areas, as long as they meet the eli- gibility criteria, will have default input values assigned, which severely penalizes the final car- bon intensity of biofuels in relation to the primary data.

The information requirements are similar (and were inspired by) to GREET modeling approach and include farming inputs (fertilizers, energy by type), industrial inputs, and yields. . It is important to notice that cherry-picking is not allowed in RenovaBio; each producer must inform and verify the complete set of production indicators to be considered in the primary data.
As mentioned to staff during the August 18th workshop, UNICA has organized one of the most extensive database on production patterns in Brazil. The data presented in this database were collected directly from the 97 production units with the Biofuel Production Certification who agreed to share their annual monitoring spreadsheets, exposing their primary information. Thus, the values presented refer only to the portion of the cultivation areas whose proof was possible. These companies represent about 43% of ethanol production in Brazil in 2018 and 2019.
As CARB is aware, Brazil has also stated production of ethanol from multicropping. This production pattern is different from corn ethanol produced in the US, including using inputs. Cur- rently LCFS does not have such a production pattern registered in CA-GREET. We understand this is an important update in the CA-GREET tool as well.

362.2 **Mechanized Harvesting** – update the mechanization to a conservative rate of 95% in all states of center-south of Brazil.

Mechanization has significantly expanded in the last decade and now represents more than 95% of the total harvested area in the Center-south. This information is supported both by official governmental data and by RenovaBio primary data collected and audited (afore-mentioned database). CARB cannot keep ignoring such evidence. Mechanization has dramatically reduced emissions in sugarcane fields, and mills should be recognized for this progress. Brazilian biofuel

[2] ANP. List of the accredited inspection companies - https://www.gov.br/anp/pt-br/assuntos/renovabio/arq/firmas-inspetoras-credenciadas.xlsx/

producers who have made significant technological investments should not be penalized by lower default assumptions.

In the Tier1 sugarcane ethanol calculator, CARB offers two default values for sugarcane mechanization for Brazil: 80% for São Paulo state and 65% for other states in the Center-South region.

362.2 cont

According to Conab (Brazilian National Supply Company), during the 2022/23 in the Center- South region of Brazil, 2.73% of the sugarcane was manually harvested. This rate has been below 10% since 2015/16. The Center-South region supplies more than 85% of all the sugarcane produced in Brazil.

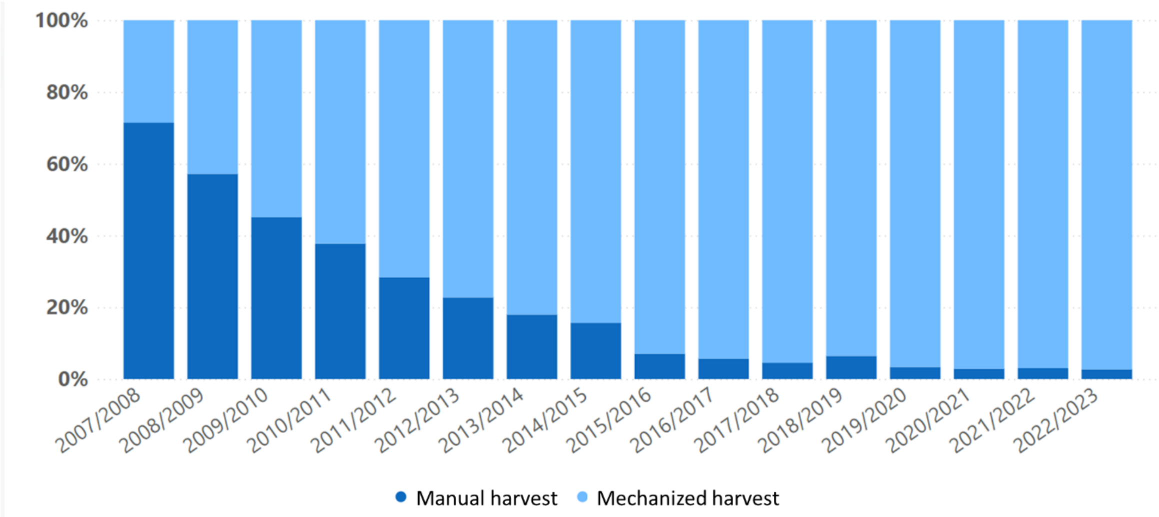

Figure 1: Ratio of manual and mechanized harvest in the Center-South region of Brazil.
Source: CONAB (Observatório da Cana)[3]

We again urge CARB to offer an option for self-declared mechanization percentage in the Tier 1 CI calculator. If for some reason this is not feasible, we respectfully ask staff to adjust the default
362.2 cont mechanization values for Center-South Brazil to a value no lower than 95%. By doing so, CARB will be scoring input more closely to actual practice and will most likely avoid Tier 2 application requests from Brazilian mills, saving time and financial resources for both the Agency and the mills.

Straw Yield –
The CA-GREET3.0 calculator (sheet: Fuel_Prod_TS cell: CI269) considers a straw yield of 0.28 wet ton straw per tonne cane; wet straw containing 15% moisture. Our specialists were unable to identify the source of this combination of values, which leads to a dry straw yield of 0.238 dry
362.3 ton straw per ton cane.
Scientific literature is consistently indicating the ratio of straw (tops and leaves) to cane stalks of about 140 kg (dry) per ton (fresh weight)[4,5], which is equivalent to 0.47 kg (dry) per kg (dry). More recent studies[6], on the other hand, have quantified the straw availability as 120 kg (dry) per ton (fresh), thus resulting in a 0.4 kg (dry) per kg (dry) ratio.

362.4 **N2O from applied N** – revise the Ratio of N2O – N ration from applied fertilizer to 0.6%, according to regional scientific evidence.

362.4 cont Currently CA-GREET 3.0 considers 0.01 kg-N2O-N/kg N-fert applied (IPCC recommendation). Independent studies found that the emission factors for regional-specific conditions (Tier 2) on the direct GHG emissions for sugarcane in Brazil are usually below the IPCC Tier 1 default value[7] due to the good drainage properties of the deep Oxisols, where sugarcane is commonly cultivated in Brazil. Carvalho et al. (2021)[8] developed an extensive work with field experiments combined with a thorough literature review. Its recommendation for the sugarcane ratoon, which receives most of the N application of the sugarcane areas and represents 4/5 of the sugarcane cycle, the average N2O–N EF from N fertilizer is 0.60%.

362.5 **N2O and CH4 from vinasse transportation** – eliminate such emissions.
CA-GREET 3.0 considers CH4 and N2O emissions from open channel transportation of vinasse, with an impact of approximately 0.24 gCO2e/MJ ethanol. Even though vinasse unlined tanks and open channels feature conditions that may lead to methane emissions (N2O emissions are very low), such transportation strategy does not reflect the regulatory conditions of vinasse logistics in Brazil. Regulations in the state of São Paulo, for example, have established back in 2005 schedules for impermeabilization of vinasse tanks and channels [9] . Furthermore, mills have also adopted systems based on closed tanks and pipes, which further reduce methane emissions during vinasse transportation[10]. Therefore, we recommend CARB to disregard CH4 and N2O emissions from open vinasse channels as a representative condition considered in CA-GREET as such conditions does not represent real practice.

362.6 **Credits for electricity surplus** –
One important revision is the value of electricity surplus credits kg CO2eq/MWh for sugarcane ethanol. The surplus electricity from sugarcane mills plays a fundamental role in the Brazilian electricity mix. Hydropower, which relies on water reservoirs and rainfall regimes, accounted for most of the electricity production in Brazil. Hydroelectric environmental restrictions often push the electric system to other sources (such as natural gas, or diesel) with much higher cost and emissions, but more reliability.
The periods of heaviest use of high-cost electricity sources are marked with “red flags,” as presented in figure 1. This occurs in the dry season (winter), when the reservoir levels of the hydro- electric plants are low, and the sugarcane harvesting is at its highest levels, avoiding the use of oil and natural gas power plants.

---

[7] The default value for EF_1 has been set at 1% of the N applied to soils or released through activities that result in mineralization of organic matter in mineral soils. But in the 2019 Refinement to the 2006 IPCC Guidelines, alternative emission factors, disaggregated by climatic zone and fertilizer type, are provided. In wet climates, the default value has been set at 0.6% of organic N inputs and 1.6% of synthetic N inputs. For $Frac_{LEACH-(H)}$ and EF_5, the new aggregated default values are 0.24 and 0.011, respectively.

Source: UNICA (2019)[11]

Therefore, the correct assumption to calculate electricity credits in Brazil is using electricity at the margin. This approach was taken by CARB in the initial regulation and should be reinstated.

362.6 cont

Further, in Tier1 applications CARB is excluding export electricity credits generated in the off-season months from sugarcane ethanol CI calculations. Mills in Brazil have the option to store their own bagasse to produce electricity to be used in the off-season months to be exported to the grid, avoiding other more polluting sources from being tapped for energy. Brazilian sugar-cane ethanol should not be penalized for this practice, and we urge CARB to reconsider this assumption and allow the use of these credits by Brazilian mills, especially considering that the calculator already backs out the electricity exports eventually generated from third party bio-mass, which excludes the possibility of gearing.

Allow optimization in international transport: Registration of more than a single logistical route for the same facility

Due to the geographical location of Brazil and some methodological choices made by CARB, logistics represent an important share of sugarcane ethanol emissions in the LCFS. The Tier 1 calculator does not allow for a mill to register more than one logistic route with different CIs. Due to this restriction, mills must register the most conservative logistical route.

362.7 As a result, there is no benefit in choosing the most optimized logistic with lower CI. This is an unnecessary burden for the LCFS program (and ultimately to Californians) and does not help to guide better decisions considering their environmental costs.

Further, we understand there is precedent for this pledge in the LCFS program, as one single mill can register more than one pathway. In at least one case, a single renewable diesel facility has different CIs depending on the origin of its feedstock. Similar flexibility seems to be granted for RNG from manure. We would very much welcome the opportunity to engage in this discus- sion with staff.

As we mentioned below, maritime and onshore logistics can be easily tracked, particularly now that LCFS has third party verification. This also applies to pipeline logistics, which represents

[11] UNICA, “A bioeletricidade da cana,” 2019, [Online]. Available: https://www.unica.com.br/wp-content/uploads/2019/07/UNICA-Bioeletricidade-julho2019-1.pdf.

362.7 cont much lower emission levels than the direct alternative in Brazil (trucks) but not currently captured in the modeling.

Maritime Transportation – backhaul

Evidence shows that back-haul penalties for maritime transportation of Brazilian ethanol to California is significantly overestimated. CARB’s assertion that ocean tankers bringing ethanol fuel from Brazil to California will return empty to Brazil lacks evidence. CARB made clear that back-haul emission penalty is due to an overly conservative approach in case such empty (unlikely) return trips happen in the future so it can treat all biofuels fairly.

362.8 As previously mentioned, different UNICA member companies have tracked the vessels that transport their fuel to California and verified that they do not return empty to Brazil. Those companies traced at least 20 vessels from 2019 and 2020 shipments. The information provided by vessel´s operators corroborate to our explanation about logistics regarding oil/chemicals ships discharging ethanol in California, that they do not travel back empty to Brazil in any circumstances. They normally reload in the same port or somewhere else around US West Coast. If no option there, they usually load Vegoils out of Vancouver, or even Gasoline and Diesel in Central America. In the last case, they move to the Golf Coast to load chemicals like Styrene, EDC, Caustic Soda and others.

As for the logistics before loading in Brazil, our country is a net oil products (derivates) importer, as our national refining capacity is much lower than the local demand for fossil fuels, mainly diesel and gasoline. Also, Brazil imports a significant amount of ethanol annually. This scenario results in an over-supply of ships available for loading ethanol to exportation in our main ports. The reason is that these ships bring much more oil products and ethanol to Brazil than the amount of fuel we export. The graphs below illustrate the Brazilian balance for the export and import of oil products and ethanol.

Figure 3: Brazil´s Import and Export of oil products derivates, in millions of liters, from 2010 to 2019.

Source: ANP 2020 (Oil and gas national agency)

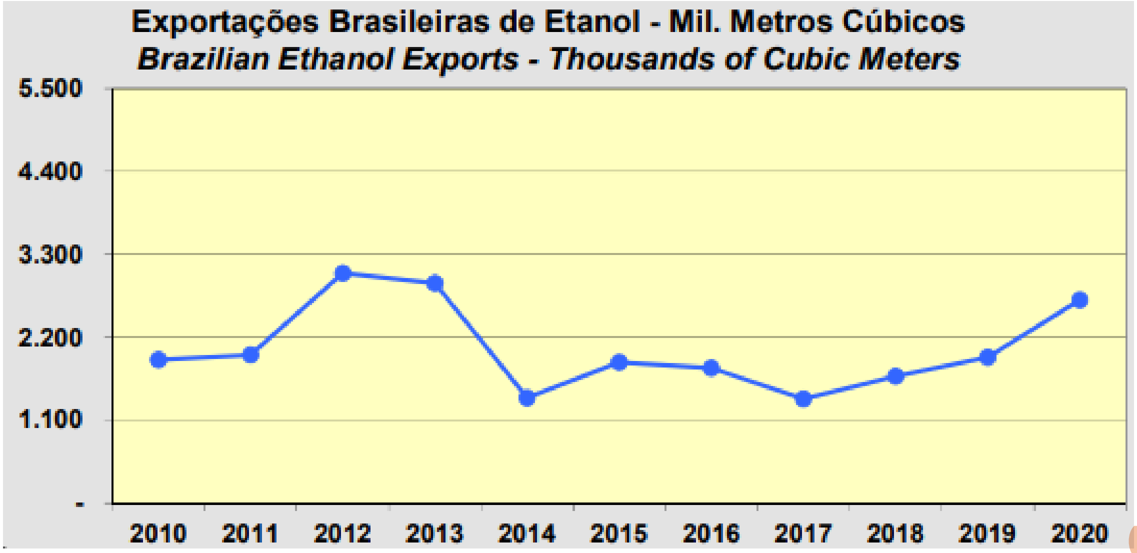

Figure 4: Brazilian Ethanol Exports, in millions of liters, from 2010 to 2020.
Source: UDOP 2020 – Bioenergy National Union

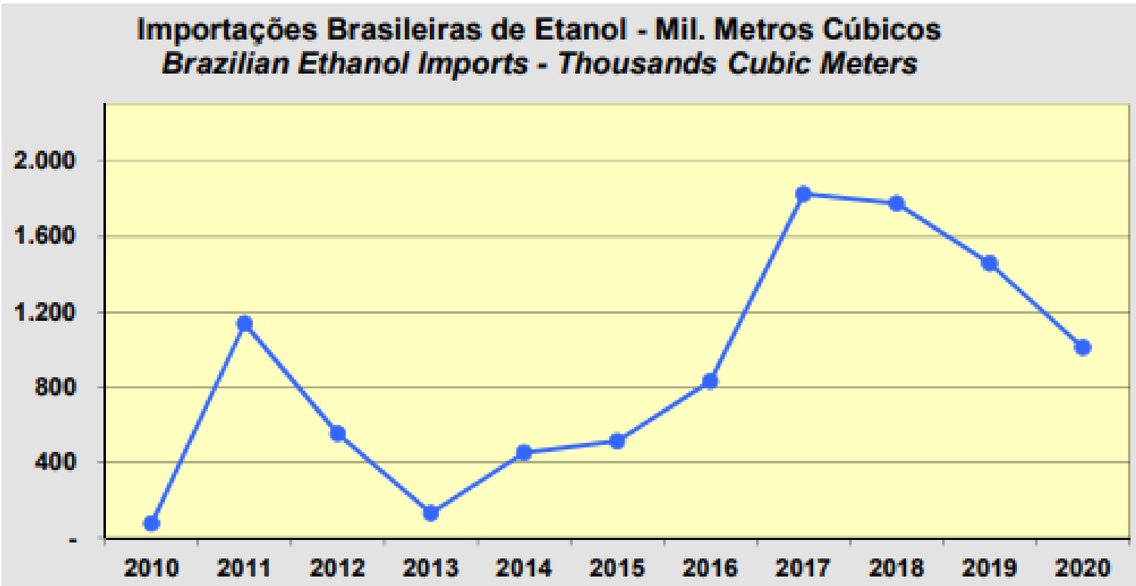

Figure 5: Brazilian Ethanol Imports, in millions of liters, from 2010 to 2020.
Source: UDOP 2020 – Bioenergy National Union

Taking the year of 2019 as reference, Brazil has imported 36.8 and exported 13.7 billion liters of oil products, resulting in a 23.1 billion liters deficit of oil products. Also, Brazil has imported around 1.5 and exported 1.77 billion liters of ethanol. This shows that a significantly higher volume of fuels (oil derivatives) arrives in Brazil rather than leave the country annually, corroborating to the scenario stated by our mill's shipping chartering team and vessels operators
362.8 cont that there is an over-supply of liquid fuel ships in Brazil.

It means that Brazilian fuel supplier companies do not need to hire empty vessels from overseas to export their products. These vessels are constantly available in our ports (mainly Santos port) and they have preference to load ethanol or oil products at the same port where they are discharged in Brazil than travel to another place to load again due to the simple fact that this is more economically attractive.

Assuming the energy consumption and associated emissions of the ocean tanker's round trip be attributed to sugarcane ethanol is speculative and arbitrary. This approach causes a tremendous damage to Brazilian ethanol competitiveness in the California market.

362.8 cont We urge staff not to impose backhaul penalties on Brazilian sugarcane ethanol, since these penalties are not supported by data or shipping practices. Maritime logistics can be easily tracked, particularly now that the LCFS has third party verification, and the agency should defer to verification bodies to make a decision on such penalty, based on their traced data.

362.9 **Recognize climate-smart agriculture practices in Brazil.** Allow for gains in Soil Organic Carbon (SOC) that are supported by scientific literature and verifiable.

From Agroecological Zonings to the current Sao Paulo state's Greener Ethanol Protocol, there are several initiatives to consolidate and advance sustainable management practices in the sugarcane sector in Brazil. We now have a far greater understanding of the changes in C stocks when climate-friendly management practices such as no till, crop rotation, conservation of riparian vegetation, sugarcane green harvesting, pasture recovery, and integrated systems are adopted. Unfortunately, most land use models (including the GTAP-AEZ_EF) didn't incorporate those improvements, nor did the LCFS. Although updated versions of those models should include scientific evidence in their structure, those gains can also be recognized at the field level using accurate indicators. Here we present evidence on the positive impacts of green harvesting compared to "burned fields" baseline and multicopying against "single cropping".

Sugarcane green harvesting

In areas previously occupied by sugarcane, changes in SOC for sugarcane depend on the harvesting technique. Sugarcane fields are replanted only after 5-6 years; thus, "perennial crop" is a better representation than "long-term cultivated crop" of all harvesting techniques. In contrast to traditional manual harvesting systems (where cane used to be burned in the pre-harvest), green harvest system can uptake as much as 1.02 to 1.87 Mg C ha-1 year-1 in topsoil when compared to areas under the traditional pre-harvest burning practices (La Scala Jr. et al., 2012[12]). Recent studies have shown a positive correlation between post-harvest straw maintenance and increased soil carbon content in Brazil (Cerri et al., 2014[13]; Ferreira et al., 2016[14]; Carvalho et al., 2017[15]; Bordonal et al., 2018[16]). According to a study developed by Ferreira et al. (2016), sugarcane absorbed 7.6 kg ha−1 of N (average of two sites) from the straw after 3 years of maintenance in the field Cerri et al. (2014) analyzed the impact of burning and unburned sugarcane straw on soil carbon content in two areas cultivated with sugarcane in the municipality of Ribeirão Preto-SP, one with clayey soil and another with sandy soil. The authors observed that in the clayey soil area, the unburned cane system stored 6.5 t C more than the burned cane system in the 0-20 cm layer. Even in the sandy soil environment, the increase was 4.87 t C/ha (Cerri et al., 2014). The authors conclude that preserving plant biomass makes it possible to sequester C in the studied soils. Carvalho et al. (2017) evaluated the impacts of sugarcane residue removal on soil C stocks in two areas of the state of São Paulo. In one of the sites, soil C stocks were reduced with the total removal of shoot residues, while the partial removal of sugarcane residues did not reduce soil C stocks in any of the areas (Carvalho et al. al, 2017).

Multicropping

La Scala et al. (2012) reviewed on the accumulation of SOC due to the change in the management of the main Brazilian agricultural activities[17]. The study review indicates that in soybean-corn and related rotation systems, there is significant soil carbon uptake throughout the year of conversion from conventional practices to no-till, with an average rate of 0.41 Mg C ha-1 yr-1. According to Dieckow et al. (2005, cited by La Scala et al., 2012), the main factors that contribute to the accumulation of C in the soil of annual crops are no-tillage and crop rotation with leguminous plants, which remove atmospheric nitrogen through a symbiotic interaction, leaving large amounts of dry matter on the soil surface. Petter et al. (2017) evaluated the effect of different agricultural management systems on carbon stocks in Latosols in southern Amazonia, in the Brazilian state of Mato Grosso[18]. The authors emphasize that the "management systems traditionally used in the Cerrado region characterized by the cultivation of soy monoculture and/or soybeans in the summer with second crop corn may not be sufficient to maintain C stocks in the Amazon", but the soybean-corn rotation system showed higher C stocks than the single soybean.

By-Products Optimization

362.10

The use of new technologies in the sugarcane industry has advanced significantly in recent years, especially regarding the potential to extract the energy content of its by-products, wastes and residues. A great example of this is the production of biogas from vinasse and filter cake, whose energy content of these residual raw materials can be extracted via the metagenesis process, without removing its nutritional characteristics, which are reused in sugarcane fields. In turn, the generated biogas can be purified and produce biomethane, a renewable gas that can directly replace natural gas in several industrial processes, or even diesel in automotive vehicles.

In this context, new investments for the energy reuse of sugarcane by-products can be unlocked with the support of decarbonization programs such as LCFS/CARB, and thus provide greater potential for reducing carbon emissions globally and support the program itself on reaching its carbon intensity reduction targets smoothly and within potential lower costs than other unproved technologies.

For that, we asked CARB to recognize the reduction of carbon emissions generated by sugarcane by-products when displacing a fossil fuel, through the sugarcane- ethanol CI´s reduction. In our understanding, this recognition is provided for in the life cycle analysis methodology through the expansion of the LCA system´s boundaries, based on the con- sequential approach used by LCFS/CARB

***

We appreciate the opportunity to submit this feedback and we look forward to discussing with CARB staff the improvements to the scoring methodology in this upcoming rulemaking pro- cess. You can count on our continued support.

Sincerely,

Julia Tauszig

Re: Anew Climate Comments Regarding the Proposed Amendments to the Low Carbon Fuel Standard as outlined in the Staff Report: Initial Statement of Reasons, published on January 5, 2024

Dear Mr. Botill:

Anew Climate, LLC ("Anew") is one of the largest climate solutions providers in North America and has an established track record of participating in California's various sustainability programs, including the Low Carbon Fuel Standard ("LCFS"). We commend the California Air Resources Board ("CARB") and its staff for its successful implementation of the LCFS, driving the decarbonization of California's transportation sector, and proposing amendments to the LCFS in response to the 2022 Scoping Plan Update. The LCFS has a significant role in helping California achieve its ambitious climate goals and we appreciate the opportunity to provide comments on the proposed amendments as outlined in the Initial Statement of Reasons ("ISOR").

Increased Program Ambition and Timely Implementation of a Step-Down in CI Targets Are Critical to the Success of the LCFS

Given the LCFS credit surpluses generated over the last two years, a significant and near-term step-down in the Annual Carbon Intensity (CI) Benchmarks is critical. Based on available market information to date, the LCFS credit bank will continue to grow in 2024 as more credits are being generated than are needed to meet the current CI benchmarks. This will cause the market to stall or even fall further, undermining a key goal of the program - to incentivize investment in low-carbon fuels and fuel technologies.

363.1 A significant step-down in CI benchmarks as soon as possible is the only feasible way in the near term to prevent continued building of the credit bank. In addition, we recommend a step-down of at least 7% to a level of at least 20.75% below the 2010 baseline.

In response to the recent over-performance in the LCFS market, staff proposed a one-time step-down in the form of a 5% reduction in carbon intensity beginning in 2025. In the ISOR, CARB noted accurately that "[a] step-down in stringency was strongly supported by feedback provided by stakeholders, particularly in response to February and May 2023 technical workshops. The step-down reflects the current effectiveness of the program, which suggests that the pace of CI reductions can be increased through the benchmarks."[1]

Given the ongoing overcompliance and related realities in the market, many groups initially urged CARB to target an implementation date of no later than January 2024. CARB subsequently invited comment on a potential mid-year 2024 implementation date, which we supported in our previous comments and still support today to the extent feasible. We understand the complexities involved with modeling revisions to the LCFS program and developing proposed amendments and appreciate CARB's continued efforts to conclude this process in the near future. Given the dramatic oversupply in the market, implementation of a step-down as soon as possible is critical to the integrity of the market going forward. Near-term action by CARB would send a strong signal that California remains committed to rapid decarbonization of its transportation sector and that investments in low-carbon fuels continue to be adequately rewarded and incentivized in California.

We agree with other stakeholders that a **step-down of at least 7% to a CI reduction level of at**
363.1 **least -20.75% in 2025 over the 2010 baseline** is appropriate and necessary to create the desired
market response for market impact. We believe this is one of the most consequential and important steps CARB could take in this rulemaking process and it is vital to the future of the LCFS program.

We Support a 30% or Greater Reduction in Carbon Intensity by 2030

While we would also support a higher CI reduction target, we recognize that a reduction scenario of at least 30% would help set California on a path to meet its ambitious target of at least a 40%
363.2 reduction in economy-wide GHGs by 2030 and carbon neutrality by 2045. Strong CI reduction
goals will continue to accelerate carbon reductions in the transportation sector while establishing clear market signals that will drive innovation and investments.

We Support Tightening the Automatic Acceleration Mechanism

We have consistently supported the concept of creating an automatic adjustment mechanism ("AAM") as a tool within the LCFS and appreciate the inclusion of the AAM in CARB's proposal. We urge CARB to design the details of the mechanism to ensure that the AAM is triggered when the market truly needs it.

The AAM should be amended such that it could be triggered as soon as 2026 if the applicable trigger conditions are met. Additionally, the AAM should be triggered when both the "Credit
363.3 Bank to Average Quarterly Deficit Ratio" exceeds 2.5 and the annual credit generation exceeds
the annual deficit generation for the compliance year preceding the year of the May 15 announcement.

Additional RNG-Related Comments

Anew appreciates the many occasions on which CARB staff has explicitly reiterated the Board's support for RNG throughout the informal workshop process and in the ISOR. If CARB truly wants methane abatement from sources such as agricultural wastes to continue, this rulemaking must

[1] California Air Resources Board, Initial Statement of Reasons ("ISOR"), January 5, 2024, p. 25

convince the clean fuel investment community that RNG will remain a viable and important contributor to the LCFS framework.

Despite assertions to the contrary, there is no credible evidence that decarbonization programs like the LCFS incentivize the growth or consolidation of large dairies or other concentrated animal feeding operations ("CAFOs"). Even skeptical academic experts studying this issue have found no empirical evidence to support the "perverse incentive" claims made by some opponents of avoided methane crediting.[2] Anew is partnered with swine and dairy farmers who are committed to reducing emissions from their waste products. Our direct experience aligns fully with what the data indicates: decisions around development and operations in the dairy and swine livestock sectors are firmly driven by strategic intent to maximize current and future value in the meat and milk markets, while maintaining strong environmental stewardship – not by increasing RNG value or an intent to incur additional waste production.

As Americans consume meat and dairy products, the companies developing RNG projects are investing at-risk capital to abate emissions from the waste products of an essential industry. The capture and conversion of methane creates undeniable and immediate climate benefits. The LCFS today correctly recognizes RNG from agricultural digesters as an impactful methane abatement opportunity for lowering GHG emissions of livestock operations – we urge CARB to stay the
363.4 course towards realizing the full climate benefit of the substantial investments made to date and providing investors with the clarity and confidence necessary for continued development.

Avoided Methane Crediting Phase-Out

Methane is the second-largest contributor to global warming after carbon dioxide due to its alarmingly high concentration in the atmosphere and the fact that it is a potent greenhouse gas (GHG) with impact over 80 times greater than carbon dioxide over a 20-year period. The critical need to address methane as a potent short lived climate pollutant was well stated in CARB's 2017 Short Lived Climate Pollutant (SLCP) Reduction Strategy and echoed by other leading authorities. There is no more effective or immediate step that can be taken to address climate change than aggressively and rapidly reversing emissions of fugitive methane from all sectors, including society's organic waste streams.

We therefore strongly urge CARB to refrain from imposing an arbitrary end-date for avoided
363.5 methane crediting. Any such measure would not only hinder continued investment into methane abatement at farms that LCFS has been instrumental in catalyzing, but also jeopardize existing RNG production assets, which are subject to significant operational expense.

Mandatory methane abatement from farming operations is not currently on the horizon either at the state level in California or at the federal level. If mandatory abatement is implemented, the current LCFS regulation already contemplates in Section 95488.9(f)(3)(B) the phase-out of avoided methane crediting for projects subject to mandatory abatement. Given the absence of mandatory methane abatement and the continued methane emissions from farming operations that

2 Smith, Aaron, "Are Manure Subsidies Causing Farmers to Milk More Cows?" April 8, 2023. Available at https://agdatanews.substack.com/p/are-manure-subsidies-causing-farmers?r=i2qe&utm_campaign=post&utm_medium=web

are meeting America's meat and dairy demands, imposing a specific date for phasing out avoided methane crediting does not make sense for the climate. Capturing methane from California's methane sources (e.g., landfills, dairies, and wastewater) is critical for achieving California's climate targets. As staff noted in the ISOR, "[…] capturing methane from dairies is one of the primary measures for achieving the state's 2045 greenhouse gas reduction targets and SB 1383 methane reduction target."[3] Without anaerobic digesters, California would not be able to meet its SB 1383 methane reduction goals. Eliminating biomethane pathways used to produce hydrogen may also unduly restrict the development of low-CI hydrogen supply that California needs in order to displace fossil fuels. Increasing the supply of low-CI renewable hydrogen is a key strategy identified in the 2022 Scoping Plan Update and supports MDV and HDV ZEVs."[4]

While we oppose putting any end-date on avoided methane crediting, we recognize that CARB has faced unsubstantiated criticism and repeated calls for an immediate or near-term phase-out. We commend CARB for taking a measured position in support of avoided methane crediting generally and opposing any near-term phase out. We strongly urge CARB to continue following
363.5 climate science on a technology-neutral basis and to maintain the framework that has catalyzed unparalleled investment into methane abatement at swine and dairy operations.

CARB Should Maintain Eligibility for Delivery of Biomethane from All Sources

Currently, the LCFS regulation allows for indirect accounting of biomethane when injected into the North American natural gas pipeline system. In the ISOR, staff proposed that biomethane projects that break ground after December 31, 2029 in which biomethane is injected into a common carrier pipeline or claimed indirectly under the LCFS program for use as a transportation fuel or input to hydrogen production must meet new deliverability requirements. Starting January 1, 2041 for bio-CNG, bio-LNG and bio-LCNG pathways and January 1, 2046 for biomethane used as an input to hydrogen production, the entity reporting biomethane must demonstrate that the pipeline or pipelines along the delivery path physically flow from the initial injection point toward the fuel dispensing facility at least 50 percent of the time on an annual basis. The stated reason for these new deliverability requirements is that these requirements would "help ensure that California is making progress on the state's methane reduction targets."[5]

We appreciate that CARB has resisted pressure to include immediate new directional flow requirements for biomethane pathways, and that the proposal would not impact any biomethane fuel pathways for projects that break ground before January 1, 2030. However, we do not agree with CARB's decision to impose directional flow requirements on deliveries from biomethane
363.6 projects that break ground in 2030 or later. Given the realities of the interconnected U.S. gas market, the 50% directional flow requirement is arbitrary and provides preferential treatment to fossil gas imported to California relative to imported RNG.

A Full Credit True Up Would Reflect the True Environmental Performance of RNG Pathways

363.7 We support the proposed inclusion of a "Credit True Up" after Annual Verification. When implemented properly, such a concept can ensure that the LCFS program correctly accounts for the full GHG benefits all fuel pathways produce. Such a true up should apply both in the case of temporary pathways, as originally proposed by CARB during previous workshops, as well as for provisional and fully certified pathways.

Biological systems such as anaerobic digesters experience substantial increases and decreases in gas production due to weather, livestock herd changes, and other factors that are not present in other fuel pathways. Because the carbon intensity of the gas from these systems is calculated against a quantity of avoided methane emissions, these variations in biogas production operating conditions result in outsized changes in the digesters' carbon intensity (CI) scores every year. Pathways should be allowed to fully "true up" LCFS credit generation to their actual CI score once that score is determinable based on actual greenhouse gas performance data.

363.8 We support the provisions in the proposed rule that provide for generation of additional credits if the verified CI is lower than the certified pathway CI based on the incrementally lower verified score using backward-looking actual performance. This true up process should be automated by CARB in the LRT-CBTS system for all fuels. 363.9 However, we do not support the Proposed Rule's approach requiring a 4x "pay back" in cases where a verified CI exceeds the certified CI. This is overly punitive and not symmetrical. Instead, we recommend that if the verified CI is higher than the certified CI, the project should simply repay CARB for any excess credits claimed, and not be subject to any further enforcement liability unless there is malfeasance or other conduct contrary to the objectives of the program.

Anew is proactively developing an updated CI management approach to ensure we continue to provide maximum value recognition potential to our partners coupled with compliance risk mitigation.

Tier 1 Calculator Improvements

363.10 Anew supports allowing fuel pathway applicants to submit site specific inputs to demonstrate fugitive emissions on the 'Biogas-to-RNG' tab as outlined in comments submitted by the Coalition for Renewable Natural Gas in response to the draft Tier 1 Calculator. In addition, Anew requests that CARB allow fuel pathway applicants to submit site specific inputs to demonstrate digester leakage emissions on the 'Avoided Emissions' tab. This would allow projects to provide actual operating values that may differ from the default values of 2% for enclosed vessels and 5% for covered lagoons.

Regarding GREET inputs for L1. (1-6).14 Retention Time and Drainage, it is Anew's understanding that in the proposed GREET calculator for each September, "System Emptied in This Month" must be selected by the fuel pathway applicant. This assumption requires that all projects model their operations to include a complete annual cleanout of volatile solids. A complete annual cleanout is currently only required as a baseline assumption for greenfield projects in Table A.10 of the Compliance Offset Protocol for Livestock Projects.

The implementation of this proposed default assumption could result in non-greenfield projects being certified with a carbon intensity that is not representative of normal operating conditions. It could also result in a project's baseline methane emission levels being set below what would have otherwise been emitted to the atmosphere. This proposed default assumption may be more applicable to the average dairy operation, but the same conclusion is not as appropriate for the average swine operation. Swine industry leaders and project operators have expressed that lagoons are cleaned out far less frequently than annually over a 10 to 15-year time frame. Therefore, on the 'Manure-to-Biogas (LOP Inputs)' tab, applicants should be able to enter the project-specific lagoon cleanout frequency for swine livestock populations in the Tier 1 Calculator. Applicants should be able to select from lagoon cleanout frequencies that are less frequent than annual and have default inputs "amortized" according to CARB's current guidance document.

363.11 As an alternative, Anew encourages CARB to consider allowing swine projects to submit their site-specific lagoon clean out frequencies as part of a Tier 2 fuel pathway registration. The annual loss in volatile solids results in a significant detrimental impact to the baseline methane emissions of swine projects and unfairly penalizes the project's CI score. Anew appreciates CARB's intention to simplify and streamline the project registration process, however, this should not be done at the expense of swine projects. To accurately reflect actual operating conditions of swine manure projects and minimize pathway registration processing time, we urge CARB to consider allowing applicants to enter actual cleanout frequencies by project in the Tier 1 Calculator.

EV Considerations

363.12 Anew is supportive of the addition of medium and heavy duty ("MHDV") Fast Charging Infrastructure ("FCI") credits. The adoption of MHDV vehicles into private fleets remains an economic challenge that LCFS crediting could help address. Given the difficulties with adoption, we believe the 50% reduction for private fleets should be eliminated. Additionally, requiring proximity to a Federal Highway Administration Alternative Fuel Corridor unnecessarily restricts private operations and should be applicable only to public infrastructure projects. The minimum power requirement of 250kW also unduly restricts private operations. Operating multiple lower power chargers overnight provides many operations with the opportunity to charge in a manner more suited to extended battery life, incur less operational costs associated with moving vehicles in and out of chargers, especially in off hours, and lower utility impact and investment requirements by spreading a lower power load over a longer period of time. CARB already envisions overnight charging based on the exception to the requirement of being within 1 mile of an AFC.

363.13 We support continuing the Light Duty Vehicle ("LDV") FCI. However, in our view, the geographic restrictions, particularly the 10-mile requirement from any fast charging station, will effectively eliminate too many of the major routes in the states and cities/towns that have a minimal amount of charging but much less than is required based on EV adoption. Geographic limitations of this nature would encourage a disproportionate amount of infrastructure in locations that have inherently low utilization and would not further the objective of increased EV adoption. As an alternative, we ask CARB to consider FCI approvals to maintain a balance between the number of publicly available fast chargers and the number of EVs registered in a given area. If CARB is looking to reduce the number of overall LCFS credits from LDVs while encouraging continued adoption, it would be more effective to remove base credits from LDVs available to the utilities and allocate them to FCI credits. This approach would directly address one of the largest barriers to continued growth of EV adoption.

We thank CARB for its important work in implementing the LCFS program. Should you have any questions about anything we have stated here or seek further clarification, please contact Randy Lack at rlack@anewclimate.com

Sincerely,

Anew Climate, LLC

Brad,Davies,brad.davies1111@gmail.com,90032,CA,"Your proposed amendments to California's Low Carbon
Fuel Standard are a climate policy failure that backslides on the state's role as a climate leader.
364.1 The program subsidizes combustion fuels to the tune of billions of dollars per year and has no place
in our toolkit of climate policies for the 2020s. There is too much on the line for our climate to
get this critical program so wrong.

Your budget proposes significant delays and cuts of hundreds of millions of dollars to vital zero-
emission transportation programs, which makes it all the more urgent to use the Low Carbon Fuel
364.2 Standard to more fully support zero-emissions transportation. Historically, California has thrown
good money after bad, and devoted 80% of the LCFS's $3 to 4 billion each and every year to combustion
technology. It would be wild to allow these funds to continue to languish on the climate sidelines,
instead of anchoring our transition to a zero-emissions future.

The world has changed a lot since the implementation of the LCFS in 2009. Unlike the 2000s, we have a
north star goal for our climate and the air we breathe: zero emissions transportation. Continuing to
invest the billions in revenue from the LCFS into harmful and polluting biofuels that end up
combusted, instead of electric vehicles powered by clean energy, hampers our efforts to fight the
climate crisis while enriching oil companies and industrial agriculture.

I urge you to correct your course and modernize the program by reflecting your consensus that the
364.1 only way to meet air quality standards is through eliminating combustion altogether, not piling on
ctd billions of dollars in lavish incentives for combustion each and every year. By focusing on real air
pollution solutions, you could add a clean air multiplier to the credits system, especially for
public fleets that transport many people at once, would deliver major benefits for California's air
364.3 quality and throw a lifeline to cash-strapped transit agencies that low-income Californians depend on
for mobility.

California cannot meet our clean air and climate goals without harnessing the power of the Low Carbon
Fuel Standard and overhauling this multibillion-dollar program for our zero emissions future. Please
act expeditiously to reform the program to achieve our state's ambitious goals."

Your budget proposes significant delays and cuts of hundreds of millions of dollars to vital zero-emission transportation programs, which makes it all the more urgent to use the Low Carbon Fuel Standard to more fully support zero-emissions transportation. Historically, California has thrown good money after bad, and devoted 80% of the LCFS's $3 to 4 billion each and every year to combustion technology. It would be wild to allow these funds to continue to languish on the climate sidelines, instead of anchoring our transition to a zero-emissions future.

The world has changed a lot since the implementation of the LCFS in 2009. Unlike the 2000s, we have a north star goal for our climate and the air we breathe: zero emissions transportation. Continuing to invest the billions in revenue from the LCFS into harmful and polluting biofuels that end up combusted, instead of electric vehicles powered by clean energy, hampers our efforts to fight the climate crisis while enriching oil companies and industrial agriculture.

I urge you to correct your course and modernize the program by reflecting your consensus that the only way to meet air quality standards is through eliminating combustion altogether, not piling on billions of dollars in lavish incentives for combustion each and every year. By focusing on real air pollution solutions, you could add a clean air multiplier to the credits system, especially for

public fleets that transport many people at once, would deliver major benefits for California's air quality and throw a lifeline to cash-strapped transit agencies that low-income Californians depend on for mobility.

California cannot meet our clean air and climate goals without harnessing the power of the Low Carbon Fuel Standard and overhauling this multibillion-dollar program for our zero emissions future. Please act expeditiously to reform the program to achieve our state's ambitious goals."
Thomas,Smith,tommyburtonsmith@gmail.com,93035,CA,"Your proposed amendments to California's Low Carbon Fuel Standard are a climate policy failure that backslides on the state's role as a climate leader. The program subsidizes combustion fuels to the tune of billions of dollars per year and has no place in our toolkit of climate policies for the 2020s. There is too much on the line for our climate to get this critical program so wrong.

The world has changed a lot since the implementation of the LCFS in 2009. Unlike the 2000s, we have a north star goal for our climate and the air we breathe: zero emissions transportation. Continuing to invest the billions in revenue from the LCFS into harmful and polluting biofuels that end up combusted, instead of electric vehicles powered by clean energy, hampers our efforts to fight the climate crisis while enriching oil companies and industrial agriculture.

I urge you to correct your course and modernize the program by reflecting your consensus that the only way to meet air quality standards is through eliminating combustion altogether, not piling on billions of dollars in lavish incentives for combustion each and every year. By focusing on real air pollution solutions, you could add a clean air multiplier to the credits system, especially for public fleets that transport many people at once, would deliver major benefits for California’s air quality and throw a lifeline to cash-strapped transit agencies that low-income Californians depend on for mobility.

California cannot meet our clean air and climate goals without harnessing the power of the Low Carbon Fuel Standard and overhauling this multibillion-dollar program for our zero emissions future. Please act expeditiously to reform the program to achieve our state’s ambitious goals."
John,Fasolas,jfasolas@gmail.com,95018,CA,"Your proposed amendments to California’s Low Carbon Fuel Standard are a climate policy failure that backslides on the state’s role as a climate leader. The program subsidizes combustion fuels to the tune of billions of dollars per year and has no place in our toolkit of climate policies for the 2020s. There is too much on the line for our climate to get this critical program so wrong.

Your budget proposes significant delays and cuts of hundreds of millions of dollars to vital zero-emission transportation programs, which makes it all the more urgent to use the Low Carbon Fuel Standard to more fully support zero-emissions transportation. Historically, California has thrown good money after bad, and devoted 80% of the LCFS's $3 to 4 billion each and every year to combustion technology. It would be wild to allow these funds to continue to languish on the climate sidelines, instead of anchoring our transition to a zero-emissions future.

The world has changed a lot since the implementation of the LCFS in 2009. Unlike the 2000s, we have a north star goal for our climate and the air we breathe: zero emissions transportation. I urge you to correct your course and modernize the program by reflecting your consensus that the only way to meet air quality standards is through eliminating combustion altogether, not piling on billions of dollars in lavish incentives for combustion each and every year. By focusing on real air pollution solutions, you could add a clean air multiplier to the credits system, especially for public fleets that transport many people at once, would deliver major benefits for California’s air quality and throw a lifeline to cash-strapped transit agencies that low-income Californians depend on for mobility.

California cannot meet our clean air and climate goals without harnessing the power of the Low Carbon Fuel Standard and overhauling this multibillion-dollar program for our zero emissions future. Please act expeditiously to reform the program to achieve our state’s ambitious goals."
Darl,Sabraw,desabraw@gmail.com,92262,CA,"Your proposed amendments to California’s Low Carbon Fuel Standard are a climate policy failure that backslides on the state’s role as a climate leader. The program subsidizes combustion fuels to the tune of billions of dollars per year and has no place in our toolkit of climate policies for the 2020s. There is too much on the line for our climate to get this critical program so wrong.

Your budget proposes significant delays and cuts of hundreds of millions of dollars to vital zero-emission transportation programs, which makes it all the more urgent to use the Low Carbon Fuel

Standard to more fully support zero-emissions transportation. Historically, California has thrown good money after bad, and devoted 80% of the LCFS's $3 to 4 billion each and every year to combustion technology. It would be wild to allow these funds to continue to languish on the climate sidelines, instead of anchoring our transition to a zero-emissions future.

The world has changed a lot since the implementation of the LCFS in 2009. Unlike the 2000s, we have a north star goal for our climate and the air we breathe: zero emissions transportation. Continuing to invest the billions in revenue from the LCFS into harmful and polluting biofuels that end up combusted, instead of electric vehicles powered by clean energy, hampers our efforts to fight the climate crisis while enriching oil companies and industrial agriculture.

I urge you to correct your course and modernize the program by reflecting your consensus that the only way to meet air quality standards is through eliminating combustion altogether, not piling on billions of dollars in lavish incentives for combustion each and every year. By focusing on real air pollution solutions, you could add a clean air multiplier to the credits system, especially for public fleets that transport many people at once, would deliver major benefits for California's air quality and throw a lifeline to cash-strapped transit agencies that low-income Californians depend on for mobility.

California cannot meet our clean air and climate goals without harnessing the power of the Low Carbon Fuel Standard and overhauling this multibillion-dollar program for our zero emissions future. Please act expeditiously to reform the program to achieve our state's ambitious goals."
Daniel,Rossman,drdrums11@gmail.com,90292,CA,"Your proposed amendments to California's Low Carbon Fuel Standard are a climate policy failure that backslides on the state's role as a climate leader. The program subsidizes combustion fuels to the tune of billions of dollars per year and has no place in our toolkit of climate policies for the 2020s. There is too much on the line for our climate to get this critical program so wrong.

Your budget proposes significant delays and cuts of hundreds of millions of dollars to vital zero-emission transportation programs, which makes it all the more urgent to use the Low Carbon Fuel Standard to more fully support zero-emissions transportation. Historically, California has thrown good money after bad, and devoted 80% of the LCFS's $3 to 4 billion each and every year to combustion technology. It would be wild to allow these funds to continue to languish on the climate sidelines, instead of anchoring our transition to a zero-emissions future.

The world has changed a lot since the implementation of the LCFS in 2009. Unlike the 2000s, we have a north star goal for our climate and the air we breathe: zero emissions transportation. Continuing to invest the billions in revenue from the LCFS into harmful and polluting biofuels that end up combusted, instead of electric vehicles powered by clean energy, hampers our efforts to fight the climate crisis while enriching oil companies and industrial agriculture.

I urge you to correct your course and modernize the program by reflecting your consensus that the only way to meet air quality standards is through eliminating combustion altogether, not piling on billions of dollars in lavish incentives for combustion each and every year. By focusing on real air pollution solutions, you could add a clean air multiplier to the credits system, especially for public fleets that transport many people at once, would deliver major benefits for California's air quality and throw a lifeline to cash-strapped transit agencies that low-income Californians depend on for mobility.
